Measurement and Scaling

**Measurement** means assigning numbers or other symbols to characteristics of objects according to certain prespecified rules.

- One-to-one correspondence between the numbers and the characteristics being measured.
- The rules - standardized and applied uniformly.
- Rules must not change over objects or time.
Scaling involves creating a continuum upon which measured objects are located.

Consider an attitude scale from 1 to 100. Each respondent is assigned a number from 1 to 100, with 1 = Extremely Good, and 100 = Extremely bad.

Primary Scales of Measurement

Nominal Scale

- labels or tags for identifying and classifying objects.
- one-to-one correspondence between the numbers and the objects.
- Operation: counting.
- Statistics: frequency counts
Primary Scales of Measurement

Ordinal Scale

- Numbers indicate the relative extent to which the objects possess some characteristic.
- Can determine whether an object has more or less of a characteristic than some other object, but not how much more or less.
Primary Scales of Measurement

Interval Scale

- Numerically equal distances on the scale represent equal values in the characteristic being measured.
- It permits comparison of the differences between objects.
- Any positive linear transformation of the form $y = a + bx$ will preserve the properties of the scale.
- Eg. Very good to very bad rated as 5 to 1.
Primary Scales of Measurement

Ratio Scale

- Possesses all the properties of the nominal, ordinal, and interval scales.
- It has an absolute zero point.
- It is meaningful to compute ratios of scale values.
- Only proportionate transformations of the form $y = bx$, where $b$ is a positive constant, are allowed.
- All statistical techniques can be applied to ratio data.

A Classification of Scaling Techniques

Figure 8.2

Scaling Techniques

Comparative Scales
- Paired Comparison
- Rank Order
- Constant Sum
- Q-Sort and Other Procedures

Noncomparative Scales
- Continuous Rating Scales
- Itemized Rating Scales
- Likert
- Semantic Differential
- Stapel
A Comparison of Scaling Techniques

- **Comparative scales** involve the direct comparison of stimulus objects. Comparative scale data must be interpreted in relative terms and have only ordinal or rank order properties.

- In **noncomparative scales**, each object is scaled independently of the others in the stimulus set. The resulting data are generally assumed to be interval or ratio scaled.
Relative Advantages of Comparative Scales

- Small differences between stimulus objects can be detected.
- Same known reference points for all respondents.
- Easily understood and can be applied.
- Involve fewer theoretical assumptions.
- Tend to reduce halo or carryover effects from one judgment to another.
Relative Disadvantages of Comparative Scales

- Ordinal nature of the data
- Inability to generalize beyond the stimulus objects scaled.
Comparative Scaling Techniques
Paired Comparison Scaling

- A respondent is presented with two objects and asked to select one according to some criterion.
- The data obtained are ordinal in nature.
- Paired comparison scaling is the most widely used comparative scaling technique.
- With $n$ brands, $\left[ \frac{n(n - 1)}{2} \right]$ paired comparisons are required.
**Instructions:** We are going to present you with ten pairs of shampoo brands. For each pair, please indicate which one of the two brands of shampoo you would prefer for personal use.

<table>
<thead>
<tr>

<td>1</td>
</tr>
<tr>
<td>Number of Times Preferred(^b)</td>
<td>3</td>
<td>2</td>
<td>0</td>
<td>4</td>
<td>1</td>
</tr>
</tbody>
</table>

\(^a\)A 1 in a particular box means that the brand in that column was preferred over the brand in the corresponding row. A 0 means that the row brand was preferred over the column brand. \(^b\)The number of times a brand was preferred is obtained by summing the 1s in each column.
The most common method of taste testing is paired comparison. The consumer is asked to sample two different products and select the one with the most appealing taste. The test is done in private and a minimum of 1,000 responses is considered an adequate sample. A blind taste test for a soft drink, where imagery, self-perception and brand reputation are very important factors in the consumer’s purchasing decision, may not be a good indicator of performance in the marketplace. The introduction of New Coke illustrates this point. New Coke was heavily favored in blind paired comparison taste tests, but its introduction was less than successful, because image plays a major role in the purchase of Coke.

A paired comparison taste test
Comparative Scaling Techniques

Rank Order Scaling

- Respondents are presented with several objects simultaneously and asked to order or rank them according to some criterion.
- It is possible that the respondent may dislike the brand ranked 1 in an absolute sense.
- Furthermore, rank order scaling also results in ordinal data.
- Only \((n - 1)\) scaling decisions need be made in rank order scaling.
**Instructions:** Rank the various brands of toothpaste in order of preference. Begin by picking out the one brand that you like most and assign it a number 1. Then find the second most preferred brand and assign it a number 2. Continue this procedure until you have ranked all the brands of toothpaste in order of preference. The least preferred brand should be assigned a rank of 10.

No two brands should receive the same rank number.

The criterion of preference is entirely up to you. There is no right or wrong answer. Just try to be consistent.
### Preference for Toothpaste Brands

Using Rank Order Scaling

</tbody>
</table>
Comparative Scaling Techniques
Constant Sum Scaling

- Respondents allocate a constant sum of units, such as 100 points, to attributes of a product to reflect their importance.
- If an attribute is unimportant, the respondent assigns it zero points.
- If an attribute is twice as important as some other attribute, it receives twice as many points.
- The sum of all the points is 100. Hence, the name of the scale.
Importance of Bathing Soap Attributes
Using a Constant Sum Scale

Figure 8.5

Instructions

On the next slide, there are eight attributes of bathing soaps. Please allocate 100 points among the attributes so that your allocation reflects the relative importance you attach to each attribute. The more points an attribute receives, the more important the attribute is. If an attribute is not at all important, assign it zero points. If an attribute is twice as important as some other attribute, it should receive twice as many points.
