About the Editors

Editor-in-Chief

Ross M. Mullner is a health services researcher and a public health professional. For over 30 years, he has worked as an academic, healthcare administrator, and consultant. He is an associate professor of health policy and administration at the School of Public Health of the University of Illinois at Chicago. He also holds appointments in the University of Illinois's School of Pharmacy, Department of Pharmacy Administration, and the College of Medicine, Department of Psychiatry. Before joining the faculty of the University of Illinois, he was Director of Research at the American Hospital Association's Healthcare Research and Educational Trust (HRET) and Associate Director of the Hospital Data Center. He has authored seven books and more than 90 articles in the areas of healthcare data, hospital financial management, and health insurance coverage. His work has appeared in journals such as *New England Journal of Medicine*, *Health Services Research*, *Medical Care*, and *Social Science and Medicine*. He is the associate editor of *Journal of Medical Systems* and has served on the editorial boards of *Health Services Research*, *Inquiry*, and *Quality Management in Health Care*. To keep abreast of the healthcare literature, he has written 45 book reviews for *Library Journal*, *Choice*, and *Inquiry*. He has served on a number of national boards and has been a consultant to a number of government and healthcare organizations, including the national Institute of Medicine (IOM), U.S. Government Accountability Office (GAO), Health Resources and Services Administration (HRSA), Joint Commission, and Cancer Treatment Centers of America. He recently served as special assistant to the director of the Illinois Department of Healthcare and Family Services. He has received a number of honors for his work, including being elected to Who's Who in Medicine and Healthcare, Who's

Who in America, and Who's Who in the World. He earned his bachelor's degree from Chicago State University, and two master's degrees and a doctoral degree from the University of Illinois.

Associate Editors

Tricia J. Johnson is a health economist and an academic. She is the director of the Center for Health Management and Policy Research and an assistant professor in the Department of Health Systems Management at Rush University. She is also an economist for Rush Medical Group at Rush University Medical Center in Chicago. She is a 2008–2009 Fulbright Scholar to Austria at the Vienna University of Economics and Business Administration, working with its Department of Economics, Institute for Social Policy and Research, and Institute for Health Care Management and Health Economics. Her research interests focus on economic issues related to healthcare providers and consumers, including the globalization of the healthcare industry and understanding the economic factors affecting consumers' healthcare decisions. She has an interest in understanding the drivers of healthcare utilization and expenditures, where her work has focused on the hospital environment, patient safety, and occupational injuries. In addition, she does work related to the cost-effectiveness of healthcare and community-based interventions. She is currently the principal investigator on a project to examine how anticipated access to Medicare influences people's decisions about healthcare use prior to age 65, and how these decisions influence long-term health outcomes. She is also a coinvestigator on projects funded by the Cardinal Health Foundation, Alfred P. Sloan Foundation, National Institute on Aging, and National Institute of

Nursing Research. She has received grant funding from the World Bank and the Albanian Ministry of Health as well as the U.S. Department of Commerce for professional training programs in hospital and financial management. She earned her bachelor's degree from Coe College, a master's degree from the University of Iowa, and a doctoral degree from Arizona State University.

Robert F. Rich is a political scientist and public policy analyst. He is the director of the Institute of Government and Public Affairs (IGPA) and professor of law, political science, medical humanities and social sciences, community health, and health policy and administration at the University of Illinois. In 2004, he was a visiting scholar at the Max Planck Institute for Foreign and International Social Law in Munich, Germany. In 2003, he was the Mercator Professor at the Humboldt University in Berlin,

Germany, and he was also appointed a Permanent Fellow in the European Center for Comparative Government and Public Policy. Before joining the faculty of the University of Illinois, he served on the faculties of the Heinz School of Urban and Public Affairs at Carnegie-Mellon University, the Woodrow Wilson School of Public and International Affairs at Princeton University, the University of Michigan Institute for Social Research, and the University of Chicago. He is the author of seven books and more than 50 articles in the areas of health law and policy, federalism, information policy, and science and technology policy. His most recent book, *Consumer Choice: Social Welfare and Health Policy*, was published in 2005. He earned his bachelor's degree from Oberlin College and his master's degree and doctorate from the University of Chicago.

Introduction

The Field

There is a critical paradox at the very heart of modern healthcare. Today, as never before, healthcare has the ability to save lives and enhance the duration and quality of life. Advances in healthcare such as open-heart surgery, organ transplants, and test-tube babies stand at the forefront of human endeavor. At the same time, however, healthcare has become so enormously costly that it can easily bankrupt governments and impoverish families and individuals.

America is facing a growing healthcare crisis. It spends more money on healthcare, in terms of both total amount and per capita spending, than any other nation on earth. Yet America has a relatively high infant mortality rate and a low life expectancy compared with other industrialized nations such as Canada, the United Kingdom, and Japan. Many of America's hospitals and nursing facilities provide poor-quality healthcare. Medical errors and unsafe conditions are common, resulting in thousands of patient deaths annually. Millions of Americans are unable to access healthcare, especially those without health insurance and those who are underinsured. For many Americans, routine and preventive care is unaffordable. And many who do receive healthcare are unable to pay for it; healthcare expenses are the leading cause of bankruptcy in America. Although politicians, business leaders, health practitioners, and the general public all agree that America's current healthcare system needs to be reformed, there is no consensus on how to accomplish it.

Health services research addresses these and other crucial issues. Specifically, the multidisciplinary field of health services research focuses on

the study of the accessibility, costs, quality, and outcomes of healthcare. Access to healthcare includes everything that facilitates or impedes the use of healthcare services. Cost of healthcare includes the payments by insurers and individuals for healthcare services as well as the cost of lost wages and the societal cost of decreased productivity. Quality of healthcare encompasses elements of the structure, process, and outcomes of healthcare. Outcomes of healthcare include death, disease, disability, discomfort, and dissatisfaction with care. The overall aim of health services research is to improve the equity, efficiency, and effectiveness of healthcare, mainly by influencing and developing public policies.

Rationale for This Encyclopedia

This encyclopedia is needed and timely for three major reasons. First, the field of health services research has grown enormously over the past two decades, with an ever-widening range of topics being studied. Second, the organization, financing, and delivery of healthcare have become increasingly complex. Third, because health services research is highly multidisciplinary, including areas such as health administration, health economics, medicine, medical sociology, political science, public policy, and public health, there is no single extant reference source that captures the diversity and complexity of the field. The *Encyclopedia of Health Services Research* was designed to fill this void. This encyclopedia is the first in the field, and it is one of the largest single works ever published on health services research.

The encyclopedia is designed to be an introduction to the various topics of health services research for an audience including undergraduate students,

graduate students, and lay audiences seeking non-technical descriptions of the field and its practices. It is also useful for healthcare practitioners wishing to stay abreast of the changes and updates in the field and doctorate-level academics seeking a portal into a new specialty area.

Content and Organization

To help the reader navigate the encyclopedia, a detailed Reader's Guide comprising 16 sections is provided. Additionally, there is a list of the entries presented in alphabetical order. The individual entries range in length from approximately 500 words for the biographies of current and past leaders, to 1,000 words for associations, foundations, and research organizations, to 3,000 words for major concepts and topics such as health insurance, risk, and quality of healthcare. Each entry is designed to provide the reader with a basic description and understanding of the topic. Following each entry is a Further Readings and a Web Sites section that can take the reader to the next level.

Although the field of health services is large, the encyclopedia attempts to be as comprehensive as possible without being overly redundant. To accomplish this, all entries include several associated topics and cross-references. In a small number of cases, a topic that was covered in the context of a larger topic did not receive its own entry; in those cases, the smaller topic is listed with a cross-reference to the entry in which it is discussed.

How the Encyclopedia Was Created

The encyclopedia was developed in six steps.

First, leading health services researchers in the United States were invited to serve on the encyclopedia's advisory board. All the advisory board members are prestigious academicians, healthcare managers, and researchers who have published in the field of health services research. Two of the board members, Steven Shortell and Katherine Swartz, were former long-time editors of *Health Services Research* and *Inquiry*, respectively.

Second, the encyclopedia's editors developed a draft list of topic headwords. To make sure the list was as comprehensive as possible, six journals that publish the majority of health services research articles were reviewed for the past 10 years. The

journals included *Health Affairs*, *Health Services Research*, *Inquiry*, *Journal of Health Services Research and Policy*, *Medical Care*, and *New England Journal of Medicine*. The draft list was then reviewed by the entire advisory board, which made a series of additions and subtractions.

Third, the editors and the advisory board identified and invited contributors. The editors also searched the literature to find individuals who published on certain topics and invited them to submit entries. The invited authors ranged from promising young doctoral students to the most well-known luminaries in the field.

Fourth, all the contributors were given basic guidelines and instructions regarding the writing of their entries. In particular, they were encouraged to be as thorough as possible in describing the entire topic area and to write in clear, nontechnical, accessible language.

Fifth, the editor and associate editors then reviewed all the entries and asked the authors for revisions as necessary.

Sixth, the editors finalized the volumes and compiled the bibliography and appendix.

Acknowledgments

This encyclopedia is a testament to the efforts of a large number of dedicated and talented people. First, I would like to thank the advisory board for their time, effort, and encouragement, particularly Lu Ann Aday and Michael Morrissey. I am indebted to the many first-rate scholars and professionals who authored the entries. And, of course, I would like to thank the publishing team at Sage, particularly Jim Brace-Thompson, Carole Maurer, and Laura Notton.

I also appreciate the advice, counsel, and friendship of my current and former colleagues at the University of Illinois School of Public Health: Gary Albrecht, Kendon Conrad, Gregory Finlayson, Sally Freels, Benn Greenspan, Louis Rowitz, and Richard Sewell. Special thanks also go to Kathryn Langley and Jared Lane K. Maeda for their editorial assistance.

On a personal level, I want to thank my wife, Linda, for her unyielding support, and my two sons, Erik and Jason.

Ross M. Mullner

A

AARP

The AARP (formerly the American Association of Retired Persons) is the nation's largest association representing individuals 50 years of age or older. With more than 39 million members, the AARP is an influential advocate at the federal, state, and local levels on public policy issues concerning aging and the elderly, and it is also instrumental in shaping public opinion. The AARP conducts policy research, publishes various reports and several widely circulated popular magazines, and sells various products and services, including life and health insurance, prescription drugs, and travel services.

History

Ethel Percy Andrus (1884–1967), a retired California high school principal, and Leonard Davis (1925–2001), a New York insurance executive, founded the AARP in 1958. Andrus taught in California for many years, becoming that state's first female high school principal. After retiring, she became concerned with the poverty her fellow retired teachers experienced who were living on meager pensions. Davis, with Andrus's encouragement and help, pioneered insurance programs for retirees. He would eventually form the Colonial Penn Group of insurance companies, and he went on to found the Leonard Davis Institute of Health Economics of the University of Pennsylvania.

Before founding the AARP, Andrus established the National Retired Teachers Association (NRTA) in 1947. Andrus's initial goal was to promote her philosophy of productive aging and to respond to the needs of retired teachers. After successfully working with Davis to develop insurance policies for them, Andrus developed other benefits and programs, including an early discount mail-order pharmacy service. With the growing success of the NRTA's programs, thousands of other retirees who were not teachers wanted to obtain them. So in 1958, Andrus and Davis established a new organization open to all retired individuals—the American Association of Retired Persons (AARP). In 1999, the association changed its name to AARP.

Membership

Membership in the AARP is open to any person aged 50 or older. Members need not be U.S. citizens or residents. Most members live in the United States, although about 40,000 members live outside the country. Although most AARP members are retired, more than 40% of its members work part- or full-time, which is why the association shortened its name from the American Association of Retired Persons to simply AARP. The median age of members is 65 years; slightly more than half of the members are women.

Vision, Mission, and Organizational Structure

The AARP is a nonprofit, nonpartisan organization. Its vision is for a society in which everyone

ages with dignity and purpose, and it helps people fulfill their goals and dreams. Its mission is dedicated to enhancing the quality of life for all as they age and to leading positive social change and delivering value to members through information, advocacy, and service.

The AARP is organized into a central headquarters, state offices located in all 50 states, the District of Columbia, Puerto Rico, and the Virgin Islands, and more than 2,500 local chapters throughout the nation. Its national headquarters is located in Washington, D.C., to allow its staff and volunteer leaders access to the federal government. The national headquarters coordinates the activities of the field operations and state offices and supports the initiatives of the local chapters, which are separately incorporated groups that provide members with opportunities to volunteer in their own communities. State chapters identify areas of legislative concern locally and support volunteers and staff as they work toward accomplishing the goals and objectives of the association and its members.

The association has two affiliates: the AARP Foundation and AARP Services, Inc. The AARP Foundation's focus is to lead positive social change to help people aged 50 and older, especially the most vulnerable, by delivering information, education, and direct service to communities and families. Specific AARP Foundation programs include various training programs, free tax preparation and counseling for seniors, and homeowner interests. AARP Services, Inc., is a wholly owned subsidiary of the AARP. It manages a range of products and services made available to the association's members, provides marketing services to the association and its member service providers, and manages the association's Web site. Some of the programs that AARP Services, Inc., manages are Medicare supplement, long-term healthcare, insurance (automobile, life, and homeowners), and member discounts and savings on prescription drugs, eye health services, and eyewear products.

Advocacy Activities

The AARP is the largest advocacy group in America for those 50 years of age and older. Its advocacy activities include monitoring issues

affecting older Americans, taking public positions, and expressing its views to state and national lawmakers and regulatory agencies. The association also undertakes selective litigation in age discrimination, pension, healthcare, economic security, and consumer cases.

To define its advocacy endeavors, the AARP reviews existing data, conducts its own research, and surveys its members to gather information on their concerns and views. The association's board of directors is given the task of discussing and balancing various perspectives. The board hears from experts, elected officials, business and industry representatives, and a special advisory council consisting of 25 volunteers. The council makes recommendations to the board, which then approves federal, state, and local policies. The AARP's top advocacy priorities currently include issues such as health, financial security, independence and long-term care, and consumer protection. The association's lobbying efforts helped the passage of Medicare Part D, the Medicare drug benefit, in 2003. It was also instrumental in stopping changes to Social Security in 2005.

Criticism

Over the years, the AARP has been sharply criticized. Some have criticized the AARP's lobbying efforts, which they believe, in many instances, are geared primarily to advancing the association's business interests. Others have criticized AARP because it derives so much of its revenue from advertising, and selling insurance and other products, accusing the association of acting like a for-profit company. This allegation was taken so seriously that in 1995, Republican Senator Alan K. Simpson of Wyoming, then Chairman of the Finance Committee's Subcommittee on Social Security and Family Policy, held hearings investigating the AARP's nonprofit tax-exempt status. The investigation, however, did not reveal sufficient evidence to warrant revoking its nonprofit status. The association has also been criticized as using scare tactics to frighten its older members to influence their opinions. Last, the AARP has been criticized for assuming it can represent the views of all its very large and diverse membership. Some of its members were disappointed that it supported the passage of the Medicare Part D

drug benefit, which they viewed as being poorly designed, confusing, and complicated.

ABT ASSOCIATES

Founded in 1965 by Clark Abt, Abt Associates applies scientific research, technical assistance, and consulting expertise to a wide range of issues in social, economic, and health policy, international

development, clinical trials and registries, and business research. The company's staff of more than 1,000 is located in offices in Cambridge, Lexington, and Hadley, Massachusetts; and offices in Bethesda, Maryland; Chicago, Illinois; Durham, North Carolina; New York, New York; and more than 35 project offices around the world.

The company has more than 30 years of experience evaluating the effectiveness and impacts of health programs and policy. Its comprehensive process and outcomes evaluation and expert policy analysis help improve quality of medical care and patient safety, expand access to care, lower costs, and empower consumer choice.

Public and private healthcare initiatives face significant challenges to achieve desired outcomes while managing shifting demands and ever-increasing costs. In addition, policymakers continue to explore new strategies to ensure that people receive appropriate healthcare.

To assist clients as they address these issues, Abt Associates employs a variety of methodologies. It performs complex quantitative evaluations, including analysis of large data sets and statistical and econometric modeling. The company's qualitative evaluation capabilities include conducting focus groups, developing case studies, and reviewing the professional and scientific literature. It specializes in surveying hard-to-reach and vulnerable populations, including people with chronic medical conditions, individuals with disabilities, HIV-positive populations, families of children with special healthcare needs, Medicare beneficiaries, and Medicaid recipients. Abt Associates' capabilities include cost-effectiveness analysis, technology assessment, performance measurement, drug/medical claims analytic file construction and analysis, epidemiological studies, consumer satisfaction evaluations, literature reviews and meta-analysis, and clinical trial design and analysis.

Abt Associates also has expertise and experience in a wide range of domains, including community-based health, maternal and child health, disability and rehabilitation, post-acute care, mental health, health disparities, health outcomes and patient safety, healthcare finance, managed care, and addiction prevention, treatment, and recovery.

Over the years, Abt Associates has analyzed numerous health policy issues, examining the impact of federal and state regulatory policy on

provider behavior and quality of care. The company's health economists and clinicians have developed and refined prospective payment and case-mix reimbursement systems for a variety of provider settings, analyzed the potential impact of new payment policies on healthcare outcomes and expenditures, and evaluated the effect of regulatory change on provider behavior.

Abt Associates works closely with clients to develop evaluation and analysis strategies that provide the information they need to make informed choices. Its skilled, multidisciplinary staff includes health services researchers, clinicians, data analysts, policy analysts, health economists, statisticians, and survey research methodologists who combine technical knowledge and integrated perspectives derived from years of experience. Primary clients include federal and state healthcare and public health agencies, national provider associations, and foundations.

Examples of Health Services Research Projects

Gathering Data on Home Health to Design a New Payment System

Under the Home Health Case-Mix Development Project for the U.S. Department of Health and Human Services' Centers for Medicare and Medicaid Services (CMS), Abt Associates collected a wide range of data from a representative sample of home health agencies. It used this information to develop a model of home health resource use and to design a system of case-mix adjustment for use in Medicare's per-episode prospective payment system.

Determining Appropriate Minimum Nurse Staffing Levels

Abt Associates and its partners assisted CMS with a mandated report to the U.S. Congress on the "appropriateness" of establishing minimum caregiver nursing staffing ratios for Medicare- and Medicaid-certified nursing homes. The first objective of the study was to determine whether minimum nurse staffing ratios were appropriate. The study then examined the potential cost and budgetary implications of minimum ratio requirements.

Evaluating Drug Utilization and Coverage and the New Medicare Benefit

Abt Associates worked with CMS to assess the impact of prescription drug coverage on Medicare expenditures, to address design issues for the evaluation of prescription drug programs, and to analyze the determinants of per capita drug spending for Medicare beneficiaries. In addition, the company surveyed Medicare beneficiaries to assess their understanding of the new Medicare drug plan. Abt Associates is also working with CMS to design a more accurate methodology for estimating the costs of prescription drugs to pharmacies and physicians. Researchers at Abt Associates have also analyzed Medicaid drug expenditures, provided strategic consulting to state Medicaid programs, and designed state-level drug insurance programs for senior citizens.

Evaluating the National Healthy Start Program

The federal Healthy Start program provides comprehensive, community-based, perinatal health services to women, infants, and families in communities with high infant mortality rates. The program's goal is to reduce disparities in birth outcomes by increasing access to and utilization of health services. Abt Associates is working with the Maternal and Child Health Bureau of the U.S. Health Resources and Services Administration (HRSA) to conduct the national evaluation of Phase III of Healthy State. The company is conducting an implementation analysis to assess the success of 96 Healthy Start sites. This 2-year evaluation will result in a detailed look at the effectiveness of these sites and will help guide the program as it moves ahead.

Quality Indicators

Abt Associates and its partners are involved with quality indicators (QIs) development, validation, risk adjustment and analysis, and reporting for CMS and the Agency for Healthcare Research and Quality (AHRQ) as well as for states across various providers, including nursing homes, home health care, hospitals, and health plans. The company has developed QIs for nursing homes, validated the indicators through direct-care observation across a large, multistate sample, and worked with

states and CMS in public reporting. The culmination of these efforts was the selection of the quality measures that are currently publicly reported for all Medicare- and Medicaid-certified nursing homes. The company is developing new home health care measures in anticipation of federal pay-for-performance initiatives and assessing how consumers, clinicians, and discharge planners will use nursing home and home health care QIs to select post-acute providers. The company has worked with state organizations and is working with CMS to assess the best way to display hospital and health plan QIs to support consumer choice. It also supported the development of hospital nursing-sensitive measures and helped design the pilot initiative for public reporting.

Multiple Sclerosis Longitudinal Study

Abt Associates is conducting a 4-year epidemiological longitudinal study of 2,000 adults with multiple sclerosis (MS) for the National Multiple Sclerosis Society. Also, the company is conducting studies examining access to MS therapies and specialists, the characteristics of quality MS mental health services, and the psychosocial impacts of the disease.

Analyzing the Economic Impact of Healthcare Regulations

Abt Associates assisted the U.S. Department of Health and Human Services in analyzing the economic impact of regulations that impose economic burden beyond their benefit. The company conducted a series of town hall meetings across the country to receive public comment about quantifying regulatory burden. It conducted a major review of the literature to evaluate prior research and evidence quantifying regulatory burden. And it conducted a series of expert interviews with providers to gather detailed evidence on the economic burden of regulation in nursing homes, hospitals, physician offices, and other healthcare providers.

ACADEMIC MEDICAL CENTERS

An academic medical center (AMC) is an organization whose mission encompasses emphases on clinical care, research, and education. Typically, it includes the following elements: an accredited medical school, one or more affiliated hospitals in which a majority of the medical staff are physician-faculty members, hospital admissions that are primarily made by physician-faculty members, and an affiliated faculty practice plan that is tax-exempt

under federal law or is part of an exempt organization under an umbrella designation.

Background

The modern structure of the AMC has its roots in the highly critical Flexner Report of 1910, which criticized medical education for its lack of an evidence-based approach and paved the way for the modern, more allopathic approach. There was also a concomitant migration from the “commercial” medical school of the time to formalized programs of medical education. Subsequently, the medical education model was characterized by an academic venue, staffed by scientifically rooted faculty practicing in an associated teaching hospital. The ensuing leap in the caliber of medical education has seen highly complex organizational models and intricate connectivity through the multifaceted mission that characterizes today’s academic medical centers.

Distinguishing Features

AMCs are differentiated from public health systems, community hospitals, and safety net healthcare complexes in large measure due to distinct characteristics that came about with the advent of the AMC model of the 20th century. Additional distinguishing features, combined with the multifaceted mission of the AMC organization, go well beyond the purely academic elements that serve to differentiate AMC. These include the following.

Technology

AMCs are on front lines of emerging technology. They are the environment in which new clinical treatment methods and scientific advances are typically developed. The nature of translational research efforts and the setting in which tertiary and quaternary care is delivered embolden providers to make critical advancements in care; as such, AMCs are the setting where these advances can most efficiently occur. These advances take many forms, including new device development and testing, as well as diagnostic and treatment protocols and surgical techniques. With the scientific rigor

and evidence-based discipline present in this setting, promising clinical developments occur. An example is the discovery of the prostate-specific antigen (PSA), which led to a test that helps detect prostate cancer in men of age 50 and older. AMCs also often curtail the introduction of techniques that are unsafe or lack efficacy. One such example is the Jarvik artificial heart, which was banned when practitioners found that most of the recipients could not live more than half a year.

Prestige

The output of AMCs significantly contributes to the United States’ international presence and prestige. Healthcare is often a source of national pride and economic benefit; thus, advances in science and medicine represent a significant portion of a nation’s economic and political agenda.

Physician Scientists

AMCs are essential to the development of the United States’ base of young scientists. Federally funded programs such as the National Science Foundation’s Science, Technology, Engineering and Mathematics (STEM) program leverage AMCs to encourage the study of science, making these centers important settings for training physician scientists.

Preparedness

Along with federal and local government agencies, AMCs play an integral role in the United States’ preparedness infrastructure for national emergency and terrorism response. Routinely seen as the tertiary- and quaternary-care centers for the country in the event of any number of national health scenarios (e.g., terrorism attacks, epidemics, bioscientific responses), AMCs play key roles in drill scenarios. Without the involvement of AMCs, the nation’s response armamentarium would be substantially less robust.

Challenges

AMCs currently face a number of critical challenges, including environmental factors associated with

healthcare economics, technology advances, changes in the makeup of healthcare professions, regulations, and, increasingly, political forces. Internal structural weaknesses can also arise from internal conflicts associated with the multifaceted missions typical of AMCs, further challenging their viability. There are also influencers that revolve around future revenues and niche competition.

AMCs operate on a costly platform, in part due to their aggressive development and adoption of emerging technology as well as investigational and clinical protocols. The inherent inefficiencies of training clinical practitioners or scientific investigators places further cost pressures on such centers. There is broad recognition that the models under which AMCs operate will face substantial challenges in the years ahead, but a consensus is lacking as to the direction AMCs should take in the future.

On the immediate horizon are corresponding environmental and internal issues that threaten the viability of AMCs and will drive the industry response. Funding sources needed to support direct operating costs, as well as AMCs' associated overhead and infrastructure, are being constrained. Managed-healthcare penetration, along with federal and state-level clinical program revenues (e.g., Medicare and Medicaid), have diminished clinical income streams available to these centers. Increasing debt for medical school graduates is forcing a closer examination of tuition levels. And the percentage of funded National Institutes of Health (NIH) grant applications is declining along with other sources of research funding. Philanthropy, another source of revenues on which AMCs are highly dependent, can be volatile due to a dependence on economic conditions affecting the very wealthy.

In the realm of economic challenges, another high-profile issue is the threatened removal of the not-for-profit tax status of AMCs. Regardless of whether the motive for this threat is to "punish" not-for-profit hospitals for not providing community-based charitable care to a level consistent with the tax benefit received, or to serve as a source of property tax revenues for local government, a change in tax laws creating a substantial tax burden on AMCs could severely affect the mission and sustainability of these institutions.

Additional significant forces are on the horizon, although they are not unique to AMCs. For example, the availability of healthcare personnel is expected to be significantly affected by the aging workforce and declining enrollment in training programs, particularly nursing. In terms of training programs, there has been a trend toward more highly qualified and more costly caregivers (e.g., master of science in nursing, doctorate of pharmacy, doctorate of physical therapy) who are increasingly unwilling to perform traditional tasks associated with previous generations of healthcare professionals. Healthcare professionals, who have in recent years earned high incomes, are an increasingly attractive target for union organizers. If the efforts of these organizers are successful, unionization within AMCs personnel may increase in the coming years. Medical travel, once considered a fairly isolated market force as far as its impact on the healthcare market is concerned, has also begun to draw more attention. International private-pay patients have been an important source of income for AMCs; as international healthcare markets begin to mature, they are increasingly attracting international as well as U.S. consumers of medical services to travel abroad in search of less costly care in a more service-oriented environment. Potential failure of "safety net" hospitals, particularly in urban areas, could overload AMCs because they are a natural alternative to the typical alternative large urban provider of public acute and tertiary care.

Future Implications

Despite the distinguishing characteristics of AMCs and their critical position in our national healthcare infrastructure, these organizations are subject to numerous current and emerging political and economic forces and will need to adapt in order to continue as essential contributors to our nation's health system. AMCs will be pressed to take a proactive approach to counter the negative forces they face entering the 21st century. Their ongoing success will require leadership and continued national recognition for the major role these important institutions play in the support infrastructure of our society.

ACADEMYHEALTH

AcademyHealth (formerly the Academy for Health Services Research and Health Policy) is a non-profit, nonpartisan resource for health services research and policy and the professional home for health services researchers, policy analysts, and

practitioners. AcademyHealth represents nearly 4,000 individual members and 125 affiliated organizations in the United States and abroad. AcademyHealth seeks to improve health and healthcare by generating new knowledge and moving knowledge into action.

Mission

To achieve its mission, AcademyHealth collaborates with the health services research community and other key stakeholders to support the development of health services research by expanding and improving the scientific basis of the field by increasing the capabilities and skills of researchers and promoting the development of the necessary financial, human, infrastructure, and data sources. It also seeks to facilitate the use of the best available research and information by translating research findings and the lessons of experience into useful information for clinical, management, and policy decisions, and enhancing communication and interaction between health services researchers and health policymakers. In addition, AcademyHealth assists health policy and practice leaders in addressing major health challenges by providing high-quality policy and technical assistance by offering educational programs that advance the use of policy analysis and research and identifying areas where additional research and information are needed.

AcademyHealth's work concentrates its efforts and expertise on a variety of issues that are essential to health policy making and practice. These include healthcare financing, organization, and delivery; the problems of the uninsured; the quality and costs of care; public health systems and issues; health information technology; and long-term care.

Background

AcademyHealth was established in June 2000 following a merger between the Alpha Center and the Association for Health Services Research (AHSR).

The Alpha Center was founded in 1976 as a federally funded, regional health-planning center. It evolved into a nonprofit, nonpartisan health policy center dedicated to improving access to affordable, quality healthcare. The Alpha Center

provided expert technical assistance, objective analysis and research, and comprehensive education and facilitation services.

The AHSR was formed in 1981 and was a nonprofit professional society for individuals and organizations committed to health services research. Its mission was to educate consumers and policymakers about the importance of health services research, disseminate information generated by health services researchers, secure funding for the field, and provide networking and professional development opportunities.

To better integrate the development of the field of health services research with the use of research to inform public- and private-sector decision makers, the Alpha Center and the AHSR merged to become the Academy for Health Services Research and Health Policy in 2000. The integration of the two organizations provided a strong foundation for building a bridge between the research and user communities in the world of health policy and practice. A year and a half after the merger, the executive committee began to explore whether the organization's name accurately and effectively conveyed its mission, vision, and values. In 2003, the organization finalized its rebranding process, unveiling its new identity, AcademyHealth, at its 2003 annual research meeting.

AcademyHealth's predecessor organizations were historically at the forefront of the field of health services research, organizing the initial professional meeting of health services researchers in 1983 and working with the academic, policy making, and practitioner communities to provide professional development and networking opportunities. Building on their combined strengths, AcademyHealth provided a home for the growing multidisciplinary field and a vital resource for consumers of the field's research.

As the field of health services research has matured, AcademyHealth has devoted increased attention to developing and supporting the financial, human, and data resources that make up its infrastructure.

Organizational Structure

AcademyHealth is led by a president and governed by a board of directors representing a broad range of experience in academia, clinical practice, and industry. The board of directors of

AcademyHealth consists of 21 members who serve 4-year terms, with 5 members elected each year. Two candidate slates are developed, one for election by the board and one for election by the membership. The board elects two directors each year. The membership elects three. In June, the nominating committee submits the slate of board-elected candidates to the full board for its approval and election. The board also ratifies the slate of member-elected candidates. This slate is presented to the membership for election in September. The board meets twice annually.

Membership

The membership of AcademyHealth is diverse, including public policymakers, business decision makers, health services researchers, policy analysts, economists, sociologists, political scientists, consultants, clinicians, and students. Through journal subscriptions, conferences, professional development resources, and topic-specific interest groups, AcademyHealth fosters networking and professional growth among its members by bringing together a broad spectrum of players to share perspectives, learn from each other, and strengthen working relationships.

Individual and organizational members receive registration discounts for AcademyHealth meetings, complimentary subscriptions or reduced rates for more than 30 health publications, access to online, members-only content on the AcademyHealth Web site, and advocacy through the Coalition for Health Services Research (CHSR).

In 2004, AcademyHealth introduced interest groups, which convene members and nonmembers around focused topics for Web-based discussion forums and annual or biannual meetings. Currently, there are 15 interest groups addressing the topics of (1) behavioral health services, (2) child health services, (3) disability research, (4) disparities, (5) gender and health, (6) health economics, (7) health information technology, (8) health policy communications, (9) the health workforce, (10) the interdisciplinary research group on nursing issues, (11) long-term care, (12) public health systems, (13) quality, (14) research translation, and (15) state health research and policy.

AcademyHealth Reports, the quarterly membership newsletter, provides original articles on

issues affecting the field as well as regular updates on AcademyHealth-sponsored professional development and networking opportunities. AcademyHealth also publishes a monthly e-newsletter for members, *Member Update*, and a quarterly newsletter, *Partners*, comprising updates submitted by organizational affiliates.

Annual Meetings

AcademyHealth hosts two major meetings each year. The first, the National Health Policy Conference, is held each February in Washington, D.C., and offers an in-depth look at key health policy issues for the year ahead. The conference brings together policy professionals, practitioners, and researchers to discuss policy challenges, debate potential solutions, and identify the research needed to inform the policy process.

The second, the Annual Research Meeting, is generally held each June. The meeting brings together researchers from around the world to share and discuss the latest health services research findings, learn new methods, debate policy issues, and network with colleagues. The Annual Research Meeting is a key component of AcademyHealth's efforts to promote and expand the scientific basis of the field. To ensure that the meeting presents top-notch research, AcademyHealth aims to have at least 40% to 50% of the content chosen by peer review. Approximately 50 meetings, large and small, are held in conjunction with the Annual Research Meeting. In addition, AcademyHealth offers timely events and briefings to convene key stakeholders from the public and private sector around critical health issues.

Seminars, Training, and Fellowships

AcademyHealth offers an array of seminars featuring comprehensive training in health services research methods and health policy tools and techniques. Seminars are offered in conjunction with the Annual Research Meetings and the National Health Policy Conference, as well as in smaller meetings and cyber-seminars throughout the year.

AcademyHealth annually offers a 3½-day program, the Health Policy Orientation, for individuals interested in learning how national health policy is

developed and implemented. During this seminar, Washington insiders provide an in-depth introduction to the key players, formal and informal policy-making process, and critical health policy issues. The program includes speakers, panel presentations, group discussions, site visits, and hands-on tutorials.

AcademyHealth also develops full-day, expert-led seminars in health services research methods. These seminars provide a forum for researchers to enhance their academic and professional knowledge base. It also offers courses designed for health policy professionals of all levels. These courses give participants the tools they need to learn how research affects policy decisions and how to use existing data sources to inform policymakers.

In conjunction with the National Center for Health Statistics (NCHS), AcademyHealth offers a health policy fellowship that brings two visiting scholars in health services research-related disciplines to NCHS for a period of 13 to 24 months to collaborate on studies of interest to policymakers and the health services research community using NCHS data systems.

Awards

Each year, AcademyHealth recognizes individuals who have made significant contributions to the fields of health services research and health policy. The Alice S. Hersh New Investigator award recognizes an outstanding early-career professional. The Article-of-the-Year award recognizes the best scientific work that the field of health services research and health policy have produced and published in the previous calendar year. The Dissertation award honors an outstanding scientific contribution from a doctoral dissertation in health services research. The Distinguished Investigator award is presented to an individual who has made a significant and long-lasting contribution to the field of health services research, and the HSR Impact award recognizes health services research that has had a positive impact on health policy and/or practice. In addition, the Student Poster award annually recognizes the best student poster presented at the Annual Research Meeting.

Working to Build the Field

AcademyHealth has undertaken a number of initiatives to strengthen the infrastructure for health services research, including a 2006 environmental scan to survey the perceived needs and expectations of both producers and consumers of health services research. The resulting report, *Strengthening the Field of Health Services Research: A Needs Assessment of Key Producers and Users*, draws conclusions regarding the infrastructure needs and research priorities of the field and suggests immediate and long-term actions to improve the impact of the field's research on health and healthcare.

The survey's findings led to a 3-year initiative to assess, build consensus, and make recommendations on strategies to address the future infrastructure needs of the field of health services research. A trilogy of summits in 2007, 2008, and 2009 will address workforce needs, methods and data, and knowledge transfer, respectively. Each will commission new research, hold a meeting of stakeholders to develop recommendations, and undertake dissemination activities to share those recommendations with key audiences.

In 2006, AcademyHealth convened a Methods Council to assist in the development of strategies for professional development in health services research methods, respond to member-reported needs, and anticipate future needs of the field. The council is made up of leading health services research methodologists who represent a wide range of disciplines and expertise. Council members serve a 3-year term. Subcommittees carry out specific tasks.

The activities of the council include the following: reviewing feedback and requests from members for new methods offerings, assessing the field's current and future needs, selecting topics and faculty for the methods seminars, providing guidance and peer review of methods publications, and providing updates to the board on AcademyHealth's research methods programs.

Among the council's first activities was the creation of a health services research glossary, which is currently on the Internet at the AcademyHealth Web site. It provides an organized, professional resource to help establish a common language and methods for health services research and assist individuals in comparing study methodologies.

These activities supplement AcademyHealth's ongoing work to develop and represent its membership base; provide professional development opportunities for researchers, practitioners, and policymakers; assist in translating research into policy solutions and advocate for the field of health services research; and support funding and authorization for the federal agencies that rely on its research.

Programs and Initiatives

To facilitate translation of research into action, AcademyHealth provides technical assistance to policymakers, researchers, government officials, and business leaders, and it disseminates vital information through research syntheses, special reports and findings, newsletters, and its Web site. AcademyHealth also serves as a program office or contractor for select foundation and government agency programs that complement its efforts to build the field and stimulate demand for this type of research among policymakers and practitioners.

International Exchange

Through its International Exchange program, AcademyHealth seeks to inform U.S. policy making with research and experiences of health systems around the world. The program brings together experts from universities, foundations, and policy centers to provide support that is non-partisan and confidential. Its work includes both AcademyHealth-sponsored initiatives and projects commissioned from outside organizations such as U.S. government agencies, international organizations, and private organizations. This includes activities such as convening expert consultations and workshops; establishing international working groups to define shared research agendas and managing comparative research projects; facilitating contact with U.S. or foreign policymakers, opinion leaders, and researchers; and producing working papers on lessons learned for the United States and other nations.

An example of such efforts is AcademyHealth's Health in Foreign Policy Forum. Held initially in 2005, the forum presents an overview of the many U.S. health policy challenges that have international

implications. Meeting topics have included global commerce and health, disease and international security, and an in-depth focus on U.S. domestic and foreign policy responses to the global shortage of health professionals.

Public Health Systems Research

To increase the visibility of public health systems research among federal and state policymakers, and to incorporate the priorities of key stakeholders, especially practitioners, into the national research agenda, with the aim of strengthening the nation's public health infrastructure, AcademyHealth is engaged in a series of projects aimed at supporting researchers, funding research, and bringing stakeholders together to link research to policy.

National Programs

AcademyHealth is the national office for the Changes in Health Care Financing and Organization (HCFO) and the State Coverage Initiatives (SCI), two national programs of the Robert Wood Johnson Foundation (RWJF). The HCFO program supports investigator-initiated research and policy analysis, evaluation, and demonstration projects examining major changes in healthcare financing and their effects on access, cost, and quality of care. The SCI program provides technical assistance to state policymakers' efforts to maintain and expand health insurance coverage.

Federal Contracts

Under contract to the Agency for Healthcare Research and Quality (AHRQ), AcademyHealth develops and implements long-range strategies to assist healthcare purchasers, health system leaders, and state and local policymakers in applying research-based evidence to policy and program development. Additionally, AcademyHealth and the Cecil G. Sheps Center at the University of North Carolina receive funding from the National Library of Medicine (NLM) to maintain the library's Health Services Research Projects in Progress (HSRProj) database. The database provides access to ongoing grants and contracts in health services research.

Coalition for Health Services Research

AcademyHealth's advocacy arm—the Coalition for Health Services Research (CHSR)—advocates for the health services research community in Washington, D.C. The coalition campaigns for enhanced funding for agencies that support health services research and works to ensure that federal agencies supporting the field continue to receive reauthorization from the U.S. Congress. Some issues for which the coalition has played an instrumental role include easing restrictions placed on researchers by the federal Health Insurance Portability and Accountability Act of 1996 (HIPAA) privacy regulations and maintaining a strong and independent peer-review process for federal grants.

The coalition involves AcademyHealth membership in the federal legislative process and works in partnership with other organizations that support its goals. To broaden support for health services research and health data, the coalition provides organizational support for both the Friends of the AHRQ and the Friends of the Centers for Disease Control and Prevention's NCHS. These "Friends" groups comprise key stakeholders for health services research and health data, including providers, patients, businesses, academic health centers, universities, and health insurance plans.

ACCESS, MODELS OF

Measuring access to healthcare is a central part of health services research and is driven by the commitment to design and evaluate the delivery of health services. However, the task of measuring access to healthcare is often complicated by the lack of agreement regarding what actually constitutes access to care.

The nation's news media often report stories of different aspects of access to healthcare to stimulate interest, including reports on the alarming growth in the numbers of underinsured or uninsured persons; stories of discrimination by healthcare providers; reports of persons who were denied care in hospital emergency departments; and accounts of individuals who were sick but could not see a provider because one was not available. While all these factors are considered access to healthcare, measuring it requires examining the specific interpersonal needs of the individual such as age, gender, race, economics, culture, disability, and sexual orientation, as well as provider issues such as their availability, reimbursement for services, provider liability issues, and commitment to providing indigent care.

Additionally, access to healthcare must take into account cultural competency, language interpreter needs, and organizational issues that affect the continuity of care and delivery of services. Resources, including location of facility, convenience of care in the community, the supply of providers in shortage areas, and public and private financing of care, must also be considered. It also requires defining what part of access to healthcare is being measured; that is, medical care, dental care, mental healthcare, or substance abuse services. The type of provider must also be identified as care physicians, physician assistants, nurses, psychologists, dentists, pharmacists, social workers, physical therapists, or other providers.

To address an issue of this magnitude, it is often helpful to use a model to systematically examine the factors that contribute to obtaining access to healthcare. Models are frameworks that use a theory or set of interrelated principles to explain or predict some aspect of behavior. Models can be used as a guide for determining why persons are or are not gaining access to healthcare. In addition, these models may help us to identify what should be examined in order to assist individuals in gaining access to care.

This entry reviews four models that have been widely used to evaluate access to healthcare: (1) the Donabedian structure-process-outcome model, (2) the Andersen Behavioral Model, (3) the health belief model, and (4) the theory of reasoned action model. This review includes an overview of the key components regarding each model, a discussion of the relationship between the model and access to care, and a brief critique of each respective model.

Models of Access to Healthcare

The Donabedian Structure-Process-Outcome Model

Developed by Avedis Donabedian at the School of Public Health at the University of Michigan in the 1970s, the Donabedian structure-process-outcome model (SPO) was constructed to examine the quality of healthcare. It is also used as a means of examining both the use of medical services and the outcomes of the delivery of services. Since its development, the SPO model has been extensively used to measure health outcomes. This model examines access to healthcare by evaluating the

providers and the organizations that deliver the medical care (the structure of the medical delivery system), the amount of care delivered to the patient by these providers (the process of the medical-care delivery), and the outcomes of the care (death, disease, disability, discomfort, and dissatisfaction).

This model has three key components that are essential to its framework. First, researchers examine the structure of medical delivery by determining the appropriateness of necessary care within its given provisions. Donabedian suggests that patients receive inappropriate care in this situation, especially when providers do not have the appropriate amounts of training and experience to treat them. Next, the process of medical delivery is examined by evaluating the extent to which the patients receive an equitable amount of care according to their medical needs, looking at the health status or severity of illness. Finally, the outcome of the delivery of care is considered by determining the extent to which the care results in an improvement in the patient's functioning.

In evaluating the system of medical delivery and applying the SPO model, one should examine the structure and process of medical delivery; however, one should also emphasize examining the impact of these factors on the outcome of medical delivery. Donabedian suggests that, in addition, one should evaluate the impact of care on a group of individuals by linking up the structure and process of care with the outcome of care. According to Donabedian, one should first examine the impact of the system of medical delivery on the outcome of care by linking the providers, organization of medical delivery, and process of medical delivery to the degree of improvement in the patient's social and psychological functioning. Next, the impact of this system can be examined by linking these to the extent to which the patient is satisfied with the care received. Third, they should be linked to the extent to which the patient's knowledge of healthcare improves, following the treatment of his or her illness. Finally, they should be linked to the extent to which the patient's overall health improves as a result of the care received. On the basis of this model, patients receive appropriate access to care when they are treated by competent providers who deliver services that are comparable in type and volume with those of other competent providers. In turn, this results in an improvement in the outcome of the

health problem (depending on the nature and the severity of the problem).

This model has been used extensively to identify systemwide factors that contribute to the outcome of care. Its benefit lies in providing a framework that can be targeted to the end results of an activity, the use of medical services, satisfaction with services, improved health, and an increase in the number of health years alive or cost reduction. As such, it has been used as a program evaluation tool. At the same time, the limits of the model lie in its lack of information on an individual level, such as patient characteristics that interact with the delivery of services. Thus, it may not work as well as measuring an individual's success in seeking services as it would in mapping out what happens across a program.

The Andersen Behavioral Model

Developed by Ronald M. Andersen at the Center for Health Administration Studies at the University of Chicago in the 1960s, the Andersen Behavioral Model (ABM) was constructed as a measure of the individual and organizational factors that contribute to the use of and satisfaction with medical services. It has evolved since then to include measures of environmental and provider factors that influence access to healthcare. The ABM focuses on examining the predisposing, enabling, and need factors that facilitate access to care. It suggests that equitable access to care may be obtained through the utilization of services as opposed to predisposing and enabling factors. The need for care is reflected by health status.

The ABM has three core components to its framework, including predisposing, enabling, and need factors. In the model, predisposing factors represent those factors that exist prior to any episode of illness such as health attitude; benefits; and social demographic factors such as age, gender, race/ethnicity, marital status, and occupation. In this model, organizational and financing factors serve as the enabling factors that facilitate the use of medical services. Organizational factors include having the usual source of care, a supply of providers, and the availability and convenience of services; financing factors include the availability and extent of health insurance coverage. In the ABM, need factors represent either the patient's subjective assessment of their need for service, such as the

number of disability days, limitations in activities, and perceived health status or an objective measure of the need for care, including a measurement of the severity of a disease.

In the application of the ABM to examining access to healthcare, one is expected to use all three components of the model to measure barriers to the equitable receipt of services. This approach would involve using the predisposing factors as measures of determining the fairness in the delivery of services: Thus, if there were significant differences in access to care by gender, then the medical system would be seen as providing inequitable care. In examining the delivery of care by these predisposing factors, one would also need to account or control for the enabling and need factors. Under this approach, equitable access is achieved when it is determined by the need for services and not by predisposing or enabling factors.

On the positive side, the ABM is widely used in both descriptive and analytical research as a benchmark for examining access to healthcare as it is a robust model from a measurement point of view. On the other hand, earlier versions of the model have been criticized for not adequately measuring the influence of culture and cultural competency and the influence of the political environment on care. It does not take into account the ever-changing world of healthcare financing and organizational policies, as found in managed-care organizations. Some researchers have found the model too cumbersome with its reliance on the need to have data on an array of factors to measure access to care. Finally, some argue that the model lacks the ability to capture aspects of the patient-provider interaction process.

The Health Belief Model

Developed by Godfrey Hochbaum and other researchers at the U.S. Public Health Service in the 1950s, the health belief model (HBM) was constructed as a means of examining factors that led to a onetime change in behavior such as screening or immunization. It was later modified by M. H. Becker to examine the use of medical services. The HBM is now used both as a means to examine the individual's motivation to change some aspect of his or her lifestyle, including diet, smoking, exercise, condom use, and medication use, and to

measure equity in the use of services. The model focuses on examining how an individual internalizes a problem and whether or not it has become a problem that is big enough to warrant immediate action; it does this without considering self-imposed or systematic barriers that may also exist. This assessment usually focuses on examining the individual's perceived susceptibility, severity of illness, benefits, barriers, cues to action, and self-efficacy.

Specifically, the HBM measures six core components: perceived susceptibility by determining the risk of an individual of contracting an illness as a result of not taking an action; perceived severity by assessing how a serious illness may affect him or her; perceived benefits by measuring the degree to which the individual follows a recommended behavior; perceived barriers by measuring the perception of the negative aspects of not taking action; cues to an action by focusing on the trigger events, or prompts, that either heighten an awareness of the importance of an activity or motivate an individual to take action; and self-efficacy by examining the extent to which an individual can successfully execute a given behavior.

When applying the HBM, access is measured by the specific reason for care, such as a visit for immunization or health screening. The observed behavior is studied against the individual factors that traditionally serve as obstacles to seeking care, and the trigger event that led to the action of seeking out care is determined.

The HBM has been widely used as a means to design and implement health educational and health behavior interventions. Its strengths lie in its ability to help map out the direction between an individual's thinking about a behavior and his or her readiness and willingness to change. However, while the model has been widely used to test health behaviors, it has been criticized as not being uniformly used. Some researchers have used only parts of the model and not all the components together. Additionally, some of the components of the model have not been validated or tested. Last, the HBM has also been criticized for not accounting for either normative behaviors or cultural factors.

The Theory of Reasoned Action

Developed by Martin Fishbein and Icek Ajzen at the University of Illinois in the 1970s, the theory

of reasoned action (TRA) is based on the notion that humans are able to rationally think about and respond to behavior based on weighing the costs and benefits of any given action. The key components of the TRA model focus on measuring the subjective norms regarding a behavior, measuring the attitude toward a behavior, and measuring how the attitudes and subjective norms can either lead to the intended act or actually execute some type of behavior.

Under the TRA model, researchers measure the subjective norm by examining what they think is important or what they think others want them to do. This is influenced by their knowledge of the factors that contribute to any given norm. Attitudes toward a behavior are measured by the degree to which an individual agrees or disagrees with a particular behavior. Last, researchers measure behavioral intent by developing and using measures that are closely related to the actual performance of a behavior.

Under the TRA, access to healthcare is considered a function of the consumers' understanding of the importance of seeking out health services and their willingness to follow up with an interest in obtaining care to actually get into the medical system. It assumes that knowing something is important and having a favorable attitude about it is a necessary precursor to obtaining access to healthcare. However, access to care is really reflected by the documentation that a person engages in obtaining care that helps her or him.

Like the HBM, the TRA model has been used extensively to examine a person's willingness to engage in healthy behaviors. This model focuses on the role of knowledge and attitudes in seeking care. Thus, its strength lies in its ability to examine the individual's motivation to seek care. However, most of the applications of the model have been related to examining behavioral intentions rather than to actual behavior. As it relates to access to healthcare, the model has been used more to determine whether or not someone would intend to seek medical care, rather than whether he or she actually obtained care. A second weakness of the TRA is a lack of consideration of the organizational and structural barriers, such as financing and environmental obstacles.

Future Implications

Measuring access to healthcare is a complicated process that requires the use of some organizing framework or model for examining the factors that facilitate entry into the medical delivery system. Four models were presented as examples of frameworks that are currently used to examine access to healthcare. While each of these models has its own strengths and weaknesses, their collective utility lies in their ability to help researchers and policymakers to use indicators for measuring the various components of access to healthcare. This assists in achieving an important objective in health services research—the promotion of theory-driven as opposed to data-driven research. Even if researchers are wedded to a particular model in looking at access to care, it is important to use an organized framework to guide the work. Otherwise, the efforts would just be analyzing the data without some sensitivity to whether or not some of the measures are duplicative or poor measures of a concept. In addition, by using a framework to drive the examination, researchers can add to the knowledge base by discovering how the framework or model can be modified to better measure access to healthcare.

ACCESS TO HEALTHCARE

Access to healthcare can be defined as the opportunity or right to receive care. One of the indicators of access to healthcare focuses on the availability of medical providers and facilities for care. A second set of indicators focuses on the availability of resources to pay for care. A third set of indicators focuses on the use of medical services. These indicators are interrelated to each other, yet they measure different aspects of access to healthcare. This entry highlights the national trends in the availability of medical providers and facilities, trends in the availability of resources to pay for care, and trends in the use of healthcare services.

Access to Medical Providers and Facilities

One of the issues in ensuring access to care is making sure that patients have access to the medical providers they need to see and the facilities they need to go to when they need health services.

Ensuring access to providers and facilities is related both to the distribution of these services and the choices consumers make regarding where to go for care. Without an adequate supply of providers and facilities for health services, patients may have to either delay seeking care or travel long distances to obtain services. This process of finding the right match between the patient, the providers, and the facilities is further complicated by the fact that care at these settings is often provided by a mix of providers, including physicians, nurses, physician assistants, physical therapists, pharmacists, social workers, and psychologists, rather than being provided solely by a physician. However, the physician has been and remains the central component of the delivery of healthcare services, either in an office-based practice or in a hospital-based practice.

Access to Providers

As regards the distribution of providers, one of the long-standing issues in the quest to equitably distribute physicians across the country is determining whether a sufficient number of physicians are being trained to meet the needs of patients. Additionally, consideration must be given to whether these physicians can be encouraged to work in historically underserved geographic areas, such as inner-city and rural areas. In 2004, there were 884,974 practicing physicians in the United States, 81% of whom worked in metropolitan areas, while 19% worked in nonmetropolitan areas. The overall number of practicing physicians has increased during the past two decades: In 1980, there were 443,502 active physicians in the nation. The number of medical school graduates grew by 12% between 1982 and 1998, but the U.S. population increased by 24% during the same time period. The increase in the supply of physicians has not kept up with the nation's population.

Several government policies have been used since World War II to foster the equitable distribution of physicians across the nation. These policies include the federal government offering incentives to states to increase the number of medical students and reducing immigration barriers to international medical graduates, the development and use of a needs-based approach by the Graduate Medical Education

National Advisory Committee (GMENAC) to manage the distribution of physicians, and the recruitment of medical specialists into managed-care organizations in the 1980s to match the expansion in the number of these organizations. Efforts to encourage physicians to practice in underserved areas have been recently complicated by declining healthcare reimbursement rates and increasing malpractice insurance rates. In terms of reimbursement rates, the federal government has traditionally reimbursed healthcare providers at a lower rate for services provided under the Medicaid program than that received from private health insurance companies. As a result, providers who practice in poor communities run the risk of receiving less payment per patient than those medical professionals who practice in other more affluent communities. Additionally, several malpractice insurance crises since the 1970s have discouraged providers from practicing in certain communities or in certain medical specialties, such as obstetrics.

In response to the gaps in the distribution of physicians in underserved communities, physician assistants and nurse practitioners have been given more latitude with regard to the healthcare services they can provide. While this approach may be necessary in poor communities with physician shortages, there are discussions within professional medical organizations regarding the optimal mix of these adjuncts to the physician labor force.

Access to Facilities

In 2004, of all the practicing physicians in the nation, 700,287 provided direct patient care. Of these, 77% worked in an office-based practice, while 23% worked in a hospital-based practice. As such, in discussing the issue of access to physicians, one must also look at medical facilities as a place where services are provided.

Several federal policies have been developed to foster the equitable distribution of medical facilities across the nation. These policies include the construction and expansion of hospitals under the Hospital Survey and Construction Act of 1946, also known as the Hill-Burton Act, and the development of community health centers to provide care for the poor.

The Hill-Burton Act was passed to promote the modernization of nonprofit hospitals in the nation.

In exchange for receiving hospital construction grants, these hospitals were required to provide free care for 20 years to eligible persons unable to pay for healthcare services. The act was later amended to include assistance for construction and modernization of nursing homes, rehabilitation facilities, outpatient facilities, and public and nonprofit health centers. The federal government has used the Civil Rights Act of 1964 to force Hill-Burton hospitals not to discriminate for receiving construction grants. In 2005, there were 316 Hill-Burton-obligated facilities in the nation.

While the Hill-Burton Act led to an increase in the number of healthcare facilities, government regulation, decreasing reimbursement, increased competition, and the growth of managed care during the past decades have led to many hospital closures across the nation. Between 1980 and 2004, the total number of hospitals in the nation, including community and specialty hospitals, declined from 6,959 to 5,759. The majority of closures occurred among community hospitals, which declined from 5,830 to 4,919; similarly, not-for-profit hospitals decreased from 3,322 to 2,967, and the number of state and local government hospitals declined from 1,778 to 1,117. On the other hand, the number of for-profit hospitals in the nation increased during this period from 730 to 835.

Since the initiation of community health centers in 1965, the number of federally funded health centers has grown to more than 1,000. More than one third of the patients seen in these centers in 2004 were Latino; another quarter were African American. The health centers serve as a major source of care for the uninsured and those on Medicaid. While the number of community health centers has increased by 58% between 1997 and 2004, this growth has not kept up with the rising rate of the uninsured during the same period.

Access to Resources to Pay for Care

Like the issue of access to providers and medical facilities for services, access to a means to pay for care continues to play a critical role in ensuring that consumers obtain access to care. Access to resources is a function of both having healthcare insurance and having adequate insurance coverage as the lack of insurance coverage translates

into barriers to getting to see a provider. As noted by the Kaiser Commission on Medicaid and the Uninsured in 2003, 42% of those who were uninsured did not have a regular source of care. In contrast, only 9% of individuals with insurance reported not having a medical home, a provider, or a facility to go to when needing care. Nearly half, 47%, of those who were uninsured had to delay seeing a medical-care provider because of the costs of care, compared with 15% of those who had healthcare insurance.

On the surface, one can address the first issue by simply noting whether or not the consumer can pay for care out of pocket or whether he or she has some form of insurance to pay for care. Public health insurance programs, including Medicare, Medicaid, State Children's Health Insurance Program (SCHIP), Veterans Health Administration, TRICARE, and private insurance can be individual coverage plans or employer-sponsored health benefits that can be used to pay for care. Both the scope of coverage and limitations of services need to be considered, which affect the type of care patients can seek and receive. Types of coverage include preventive care, chronic condition care, outpatient care, inpatient care, long-term care, mental health, substance abuse services, and prescription drug benefits. Similarly, insurance premiums, deductibles, coinsurance, caps on coverage, and exclusions help determine whether an individual has adequate health insurance or not.

With regard to the first issue, the extent of the gap in access to availability of care is usually determined by identifying the number of people who are uninsured at any given point of the year, the number who are uninsured all year long, or the number who were uninsured for more than a year. In 2005, there were 46 million Americans without health insurance coverage at some point during the year, which amounts to about one in five adults. Two thirds of the uninsured are low income, and 8 in 10 come from working families. Poor families are twice as likely as other groups to be uninsured. Latinos and Native Americans are the most likely to be uninsured, followed by African Americans, Asian Americans, and Whites. Adults between the ages of 19 and 34 are more likely to be uninsured than those of other age groups. Historically, employees of small companies are more likely to be uninsured than those who work for large companies.

Recent trends, however, indicate that some large companies have elected to not provide health insurance for their employees, and this practice changes workers' expectations for job-based coverage at large organizations. For example, between 2001 and 2005, the percentage of poor employees who had employer-based health insurance coverage dropped from 37% to 30%, while the percentage of near-poor employees who had employer-based health insurance dropped from 59% to 52%. It should be noted that the number of persons who are uninsured all year is typically less than that of those who were uninsured at any time during the year. At the same time, the number of adults who have some limitations in coverage is often higher than the number of uninsured adults. One of the underlying reasons for the number of underinsured adults is the lack of parity between types of insurance coverage, such as health, dental, substance abuse, and mental health coverage. Because deductibles are traditionally higher for dental, substance abuse, and mental health coverage, patients often delay seeking services and care in these areas.

Use of Services

While the availability of medical providers, medical facilities, and health insurance coverage are critical parts of access to healthcare, it is the actual utilization of medical services that demonstrates the extent to which persons are actually getting to see their provider when they need care. Overall nation trend data on the number of patient visits, including those for ambulatory care, inpatient stays, dental, mental health, and substance abuse services, have shown that the majority of Americans are gaining access to these services and the average volume of visits has increased. For example, 61% of the nation's population made at least one visit to a physician in 1964, while 84% of the population made one visit to a physician in 2002. In 1964, 43% of Americans made at least one visit to a dentist, compared with 65% in 2002. Additionally, hospital admissions grew from 11 per 100 persons in 1964 to 12 per 100 persons in 2002. The average number of physician visits for Americans per year increased from 4.9 in 1964 to 5.6 visits per year in 1996. In 1987, there were 3.2 visits to a psychotherapist per 100 persons. This rate remained unchanged in 1997.

Between 1992 and 1999, significant increases in hospital emergency department use were noted among persons 55 to 64 years of age and unemployed adults. During this time period, the volume of emergency department visits increased from 89.2 million to 102.8 million annually. This increase was a result of more illness-related visits as opposed to injury-related visits. There were an estimated 85 million visits made to outpatient departments in 2004. In 2003, federally qualified health centers (FQHCs) reported 50 million patient encounters for 12 million patients. Of these patients, 90% had incomes below 200% of the federal poverty level (FPL), 39% were uninsured, and 64% were of an ethnic or racial minority.

Future Implications

The availability of healthcare providers and facilities and the availability of resources to pay for care and the utilization of services are interrelated measures of access because they reflect the complexities of obtaining care. For example, having a regular provider is seen as important because a well-synchronized provider-patient relationship can lead to appropriate utilization. Having a provider in itself, however, does not equal medical utilization, but it can lead to effective medical use. The same can be said for having a means to pay for care. While having healthcare insurance is not the same as using healthcare services, it alleviates some of the barriers to obtaining care when needed. Today and in the near future, access issues are important because of the large and growing number of uninsured and the continuing maldistribution of physicians.

ACCREDITATION

Accreditation is a voluntary process through which healthcare institutions and programs are held accountable for meeting quality requirements or standards. Accreditation involves a rigorous evaluation carried out by an external independent accrediting organization. When healthcare institutions and programs gain accreditation, such accreditation can be viewed as an endorsement resulting from having met the identified requirements. While accreditation is voluntary, it may be required or accepted in lieu of other requirements to be deemed eligible for participation in government healthcare plans and funding. For example, the federal Centers for Medicare and Medicaid Services (CMS) requires

that companies participating in Medicare Part D prescription drug coverage have approved accreditation.

History

The accreditation of healthcare institutions originated in the United States in the early 20th century. In 1917, the American College of Surgeons set up a program of standards to define suitable hospitals for surgical training. This eventually developed into a multidisciplinary program of standardization, which in 1951 led to the establishment of the independent Joint Commission on Hospital Accreditation. Over time, that organization, which today is the Joint Commission, has greatly expanded its focus, and it now accredits 10 types of institutions and programs, including the following: ambulatory care; assisted living; behavioral healthcare; critical access hospitals; home care; hospitals; laboratory services; long-term care; networks; and office-based surgery.

Although the Joint Commission is the largest healthcare accrediting body in the nation, many other accrediting organizations have been established that accredit many types of healthcare institutions and programs. For example, the American Osteopathic Association's Healthcare Facilities Accreditation Program (HFAP) accredits acute-care hospitals and hospital laboratories; the National Committee for Quality Assurance (NCQA) accredits health plans, managed behavioral-healthcare organizations, managed-care organization, preferred provider organizations, and disease management programs; and URAC (formerly known as the Utilization Review Accreditation Commission) accredits many institutions and programs, including case management, claims processing, disease management, drug therapy management, and pharmacy benefit management. Most accreditation organizations are nonprofit tax-exempt organizations.

The past several decades have also witnessed the establishment of many healthcare accreditation organizations across the world. The number of such organizations has doubled every 5 years since 1990. For example, there are now 11 healthcare accreditation organizations in various European

nations. The Joint Commission has also established an international division (Joint Commission International) to accredit institutions and programs outside the United States.

Accreditation Process

The accreditation process often begins with a self-assessment by the applicant institution or program. This is followed by an on-site visit by a survey team from the accrediting organization. The survey team often consists of a multidisciplinary group of healthcare professionals. During the survey process, the team may visit various units of the institution, and they may conduct interviews with leaders, professional staff members, and others. A detailed report of the findings from the survey visit and any recommendations for improvements are presented to the institution. Finally, if the institution or program demonstrates that it meets the agreed standards, it is awarded accreditation.

It is customary for applicant institutions and programs to put substantial effort into the preparation for accreditation. To help with the process, accrediting organizations often provide or sell materials and consultation services to help prepare the institutions and programs for the impending evaluations.

The survey teams use specific standards to evaluate the institutions and programs. Usually developed by the accrediting organization, these standards work in tandem with accreditation, as they are the benchmarks relied on in the accreditation process. The standards are revised and updated on an ongoing basis to reflect the most current understanding of processes, procedures, and structures that result in improved healthcare outcomes and performance. Previously standards were often conceptualized as minimum requirements; today, however, the standards reflect optimal achievable levels of quality.

Accreditation is typically awarded for a limited period of time. This enables the periodic evaluation of the applicant institutions and programs, and it enables standards to be updated to reflect the latest research findings and guidelines to be enacted by the accrediting organizations. For example, Joint Commission accreditation is awarded for a period of 2 or 3 years, depending

on the type of organization or program (2 years for laboratory accreditation, 3 years for all others). Starting in 2004, however, the Joint Commission introduced a Periodic Performance Review component requiring some accredited institutions and programs to demonstrate continuous compliance.

Benefits and Limitations

Benefits of accreditation of healthcare institutions and programs include the following: the greater standardization of policies, procedures, and records; improved measurement of clinical and nonclinical indicators; improved quality of care and services; improved patient safety; increased marketability to the public and prospective workforce; decreased liability expenses; eligibility to participate in certain government programs; satisfaction of certain government reporting requirements; and compliance with certain mandated regulations.

Limitations of accreditation include inconsistencies between applicable regulations and accreditation requirements, the high costs associated with maintaining accreditation, and mixed findings from research on the efficacy of accreditation.

Future Implications

The increasing trend toward the accreditation of healthcare institutions and programs demonstrates a commitment to quality. Through the increasing reliance on outcome-based methods of quality improvement, the efficacy of accreditation is beginning to be understood. Studies have shown some promising findings, but the literature reports mixed findings on many measures of improvement related to healthcare accreditation, and more research is needed. Though accreditation is not mandatory, it is becoming increasingly critical to healthcare institutions and programs.

ACTIVITIES OF DAILY LIVING (ADL)

Activities of daily living (ADL) are actions performed on a daily basis to maintain personal hygiene and carry out basic activities of living independently. Measuring ADL constitutes an important element of health research programs and interventions targeting both the elderly and people with disabilities. Originally developed by Sidney Katz in the late 1950s, the Index of Independence of Activities of Daily Living, or Index of ADL, is one of the oldest and most widely used health measures. Over the years, Katz's system has been modified and expanded.

Types

Activities of daily living are broadly classified into two categories: (1) basic activities of daily living (BADL) or personal activities of daily living

(PADL) and (2) instrumental activities of daily living (IADL). A recently created third category, advanced ADL, includes activities related to occupation, recreation, and community interactions. ADL and IADL are self-reported, while advanced ADL is assessed on a case-by-case basis in clinical settings.

BADL are eating (i.e., using eating utensils, drinking), personal grooming (i.e., washing face, brushing teeth, cutting toenails, brushing hair, shaving, and bathing), using the toilet, ability to transfer from a chair to bed and to a toilet, sitting and rising from a chair, getting in and out of bed, walking inside the residence, stair climbing, being able to lift 10 pounds, and continence of bladder and bowels.

IADL are more complex and require greater concentration, skill, and coordination, such as using the telephone, driving, grocery shopping, preparing meals, doing light housework (i.e., light cleaning, straightening up), doing heavy housework (i.e., scrubbing floors, washing windows), laundry, and managing medications and finances.

Differentiating between BADL and IADL may not be possible due to differences in gender, age, and sociocultural perceptions of the variables under consideration. Performing ADL is important as it engenders self-esteem and helps individuals maintain a place in society as a parent, employee, friend, and community member. Difficulty performing ADL is most commonly a function of aging but can also be due to injury, congenital disorders, stroke, surgery, or chronic disease.

Scoring

ADL parameters are an important tool in the area of biopsychosocial medicine for evaluating functional impairments and quality of life in the disabled, elderly, and chronically ill. Katz formulated the first scoring system for ADL in 1963, and M. Powell Lawton developed an index for scoring IADL in 1969, but many additions and modifications have led to a number of scoring systems that measure a range of variables. While most scoring systems are based on the original Katz and Lawton indexes, no system is used universally. A variety of ADL and IADL scoring systems are used in geriatrics, psychiatry, and rehabilitation programs for

functional assessment protocols to assess the need for home, long-term, or nursing home care and hospitalization.

Functional Disability

Functional disability is a limitation in the performance of tasks of daily living such as maintaining personal hygiene and living independent of family or outside help. Functional impairment is not a uniform construct; it is multifaceted and can be measured with various clinical instruments. Functional status is an important determinant of self-rated health in the elderly. Independence in IADL is determined by physical ability as well as the environmental and cultural surroundings of the individual.

Worldwide, ADL decrease steadily with age. People with multiple chronic conditions such as cancer, diabetes, heart disease, arthritis, and Parkinson's disease are more likely to move from complete functionality to impairment in ADL than are those with a single condition or without disease. Cognitive problems in older adults are predictive of a decrease in functional ADL, while depression is predictive of changes in both ADL and IADL. ADL functioning is positively associated with being male, having daily contact with relatives and close friends, receiving home care, having a higher socioeconomic status, and belonging to a White culture. Though changes in functionality may be reversed with timely intervention, changes in IADL are rarely reversible.

Aging and Public Policy Issues

Although people of all ages may have difficulty performing ADL, prevalence rates rise sharply with advancing age and are considerably higher for those 85 years of age or older. ADL rating scales often classify older people as independent or dependent in self-care activities. However, with this type of classification system, little information is available on independent individuals who report some difficulty in performing self-care activities. It is standard practice to include an ADL index as a variable in public health and clinical research studies on the elderly.

Evidence shows that these measures of maintaining functionality are reliable indicators and predictors in clinical evaluations as well as in policy planning at all levels of elderly care. ADL scores are significant predictors of nursing home admissions, use of hospital and physician services, living arrangements, insurance coverage, and mortality. An increasing number of private long-term care insurance policies rely on ADL measures to establish eligibility for benefits. Public insurance programs such as Medicare and Medicaid also use ADL scores extensively to establish criteria for long-term care. IADL scores usually assess the need for home care, while compromised ADL measures determine the need for nursing home admission. Nationally, one in two residents needs help with three or more ADLs, compared with three in four nursing facility residents. A more impaired residential-care population is likely the product of complex interactions between state-level (licensing, reimbursement, etc.), facility-level (organizational characteristics and service capacity), and individual-level (resources, functional status, etc.) factors. In general, about two thirds of people who receive long-term care live in the community, while the other third live in an institutional setting. For every older adult living in a nursing home, there are two living in the community, often in a family setting, who may need equal levels of assistance.

ACUTE AND CHRONIC DISEASES

Healthcare providers, public health professionals, and health services researchers classify diseases in various ways. Some use general classification schemes, while others use more specific schemes. Diseases may be classified by their cause (e.g., bacteria, viral), whether they are communicable or noncommunicable, and whether they are infectious or chronic in nature. Infectious diseases may be further classified by their specific mode of transmission, incubation period, and portal of entry into the body. Chronic diseases may also be further classified by which organ system in the body is affected, disease outcomes, and types of intervention. Other schemes classify diseases into whether they are congenital and hereditary, allergies and inflammatory, cancer and neoplastic, metabolic, or degenerative and chronic in nature.

Many of the various disease classification schemes often overlap, and there is no single

“right” or perfect way of classifying diseases. However, one of the most commonly used schemes of classifying disease is to divide them into two broad categories: (1) acute and (2) chronic disease.

Meaning of Acute and Chronic Disease

Throughout recorded history, diseases have been classified by different means and classification schemes. What we now think of as acute and chronic diseases have been documented by the primitive hunter-gatherers of 10,000 years ago and in ancient civilizations from 6,000 years ago in Egypt, Mesopotamia, and the Indus Valley. The etymologic basis for the words *acute* and *chronic* is from the Latin. The word *acute* originates from the Latin *acutus*, meaning sharp or to sharpen. Over the years, the term has been applied to disease states and has taken on three parameters: conditions (1) of short duration, (2) of rapid onset, and (3) of severity. In contrast, the word *chronic* is derived from the Latin *chronicus* and means continuous or constant. Chronic diseases are conditions that are of long duration, slow onset, and less severity. Some expectations of chronic diseases are that they cannot be cured and they do not spontaneously resolve or disappear.

The early designation of a disease as acute or chronic was based on its duration. Although no actual time frame was designated, one thought of acute disease in terms of days or weeks, whereas chronic disease was thought of as lasting months, years, or for an entire lifetime. The National Center for Health Statistics (NCHS) now uses 3 months as the dividing line. Acute diseases are conditions lasting less than 3 months, while chronic diseases are conditions lasting for more than 3 months. However, it is important to note that the terms *acute* and *chronic disease*, and their use, vary in medicine and public health.

There is also a wide range of definitions of the words *acute* and *chronic*, depending on the audience questioned. For example, if you ask people in the general public what terms come to mind when you say the words *acute* and *chronic*, for *acute* they frequently say acute angle, acute shortage, acute sense of smell; and for *chronic* they say chronic complainer and chronically late. If you ask people in healthcare and public health what terms

come to mind when you say *acute disease*, they say acute abdomen, acute pain, and acute respiratory disease; and for *chronic disease* they say chronic cholecystitis, diabetes, and cancer.

The current standard for classifying diseases as acute or chronic is the *International Classification of Diseases* (ICD), now in its 10th revision (ICD-10). Originally published in the 1850s, the ICD was taken over by the World Health Organization (WHO) in 1948 and has become the standard for international diagnostic classification.

Why Definitions Are Inadequate

Epidemiology texts often tend to simplify the difference between acute and chronic diseases by stating that acute diseases are caused by pathogenic microorganisms, whereas chronic diseases are caused by lifestyle, certain behaviors, and the environment. While they are often true, these are not hard and fast definitions and are incorrect in many cases. Many diseases are not even defined using these terms. The term *chronic* is sometimes commonly used in some disease areas, such as cancers of the circulatory system and diseases of the heart, but absent when describing other types of cancer. In many cases, diseases will have acute phases but become quiescent or go into remission in between. Some infectious diseases are remittent in nature or have clinical and subclinical phases.

Disease Statistics and the Study of Morbidity and Mortality

The concept of classifying diseases has, at its roots, the collection of health information from populations. Collection of statistical information by sites was well-known in Florence and Venice in the 1300s, but not as a tool for analysis of health problems. John Graunt (1620–1674) analyzed the causes of death recorded in London’s Bills of Mortality. In 1662, he published the results of his analysis in *Natural and Political Observations Made Upon the Bills of Mortality*. He created the concepts of life expectancy and life tables, and he divided causes of death as being acute or chronic. In 1796, Per Wargentin (1717–1783) published the first mortality tables for an entire country, in this

case Sweden. William Farr (1807–1883), the registrar general in England, was responsible for developing the first modern vital statistics system. A very important observation made by Farr was that diseases, especially chronic diseases, seemed to involve many factors or a multifactorial etiology.

Pioneers in advancement of epidemiology and an understanding of disease in the United States were Lemuel Shattuck (1793–1859), who in 1850 reported on sanitation and public health problems in Massachusetts, and Edgar Sydenstricker (1881–1936), who in the early 1920s advanced the study of disease statistics. The ability to define diseases as acute or chronic depends on a complete understanding of the cause or etiology of these diseases and their morbidity and mortality.

The Role of Microbes in Chronic Disease

Through the nation's media, the general public is increasingly aware of human papillomavirus (HPV), a group of viruses that are sexually transmitted. There is an association of this virus with cell changes that may lead to cervical cancer. In fact, a new vaccine is available that will immunize individuals against HPV. The Advisory Committee on Immunization Practices (ACIP) had recommended to the U.S. Centers for Disease Control and Prevention (CDC) that the vaccine be given to 11- to 12-year-old girls and also recommended it for 13- to 26-year-old females who have not yet received or completed the vaccine series.

Other chronic diseases once thought to be due primarily to lifestyle factors, such as peptic ulcer disease, have been shown to be associated with microorganisms. It seems that most peptic ulcers are caused by *Helicobacter pylori* infection, which can be treated with antibiotics. A report by the American Academy of Microbiology lists more than 40 other diseases, including schizophrenia and Alzheimer's disease, that may have a microbial cause.

Acute and Chronic Concepts and Cancer

In general, cancer is considered a chronic disease. However, some cancers can be considered acute, if they progress rapidly enough. An example is acute myeloid leukemia. This is a condition in which

there are too many immature blood-forming cells in the blood and bone marrow. If untreated, it progresses rapidly. If treated, it may be forced into remission or become recurrent in nature.

Although cancer is considered a chronic disease, some cancer victims are said to be cured if their cancers do not recur or metastasize after specific lengths of time. In other words, there is no difference in causes of death in the "cured" population as compared with those who never had that cancer. Examples would be testicular cancer, Hodgkin's disease, and many types of leukemia. However, in some types of cancers, such as cancers of the lung, colon, breast, and prostate, there can be recurrence many years or decades after the original cancer. In this case, the cancers are treated and controlled.

Although it is assumed by most that cancer is a chronic disease because of the time frame involved and because in the past there was seldom a cure, it is interesting that the term *chronic* is not usually associated with cancer. In certain circumstances, the word *acute* is associated with cancer, such as in acute myeloid leukemia and acute lymphocytic leukemia. But this is not generally the case. In part, this appears to be due to the fact that there are many types of cancers, that it is such a complex set of diseases, and that each individual with the various types of cancers responds differently to treatment.

Mental Illness as a Chronic Disease

The terms *acute* and *chronic* are not often used in describing mental illness. Perhaps because mental illness is so poorly understood, often stigmatized, and underfunded, it has escaped the more typical disease classification schemes. Recently, mental illness has taken on major significance, especially since the World Bank and the World Health Organization Global Burden of Disease report was published in 1996. The report created three scenarios for what illness and disability would look like in 2020. In all three scenarios, unipolar major depression, alcohol use, and dementia ranked in the top 10 causes of illness and disability. In addition, 6 of the top 10 causes of disease and disability listed by the Organization for Economic Co-operation and Development (OECD) are mental illness.

The Three Epidemiological Revolutions

The United States and other advanced nations have gone through three epidemiological revolutions, which have shifted attention and concern from acute, infectious diseases, to chronic, degenerative diseases, to the cultural and socioeconomic causes of disease. The first epidemiological revolution began in the late 1800s and early 1900s. At that time, acute infectious diseases such as pneumonia, tuberculosis, and diarrhea were the main causes of death. Public health methods such as increased sanitation (e.g., sewage systems) and immunizations eventually led to the significant decline of these diseases. The second epidemiological revolution began in the mid-20th century. At that time, with the dramatic decline of acute infectious diseases, chronic degenerative diseases such as cancer, heart disease, and stroke became the main causes of death. The third epidemiological revolution began in the late 20th century. At that time, there was a realization that many diseases and societal problems arose because of poverty, prejudice, and changing cultural issues. Public health would now attempt to address the problems of violence, drug abuse, and teenage pregnancy.

Difference in Societal Perceptions of Acute and Chronic Diseases

There is no firm line between those diseases that are termed *acute* and *chronic*. Acute diseases may become chronic as new treatments and therapies are developed to maintain patients with a disease, or the disease itself may change into a form that is longer lasting or recurrent in nature. One example is HIV/AIDS. In the 1980s, HIV/AIDS was an acute disease that, once diagnosed, would kill rapidly through causing opportunistic infections. Since the early 1990s, with the development of powerful antiviral drugs, HIV/AIDS has become a chronic disease.

Cultural and societal biases may also help define acute and chronic disease. Beyond the time frame usually used to differentiate acute from chronic disease, our culture and society tend to approach acute diseases as if in war, saying that “viruses invade, bacteria attack, and parasites infest.” We also tend to describe treatment as consisting of

“killing bacteria, or battling an infection.” In contrast, we do not describe chronic diseases in terms of war but in terms of management. For example, physicians often encouraged their patients to daily manage their diabetes and hypertension. Furthermore, most chronic diseases have some level of stigmatization associated with them, with HIV/AIDS being the prime example.

ADAY, LU ANN

Lu Ann Aday is a health services researcher who has spent much of her academic career studying the indicators and correlates of health services utilization and access to healthcare. She has conducted a number of major national and community health surveys, and evaluations of national demonstration projects, and she has published many scholarly articles and books addressing the conceptual and empirical aspects of health services research on access to healthcare.

Born and raised in the small Texas town of Waxahachie, Aday received her bachelor's degree in agricultural economics from Texas Tech University in 1968. She then went to Purdue University to study and earned a master's degree in sociology in 1970. After completing her master's degree, she joined Volunteers in Service to America (VISTA) and served in a poor rural county in Georgia. This experience motivated her to carry out health services research on the access to healthcare for vulnerable populations. She completed her doctorate in sociology at Purdue University in 1973.

After completing her doctorate, Aday began her academic career as a research associate at the Center for Health Administration Studies (CHAS) at the University of Chicago. At CHAS, she worked closely with the noted health services researchers and medical sociologists Ronald M. Andersen and Odin W. Anderson. Aday later became senior researcher and finally associate director for research at the center. In 1986, Aday left CHAS to become an associate professor at the University of Texas School of Public Health. In 1991, she was appointed professor at the University of Texas Health Science Center at Houston, School of Public Health, Health Services Organization. In 2001, Aday became the Lorne D. Bain Distinguished Professor at the school.

Aday has published a number of books. Many of them have been published as second and third

editions, including *At Risk in America: The Health and Health Care Needs of Vulnerable Populations in the United States*; *Designing and Conducting Health Surveys: A Comprehensive Guide*; and *Evaluating the Healthcare System: Effectiveness, Efficiency, and Equity*.

Aday has served on many multinational, federal, and state boards, commissions, and committees, including the Institute of Medicine, the Agency for Healthcare Research and Quality (AHRQ), the national Institute of Medicine (IOM), and the National Cancer Institute (NCI).

During her academic career, Aday has received numerous awards and honors for research and teaching. She was inducted as a member of the IOM of the National Academy of Sciences in 1998. She received the John P. McGovern Outstanding Teacher Award in 1993 and the Minnie Stevens Piper Foundation Award for Teaching Excellence in 2000. And she received an honorary doctorate of social sciences from Purdue University in 2004.

In terms of her future research, Aday is planning to examine the perspectives, principles, and policies that would be encompassed within the field of population health ethics, in contrast to clinical medical ethics and public health ethics.

ADMINISTRATIVE COSTS

Administrative costs stem from resources used to manage or administer an organization. While they are common to all organizations, administration costs are of particular importance in the U.S. healthcare sector because of the complex nature of health services and the interaction between public and private insurers and providers of care. Another indication of the importance of administrative costs is that virtually all proposals for reforming the U.S. healthcare system include reducing the administrative burden as a key component. It is essential to note, however, that administrative costs are not always negative. Even the most efficient and productive organization must incur a certain level of administrative costs. The challenge is to eliminate only administrative costs that are wasteful or unnecessary. Specifically, this entry defines administrative costs, discusses the magnitude and types of administrative costs, and reviews health policy issues related to administrative costs.

Definition

Organizations produce outputs, which are goods and services sold to individuals or other organizations. For example, a hospital produces services such as cardiac care or orthopedic surgeries. In producing these outputs, organizations use inputs, which are resources such as labor, capital, and supplies. A hospital, for example, uses nursing care, medical supplies, equipment, and facilities to provide cardiac care. An organization's costs depend on the quantity of inputs used and the price of the inputs. Nursing costs, for instance, depend both on how many nurses are employed and on the wages they earn.

Costs can be categorized as direct costs or indirect costs. Direct costs can be linked precisely to a given output. For example, direct costs for cardiac care in a hospital would include nursing salaries,

medical supplies, and equipment for the cardiac-care unit. Indirect costs, then, are the remaining costs, which are more general in nature. The cost of utilities for the cardiac-care unit, for instance, cannot readily be distinguished from the cost of utilities for the orthopedic surgery unit or the intensive-care unit.

Administrative costs and support costs are the two main categories of indirect costs. Administrative costs stem from the managerial activities that are necessary for an organization to operate effectively, while support costs arise from other general activities needed for the smooth functioning of an organization. In a hospital, for example, costs of the human resources and quality assurance departments and salaries of upper management would be classified as administrative costs, while support costs would include expenses for facilities maintenance and housekeeping services.

Magnitude

Administrative costs in the nation's healthcare sector are substantial. At the broadest level, healthcare organizations can be categorized as being either providers of patient care or insurers. Healthcare providers include hospitals, physician practices, nursing homes, home health agencies, and many others. Insurers include public programs, such as Medicare and Medicaid, and many private insurers, such as Blue Cross and Blue Shield. Organizations in the healthcare sector incur numerous costs stemming from the complex nature of health services, the fragmented payment system, and the extensive regulation of health services.

On the provider side, administrative costs account for a considerable proportion of total costs. For example, administrative costs for hospitals and physician practices typically account for approximately 25% of total costs, while the percentage of total costs going to administrative costs in nursing homes is usually of the order of 20%. Using estimates of health expenditures from the Centers for Medicare and Medicaid Services (CMS), administrative costs in the nation's hospitals were of the order of \$150 billion in 2005, while for physician practices and nursing homes, administrative costs were about \$100 billion and \$25 billion, respectively. Another way to measure the magnitude of administrative

costs for providers is to examine the percentage of employee time spent on non-patient-care activities. Case studies indicate that in hospitals, for example, as much as 30% of staff time is devoted to documentation and recording, with more routine management activities, such as budgeting and supervision, accounting for about 7% of staff time.

For insurers, administrative costs typically are measured as a proportion of premiums and range from about 5% for Medicare to 10% to 12% for private insurers. However, estimates for Medicare and other public programs typically exclude important components of administrative costs, such as the costs of Medicare peer-review organizations and other quality-reporting requirements. Moreover, estimates using data from the national health accounts calculate the net cost of private insurance as the difference between premiums received and claims expenditures, the resulting residual including taxes and profits, as well as actual administrative costs. In addition, comparisons between public and private insurers do not take into account the fact that private health insurance plans, which are voluntary, must incur marketing costs to attract customers. Public insurance programs such as Medicare, on the other hand, are mandatory for the most part and do not encounter the same level of expenses for marketing and promotion. Finally, even comparisons across private insurers are complicated by variations in an insurer's mix of small and large employer groups and differences in methods of reporting administrative costs.

Types of Costs

In examining types of administrative costs, it is again useful to distinguish between providers of patient care and insurers. Researchers have proposed a framework for analyzing provider administrative costs, using three categories: (1) operational, (2) payer-related, and (3) regulatory costs. Operational administrative costs, which are common to all organizations, stem from management activities related to human, financial, and facility resources. To operate effectively, an organization must use resources to hire and manage staff, to set budgets and pay bills, and to purchase and maintain the plant and equipment.

The other two categories of provider administrative costs, payer-related and regulatory costs,

arise from special characteristics of the healthcare sector. For most organizations, administrative costs related to payment would be considered operational or an aspect of financial management. For healthcare providers, however, payment is complex and administratively burdensome. A single, large physician practice, for example, may have separate contracts with more than 100 insurers, each of which may have a different set of requirements for submitted claims, resulting in substantial resources needed to obtain payment for services rendered.

Healthcare providers also incur substantial regulatory administrative costs associated with government mandates, as well as requirements set by accrediting bodies. A hospital, for example, must comply with standards for state licensure and, depending on the state, certificate of need (CON) regulations, numerous federal regulations such as those set by the Occupational Safety and Health Administration (OSHA) and the Americans with Disabilities Act (ADA), and the requirements for accreditation by the Joint Commission. The Health Insurance Portability and Accountability Act of 1996 (HIPAA), in particular, has imposed wide-ranging requirements related to the privacy of patient information, with an accompanying increase in administrative costs to comply with these requirements.

More generally, other researchers have proposed a systemwide categorization of administrative costs as transaction-related, benefits management, selling and marketing, and compliance with regulatory requirements. Using insurers as an example, transaction-related costs stem primarily from the collection of premiums and the processing of claims, with the costs of benefits management being due to the activities associated with health plan design. Selling and marketing costs would include expenses from underwriting and marketing health plans mainly to employers but also to individuals. Finally, reserve requirements and premium taxes are examples of costs due to compliance with regulatory requirements.

Health Policy Issues

Proposals for reforming the U.S. healthcare system typically include recommendations that administrative costs be reduced, and most would agree

that reductions in these costs could release resources that could be devoted to providing more health services or increased health insurance coverage. Although recommendations to reduce administrative costs are common, less common are specific proposals for how to accomplish this objective.

One study that estimated healthcare administrative costs in the United States and Canada concluded that administrative costs are considerably higher in the United States than in Canada and argued that the United States should adopt a Canadian-like single-payer system of universal coverage. However, others have pointed out that definitions of administrative costs differ between the United States and Canada. For example, U.S. estimates typically include administrative costs associated with research, while estimates for Canada do not. In addition, single-payer systems may have hidden social costs due to longer patient waiting times and the unavailability of some services. Yet another criticism is that while moving to a Canadian-like system might reduce administrative costs, total expenditures on healthcare would likely increase due to greater utilization because more people would have health insurance coverage.

At the organizational level, the real challenge is to distinguish between necessary and unnecessary administrative costs. Even the most efficient and productive provider or insurer must incur a certain level of administrative costs. Thus, efforts to control administrative costs must focus on eliminating costs due to waste and other forms of inefficiency rather than on simply reducing overall costs. For providers, in particular, adverse effects could result from a simple proportionate decrease in administrative costs because costs associated with certain administrative activities are essential for the provision of safe, effective, high-quality patient care.

For the nation's healthcare system as a whole, policy changes have the potential to result in substantial reductions in unnecessary administrative costs. For providers, the multitude of payers, each having specific, and often quite different, paperwork requirements, is an obvious target. Policy changes aimed at standardizing the methods of billing for and collecting payment could lead to significant reductions in payer-related administrative costs.

Regulation is another area in which broad-based policy changes could have a big impact, given the remarkable number and scope of regulations affecting providers and insurers. For

example, a study in 1976 by the Hospital Association of New York reported that 164 different agencies regulated 109 different areas of hospital operations. Since that time, these differing, and sometimes competing, regulatory requirements have soared. Increased collaboration among regulatory agencies, perhaps mandated by federal legislation, could both decrease administrative costs and insure improved coordination of regulatory activities.

New regulatory programs typically are designed to improve the safety or quality of healthcare. For example, the CMS is moving toward mandatory reporting of quality information as part of its pay-for-performance initiative. New regulatory programs, however, typically entail additional costs, resulting in an even greater administrative burden for providers. Unfortunately, coordination between existing and new regulations is rare, leading to increased, and sometimes even contradictory, administrative requirements.

Future Implications

Administrative costs in the nation's healthcare sector are a continuing source of policy concern. While all organizations incur costs associated with managerial or administrative activities, organizations in the healthcare sector face a complex system of payments, with each provider payment being from public programs (primarily Medicare and Medicaid) and many different private insurers and with each payer having separate and often quite different paperwork requirements. Furthermore, organizations in the healthcare sector face regulations set by numerous government agencies at all levels—local, state, and federal—with differing agencies having sometimes conflicting requirements. Reducing administrative costs clearly has the potential to constrain the growth of health expenditures in the nation, but cost control programs must carefully distinguish between necessary and unnecessary administrative costs to avoid potentially adverse effects on the effectiveness, safety, and quality of patient care.

ADVERSE DRUG EVENTS

The use of medications (pharmaceutical drugs consisting of prescription and over-the-counter drugs, biologics, vaccines, and/or dietary supplements) generally results in beneficial, defined therapeutic outcomes when these drugs and related medications are taken properly and appropriately monitored. Nevertheless, there are inherent risks in using any medications. Adverse drug events are frequent and costly consequences of medication use. They are widely reported to be a significant cause of patient morbidity and mortality, and they cost billions of dollars in annual healthcare expenditures.

There is no universally accepted definition for an adverse drug event, and numerous definitions exist. Most definitions are similar to those put forth by the World Health Organization (WHO)

and/or the U.S. Food and Drug Administration (FDA). The WHO defines an adverse drug event as any response to a drug that is noxious and unintended in doses normally used in people for diagnosis, prevention, and treatment. The FDA describes serious adverse drug events as events that result in patient death, life-threatening outcomes, hospitalization, disability, congenital anomaly, and outcomes requiring healthcare interventions.

Adverse drug events include both preventable and unavoidable events, the latter of which are also known as adverse drug reactions. An adverse drug reaction is an unintended, undesired, and unexpected response to a drug that negatively affects a patient. It may result in the need to change drug therapies and/or other treatments; hospitalization or other institutional admission or prolonged stay; and patient complications, including disability or death. Common side effects of pharmaceutical drugs are not generally considered to be adverse drug reactions.

Adverse drug events include the following: unexpected, injurious adverse drug reactions experienced during use of the medicine; and harmful outcomes secondary to preventable medication errors, including errors of omission or commission. The causes of medication errors (i.e., preventable adverse drug reactions) are multifactorial and can be related to drug prescribing, order communication, dispensing, administration, monitoring, product packaging and labeling, product nomenclature, education, monitoring, and other product use. Medication errors result from failed systems, lack of knowledge, and lapses in performance or mental processes—regardless of whether the medication is under the control of the patient, caregiver, or healthcare practitioner. Medication errors may be caused by defective systems involving patients and caregivers, healthcare practitioners, regulators, manufacturers, healthcare organizations, and other entities.

In addition to physical afflictions, adverse drug events impose a significant economic burden on society. The number of people who reportedly died from medication errors increased 2.5-fold from 1983 to 1993. The national Institute of Medicine (IOM) estimated that approximately 106,000 individuals died from an adverse drug event in 1994, and an estimated 2.2 million individuals were hospitalized with a serious adverse drug event. In

2006, the IOM concluded that at least 1.5 million preventable adverse drug events occur in the United States annually, and the true number might be much higher. The IOM conservatively estimates the 2006 national hospital costs associated with adverse drug events at \$3.5 billion.

In 1995, Johnson and Bootman developed a probability pathway model to estimate the direct cost of managing drug-related morbidity and mortality in the ambulatory-care setting in the United States. Their results showed that drug-related mortality and morbidity cost \$76.6 billion per year. An updated analysis based on that 1995 model showed that the cost of drug-related problems among ambulatory Americans more than doubled in 2000 to an estimated \$177.4 billion, with hospital admissions accounting for \$121.5 billion or 69% of the total costs. These costs are borne by patients, families, health insurers, government, healthcare providers, employers, and others.

Reporting Systems

Identification and reporting of adverse drug events is a crucial first step in improving patient safety. For optimal risk communication and quality improvement purposes, it is worthwhile to track potential as well as the actual adverse drug events since they can all lead to patient injury in the future.

There are a number of national surveillance systems for reporting errors, adverse events, and near misses. These systems vary with respect to scope and whether they use active or passive surveillance mechanisms. Passive systems rely on the spontaneous, voluntary reporting of observed adverse events by clinicians and others who are involved with the event, while active reporting involves the regular, periodic collection of event data or medical records from healthcare providers or facilities. Spontaneous voluntary reporting has long been the primary mechanism to identify adverse events; however, it is believed that spontaneous reports can identify only 1 in 20 adverse drug events.

The major passive adverse drug event reporting and surveillance systems include the following: U.S. FDA—MedWatch program, U.S. Department of Health and Human Services—Vaccine Adverse Event Reporting System (VAERS), United States Pharmacopeia (USP)—MEDMARX[®], and the

USP/Institute for Safe Medication Practices (ISMP)—Medication Error Reporting Program.

The U.S. FDA's MedWatch program is a voluntary reporting system for healthcare providers or consumers regarding serious adverse events, product quality problems, or product use errors. Reportable products under MedWatch include FDA-regulated drugs, biologics, medical devices, cosmetics, and special nutritional products.

The VAERS is a cooperative program of the U.S. FDA and the Centers for Disease Control and Prevention (CDC). The VAERS system tracks adverse events believed to be associated with a given vaccine, which are voluntarily reported, analyzed, and made available to the public.

The USP is a private, quasi-regulatory organization. It administers MEDMARX[®], an Internet-accessible medication error and adverse drug reaction reporting system for participating hospitals and healthcare systems. The USP national database includes records on more than 1.1 million events and consists of proprietary data compiled from participating institutional subscribers. The USP/ISMP-Medication Errors Reporting Program (MERP) collects and reviews reports of actual and potential medication errors submitted by healthcare professionals. The USP/ISMP-MERP attempts to determine the causes of medication errors, including name label and packaging hazards.

The major active governmental surveillance systems for adverse drug events include the following: U.S. FDA-Adverse Event Reporting System (AERS), National Electronic Injury Surveillance System-Cooperative Adverse Drug Events Surveillance System (NEISS-CADES), and the Substance Abuse and Mental Health Services Administration-Drug Abuse Warning Network (DAWN).

The U.S. FDA-AERS includes data from adverse drug reaction reports submitted by pharmaceutical manufacturers (as required by regulation) and voluntary submissions through MedWatch. The AERS includes the FDA-regulated drugs and biologics.

The NEISS-CADES is a collaborative, multi-agency program administered by the CDC, the Consumer Product Safety Commission, and the U.S. FDA. This system includes survey data on injuries and adverse drug effects that are extracted from the medical records from emergency department visits at 64 selected U.S. hospitals. The FDA and CDC analyze these data with the goal of

developing interventions for preventing future adverse drug events.

The Substance Abuse and Mental Health Services Administration-DAWN collects drug- and alcohol-related data from emergency department visits and medical examiner records in 22 U.S. cities regarding adverse events associated with the nonmedical use of legal or illegal drugs and other substances.

Although not limited to adverse drug events, there are also a number of state adverse-event-reporting programs. In 2008, 26 states and the District of Columbia had laws or regulations for the mandatory reporting of adverse events to state agencies by hospitals and other healthcare facilities. These include very serious events that could result in patient death, harm, or serious injury, such as “never events” or “sentinel events” as categorized by the National Quality Forum or the Joint Commission.

In the private sector, the Health Maintenance Organizations Research Network (HMORN) conducts an active surveillance system. The HMORN researches and disseminates information about adverse events reported through managed-care health plans’ defined populations, providers, delivery systems, and data. In 2008, 15 large managed-care plans were included in the network consortium.

A few commercial online event-reporting systems exist for spontaneous reporting in acute-care settings, and one healthcare alliance (Premier, Inc.) developed a proprietary incident reporting system for pharmacy, infection control, and incident management. Benchmarking capabilities from such online incident reports is a helpful process, albeit limited by insufficient database linkages. Current reporting systems in acute-care settings may have the capability to include UB-92, UB-04, or equivalent electronically transmitted billing submission discharge data (e.g., age, gender, diagnosis, and procedures) for inpatients, but are limited by lack of clinical indications, double counting of patients, unknown linkages between prescriber/drug and drug/indication, and other issues.

The described adverse drug events-reporting systems provide numerous advantages. Yet the ability to learn from most of them is hindered by underreporting, limited scope, unknown rates of

adverse event occurrence, lack of standardization, and individual event reports that cannot be combined and/or generalized. The use of administrative data, such as claims and discharge data, represents another major method for measuring adverse drug events. Limitations of only using administrative data include incomplete information that is bereft of clinical detail and potential bias in coding reimbursable conditions. More optimal systems combine methods from multiple sources to estimate the incidence and prevalence of adverse drug events within systems as well as to determine causes and outcomes.

Research and Strategies

Research studies examining adverse drug events have accumulated since the 1960s, and findings demonstrate considerable variations in incidence rates, risk factors, and definitions. Identification of adverse drug events is a crucial first step in improving patient safety. One reason why it is difficult to study them is that reliable identification and classification of events is difficult. The necessary prerequisite to studying adverse drug events is to identify them accurately and consistently. The main methods of detecting adverse drug events are through direct observation by trained observers, voluntary reporting, and chart review. More optimal use of information technologies should aid future research.

Most existing studies have focused on adverse drug events among hospitalized patients rather than outpatients (including those in community settings). Most articles on hospital-based safety systems rely on incident reports by clinicians, case studies, events detected by local computer systems, and review of the chart or clinical record. Published information on event detection in hospitals is typically available from individual reports, which renders it difficult or impossible to compare study results and evaluate rates to explore characteristics and causes. As strategies for preventing and reducing the impact of adverse drug events in the outpatient setting are developed, an important component will be the newly implemented Medicare’s Medication Therapy Management Services (MTMS).

The prevalence of prescription medication use among the ambulatory adult population increases

with advancing age. Even though most medication errors do not result in injury, the extensive use of medications by the geriatric population suggests that sizeable numbers of older persons are affected. Previous studies on risk factors associated with adverse drug events in elderly populations documented that demographic and socioeconomic characteristics, multiple chronic disease condition, recent hospitalization, previous adverse drug event history, and specific medications can affect the occurrence of adverse drug events. MTMS is part of the Medicare Prescription Drug, Improvement and Modernization Act of 2003, which provided (among other provisions) a voluntary outpatient prescription drug benefit to Medicare beneficiaries starting in January 2006. Local or regionally based MTMS are intended for a targeted Medicare population, which is defined as those individuals who have multiple chronic diseases, are taking multiple prescription drugs, or are likely to incur high medication expenses. The purpose of MTMS is to optimize therapeutic outcomes and decrease costs by improving medication use and reducing adverse drug events in the targeted population.

Patients, healthcare providers, and private and government organizations should work together to enhance the identification and reporting of adverse drug events. Greater analysis of adverse drug event reports will help in information dissemination and education to prevent and minimize their occurrence and associated problems. Various recommendations to prevent adverse drug reactions and medication errors have been posited. These include encouraging patients to take a more active role in their healthcare, increasing communication between patients and healthcare providers, using more effective information technologies in the medication-use process, increasing the monitoring of patient safety, and calling for the U.S. FDA and other regulators to work with pharmaceutical manufacturers and others to improve drug product packaging and labeling.

ADVERSE SELECTION

Adverse selection arises in markets where there is asymmetric information between buyers and sellers. Asymmetric information occurs when one party in a transaction or contract has information that is not observable to the other party. Adverse selection is a term commonly used by economists, insurers, statisticians, and policymakers to explain what happens when individuals have unobserved characteristics and make their choices based on those characteristics. Moral hazard is another important aspect of health insurance markets and is often studied in the same context as adverse selection. Moral hazard defines the situation where the cost of one's action is shared with another party (e.g., insurer), and this causes one to behave differently than one otherwise would if one were responsible for the full cost of one's action. For example, an insured person may consume more healthcare with insurance than he or she would if he or she paid out of pocket. In contrast, adverse selection occurs when an individual enters a contract based on his or her private and unobservable information. An example of this is an expectant mother choosing an employer that offers generous maternity benefits over one that does not.

Insurance is designed to provide protection from unexpected risks. However, an individual may have a better understanding of his or her future healthcare needs than a health insurer. Individuals may know their expected health expenditures through their parents' medical histories or from genetic tests. Adverse selection occurs when they choose insurance coverage with this in mind. If insurance companies are not aware of individual risk levels, then insurance markets may experience adverse selection as a result of high-expected-cost individuals purchasing more comprehensive coverage. This will likely lead to higher premiums and could drive low-expected-cost individuals to less

comprehensive insurance policies. In contrast, if potential risks are common information for both parties, then high-risk individuals may face barriers to coverage of predictable expenditures because insurers will exclude likely events from an insurance policy.

The Lemon's Principle

The concept of adverse selection was first formally introduced by George A. Akerlof in his 1970 seminal article titled "The Market for Lemons: Quality Uncertainty and the Market Mechanism." In the article, Akerlof presents adverse selection in the context of a used car market where the sellers know the quality of the car they are selling and the buyers are only aware of the distribution of the quality of the cars for sale. The quality of a used car could vary from good to bad (a lemon), but the buyers have no way of identifying the quality of each car, especially if all cars are sold at the same price.

Consider a market where there are five used cars with varying quality levels for sale. For simplicity, we will assign a cardinal index of values to each of these cars: 0, 0.25, 0.5, 0.75, and 1. Assume that the seller's reservation sale price (i.e., lowest price) of each car is equal to $\$2,000 \times \text{quality}$. If the market price is set at $\$2,000$ initially, then all five cars would be offered for sale. However, since the buyer only knows the distribution of the quality of cars, his offer price will be equal to $\$2,000 \times \text{average quality}$ (0.5), or $\$1,000$. Thus, no cars would sell for $\$2,000$. If the market price is then brought down to $\$1,000$ to accommodate the buyer's offer, then the two best cars would exit the market since the new market price is lower than their reservation value. The withdrawal of the two best cars results in a drop in the average quality of the remaining cars to 0.25, and the buyer's offer price would then fall to $\$500$. Again, no cars would be sold. If the market price falls further to match the buyer's offer at $\$500$, the next best car would exit the market, leading to a further drop in the average quality of the remaining cars in the market. A continuation of this pattern leads to bad cars driving the good cars from the market, leaving no market in the end. This example, known as the lemon's principle, is an extreme case of adverse selection.

However, in most cases, trade is not totally eliminated, though market allocations may result in economic inefficiencies.

Adverse selection is a common consideration in health insurance markets. Individuals with higher expected healthcare costs prefer more generous health insurance plans than do individuals with lower expected healthcare costs. Thus, more generous health insurance plans will offer higher premiums to profitably provide generous coverage. This is analogous to Akerlof's lemon's principle. A health insurance company offers premiums designed to cover the average cost of health expenditures as well as fixed costs. If at this premium low-risk individuals decline health insurance, the premium will rise to reflect the higher expected expenditures of the individuals who select the plan. This cycle results in high-risk individuals driving the low-risk individuals from the health plan. In the context of insurance, this is called an adverse selection "death spiral" if it continues until no insurer can profitably offer a policy. The empirical evidence on the existence of adverse selection death spirals is mixed. In 2002, Thomas Buchmueller and John DiNardo found no evidence of a death spiral when insurers were restricted to offering the same premium to groups of individuals by community rating laws.

Pooling and Separating Contracts

In the above example, a pooling contract was offered. Under adverse selection, a pooling contract will lead low-risk individuals to decline coverage. It is possible for the insurance company to offer two health plans: one targeted at high-risk individuals and the other targeted at low-risk individuals. This is known as a separating contract, which could lead to a separating equilibrium where both types of individuals accept some form of coverage against future expenditures. The term *equilibrium* refers to a market equilibrium (price equilibrium) where the number of contracts offered by the insurer at a given price is equal to the number of contracts sought by individuals at that price. A health plan may offer partial coverage at a reduced premium and a second contract with full coverage. Under certain conditions, an equilibrium could be sustained where low-risk individuals select partial

insurance and high-risk individuals choose full coverage. An example of partial coverage might be a plan with an extremely high deductible.

Adverse selection may lead to a distortion in the quality of services offered. Richard Frank and his colleagues examined adverse selection in managed-care markets, where health plans offer coverage for different types of diseases. They show that as a consequence of adverse selection, health plans have an incentive to distort the quality of (or access to) certain types of care in order to attract low-risk enrollees and deter high-risk ones. They predict that a health plan will avoid high-cost enrollees by offering limited coverage for chronic (i.e., predictable) conditions, especially when they are highly correlated with other types of health expenditures.

Asymmetric Versus Imperfect Information

In the lemon's problem, the sellers had more information about the cars than did the buyers, and in the health insurance market, the buyers had more information about their future healthcare expenditures than did the insurers. If both parties had the same information about the product being exchanged, then adverse selection would not occur. This is true even if it is not perfect information. This is important because if both parties have the same information regarding average expected health expenditures, all beneficiaries may be willing to join a plan that protected against unexpected expenditures at the average expected price, and pooling would occur.

Addressing Adverse Selection

Many research studies have explored ways to overcome market inefficiencies due to adverse selection. Michael Spence introduced the concept that there are ways in which an individual can send a signal regarding his or her risk type. High-quality producers of a product will find a mechanism to reveal their unobserved quality to buyers in a way that low-quality producers cannot profitably replicate. Although signaling is common in other markets, individuals tend to reveal verifiable private information to obtain better coverage in health insurance markets.

It is common for disability insurers to require a comprehensive medical examination and detailed health information before providing disability coverage. They then design a contract that takes the person's medical history into account and may exclude certain causes of disability. Health insurance companies respond to adverse selection by excluding preexisting conditions during the 1st year of newly acquired coverage. Furthermore, the companies tend to offer a set of health plans with varying amounts of premiums and deductibles so that individuals can select an appropriate plan based on their risk type. For example, a healthy person may prefer to be in a low-premium, high-deductible plan rather than in a high-premium, low-deductible health insurance plan.

AGENCY FOR HEALTHCARE RESEARCH AND QUALITY (AHRQ)

The Agency for Healthcare Research and Quality (AHRQ), which is part of the U.S. Department of Health and Human Services (HHS), is one of the nation's largest supporters of health services research initiatives. AHRQ's broad mission is to improve the quality, safety, efficiency, and effectiveness of healthcare for all Americans. To fulfill its mission, AHRQ conducts and supports health services research, both within the agency and through grants and contracts to universities, healthcare systems, hospitals, and physicians' offices. AHRQ also works closely with its sister agency the National Institutes of Health (NIH), which conducts biomedical research.

Background

A number of federal organizations preceded the AHRQ. The federal Omnibus Budget Reconciliation Act of 1989 established its immediate predecessor, the Agency for Health Care Policy and Research (AHCPR). The purpose of AHCPR was to enhance the quality, appropriateness, and effectiveness of healthcare services and access to healthcare. At the time, the AHCPR was the successor to the National Center for Health Services Research and Health Care Technology Assessment. As a research agency, the AHCPR supported studies and reviews to improve the quality of healthcare. One of its major responsibilities was to use research to develop, review, and update clinical practice guidelines to advise healthcare practitioners in the prevention, treatment, and management of specified health conditions. This guideline development program continued until 1996. Some of the clinical practice

guidelines issued by the agency were highly controversial, and specific medical societies lobbied their legislators to end the funding of the AHCPR.

In 1999, the U.S. Congress passed legislation reauthorizing the AHCPR but changed its name to the Agency for Healthcare Research and Quality. This change was strategic and intentional because it confirmed the agency's dedication to scientific research. Removal of the word *policy* clarified that the agency does not determine healthcare policy. While the AHRQ does not direct policy, it continues to support research and inform policymakers.

Although the AHRQ is no longer obligated to develop clinical practice guidelines, the agency retains many critical functions. Specifically, the AHRQ must (a) meet the information needs of its consumers (patients, practitioners, health system leaders, and policymakers) so that they can make more informed decisions; (b) build the evidence base for what works and does not work in healthcare and develop the information, tools, and strategies that decision makers need; (c) continue the national Medical Expenditure Panel Survey (MEPS) to evaluate various cost-related issues, including the types of healthcare services Americans use, the access and frequency of healthcare service use, and the amount of money Americans pay for care; (d) develop a database that provides information to states on their residents' access to healthcare services and on the quality and use of those services; (e) establish the Centers for Education and Research on Therapeutics (CERTs) as a permanent program; and (f) support the use of clinical practice guidelines through Evidence-Based Practice Centers (EPCs), National Guidelines Clearinghouse, and the U.S. Preventive Services Task Force.

During its transition from the AHCPR to the AHRQ, John M. Eisenberg provided pivotal leadership that positioned the agency for its current functions. Like its predecessor, the AHRQ continues to have a well-educated multidisciplinary staff. Scholars from disciplines such as health services research, dentistry, medicine, nursing, and public health work to support other scholars and investigators in the pursuit of knowledge.

Current Centers and Programs

AHRQ's organizational structure supports its key mission through a number of focused centers.

Specifically, the centers include the following: (a) quality improvement and patient safety; (b) outcomes and effectiveness of care; (c) clinical practice and technology assessment; (d) healthcare organization and delivery systems; (e) primary care (including preventive services); and (f) healthcare costs and sources of payment. The staff in these centers accomplish the work using a variety of funding mechanisms, such as grants and contracts, and in-house research. Through these various strategies, the agency forms effective partnerships with other government agencies, academic institutions, and industry.

Specific Projects

The AHRQ supports 12 EPCs. The functions of the EPCs are to review and synthesize available knowledge of various healthcare topics and describe the quality and the strength of that evidence—specifically research findings. The synthesized information is then made available to providers, insurers, and others for use in determining their own practices and policies. Topics can be nominated by various public or private organizations as well as the agency and are examined to determine whether or not there exists a sufficient scientific base to warrant the synthesis and review. The importance of the topic to large segments of the population, such as those receiving Medicare or Medicaid, or those associated with high costs or chronic illnesses are typical subject areas.

The AHRQ provides core support for 14 CERTs and their coordinating centers. The U.S. Food and Drug Administration (FDA) also provides funding, and individual centers may receive funding from other public or private sources. Broadly, the CERTs are to develop and disseminate knowledge about a range of products that may be used to prevent or treat disease. The desired result is that patients and providers will use such information to determine appropriate use—not over- or underutilization. Specifically, the program objectives are (a) to increase awareness of both the uses and risks of new drugs and drug combinations, biological products, and devices, as well as of mechanisms to improve their safe and effective use; (b) to provide clinical information to patients and consumers,

healthcare providers, pharmacists, pharmacy benefit managers, purchasers, health maintenance organizations (HMOs) and healthcare delivery systems, insurers, and government agencies; and (c) to improve quality while reducing the cost of care by increasing the appropriate use of drugs, biological products, and devices and by preventing their adverse effects and the consequences of these effects (such as unnecessary hospitalizations).

Another mandate is to convene the U.S. Preventive Services Task Force (USPSTF), an interdisciplinary group of clinicians and scientists with expertise in primary-care services. This group uses established guidelines to review evidence about preventive services and makes recommendations, mostly directed at those who provide primary care. Agency staff works closely with one EPC, which focuses on this assignment, to develop materials for consideration by the panel. Other federal agencies also contribute to the scientific effort. Additionally, other experts and organizations review draft documents to obtain the best and clearest guidance. The statements in the published guidelines become the standard of care nationwide.

In existence since 1996, the Medical Expenditure Panel Survey (MEPS) provides a unique resource on the cost and use of healthcare and health insurance coverage in the nation. Information is collected on two components: (1) households and (2) insurance. Over a 2-year study period, data are collected on all members of selected households, including their health conditions, access to care, health insurance coverage, and employment. By interviewing respondents over the 2-year study period, data about changes in health conditions, employment, and other factors can be examined for their potential impacts. The health insurance component is also known as the Health Insurance Cost Study and obtains data from employers on the coverage provided to their employees, its costs, and what benefits are provided.

Since 1988, the Healthcare Cost and Utilization Program (HCUP) has been the largest all-payer collection of hospital inpatient-care statistical information in the nation. It gathers longitudinal data on hospital costs, including all-payer and encounter-level data. These data are available to scholars and others and are useful particularly to those who are examining statewide data. Like most AHRQ products, the information is available on the agency's

Web site. The HCUP is also a good example of how the AHRQ does not make policy but provides important resources for those who do.

The HIV Research Network (HIVRN) is sponsored by the agency and several other organizations of the federal government. The network includes 18 member practices that treat about 14,000 patients and report conditions of HIV patients, therapeutic interventions, and services delivered. Combining these data provides a resource for understanding patterns in management. While data are made public through HIV Net, the network does not release information that can potentially identify participating practices, individual patients, or locations.

To provide information to its many consumers, the AHRQ supports a number of other projects. Over the years, AHRQ has invested millions of dollars to implement and improve the nation's health information technology. To share the experience and knowledge of its health information technology grantees, the agency developed the National Resource Center for Health Information Technology (Health IT). Through this center and its Web site, the agency provides resources for organizations to use in assessing their health-related information technology. The center's Web site contains a wealth of information, including a compendium of surveys and a tool kit.

The Patient Safety Network (PSNet) is a compilation of articles and recent findings related to patient safety issues. It is funded by the agency and guided by a national advisory board. Individuals may receive the updates online through a registration process.

Another important agency project is the National Consumer Assessment of Healthcare Providers and Systems (CAHPS). Individuals and organizations can use CAHPS to assess the patient-centeredness of care, compare and report on performance, and improve the quality of care. The health plan survey component of CAHPS, which began in 1998, now anchors this group of surveys that organizations can use to evaluate their own performance in comparison to the national database.

The AHRQ maintains an excellent series of Web sites, and personal contact and support from agency staff are easily available.

AIKEN, LINDA H.

Linda H. Aiken is an influential nurse leader and researcher in the field of nursing outcomes research. Aiken is the Claire M. Fagin Leadership Professor of Nursing, professor of sociology, and director of the Center for Health Outcomes and Policy Research at the University of Pennsylvania. She is also a senior fellow at the Leonard Davis Institute for Health Economics, and research associate in the Population Studies Center, and she codirects the National Council on Physician and Nurse Supply.

Aiken conducts research on healthcare outcomes and health workforce policy. She is the principal investigator of a five-country study of hospital-care outcomes in the United States, Canada, England, Scotland, and Germany and is involved in evaluating the impact of 90 healthcare partnerships funded by the United States Agency for International Development (USAID) in Eurasia.

Prior to joining the faculty of the University of Pennsylvania in 1988, Aiken was vice president of the Robert Wood Johnson Foundation (RWJF), where she directed the research and evaluation program. While at the foundation, she designed a \$100 million demonstration initiative to improve care for the chronically mentally ill, for which she received a unique Joint Secretarial Commendation from the Secretary of the U.S. Department of Health and Human Services and the Secretary of the U.S. Department of Housing and Urban Development.

Aiken has received many awards and honors for her work. She received the William B. Graham

Prize for Health Services Research, the Ernest A. Codman Award from the Joint Commission, the Baxter Episteme Award from Sigma Theta Tau International, the Barbara Thoman Curtis Award from the American Nurses Association (ANA), and the Distinguished Investigator awards from AcademyHealth. Aiken is also the recipient of three American Academy of Nursing Media Awards.

Aiken is an elected member of the national Institute of Medicine (IOM), where she is a member of the Board on Health Care Services. She is a fellow and former president of the American Academy of Nursing and an Honorary Fellow of the Royal College of Nursing of the United Kingdom. Aiken is also an elected fellow of the American Academy of Arts and Sciences, and the National Academy of Social Insurance, and a Distinguished Fellow of the Academy for Health Services Research and Health Policy. In addition, she is a member of the Council on the Economic Impact of Health System Change, and she has served on the Medicare Physician Payment Review Commission (PPRC) for 6 years.

Aiken received her bachelor's (1964) and master's (1966) degrees in nursing from the University of Florida, Gainesville, and her doctorate degree (1973) in sociology and demography from the University of Texas at Austin. She was a postdoctoral research fellow (1973–1974) in medical sociology at the University of Wisconsin, Madison.

Aiken has made many notable contributions to public health through innovative health services research, and she has had a significant impact on the way healthcare is delivered. Her work has greatly influenced nursing policies and practices, including nurse recruitment and retention, nurse work force supply, patient-care practices, and staffing. Aiken's work continues to be recognized by scholars and practitioners for her many contributions to improving health and medical care nationally and internationally.

ALLIED HEALTH PROFESSIONALS

Allied health professionals are the staff involved with the delivery of healthcare or related services pertaining to the identification, evaluation, and prevention of diseases and disorders. They are also involved in dietary and nutrition services, rehabilitation, and health system management. In the United States, there are more than 6 million allied health professionals from a myriad clinical support and technical occupations in healthcare services. According to the U.S. Department of Labor, about 60% of the nation's healthcare workforce is composed of allied health professionals.

Allied health professionals represent more than 70 areas of expertise, and they are trained in more than 2,500 higher-level educational institutions in the nation. These professionals include dental hygienists, diagnostic medical sonographers, dietitians, medical technologists, occupational therapists,

physical therapists, radiographers, respiratory therapists, and speech-language pathologists.

Although there is no standard definition or number of health professions that consistently fall under the term *allied health professionals*, it is clear that these professionals have an important impact on the nation's healthcare system. They are actively engaged in the provision and delivery of health services, working alongside physicians, nurses, pharmacists, dentists, optometrists, and podiatrists.

Need for Allied Health Professionals

The widespread field of allied health became well-known after the passage of the federal Allied Health Professions Personnel Training Act of 1966. This act specifically identified the growing need for standardized education and support for allied health professionals.

Today, because of the aging of the nation's population, the increase in the number of people with chronic diseases, and the development of new medical technology, there is a growing demand for allied health professionals. These professionals increase the efficiency of clinicians by providing support services.

Schools of allied health professions are attempting to meet the need for quality education of this broad professional group by fostering research, creating professional networks, and providing early exposure to high school students of the varied allied health professions available. The federal government provides funds for individuals needing financial assistance for education in allied health professions. The government also recruits and trains professionals to work in shortage areas. Because of the nation's changing demographics, there is a need to address disparities in higher-level education based on ethnicity, socioeconomic status, and area of residence. For example, the changing ethnic composition of the nation will result in an increasing need for culturally competent healthcare providers who are bilingual and bicultural. In particular, individuals from traditionally underrepresented ethnic populations in higher education need to be recruited to diversify the allied health professional workforce. Shortages in rural areas also need to be addressed.

Issues Facing Allied Health Professionals

Certification and/or licensure differ for each allied health profession, and specialized training and education are required for all types of allied health professionals. Accreditation is a process in which educational programs in schools of allied health professions are reviewed so that standards, guidelines, and requirements remain consistent between schools and programs. Not all programs of allied health professions are accredited, so it is important for prospective students to assess the characteristics of educational programs through the Commission on Accreditation of Allied Health Education Programs (CAAHEP).

Allied health professionals have struggled for autonomy from other health professionals, and not all allied health professionals have the same requirements and restrictions in their practices. For example, insurance companies may only cover services of an allied health professional, such as a physician assistant, when working under a physician's direct supervision. Some practitioners may oppose competition from allied health professionals who provide similar healthcare services; especially as allied health education becomes more sophisticated. As allied health education continues to build on higher-quality programs that increase the scope of knowledge and expertise for allied health professionals, patients may seek services exclusively from them. Limitations currently exist for a patient to see a physician assistant, but this may change in the future. An ongoing discussion is currently taking place in terms of federal legislative policy regarding the scope of privileges available to allied health professionals.

Future Implications

The U.S. Department of Labor, Bureau of Labor Statistics, predicts that more than 90% of allied health professionals will grow at or above the average of all occupations through the year 2014. These statistics indicate a projected shortage of allied health professionals based on the need for their specialized services.

Healthcare is often viewed as being strictly under the domain of physicians and nurses. Promoting a greater understanding of the diverse

range of health professionals will likely result in higher levels of enrollment in schools of allied health professions, reducing their expected shortage. Faculty of schools of allied health professions are currently engaged in research concerning the factors related to the productivity, learning needs, and administration of allied health professionals and current issues facing their students and workforce.

ALTMAN, DREW E.

Drew E. Altman is a leading expert on national health policy issues and an innovator in the private foundations. He currently serves as the president and chief executive officer of the Henry J. Kaiser Family Foundation, one of the nation's largest private foundations devoted to health

policy and health communications. Located in Menlo Park, California, with major facilities in Washington, D.C., the Kaiser Family Foundation is a leading independent voice and source of research and information on healthcare in the United States. The foundation serves as a nonpartisan source of facts, information, and analysis to inform policymakers, the healthcare community, and the public. It runs its own research and communications programs, often in partnership with other organizations. In 1991, Altman oversaw a complete overhaul of the foundation's mission and operating style that served as a catalyst to enhance its standing today as a premier health policy and communications foundation.

Altman received his bachelor's degree from Brandeis University and a master's degree in political science from Brown University. He later completed his doctorate degree in political science at the Massachusetts Institute of Technology (MIT), where he later taught graduate courses in public policy. Altman went on to do postdoctoral work at the Harvard School of Public Health before entering public service.

Altman is a former commissioner for the Department of Human Services for the state of New Jersey, under Governor Thomas H. Kean, where he developed pioneering programs in welfare reform, Medicaid managed care, school-based services, and services for homeless people. From 1981 to 1986, he served as a vice president at the Robert Wood Johnson Foundation (RWJF). At the RWJF, he developed model national demonstration programs for HIV services and health services for homeless people. During President Carter's administration, Altman served as a special assistant in the Office of the Administrator of the Health Care Financing Administration (HCFA) (now the Centers for Medicare and Medicaid Services [CMS]). Prior to joining the Kaiser Family Foundation in 1990, Altman served as the director of the Health and Human Services program at the Pew Charitable Trusts.

Altman is a member of the national Institute of Medicine (IOM), where he serves on the governing council, and the American Academy of Arts and Sciences.

AMBULATORY CARE

The National Center for Health Statistics (NCHS) defines *ambulatory care* as healthcare that is provided to persons in physician offices, hospital outpatient departments, and hospital emergency departments without their admission to a health-care facility. Ambulatory care consists of a wide array of medical and healthcare services, including diagnosis, observation, treatment, rehabilitation, and preventive services. The term *ambulatory care* refers to the fact that persons who are given this type of care are generally able to ambulate or walk about, unlike some hospital inpatients who may not be able to leave their beds.

Utilization

Patient concerns or medical conditions that are addressed through ambulatory care vary widely. Nationally, about 50% of all physician visits in the United States in 2005 were due to specific symptom complaints such as respiratory or musculoskeletal

issues. A general medical examination, however, was the specific reason most often cited for a physician visit, making up about 7% of all ambulatory-care visits. About 18% of all visits were for preventive-care purposes, and 33% of visits were for new conditions or infectious diseases. Through these visits, there are a wide variety of services that are offered. Diagnostic or screening services were ordered at 87% of ambulatory visits. Health education was ordered or provided at 38%, nonmedication treatment (consisting of services such as physical therapy, psychotherapy, or wound care) was ordered at 18%, and surgical procedures were ordered or performed at 6% of office visits.

The Healthcare System

Ambulatory care is the primary means by which medical care is provided to the U.S. population, constituting more than 1 billion visits yearly. In 2003, this accounted for about 27% of the nation's healthcare spending. In 2005, nearly 60% of all visits were to primary-care specialists (more than 22% to generalists and family medicine physicians), and the remaining 40% of total visits split nearly evenly between surgical and medical specialists.

As the U.S. healthcare system is scrutinized and reassessed to improve its overall effectiveness, the important role of ambulatory care in the ability to improve quality and control costs is being realized. In 2004, the National Quality Forum (NQF) met to identify a set of performance measures that will be used to improve the quality of ambulatory care in furthering this ideal. The 10 priority areas that were identified include patient experience with care; coordination of care; asthma; prevention (primary and secondary, including immunization); medication management; heart disease; diabetes; hypertension; depression; and obesity. These measures have been prioritized and focused in subsequent years through the Ambulatory Care Project, which is aimed at standardizing ambulatory-care performance measures and, in doing so, improving quality in the ambulatory setting.

The Agency for Healthcare Research and Quality (AHRQ) estimates that by improving the quality of and access to primary care through projects such as the Ambulatory Care Project, the nation might be

able to avoid more than 4 million hospitalizations each year. This could result in billions of saved healthcare dollars by enhancing access to effective treatments and focusing on prevention in an ambulatory setting in regard to chronic illnesses such as diabetes, congestive heart failure, asthma, and hypertension. It is estimated that in 2004, a total of \$29 billion was spent on inpatient care for 12 potentially preventable conditions, including \$2.6 billion for kidney damage due to long-standing uncontrolled diabetes and \$8.3 billion for complications involving congestive heart failure. Chronic illness visits currently make up a significant portion of ambulatory-care visits, constituting about 40% of visits in 2005. However, chronic care can be greatly improved, and illness exacerbations and secondary complications can be avoided, through enhanced access to primary-care settings.

Future Implications

As medical care in the nation continues to evolve and factors such as cost, quality, and attention to health promotion and chronic disease control have an impact on shaping the healthcare system, the idea and manifestation of ambulatory care will, as well, continue to change. Primary care will likely become more central, and a more patient-centered approach will take shape. A currently perceived strength of ambulatory care, in consideration of patient preference and health outcomes, is continuity of care. This is evidenced by the fact that in 2005, 87% of ambulatory visits in the nation were by established patients at that location and about 50% of all physician visits were with the patient's primary-care physician. The strength of continuity of care is central to the idea of patient-centered medical home, which will become a crucial aspect in comprehensive, personalized, high-quality care coordinated through a team approach. The idea, initially introduced by the American Academy of Pediatrics (AAP) in 1967, has undergone revision and is now being promulgated as a comprehensive plan by the American Academy of Family Physicians (AAFP), the AAP, the American College of Physicians (ACP), and the American Osteopathic Association (AOA) to improve outcomes, increase value, and help defragment the U.S. healthcare system.

Rapid advances in information technology may, as well, transform the concept of ambulatory care in novel ways. The electronic health record will contribute to efficiency, accuracy, and continuity in patient care and will be central to the impact that ambulatory care may provide in improved outcomes. Information technology may also alter the current practice model significantly through a greater ability to provide comprehensive services in home visits and greater access to patient education and ease of patient self-management coaching and patient empowerment, in addition to potential development of e-visit consultations. Electronic prescribing or e-prescribing will ensure more accurate and reliable medication management, cutting costs and greatly decreasing medical errors.

In addition to the philosophy of ambulatory care of striving to provide high-quality, patient-centered care within the community, ambulatory care, as well, offers significant cost savings and improved patient outcomes. Ambulatory care in the United States currently offers a wide range of services and is positioned to be a central component in the future direction of its evolving healthcare system.

AMERICAN ACADEMY OF FAMILY PHYSICIANS (AAFP)

The American Academy of Family Physicians (AAFP) is the national professional association for family physicians. Representing nearly 94,000 physicians and medical students in the United States, it is one of the nation's largest medical associations. The AAFP's mission is to improve the health of patients, families, and communities by serving the needs of its members with professionalism and creativity. Its vision is to transform healthcare to achieve optimal health for all.

Decades of research clearly show that healthcare systems based on the patient-centered primary care that family physicians provide results in better health outcomes, lower costs and more equitable healthcare than systems based on fragmented and over-specialized care. The American Academy of Family Physicians (AAFP) is leading the charge to bring necessary improvements, conveniences, and modernizations in how medicine is practiced and coordinated. The academy is working with policy-makers and business leaders to demonstrate the efficacy of a patient-centered, primary-care-focused healthcare system and to bring about needed national reform.

History

Headquartered in Leawood, Kansas, the AAFP was originally known as the American Academy of General Practice. In 1971, its name was changed to reflect more accurately the changing nature of primary healthcare. The original purpose of the academy was to promote and maintain high quality for family physicians who provide comprehensive care

to the public. Over the years, the academy has expanded its purpose to also include (a) providing advocacy for the education of patients and the public in all health-related matters; (b) preserving and promoting quality cost-effective healthcare; (c) promoting the science and art of family medicine; (d) preserving the right of family physicians to engage in medical and surgical procedures; (e) providing advocacy, leadership, and representation; and (f) maintaining and providing an organization to represent the needs of its members.

The academy was instrumental in the establishment of family medicine as medicine's 20th primary specialty in 1969. The specialty was created to fulfill the generalist function in medicine.

The Profession

Family physicians provide the majority of primary care in the United States. In fact, annually nearly one in four of all physician office visits in the nation are made to general and family physicians. And family physicians provide the majority of care for America's underserved rural and urban populations.

Providing patients with a personal medical home, family physicians deliver a wide range of acute, chronic, and preventive medical-care services. Unlike some physicians who are limited to a particular organ, disease, age, or gender, family physicians integrate care for patients of both genders across the full spectrum of ages. Family physicians are dedicated to providing patients with a medical home where patients experience seamless, coordinated care with caring. They treat the whole person and foster an ongoing, trusting, personal physician-patient relationship.

Like other medical specialists, family physicians complete a 3-year residency program after graduating from medical school. As part of their residency, they participate in integrated inpatient and outpatient learning and receive training in six major medical areas: (1) pediatrics, (2) obstetrics and gynecology, (3) internal medicine, (4) psychiatry and neurology, (5) surgery, and (6) community medicine. They also receive instruction in many other areas, including geriatrics, emergency medicine, ophthalmology, radiology, orthopedics, otolaryngology, and urology.

Organization

The AAFP is governed by a Congress of Delegates composed of two delegates from each of the association's 55 constituent chapters, as well as delegates from residents and student groups, new physicians, and special constituencies groups. The congress meets annually and establishes the academy's policies and programs. The academy's board of directors and other standing and special commissions and committees then carry out these policies and programs. Delegates to the congress elect the board, which in turn appoints commission and committee members.

To support its advocacy efforts, the academy maintains a Government Relations office in Washington, D.C., for liaison with the U.S. Congress and the federal government.

Activities and Services

Family medicine was the first medical specialty to require its physicians to pursue continuing medical education (CME). A primary responsibility of the academy is to develop and provide its members with CME programs aimed at ensuring family physicians remain educated on the latest medical technologies, treatments, and techniques. To maintain active membership, the academy requires its members to earn 150 credits of CME every 3 years. The annual Scientific Assembly is the academy's largest meeting for continuing education, drawing more than 17,000 physicians and visitors.

To facilitate communication with its members and with patients, the academy also operates two Web sites, www.aafp.org and www.familydoctor.org. The academy's physician-focused Web site, www.aafp.org, provides resources for members, including the full text of the academy's publications. The physician-reviewed patient Web site, www.familydoctor.org, features searchable, easy-to-understand information on more than 500 medical conditions and illnesses. The site also includes Spanish language content, a drug database, and self-diagnosis flow charts.

To advance the discipline and provide resources for its members, the AAFP also publishes several peer-reviewed journals, including the nation's leading primary-care clinical journal, *American Family*

Physician. Other publications include *Family Practice Management* and a bimonthly research journal, *Annals of Family Medicine*. In addition to its peer-reviewed journals, the academy also publishes *AAFP News Now*, an all-member news and features publications available online, via e-mail, and by postal mail service.

AMERICAN ACADEMY OF PEDIATRICS (AAP)

The American Academy of Pediatrics (AAP) is a membership and child advocacy organization, supporting the professional needs of its 60,000 members and advocating for children's health and safety in a broad range of venues. The AAP's mission is to attain optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults.

Members of the AAP, who are largely in the United States, Canada, and Latin America, comprise pediatricians, pediatric medical subspecialists (such as pediatric cardiologists or adolescent health specialists), and pediatric surgical specialists. Members are board certified and called Fellows of the American Academy of Pediatrics, or FAAPs. Board certification is accomplished through the American Board of Pediatrics.

The central office of the organization is in Elk Grove Village, Illinois, a suburb of Chicago. It is a not-for-profit Illinois corporation. The AAP's Department of Federal Affairs is located in Washington, D.C.

The AAP was founded in 1930 by 35 pediatricians in response to the need for an independent pediatric forum to address children's needs. At that time, the idea that children had unique developmental and health needs was new. Preventive health practices now accepted as standard child healthcare (i.e., immunization, regular health exams) were only just beginning to change the custom of treating children as "miniature adults."

Organization

Today, the AAP is governed by a board of directors consisting of 10 members, who are elected by their regional districts and, thus, also serve as

district chairpersons. Members also vote each year for a national vice president, who also serves as president-elect. The executive committee, consisting of the president, president-elect, vice president, and executive director, conducts AAP business on a daily basis.

At the state level, there are AAP chapters, which are individually incorporated, have their own bylaws, and further the aims of the national organization as well as their local priorities.

More than 30 national committees develop many of the AAP's policies and programs, under the direction of the board of directors, to help achieve the academy's goals and objectives. Examples of national committees include the Committee on Nutrition, the Committee on Early Childhood, Adoption and Dependent Care, and the Committee on Injury, Violence and Poison Prevention.

In addition to being involved with the committees, members can participate in 1 of 46 sections pertaining to specific pediatric subspecialties, surgical specialties, or multidisciplinary areas. Section members are instrumental in providing educational sessions at the AAP's annual National Conference and Exhibition, as well as assisting with development of statements and practice guidelines, and many other projects. Examples of current AAP sections include Bioethics, Critical Care, Dermatology, Perinatal Pediatrics, and Uniformed Services, to name a few.

The AAP also has a small number of councils that incorporate many of the functions of committees and sections but provide for a broader vision and wider array of activities. Examples of councils include Communications and Media, Community Pediatrics, and Sports Medicine and Fitness.

Policy and Clinical Guidance

The AAP provides guidance to its members and the public on a wide range of issues. Its "Recommendations for Preventive Pediatric Health Care" form the basis of preventive care for each age, and the AAP is one of three organizations that collaborate to produce the annual *Recommended Immunization Schedule* for children and adolescents, which is used by schools, public health agencies, and private pediatric practices. In addition,

the AAP has issued statements of policy as well as technical reports on a vast array of topics, and practice guidelines on clinical issues.

Advocacy

The AAP advocates access to care for pediatric patients encompassing all aspects of accessibility, including financial, geographic, physical, and communicative access. The AAP believes that all children, women, and their families must have adequate health insurance regardless of income. All health insurance plans should have a comprehensive age-appropriate benefits package.

The AAP also believes that each child should have a “medical home”—a place where care is accessible, family centered, continuous, comprehensive, coordinated, compassionate, and culturally effective. The AAP works with government, communities, and other national organizations to help shape these and many other child health and safety issues.

Priorities

As 2010 approaches, priority issues for the AAP include (a) universal healthcare coverage for all children; (b) increased efforts to prevent and reduce childhood obesity; (c) expanded education about childhood health issues for parents and pediatricians; (d) greater understanding and research in human genetics; (e) increased efforts to reduce prematurity; and (f) improvements in vaccine efficacy and delivery. Mental health and oral health services are also priorities.

Engaging Government

The AAP's Office of Federal Affairs has been the academy's link to federal legislative activities in Washington, D.C., for nearly 40 years, giving pediatricians the information and tools necessary to become effective child advocates through Congress and/or federal agencies. This office works on issues affecting children's healthcare coverage, immunizations, pediatric drugs and medical devices, and much more. The academy was the driving force behind a pediatric

drug-labeling bill that requests drug companies to study their drugs in children, as well as the State Children's Health Insurance Program (SCHIP), an expansion of Medicaid that enables children from limited-income families to access comprehensive healthcare.

AAP staff also assists members in advocating for their patients at the state level by monitoring child health legislation and facilitating participation in the legislative and regulatory process. Issues that may be addressed at the state level include Medicaid, injury and violence prevention, immunizations, and many others.

Research

The AAP is home to several long-term research programs to enhance the delivery of healthcare to children. Its Pediatric Research in Office Settings program conducts studies using a network of 1,800 pediatricians working in office-based practices.

Publications, Public Information, and the Media

The academy has the largest pediatric publishing program in the world, with 120 titles for consumers and 400 for physicians and other healthcare professionals. In addition, AAP works extensively with the media and carries out public information campaigns to ensure that timely, accurate and focused messages and information reach families and professionals. The AAP publicizes the latest research in its journal, *Pediatrics*, as well as the latest AAP policies, campaigns, and partnerships with other organizations.

Community-Based Initiatives

The AAP works with community-based organizations on many programs, including numerous grant-funded projects. For example, the Community Access to Child Health (CATCH) Program supports pediatricians and communities that are involved in community-based efforts for children. The Healthy Tomorrows Partnership for Children Program is a cooperative agreement between the federal Maternal and Child Health Bureau and

the AAP, with federal grants awarded to support community-based child health projects that improve access to health services for mothers, infants, children, and adolescents.

Member Education

Recognizing that ongoing education of pediatricians is a cornerstone of promoting optimal care for children, one of AAP's major activities is continuing medical education (CME), with numerous opportunities for learning, including the annual National Conference and Exhibition and AAP's scientific journal, *Pediatrics* (which is printed in English and five other languages, including Chinese). Member pediatricians are offered printed and online learning products such as PREP: The Course. The AAP's online Pedialink service connects members to courses all over the country. The latest news from the organization is delivered through its monthly publication, *AAP News*.

AMERICAN ASSOCIATION OF COLLEGES OF NURSING (AACN)

The American Association of Colleges of Nursing (AACN) is a nonprofit institutional membership association dedicated exclusively to furthering nursing education in America's universities and 4-year colleges. The AACN represents schools of nursing at more than 600 public and private institutions of higher education. Its mission is to serve as the national voice of baccalaureate and graduate-degree nursing education. The association also includes the Commission on Collegiate Nursing Education (CCNE), which accredits baccalaureate and graduate nursing programs.

Background

In 1965, the American Nurses Association (ANA) took the position that nursing education should take place at institutions of higher education. At the time, most nurses were trained in hospital-based diploma programs. The ANA policy eventually led to the demise of hospital programs and the rise of associate and baccalaureate degree programs in nursing at colleges and universities. As a result, the AACN was formed in 1969 to establish quality standards for bachelor's and graduate-degree nursing education. It also assisted deans and directors of nursing programs to implement its standards and promoted public support of baccalaureate and graduate education of nursing.

Membership

The AACN is composed primarily of institutional members. Membership in the association is open to any institution offering a baccalaureate or higher-degree nursing program. The dean or other chief administrative nurse in the nursing program serves as the institutional representative in the association. Other categories of individual membership include the following: Emeritus, Honorary, and Honorary Associate. Individual membership is conferred at the discretion of the board of directors of the association.

Organization and Structure

An 11-member board of directors governs the AACN. Each of the members of the board represents a member institution. The board consists of four officers and seven members-at-large, all elected by the membership for 2-year terms.

Much of the association's work is conducted through the efforts of various committees and task forces, represented by nurse faculty and nurse leaders from across the country. Its committees include Finance, Government Affairs, Membership, Nominating, Program, and Project Evaluation and an educational benchmarking survey advisory group. Its task forces include Academic Careers, Clinical Nurse Leader, and Revision of the Essentials of Baccalaureate Nursing Education and a cultural competency advisory group.

Products and Services

The AACN is very active in terms of professional networking and providing key updates to its members concerning nursing higher education. To keep its membership informed, the association publishes the *Journal of Professional Nursing* six times a year for nurse educators, researchers, and practitioners and the *Syllabus*, a bimonthly newsletter that provides information and updates on the status of nursing higher education. It also holds semiannual meetings in Washington, D.C., offering nursing deans and faculty the opportunity to discuss important issues facing nursing legislation and education.

In 1996, the association established the Commission on Collegiate Nursing Education (CCNE). The CCNE, which is an autonomous arm of the association, has the sole purpose of accrediting baccalaureate and graduate nursing education programs.

Current Activities

The AACN continues to emphasize the need for baccalaureate education in nursing, versus an associate's degree in nursing or a nursing diploma. The association is also actively involved with health policy. It aggressively seeks federal funds for nursing education and research. It frequently

produces legislative updates on issues effecting nursing education. It tracks and monitors nursing bills in the U.S. Congress, and it often submits written congressional testimony. The association actively works with Congress and the federal government to increase funding of nursing workforce development programs, nursing graduate students, schools of nursing, academic health centers that provide nursing education, and loan programs to increase nursing faculty.

AMERICAN ASSOCIATION OF PREFERRED PROVIDER ORGANIZATIONS (AAPPO)

The American Association of Preferred Provider Organizations (AAPPO) is the leading national association of preferred provider organizations (PPOs) and affiliate organizations. It was established in 1983 to advance awareness of the benefits—greater access, choice, and flexibility—that PPOs bring to American healthcare. The AAPPO has 400 members representing 125 different organizations.

Definition and Popularity of PPOs

A PPO is a healthcare delivery system where providers contract with the PPO at various reimbursement levels in return for patient steerage into their practices and/or timely payment. PPOs differ from other healthcare delivery systems in the way they are financed and provide more choice, benefit flexibility, and enrollee access to providers and medical services both in- and out-of-network.

PPOs are widely popular with consumers and healthcare purchasers. In 2007, more than 158 million individuals in the nation were enrolled in a PPO program, which indicates that 64% of Americans with healthcare coverage receive their healthcare services through a PPO delivery system. The fact that PPOs have delivered exactly what the public has called for—choice, flexibility, and a balance between the delivery of appropriate care and cost control—is the primary reason for this strong market share.

Mission and Mandate of AAPPO

Since its inception, the AAPPO has been the only association advocating solely on behalf of PPOs and continues to lead the way in the promotion, support, and advocacy of the PPO industry. The association's vision is to continue to be the most-valued trade association for organizations that use, develop, and support PPO networks and products. Its mission is to advance and promote the PPO industry for AAPPO members and their stakeholders, providers, and consumers by (a)

informing and educating the public policy community about the PPO delivery model; (b) facilitating PPO best practices by developing and advancing PPO industry practices and guidelines; (c) promoting PPO networks and benefit products as the preferred healthcare solution; and (d) supporting professional growth through comprehensive PPO training programs to meet ongoing employee needs for organizations that use, develop, and support PPO networks and products.

The AAPPO prides itself in being responsive to its members and providing programs and activities to specifically support their business needs. The association promotes the visibility, clarity, awareness, value, and benefits of the PPO delivery model. These efforts educate and inform all marketplace sectors that regulate, use, and support the PPO delivery system. In this era of constant change, demonstrating the value the PPO model brings to U.S. healthcare is essential.

Specifically, AAPPO's mandate is (a) to provide PPOs with the information they need, when they need it; (b) to represent the industry's interests and concerns in government; and (c) to improve healthcare professionals' industry knowledge and business acumen through a variety of educational programs.

Providing Critical Information to PPOs

The AAPPO provides a broad array of information to meet PPO business needs and help PPOs achieve their goals. White papers and webinars are one source of information in which issues of the day are researched, analyzed, and summarized from the perspective of PPOs. Another source is RapidResource, a comprehensive source of PPO information. RapidResource is published annually and contains three critical products: (1) the market and industry trend report, which provides stakeholder perspectives on the industry; (2) current statistics and trends; and (3) insightful analysis and future strategies for PPOs. The PPO DataSource is a national database, including executive contact information, office locations, and more. The directory of operational PPOs is a quick online connection to find the location, geographic coverage, and specific details of any PPO nationwide. The AAPPO also organizes the Annual Forum, an informational

and networking conference where attendees can exchange ideas, share perspectives, and discuss solutions specific to PPOs. Another type of information is iState, which monitors state regulation and legislation in all 50 states and provides the information in an online, sortable format.

Advocating for PPOs

The AAPPO represents the industry's interests and concerns in legislative and regulatory issues in several ways. Capital Caucus is an annual event in Washington, D.C., used to facilitate two-way exchange between policymakers and the administration and PPO business leaders. Through its legislative outreach, the AAPPO continually educates individuals in the national and state regulatory arena about PPO business practices. With membership in healthcare coalition and programs, the benefits and value of the PPO healthcare delivery model are represented within healthcare coalitions and other healthcare programs. The AAPPO also provides state-level advocacy, in which it monitors and acts on critical issues occurring at the state level.

Educating PPO Professionals

The AAPPO is dedicated to advancing the education of healthcare professionals. In addition to the information provided to members, the association has also developed the academy, a high-quality, online education program. Students learn at their own pace, anywhere they can access a computer with an Internet connection. Courses include an overview of the PPO industry as well as in-depth courses related to four key study areas: (1) customers, (2) medical management, (3) providers, and (4) claims. The association's academy bestows certifications to students who successfully complete all required classes in a study area.

Organization and Committee Structure

The AAPPO has established a number of innovative committees to serve as working groups to pursue areas of specific interest to the association and its members. These committees meet electronically

and in person throughout the year to help further the mission of the association. The association's committee members work to set the association's public policy goals, guide communication initiatives, and identify and address important issues. The Business and Membership Development Committee works to promote the association's business initiatives and recruitment goals. The Education Advisory Committee is responsible for the oversight of course curriculum, course development, and policies and procedures to support the association's Academy. The Medical/Provider Affairs Committee develops the association's policies on issues relating to building and maintaining effective relationships with providers and their representative organizations. The Political Action Committee (PAC) is crucial for building relationships with state and federal legislators, and it educates the association's membership about the fundamental operations of the PAC and the importance of contributing to it. The Public Policy Committee supports the association's goal to educate policymakers about the PPO industry and the unique role PPOs play in the healthcare delivery system. The Rules, By-Laws and Nominations Committee provides oversight for the association's governance, rules, and nominations. The Executive Committee, Compensation Committee, and the Audit Committee provide support to the board of the association.

AMERICAN COLLEGE OF HEALTHCARE EXECUTIVES (ACHE)

The American College of Healthcare Executives (ACHE) is an international professional society of more than 30,000 healthcare executives who lead hospitals, healthcare systems, and other healthcare organizations. The ACHE's mission is to advance its members and healthcare management excellence through high ethical standards, pertinent knowledge, and a relevant credentialing program. While achieving this mission, the organization promotes the values of integrity through high ethical conduct, and lifelong learning by innovation and continuous organizational and professional improvement, leadership training by example and mentorship, and diversity via inclusion and embracing the differences of its members and of the healthcare communities served.

History

ACHE was originally founded in 1933 as the American College of Hospital Administrators. The founders of the society were concerned that individuals with little or no training or experience in hospital administration were managing many of the nation's hospitals. The goal of the society was to elevate the standards of competence of hospital administrators through the process of education and training. In 1985, the society's name was changed to the American College of Healthcare Executives to more accurately describe its diverse membership and its expanded scope.

Structure and Leadership

The ACHE membership is divided into six districts: five geographical districts and a sixth district composed of military affiliates. Within the

six districts, there are 53 locally led chapters. Two affiliated groups, (1) the Women's Healthcare Executive Networks (WHENs) located in the United States and (2) the Healthcare Executive Groups (HEGs), represented in India, Mexico, Saudi Arabia, Turkey, and the United Arab Emirates, were established, along with local chapters, to provide members access to networking, education, and career development at the local level and to address local, national, and international healthcare management needs.

The central office of ACHE is located in Chicago and houses the administration, including the president and chief executive officer, executive vice president, and other vice presidents of the organization.

The chapter board or board of directors is composed of annually elected officers and directors from each chapter. The chapter board manages general chapter operations and ensures that the chapter meets its goals and objectives. The board of governors, also elected and voluntary, operates like a traditional board of directors in that it has the authority to manage and control the affairs and funds for the overall organization. The highest organizational authority resides with the Council of Regents, which provides guidance and advice for the board of governors, representing the members and chapters. The Council of Regents has eight specific powers, including the right to elect the chairman, officers, and members of the board of governors and to approve or to disapprove recommendations, reports, actions, or resolutions placed before the council.

Membership and Credentialing

The eight categories of membership in ACHE are those of (1) Members, (2) Fellows, (3) Life Fellows, (4) Honorary Fellows, (5) Student Associates, (6) Faculty Associates, (7) International Associates, and (8) Retired Affiliates. A professional certification designated by ACHE is as a Fellow of the American College of Healthcare Executives (FACHE). To become board certified in healthcare administration as a FACHE, members must pass the Board of Governors Examination in Healthcare Management as well as fulfill other rigorous

requirements such as completing 40 hours of continuing education credit, 3 years of tenure as an ACHE member, 5 years of healthcare management experience (with a postbaccalaureate degree, 8 years if applying without) and demonstrating participation in civic and leadership activities.

Education

ACHE is well-known for organizing and sponsoring educational events, such as the annual Congress on Healthcare Leadership, which draws approximately 4,000 participants each year. Quality improvement, physician relations, information technology, and governance are examples of topics covered at the ACHE Congress. It is through the Congress on Healthcare Leadership, conferences, seminars, and special programs, such as the Board of Governors Examination Review Course and the Senior Executive and Leadership Development Institutes, that ACHE provides its members with continuing education and national networking opportunities. Distance-learning options such as audio/Web conferences, online seminars, self-study courses, and audio conference CDs are also available.

Publishing

The Health Administration Press (HAP) is a division of the Foundation of the American College of Healthcare Executives. Founded in 1972 with support from the W. K. Kellogg Foundation, the HAP is one of the largest publishers of books and journals on all aspects of health services management, including textbooks for use in undergraduate and graduate courses. The press also publishes the *Journal of Healthcare Management*, *Frontiers of Health Services Management*, and *Healthcare Executive Magazine*. It also produces courses for the ACHE Self-Study Program.

Career Services

ACHE's Healthcare Executive Career Resource Center (HECRC) offers career services, including leadership assessment tools, career development programs and resources, and personalized

career-planning assistance. Additionally, HECRC offers guidance in mentoring and executive coaching.

Policy Campaigns

ACHE encourages its members and affiliates to advocate organ and tissue donation through the U.S. Department of Health and Human Services' Gift of Life program. Because ACHE also recommends that all healthcare executives work to support access to healthcare services for all people, ACHE is raising awareness through two programs: (1) Covering Kids & Families and (2) Cover the Uninsured Week.

Public policy statements are developed at the ACHE committee level that address current issues such as executive responsibility (a) to foster healthcare access, (b) to serve the community, (c) to ensure organizations are following emergency preparedness plans, and (d) to strengthen healthcare employment opportunities for persons with disabilities.

Research

ACHE conducts research on a number of healthcare management areas, including factors affecting the career attainments of healthcare executives as well as trends and recommended practices affecting the profession. Topics of study outcomes recently addressed include a comparison of the career attainments of men and women healthcare executives, top issues confronting hospitals, and the impact of hospital chief executive officer turnover in U.S. hospitals.

AMERICAN ENTERPRISE INSTITUTE FOR PUBLIC POLICY RESEARCH (AEI)

The American Enterprise Institute for Public Policy Research (AEI) is a private, nonpartisan, not-for-profit organization dedicated to the research of government, economic, political, and social welfare issues. Located in Washington, D.C., AEI's purpose is to preserve and strengthen the foundations of freedom—limited government,

private enterprise, vital cultural and political institutions, and a strong foreign policy and national defense—through scholarly research, open debate, and publications.

History

Founded in 1943, the AEI is home to some of America's most accomplished public policy experts. AEI scholars strive to elevate the public policy debates regarding the nation's most pressing issues, educate the public, and contribute sound recommendations for reform. Their research is disseminated to a broad audience of domestic and international policymakers, academics, business executives, the media, and the general population, through various publications, conferences, seminars, working groups, and government testimony.

The AEI employs nearly 190 individuals and works with approximately 70 adjunct scholars. The institute's work is supported through financial contributions from foundations, individuals, and corporations as well as through earnings from an endowment. The AEI's president, in consultation with the institute's Council of Academic Advisers, sets its research agenda. In addition, each year, the Council of Academic Advisers awards AEI's Irving Kristol Award to an individual who has made a notable contribution to improving public policy and social welfare.

The AEI has three main research divisions: (1) Economic Policy Studies, (2) Social and Political Studies, and (3) Defense and Foreign Policy Studies. There are also several specialized programs, among them the W. H. Brady Program on Culture and Freedom, the National Research Initiative, the AEI Press, and *The American* magazine.

Health Policy Studies Program

One of the AEI's most important research efforts is its Health Policy Studies Program. AEI sponsors a robust program of original research to address some of the most contentious issues in the current health policy debates, such as costs, economic incentives, the role of government and the market, and the medical well-being of patients. AEI's health policy scholars possess a

wealth of knowledge and experience, along with extensive worldwide contacts among policymakers, academics, and business executives. Several of the program's experts have served in top positions in various parts of the federal government and the U.S. Congress, including the Food and Drug Administration (FDA), the Centers for Medicare and Medicaid Services (CMS), the President's Council of Economic Advisers (CEA), the U.S. Department of Health and Human Services (HHS), and the Congressional Budget Office (CBO).

Scholars in the AEI's Health Policy Studies Program have been among the leaders in the recent debates on Medicare reform, the reimportation of prescription drugs, health coverage for the uninsured, the role of the FDA, the development of vaccines, and the effects of price controls on pharmaceutical research and development. AEI health policy scholars, along with a network of academic experts at affiliated universities and institutions across the country and abroad, will likely continue to make major contributions to these and other debates. They aim to (a) establish a healthcare and public health agenda centered on the themes of competitive markets, personal choice, and progress in science, technology, and practice; (b) construct reform proposals that apply the best economic thinking to the dynamics of healthcare; and (c) provide policymakers, the media, and the broader public with an objective assessment of the private sector's contributions to innovation in the delivery and financing of medical care and insurance coverage.

The AEI's health policy scholars work at the juncture of policy and practice. They strive to improve government policy through scholarly research, and an array of publications, conferences, seminars, as well as through discussions with government officials, academic experts, and industry leaders. Their work has helped to shape—and will likely continue to shape in the years to come—important policy debates.

AMERICAN HEALTH CARE ASSOCIATION (AHCA)

The American Health Care Association (AHCA) is a federation of affiliated state health organizations, together representing more than 10,000 nonprofit and for-profit assisted living, nursing homes, developmentally disabled, and subacute-care providers that care for more than 1.5 million individuals in the nation. The AHCA represents the long-term care community to government, business, and the general public. It also serves as a force for change within the long-term community, providing information, education, and administration tools.

Background

Since 1949, the AHCA has been working to improve the standards of the long-term care profession and to promote a better understanding of what constitutes a supportive, quality-focused care environment. Since its founding, the AHCA's objectives have remained consistent, with only minor changes. Specifically, the association's objectives, which were codified in 1946, include improving the standards of service and administration of member nursing homes; securing and meriting public and official recognition and approval of the work of nursing homes; and adopting and promoting programs of education, legislation, better understanding, and mutual cooperation.

Together with its 50 state affiliates and in concert with other key stakeholders, the AHCA currently seeks to encourage (a) a stable financing system that enhances long-term care quality; (b) an oversight system that is fair, consistent, and rewards quality; and (c) a workforce that can meet the growing needs of the long-term care profession and the nation.

Products and Services

In 2002, the AHCA helped launch Quality First, a profession-wide quality improvement initiative. Quality First was followed by the Centers for Medicare and Medicaid Services' (CMS) Nursing Home Quality Initiative (NHQI), which began to track progress on specific clinical measures of nursing home care quality. In 2006, the association cofounded and is leading a coalition of healthcare providers, caregivers, medical and quality improvement experts, government leaders, consumers, and other stakeholders who are working to improve care quality through the voluntary Advancing Excellence in America's Nursing Homes campaign. Advancing Excellence is a quality initiative that is designed around measurable quality goals, which are supported by the campaign's coalition of providers, caregivers, consumers, and key stakeholders. More than 6,600 providers—predominantly AHCA members—already participate in this important initiative, which the association and its state affiliates strongly endorse.

The AHCA relies on its members' clinical expertise, especially members of their Clinical Practice Committee, to guide the association's efforts to ensure that long-term care settings have the most appropriate clinical protocols and Web site resources. The association also collaborates with a variety of key partners and clinical experts in promoting best practices. For example, the association partnered with the Alzheimer's Association to improve clinical-care standards. This partnership resulted in the Alzheimer's Association issuing its publication *Dementia Care Practice Recommendations for Assisted Living Residences and Nursing Homes*, which focuses on end-of-life care.

Whether the AHCA is working with other healthcare professionals on clinical issues, with the federal government on initiatives to enhance quality, or with the U.S. Congress to preserve much-needed funding for long-term care and services, the association recognizes that 80% of long-term care residents rely on Medicare and/or Medicaid to pay for the care they need. This means that the organization's membership cares for some of our country's most vulnerable citizens. In fact, the average nursing home resident is an 85-year-old grandmother with cognitive or functional impairments and multiple comorbidities that typically require nine medications per day. With this membership in mind—along with the fact that 77 million baby boomers are edging toward retirement—the AHCA remains focused on ways to create a better, more stable workforce that can meet the growing needs of all healthcare consumers.

The AHCA actively works to educate elected officials and their staff members about the long-term care needs of America's seniors so that our "Greatest Generation" and others will continue to have access to the most appropriate care in the most appropriate setting. The AHCA's legislative team also calls on policymakers and government officials from the White House, the Centers for Medicare and Medicaid Services (CMS), the U.S. Department of Health and Human Services (HHS), the Department of Labor (DOL), and congressional offices on both sides of the aisle to address the many challenges confronting today's long-term care system.

Underpinning the association's education and advocacy efforts are several important

components—public affairs and both grassroots and grass-tops outreach. The association’s public affairs team directs positive media attention to the work of its membership and generates media interest that supports its advocacy, which can spur on its quality and other initiatives. The organization’s grassroots and grass-tops supporters assist the advocacy arm and allow the association’s legislative and public affairs teams to demonstrate just how important each member is to the collective advocacy agenda. One of the grassroots activities that the association promotes with its membership is the facility tour. A facility tour is an extremely effective way for providers to educate U.S. congressional members about long-term care and related issues. Touring a facility also presents a positive media opportunity—for the facility, for the elected official, and for the long-term care profession.

The AHCA’s political action committee (AHCA-PAC) adds even more depth to its advocacy efforts. AHCA-PAC hosts a number of fund-raising events and has helped establish several mini-PACs that concentrate on more regional and state-level PAC outreach.

The AHCA and the National Center for Assisted Living (NCAL) continue to join forces to promote member communication as well as increase the number of positive stories about long-term care in the mainstream news media. Member feedback has also helped shape some of the communications, including a recent Web redesign and upgrades to the association’s management system, which will further enhance AHCA staff’s ability to serve its membership better.

The AHCA’s public affairs team also ensures that long-term care has a presence in major newspapers and broadcast media throughout the year. The association has been quoted or featured in *The New York Times*, *The Wall Street Journal*, and *The Washington Post* as well as numerous local newspapers. The AHCA has contributed to national news programs as well, including *NBC Nightly News*, the *CBS Evening News*, and PBS’s *Nightly Business Report*.

AMERICAN HEALTH PLANNING ASSOCIATION (AHPA)

The American Health Planning Association (AHPA) is a national organization whose members are agencies and individuals engaged in some aspect of the broad and sometimes controversial field of health planning and capacity regulation, such as Certificate of Need (CON). Since its founding in 1971 (as the American Association of Comprehensive Health Planning, and it changed

its name to the present in 1977), the membership, focus, and activities of the association have shifted, reflecting the changing scope and role of health planning in the United States. Today, the association is perhaps best known for its Web site and annual publication of a directory of state CON programs.

The Rise of Health Planning

When the AHPA was founded, health planning was starting to be viewed by national policymakers as offering a possibility of both slowing down the escalating rise in healthcare costs and ensuring that healthcare resources were better allocated based on community need. Health planning had been in place on a smaller scale since the early 1960s, when Kodak and Blue Cross and Blue Shield formed a joint effort in Rochester, New York. It was also part of several federal health programs and adopted by a number of states as both a regulatory and voluntary measure to control the expansion of institutional healthcare services, most frequently hospitals and nursing homes. Most prominent among the early federal programs was the Partnership for Health Act of 1966, which set up a network of state-level (Comprehensive Health Planning CHP-A) and within-state regional (Comprehensive Health Planning CHP-B) voluntary health-planning agencies. At the state level, New York led the way on both the regulatory and voluntary planning fronts by enacting the first state CON legislation, and in the Rochester area, a council of hospital and industry attempted to plan the expansion of hospital services to meet community needs.

As health planning gained momentum, representatives from these scattered experiments formed the AHPA to create a focus and organize a professional movement to support health planning. The association was organized around several principles common to most health-planning efforts that are still in place today: (a) community participation in decision making regarding the allocation of healthcare resources; (b) equity in access to healthcare services regardless of income and insurance status; (c) the use of population need as the underlying rationale for deterring the quantity and location of healthcare resources;

(d) a balanced and more holistic view of healthcare that recognizes that an effective healthcare system requires a wide range of services from basic primary care to technologically sophisticated and highly specialized services; (e) a concern for the efficient delivery of healthcare and cost containment; and (f) a necessary role for the legislative policy process at the federal and state government levels.

National Health Planning Program

Health planning reached its full maturity in the United States with the passage of the National Health Planning and Resource Development Act of 1974. PL 93-641, as it came to be known in health-planning circles, established a federally directed system of 50 state and more than 200 local health systems agencies (HSA), each with regulatory authority to conduct health planning enforced by state-level CON laws and federal regulations. The law tasked the U.S. Department of Health, Education, and Welfare (DHEW) (forerunner of the U.S. Department of Health and Human Services [HHS]) to develop extensive national guidelines for how the health-planning agencies were to be composed, operate, and make decisions.

The AHPA's membership grew dramatically during this period, with many members coming from newly established health-planning agencies. Driven by PL 93-641, AHPA took on the role of a professional trade association focusing much of its efforts on lobbying the U.S. Congress in support of continuing federally sponsored and funded health planning, along with monitoring rules issued by DHEW on how the health-planning law should be implemented. Beyond the focus on federal health planning, the AHPA also served as a clearinghouse for state-level CON laws, advanced the development and use of health-planning technical methods, and became a forum for the growing number of health planners across the nation. The forum function culminated each year with a national conference that often drew hundreds of health planners, planning agency directors and board members, academics, and healthcare administrators along with lawyers and consultants involved in a cottage industry, which specialized in assisting healthcare institutions navigating the approval process for

expansion, new construction, and purchase of expensive medical technology.

During this period, membership in the association gravitated to several spheres of interest: (a) national health policy and the role of a federal health-planning program; (b) health planning as a mechanism for community involvement in health system decisions; (c) the technical aspects of health planning; and (d) the use of data and analysis in decision making.

After National Health Planning

As the 1970s drew to a close, federal health planning fell out of favor with national policymakers as a more conservative political climate took hold, and the use of market mechanisms to control healthcare costs and structure the healthcare system gained support. The AHPA found itself fighting a losing political battle to save the national health-planning program and PL 93-641 was repealed at the urging of the Reagan Administration in 1986. Without the federal sponsorship and funding, many state and local health-planning agencies closed, redirected their efforts, or were absorbed into related organizations. The retrenchment was most dramatic at the local level, where the majority of local health-planning agencies simply disbanded.

The lack of a federal health-planning program and the demise of many health-planning agencies both reduced the membership base of the association and changed its focus. The change in membership was most dramatic in the loss of organizational members, formerly the federally sponsored local health systems agencies and state health-planning and development agencies. The association's membership became less institutional, and the association became more a professional society of individuals working or having an interest in health planning. CON, which was retained in some form by almost three quarters of the states as a regulatory remnant of national health planning, took on a heightened focus of the association as state CON directors and their senior staff looked to it as the principal national forum for this state-sponsored regulatory activity.

The AHPA became a strong defender of CON after a far-reaching and critical federal report was released in 2004 (*Improving Health Care: A Dose*

of Competition, authored by the Federal Trade Commission and the U.S. Department of Justice), which called for its elimination. One of the association's major activities is the publication of an annual national directory, which inventories each state's CON program.

Beyond CON, the association's leadership also sought to rediscover and promote the broader value of health planning reflected in its original principles and to document the need for health planning to deal with the growing national concern that the healthcare system was under great strain. The broader interest overlapped into public health, and the association sought a closer affiliation with the American Public Health Association's Community Health Planning and Policy Development (CHPPD) section, whose members shared AHPA's interest in health reform and population health.

Today, the AHPA and the CHPPD section regularly cosponsor professional presentations at the American Public Health Association's annual meeting, and they jointly publish a bibliography on health planning. The AHPA continues to serve as a forum for health planning in all its diverse forms. The association maintains an active board of directors, but its presence is largely through its Web site, where health-planning activities from across the nation are tracked and reported; issue papers on health planning, regulation, and public health are posted; and informational resources relevant to health planning are linked.

AMERICAN HOSPITAL ASSOCIATION (AHA)

The American Hospital Association (AHA) is a nonprofit organization that aims to improve the health of individuals and their communities. The AHA represents, leads, and serves the institutions that deliver medical care. Its institutional membership includes nearly 5,000 of the nation's hospitals—almost 90% of all registered hospitals—as well as healthcare networks and other patient-care facilities. Its individual membership includes 37,000 health professionals such as risk managers, engineers, social workers, and nurse executives, who join through approximately 15 different personal membership groups or professional societies.

History

The AHA was founded in 1899 as the Association of Hospital Superintendents by eight hospital administrators in Cleveland, Ohio. Their purpose for establishing this association was to develop a vehicle for discussion, analysis, and resolution of common concerns and issues regarding managing a hospital. In 1906, the membership was expanded beyond hospital chief executives, and the name of the organization was changed to the American Hospital Association. In 1918, institutional membership was established.

Historically, the AHA's actions have reflected the dual mission of achieving economy, efficiency, and solvency in hospital management and providing better hospital care for all. In response to the public's inability to pay for hospital care as a result of the Great Depression, the AHA recognized a need and defined a set of principles for hospital insurance plans in 1937, which later became

known as Blue Cross. In 1942, the AHA spearheaded the establishment of the Commission on Hospital Care, which led to a huge program of hospital construction known as Hill-Burton. The AHA supported efforts to pass the Medicare legislation of 1965, which covered hospital care and other services for the nation's seniors.

The cost of medical care is a major concern for the AHA today. The United States spends more on medical care than does any other nation, and hospital care alone accounts for the largest portion of spending—about one third. Factors associated with these costs include new treatments and technology and greater demand. In addition to the increased costs to provide care, hospitals often do not get paid for the care they provide. Many of the nation's hospitals report losing money serving Medicare and Medicaid patients.

The AHA has changed significantly since its inception. It has evolved from a small club for hospital administrators to an effective and forceful advocate for the nation's hospitals. To achieve its goals and serve its constituents, the AHA generates, collects, uses, and shares an important body of healthcare-related information.

Size and Structure

When it was first founded as the Association of Hospital Superintendents, the AHA was located in Cleveland, Ohio. Although subsequently the organization was briefly headquartered in Washington, D.C., since 1920 the AHA's headquarters have been located in Chicago, Illinois. An office in Washington, D.C., was also established to secure better access to federal agencies for advocacy, policy, and communication initiatives.

The AHA's services and policies are determined by a governing structure that includes a board of trustees, a house of delegates, and nine regional policy boards. The role of the regional policy boards, comprising state hospital association executives, is to debate and analyze important healthcare policy issues from a local perspective prior to submitting the issues to the house of delegates for consideration.

The house of delegates comprises members from state associations as well as constituency sections. State associations are apportioned delegates to the

house based on the amount of dues paid by the institutional members in each state. The constituency sections also shape policy and represent special interests among hospitals. These sections include Health Care Systems, Small or Rural Hospitals, Metropolitan Hospitals, Federal Health Systems, Long-Term Care and Rehabilitation, Psychiatric and Substance Abuse Services, and Maternal and Child Health. After debates within the house, it is the responsibility of the board of trustees to exercise its final decision-making authority over the formal adoption and execution of AHA policy.

The AHA is broadly organized into the following units: (a) advocacy and public policy, (b) leadership and business development, (c) strategic policy planning, (d) member relations, (e) federal relations, and (f) strategic communications. The AHA has also established numerous subsidiary organizations that are critical to its business: (a) The Health Forum; (b) AHA Financial Solutions, Inc.; (c) the Center for Healthcare Governance; (d) the Health, Research and Educational Trust; (e) the American Organization of Nurse Executives; and (f) the Institute for Diversity in Health Management. The Health Forum encompasses the publishing, data, and education activities of the AHA. AHA Financial Solutions, Inc., maintains a comprehensive portfolio of financial products such as insurance and investment vehicles for members. The Center for Healthcare Governance builds stronger and better hospital boards. The purpose of the Health Research and Educational Trust is to conduct innovative research on issues related to effective, strategic, and improved healthcare delivery that significantly affect the health of the community. The American Organization of Nurse Executives is a professional association for nurses in leadership and management positions. The Institute for Diversity in Health Management works to achieve diversity in healthcare settings.

To provide education and serve as a source of information for healthcare leaders, the AHA maintains a resource center. This unit responds to the information needs of its members, libraries, the public, healthcare researchers, and others on a broad range of healthcare issues such as health professional planning, healthcare financing, and regulatory issues by providing statistical and analytic reports and documents. The resource center

maintains an extensive library with collections on health administration, including more than 64,000 books and historical documents.

Products and Activities

The AHA's products and activities are concentrated within two different arenas: (1) policy and advocacy and (2) data and information.

The AHA spends approximately \$15 million a year on advocacy. The AHA has identified many important issues affecting the nation's hospitals. Some of the key issues are listed below.

With approximately two thirds of the nation's hospitals getting paid less than it costs to care for Medicare patients, the AHA seeks to achieve increased Medicare payments to hospitals. Similarly, the AHA opposes payment cuts to hospitals under the Medicaid program.

With the uninsured using the nation's hospitals as their primary source of care, the AHA is working to extend healthcare access and coverage to the uninsured. Furthermore, the AHA supports medical liability reform to prevent further deterioration in patient access to care.

Given recent concerns that nonprofit hospitals are not providing sufficient charity care, the AHA is working to clarify and improve hospital billing and collection standards.

The AHA advocates the creation of a better healthcare system. For example, since providing care to individuals with chronic diseases is increasingly costly and fragmented, the AHA supports changes in the payment system that reward coordination of care. Also, the AHA supports eliminating racial and ethnic health disparities in medical-care treatment and outcomes. Finally, underscoring the immense potential of health information technology to improve the quality of care, the AHA is seeking regulatory relief and increased funding for the nation's hospitals for health technology improvements.

The AHA is pursuing continued funding to achieve disaster and emergency readiness among the nation's hospitals.

The AHA is working to facilitate the adoption of new standards for the management of patient health information as embodied in the Health Insurance Portability and Accountability Act of 1996 (HIPAA).

The AHA offers many data- and information-related products. Among its many management publications are *Health Facilities Management*, *Hospitals & Health Networks*, *H&HN's Most Wired Magazine*, *Materials Management in Health Care*, and *AHA News*, a weekly newspaper for hospital managers. The AHA also produces materials related to patient education, staff development, and many other areas related to hospital administration.

The AHA's research and statistical publications include the journal *Health Services Research* and two annual reports, the *Guide to the Health Care Field* (a detailed listing of all hospitals in the nation) and *AHA Hospital Statistics* (a detailed statistical report for states and geographic regions in the nation). In addition, the AHA publishes (in collaboration with Avalere Health) *TrendWatch*, a series of reports that explore trends affecting hospitals and the healthcare system. The AHA serves as the official U.S. clearinghouse on medical coding for the proper use of the ICD-9-CM systems and Level I HCPCS (CPT-4 codes) for hospital providers. The AHA also publishes a variety of research reports and papers on special topics such as the healthcare system, information technology, financial issues, and workforce issues.

AMERICAN MEDICAL ASSOCIATION (AMA)

The American Medical Association (AMA) is a nonprofit organization that seeks to promote the art and science of medicine and the betterment of public health. The AMA works to “help doctors help patients” through aggressive advocacy of important healthcare issues, publishing an extensive series of medical journals, and providing its membership a variety of professional programs and activities designed to facilitate the practice of medicine. One of the most influential professional associations of physicians in the United States, the AMA includes about one fourth of all U.S. physicians as its members and spends more than \$15 million a year on its lobbying efforts. Through its main policy-making body, the House of Delegates, the AMA gives voice to issues affecting all physicians.

History

The AMA was founded in 1847 to advance the scientific disciplines, define and improve the standards in medical education, establish a code of medical ethics, and improve the public's health. It was officially incorporated in 1897. Founded as a result of a resolution calling for a national medical convention that was submitted to the Medical Society of the State of New York by Dr. Nathan Smith Davis (1817–1904), the initial meeting of the AMA was attended by 250 physicians representing 28 states. From the onset, membership in the AMA was voluntary.

The AMA became established as a viable institution around the turn of the 20th century. At this time, a new structure of internal governance was implemented that relied on the election of an apportioned number of delegates from each state medical society. Each state medical society in turn was supported by county medical societies. This change in governance structure served to ultimately

unify, enable, and effectively organize the nation's medical profession.

The membership of the AMA has grown from around 8,000 to 10,000 in 1900 to approximately 245,000 today. During the 1960s, the membership market share of the AMA reached its zenith, representing about 70% of the nation's physicians. The profusion of national specialty medical societies has been cited as one of the reasons for the AMA's decline in membership market share over the past several decades, with more physicians preferring to join societies representing their specific specialty rather than the entire profession. Responding to these membership trends, in 2004 the AMA launched a national advertising campaign for the first time in its history.

The AMA has always taken strong positions on a range of healthcare policy issues that it has believed protect physicians, their patients, and the practice of medicine. Examples of issues it has championed throughout the years are (a) advocating against the use of patent medicines or nostrums of dubious content and effectiveness (1900); (b) recommending nationwide polio vaccines (1960); (c) opposing tobacco use (1971); (d) opposing discrimination against AIDS patients (1987); and (e) supporting the Patients Bill of Rights legislation (2000). The AMA was a primary force in establishing the accrediting authority for physician medical education programs, and in 1942, the Liaison Committee on Medical Education and today, along with the Association of American Medical Colleges (AAMC), continues to sponsor the work of the Liaison Committee. The AMA also had an important role in establishing the Joint Commission, an organization that evaluates and accredits approximately 15,000 hospitals, nursing homes, group practices, ambulatory-care centers, hospice services, and laboratories.

A consistent priority for the AMA has been protecting physician sovereignty—that is a physician's right and authority to determine how he or she practices medicine. Reflecting this concern, the AMA opposed in the early 1900s a form of medical practice called “contract” practice. Similar in concept to the health maintenance organizations (HMOs) of today, contract practice physicians agreed to care for a defined group of patients in return for a specified amount of money. The AMA also initially opposed the establishment of Medicare

in 1965, concerned about government's intrusion into medicine. Today the AMA is advocating for Medicare Physician Payment reform, as the current payment formulas are expected to lead to pay cuts for physicians and reduced access to care for the nation's seniors.

Given the AMA's size and influence, sometimes the positions it takes to protect the practice of medicine generate controversy. For example, the AMA has confronted the Sherman Antitrust Act several times in its history: once in the 1940s for hindering and obstructing the business of an HMO, the Group Health Association, Inc., and once in 1987 in its attempt to boycott chiropractors on the grounds that the science on which that profession was based was neither rigorous nor sound. More recently, the AMA's decision in 1997 to accept payment for endorsing commercial healthcare products without testing them generated much debate within the medical profession and the media on the subject of medical ethics.

Size and Structure

The AMA's headquarters are located in Chicago, where it employs around 1,000 individuals. It maintains an office in Washington, D.C., that focuses on advocacy and government relations, and it also maintains an office in New Jersey that focuses on its publishing operations.

The AMA is organized into five general areas: (1) membership, (2) business operations, (3) core operations, (4) governance, and (5) administration and operations. Membership units focus on recruiting and retaining physician members. The business operations units include publishing, database maintenance and products, consumer books and products, and the AMA Insurance Agency. The core operations units focus on developing policy and establishing professional standards, including those related to medical education, public health and medical ethics; advocacy at the private sector, state, and federal levels and research to support that advocacy; maintaining relationships with state, county, and specialty societies; and marketing and communications. The governance units include serving and supporting the AMA's Board of Trustees and the House of Delegates. Last, the administration and operations units provide

administrative and operational support for other AMA units.

The AMA's governing structure is a federation, with separate medical societies supporting and contributing to the political whole. Elected representatives from state medical societies, national medical specialty organizations, and the federal health services sit in the AMA's House of Delegates. Each society is allocated a number of representatives based on its level of AMA membership. The House of Delegates is the principal policy-making body of the AMA, debating and voting on resolutions submitted by its representatives, which in turn provide direction for its programmatic efforts.

Other bodies also shape the policy and direction of the AMA. Elected by the House of Delegates, the AMA's Board of Trustees oversees and guides its activities. Five different councils help shape policy and focus on one of the following issues: medical ethics, long-range planning, medical education, socioeconomic issues affecting the practice of medicine, and medical, public health, and scientific issues affecting medicine. The AMA also incorporates the views of special groups or sections of physicians, including medical students, resident physicians, young physicians, organized medical staff, group practice physicians, women physicians, minority physicians, international medical graduates, senior physicians, medical schools, and gay, lesbian, bisexual, and transgender physicians.

Products and Activities

Although considerable AMA activity is devoted to membership development and retention, its most visible products and activities involve information and advocacy.

The AMA is one of the largest publishers of medical information in the world. Its flagship publication, the *Journal of the American Medical Association (JAMA)* is published in 10 languages, and print editions are circulated in 113 countries. In addition, the AMA publishes nine specialty journals, called the Archives Journals (*Archives of Dermatology*, *Archives of Facial Plastic Surgery*, *Archives of General Psychiatry*, *Archives of Internal Medicine*, *Archives of Neurology*, *Archives of Ophthalmology*, *Archives of Otolaryngology—Health and Neck*

Surgery, *Archives of Pediatrics and Adolescent Medicine*, and the *Archives of Surgery*), which are also available in print editions internationally. Both *JAMA* and the Archives Journals are peer reviewed and available online. *JAMA* is published weekly, while the Archives Journals are published on a monthly or bimonthly basis. In addition to its journals, the AMA publishes a newspaper for physicians called *American Medical News*.

Other AMA products and services include resources that support professional development and facilitate the practice of medicine. For example, the AMA publishes *Current Procedural Terminology (CPT)*, the guidebook for physicians' offices on how to correctly classify and code medical procedures for appropriate reimbursement from Medicare. The AMA offers online continuing medical education programs. It publishes a variety of directories related to graduate medical education and hosts online a *Fellowship and Residency Electronic Interactive Database (FREIDA)* for medical students and residents to research and compare the characteristics of residency programs. It also publishes a wide variety of medically related books on topics such as guides impairment resources, health, medical law and ethics, practice management, and career development. The AMA disseminates its policy positions through an online database called PolicyFinder.

An important resource that supports a variety of the AMA's products and services, such as its membership development efforts, marketing activities, and outreach programs, is the AMA Physician Masterfile. The Physician Masterfile is a large database that includes biographic, medical education and training, contact, and practice information on more than 800,000 physician records. In cooperation with the Association of American Medical Colleges (AAMC), data are collected on individuals from medical school through residency training. The AMA continues to collect practice information from physicians throughout their entire medical careers. Data collection techniques involve the use of primary source data (i.e., data from the original source and in its original form) collected from agencies such as licensing and medical specialty boards as well as surveying the physicians directly. Data are updated continuously. In addition to physician records, the Physician

Masterfile includes information on 125 medical schools, 7,900 graduate medical education programs, 1,600 teaching institutions, and 19,000 medical group practices.

Several products are derived directly from the Physician Masterfile. The AMA offers the online DoctorFinder for patients. It also licenses data to companies that specialize in direct mailing, marketing services, the management of complex pharmaceutical call reporting systems, data integration services, and other health-related and research activities. Data from the Physician Masterfile are also frequently used by hospitals, licensing boards, group practices, and other healthcare organizations to verify physicians' credentials. Although health services and policy researchers often use the Physician Masterfile, the AMA itself no longer conducts this type of research, having reduced its capacity to do so in the 1990s.

A significant and visible activity of the AMA is advocating for physicians on important professional and public health issues of the day. The AMA has established several units to assist in this effort: (a) the Grassroots Action Center, which helps physicians communicate with their federal legislators; (b) the Advocacy Resource Center, which advances state legislative advocacy efforts in partnership with state societies; and (c) the American Medical Political Action Committee (AMPAC), which makes campaign contributions to medicine-friendly candidates and provides political education activities.

The top items on the AMA's current policy agenda are the following: (a) placing limits on non-economic damages in medical liability cases as a key part of a broader effort to effect medical liability reform; (b) lobbying for reforming Medicare's physician payment system by replacing the current physician payment formula with a system that combines stable increases in reimbursement for physicians with less paperwork; (c) incrementally expanding coverage for the uninsured and increasing access to care through the implementation of a consumer-driven, market-based plan (toward this end, the AMA signed on with other large organizations to support the Health Coverage Coalition for the Uninsured [HCCU]); (d) improving the health of the public by promoting healthier lifestyles, working to eliminate health disparities, and improving disaster preparedness, resulting in the

establishment of a Center for Public Health Preparedness and Disaster Response; (e) improving patient safety through continued support of the National Patient Safety Foundation (NPSF) and through continued advocacy at the national level; and (f) ensuring that physicians set standards for quality care by convening the Physician Consortium for Performance Improvement, with representatives from more than 100 national specialty and state societies, which aims to establish evidence-based clinical performance measures.

AMERICAN NURSES ASSOCIATION (ANA)

The American Nurses Association (ANA) is a personal membership society supporting the professional needs of the 2.9 million registered nurses (RNs) in the United States. The ANA comprises 54 constituent member organizations and more than 150,000 members. Headquartered in Silver Spring, Maryland, the ANA is a nonprofit, non-government organization, supported primarily by membership dues, the sale of publications, and revenue from certification programs.

The ANA promotes standards of nursing practice based on scientific evidence, the rights of nurses in the workplace, development of new nursing service delivery models to respond to changing healthcare demands, and policy advocacy for its members on nursing and health related issues. The ANA's stated mission is "nurses advancing our profession to improve health for all." The overall goals of the ANA are to foster high standards of nursing practice, promote the economic and general welfare of nurses in the workplace, convey a positive image of nursing, and lobby the U.S. Congress and the Administration on health issues affecting nursing and the health of the public.

Current strategic priorities of the ANA include the following: (a) professional practice and excellence, (b) healthcare and public policy, (c) knowledge and research, (d) the unification of the profession, and (e) advocacy for workforce and workplace.

History

The ANA is more than 100 years old. It was founded in 1896 as the Nurses Alumnae Association, with 20 nurses attending the first meeting to create a professional association for nurses. However, none of these attendees were registered nurses, as there were no licensing regulations for nursing at that time. The stated goals of the new organization were "to establish and maintain a code of ethics; to elevate the standards of nursing education; to promote the usefulness and honor the financial and interests of nursing." In 1900, the organization published *The American*

Nurse, and a year later, the first state nursing organizations were formed to help regulate the practice of nursing. In 1911, the organization changed its name to the American Nurses Association. Over the decades, the number of ANA members has grown, and the organization attempts to represent the interests of all nurses in the nation.

Structure and Function

Governance

The ANA is organized into constituent member organizations and affiliated organizations. The ANA has constituent member organizations in every state, the District of Columbia, Guam, and the U.S. Virgin Islands. Federal nurses also have their own constituent member organization. These constituent members govern the association through the ANA House of Delegates, which consists of members from each constituent organization. There is also an elected board of directors, and these two entities provide the governing structure for the ANA.

A key committee in the governance structure of the ANA is the Congress on Nursing Practice and Economics (CNPE), a deliberative body of the association's members with diverse clinical and practice experiences and perspectives. The CNPE focuses on establishing nursing's approach to emerging trends within the healthcare industry by identifying issues and recommending policy alternatives to the ANA board of directors.

Affiliate Organizations

The ANA has several affiliated organizations, including (a) the American Nurses' Foundation (ANF), (b) the American Nurses Credentialing Center (ANCC), (c) the American Academy of Nursing (AAN), and (d) the American Nurses Association Political Action Committee (ANA-PAC). These affiliate organizations are separate but related arms of the ANA, which take major responsibility for key ANA functions.

The ANF, which was established in 1955, is the research, education, and philanthropic arm of the

ANA. The ANF raises funds and awards grants to support advances in nursing science, education, and practice. Since its formation, the ANF has awarded more than 950 nursing research grants, totaling more than \$3.5 million.

The AAN, which was established in 1973, is the leadership and scholarship arm of the ANA. Academy fellows are nurse leaders in practice, research, and education, who are elected by their colleagues for membership in the AAN. The AAN aims to serve the public through the generation, synthesis, and dissemination of nursing knowledge.

The ANCC, which was established in 1973, is the arm of the ANA that provides tangible recognition of professional achievement and expertise in functional and clinical areas of nursing. The American Board of Nursing Specialties and the National Commission for Certifying Agencies, both well recognized throughout the certification healthcare credentialing community, accredit most of the ANCC's examination and certification processes.

The ANCC is also responsible for the Magnet Recognition Program, which recognizes healthcare organizations that meet standards of nursing excellence. This program is based on quality indicators and standards of nursing practice as outlined in the *ANA Scope and Standards for Nurse Administrators*. Magnet designation is intended as a benchmark for measuring the quality of care that consumers can expect to receive in a healthcare facility. The popular weekly newsmagazine *U.S. News and World Report* uses the Magnet designation as one of its criteria for recognizing America's best hospitals. Of the 18 hospitals listed on the U.S. News and World Report Honor Roll for 2007, 11 were Magnet hospitals.

The American Nurses Association Political Action Committee (ANA-PAC), which was established in 1974, is the lobbying arm of the ANA. The ANA-PAC raises voluntary money from members and contributes these funds to support candidates for public office who have demonstrated their support for the legislative agenda of the ANA. The ANA-PAC is bipartisan and works with both national parties to fund candidates who support nursing and the ANA's nursing agenda.

Publications

The ANA produces several publications on nursing and health policy issues. These include *The American Nurse*, a monthly newspaper, *American Nurse Today*, a monthly journal, and *OJIN: The Online Journal of Issues in Nursing*, a peer-reviewed online journal. In addition, the ANA publishes a wide variety of books and policy documents, including the *ANA Scope and Standards of Nursing Practice* for nursing as a whole and for a variety of clinical specialties in nursing.

Position Statements

The ANA represents nurses by developing guidance for clinicians such as established definitions of the profession, educational preparation for the profession, certification and credentialing, and standards and competencies. The ANA currently publishes 21 standards in cooperation with various specialty nursing organizations. These standards are updated at least every 5 years through a process overseen by the Congress on Nursing Practice and Economics (CNPE).

The ANA also is responsible for developing and promulgating the *Code of Ethics for Nurses*, which is considered one of the most important documents of the association. In addition, the ANA forms working groups to develop position statements on issues of concern to nursing such as end-of-life care, disaster preparedness, health system reform, and quality of care.

Political Activities

The ANA advocates for federal and state legislation and regulations supporting nursing practice. Such political action addresses both workplace issues such as safety, staffing to patient ratios, wages, and working conditions, and issues related to protecting the health of the public. ANA policy priorities include supporting healthcare reform efforts, expanding the roles for nurses and advanced practice nurses in healthcare delivery, increasing federal funding for nursing education and nursing workforce development, and providing greater workplace safety for nurses. In addition, the ANA has been involved in advocating for Medicare

reform, passing patients' rights legislation, providing greater protection for whistle-blower nurses, increasing the reimbursement for healthcare services, and providing greater public access to healthcare.

AMERICAN OSTEOPATHIC ASSOCIATION (AOA)

The American Osteopathic Association (AOA) is a member association that represents more than 61,000 (as of 2008) osteopathic physicians (DOs). With headquarters in Chicago, the AOA has a mission of advancing the philosophy of osteopathic medicine by promoting excellence in education, research, and the delivery of quality, cost-effective healthcare within a distinct, unified

profession. The AOA also works to promote public health; encourages scientific research; serves as the primary certifying body for DOs; is the accrediting agency for osteopathic medical colleges; and has federal authority to accredit hospitals and other healthcare facilities.

History

Founded in 1897 by a group of 16 students from the American School of Osteopathy in Kirksville, Missouri, the AOA aimed to organize the efforts of individual physicians and osteopathic medical colleges to advance the osteopathic medical profession. On April 19, 1897, the committee created a constitution and permanently established the association. Originally the American Association for the Advancement of Osteopathy, the name changed to the American Osteopathic Association in 1901.

Leadership

The AOA's leadership includes a board of trustees comprising a president, president-elect, two past presidents, three vice presidents, 18 additional trustees, an intern-resident representative, and a student representative as well as a house of delegates comprising DOs representing osteopathic medical state and regional societies and specialty colleges, a speaker, and a vice speaker.

Board Certification

The AOA, through its official certifying body, the Bureau of Osteopathic Specialists, and its 18 member certifying boards, offers 85 board certifications in specialties, subspecialties, and areas of added qualifications. Recognition by one of the certifying boards of the AOA means a DO has completed specific specialty or subspecialty training, has passed a rigorous board examination, and has met other board-specific requirements.

The AOA specialty certifying boards, through the Bureau of Osteopathic Specialists, define the qualifications required of DOs for certification and recertification in each specialty; determine the qualifications of osteopathic physicians

as specialists for certification in each specialty; conduct examinations for certification; issue certificates, subject to the approval of the AOA Bureau of Osteopathic Specialists, to those physicians who are found qualified for certification in each specialty; recommend revocation of certificates for cause; and use every means possible to maintain a high standard of practice in each specialty within the osteopathic medical profession.

DOs can become AOA board certified in anesthesiology, ophthalmology and otolaryngology, dermatology, orthopedic surgery, emergency medicine, pathology, family practice, pediatrics, internal medicine, physical medicine and rehabilitation, neurology and psychiatry, preventive medicine, neuromusculoskeletal medicine, proctology, nuclear medicine, radiology, obstetrics and gynecology, and surgery as well as a number of subspecialty and added qualification areas of medicine such as cardiology, neurophysiology, geriatrics, and medical toxicology.

Certification requirements vary by specialty. At a minimum, candidates for AOA certification must have a valid state license to practice medicine, have completed a 1-year internship followed by completion of an approved residency training program, have passed the board examination or examinations, and be members of the AOA or the Canadian Osteopathic Association.

To maintain board certification, AOA board-certified physicians must complete a minimum of 120 hours of approved and documented AOA continuing medical education credits within a 3-year period, of which 50 hours must be in their general specialty. The American Osteopathic Board of Family Physicians is an exception, requiring 150 hours with 50 hours still in the general specialty.

Board certification is a voluntary process and is not a requirement to practice in a medical specialty. DOs who have been trained in programs accredited by the Accreditation Council for Graduate Medical Education rather than in programs approved by the AOA also have the option of certifying through the American Board of Medical Specialties (ABMS). A majority of DOs continue to be certified through the member boards of the AOA, with some of those being dually certified by both AOA and ABMS boards.

Accreditation

The AOA's Commission on Osteopathic College Accreditation (COCA) is recognized by the U.S. Department of Education as the only accrediting agency for predoctoral osteopathic medical education in the United States. Accreditation action taken by the COCA means that an osteopathic medical school (a) has appropriately identified its mission; (b) has secured the resources necessary to accomplish that mission; (c) shows evidence of accomplishing its mission; and (d) demonstrates that it is capable of accomplishing its mission in the future. Accreditation of an osteopathic medical school means that it incorporates the science of medicine, the principles and practices of osteopathic manipulative medicine, the art of caring, and the power of touch within a curriculum that recognizes the interrelationship of structure and function for diagnostic and therapeutic purposes and recognizes the importance of addressing the body as a whole in disease and health.

Accreditation signifies that an osteopathic medical school has met or exceeded the AOA standards for educational quality with respect to (a) mission, goals, and objectives; (b) governance, administration, and finance; (c) facilities, equipment, and resources; (d) faculty; student admissions, performance, and evaluation; (e) preclinical and clinical curriculum; and (f) research and scholarly activity.

In addition, the AOA approves osteopathic internship and residency training programs through its Program and Trainee Review Council (PTRC). The PTRC receives reports and recommendations from evaluation committees of osteopathic specialty practice organizations for osteopathic internship and residency program approvals, denials, and increases or decreases in size and takes final action on all recommendations. In addition, the PTRC also accepts requests for AOA approval of individual DO trainees' internships or residencies that were not originally AOA-approved programs.

Recognizing the need for a new system to structure and accredit osteopathic graduate medical education, the AOA established the Osteopathic Postdoctoral Training Institutions (OPTI) in 1995. Each OPTI is a community-based training consortium comprising at least one college of osteopathic medicine and one hospital. Other hospitals and ambulatory-care facilities may also partner within

an OPTI. Community-based healthcare facilities, such as ambulatory-care clinics, rehabilitation centers, and surgical centers, may attain the educational resources and support necessary to provide physician training with an OPTI's assistance.

The AOA also provides continuing medical education (CME). The AOA Board of Trustees establishes accreditation policy for osteopathic CME sponsors. The AOA Council on Continuing Medical Education has been given authority by the AOA Board of Trustees to monitor osteopathic CME and to grant or deny Category 1 accreditation status to osteopathic CME sponsors.

Additionally, the AOA accredits medical facilities through its Healthcare Facilities Accreditation Program (HFAP). This program has been providing medical facilities with an objective review of their services since 1945. The program is recognized nationally by the federal government, state governments, insurance carriers, and managed-care organizations.

It is one of only two voluntary accreditation programs in the United States authorized by the Centers for Medicare and Medicaid Services (CMS), formerly the Health Care Financing Administration (HCFA), to survey hospitals under Medicare. The AOA accreditation program was developed in 1943 to 1944 and implemented in 1945. Under this program, hospitals were surveyed each year. In this manner, the AOA was able to ensure that osteopathic medical students received their training through rotating internships and residencies in facilities that provided high-quality patient care.

In 1965, Medicare and Medicaid were introduced, and the AOA applied to the HCFA, now CMS, for deeming authority to survey hospitals under the Medicare Conditions of Participation.

In 1995, the AOA applied for and received deeming authority to accredit laboratories within AOA-accredited hospitals under the Clinical Laboratory Improvement Amendments of 1988.

The program also accredits ambulatory care/surgery, mental health, substance abuse, physical rehabilitation medicine facilities, critical access hospitals, and long-term acute-care hospitals. Additionally, in 2006, HFAP announced that its first disease certification program—the HFAP Primary Stroke Center—had been developed. This 2-year certification is limited to HFAP-accredited

healthcare facilities. On-site survey is required every 2 years to validate ongoing compliance with HFAP standards.

Professional Publications

The AOA also produces two monthly publications for the osteopathic medical profession. *JAOA—The Journal of the American Osteopathic Association (JAOA)* is the official scientific publication of the AOA as well as the scholarly, peer-reviewed publication of the osteopathic medical profession. It provides a forum for communicating and disseminating philosophical concepts, clinical-practice observations, and scientific information as well as defines the current status of the profession. It is directed toward the osteopathic primary-care physician with a broad range of interests and provides a clinical and scientific update for the osteopathic specialist.

JAOA publishes original investigations, current reviews with an expert critical viewpoint, and didactic discourses in a wide variety of clinical fields. For the interest and information of its readers, *JAOA* may contain medical education articles, editorials, columns, book reviews, abstracts, and special-interest articles at the editor-in-chief's discretion. These articles customarily will be of clinical-scientific interest or related to issues and trends that have a bearing on the osteopathic medical profession. Controversial articles and letters may, at the editor-in-chief's discretion, be published in *JAOA*, provided that the source or author is clearly identified. DOs can receive a half-hour of Category 2-B continuing medical education credit for each issue they read of the *JAOA* and 2 hours of Category 1-B credit each time they complete a quiz in the journal or its supplements.

The DO magazine contains news of the osteopathic medical profession and its members; articles of professional and personal interest to DOs and osteopathic medical students; legislative developments; meeting coverage; clinical updates; and an extensive listing of osteopathic continuing medical education programs. DOs can earn 1 hour of Category 1-B credit for each quiz they complete from *The Whole Patient* supplements to *The DO*, the AOA's *Women and Wellness Newsletter*, and the AOA's *Health Watch* newsletter. DOs who do

not complete the quizzes can still obtain a half-hour of Category 2-B credit for each issue and supplement of *The DO* they read.

AMERICAN PUBLIC HEALTH ASSOCIATION (APHA)

The American Public Health Association (APHA) is the oldest, largest, and most diverse organization of public health professionals in the world. It has been working to improve the nation's public health since its inception in 1872. The association aims to protect all Americans and their communities from preventable, serious health threats and strives to ensure that community-based health promotion and disease prevention activities and preventive health services are universally accessible in the United States. The APHA represents a broad array of health professionals and others who care about their own health and the health of their communities. It builds a collective voice for public health, working to ensure access to health-care, protect funding for core public health services, and eliminate health disparities, among a

myriad other issues. The APHA's strength is rooted in the dedication and passion of its members and countless other individuals, agencies, and foundations who are concerned about improving and protecting the nation's health.

History

The APHA grew out of the growing recognition by a physician named Stephen Smith and others in the medical profession that squalid living conditions caused epidemics of infectious diseases, such as typhus fever and cholera, and their frustration with the incompetence and ignorance of local officials, such as Boss Tweed and Tammany Hall, in denying these unsanitary conditions. As the citizenry became more interested in organizing local boards of health and in establishing a national chain of communications in public health, the APHA was formed in 1872 as the vehicle to carry out these activities. Its charge was to hold annual meetings and produce publications to awaken and maintain the active and permanent interest of the people in sanitary administration, greatly facilitate the enlightenment of the public, and promote the appointment of more competent health authorities. The first meeting attracted 15 people.

Over its long history, the APHA has embraced numerous topics, shifting its primary focus from laboratory aspects of water pollution, milk sanitation, hygiene education, control of tuberculosis, and infectious diseases in the 1890s to eliminating disparities in healthcare, designing healthy communities, obesity, smoking cessation, disaster preparedness, building the public health workforce, and improving the public health infrastructure in the 2000s. In this time, it has participated in some of the most extraordinary achievements of modern times—achievements that have increased the average life expectancy from 45 to more than 75 years of age. Advances in many areas of public health and practice have dramatically lessened the incidence of disease and injury, adding 25 of those years to our lives.

Size and Structure

Today, the APHA boasts nearly 50,000 members, including its affiliates. APHA members include

nurses, physicians, environmentalists, educators, dietitians, nutritionists, scientists, laboratory workers, health information specialists, dentists, podiatrists, and students. They are supported by 24 Sections and seven Special Interest Groups on a variety of professional interests, a Student Assembly, and special membership categories, including transitional membership—a limited membership open only to current student members who have completed their degree and are transitioning into the workforce; special health workers; retired members; and consumer members.

Each day, APHA members, working in health agencies, nonprofit organizations, educational settings, and medical facilities, tackle public health challenges every bit as tenacious as those faced by their 19th-century predecessors, as longer lives, sedentary habits, and poor nutrition give rise to a new spectrum of health problems. Environmental hazards continue to threaten public health, and economic factors profoundly affect access to health insurance coverage and consequently to healthcare. And efforts by lawmakers to reduce government spending threaten the nation's long-standing commitment to public health programs and education.

Products and Activities

The APHA publishes the *American Journal of Public Health*, a monthly, peer-reviewed journal published continually since 1911, and *The Nation's Health*, the APHA's award-winning newspaper, both communicating the latest public health science and practice to members, opinion leaders, and the public.

The APHA's annual meeting brings together thousands of public health professionals, agencies, and partners to network and share the latest public health data and trends, as well as set policy on emerging public health concerns.

The Public Health Exposition is the showplace for hundreds of leading organizations in the public health market, offering the latest in software, programs, publications, educational opportunities, and more in the field of public health.

The APHA offers a large number of accredited continuing education programs for many public health disciplines, including registered nurses, certified health educators, physicians, laboratory

professionals, registered dietitians, chiropractors, and dental professionals.

The APHA is a leading publisher of books promoting sound scientific standards, action programs, and public policy to enhance health. Two of the mainstays of the publications program are *Standard Methods for the Examination of Water and Wastewater*, published continually since 1917, and now in its 21st edition; and the *Control of Communicable Diseases Manual*, published continually since 1920, and now in its 18th edition—and still the most widely recognized and used resource on infectious diseases in the world.

The APHA's government affairs staff represents its members' concerns on Capitol Hill, in regulatory agencies, and in executive offices at the federal, state, and local levels. The APHA is one of the leading public health organizations with full-time advocates in the nation's capital.

National Public Health Week each year highlights an area of public health concern and encourages nationwide participation through the sections and affiliates.

The Public Health Career Mart brings together employers and employees, offering a wide variety of public health career opportunities. Added features at the annual meeting include one-on-one career-counseling sessions with professional counselors and interview time with prospective employers.

Future Implications

In the future the APHA will continue to build a collective voice for public health, working to ensure access to healthcare, protect funding for core public health services, and eliminate health disparities, among a myriad other issues. The APHA's strength will continue to be rooted in the dedication and passion of its members and countless other individuals, agencies, and foundations who are concerned about improving and protecting the nation's health.

AMERICAN SOCIETY OF HEALTH ECONOMISTS (ASHE)

The American Society of Health Economists (ASHE) is a professional organization dedicated to promoting excellence in health economics research in the United States. The society's leading mission is to provide a forum for emerging ideas and empirical results of health economics research. Through a set of professional activities, it aims to advance health economics research in the nation, achieve widespread recognition for the field of health economics, and enhance individual and societal health by providing evidence and expertise for the development of public and private health policies.

The academic field of health economics has experienced very rapid growth in the past three decades. Commensurate with this growth has been a similar growth in research productivity and quality along with job opportunities in academe, government, and industry. The ASHE was formed to respond to the excess demand for an outlet for health economics and policy research as well as to

provide for interaction among those conducting the research, funding the research, and making use of the research. The society makes every attempt to be inclusive, attracting the young and old, the experienced and inexperienced, leaders in the field, and graduate students preparing to enter the field.

The main venue through which the mission of the ASHE is accomplished is its biennial conference. The inaugural conference of the society was held at the University of Wisconsin, Madison, in June 2006. More than 500 individuals attended the conference, where more than 300 research articles were presented and 100 poster sessions were held. Professor Joseph P. Newhouse, the John D. MacArthur Professor of Health Policy and Management, Harvard University, and the inaugural president of the society, presided over the conference along with Jody L. Sindelar, professor in the School of Public Health at Yale University, and the president-elect of the organization. And Michael Grossman, Distinguished Professor of Economics, City University of New York Graduate Center, and Program Director of Health Economics at the National Bureau of Economic Research, was designated to serve as president after Sindelar's term of office. At the conference, the society awarded ASHE Medals to two health economists who were 40 years of age or younger and judged by their peers to have made outstanding contributions to the field. The medals were awarded to David M. Cutler, Otto Eckstein Professor of Applied Economics at Harvard University, and to Jonathan Gruber, professor of economics at the Massachusetts Institute of Technology (MIT). The second biennial conference was held at Duke University, Durham, North Carolina, in June 2008. And the third biennial conference will be held at Cornell University, Ithaca, New York, in 2010.

All the biennial conferences have broad themes, but they are equally inclusive in topics represented in the research that is presented. The society is a domestic organization open to the presentation of research results related to domestic issues. While most members are from academic institutions, there is substantial representation from government and industry as well as other countries.

The ASHE was formed under the umbrella of the International Health Economics Association (iHEA), with the full support of Professor Tom E. Getzen of Temple University, Philadelphia,

Pennsylvania, executive director of the iHEA. The first executive director of the ASHE was Professor Richard J. Arnould of the University of Illinois at Urbana-Champaign. Memberships to ASHE were initially offered in 2005 jointly with iHEA memberships. Independent memberships were first offered in 2007. The ASHE plans to be an independent not-for-profit organization in 2010. The society is governed by a board of directors, initially formed by appointment but with elections commencing in 2007, and it operates subject to the bylaws established by the board. Currently, the ASHE has approximately 800 members.

AMERICA'S HEALTH INSURANCE PLANS (AHIP)

America's Health Insurance Plans (AHIP) is a large national trade association representing more than 1,300 member companies that provide health, long-term care, dental, disability, and supplemental insurance coverage to more than 200 million people in the United States. AHIP's principal purpose is to represent the interests of its members on legislative and regulatory issues at the federal and state levels, and with the media, consumers, and employers. Its goal is to provide a unified voice for the nation's health insurance industry, to expand access to high-quality, cost-effective healthcare to all Americans, and to provide consumers with a wide array of health insurance plans.

Background

Located in Washington, D.C., AHIP was formed in 2003, through the merger of the Health Insurance

Association of America (HIAA) and the American Association of Health Plans (AAHP).

Its oldest predecessor, the HIAA, was formed in 1956. HIAA's mission was to be the most influential advocate for the nation's private, free-enterprise healthcare system. Throughout its history, HIAA strongly opposed legislative efforts to regulate private health insurance and the establishment of national health insurance. It successfully helped defeat the Clinton administration's national health-care reform plan of 1993. To stop the Clinton plan, HIAA established a group of organizations that oppose the plan, created an aggressive grassroots campaign against the plan, and spent millions of dollars airing a powerful television commercial criticizing the plan. The TV commercial, *Harry and Louise*, depicted a middle-class couple who were despairing over the proposed plan's complex bureaucratic nature. It decried the plan as big government at its worse and featured the phrase, "They choose, we lose."

Its second predecessor, the AAHP, was formed in 1996. AAHP's mission was to present a strong, unified voice for the nation's managed-care industry and a positive image of the industry to the general public. In the late 1990s, AAHP attempted to defend the managed-care industry, which was becoming increasingly unpopular with the general public, and it was facing increasing scrutiny by the U.S. Congress concerning the tactics it used to save money.

Organization and Structure

AHIP is governed by a board of directors. The board, which comprises 56 individuals who represent various insurance companies, works to shape and guide the association's policies, programs, and research. It receives directions and input from operating and product committees, the policy committee, and the executive committee as well as issue-focused task forces, subcommittees, and working groups. The president of AHIP, who is responsible for the operations of the organization, also reports to the board.

Products and Services

AHIP provides information and services through newsletters, a magazine, and online services. It also

offers a combination of conferences, self-study courses, and programs that assist health professionals in staying abreast of important issues in healthcare. Each year, the organization hosts a number of conferences that are open to AHIP members, state health insurance trade organizations, and other leaders in healthcare. Recent conference topics included insurance product innovation and diversification, value-based healthcare, employer wellness programs, and chronic-care models of care.

AHIP Solutions is a program to help members identify the most capable and expert partners for specific business needs. These areas of need include Medicare/Medicaid, the Health Insurance Portability and Accountability Act of 1996 (HIPAA), risk and reinsurance, eHealth and eBusiness solutions, claims processing and cost management, disaster recovery and consumer-directed healthcare. Agreements between the partners and AHIP are structured to assist in marketing partners' services to members.

AHIP Foundation

The association also has a nonprofit foundation. The AHIP Foundation has the mission of enhancing the quality of healthcare delivery in managed-care settings through effective treatment systems, evidence-based medicine, performance measurement, and quality improvement. Additionally, the foundation seeks to increase the insurance industry's ability to serve diverse populations through the training and development of minority health plan managers and through the support of programs targeted toward minority populations. To accomplish this, the foundation has three programs: the Executive Leadership Program, the Executive Leadership Program for Medical Directors, and the Minority Management Development Program.

Current Efforts

AHIP's latest endeavor is a proposal to expand access to health insurance coverage to every American. The plan would expand access to health insurance coverage to all children within 3 years of age and 95% of adults within 10 years. According to AHIP, the plan would expand eligibility for public programs, enable all consumers to

purchase health insurance with pretax dollars, provide financial assistance to help working families afford coverage, and encourage states to develop and implement access proposals. A plan of this magnitude would cost the federal government approximately \$300 billion over a 10-year period and call for some radical changes in healthcare policies. Some of the key elements of the AHIP plan include expanding the State Children's Health Insurance Program (SCHIP) to make eligible all uninsured children from families with incomes less than 200% of the Federal Poverty Level (FPL), establish a Universal Health Account that would allow individuals to purchase any type of healthcare insurance, and establish a health tax credit of up to \$500 for low-income families who secure health insurance for their children.

ANDERSEN, RONALD M.

Born in Omaha, Nebraska, in 1939, Ronald Max Andersen received his bachelor's degree (1960) from the Santa Clara University and his master's (1962) and doctorate (1968) degrees from Purdue University. From 1974 to 1990, Ronald Andersen worked at the Center for Health Administration Studies (CHAS) in the Graduate School of Business at the University of Chicago. From 1980 to 1990, he was the director of the Program for Health Administration and CHAS. In 1991, he became the Wasserman Professor of Health Services and Sociology at the University of California, Los Angeles (UCLA). In 2004, he became Professor Emeritus.

During his academic career, Andersen has made major conceptual and methodological contributions to the study of healthcare utilization behavior and access to healthcare through the design and conduct of large-scale community, national, and cross-national health surveys. In 1968, he published a monograph introducing the behavioral model of families' use of health services, based on an analysis of a 1963 national survey of healthcare utilization and expenditures. This model, and Andersen and his colleagues' successive adaptations of it, continue to guide much of the explanatory research on healthcare utilization behavior.

Andersen's subsequent work built directly on these interests. He was principal investigator for national health surveys conducted in 1970 and 1976. The latter survey extended his earlier conceptual and empirical work on utilization to examining the issues of access to healthcare. The access

framework developed in connection with that survey served to guide the development of community-survey-based evaluations of the Community Hospital Program and Municipal Health Services Program, conducted by the CHAS, with support from the Robert Wood Johnson Foundation. Andersen was also the principal investigator for subsequent projects to conduct secondary analyses of data collected through these and related state, community, and national surveys.

Andersen also provided leadership in the study of healthcare delivery system issues in the United States through the design and implementation of the National Study of Internal Medicine Manpower, a national evaluation of home-care programs for ventilator-assisted children, studies of health services use by the homeless, and evaluation of community-based dental programs and related dental health profession needs. He extended the application of his empirical and conceptual interests in these areas to the design and conduct of cross-national comparative studies of utilization and access through the World Health Organization (WHO) International Collaborative Study of Dental Manpower Systems in Relationship to Oral Health Status.

Andersen has received numerous awards and honors. He was named the Fred and Pamela Wasserman Professor of Health Services at the UCLA School of Public Health. His contributions were acknowledged by colleagues in the fields of medical sociology and health services research through his receipt of the Leo G. Reeder Distinguished Medical Sociologist Award from the Medical Sociology Section of the American Sociological Association (1994), the Association for Health Services Research Distinguished Investigator Award (1996), and the Health Services Research Prize from the Baxter Allegiance Foundation (1999). His lifetime scholarly achievements were acknowledged by his receiving the Distinguished Alumnus Award (1998) and an honorary doctorate degree (1999) from Purdue University.

ANDERSON, ODIN W.

Odin W. Anderson (1914–2003) is a worthy candidate for "the father of medical sociology." After World War II, a few sociologists in the United States began to take interest in medical sociology (although the term had not yet been coined). In 1960, a section on the sociology of medicine was established within the American Sociological Association (ASA), and quickly it became one of the largest sections. Anderson was a member of the founding committee for this section and its second chair. In the following decades, other academic disciplines, including economics, political science, and operations research began to study health services, and philanthropic foundations

and the federal government became interested in funding research on the health services industry, destined to become the largest industry in the nation. Anderson's career spanned these periods of significant growth of the health services sector and profoundly influenced its study.

Born in Minneapolis, Minnesota, in 1914, Anderson received his bachelor's degree (1937) and master's degree in sociology (1938) from the University of Wisconsin–Madison. He then moved to the University of Michigan, where he received a bachelor's degree in library science (1940) and his doctorate degree in sociology (1948). While at Michigan, Anderson became the first sociologist to work in a school of public health, helping establish a research program in medical care and a health services research library. In 1949, he accepted an associate professor position on the Faculty of Medicine, University of Western Ontario, Canada—another first for a sociologist to join the faculty of a medical school. There, he studied the emerging areas of social epidemiology and also began to work in the utilization of physician services in a nearby medical insurance plan.

In 1952, Odin Anderson became the research director of the Health Information Foundation (HIF), located in New York. This nonprofit research agency was founded by pharmaceutical and chemical industries in 1950 to provide information and data for public policy formulation in the United States. Anderson developed and directed a unique and highly successful research program based on national surveys of the medical-care use and expenditures of the nation's population and cross-national comparisons of the operation of health services delivery systems and health insurance.

The HIF moved to the University of Chicago in 1962, where it was renamed the Center for Health Administration Studies. Anderson continued to serve as the research director and became a professor in the Graduate School of Business and the Department of Sociology. CHAS flourished under Anderson's direction, expanding its national and international health services research program with support from foundations and the federal government. The center served as a national model and reference point for health services research.

In 1980, on reaching the mandatory retirement age of 65 at the University of Chicago, Anderson returned to the University of Wisconsin–Madison

with a half-time professorship in the Department of Sociology. He also continued to teach and to conduct research for another 10 years at CHAS as Professor Emeritus. In this last period of his career, he continued to be incredibly productive, conducting a study of Health Maintenance Organizations (HMOs) in Minneapolis–St. Paul and Chicago, writing a book on health services in several countries, and writing a history of the development of American health services since 1875.

Anderson was a prolific writer, and many of his publications are considered classics in the field. His legacy of publications and lessons for the fields of medical sociology and health services research has been validated by numerous recognitions. The Section on Medical Sociology of the American Sociological Association cited him as a Distinguished Medical Sociologist (1980), and the Association for Health Services Research cited him as a Distinguished Health Services Researcher (1985). He was awarded the Baxter Alliance Distinguished Health Services Researcher Prize (1999). And he received honorary doctoral degrees from the Faculty of Medicine, University of Uppsala, Sweden (1977), and the College of Osteopathic Medicine, Chicago (1979).

His enduring research contributions for the fields of medical sociology and health services research include a conceptual systems approach for understanding the health services enterprise; empirical data systems for actuaries, economists, and policy-makers about the financial problems of healthcare consumers; fundamental approaches to cross-national comparisons and the understanding of generic health services systems problems; and understanding the social, political, and economic environments in which American health services developed. He was a trusted advisor to more than 500 consultants and administrators in hospitals and medical-care plans across the nation and in numerous foreign countries. And he mentored many graduate students who subsequently worked in more than 30 universities in the nation and abroad and numerous others who work in government and nongovernment agencies. Anderson's influence on these students has been enormous, and his conceptual thinking and approach to medical sociology and health services research continue through their efforts.

ANTITRUST LAW

Antitrust law seeks to maintain an environment of free and fair competition in markets for goods and

services. Its implementation is based on the assumption that abusive business practices that corrupt the free market can create inefficiencies and excessive costs for consumers. To this end, antitrust law addresses two kinds of potential abuses, one involving collusion among separate firms that compete with one another and the other involving willful efforts by a single firm to monopolize a market.

Antitrust law affects many kinds of healthcare business arrangements, including the relationships between providers and insurance companies, the functioning of professional societies, the composition of hospital medical staffs, and the growth of health systems. Its influence shapes key aspects of the healthcare industry that are based on these arrangements, such as the size of provider networks, the structure of business collaborations, the nature of price negotiations between providers and health maintenance organizations (HMOs), and the disciplinary process for clinicians who violate hospital quality standards. Health services researchers study antitrust law to understand better the economic dynamics of healthcare. The results of these investigations and analyses provide fuel for ongoing debates about the appropriate roles of government and of private markets in allocating healthcare goods and services.

Legal Framework

Three federal statutes are central to antitrust law in the United States. The most important of these is the Sherman Act, which was enacted in 1890. Section 1 of that law (codified as 15 U.S.C. §1) prohibits any “contract, combination . . . or conspiracy in restraint of trade.” Such arrangements have been interpreted by the courts to include various forms of collusion among competitors, including price fixing, group boycotts, market allocation agreements, exclusive dealing, and tying arrangements. Section 2 (codified as 15 U.S.C. §2) prohibits monopolization, attempted monopolization, and conspiracies to monopolize. Growth in the size of a company due to business success alone is not sufficient to violate this provision. Rather, monopoly power must be achieved or maintained through willful anticompetitive conduct, such as the use of threats, intimidation, coercion, or boycotts. However, monopolization of a market does not

require the elimination of all competition. It is sufficient that a single firm achieves sufficient market power to be able to raise prices unilaterally without suffering competitive harm.

The interplay of these two provisions of the Sherman Act can be especially problematic for healthcare providers. Collaboration with competitors, as may take place between physician practices or between hospitals in negotiations with HMOs, can violate Section 1. However, merging with or acquiring a competitor to form a single larger entity to gain bargaining leverage can create liability under Section 2 if it creates too great a market share. The result of this legal dynamic can significantly limit the strategic options available to providers.

Violations of the Sherman Act can trigger three levels of enforcement. The most serious abuses may subject the violator to criminal penalties. Less severe infractions may result in government-imposed fines. Private parties may also sue antitrust violators for damages based on any economic harm that they have sustained. This is a particularly potent enforcement threat because a violation may affect many businesses and consumers who can become plaintiffs, and if they succeed in court, they are entitled to recover treble damages, which is an amount representing three times their actual financial loss.

The second statute is the Clayton Act, Section 7 of which (codified as 15 U.S.C. §18) prohibits mergers and acquisitions that may substantially lessen competition or tend to create a monopoly. This law does not punish violators but rather permits regulators to force them to unwind suspect transactions. For example, a hospital that gains too large a market share by acquiring competitors may be ordered to divest some of them. Courts will generally consider factors such as the market share, market concentration, and market power of the acquiring company in deciding whether a transaction has violated this law.

The final statute is the Federal Trade Commission (FTC) Act, Section 5 of which (codified as 15 U.S.C. §45) prohibits unfair and deceptive trade practices. Courts have interpreted such practices to include antitrust violations. This statute does not extend the range of activities subject to antitrust enforcement, but rather grants enforcement authority concerning violations of other laws, including the Sherman and Clayton acts, to the FTC.

Antitrust Principles and Healthcare Markets

Observers have noted a mismatch between the conceptual foundations of antitrust law and the functioning of healthcare markets. In healthcare, three underlying assumptions about traditional market structure are missing. These are the assumptions that buyers can make informed decisions, that they respond to changes in price, and that they are aware of the full costs of their purchases. Patients, as consumers, lack the information and expertise to evaluate purchasing decisions. They must rely for advice on their physicians, who are the sellers of services, a situation that economists call *asymmetry of information*. Price fluctuations are unlikely to affect patients' purchasing decisions because the goods and services involved are essential to maintaining life and health, a situation that economists call *price inelasticity of demand*. Finally, and perhaps most significantly, neither patients nor their physicians are exposed to the full financial consequences of purchasing decisions because of the role of insurance in covering the costs, a situation known as *moral hazard*. As a result of this mismatch, the role of antitrust law in attempting to protect consumers by maintaining a traditional economic market in healthcare has been controversial.

The function of third-party insurance coverage for healthcare costs has posed particular challenges for antitrust enforcement. The Sherman Act was passed to help buyers who were exploited by collusive or monopolistic practices of sellers, and courts have tended over the years to interpret it to favor buyers over sellers. It was enacted in an era when many major American industries were controlled by single companies or by trusts composed of a few of them. In healthcare, however, the buyer of services is usually an insurance company that pays the bills, even though the actual consumer is an individual patient, and the seller is often a physician practicing alone or in a small group. As a result, the act has at times had the effect in healthcare of protecting large corporate entities against the actions of individuals. For example, some courts have characterized group negotiation by physicians with HMOs as a form of price fixing. Some physicians have argued that the U.S. Congress should grant an exception to the antitrust laws for such joint bargaining similar to the one that applies to labor unions.

Antitrust law has also presented a challenge for hospitals and professional societies that discipline physicians for infractions of quality standards. For example, hospital credentials committees, which decide who will be permitted to practice within the institution, are composed of experienced physicians who often maintain practices of their own. Therefore, they may be economic competitors of those whose competence they must judge. In a number of instances, physicians who have lost hospital privileges have sued the institution involved, alleging that its actual motives were to stifle competition rather than to maintain quality. Courts have generally ruled against the physicians in these cases, and the U.S. Congress has further protected hospitals that engage in good faith peer review of hospital staff members from antitrust liability through a law known as the Health Care Quality Improvement Act of 1986. Nevertheless, the threat of litigation persists as healthcare, unlike most other industries, must continue to rely on the expertise of market competitors to enforce quality standards.

Regulatory Agencies

Two federal agencies have primary responsibility for enforcing the antitrust laws. These are the U.S. Department of Justice (DOJ), through its antitrust division, and the FTC. Either agency can bring a legal action against a violator for civil penalties, including fines or an injunction, although the FTC is limited in its authority to act against nonprofit organizations, such as nonprofit hospitals. Only the DOJ can act when criminal penalties are sought. In addition to federal enforcement, states attorneys general can proceed against violators under antitrust laws that have been enacted in most states.

Enforcement agencies have considerable discretion in selecting the targets of their activities. This latitude can play an especially important role in the implementation of antitrust law in healthcare because of the conceptual ambiguities in applying legal principles that assume a traditional market structure to healthcare markets. To reduce uncertainty and to guide private decision making, the DOJ and the FTC have jointly issued regulations that offer prospective guidance on healthcare business practices that

they will consider to be legitimate under the Sherman Act and therefore exempt from prosecution. These are called Safety Zones, and they devote particular attention to the integration of physician practices. Under these rules, factors such as market share, exclusivity rules for network members, and the extent of financial risk sharing among members determine when physicians may form networks without fear of antitrust enforcement.

Future Implications

Antitrust law seeks to improve the healthcare system by controlling certain kinds of abusive business practices that can inflate costs. These practices include collusion between competing firms and growth in the market share of single firms that is sufficient to create monopoly power. However, the structure of healthcare creates challenges for antitrust enforcement because the purchase and sale of healthcare goods and services do not fit the characteristics of traditional markets. This is the result of several factors, most notably the role of insurance in buffering patients from the full costs of the goods and services they consume.

Long-standing judicial interpretations of the antitrust laws that generally favor buyers over sellers have also created anomalies in enforcement policy. In traditional markets, buyers tend to be individual consumers, and sellers to be large corporate entities; however, in healthcare, the buyer is often not the actual patient but rather an insurance company, while the seller may be an individual physician. The key antitrust regulatory agencies, the DOJ and the FTC, have tried to address this incongruity with regulations that set forth special enforcement policies regarding antitrust in healthcare. Nevertheless, antitrust policy continues to raise larger questions concerning the effectiveness of applying market concepts to an industry whose functioning does not fit many traditional economic assumptions.

ARROW, KENNETH J.

Kenneth J. Arrow was one of the most prominent economic theorists of the 20th century. Arrow's classic 1963 article "Uncertainty and the Welfare Economics of Medical Care" launched the field of health economics. His landmark article addressed the role of market competition in delivering healthcare services, the implications of moral hazard (the notion that health insurance increases demand for healthcare services), the uncertainty inherent in healthcare, the role of nonmarket social institutions, the existence of extreme information asymmetry (the inequalities of information between insurer, physician, and patient), and the importance of trust in the physician-patient relationship, given the existence of information asymmetry.

Arrow is currently the Joan Kenney Professor of Economics and Professor of Operations Research, Emeritus, at Stanford University, and senior fellow at the Center for Health Policy at the Freeman Spogli Institute for International Studies, the Center for Outcomes Research, and the Institute for Economic Policy Research, all at Stanford. In 1972, Arrow won the Nobel Prize in Economics for his work on general equilibrium theory and welfare theory. In 2004, he also was awarded the National Medal of Science, the nation's highest scientific honor, for his contributions to understanding decision making under imperfect information and bearing risk.

Arrow was born in 1921 in New York City. He earned a bachelor's degree in social science from the City College of New York (1940) and a master's degree in mathematics (1941) and a doctorate degree in economics (1951) from Columbia University. During World War II, he served as a weather officer in the U.S. Army Air Corps, rising to the rank of captain. From 1946 through 1949, he was a graduate student at Columbia University and a research associate at the Cowles Commission for Research in Economics at the University of

Chicago. In 1949, he began teaching economics and statistics at Stanford University, where he eventually achieved the rank of professor. In 1968, Arrow left Stanford to become a professor of economics at Harvard University. He remained at Harvard until 1979. That year, he returned to Stanford University and remained there until 1991, when he retired and became professor emeritus.

Arrow is the recipient of numerous awards and honors. He received the John Bates Clark Medal of the American Economic Association. He is an elected member of the National Academy of Sciences and the American Philosophical Society. Arrow was also a fellow of the American Academy of Arts and Sciences, the Economic Society, the Institute of Mathematical Statistics, and the American Statistical Association. He was the president of the Econometric Society, the Institute of Management Sciences, and the American Economic Association. He holds honorary degrees from the University of Chicago, the City University of New York, and the University of Vienna.

Arrow's broad research interests include the economics of information and organization, collective decision making, general equilibrium theory, and environment and growth. His major contribution in the field of economics was his work in social choice theory, particularly his impossibility theorem. Arrow also pioneered research in endogenous growth and information economics, which explained the source of technical change and why firms innovate. And his research on information economics investigated the problems caused by asymmetric information in various markets.

ASSOCIATION FOR THE ACCREDITATION OF HUMAN RESEARCH PROTECTION PROGRAMS (AAHRPP)

The Association for the Accreditation of Human Research Protection Programs (AAHRPP) is a nonprofit association, based in Washington, D.C., that works with organizations that conduct human research to raise the level of protection for research participants. The association accredits organizations that can demonstrate that they provide participant safeguards that surpass the threshold of federal requirements. Its accreditation program uses a voluntary, peer-driven, educational model that includes site visits and a set of performance standards and outcome measures.

History

The AAHRPP was founded in 2001 by seven nonprofit organizations with an interest in human research protection. The founding members were the Association of American Medical Colleges (AAMC), Association of American Universities (AAU), Consortium of Social Science Associations (COSSA), Federation of American Societies for

Experimental Biology (FASEB), National Association of State Universities and Land-Grant Colleges (NASULGC), National Health Council (NHC), and the Public Responsibility in Medicine and Research (PRIM&R).

In 2005, AAHRPP was awarded a federal 5-year contract by the U.S. Department of Veteran Affairs (VA) for the accreditation of all the VA's Human Research Protection Programs. During the course of the contract, AAHRPP will administer its accreditation program to all 120 VA facilities. In 2006, AAHRPP accredited its first international medical center, the Samsung Medical Center, in Seoul, Republic of Korea. In 2007, AAHRPP accredited a total of 47 organizations, which included both major universities and VA facilities.

Mission

Responding to increased public concern for protecting human research participants, AAHRPP seeks not only to ensure compliance with existing regulations but also to raise the bar in human research protection by helping organizations reach performance standards that surpass the threshold of federal requirements. Accreditation by AAHRPP signifies that an organization is committed to the most comprehensive protections for research participants and the highest quality research. AAHRPP works to protect the rights and welfare of research participants and promote scientifically meritorious and ethically sound research by fostering and advancing the professional and ethical conduct of persons and organizations that engage in research with human participants.

Eligibility for Accreditation

AAHRPP accredits any eligible organization that seeks accreditation. Most organizations that conduct human research are also involved in other activities that are not directly related to their research activities: Universities are involved in teaching and service, hospitals are involved in patient care and community outreach, and companies are involved in marketing and distribution activities. AAHRPP only accredits an organization's human research protection program.

Accreditation Process

AAHRPP's accreditation process uses a set of objective standards to evaluate the quality and level of protection that an organization provides research participants. The accreditation process consists of four steps: (1) application preparation—the organization conducts a self-assessment to evaluate its program and makes improvements; (2) on-site evaluation—a team of experts review materials and performs an on-site evaluation visit; (3) council review—the AAHRPP's council on accreditation reviews the report, deliberates on the team's findings, and determines accreditation status; and (4) notification of accreditation status—the organization receives a report detailing its accreditation status.

Standards and Principles

The goal of AAHRPP's accreditation is to improve the systems that protect the rights and welfare of individuals who participate in research. In addition, accreditation can help communicate to the public the strength of an organization's commitment to the protection of human research participants. It will also improve the overall quality of research by consistently applying high standards and practices, raising the global benchmark for human research protection.

To help promote all these goals, AAHRPP has adopted nine principles for accreditation of human research protection program. These nine principles serve as the foundations for the content of the AAHRPP accreditation standards. The standards themselves are designed to help organizations consistently meet ethical principles and standards for protecting research participants, yet be flexible enough to account for the diverse institutional and cultural contexts in which research is conducted and reviewed. The nine principles are as follows: (1) protecting the rights and welfare of research participants must be an organization's first priority; (2) protecting research participants is the responsibility of everyone within an organization and is not limited to the institutional review board (IRB); (3) striving to exceed the federal requirements and continually seeking new safeguards for protecting research participants while advancing scientific progress must be integrated into an organization's

mission; (4) the standards for protecting participants in human research will be clear, specific, and applicable to research across the full range of settings (e.g., university-based biomedical, behavioral, and social science research, independent review boards, hospitals, government agencies, and others); (5) the standards will identify outcome measures that organizations can use to assess and demonstrate quality improvement over time; (6) the standards will be performance-based, using objective criteria and measurable outcomes to evaluate whether a human research protection program effectively implements the standards; (7) the accreditation process will provide a clear, understandable pathway to accreditation, along with equally clear pathways for appeal and the remediation of identified shortcomings; (8) the accreditation process will be educational, involving collegial discussion and constructive feedback; and (9) the accreditation process will be responsive to changes in federal regulations and to standards that will evolve based on what AAHRPP learns from accrediting organizations from research settings.

Domains and Standards

AAHRPP's approach to voluntary accreditation incorporates five domains of a highly developed human research protection program. The domains refer to different areas of responsibility that must be addressed. Meeting the requirements for all five domains is the responsibility of the organization seeking accreditation. Altogether, there are 20 AAHRPP standards within the five domains. Each standard is followed by one or more elements. The five domains are the following: (1) the organization—the entity that assumes responsibility for the human research protection program and applies for accreditation (i.e., an academic institution, clinic, hospital, managed-care organization, contract research organization, or corporate entity, such as a pharmaceutical or biotechnology company, or independent review board); (2) research review unit—the arrangements that the organization has made for an independent review of ethical and scientific aspects of each research protocol involving human participants (such activities are generally carried out by an IRB); (3) investigator—the

various arrangements that the organization has made for ensuring that individuals who plan to conduct research, whether as a principal investigator, coinvestigator, or other member of a research team, understand and fulfill their responsibilities; (4) sponsored research—the organization’s arrangement for structuring its relationships with those who fund or initiate research external to the organization, such as federal agencies, foundations, individual donors, and corporations (e.g., pharmaceutical or biotechnology companies); and (5) participant outreach—the arrangements the organization has made for understanding the social, psychological, and physical needs and concerns of research participants and their communities.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES (AAMC)

The Association of American Medical Colleges (AAMC) is a nonprofit organization that seeks to improve the nation’s health by enhancing the effectiveness of academic medicine in three mission areas: (1) medical education, (2) medical research, and (3) patient care. In the pursuit of its mission, the AAMC serves the organizations that constitute the medical education system—medical schools, teaching hospitals, and academic and professional societies—and the individuals in this system—medical school faculty, medical students, and medical residents.

History

The AAMC was initially formed in 1876 as the Provisional Association of Medical Colleges, and its broad mission was to “consider all matters relating to reform in medical college work.” That it was formed in the late 1800s is a reflection of the tremendous changes occurring at this time in higher education in general and medical education in particular. The nation’s leading medical schools were advocating and implementing higher standards in medical education such as a longer academic year, more years of training, more stringent entry and graduation requirements, and more intensive training in the biological sciences.

As the nation’s medical education system has evolved, so too has the AAMC. At its inception in 1876, the Provisional Association of Medical Colleges represented only 22 of the nation’s medical schools. Today, the AAMC represents not only 125 U.S. and 17 Canadian medical schools but also 400 teaching hospitals (including 98 related health systems and 68 U.S. Department of Veterans Affairs’ [VA] medical centers), 94 professional societies to which approximately 109,000 medical faculty belong, and 171,000 medical students and residents.

Size and Structure

The AAMC is located in Washington, D.C., and employs nearly 400 individuals. Its mission and service role are clearly reflected in its organization.

About half of the AAMC's staff is concentrated in five offices that support and service the organization's specific program areas, the public, and its members. The other half of the AAMC's staff is concentrated in six divisions that reflect its mission or program areas. These divisions focus on diversity policy and programs, healthcare affairs, biomedical and health science research, medical education, medical school affairs, and medical school services and studies. The medical education division leads the AAMC's efforts to improve the quality, content, and conduct of medical education programs. The medical school affairs division offers faculty and administrators professional development programs and services and supports medical schools in the areas of admissions, academic progress and promotion, and financial aid. The medical school services and studies division manages the AAMC's medical school admission and application services and supports the residency match process.

The AAMC also maintains three specialized units. Two units have recently been established to highlight high-priority mission areas and stimulate development and support of innovations in these areas. One unit focuses on innovations with respect to improving clinical care, while the other focuses on innovations for improving medical education. The third unit is the Center for Workforce Studies, which develops data resources and collaborates on the research necessary to understand and inform decision making related to physician workforce issues.

Member groups or councils represent the various groups served by the AAMC within its organizational structure. Each group meets regularly and works with the AAMC to identify issues, develop policies, and plan programs within its own area of expertise and interest. Three of these member groups are governing councils: (1) the Council of Deans, (2) the Council of Teaching Hospitals and Health Systems, and (3) the Council of Academic Societies. These three councils, along with the Organization of Student Representatives and the Organization of Resident Representatives, elect

representatives to the Executive Council, which is the AAMC's 30-member governing body.

Products and Activities

The AAMC administers and/or supports a wide range of programs and activities related to its mission areas of medical education, medical research, and patient care. For example, the AAMC offers professional development programs, advocates for legislation critical to its mission, sponsors a loan program for medical students and residents, and publishes more than 100 books, statistical reports, documents, and periodicals. A common thread that runs through all the efforts of AAMCs is an emphasis on research, data collection, analysis, and reporting.

Since a major focus of the AAMC is facilitating and monitoring the medical education process, many of its products involve some aspect of the process. The AAMC helps staff the Liaison Committee on Medical Education (LCME), which accredits medical schools leading to the MD degree, and publishes descriptions and the admission requirements of each medical school in the book *Medical School Admission Requirements*. The AAMC administers the test required for admission to medical school called the Medical College Admission Test, or MCAT®. First-year applications to medical school are funneled through a centralized application service called the American Medical College Application Service or AMCAS® that the AAMC helps administer. As medical students graduate, the AAMC administers the Medical School Graduation Questionnaire, which asks students about their medical school experiences; the data are compiled and made available to medical schools, researchers, and others. The AAMC provides services to the National Residency Matching Program (NRMP), the organization that matches medical school graduates to residency programs. The AAMC manages the Electronic Residency Application Service, or ERAS®, that transmits documents such as applications and letters of recommendation to residency and fellowship programs. In cooperation with the American Medical Association (AMA), the AAMC conducts the National Graduate Medical Education Census, which obtains information on residency program characteristics and rosters of residents.

Future Implications

At its inception more than 130 years ago as the Provisional Association of Medical Colleges, the AAMC focused simply on medical education. Today, the AAMC has broadened its focus to address complex political, social, and economic issues that affect the ability of physicians to provide quality medical care. Specifically, the AAMC has identified seven issues that have already spurred the development of several initiatives and will guide its future programming. The issues are (a) improving racial and ethnic diversity within the nation's medical schools, and ultimately within the physician workforce; (b) addressing and solving the issue of Americans without health insurance, a burden shouldered disproportionately by academic medical centers; (c) maximizing medicine's readiness to respond to large-scale disasters that threaten the health of the public through developing and incorporating new curricula within the nation's medical schools; (d) ensuring patient-centered, quality healthcare; (e) securing sufficient numbers and the right types of physicians to meet the nation's future healthcare needs; (f) mitigating the impact of medical student debt on practice choices; and (g) assisting those medical schools, medical centers, and students affected by Hurricane Katrina.

ASSOCIATION OF UNIVERSITY PROGRAMS IN HEALTH ADMINISTRATION (AUPHA)

The Association of University Programs in Health Administration (AUPHA) is a global network of colleges, universities, faculty, individuals, and organizations dedicated to improving health outcomes by promoting excellence in healthcare management education. AUPHA fosters excellence and innovation in healthcare management education, research, and practice by providing opportunities for member programs to learn from each other, by influencing practice, and by promoting the value of healthcare management education. It is the only nonprofit entity of its kind that works to improve the delivery of health services—and thus the health of citizens—throughout the world by educating professional managers at the entry level.

AUPHA's membership includes baccalaureate and master's degree programs in health administration education in the United States and Canada. Its faculty and individual members represent more than 500 colleges and universities. In addition, a

large number of healthcare institutions, hospitals, and other health services delivery organizations and associations worldwide participate in, and benefit from, the network and services of the association.

History

AUPHA grew out of the efforts of the W. K. Kellogg Foundation to professionalize the management of hospitals following World War II. As the war wound down, the foundation identified the improvement of the hospitals in the United States and Canada as a priority for programming because the hospital sector had been neglected during the war years. The decision was influenced by the presence on the staff of Andrew Pattullo, who had come to the Kellogg Foundation from the University of Chicago program in hospital administration, and by the fact that Mr. Kellogg had been the administrator of the Battle Creek Sanitarium, an Adventist institution headed by his brother.

The founding programs in AUPHA were the University of Chicago, Northwestern University, Columbia University, University of Minnesota, University of Toronto, Washington University, and Yale University. In 1950, AUPHA was incorporated in Illinois as a not-for-profit organization.

The Kellogg Foundation was the moving force behind the development of the field from an advisory committee headed by Charles E. Prall in the late 1940s through the founding of AUPHA. Andrew Pattullo participated in all the early developments, including funding most of the programs. And some small grants to the association supported projects during the years 1949 to 1963.

From the outset, AUPHA set standards for admission to the association. The first set of standards included the requirement that programs granting master's degrees require students to have at least one academic year of courses (of which a third must be directly concerned with hospital administration) and a year of residency or equivalent experience, have two professionally qualified faculty members, and have a degree of autonomy in operations. These standards were modified many times over the years before the establishment of the quasi-independent Accrediting Commission on Graduate Education for Hospital Administration in 1966.

Over the years, healthcare administration education has changed, and AUPHA has changed along with it. From an original membership of seven graduate programs in the United States and Canada, it has grown to more than 160 graduate and undergraduate programs in North America and hundreds of personal, corporate, and affiliated program members all over the world. AUPHA is now an international consortium of graduate and undergraduate health administration programs and practitioners engaged in the development of health management education.

Yet many of the founding principles of the AUPHA remain the same. The association continues to provide forums for discussion where leaders from the field can gather to share information on educational methods and research. And it continues to serve as an effective advocate for the health administration education community before various legislative and executive bodies. Most important, AUPHA continues to focus on providing its members with the tools, research, venues, support, and forums that enable each program, as well as healthcare administration education as a whole, to evolve and thrive in a constantly changing industry.

Vision

AUPHA's vision is to improve health outcomes by promoting excellence and innovation in healthcare management education.

Mission

AUPHA fosters excellence and innovation in healthcare management education, research, and practice by providing opportunities for member programs to learn from each other, by influencing practice, and by promoting the value of healthcare management education.

Values

AUPHA supports five values:

1. *Excellence*: The Association believes that excellence in education (scholarship, teaching, and research) leads to excellence in healthcare practice and ultimately leads to improved healthcare outcomes.

2. *Innovation*: The Association promotes innovation, encourages the adoption of new strategies, and disseminates best practices in healthcare management education.
3. *Collaboration*: The Association collaborates in the generation and translation of research and the integration of theory and practice in interprofessional work environments.
4. *Diversity*: The Association believes that diversity—in people, in programs, and in perspectives—is essential for an effective interprofessional workforce.
5. *Learning*: The Association pursues continual learning to advance and share knowledge, to foster the development of pedagogy, and to improve teaching and practice.

Programs and Services

The Faculty Forums

The faculty forums foster communication and support collaborative activities that are of special importance to their members, as well as to the field of practice. Only current members can participate in these unique and active groups.

Web Site Resources

Program member faculty have access to a variety of curricular materials geared toward the topics of the faculty. The materials include case studies, class outlines, simulation programs, and class exercises and tests/assessments.

Prizes, Awards, Scholarships, and Fellowships

AUPHA provides and administers several prizes, awards, scholarships, and fellowships each year for faculty and students from member programs, such as the William B. Graham Prize for Health Services Research, the Triad Hospitals Corris Boyd Scholars Program, the Bugbee-Falk Book Award, the David A. Winston Health Policy Fellowship, the John D. Thompson Prize for Young

Investigators, and the Filerman Prize for Innovation in Health Services Management Education.

Publications

AUPHA publishes every 2 years the *Healthcare Management Education Directory of Programs*. This publication is a comprehensive listing of all AUPHA member healthcare management programs. It features information on baccalaureate, master's, doctoral, executive, and distance education programs, including admissions procedures and costs including tuition, room and board, fees, and books.

The AUPHA publishes quarterly the *Journal of Health Administration Education*. This peer-reviewed journal contains scholarly articles on various research topics, case studies, and essays by leading healthcare management and administration educators and professions.

The association also publishes the *AUPHA Exchange*, an electronic quarterly newsletter on various issues in healthcare management education, with a brief monthly supplement containing news from program members and a list of current employment opportunities.

Program Support

AUPHA staff and faculty provide program consultation regarding the membership process and the undergraduate certification process. Specialized consultation is also available on request. The Commission on Accreditation of Healthcare Management Education (CAHME) offers accreditation to qualified graduate academic programs.

Surveys and Data Collection

Members of AUPHA have access to various survey reports and data gathered by the association, such as the Annual Survey of Health Administration Programs, the Faculty Salary Survey, current Trend Data for Health Administration Education, and meeting presentations.

B

BENCHMARKING

Benchmarking in healthcare is an active process of continuously evaluating critical processes and/or clinical outcomes and comparing those results with similar organizations or populations. Benchmarking is a measure of best-practices performance. Based on benchmarking results, best practices can be identified and adopted, thus achieving superior performance. Benchmarking is useful in healthcare for both operational and clinical processes. This is particularly true in the clinical-practice environment, where providers are increasingly being held accountable by regulators and accreditation organizations for outcomes. Payers are also holding providers accountable for outcomes as part of pay-for-performance initiatives and value-based purchasing decisions.

Background

Benchmarking originated in industries outside of healthcare to improve product quality, service, delivery, and practices. Benchmarking has its historical roots in *kaizen*, or the Japanese philosophy of continuous improvement and competitive advantage. This technique can enable industries to achieve superior performance and practices by investigating and comparing their practices and outcomes with those of similar organizations. Benchmarking provides the opportunity to identify best practices for an industry and promotes

the adoption of universal standards that the organization and industry strive toward. A central part of benchmarking are the performance measures that establish the benchmark and the benchmark partners, which can be allies or competitor organizations against which comparisons are made. The core components of the benchmarking process include understanding one's own organizational performance, analyzing the performance and outcomes of competitors or sister organizations with superior performance, and implementing the practices that improve performance and outcomes. Benchmarking can instruct an organization about what can be achieved and how superior results can be attained.

Benchmarking can be useful for healthcare organizations to determine their core competencies and how they compare against their competitors. It can also be used to identify top performers relative to selected outcomes or care processes, determine where an organization is in relationship to those outcomes, and position it to understand how to improve its own care processes through identification and implementation of best practices to achieve better outcomes. Through the use of benchmarking, healthcare organizations can also gain a better understanding of their business performance, including its strengths and weaknesses. This process allows an organization to develop strategies that facilitate better management and performance improvement on a continual basis. Benchmarking can be used as a management tool to overcome paradigm blindness, or thinking that the way processes are currently done is the best.

Additionally, it can also lead to improved organizational effectiveness.

The concept of benchmarking has grown in healthcare since costs have been escalating and payers have been demanding that healthcare organizations deliver the highest quality of care for their money. In addition, the widespread use of performance measures by accrediting bodies such as the Joint Commission, the National Committee for Quality Assurance (NCQA), and governmental agencies including the Centers for Medicare and Medicaid Services (CMS) to monitor healthcare organization performance has allowed benchmarking to become more prevalent by allowing individual organizations to compare their performance and outcomes with similar organizations. This permits an organization to develop innovative strategies and techniques that will enable it to improve its performance. Benchmarking has become essential for healthcare organizations to survive in a competitive marketplace where performance and outcomes are measured. Thus, benchmarking allows organizations to learn from their competitors or sister organizations how to address similar issues that they are confronting.

Types of Benchmarking

There are several types of benchmarking that organizations may use to meet their needs. Strategic benchmarking focuses on the strategies of companies and involves a comparative analysis of the success and failures of these strategies. This can be achieved through customer satisfaction surveys. A limitation of strategic benchmarking is that it may be difficult to obtain strategy information on benchmarking partners.

Functional benchmarking is a tool used by companies to evaluate the success of core business functions. Although in functional benchmarking there does not need to be a focus on direct competition, the benchmark partner should be in a similarly characterized industry to allow for useful comparisons.

Another type of benchmarking is best-practices benchmarking. In this type of benchmarking, the work processes of an organization and the management processes behind them are examined.

Last, product benchmarking, or competitive product analysis, examines competitors' product

concept, costs, and alternative designs by analyzing the competitors' product.

Benchmarking in Healthcare

Benchmarking in healthcare typically involves comparing an organization's own data with a credible external source to facilitate decision making and informing the quality improvement process. Clinically, benchmarking is used to encourage providers to achieve a higher level of performance by changing and, as appropriate, standardizing practice patterns and to reduce resource utilization by identifying cost-effective treatment strategies. Additionally, managed-care organizations (MCOs) may use community health benchmarks to improve the overall care of a population. For example, MCOs may benchmark their performance of clinical population parameters, such as the performance indicators developed and employed by the NCQA related to obesity, vaccination status, and diabetes. Operationally, benchmarking is used to look at cost and efficiency parameters, such as length of stay, referral rates per 1,000 patients, cost per member per month, and costs of clinical ancillary departments. Furthermore, benchmarking is used for contracting purposes to help understand whether the assumptions underlying proposed contract rates are valid (e.g., cost per member per month, utilization data, cost data, severity scores). Regardless of the application, benchmarking has become an important tool for improving performance and to inform decision making.

The Benchmarking Process

Central to a successful benchmarking initiative is to clearly understand and articulate the goals of the project. Once established, four relatively standard phases are followed to execute the benchmarking project. The four phases are planning, data collection and analysis, integration, and action plan. The planning phase is the period that organizations use to set goals, identify what will be benchmarked, select the benchmarking partners or data source to benchmark performance against, and determine data collection methods. There are instances when an organization might choose to join a benchmarking initiative voluntarily or

because of the need to meet accreditation standards. An organization might belong to a group-purchasing organization, such as Premier, Inc. or the University HealthSystem Consortium (UHS), which have benchmarking databases and initiatives available to members. Alternatively, an organization might be part of an integrated health system that conducts benchmarking initiatives or participates in focused benchmarking initiatives, such as the National Anticoagulation and Benchmark Report (NABOR) initiative managed by EPI-Q, Inc. and funded through a pharmaceutical sponsorship. The goal setting and identification of benchmark partners are the most important components of this phase since the organization needs to establish what will be benchmarked and choose an appropriate partner or data source to make a realistic comparison.

In the data collection and analysis stage, the data are analyzed to identify competitive gaps or gaps between where practice should be and where it currently is for the participating organization. Expected performance levels are based on the top performers in the benchmark database. Future performance levels are then projected based on these gaps, and areas for improvement are identified. In some instances, a benchmarking initiative can identify gaps in national treatment patterns.

During the integration phase, the results from the analysis are communicated to the organization. The findings are also used to integrate the actions that will be taken as well as to compile objectives and goals for the organization.

In the action plan phase, the organization executes the action plan based on the recommendations. As the action plan is implemented, the organization must continue to monitor its performance, so that it reaches its optimal potential, and recalibrate the benchmarking measures as needed.

An example of the benchmarking process is the NABOR project, which identified a significant issue in the management of patients with thromboembolic disease who were at increased risk of developing stroke and hemorrhage. The NABOR benchmark database included 4,000 patients from 38 U.S. hospitals in which many practitioners believed that their institution's performance was at least average. The results of the benchmarking initiative revealed, however, that less than half of

the patients in this study received appropriate therapy that would mitigate the risk of experiencing a life-threatening event. Furthermore, even if patients received appropriate treatment for thromboembolism, the drug dosing delivered was either too low or too high, which increased the risk of experiencing a significant life-threatening event. The Steering Committee of the NABOR project, comprising leaders of national thought in the United States, communicated the results back to individual hospitals along with recommendations to be considered. The individual hospital project groups evaluated the recommendations and created an action plan for their respective institutions. In response to the recommendations, several hospitals in the NABOR project established anticoagulation clinics. And based on data from the NABOR benchmark database, those hospitals that did establish anticoagulation clinics were among the top performers.

Challenges for Benchmarking

There are many challenges that remain for organizations that use benchmarking. One of the challenges includes setting a benchmark that is both realistic and based on available and credible evidence. The intended benchmark should be feasible and practical, based on the organization's current performance in addition to the resources available for carrying out the action plan. Caution should also be used when evaluating data to ensure that a benchmark is in fact representative of best practices. It is possible that a benchmark database might have all the partners exhibiting average performance. If all organizations are striving toward "average" performance, it will make the participating organization also attempt to achieve only an average performance. Therefore, when an organization is evaluating whether to participate with partners or a vendor in a benchmarking initiative, it is important that the data reports on outcomes are at least in the upper quartile, if not the top decile, of performance.

Organizations may also face a difficulty in arriving at a consensus benchmark as clinicians and administrators may have different views on what is or is not an appropriate benchmark. Another challenge is to find a benchmarking partner that is appropriate and similar in nature for the organization to

compare itself against. It may be difficult, however, to find information that is publicly available on a competitor organization's strategies.

In conclusion, benchmarking has been used by organizations to outperform their competitors. This concept is starting to be routinely used by healthcare organizations to provide high-quality care under the increasing pressures of cost containment. In an increasingly competitive healthcare marketplace, benchmarking is a technique that will ensure the superior performance of healthcare organizations.

BERWICK, DONALD M.

Donald M. Berwick is a leading authority in the area of healthcare quality and quality improvement. Berwick cofounded and is president and chief executive officer of the Institute for Healthcare Improvement (IHI), a not-for-profit organization based in Cambridge, Massachusetts, dedicated to improving quality in healthcare that was formed in 1991. Berwick is professor of health policy and management at the Harvard School of Public Health and clinical professor of pediatrics and healthcare policy at the Harvard Medical School. In addition, Berwick is an associate in pediatrics at Children's Hospital in Boston and a consultant in pediatrics at the Massachusetts General Hospital.

Berwick has published numerous articles in professional journals on the subjects of healthcare policy, decision analysis, technology assessment, and healthcare quality management. He also has authored or coauthored several books, including *Escape Fire: Designs for the Future of Health Care* (2004), *New Rules: Regulation, Markets and the Quality of American Health Care* (1996), and *Curing Health Care: New Strategies for Quality Improvement* (1990). And he is a member of several editorial boards, including the *Journal of the American Medical Association*.

Throughout his long and illustrious career, Berwick has served as the chair of various national committees, including the Health Services Research Review Study Section of the Agency for Health Care Policy and Research from 1995 to 1999 and the National Advisory Council of the Agency for Healthcare Research and Quality (AHRQ) from 1999 through 2001. From 1990 to 1996, Berwick served as the vice chair of the U.S. Preventive Services Task Force and

was the first “Independent Member” of the Board of Trustees of the American Hospital Association (AHA) from 1996 through 1999. Berwick cofounded and was a co-principal investigator for the National Demonstration Project on Quality Improvement in Health Care. Berwick is a past president of the International Society for Medical Decision Making and is an elected member of the national Institute of Medicine (IOM). He has served on the IOM’s governing council and has acted as a liaison to the IOM’s Global Health Board since 2002.

In 1997, President Clinton appointed Berwick to the Advisory Commission on Consumer Protection and Quality in the Healthcare Industry. This commission was cochaired by the Secretaries of Health and Human Services and Labor and it was given the responsibility to gain a better understanding of the issues facing the changing healthcare delivery system and build consensus on ways to ensure and improve healthcare quality.

Berwick is the recipient of numerous awards, including the Earnest A. Codman Award, the first Alfred I. DuPont award for excellence in children’s healthcare from Nemours, the Award of Honor from the AHA for outstanding leadership for improving healthcare quality, the Heinz Award for public policy, the Purpose Prize, and the William B. Graham Prize for Health Services Research. In 2004, Berwick was inducted as a fellow of the Royal College of Physicians in London. The following year, he was appointed as honorary Knight Commander of the Most Excellent Order of the British Empire.

Berwick received his bachelor’s degree from Harvard College, a master of public policy degree from Harvard’s John F. Kennedy School of Government, and a doctor of medicine degree from Harvard Medical School.

BIOTERRORISM

Bioterrorism is the intentional release of biological agents used to cause casualties to a population. Bioterrorism can also be directed to livestock, food, and the environment. The intrinsic features necessary for a bioterror agent include infectivity, virulence, toxicity, pathogenicity, incubation period, transmissibility, stability, and lethality. As of 2008, nine nations in the world are believed to have the capability for biologic warfare agent production: Iran, Israel, North Korea, China, Libya, Syria, Taiwan, Russia, and the United States.

Classification of Diseases/Agents

The Centers for Disease Control and Prevention (CDC) classifies particular bioterrorism diseases/agents into one of three categories: A, B, and C.

Category A diseases/agents are considered high priority due to their ability to be transmitted easily from person to person, which can result in high mortality rates. Public panic and social disruption may ensue, so special action for public health preparedness is necessary. This category includes anthrax (*Bacillus anthracis*), botulism (*Clostridium*

botulinum toxin), plague (*Yersinia pestis*), smallpox (variola major), tularemia (*Francisella tularensis*), and the viral hemorrhagic fevers (filoviruses and arena viruses). Except for botulism, these illnesses usually present initially as a flu-like illness with low-grade fever and fatigue.

Category B includes the second level of high-priority diseases/agents, with moderate dissemination and morbidity rates and relatively low mortality rates. These agents require specific CDC enhancements of diagnostic capability and disease surveillance. This category includes brucellosis (*Brucella* species); epsilon toxin (*Clostridium perfringens*); and food and water safety threats such as *Salmonella*, *Shigella*, vitrio cholera, glanders (*Burkholderia mallei*), melioidosis (*Burkholderia pseudomallei*), Q fever (*Coxiella burnetii*), ricin toxin from castor beans, staphylococcal enterotoxin B (as an incapacitating agent), typhus fever (*Rickettsia prowazekii*), and viral encephalitis (alpha viruses).

Category C includes diseases/agents that are emerging pathogens that can be engineered for mass dissemination in the future due to availability, ease of production, and potential for high morbidity and mortality. Examples include the napah virus and hantavirus.

Responsible Agencies

The public health infrastructure is the central component to monitor exposure to bioterrorism diseases/agents, identify the specific action required to prevent primary and secondary exposure, provide containment measures, and respond with necessary medical supplies. The basic premise of the National Response Plan (NRP, Version 4.0) developed by the U.S. Department of Homeland Security is that such incidences are handled at the lowest jurisdictional level possible.

Four federal agencies will likely be involved in any response to bioterrorism in the country: (1) U.S. Department of Homeland Security (DHS), (2) U.S. Department of Health and Human Services (HHS), (3) U.S. Department of Defense (DoD), and (4) U.S. Department of Veterans Affairs (VA).

Founded in 2002, the DHS contains four important programs: (1) National Disaster Medical System, (2) Strategic National Stockpile, (3) Metropolitan

Medical Response System, and (4) Federal Emergency Management Agency (FEMA).

The HHS encompasses more than 300 programs, including the following: CDC; Food and Drug Administration (FDA), Health Resources and Services Administration (HRSA), and the National Institutes of Health (NIH).

The DoD is the support agency for almost all the emergency functions of the NRP, under the Military Support to Civil Authorities (MSCA) doctrine. The MSCA is operationally directed through the U.S. Northern Command in Colorado Springs, Colorado.

Last, the VA through its hospital and clinic network will also play a support role.

The anthrax attacks in 2001 have demonstrated the need for a coordinated approach to identify and deliver antibiotics through the public health system. Subsequent to the attacks 33,000 individuals were initially placed on antibiotics, with about 10,000 individuals completing a 60-day course of antibiotics. The U.S. Army Medical Research Institute for Infectious Diseases (USAMRIID) performed approximately 19,000 anthrax surveys from clinical specimens. The cost to decontaminate the Hart Senate Office Building was estimated to have exceeded \$23 million. This was a secondary cost from attacks that involved only 22 cases.

Response Approaches

A comprehensive approach to biologic exposure would include incident command if a point source is identified, decontamination, quarantine, personal protection, diagnostic testing, vaccination, and antibiotic treatment.

Incident Command

When a specific source is identified, the incident command team is usually positioned uphill, upwind, or upriver from the site, and it should not be located near any building exhaust system. An isolation distance of at least 80 feet is recommended. First responders should handle the site of such an incident as a potential crime scene and should also be aware of explosive devices that could be used to disseminate the substances. First responders should also avoid wet surfaces or puddles.

Decontamination

In general, a biological attack is less likely to occur than a radiological or chemical terrorist attack. Because of the incubation period associated with a biological attack, patients will likely seek medical attention in waves from their primary-care physicians, in clinics, or in hospital emergency departments. Thus, decontamination procedures are less likely to be an issue.

Regarding specific decontamination issues, the focus is usually on contaminated environmental surfaces. Following the aerosolization of biological agents, rapid-assay kits should be used to identify contaminated surfaces, although false-positive results are common.

Plague is sensitive to heat and light and will not survive for a period of time outside the individual host. Botulinum toxin is destroyed by heating liquid or food to a temperature of 85 °C (185 °F) for at least 5 minutes. Through aerosolization, botulinum toxin usually becomes detoxified in the atmosphere within 2 days. Tularemia survives in cold, moist environments. Decontamination of environmental surfaces can be achieved by washing with a 10% bleach solution, then using a 70% concentration of rubbing alcohol after 10 minutes to wash away the bleach.

With regard to the hemorrhagic fever (yellow fever) virus, contamination linens should be placed in double bags and washed in hot water with bleach or autoclaved. Incineration is also an option. Equipment should be cleaned with a disinfectant or a 1:100 dilution of household bleach. It is not expected that the virus can persist for prolonged periods in the environment.

Chlorination or boiling of contaminated water is effective in eradicating cholera or tularemia. Smallpox does not survive for longer than 1 hour in the environment. Standard bleach or quaternary ammonia compounds can be used to clean environmental surfaces.

Quarantine

The term *quarantine* refers to the compulsory physical separation of individuals. It may involve movement restriction and/or segregation of individuals into specific geographical areas to halt the spread of a contagious disease. Such efforts may

include travel restrictions, public-gathering restrictions, and isolation of affected individuals. The federal government has the authority to impose these restrictions across state lines through the CDC. The DoD and FEMA may also assist in this effort.

Using quarantine, especially with patient isolation, must be considered for smallpox, plague, and viral hemorrhagic fever. With regard to quarantine for smallpox exposure, isolation of individual contacts, especially any person with a fever of more than 38 °C (100.4 °F) for a 17-day period, should be considered. The decision to quarantine is based on vaccination status, risk of exposure, and risk of disease.

Quarantine should be considered for livestock with Q fever or glanders, but it would be unlikely to infect humans. Quarantine is not necessary for anthrax, botulism, tularemia, brucellosis, cholera, *Cryptosporidium parfringens*, *Escherichia coli* (0157:H7), melioidosis, psittacosis, ricin, salmonella, shigella, straphylococcus, enteroroxin B, and typhus.

Personal Protection

With the biological agents that do not exhibit human transmission (i.e., anthrax, botulism, tularemia, brucellosis), standard precautions are appropriate. In addition to standard precautions, healthcare workers should wear a surgical mask if within 4 feet of a patient with plague (treated for less than 2 days). Airborne and contact precautions should be used for smallpox and viral hemorrhagic fever. Antibiotic contact prophylaxis should be considered for workers exposed to patients with plague, glanders, and melioidosis.

Essentially, personal exposures should be investigated in case of unprotected contact within 4 feet of vital exposures, breaches in protection, or febrile (more than 100.4 °F or 38 °C) illness in individuals occurring within 3 weeks of exposure.

Smallpox and viral hemorrhagic fever patients should be placed in private rooms with negative air pressure (6–12 air exchanges per hour) and dedicated medical equipment. Personnel should wear N-95 respirators, double gloves, impermeable gowns, goggles or face shields, and shoe covers.

Diagnostic Testing

Bacterial agents can usually be identified through traditional culture techniques and colony identification. Direct fluorescent antibody (DFA) techniques on capsule antigens are also a useful modality, especially when identifying bacterium in tissues. Polymerase chain reaction (PCR) can be used to detect and amplify genetic material from bacteria and is useful in identifying subtypes of organisms.

The Laboratory Response Network (LRN) was organized in 1999 and involves more than 150 clinical, military, veterinary, agricultural, and water and food testing facilities; it is coordinated through the CDC. It also has laboratories in Canada, the United Kingdom, and Australia. The purpose of the LRN is to rapidly identify threat agents and to conduct definitive testing for these agents. LRN laboratories are designated as sentinel (hospital-based laboratories), reference (to confirm the initial results), and national (designed to handle highly infectious agents and identify specific strains).

Viral testing can be complicated. For example, smallpox can be detected via dermatologic (vesicular) specimens obtained through barrier precautions by scraping the base of a vesicle or by obtaining a 4-mm dermal punch biopsy. Viral detection can be achieved via electron microscopy or with PCR technology. Serum analysis can be used to detect smallpox or viral hemorrhagic fever. The latter agent should be referred to the CDC or the USAMRIID.

Biological toxin identification also presents its own unique challenges. The mouse bioassay, using 30 ml of serum or gastrointestinal contents from the patient, is the primary modality to identify botulism toxin. Disease is usually evident within 24 hours. Electromyography (EMG) is the primary clinical modality in diagnosing botulism with its characteristic findings (repetitive nerve stimulation) at 20 to 30 Hz: short duration of motor unit potentials, polyphasic motor unit potentials, decreased amplitude of compound muscle action potentials of proximal muscle groups following a single nerve stimulus, and normal sensory and nerve conduction velocity. The CDC is currently developing a urinary ricin assay to be used with the LRN.

Vaccination

Vaccines, in various stages of testing, have been developed for anthrax, plague, smallpox, tularemia, hemorrhagic fever, cholera, Q fever, and typhus. The FDA licenses the vaccines for anthrax, hemorrhagic fever, Japanese B encephalitis, smallpox, and the plague.

The anthrax vaccine is a series of six doses. Used since 1997 by the U.S. military, the anthrax vaccine has been developed from a cell-free filtrate of the nonencapsulated attenuated strain of the bacterium. Systemic events (headache, fever, vomiting) occur in about 1% of individuals (women are at a greater risk than men), while the local reaction rate is about 3.6%.

The smallpox vaccination was routinely given to infants under the age of 1. It is estimated that about 50% of the U.S. population has not received the vaccine. It is thought that the duration of immunity is about 10 years, although neutralizing antibodies can be detected for up to 30 years.

Primary smallpox vaccination (preventive) that uses a bifurcated needle has been advocated for military and healthcare personnel. The military experience noted a rate of 82 per million vaccinated for generalized vaccinia. There were also 37 cases of myopericarditis (of 450,000 vaccinated), with recovery in all individuals. Encephalitis occurs at a rate of 1 in 300,000. Severe adverse reactions can be treated with vaccine immune globulin (VIG), with an intramuscular dose of 0.6 ml/kg.

Postexposure vaccination for smallpox may offer some protection if given within 4 days of exposure. Persons identified as being at risk (face-to-face contact with a household member or within 6.5 feet of a suspected case) should be considered for vaccination. The CDC is the sole distributor for the vaccine and VIG.

For hemorrhagic fever virus, the yellow fever live attenuated vaccine has limited usefulness due to the long period before an immune response develops (which can take up to 10 days), limited supplies, and an adverse-effect profile.

A live attenuated vaccine for tularemia is being developed, but as in the yellow fever vaccine, the long period for neutralizing antibody development (2 weeks) makes this vaccine less useful for postexposure prophylaxis.

The vaccines for Q fever, cholera, and botulism (using pentavalent antitoxin) are in various stages of development, as are the vaccines for viral encephalitis, Rift Valley fever, chikungunya fever, and Junin virus.

Antibiotic Treatment

Antibiotics are the mainstay of therapy for biological agents that are related to bacterial infection. For most of these agents (i.e., anthrax, plague, psittarosis, tularemia, cholera), a combination of a fluoroquinolone and doxycycline is the medical treatment of choice. Antibiotics are not useful therapy for botulism, ricin, or any viral agent.

Future Implications

In the event of a bioterrorism attack, patients exposed to the agents are likely to have subtle symptoms presenting in outpatient clinics. These patients, however, are likely to occur in large numbers, and thus healthcare facilities will need to follow the basics of emergency preparedness in order to deal with the entity.

BLUE CROSS AND BLUE SHIELD

The Blue Cross and Blue Shield brands are the most recognized health insurance brands in the country. The Blue Cross plans provide health insurance coverage for hospital services, while the Blue Shield plans provide coverage for physician services. There are currently 39 Blue Cross and Blue Shield companies in the United States, which collectively employ more than 150,000 individuals nationwide. Nearly 65.8 million members are enrolled in preferred provider organizations (PPOs), 12.9 million in fee-for-service plans, 15.8 million in health maintenance organizations (HMOs), and 4.8 million in point-of-service (POS) products. The Blue Cross and Blue Shield companies boast that they collectively insure one out of every three Americans. If all the Blue Cross and Blue Shield plans were one company rather than 39 confederated companies, it would be one of the top 20 employers in the nation. The plans have contracts with 90% of all U.S. hospitals and 80% of physicians. In recent years, the companies have been in the spotlight as they pursue business interests that some say contradict their history as nonprofit firms with a community-benefits tradition.

History

The original Blue Cross company was an outgrowth of the Baylor Plan, a nonprofit health insurance plan established in Houston, Texas, in 1929 by Francis Ford Kimball to provide coverage for teachers through a prepayment plan of 50 cents a month. The Houston plan was the forerunner of the Blue Cross plans that provided hospital services. The Blue Cross name and symbol were created in 1934 by E. A. van Steenwyk from St. Paul, Minnesota's group health plan. Blue Cross's former Chicago headquarters was housed in the American Hospital Association (AHA) building.

Blue Cross plans later developed in New York, New Jersey, and California. By 1935, there were 15 plans in 11 states. The number of Blue Cross plans had grown from 56 to 80 between 1940 and 1945, and enrollment increased from 6 million to 19 million.

During this period, a comparable plan to cover physician services was also established in the states of Washington and California. From these physician plans, the medical societies around the nation began to develop prepaid insurance programs that covered physician services. In 1946, a number of plans banded into a national group called the Associated Medical Care Plans, overseen by the American Medical Association (AMA), and informally adopted the Blue Shield as its symbol. This organization eventually became the Blue Shield Association (BSA). The Blue Shield plans that provided physician services had an early enrollment of 3 million. In the 1960s, there were 148 Blue Cross and Blue Shield plans in the United States; some providing hospital insurance under the Blue Cross plans and others providing physician coverage under the Blue Shield plans.

In 1961, Walter J. McNerney (1925–2005), who was recruited by the Michigan Blue Cross plan from the University of Michigan to examine the hospital and medical care costs and insurance coverage in that state, became the president of the Blue Cross Association. The McNerney era was marked by numerous changes in the nation's healthcare system, including the development of the federal Medicare and Medicaid programs in 1965, utilization and case management initiatives, the collaboration of plans to offer national products, preadmission testing programs, and

HMO sponsorship. McNerney was instrumental in moving the Blue Cross plans away from the control of the AHA, an early sponsor of the hospital insurance concept, and the AMA, which managed the BSA. In 1972, the Blue Cross and Blue Shield companies formally separated from the AHA, which ushered in the tensions between the organizations.

McNerney was intent on merging the Blue Cross and the Blue Shield plans and ultimately undertook an extensive strategic planning initiative to examine the plans and seek cooperation of the plans across the nation. His stated goal was to limit the number of plans operating in the states. The plans were developed under three different organization types—stock, mutual, and nonprofit. These organization models continue to exist in 2008. The nonprofit plans were established with no individual or organizational entity with an ownership interest, and control rested with the board of directors. The stock companies are those in which the financial ownership consists of capital stock, which is divided into shares, and control rests with stockholders. Mutual companies are corporations without capital stock; ultimate control is with policyholders. Although there has been considerable debate in recent years about the ownership type of the company, the ownership of the plans is transparent to its members.

During the 1980s, hospital cost escalation was considerable. As a result, President Jimmy Carter attempted to introduce cost controls by legislating caps on health spending. The Carter administration desired to limit annual hospital cost increases and capital spending as well as physician reimbursement under Medicare and Medicaid. The reception to these proposals was lukewarm. While the voluntary effort to control healthcare costs was introduced, there was little done to implement healthcare change. When Ronald Reagan was elected president in 1982, a procompetitive, anti-regulatory strategy toward controlling healthcare costs was introduced. The HMO model took hold, with its prospective payment that rewarded providers for minimizing costs. Alain Enthoven, a Stanford economist and consultant to the Reagan administration, introduced the consumer choice philosophy, which advocated cost-efficient benefit programs. With the consolidation of the Blue Cross and Blue Shield plans, the development of

the Blue Cross Blue Shield Association (BCBSA), and the move to interplan collaboration for the benefit of the plan members, new HMO products were introduced with the stated benefit of controlling healthcare utilization and costs.

Blue Cross and Blue Shield continued to collaborate with federal and state governments in providing healthcare benefits. The BCBSA was instrumental in advocating for the benefit management of the federal Medicare and state Medicaid products along with HMO and indemnity products. It became a major benefits manager for the federal government when the Federal Employee Health Benefits Plan was introduced in 1960 to provide coverage for 9 million federal employees and their dependents, including members of the U.S. Congress.

Conversion From Nonprofit to For-Profit Status

In 1994, BCBSA voted to change its charter to allow for-profit conversions of plans if the plans met specific guidelines. These included safeguards such as control of branded subsidiaries by the parent plans, accreditation for managed-care companies, codes of conduct for officers, rules for disclosure of records, agreement to mandatory dispute resolution, and financial standards and guarantees. Blue Cross Blue Shield of California was the first conversion, and it changed its name to Wellpoint. Since 1994, 14 of the 42 state BCBS plans in the United States have changed their tax status from nonprofit to for-profit. The stated rationale for conversion of tax status is to raise capital to better compete with commercial insurance companies, such as Aetna, Cigna, and the UnitedHealth Group.

In 1994, as the first plan to convert, Blue Cross of California received minimal public scrutiny. The denial of Blue Cross and Blue Shield of Maryland's for-profit conversion by the State Insurance Commissioner in March 2003, followed by the Kansas Supreme Court blocking the acquisition of the Blue Cross plan by the for-profit Anthem and the subsequent retractions of the New Jersey and North Carolina Blue Cross and Blue Shield plans of their proposed conversion initiatives have raised the visibility of the conversion phenomenon. As the numbers of plan

conversions increased to include California, Colorado, Connecticut, Georgia, Indiana, Kentucky, Maine, Missouri, Nevada, New Hampshire, New York City, Ohio, Virginia, and Wisconsin, the public is raising questions about the consequences of such conversions. From 1990 to 1993, Blue Cross and Blue Shield plans in Maryland, New Jersey, New York, West Virginia, and Washington, D.C., encountered a series of U.S. Senate investigations into their financial management practices. In response to these investigations, the BCBSA developed a code of conduct to guide plan entrepreneurship.

As the U.S. economy changed, large multistate clients wanted an extensive network of providers, affordable products, efficient customer service, and limited intrusion by the insurer into medical management. Blue Cross Blue Shield's competitors provided such an alternative with their products and services. Blue Cross responded in kind to these competitor threats by investing extensively in information and billing systems, cultivating excellent provider relations, and introducing preferred provider product offerings with limited medical management. The BCBSA's introduction of the Blue Card benefit in 1994 that allowed interplan use of services by members was an initiative to provide a rational system of services as members moved between states and traveled outside the continental United States.

Health Insurance Consolidations

The U.S. healthcare environment changed dramatically between 1980 and 2002 for health insurance companies and hospitals. Large multistate insurance companies providing health insurance coverage in conjunction with financial, casualty, and life insurance had become the norm. It quickly became apparent that healthcare required a different type of insurance, leading companies to divest or expand into health insurance. For example, MetraHealth was formed in 1995 through the combination of the group healthcare business of Metropolitan Life Insurance Company and the Travelers Insurance Company. MetraHealth served millions of Americans with its healthcare plans, and it operated in all 50 states. The company's managed-care networks included 29 HMO licenses, 72 point-of-service

networks, and PPOs managed in more than 90 markets nationwide. In addition to its full range of both managed care and indemnity plans, the company offered managed behavioral health, managed pharmacy, data analysis, demand management, managed workers' compensation, and third-party administrator services. In 1995, UnitedHealth Group purchased MetraHealth, bringing the services of MetLife and Travelers under its umbrella.

In 1990, the Associated Insurance Companies of Indianapolis (the forerunner to Anthem Blue Cross and Blue Shield located in Indiana, which has grown to incorporate more Blue Cross plans under its umbrella) purchased the Dallas-based American General Insurance Company. This acquisition of a diversified insurance company that would compete with other Blue Cross and Blue Shield plans outside Indiana introduced plan competition and diversity in the Blue Cross and Blue Shield organization.

Between 1996 and 1998, Aetna Insurance Company acquired U.S. Healthcare, and then the healthcare divisions of The New York Life Insurance Company (NYLIC) and Prudential Insurance Company, making it the largest health insurance company in the nation, covering 21 million lives. Aetna, as the largest health insurer, expanded into healthcare and eliminated unprofitable lines of business. Aetna's management decided that it could no longer be the "department store of insurance." Smaller specialty firms that possessed greater levels of management focus and were quicker to adapt to market changes were undermining its role as a traditional multiline insurer trying to compete in all insurance markets. Aetna's decision in 1991 to exit individual health lines ended a 91-year-old coverage. In 1991, it exited the automobile and homeowners insurance markets, and in 1996, it left the property casualty market, based on market profitability and company expertise and resources.

As the largest health insurance company between 1998 and 2000, Aetna became the market leader. With its acquisitions U.S. Healthcare, Prudential, and NYLIC, providers were finding that the major part of their business was being dictated by one company that had previously been four separate companies. In 1999, the provider community started to revolt against the consolidation and

mergers in the health insurance industry, HMO capitation, and failure of insurers to adhere to prompt payment laws.

With the consolidation in the hospital and commercial insurance industries, the nonprofit Blue Cross plans began to respond to the competition presented by large national and regional insurance plans. The conversion phenomenon and BCBSA's development of a division to handle national accounts, The Blue Card, that crosses the jurisdictional boundaries of state Blue Cross plans represented an internal management decision to respond to the changes in the hospital and insurance industries. The Blue Card initiative was an acknowledgment that multistate employers wanted to deal with a corporate entity that could resolve interstate insurance issues and did not want to negotiate between multiple Blue Cross plans. It also recognized that the Blue Cross and Blue Shield organization, regardless of its ownership or state boundaries, needed to provide a seamless system of care for its member companies and their employees. When the public viewed the Blue Cross plans, they saw one company, not 39 independent licensees of the BCBSA. Its commercial competition was investing tremendous resources into providing national services, and The Blue Card introduced a national product for the companies. In addition, the Blue Healthcare Bank was established in 2007 to provide healthcare-related banking in all 50 states of the nation. The bank services customers with high deductible health savings accounts (HSAs). The Blue Cross bank was a direct result of the commercial insurance giant UnitedHealth Group's Exante Bank acquisition.

The internecine warfare between the various Blue Cross plans appears to have settled down in 2008. Scott Serota, the president and CEO of the BCBSA, has quietly introduced new products with The Blue Card, pursued the collaboration with America's Health Insurance Plans (AHIP) to promote portability standards for patient information through the electronic health record, promoted the Patient-Centered Primary-Care Collaborative to secure primary-care medical homes for enrollees, and promoted Medicare E-prescribing. Once again, Blue Cross and Blue Shield is increasing its membership, innovating with new products and programs, and collaborating with other insurers to advance the insurance industry.

Future Implications

The Blue Cross and Blue Shield companies have undergone a dramatic change since the early founding of the company in 1929. The company has endured because of its early association with the hospital industry. The cost control movement, the organization's strategic plan, internal company reorganization, the procompetition movement, new product offerings, and the growth of the uninsured has fundamentally changed Blue Cross as it was originally envisioned. Nonetheless, the Blue Cross and Blue Shield companies remain a formidable brand and continue to dominate other insurers in their local markets.

BROOK, ROBERT H.

Robert H. Brook is an internationally recognized expert on quality assessment and quality assurance. Brook and his colleagues at the University of California, Los Angeles (UCLA) and the RAND Corporation are widely credited with developing pioneering methods for studying the appropriateness of medical care and measuring quality. Brook's seminal work on healthcare quality and health status measurement has led to the development of policies for improved health and quality. His research has also created the scientific basis for deciding if many different medical and surgical procedures are used appropriately.

Brook is professor of medicine and health services at the UCLA, where he directs the Robert Wood Johnson/UCLA Clinical Scholars Program. He is also vice president and director of the RAND Corporation's Health Sciences Program.

Brook received his bachelor of science degree from the University of Arizona. He went on to receive a medical degree from Johns Hopkins Medical School and a doctorate of science degree from Johns Hopkins School of Hygiene and Public Health.

Since 1974, Brook has served on the faculty of the UCLA. Over the course of more than 30 years at that university, he has trained many healthcare industry leaders. As the director of the Robert Wood Johnson Clinical Scholars Program, he has been pivotally involved in training physicians to take an active role in policy and to focus on healthcare at the community level.

Brook's contributions have been recognized with a number of awards and honors, including the Baxter Foundation Prize for excellence in health services research, the Institute of Medicine's Lienhard Award, the Rosenthal Foundation Award of the American Association of Physicians, the Peter Reizenstein Prize, the Distinguished Health Services Research Award of the Association of Health Services Research, the Robert J. Glaser Award of the Society of General Internal Medicine, the National Committee for Quality Assurance (NCQA) Health Quality Award for the pursuit of healthcare quality at all levels of the health system and research, and America's 2000 Advocacy Award for Sustained Leadership at the National Level. Brook

also was selected as one of the 75 Heroes of Public Health by Johns Hopkins University in 1991. He is a member of the National Academy of Sciences, Institute of Medicine (IOM); the American Society for Clinical Investigation; the American Association of Physicians; and the Board of Overseers at the University of California Davis Medical School.

Brook has published nearly 300 medical articles throughout his career. As a board-certified internist, he has conducted revolutionary work in the field of quality measurement that has led to the development of measurement tools used by the government, physicians, and other groups. Brook has focused specific attention on developing health status and quality measures for vulnerable populations, including the elderly, HIV-positive individuals, and special-needs children.

Recently, Brook was appointed the chair of a panel on coronary artery bypass graft surgical outcomes that will advise California's Office of Statewide Health Planning. Brook has dedicated his career to improving the effectiveness and efficiency of the healthcare delivery system, and his work has transformed the way in which healthcare quality is evaluated. Because of Brook's substantial contributions in this field, policymakers have incorporated his research findings into national healthcare policy standards.

BROOKINGS INSTITUTION

The Brookings Institution is one of the nation's oldest research and policy organizations dedicated to questions of governance and the economy. Although the Brookings Institution is now only one of the many Washington think tanks, its long history of influence and volume of research output ensure that it remains a prominent one. While healthcare issues have not historically been its chief focus, the relationship of health to economics is an emerging research interest, and the Brookings Institution has immersed itself in the debates surrounding healthcare and national spending priorities.

History

The Brookings Institution was formed in 1927 by the merger of the Institute for Governmental Research and the Carnegie Corporation's Institute of Economics, two small research and policy organizations. These two predecessor organizations were formed to provide the federal government with statistics and research aimed at meeting administrative and budget policy needs arising from the growth of government in the early 20th century and U.S. involvement in World War I.

A third institution, the Brookings Graduate School, was also involved in the merger. The school was founded in 1922 as an independent institution by Robert S. Brookings (1850–1932), a

businessman, philanthropist, and governmental reformer. Brookings was a friend of the American industrialist Andrew Carnegie (1835–1919) and played a leading role in improving Washington University's School of Medicine, which, as a result, was described in positive terms in Abraham Flexner's 1910 report on the state of medical education in the United States. Brookings shared Carnegie's interest in questions of public policy and governance and had founded his school to contribute to the education of students interested in serving in the government.

The new institute, headquartered in Washington, D.C., and, in its original location, close to the White House, was to serve as a source of professional and nonpartisan research and advice to the federal government. The Institution's first president was the economist Harold G. Moulton.

The Great Depression and President Franklin D. Roosevelt's attempts to deal with it provided the Brookings Institution with an enormous challenge. Despite the institute's later reputation as an advocate of liberal policies, Brookings researchers were critical of Roosevelt's New Deal policies and their curbs on what they considered to be the prerogative of the free market. The institute was similarly critical of aspects of the policies of the Truman administration.

Despite its criticisms, however, the Brookings Institution grew in prominence, becoming especially influential during the period of its second president, Robert Calkins (1952–1967). During this time, the John F. Kennedy and Lyndon B. Johnson administrations frequently consulted the Institution. In addition, the Institution added foreign policy research to its traditional focus on domestic policy issues.

Over the years, the Institution evolved into the archetype of the powerful Washington think tank. During the tenure of its third president, Kermit Gordon (1967–1977), Brookings also became the target of rhetorical hostility from the executive branch. Members of the Nixon administration openly criticized the institute because of its influence and the perceived opposition of its staff to the President's policies.

Bruce MacLaury became Brookings's fourth president in 1977, followed by Michael Armacost, a former staffer for President Ronald Reagan, in 1995. Some commentators remarked

at the time that Armacost's appointment represented an official recognition by the institute of the new prevalence of conservative ideas in Washington.

The current president of the Brookings Institution is Strobe Talbott, a former journalist and U.S. secretary of state in the Clinton administration. Talbott became president of the institute in 2002.

Current Activities

While the Brookings Institution has not historically emphasized healthcare issues in its research, in July 2007 it created the Engelberg Center for Health Care Reform. The founding director of the new center is Mark B. McClellan, former commissioner of the U.S. Food and Drug Administration and administrator of the Centers for Medicare and Medicaid Services (CMS). The center will serve as the hub of Brookings activities related to health policy. Its mission is to effect lasting change by providing practical solutions that result in high-quality, innovative, and affordable healthcare. The center plans to focus on four key areas: improving the quality of medical care, increasing access to affordable health insurance coverage, reducing the costs of public and private programs, and encouraging rapid and effective innovation for the development of more personalized medicines.

Other areas of the institute also focus on healthcare. The Health Policy Initiative sponsors events, coordinates research, and publishes papers on healthcare spending and resource allocation. The Global Health Financing Initiative, organized in 2006 with funding from the Bill and Melinda Gates Foundation, focuses on similar issues in the countries of the developing world. The Wolfensohn Center for Development (initiated in 2006 and named after James Wolfensohn, the former head of the World Bank), the Hamilton Project (named after Alexander Hamilton), and the Center on Children and Families also deal, at least peripherally, with health issues. An undertaking launched in 1998 with the American Enterprise Institute (AEI), another prominent think tank, is called the Joint Center for Regulatory Studies and deals with topics including health policy and economics.

Publications

The Brookings Institution has a large number of outlets for the dissemination of its research efforts. *The Brookings Bulletin*, a quarterly launched in 1962, served as its house organ until 1982, when it was succeeded by the quarterly *Brookings Review*. The *Brookings Review* was retired in 2003, but the Institution currently publishes an array of periodical titles on an annual or semiannual basis. Among these journals, articles on medicine, public health, medical insurance, and other health-related topics appear in the *Brookings Papers on Economic Activity* and *The Future of Children*, copublished with Princeton University's Woodrow Wilson School of Public and International Affairs.

The Brookings Institution Press also publishes a wide variety of books dealing with aspects of medicine, medical education, medical insurance, economic and social health policy, and biomedical technology.

In addition to its publishing efforts, Brookings researchers also submit items to newspaper opinion and editorial pages, appear before U.S. congressional panels, and make themselves available for speaking engagements and broadcast media appearances.

CANADIAN ASSOCIATION FOR HEALTH SERVICES AND POLICY RESEARCH (CAHSPR)

The Canadian Association for Health Services and Policy Research (CAHSPR) is Canada's largest and most diverse health services and policy research association. Incorporated in 2004, the CAHSPR evolved from the Canadian Health Economics Research Association (CHERA), in response to changes in Canada's health services research landscape. The CHERA, which began in 1985, primarily focused on health economics and policy. Over the years, it evolved into a broader organization with diverse members, including not only health economists but also health services researchers, policy analysts, and other professionals. Over time, there was a belief by many outside individuals and organizations that because of its name and official objectives, the CHERA was narrowly focused on health economists. The association's members saw this as a significant barrier to the organization's continued growth.

In 2002, the leadership of the CHERA decided to survey its members as well as external stakeholders to determine if there was interest in broadening the mandate and membership of the organization. The response was overwhelmingly supportive of making changes to the organization and having it become a national, broad-based, interdisciplinary health services and policy research association for practitioners, users, and students

of health services and policy research. The proposed new organization was formally introduced at the Institute of Health Services and Policy Research symposium that was held in November 2003. And the CHERA transitioned into the CAHSPR.

Key Features

The key features of the CAHSPR are as follows: It is multidisciplinary; it is committed to improving the quality, relevance, and application of health services and policy research; its membership includes both health services and policy researchers from a wide range of disciplines and consumers of research from government and nongovernment organizations and industry.

These features allow the CAHSPR to be in a unique position to foster and support linkages between researchers and decision makers; to promote knowledge transfer, exchange, and integration; to encourage education and training; and to advocate for research and its more effective use in planning, practice, and policy making.

Member Services

The CAHSPR provides a number of services to its members and others, including organizing an annual conference, publishing a peer-reviewed journal, distributing information through a weekly listserv, and supporting interdisciplinary research and knowledge transfer.

One of the most important activities of the CAHSPR is its annual conference. The association's inaugural conference was held in Montreal in May 2004. The themes of this conference were "Learning From International Comparisons" and "Knowledge Exchange Between Researchers and Decision-Makers." In September 2005, the association's second annual conference was again held in Montreal, this time in conjunction with the Jean-Yves Rivard Conference and the International Conference on the Scientific Basis of Health Services. The theme was "Canada's Health Priorities: Building and Maintaining Research Capacity." The third annual conference, which took place in September 2006, had the theme "Insight, Interaction and Innovation: New Approaches to Health Services, Research, Policy and Management." It was held in conjunction with the National Healthcare Leadership Conference in Vancouver, British Columbia. In June 2007, the association's fourth annual conference, "Leading, Linking and Listening: Knowledge Exchange at the Frontiers of Health Services and Policy Research," was once again held in conjunction with the National Healthcare Leadership Conference in Toronto. The association's fifth annual conference was held in May 2008 at Gatineau, Quebec. Its theme was "Bridging Silos." Whenever possible, the association holds its conferences consecutively or concurrently with other organizations to maximize the opportunity for collaboration between other researchers and decision makers.

The CAHSPR publishes *Healthcare Policy*. This quarterly journal includes original scholarly and research articles that support health policy development and decision making. The articles address diverse topics such as governance, organization, and service delivery to funding and resource allocation. The journal's diverse readership includes health system managers, practitioners, policymakers, educators, and academics. In line with the interdisciplinary nature of the CAHSPR, the journal is open to researchers from a broad range of disciplines. The submission of articles from decision makers and researcher–decision maker collaborations that address knowledge exchange and application are strongly encouraged.

Healthcare Policy has adopted the themes identified in 2004 through a national consultation initiated by the Canadian Health Services Research

Foundation, the Institute of Health Services and Policy Research (within the Canadian Institutes of Health Research), the Canadian Institute for Health Information, the Canadian Coordinating Office for Health Technology Assessment, the Advisory Committee on Governance and Accountability of the Federal-Provincial-Territorial Conference of Deputy Ministers of Health, and the Health Statistics Division of Statistics Canada. The consultation was intended to establish both a primary research agenda and a research synthesis agenda to recognize the immediate needs of policymakers, managers, and the public for accessible summaries of research evidence. The research themes that were identified and drive the content of *Healthcare Policy* include workforce planning, training, and regulation; management of the healthcare workplace; timely access to quality care for all; managing for quality and safety; understanding and responding to public expectations; sustainable funding and ethical resource allocation; governance and accountability; managing and adapting to change; linking care across place, time, and settings; and linking public health to health services.

The CAHSPR distributes an informational e-mail to all members on a weekly basis. The e-mail includes information on a variety of topics of importance to members, including career opportunities, CAHSPR activities and upcoming events, links to course materials for student members, and current research and policy items of interest to members.

These services allow the association to provide support for interdisciplinary research and knowledge transfer. It provides a home for decision makers from the healthcare sector who are interested in research outcomes and participating in research collaborations. In addition, the association works closely with the Canadian College of Health Services Executives (CCHSE), the Canadian Institute for Health Research (CIHR), the Canadian Health Services Research Foundation (CHSRF), and other organizations to strengthen the connection between researchers and research users within Canada's healthcare system.

Organization

The CAHSPR is governed by a board of directors, which is composed of a president, president-designate,

past president, secretary (appointee), treasurer (appointee), a minimum of six and a maximum of nine directors, a student representative (nonvoting), representatives from each study group (nonvoting), current conference convener (nonvoting), upcoming conference convener (nonvoting), the Emmett Hall Foundation president (ex officio), and an executive director (nonvoting). The president, president-designate, past president, secretary, and treasurer are the officers of the association. The day-to-day operation of the association is the responsibility of an executive director.

Its immediate objective was to bring together provincial governments, health institutions, and the private sector as partners to engage in practical research that would identify what works in Canada's healthcare system, what does not work, and what procedures and interventions require further evaluation. The original commitment through the federal budget was CAN\$65 million. While it was originally envisioned that the Medical Research Council of Canada would administer the fund, the Canadian College of Health Services Executives (CCHSE) allowed its own foundation to be transformed into the Canadian Health Services Research Foundation. In November 1996, the CCHSE's board of directors changed the name and objectives of the foundation—those changes were subsequently approved by Industry Canada.

Purpose

According to the supplementary letters patent, the CHSRF was established for the purpose of identifying research gaps and needs in the field of health services research and defining priorities; the funding of peer-adjudicated research into the management, organization, and effectiveness of health services, including research into the outcomes of health-affecting interventions as well as into the organization and management of institutional and noninstitutional models of health services delivery; and the promotion of best practices of health services delivery and the communication of research outcomes.

As an endowment, the CHSRF was designed to work at arm's length from government, with stable funding at a sufficient level to have an impact on health services in Canada. At the time of its formation, the CHSRF received CAN\$66.5 million. Since then, it has received a total of CAN\$151.5 million in endowment contributions. During its history, the foundation has used its endowed funds to support applied research projects, open grants competitions focusing on priority themes identified by managers and policy-makers, the development of the Canadian Institutes of Health Research (CIHR), education and mentoring Chairs, regional training centers, nursing research, and knowledge transfer. The most recent contribution of CAN\$25 million was specifically

CANADIAN HEALTH SERVICES RESEARCH FOUNDATION (CHSRF)

The Canadian Health Services Research Foundation (CHSRF) was created through the Canadian federal budget in March 1996. It was established in response to federal and provincial government interest in renewing Canada's healthcare system.

directed at developing the capacity of health service executives and their organizations to use research.

Mission and Vision

Between 1997 and 2002, the mission of the CHSRF was to improve the health of Canadians by promoting and funding health services research and increasing its quality, relevance, and usefulness for policymakers and managers by encouraging in its peer-reviewed funding a focus on issues of importance for decision makers, the regular sharing of results and issues between decision makers and researchers, the persuasive communication of research results and the training and support of health services and nursing researchers; funding syntheses of research and experience and encouraging user-friendly communication of research results and their implications for decision makers; working with health service organizations to increase their ability to acquire, appraise, adapt, and apply research to policy making and management; and developing relationships with partners and cosponsors who uphold the foundation's goals of generating and promoting the use of health services and nursing research that is relevant to decision makers' needs.

As the result of a 2002 external review, the CHSRF worked with the Canadian Institutes of Health Research (CIHR) and transferred research project funding to the CIHR in favor of supporting four to six programs of research, capacity development, and knowledge transfer.

The current vision of the CHSRF is "a strong Canadian healthcare system driven by solid, research-informed management and policy decisions," and the mission of the foundation is "to support evidence-informed decision making in the organization, management, and delivery of health services through research, building capacity and transferring knowledge." The strategy adopted by the CHSRF to work toward this vision and mission is "to bring researchers and decision makers together regularly to understand each other's goals and professional culture, influence each other's work, and forge new partnerships." The

foundation has also established strategic objectives to create high-quality new research that is useful for health service managers and policymakers (especially in the foundation's priority theme areas); to increase the number and nature of applied health services and nursing researchers; to get needed research into the hands of health system managers and policymakers in the right format, at the right time, and through the right channels; and to help health system managers, policymakers and their organizations to routinely acquire, appraise, adapt, and apply relevant research in their work.

Priorities and Programs

The CHSRF supports management and policy research in health services and nursing, and the dissemination of research results through research funding for both researchers and decision makers, training opportunities for senior decision makers, training and personnel development for new and established researchers from within the field as well as those who are prepared to apply skills from other fields to health systems, services and resources to support communication and research dissemination, and recognizing excellence and achievement in doing, supporting, communicating, and using research results. In 2005, CAN\$13.6 million was allocated for these purposes.

The CHSRF groups its priorities into various themes. While these change over time, in 2008, they included the following: managing for quality and safety, management of the healthcare workplace, primary healthcare, nursing leadership, organization, and policy. Past themes have included centralization and aggregation of health services, informed public participation in decision making, health and human resources, and managing continuity. Current priorities are posted on the CHSRF's Web site.

Specific activities of the CHSRF include research, exchange, and impact for system support; commissioned research; nursing research fund; an executive training for research application program; building capacity for applied and developmental research and evaluation in health services and nursing; the Harkness Associates program; the

health services research advancement award; and bringing out publications designed to translate research into information that is accessible to decision makers.

Organization

Located in Ottawa, the CHSRF is governed by a board of trustees of up to 14 people, many of whom are researchers and decision makers. Trustees are elected for 3-year renewable terms. The CHSRF employs a staff of approximately 50 individuals, and it is led by a chief executive officer who is responsible for the day-to-day operations of the foundation.

CANADIAN INSTITUTE OF HEALTH SERVICES AND POLICY RESEARCH (IHSPR)

The Canadian Institute of Health Services and Policy Research (IHSPR) is 1 of 13 institutes of the Canadian Institutes of Health Research (CIHR). The CIHR were created in June 2000, when an act of the Canadian Parliament came into force. This act states that the CHIR will achieve their objectives through “encouraging interdisciplinary, integrative health research through the creation of health research institutes” and established a governing council, which is responsible for the creation of health research institutes. The purpose of the institutes is to support individuals, groups, and communities of researchers for the purpose of achieving the objectives of CIHR. In July 2000, the governing council of CIHR established the IHSPR, and in December 2000, Morris Barer of the University of British Columbia was appointed its first scientific director.

The CIHR are considered “virtual” institutes in that they are not housed in a central location and can be considered a focal point for networks of researchers with common interests. The location of each institute’s office is determined by its respective scientific director. For the first 5 years of its operation, the IHSPR was located in Vancouver, British Columbia. In September 2006, Colleen M. Flood was appointed the scientific director of IHSPR, and with this appointment, the institute’s office was relocated to Toronto.

Vision, Goals, and Objectives

Like all the institutes, the IHSPR’s “objective is to excel, according to internationally accepted standards of scientific excellence, in the creation of new knowledge and its translation into improved health for Canadians, more effective health services and products, and a strengthened Canadian healthcare system.”

The IHSPR’s vision, mandate, values, and guiding principles are discussed below.

Vision

The vision of the institute is to strengthen Canada's healthcare system through health services and policy research. Specifically, its vision is of a vibrant community of excellent researchers who conduct outstanding health services and policy research that informs Canadians about their healthcare system, is used by decision makers to strengthen Canada's healthcare system, and influences health and social policy in Canada and abroad.

Mandate

The mandate of the institute is to support health services and policy research and its timely translation. Specifically, it is to support outstanding research, capacity building, and knowledge translation initiatives designed to improve the way healthcare services are organized, regulated, managed, financed, paid for, used, and delivered, in the interest of improving the health and quality of life of all Canadians.

Values

The institute's fundamental and core values that influence its decision making, strategic activities, and operations are (a) international excellence; (b) ethically responsible research; (c) scientific rigor; (d) diversity in theoretical and methodological approaches; (e) innovation; (f) impartial, arms-length, peer, and merit adjudication; (g) involvement and recognition of, and respect for, a wide range of partners from all relevant sectors, provinces, and other countries; and (h) a transparent approach that facilitates accountability to all Canadians.

Guiding Principles

The institute is guided in its strategic and operational activities by the following principles: (a) provide leadership through working collaboratively with key partners in identifying, coordinating, focusing, and integrating health services and policy research and knowledge translation priorities for Canada; (b) support superb research and researchers involved in addressing the problems confronting healthcare decision makers of today

and tomorrow; (c) encourage productive collaboration among researchers who use diverse methods and offer varied types of expertise; (d) uphold the principles of academic freedom, independence, and the right to publish; (e) address, wherever possible and practical, regional and other disparities in Canada's capacity to undertake outstanding research in the domain of the institute's mandate; (f) facilitate access to data that can be used to conduct health services and policy research, at the same time working with partners to ensure that access protocols respect the privacy of information on individual patients, providers, and organizations; (g) support initiatives that will result in the timely translation of relevant research knowledge; (h) provide timely responses to all those who communicate with staff of the institute; and (i) interact with all individuals and organizations with integrity and respect.

As a dynamic organization, the specific goals and objectives of the IHSPR are expected to evolve as changes occur in the environment in which the institute operates. However, strategic planning is guided by five key areas, corresponding to the institute's planning, reporting, and accountability structure: (1) creation and synthesis of outstanding research; (2) building a community of outstanding researchers in innovative environments; (3) translating health research into action; (4) developing and nurturing effective partnerships and public engagement; and (5) promoting and facilitating organizational excellence in all institute activities, and with the CIHR generally. The institute's current goals and objectives are listed in its Web site.

Activities and Funding

To achieve its mandate, the IHSPR initiates and administers funding programs, supports knowledge transfer between researchers and decision makers, initiates the establishment of strategic partnerships, and develops and disseminates publications and other resources.

Between FY1999–2000 and April 2007, the institute awarded CAN\$135 million. During FY2006–2007, it awarded CAN\$24.2 million to 371 projects. The institute's funding opportunities announced during 2006 included fellowship awards, grants for pandemic flu preparedness, partnerships for health

system improvement, knowledge translation, access to care, and the development of wait-time benchmarks.

Knowledge translation is another important function of the IHSPR. Knowledge translation is the exchange, synthesis, and application of knowledge within a complex set of interactions among researchers and users, which accelerates the capture of the benefits of research through improved health, more effective services and products, and a strengthened healthcare system. Knowledge translation is required as an integral part of all institute-funded initiatives. In addition, the institute supports knowledge translation through the journal *Healthcare Policy*, through the development of knowledge translation casebooks, and through other direct-funding programs.

Healthcare Policy is the first Canadian journal dealing with a wide range of policy-related health issues from a multidisciplinary perspective. The institute was instrumental in establishing the journal, in partnership with the Canadian Association for Health Services and Policy Research (CAHSPR). The journal is published quarterly and is available in electronic and print formats.

Casebooks are an approach to knowledge translation that showcases creative initiatives taken to share knowledge between researchers and decision makers. The first knowledge translation casebook developed by the institute was *Evidence in Action, Acting on Evidence*. This publication draws from the experiences of individuals, teams, and organizations from across Canada, and it describes a broad range of knowledge translation activities, including what worked, what did not work, and lessons learned. A second casebook titled *Moving Population and Public Health Knowledge Into Action: A Casebook of Knowledge Translation Stories* was developed in partnership with the Canadian Population Health Initiative. This casebook focuses on population and public health research. Topics include aboriginal health, child and youth health, women's health, occupational and workplace health, and infectious and chronic diseases.

The IHSPR has initiated special knowledge translation activities in recent years, including funding research syntheses, and contributing to the establishment of national benchmarks for wait times for selected healthcare services. Research

synthesis is the process of using systematic methods to aggregate data from multiple studies on a particular topic. Syntheses can make an important contribution to the process that decision makers and healthcare administrators use when establishing policy. Syntheses translate a body of knowledge into information useable by those who can use it to inform their decisions.

The development of national benchmarks on wait times is an important contribution to the Canadian healthcare system. Within a single-payer healthcare system such as the one operating in Canada, it is necessary to have research evidence that identifies wait times that do not exceed lengths that have been shown to have negative effects on people's health. The institute has funded research teams to contribute to developing this evidence that was subsequently used as part of the process of developing national benchmarks. The institute-funded research on wait times continues.

Organization

As part of the CIHR, the IHSPR is ultimately accountable to the Canadian parliament. A governing council is responsible for the management of the property, business, and affairs of all the institutes. Each of the institutes is led by a scientific director who has responsibility for building the institute and research capacity; establishing and nurturing partnerships; fostering networking, knowledge dissemination, and communications; and conducting research. An institute advisory board provides advice to each scientific director on strategic directions for the institute. This is a key link between institute and stakeholder communities and is a source of broad community engagement.

CANCER CARE

Cancer care involves an entire team of medical specialists who care for patients with this chronic condition. Although the diagnosis of cancer generally begins with an oncologist or other physician, a healthcare team comprising nutritionists, social workers, and even pastoral counselors may work with the patient. Depending on the stage and type of cancer, a patient may undergo surgery, chemotherapy, radiation therapy, or immunotherapy. Additionally, patients may seek out complementary and alternative treatments, such as nutritional therapy, that may be essential to healing and transforming cancer patients into cancer survivors.

Each of the various cancer treatments can affect recovery in a different way. Cancer and its associated therapies can often cause nutrition-related side effects, which may impede the recovery of patients. Furthermore, because cancer treatments can interfere with a patient's appetite, taste, sense

of smell, and his or her ability to consume enough food, this may result in various side effects. Cancer patients may also be confronted with emotional problems, such as giving up hope that they will survive treatment. Therefore, trained social workers and pastoral counselors, working together with the oncologist and nutritionist, can help patients during this difficult time. Getting patients to focus on recovery and convincing them to consume the right kinds of food during and after treatment helps them stay strong.

Diet and Nutrition Therapy

Research has shown that cancerous tumors may produce chemicals that change the way the body uses nutrients. The human body's use of proteins, carbohydrates, and fats may be affected, especially by stomach and intestinal tumors. To ensure proper nutrition, a cancer patient has to consume enough foods that contain the essential nutrients of vitamins, minerals, protein, and carbohydrates. Malnutrition can cause cancer patients to be weak, tired, and unable to resist infections or withstand needed cancer therapies. Not consuming enough protein and calories is a common nutrition problem faced by many cancer patients as these are important for healing, fighting infection, and providing enough energy for daily activities. Sometimes a patient may appear to be eating enough, but the body may not be able to absorb all the nutrients. Thus, diets high in protein and calories can help prevent the onset of cachexia, a disease common among cancer patients who appear to be physically wasting away.

Nutrition therapy can help maintain body weight and strength, prevent body tissue from breaking down, rebuild tissue, and fight infection. Nutritional guidelines for cancer patients can be very different from the usual suggestions for healthful eating. People who eat as suggested during cancer treatment may be able to handle higher dosages of certain anticancer treatments.

Another treatment that may help relieve cancer symptoms and side effects that cause weight loss is through natural drug supplements. These are natural drugs that can relieve the symptoms of nausea, vomiting, diarrhea, and constipation and increase the production of pancreatic enzymes.

Surgery

More than half of all patients who have cancer, including head, neck, stomach, and intestinal cancer, elect to have surgery. The surgical procedure may involve the removal of all or part of the affected organ. Surgery increases the body's need for nutrients and energy to heal the wounds. This can also result in complications that affect a patient's ability to eat and metabolize food.

Surgery to the neck and head often cause chewing and swallowing problems. In addition, stress due to the amount of tissue removed during surgery may also affect the appetite. Surgery for cancer in the digestive tract may reduce the ability of the gastrointestinal system to work properly and may inhibit the digestion of food. Furthermore, removal of a part of the stomach may cause the feeling of fullness for the patient before enough food has been eaten. Stomach surgery can also cause dumping syndrome or the emptying of the stomach into the intestines before food is digested. Because the organs of the digestive system normally produce important chemicals and hormones, which are needed for digestion, surgery on these organs may affect the body's ability to absorb nutrients and vitamins. Additionally, levels of sugar, salt, and fluids in the body may become unbalanced.

Nutrition therapy may be able to treat these complications and allow cancer patients receive the nutrients they need. Some of the nutrition therapy for cancer surgery patients may include enteral nutrition or feeding liquid through a tube into the stomach or intestine; parenteral nutrition or feeding through a catheter into a vein; medicines to increase appetite; and nutritional supplement drinks.

It is common for patients to experience pain, tiredness, and loss of appetite after surgery. Some patients may not be able to consume their regular diet because of these symptoms. Thus, the following eating tips are commonly recommended by physicians: (a) Avoid carbonated drinks—such as soda pop—and gas-producing foods, including beans, peas, broccoli, cabbage, Brussels sprouts, green peppers, radishes, and cucumber; (b) increase fiber by small amounts and drink lots of water, if regularity is a problem, and good sources of fiber include whole-grain cereals—including

oatmeal and bran—beans, vegetables, fruit, and whole-grain breads; (c) select high-protein and high-calorie foods to help surgical wounds heal—excellent food choices include eggs, cheese, whole milk, ice cream, nuts, peanut butter, meat, poultry, and fish; and (d) increase calories by frying foods and using gravies, mayonnaise, and salad dressings.

Chemotherapy

Chemotherapy is a cancer treatment that uses drugs to stop the proliferation of cancer cells, either by killing the cells outright or by stopping those cells from dividing. Because chemotherapy targets rapidly dividing cells, healthy cells that usually grow and divide rapidly may also be affected by the cancer treatments. These include cells in the mouth as well as in the digestive tract.

There are a number of nutrition-related side effects that often occur during chemotherapy that affect a person's ability to eat and digest food properly. Some of the most common side effects include anorexia, nausea, vomiting, diarrhea, constipation, inflammation, and infections.

The side effects of chemotherapy may also make it difficult for a patient to obtain the nutrients needed to regain healthy blood cell counts between successive chemotherapy treatments. Thus, nutrition therapy can help patients get the appropriate nutrients to tolerate and recover from chemotherapy as well as prevent weight loss and maintain overall general health. Nutrition therapy for patients undergoing chemotherapy may include supplements high in calories and protein and enteral nutrition or tube feedings.

Radiation Therapy

Radiation therapy is a cancer treatment that uses high-energy X rays and other forms of radiation to kill cancerous cells. There are two basic types of radiation therapy: external radiation therapy, which uses a machine outside the body to send radiation to the cancer, and internal radiation therapy, which uses a radioactive substance sealed in needles, seeds, wires, or catheters that are placed directly into or near the cancer site. Radiation therapy can often harm healthy cells in the treatment area. Side effects can occur when

healthy cells that are near the cancerous cells are affected by the radiation treatments. These side effects depend mostly on the dose of radiation and the part of the body that is treated.

Radiation therapy that is performed near the digestive tract is likely to cause nutrition-related side effects. Radiation therapy to the head and neck may cause anorexia, taste changes, dry mouth, inflammation of the mouth and gums, swallowing problems, jaw spasms, cavities, or infection, while radiation therapy to the chest may cause swallowing problems, esophageal reflux or a backward flow to the stomach. In addition, radiation therapy to the pelvis or abdomen may cause diarrhea, nausea and vomiting, inflammation of the rectum or intestine, and fistula in the stomach or intestines. Some long-term effects can include narrowing of the intestine and poor absorption or blockage in the stomach or intestine. Radiation therapy may also cause exhaustion, which can lead to a decrease in appetite and a reduced desire to eat.

Nutrition therapy may be able to treat some of these side effects associated with radiation therapy, and it can provide the patient with enough calories and protein to tolerate the treatment, prevent weight loss, and maintain general health. The therapeutic regimen may include nutritional supplement drinks between meals, tube feedings, or other changes, including eating small meals throughout the day and choosing certain kinds of food.

Immunotherapy

Immunotherapy or biological therapy is a form of cancer treatment that uses a patient's own immune system to fight cancer. Substances that are made by the body or made in a laboratory can be used to boost or restore the body's natural defenses against cancer. Some of the most common side effects associated with immunotherapy include fever, nausea, vomiting, diarrhea, anorexia, and exhaustion.

Nutrition therapy can be used to treat the nutrition-related side effects of immunotherapy. If these side effects are not addressed, weight loss and malnutrition may occur and lead to complications during recovery, such as poor healing or infection.

Psychosocial Interventions

There are also psychosocial interventions available for cancer care, such as counseling, that are a part of the offerings at major hospitals. These interventions may include education, behavioral training, individual psychotherapy, and group interventions.

According to researchers at the University of California at Los Angeles School of Medicine, there is a need for a wide variety of psychosocial interventions for cancer patients as these types of interventions positively affect the survival of cancer patients. Furthermore, the need for a variety of psychosocial interventions is enhanced, as increasing numbers of patients with cancer survive longer.

Excellent communications skills in the oncologist can also help patients understand that complementary therapies are available to them. A study reported that communication within the field of oncology is a core clinical skill but one in which few oncologists or cancer nurse specialists have received much formal training. Additionally, communication difficulties may interfere with the recruitment of patients into clinical trials, which may result in delaying the introduction of efficacious new treatments. Oncologists have acknowledged that insufficient training in communication and management skills is a major factor contributing to their own stress, lack of job satisfaction, and emotional burnout. As a result, there have been various initiatives targeted at improving basic communication skills and training for healthcare professionals in the cancer field.

Researchers have also noted that there is a growing acknowledgment about the role that faith plays in patients seeking out cancer therapy as well as in healing. Thus, many cancer hospitals have increased the role of chaplains and pastoral care personnel in cancer care units. One study noted that decisions regarding cancer treatment choices can be difficult and that many factors may influence the patient's decision to undergo treatment. A poorly understood factor is the role of a patient's faith in how he or she makes medical decisions. In this study, researchers interviewed more than 100 patients with advanced lung cancer, their caregivers, and 257 medical oncologists. The study participants were asked to rank the importance of their cancer physician's recommendation, faith in

God, ability of the treatment to cure disease, side effects, family physician's recommendation, spouse's recommendation, and children's recommendation as factors that might influence their treatment decisions. The findings revealed that all three groups ranked the oncologist's recommendation as the most important, and patients and caregivers ranked their faith in God second. The researchers concluded that patients and caregivers agree on the factors that are important in deciding treatment for advanced lung cancer; however, their decision differed from physicians. All the groups agreed that the oncologist's recommendation was the most important. The results indicated that this was the first study to demonstrate that faith is an important factor in medical decision making.

Another study also found a positive role for religious faith in cancer care for breast cancer patients. The study identified and examined the religious and spiritual coping strategies of elderly women newly diagnosed with breast cancer. For this study, 33 women, aged 65 and older, of various religious denominations were recruited, within 6 months of diagnosis. The findings from this study showed that religious faith either stayed the same or increased during the cancer crisis. Three themes also emerged from the analysis: Religious faith provided the respondents with the emotional support necessary to cope with breast cancer; faith communities provided social support for patients; and faith provided patients with the ability to make sense of their lives during cancer.

In another study, it was found that cancer patients have a range of psychosocial needs that require particular support interventions. Although patients may have strong needs that relate to identity, emotional, spiritual, and practical issues, they are less commonly expressed. Furthermore, patients may have particular needs based on their tumor type, severity of illness, age, gender, health status, and socioeconomic and other social factors.

Many cancer treatment centers seek to provide patients with the necessary tools to cope with their illness when treating their patients. One center, for example, offers daily spiritual gatherings for cancer patients and holds classes in praying the rosary for Roman Catholic, Orthodox, and Anglican patients, as well as Bible study for evangelical Protestants. Even patients who do not come from a strong religious background are encouraged to

connect with their spiritual side by the mind-body therapies there during the cancer care treatment. Patients can be instructed in spiritual practices such as yoga, Tai Chi, or other techniques from the Far East that can be used to concentrate the mind and body and help facilitate the healing process from cancer therapy.

Future Implications

With the aging of the nation's population, the number and rate of cancer patients will continue to increase. To meet their needs, cancer care will involve many different facets in the healing process, including traditional as well as complementary and alternative treatments. A medical team must work in synchrony to effectively care for cancer patients. Additionally, oncologists and other healthcare team members must be cognizant and attentive to cancer patients' unique needs to better facilitate cancer care and achieve the best possible outcome.

CAPITATION

Capitation is the prepayment for patient health-care services. Generally, capitation payments are based on a per-member per-month (PMPM) basis. While all types of physicians can be compensated on a capitated basis, primary-care physicians in family practice, internal medicine, and pediatrics are often paid on a capitated basis. The capitation rate includes services provided by the physicians, and it usually also includes diagnostic tests performed in their offices. The capitation rates vary with the age and gender of the patients. For example, the capitation rate for a child under 1 year of age is higher than the rate for a 2- to 5-year-old child because the number of physician visits is expected to be greater. Similarly, the capitation rates for women between the ages of 18 and 40 are higher because the utilization of services is expected to increase due to their child-bearing years.

Overview

Capitation in the United States is often associated with managed-care organizations; however, the concept dates as far back as the Middle Ages.

It is recorded that under the rule of Henry I of England and Normandy that John of Essex received an honorarium of 1 penny per day for serving in a physician's role, a sum equal to that paid for a foot soldier or blind person of the time.

Some early American physicians were also paid on a capitated basis. The author Samuel Clemens, better known as Mark Twain, noted that while he was growing up in Hannibal, Missouri, his parents paid a local physician \$25 annually to care for his family when they were ill.

At the height of the managed-care movement, in the 1980s and 1990s, many physicians were paid a lump sum each month to deliver primary and/or specialty services for patients. Patients were required through insurance arrangements to designate a primary-care physician through whom all their primary services would be provided. The physician then would have a panel of patients they could see on a walk-in or appointment basis. Primary care, internal medicine, and pediatrics were the clinical areas that were customarily designated for capitation payment.

In the late 1990s, physician capitation expanded from individual physicians to encompass physician group practices. Insurers used enhanced capitation schedules to recruit large physician networks and then introduced the global capitation philosophy, which incorporated multiple primary physicians and ancillary services. As the capitation phenomenon grew, some practices realized that they were poorly managing the PMPM rate that they were being paid. Patients started demanding more services, and the physicians were demanding enhanced payment. Thus, insurers introduced enhanced quality payments and bonus payments for meeting performance standards.

The clinical changes in the specialties of cardiology and orthopedics that incorporated diagnostic and technological advancements were revolutionizing those disciplines. As a result, insurance companies wanted to expand capitation payment into those clinical specialties; however, this did not catch on as a payment method. Incorporating the broad array of procedures and equipment into specialty capitation transferred too much risk to the physician. Providers who tried to manage patients under a capitation arrangement found it difficult to meet their financial expectations.

Calculation of Capitation

Every physician office has a bill collection and utilization profile. An insurance or managed-care company will use an actuary to develop a profile of the physician. For example, the average primary-care physician may charge \$100 per visit. Based on the age of the patient, the physician may expect to see the patient 2.5 times a year. Therefore, in a year, the billed rate would be $\$100 \times 2.5 \text{ visits} = \$250/12 \text{ months per year} = \20.83 per member per month. For every patient with the same gender and age, the physician would receive \$20.83 per month. Although this amount is high, it can be used for illustration purposes. Moreover, the case-mix of the patients in an office may affect the physician compensation. For example, a physician with a large HIV/AIDS patient population may receive a higher capitation rate because of the complexity of the care the patients need to receive. In other cases, the location of the physician's office may also affect the capitation rate because the cost of living in certain areas may dictate a higher capitation rate. A particular primary-care specialty may also dictate that a physician be paid more than another such as in the case of an internist being paid more than a family practitioner.

Advantages and Disadvantages of Capitation

The advantage of capitation for the physician is that he or she can negotiate a contractual relationship with an insurance company for a payment. Through the insurance company relationship, the insurer will have members who require a physician relationship. The patient-member is required to designate a primary-care physician who is responsible for his or her care. The patient can then presumably visit the physician on an unlimited basis under the capitation arrangement. In this example, the physician assumes the risk of managing the patients in a manner that allows his or her practice to make a profit.

The advantage of capitation for an insurer is that there is predictable budgeting and the delegation of medical management to the provider. For the provider's part, there is also a predictable income and steady payment on a biweekly or monthly basis from the insurer. For the patient, the

advantage is that there is a relationship with a primary-care physician and minimal out-of-pocket expenditure for services.

In terms of disadvantages, physicians may assume too much risk by having many capitated patients who are severely ill and need medical services. Furthermore, some payers, particularly Medicaid, may not adequately pay, or not pay in a timely manner, for their capitated patients.

Future Implications

Today, capitation remains an important physician payment method, especially in areas dominated by managed-care organizations. This is the case in some of the western parts of the nation, where large health maintenance organizations (HMOs) are the dominant providers of care. However, for the most part, capitation is no longer the preferred payment source of physicians because many prefer to unbundle their services and be paid on a fee schedule. This may change as healthcare expenditures continue to increase and federal and state governments along with employers move to reduce costs through the capitated model of care.

CARVE-OUTS

The term *carve-outs* in the health insurance industry relates to the unique healthcare services that are removed or carved out from a given set of insurance benefits. The carved-out services are provided by a separate vendor or company that offers expertise to a given membership base, and provision of these services involves a contract that is separate from any made with a managed-care organization. The concept of carve-outs was popularized in the late 1980s, when managed care accelerated in the United States due to rising healthcare costs. Carve-outs have advantages as well as disadvantages for healthcare providers and consumers.

Overview

Carve-outs represent a model of contracting for specialty care with providers as a way of controlling rising healthcare costs. Carve-out contracts can include care for patients with certain conditions, particular services, or care for an entire subpopulation of patients. Carve-outs are distinct because they involve a set of providers or management organizations different from those that are otherwise available for patients within a health plan. They permit a unique set of managed-care techniques to be applied to an area of care that is costly or involves complex benefits. Carve-out arrangements can occur at different levels of the healthcare system, including the payer, health plans, or group practices to manage a portion of the insurance risk. Carve-outs appear to lower the associated costs of healthcare for employers and health plans, although whether or not they improve patient outcomes is unclear. In addition, carve-outs may change the competition dynamics among health plans.

In the 1980s, insurance companies developed large utilization review programs with elaborate referral systems that quickly frustrated enrollees and primary-care physicians because of the paperwork involved in getting a referral. Behavioral health, dental care, and worker's compensation services were unique and required specialized oversight. For the most part, the staffs employed by the insurance companies had general medical/surgical backgrounds, and therefore they found it difficult to approve specialty referrals to services for which they had limited formal training. In response to these knowledge gaps, insurance and managed-care companies recruited nurses and physicians who had expertise in behavioral health, dental care, and worker's compensation to fill this void and develop carve-outs.

Advantages and Disadvantages of Carve-Outs

The intent of carve-outs is to deliver efficient and cost-effective services by a central source that has expertise in a particular service. Some examples of carve-outs include dental care, mental health, workers compensation, and pharmacy benefits. The advantages of carve-outs include the following: economies of specialization, enhancement in access to care, the knowledge and expertise that comes with specialization, better coordinating of services with medical and surgical services, control of utilization, and using market power to affect quality. In contrast, the disadvantages of carve-outs include the lack of coordination between various providers and the time needed to perform the coordination. Oftentimes, patients are caught in the middle, and they do not have anyone to serve as their advocate. In some cases, companies have in-sourced their carve-outs to limit the confusion. Some of the coordination difficulties have occurred prominently in the mental health area.

Carve-Out Examples

The number of specialty service companies in dental care, mental health, workers' compensation, and pharmacy benefits has greatly increased. For example, several states have developed contractual relationships with trade unions for carve-out dental services.

Behavioral or mental health services are another example of frequent carve-outs. The types of services under the behavioral health umbrella include the following: hospital inpatient services, residential treatment, partial hospitalization, intensive outpatient programs, outpatient treatment, and employment assistance programs. In the early 1990s, many state governments were trying to move their Medicaid recipients into more cost-efficient services. State governments anticipated that they could take advantage of the cost savings offered in managed care, and they began to promote Medicaid managed-care programs; Medicaid recipients were moved into plans with defined benefits with an associated per-member per-month (PMPM) rate. Often, the state's Medicaid recipients were given a choice of two managed-care programs to join. The very nature of Medicaid recipients with their socioeconomic problems and their associated mental health issues moved states to carve out mental health services from medical and surgical services.

Many state workers' compensation programs were established in the United States at the beginning of the 20th century. These programs provide medical care and disability income to workers who are injured in the course of their employment. Under the programs, the injured worker is prohibited from bringing a lawsuit against the employer, and the employer is obligated to pay the mandated benefits. Since workers' compensation programs are mandated by the states, the programs are funded primarily through private insurance companies, state funds, or self-insurance provided by employers. Employers that want to protect themselves from the specialized legal and regulatory nature of the workers' compensation program often carve out these services to companies with this clinical and legal expertise.

Pharmacy benefits have also been carved out to pharmacy benefit managers (PBMs). Pharmacy benefits are currently the third largest healthcare benefit expenditure of insurance plans after hospital and outpatient medical benefits. The percentage increase in pharmacy benefits has increased to the double digits to 10.1% of healthcare expenditures in 2006. And because of the aging and increasing longevity of the nation's population, pharmacy services will likely continue increasing in the near and distant future.

Future Implications

The future of carve-outs is unclear. The U.S. healthcare system is dynamic, and the nature of services will continue to change as economic incentives shift. There are many opportunities to change the nation's healthcare system so that it meets better the expectations of federal and state governments, employers, insurers, and individuals. As long as carve-outs add efficiencies, limit healthcare expenditures, offer enhanced access to services, and coordinate care, they will likely continue to play a role in the nation's healthcare system.

CASE MANAGEMENT

Case management is a clinical tool that is used to increase the efficiency and effectiveness of

client health and social services and control costs at the same time. The Case Management Society of America (CMSA) defines *case management* as a collaborative approach to assess, plan, facilitate, and advocate for services that meet the health needs of individuals and to increase the quality and cost-effectiveness of client outcomes. More generally, case management helps coordinate resources and services; advocates for client's/patient's rights; monitors and manages clients/patients throughout episodes of illness across all care settings and systems; and addresses clients'/patients' physical, emotional, social, mental, and economic needs.

Case managers often help clients navigate between the different stages of care and providers as well as to help facilitate payment by private or government payers. The broad goals of case management seeks to prevent rehospitalization, prevent inappropriate hospital emergency department use, and reduce the number of lost days of work the client experiences to arrange for care. Case management also acknowledges the role of other systems, such as the labor, financial, and legal systems, in implementing healthcare.

Overview

Case management has its origins in the community mental health movement following the deinstitutionalization of the mentally ill that began in the 1950s. Client-centered community support systems for the deinstitutionalized mentally ill were created under the Community Support Program at the National Institute of Mental Health (NIMH). Due to the lack of sufficient public funding for care, individual case managers, who were mostly in the field of social work, assumed the responsibility for linking mentally ill clients to needed community mental health services and support. The case manager identified the resources and support systems in the communities, provided counseling, and assisted with the tasks of daily living while providing linkages to needed services. The private-sector interest in case management grew following World War II as a method to control the healthcare costs of returning veterans with complicated injuries who needed treatment from multiple providers. The foundation for

the modern case management model was established in the 1970s through the Medicare and Medicaid programs, which used social workers as caseworkers to facilitate care provided by multiple health and social service providers for identified special-needs populations, such as the elderly and those with mental illness.

As the healthcare system and the management of disease and disability have grown increasingly complex and fragmented, the need for case management has increased substantially. The application of case management, however, varies based on three criteria—the profession of the individual providing the case management services (i.e., registered nurse or social worker), the population receiving the services (i.e., the elderly or individuals with mental illness), and the type of organization providing the case management (i.e., hospital or insurance company).

A social service/public health model focuses on patient advocacy and access to services in a fragmented healthcare system. The case management model that has emerged from the managed-care sector, however, has been motivated by cost containment and encourages the utilization of cost-effective community care.

In the current environment of escalating healthcare costs, case management has become a popular method to control costs and eliminate the duplication of services and prioritize less costly services that may be equally effective. The managed-care model of case management that has been increasingly used, however, is primarily driven by cost containment as opposed to the client-centered approach of the public health model. As a result, appropriate care may be compromised by denying treatments that may be clinically necessary or by discharging patients earlier than recommended.

Case management can be of great value when dealing with the complex needs of clients who have multiple health and social issues, such as individuals with mental illness, HIV/AIDS, or substance abuse problems. Case managers typically use a client-centered approach to assess clients in a holistic manner, prioritize and advocate for their needs, and navigate them through the continuum of care.

Case managers can be internal to an organization by working within a program or facility.

On the other hand, external or independent case managers are often employed by insurance companies and are hired to provide case management services. External case managers try to facilitate coordination of care among various providers, programs, systems, and facilities.

Although case management may be implemented differently across various settings, the five common goals of case management are (1) enhancing continuity of care; (2) providing access to cross-sectional service delivery that is comprehensive, coordinated, and ongoing; (3) enhancing accessibility by overcoming administrative barriers; (4) enhancing accountability by designating a case manager as the point of contact for the responsibility of ensuring the effectiveness of the system; and (5) enhancing efficiency by increasing the likelihood of clients receiving timely delivery of appropriate services. Some of the key functions of case management include assessment, planning, linking, monitoring, and advocacy. Outreach is also sometimes identified as another function of case management.

Case management is also a key component of systems of care. When case management is a part of the system of care, it has the fiscal authority to procure needed services for clients. For example, a community agency can develop a memorandum of understanding with other agencies to provide care to their clients. This approach helps enhance a seamless continuity of services. Systems of care can be located in a single multiservice center acting as a one-stop shop for clients. On the other hand, the systems of care can use a saturation approach, mobilizing the entire spectrum of services from medical to social services, and financial and legal services. Additionally, treatment services, rehabilitation, housing, employment, and other supports can be included.

Case Management Settings and Service Delivery

Case management has been used across a variety of settings to improve service provision, service coordination, and health outcomes. Some of the individual needs that case managers address include healthcare and social issues, acute and chronic illnesses, substance abuse, homelessness, mental illness, domestic violence, and long-term

care. Hospitals often treat patients with complicated healthcare needs and therefore use case managers to help facilitate access to and coordination of services to ensure a smooth transition across the continuum of care. Case management is also used in long-term care to help clients attain needed services such as rehabilitation, nursing home facility placement, and home health care.

In addition, the context of service delivery must be taken into account when considering the range of services provided under case management. To receive and effectively use healthcare services, the client who is living in the community will need stable and safe housing, adequate nutritional intake, and a source of income or financial assistance. The client is involved in the process of service linkages; his or her background and preferences are taken into account when identifying a service delivery system, including ethnic group affiliation, cultural practices, language, and neighborhood.

Models of Case Management

Numerous models of case management exist; however, they can generally be categorized into four groups: the broker model, the rehabilitation model, the full support model, and the strengths model. The broker case management model is the least intensive and case managers in this model generally have high caseloads. Under the broker model, the case manager links the client with a service provider. The rehabilitation and full support models, however, are more intensive. Under these models, case managers identify the client's strengths and weaknesses and work to address the barriers that prevent them from functioning independently in the community. The full support model also includes an in-house team of service providers to treat clients who have complex and long-term needs. Last, the strengths model focuses entirely on the client's strengths. The case manager works with the client to develop client-centered goals and relies heavily on the client-case manager relationship. This model requires thorough outreach and follow-up services.

Case management is used mostly on a short-term basis for hospital discharge planning, rehabilitation, or end-of-life planning. Longer-term case management may be used for chronic or

complex diseases such as cancer, diabetes, and asthma. Case management has also been used in communities to coordinate care for low-income pregnant women to reduce low-birth-weight or premature babies to reduce infant mortality. Clients who use case management may also include the mentally ill, children with mental health and behavior problems, the elderly, and those with developmental or physical disabilities.

Case managers generally receive referrals from client identification and outreach in the medical community; case managers may also identify clients through their outreach. Case managers develop a therapeutic relationship with their clients to help facilitate care. After client identification, case managers assess the clients' needs for obtaining care. The case manager identifies those barriers that the client confronts in accessing, obtaining, and receiving needed healthcare services. This may include identifying the financing for care, locating transportation to care, and identifying the appropriate treatment and geographic location for that treatment. The case manager facilitates the timely treatment and receipt of services by linking the client with the service provider. Monitoring is a core component of case management since clients' needs change over time, especially with complex and multiple disabilities or medical problems. Case management is particularly important when medical services are difficult to understand or when navigating healthcare services is uncoordinated. If a client needs ongoing healthcare services over time and continuity of care is critical, case managers can link and monitor service use. Case management is also helpful when a patient has multiple comorbidities and has a need for multiple services. The case manager coordinates care when there is a need for attention to provide multiple services at any one point in time.

The case manager functions as the patient's navigator, and the caseload can vary, depending on the client's severity of need, type of medical care needed, and the duration of medical service utilization. The case manager is typically a social worker, registered nurse, or paraprofessional. The training and supervision of case managers includes training in service coordination and service evaluation. With the increased use of case management by insurance companies, professionals in various disciplines have also started to use

case management with increasing frequency, including rehabilitation counselors and occupational therapists.

Effectiveness of Case Management

The effectiveness of case management has been seriously debated, and there are no clear answers. Although some studies have found case management to be not effective in attaining improved patient health status and cost-effective outcomes, other studies have found the opposite result. Because case management is integrated with other client support services in various settings and has broad goals, this concept is very difficult to evaluate and measure. The effectiveness of a program depends on a variety of factors, including the program design, how well it was implemented, and how well it conforms to evidence-based practices. Measuring the effectiveness of case management interventions can prove challenging. However, researchers can use scales, client interviews, and questionnaires to gain further insight.

Future Implications

Case management could potentially have an impact on reducing the costs for healthcare services. Nonetheless, health services research on case management has to include the variations in case management models. Investigators, therefore, continue to explore the outcomes in access to services, systems performance, cost-effectiveness, and service patterns. Although some studies point out that case management has been ineffective in meeting its intended goals of coordinating patient care and reducing costs, other research studies have pointed out that it can increase access to care and subsequently improve health outcomes. When patients are provided with case management, there is a decreased chance of duplicating unnecessary medical services and an increased chance of providing appropriate and necessary care. Case management remains a promising tool to help certain populations obtain needed and essential social and health services. It is likely that case management will continue to be used by hospitals, insurance companies, and others to control rising healthcare expenditures and adequately manage

the health of special-needs populations and the chronically ill.

CASE-MIX ADJUSTMENT

A variety of situations in health services research demand the use of some type of case-mix or acuity adjustment, that is, adjustment made on the basis

of the characteristics of those receiving services. Case-mix adjustment is crucial in reimbursement for health services, especially in any prospective reimbursement model. For example, the services needed by an 80-year-old diabetic with arteriosclerotic heart disease who is admitted to a hospital for an acute exacerbation of congestive heart failure will differ dramatically from those required by a 25-year-old athlete admitted for repair of a torn knee ligament. Equitable and effective reimbursement models must take such differences into account. The first widely used case-mix adjustment system was the Diagnosis Related Groups (DRGs) used by Medicare since 1983, which paid a specific amount for acute care depending on a hospital patient's discharge diagnosis, gender, age, procedures, and comorbidities.

Any attempt to analyze individual health outcomes also requires researchers to include in their models those individual characteristics that affect a patient's likelihood of a better or worse outcome. The likelihood of in-hospital mortality will differ dramatically between a patient who has fallen and sustained a serious closed head trauma and a similar patient whose fall resulted in a hip fracture. These types of adjustments are also necessary when one analyzes some measures of process quality. The presence or absence of specific care practices may depend on the severity of one's illness.

Finally, case-mix adjustment is crucial when one attempts to measure provider performance, either for quality assurance or some pay-for-performance model. Mortality rates in tertiary care hospitals may be higher than mortality rates in community hospitals due to the differing nature of their patient populations. Failing to adjust for those differences may significantly distort one's judgment concerning differences in the quality of care provided by those two types of acute care settings.

Nursing Home Example

The Medicare resource utilization group (RUG) models used in nursing homes are examples of case-mix classification systems used for reimbursement. The steps in the development of the RUG models are the same as those that might be used in any healthcare setting. First, a sample of

nursing homes (i.e., healthcare providers) is selected for participation in the development of the classification model. The sample must meet minimum quality criteria. Second, researchers conduct a time study in the chosen nursing homes, in which each staff member or caregiver records how they spend all their time over a 1- to 3-day period. The care time provided by each type of staff member (e.g., registered nurse, nurse aide) will eventually be weighted by his or her relative salary level. Third, at roughly the same time, each resident in the selected nursing homes is assessed using a multidimensional assessment tool that evaluates his or her need for care. Fourth, statistical analyses are performed on the data concerning roughly half to two thirds of the residents. These analyses result in the identification of groups of residents who received roughly the same amount of wage-weighted care time and had relatively similar health problems or levels of impairment. The degree to which these groups explain the statistical variation in weighted care time is an important criterion for choosing among potential classification models. In nursing homes, for example, these models usually explained between 50% and 70% of the statistical variance in weighted care time. Fifth, the chosen patient classification model is validated on data from the remaining residents. Sixth, one group of residents is chosen to serve as the index group and given a case-mix index of 1.0. Every other group of residents is assigned a case-mix index that reflects the relative average weighted care time provided to that group compared with the average weighted care time provided to the index group. Seventh, in some instances (RUG-III), case-mix indexes are adjusted, based on clinical judgments. Finally, the case-mix index for the group into which a patient falls can then be used to adjust all, or a portion of, the payment for that provider's services to that patient.

Common Criticisms

One of the most common criticisms of all case-mix classification systems comes from healthcare providers. Some providers invariably believe that these models fail to capture the true level of need exhibited by their clients, patients, or residents. This means, of course, that these providers see themselves

as not receiving appropriate reimbursement for the care they give. The implementation of these models creates both winners and losers in terms of reimbursement levels. For this reason, the models are often implemented in a "soft" manner with wide corridors around presumptive reimbursement levels for nursing homes. Over time, however, these corridors narrow as the providers adjust to this new reimbursement model.

Among advocates and academics, the most common criticism is that these models only replicate the care provided. Case-mix classification models do not identify ideal patterns of care or recognize and reimburse best practices. The resource use estimates that form the core of these models, whether they are weighted hours of care in a nursing home or days of care in a hospital, rest on current care patterns. These patterns can be excellent, adequate, or inadequate. Those involved in nursing home resident classification have a standard response to this argument. They believe that the relative differences reflected by case-mix indexes reflect real differences among residents. They admit, however, that the specific hours of care provided to the index group may not be ideal. As reassuring as this argument seems, it currently lacks a strong base of empirical evidence.

Also, for long-term care, such models pay a provider more if it allows someone to decline or become more seriously ill. In essence, these models can arguably be said to offer incentives exactly the opposite of pay-for-performance models. Professional ethics, state inspections, the availability of ombudsmen and consumer advocates, and reports to consumers of provider performance would all seem to counterbalance such perverse financial incentives. At times, it seems that these "counterincentives" may not function as well as one would hope. In acute care, one must only remember concerns about "quicker and sicker" hospital discharges as a result of the implementation of the Medicare DRG system to realize such concerns are unwarranted. In long-term care, one simply needs to remember the state residential care reimbursement model that paid for the care of residents in wheelchairs and those residential care homes that allegedly put all their residents in wheelchairs, needed or not, to maximize reimbursement.

In performance-measurement or consumer-reporting models, one of the most common

objectives of case-mix adjustments comes again from healthcare providers. Most provider organizations that find themselves identified as giving poorer care in a performance measurement or consumer reporting system argue that their performance is unfairly reflected in that system. They often blame any case-mix adjustment model for this error. If appropriate adjustments for the acuity or consumer needs were made, these providers argue, their organization would fare much better.

Case-Mix Adjustment in Various Settings

In adjusting quality measures, usually outcomes, acute care in many ways provides the simplest setting. The patient's stay is generally very short, the admission often involves a single presenting problem, and the patient's status at admission is clearly unrelated to the hospital's performance (assuming this is not a readmission). All these things make for somewhat less complicated risk adjustment. The nature of the primary complaint, the severity of that complaint, and the number and severity of comorbidities, along with the patient's demographic characteristics, constitute the basics for good risk, acuity, or case-mix adjustment in an acute care setting.

However, this same process is more complicated in other settings. In nursing homes, for example, the average length of stay for long-stay residents amounts to years, not days. Evaluating quality over such longer time periods when the residents are exposed to the nursing home's performance becomes difficult. A nursing home resident's health may decline between the 9th and 12th months of their stay. This decline will probably be reflected in the diminution in their ability to independently perform certain activities of daily living (ADLs). It is difficult to determine whether that decline was an unavoidable result of their disease burden or whether it might have been avoided if the nursing home had provided additional or different care in the first 9 months of their stay.

Attempting, under such circumstances, to determine how much of the change in outcomes can be attributed to the care provided by a nursing home and the "natural" process of decline is exceedingly difficult. The condition of the resident in that 12th month is inextricably intertwined with the quality

of care provided by that nursing home during the first 9 months of his or her stay. Thus, the idea of adjusting for "baseline status" unrelated to the provider's performance (as in hospitals) is quite difficult to achieve. Surprisingly, however, this difficulty has not driven nursing home researchers to move more heavily toward the use of process quality measures that often require less acuity adjustment.

Future Implications

Across the entire spectrum of health services, the eventual success of the growing movement toward pay-for-performance will depend heavily on the quality of the case-mix adjustment used in these reimbursement models. Paying more to healthcare providers that perform better is an eminently reasonable idea. However, to the degree that indicators of clinical outcomes are used as part of such a process, it is important that one understands, for such indicators, just how much of the variation among providers is a function of random fluctuation, consumer characteristics, or provider action. In essence, when the variation in a quality indicator is broken down, a sizeable proportion of that variation should be attributable to provider performance. At this time, it is unclear how attentive those pursuing the development of pay-for-performance models are to this issue.

CATO INSTITUTE

The Cato Institute seeks to broaden the parameters of public policy debate—including debates over health and medicine—to allow consideration of the traditional American principles of limited government, individual liberty, free markets, and peace. Toward that goal, the Cato Institute strives to achieve greater involvement of the intelligent, concerned lay public in questions of policy and the proper role of government.

Background

The Cato Institute was founded in 1977 by Edward H. Crane. It is a nonprofit public policy research foundation headquartered in Washington, D.C. The institute is named for *Cato’s Letters*, a series of libertarian pamphlets that helped lay the philosophical foundation for the American Revolution.

To maintain its independence, the Cato Institute accepts no government funding. Cato receives approximately 75% of its funding from individuals, with smaller amounts coming from foundations, corporations, and the sale of publications. Cato’s 2005 revenues were more than \$22.4 million, and it has approximately 95 full-time employees, 70 adjunct scholars, and 20 fellows, plus interns.

Publications Program

The Cato Institute undertakes an extensive publications program dealing with the complete spectrum of public policy issues. Books, monographs, briefing papers, and shorter studies are commissioned to examine issues in nearly every corner of the public policy debate. Policy forums and book forums are held regularly, as are major policy conferences, which Cato hosts throughout the year and from which papers are published thrice yearly in the *Cato Journal*. All these events are recorded and archived on Cato’s Web site. Additionally, Cato has held major conferences in London, Moscow, Shanghai, and Mexico City. The institute also published the quarterly magazine, *Regulation*, and a bimonthly newsletter, *Cato Policy Report*. The institute recently launched the Cato@Liberty blog, where its scholars provide timely commentary on public affairs, and *Cato Unbound*, a monthly online magazine that engages the world’s leading thinkers in the exchange of big-picture ideas.

Health Policy Studies

Cato scholars argue that individuals should be free to own and control their earnings, to engage in whatever exchanges of health-related goods and services they choose, and to engage in whatever behaviors they choose—provided they respect the equal rights of others. Cato scholars maintain that in a free and open society, the government should play no special role in health or medicine: In the absence of violence, theft, tortious injury, fraud, or breach of contract, introducing the government’s power to coerce is unwarranted, immoral, and counterproductive.

For example, Cato scholars assert that federal and state governments deny individuals the freedom to choose whether to purchase health insurance and what type; deny the freedom to choose whether and how to provide charitable care; restrict patients’ ability to choose their course of medical treatment; restrict free entry into the medical professions; prohibit the sale of human organs; and refuse to honor contracts limiting providers’ liability for malpractice. These scholars argue that individuals have a fundamental right to self-determination in each of these areas, free from any coercive restraints.

Where advocates of government regulation of drugs and medical devices claim that such regulation protects the public from unsafe products, Cato scholars maintain that government has no constitutional or moral authority to prohibit a patient from using a medical treatment that imposes costs on no one but herself or himself. Moreover, the economic literature suggests that the U.S. Food and Drug Administration (FDA) causes more morbidity and mortality than it prevents.

Likewise, proponents of medical licensing, which restricts entry into the professions and dictates what services each profession may offer, claim that it enhances the quality of care. Cato scholars say that licensure denies patients the right to be treated by the practitioner of their choice; that low-quality care is widespread despite licensing; that licensing does not improve overall quality because it reduces access to care (primarily among the poor); and the chief proponents of licensing are incumbent practitioners who profit by restricting entry; and that licensing has enabled the medical profession to resist evidence-based efforts to improve quality such as electronic medical records. Cato scholars further argue that markets—backed up by the tort system—develop voluntary means of ensuring quality, such as hospital-admitting privileges and board certification.

Cato scholars argue that laws prohibiting the sale of human organs (to transplant patients or organ brokers) restrict the freedom of individuals to control their own bodies, cause an artificial shortage of transplantable organs that leads to thousands of unnecessary deaths each year, and ominously allow the government to assert a property right in the body of every citizen.

Cato scholars also object to the refusal of courts to uphold contracts limiting a provider's liability for malpractice in exchange for reduced-price or free medical care. Opponents of such contracts argue that patients harmed by negligent providers might not be able to recover. Cato scholars counter that such a rule limits the right of consenting adults to engage in mutually beneficial exchanges that harm no one else, reduces access to care among those least able to pay, and reduces experimentation with malpractice rules that ensure both quality and access.

Cato scholars argue that the government likely does the greatest damage in the area of financing medical care. Government programs such as Medicare and Medicaid finance nearly half of all medical expenditures in the United States, displace private markets, deny adults the freedom to choose how to fund their health needs in retirement and how to assist the needy, and waste scores of billions of dollars each year on services that make patients no healthier or happier. Cato scholars argue that targeted tax breaks, principally for employer-sponsored insurance, have much the same effects: They deny workers control over their earnings and health insurance decisions, encourage wasteful spending, strip workers of their coverage when they leave a job, and hamper the pursuit of high-quality, affordable healthcare.

Cato scholars seek to eliminate these restrictions on the freedom of individuals to control their earnings and on the decisions that affect their health. Moreover, Cato scholars reject government intervention to remedy private health problems, such as obesity, diabetes, or addiction.

Health Policy Impact

The Cato Institute has played an influential role in U.S. health policy for more than a decade. In 1992, the institute published the book *Patient Power: Solving America's Health Care Crisis*, which laid the intellectual foundation for the consumer-directed healthcare movement. Two years later, Cato published a companion book, titled *Patient Power: The Free-Enterprise Alternative to Clinton's Health Plan*, for a wider audience. The book made *medical savings accounts* a household term, helped defeat President Bill Clinton's Health Security Act, and set the stage for the creation of health savings accounts in 2003.

Cato scholars continue to advocate the restoration of liberties that have been eroded by political intervention in health and medicine.

CAUSAL ANALYSIS

Does smoking cause lung cancer? It is hard to believe that this was once a question in some dispute. Yet despite the fact that there has been no randomized controlled trial (RCT) in which research subjects were randomly assigned to smoking or nonsmoking conditions with subsequent long-term follow-up to ascertain differences in health outcomes, there has long been a consensus that smoking does indeed cause lung cancer, although it is certainly not the only cause. However, although smoking-and-health is certainly not the only case where a consensus has been reached about causality, asbestos exposure being another, the research literature and the popular press are full of cases where causal impacts are in hot dispute. For example, currently bisphenol A, a chemical found in baby bottles and many other plastic products, has been tentatively associated with various health conditions. However, the extent to which the association is causal and the strength of the effect, if any, remain in dispute, and a long series of investigations will need to be conducted to resolve the matter.

Why is causal inference so difficult? Even in cases where RCTs are possible, the results are often open to challenge. In cases where randomized studies are not possible, due to ethical or other reasons, establishing causality is far more difficult. The concept of cause itself is famously elusive. Apart from definitional problems, attempts to elucidate sets of causal criteria, from David Hume to John Stuart Mill to Austin Bradford Hill, have not provided necessary and sufficient conditions for concluding that an observed association between two variables results from the causal impact of one on the other. From the standpoint of social science research, at least three issues are problematic. First, many philosophical discussions of cause begin with a deterministic relationship. If X changes, Y changes, by the same amount and for all cases under study. But in health services research relationships are usually probabilistic and heterogeneous. A change in X may or may not result in a change in Y , the amount of change may vary across units of the population, and changes in X may not be the only source of variation in Y . While statistical models are designed to cope with probabilistic outcomes, they are often based on assumptions that are difficult to defend (e.g., that the source of random noise in the data is uncorrelated with systematic sources of variation). A second problem, related to the first, is that variation in many outcomes is multicausal. For example, a teenager's proclivity to commit violent acts may have its origins in a variety of genetic and environmental factors, any one of which may be sufficient to cause violent behavior in some but not all persons exposed to the risk. Finally, in health services research, researchers are often interested in a causal sequence such that at a particular attribute, say race, puts an individual at varying levels of risk for some outcome, say discrimination, which in turn is reflected in a subsequent outcome such as access to healthcare. Demonstrating the validity of the mediational assumption is often difficult.

An important source of confusion is a failure to distinguish between research that seeks to find the *causes of an effect* and that which examines the *effects of causes*. In the former case, researchers seek to elucidate a set of variables that explain variance in some outcome, say the probability of preterm birth. The result may be a series of regression models in which various candidate variables

are considered as possible causes (risk factors) of the outcome. Not uncommonly, the variables are a mixture of demographic, biological, and psychosocial measures, and the researcher seeks to determine which of them are “important.” Studies of this kind are essentially descriptive, however sophisticated the statistical analysis, and open to the charge that this or that variable has been ignored or badly measured or that a particular population has been excluded. While it is true that work of this kind has a degree of cumulativeness as researchers come to agree on a set of relevant variables and then explore those variables in increasingly diverse populations, the process is slow and difficult to focus. Results are often presented with very little serious comparison to other studies in terms of effect sizes, samples, and other details. Given the usual constraints of journal publication, this is understandable but nonetheless lamentable.

Effects of Causes and Potential Outcomes

In contrast are studies that seek to determine the *effects of some cause*, say the effect of a particular health promotion intervention for expectant mothers on the probability of a preterm birth. Here, the focus is on a particular variable, which, at least potentially, can be manipulated. Indeed, one point of view is that of “no cause without manipulation,” ruling out causal effects of fixed attributes of individuals such as gender and race. While many argue with this point of view, at least potentially, the definition of *cause* can be lodged in the difference or change that comes about in an outcome variable as a result of exposure to different conditions. Other variables may be important, particularly if the study is not randomized, but by focusing on a particular well-defined potential cause, at least some difficulties are avoided.

Donald Rubin has formalized this idea in what has become known as the potential outcomes approach. The basic idea is quite simple. In a simple two-group study in which some subjects are exposed to some “treatment”—a drug, an educational program, a particular environment—and others are not, researchers can think of an individual as having a score on an outcome variable Y under both circumstances. For every individual i ,

there is potentially Y_{i_t} , person i in the treatment condition, and Y_{i_c} , the *same person* in the control condition. An obvious measure of effect then is $Y_{i_t} - Y_{i_c}$. But researchers do not see persons in both conditions; one of them is *counterfactual* and thus a form of missing data, a fact that has been called *the fundamental problem of causal inference*. This point is a bit subtle; typically researchers talk about “changes in X causing changes in Y .” The potential outcome approach asks researchers to think about changing the conditions under which a particular subject is observed, which leads to the counterfactual. These ideas easily generalize to multiple group designs.

Randomized designs assume that the potential effect of treatment is the same for subjects in both groups (i.e., that had subjects in the control condition been in the treatment group, the treatment effect for them would have been, on average, the same as it was for the subjects who were actually there). But when subjects self-select, it is possible that the treatment effect among the treated group would be quite different from the potential treatment effect among those who were not treated. Thus one can think about the treatment effect among the treated as opposed to the (potential) treatment effect among the non-treated. Even in crossover research designs, where subjects are observed in both conditions, they experience the conditions in a particular order (e.g., the control condition first, and for a given subject, the opposite order is counterfactual). For the sample two-group case, an obvious “solution” is to compute the difference in the means, $\bar{Y}_E - \bar{Y}_C$ as a measure of effect, realizing that the two means are computed on different groups of subjects, and the question then becomes whether that is justified.

Randomized Studies

A controlled experiment, in which subjects are assigned at random to two or more treatment conditions, is the bedrock of causal inference. This design, known in the medical literature as a randomized controlled trial (RCT), allows a researcher to rule out alternative explanations of observed postintervention differences between groups on the basis of long-run equivalence of the two groups, that is, the expected value of the group

means prior to the intervention being the same. Although investigators sometimes worry about *randomization failure* (i.e., the persistence of group differences on one or more variables after properly executed randomization), standard methods of statistical inference evaluate the probability of observed postintervention differences relative to the variability introduced by randomization. It is easy to show that if the assumptions are met, simple mean comparisons in a randomized study result in unbiased estimates of causal effect.

Despite its obvious strengths, the randomized design is not without problems. Randomization is sometimes more easily designed than done. Elaborate randomization schemes may not work in practice, research subjects may not comply with the treatment, and measurement may be biased in particular treatment groups. Generalization to the intended population (referred to as *selection bias*) is often a major source of difficulty. It may be difficult to recruit and retain subjects in RCTs, particularly those in which some risk is involved or in which a potentially effective treatment for some disease is withheld from members of the control group. In many cases, potential subjects for a study are relatively rare, and as a result the study is conducted at a number of different institutions that draw on populations that vary in numerous ways. Although a formal requirement for generalization (i.e., to support the computation of *p*-values in standard statistical analysis) is that the sample be drawn such that each member of a well-defined population has a known probability of inclusion, this is often not feasible. Instead, subjects are recruited from available sources, such as patients in medical practices or self-selected volunteers recruited in various ways. Thus, the experimental result may be generalized to an ill-defined local population, and the degree to which the intervention will be effective to the population at large is unknown.

When it can be conducted, the RCT remains the gold standard for causal inference. Unfortunately, in many areas of investigation, that standard is unreachable. In some cases, randomization is literally impossible. The effects of natural disasters on healthcare delivery are of intense interest, but hurricanes cannot be delivered at random. In other cases, randomization might, in principle, be feasible, but strong ethical barriers exist. One can

imagine a randomized study of the effects of breast-feeding but assigning mothers at random to conditions would encounter strong resistance both from ethics review boards and from the potential research subjects themselves. Finally, even when randomization is possible, it may only be feasible at the group level, as when particular hospital units and all patients in them are assigned to an intervention and other units are the controls. This design, known as a *group randomized trial*, brings with it other issues of analysis and generalization. In particular, the statistical power of such trials is notoriously low.

Observational Studies and Quasi-Experiments

In many cases then, randomized studies are simply impossible. In some cases, researchers might conclude that the trade-off between using data from a true probability sample that does not permit randomization versus a randomized study on a non-probability sample is worth it. An example in the United States is the Health and Retirement Study, in which a representative cross-sectional sample of the population 51 to 61 years of age was sampled at baseline and has been followed longitudinally for many years. Various life course events and transitions such as retirements and major illnesses occur over the course of the study. With observations at fixed intervals, these events occur more or less at random with respect to observation points, and investigators have varying amounts of pre- and postevent data. The determinants of such events can be studied (causes of effects), or their sequelae (effects of causes) can be studied. Thus the study is strong on one form of generalization at the expense of being weak on another. A study of this kind is usually referred to as *observational*, a word that highlights the passive nature of the design.

Although some researchers refer to any nonrandomized study as observational, quasiexperiments usually involve some comparison or manipulation of experimental conditions but without randomization and other aspects of control associated with true experiments. Sometimes the intervention is under the control of the researcher, such as providing an “exercise and healthy eating program” in a workplace to self-selected participants. In

other cases, the investigator takes advantage of a so-called natural experiment as might be the case when a health facility introduces an electronic clinical records system or when a change in regulation requires healthcare suppliers to deal suddenly with new clients. There are many variants on the quasiexperimental theme. Over the years, an elaborate classification of such designs, each assessed with respect to its various strengths and weaknesses, has emerged.

Faced with nonrandom assignment, the instinctive thing to do is to statistically adjust group comparisons for preexisting differences. A simple way to do this is via *blocking* or stratification of the sample on one or more variables that are associated with the outcome and that are differentially distributed across comparison groups. For example, if women were more likely to choose an exercise program than were men and it was suspected that gender was related to the outcome variable, gender could be treated as a design factor, although the result is frequently “unbalanced” because members of one gender self-select into a particular condition. This approach not only allows researchers to explore the effects of the intervention conditional on gender but also may substantially increase the statistical power of the analysis. It is relatively rare, of course, to have to deal with only one potentially contaminating variable. More commonly, there are many such variables, and researchers deal with them by treating them as linear covariates in regression-type models. This approach to analysis has been the backbone of many research areas for many years.

There are several difficulties with this approach, however. First, researchers never can know if the right covariates are in the model. In many cases, there are relatively few of the potentially important covariates actually observed. Second, most models treat the effect of covariates in simply linear and additive terms. In principle, this is not necessary; any functional form is admissible, and covariates can interact. However, relatively large sample sizes are required to deal with such complexities, and in any case, researchers often do not make the effort. A third issue is “balance.” Suppose researchers want to assess the effects of socioeconomic status (SES) on healthcare utilization. For simplicity, assume that SES is measured

in quartiles on some composite of education and income. Noting that race (measured simply as White/non-White in this example) is strongly correlated with the outcome, the researchers control on it. But the association of race and SES is such that the lowest SES quartile consists almost entirely of non-Whites and the reverse is true in the highest quartile. In such a case, what does it mean to look at the effects of SES, “holding race constant?”

Matching and Propensity Scores

One way to avoid the unbalanced comparison problem is by matching. Some decades ago, matching fell into some disrepute, largely as a result of the difficulty of matching on multiple variables. In fact, one can see the “blocking on gender” example above as a primitive form of matching. Recent work has led to a variety of sophisticated approaches to matching on multiple variables along with a set of weights indicating the quality of the match. A very popular approach is to create a set of propensity scores in which the researcher regresses a 0/1 indicator for group membership on a set of covariates and estimates the probability of being in one group or another based on them. The estimated probability summarizes all the available information in the covariates and allows the researcher to stratify the sample on propensity scores, assess the balance across groups on those scores, and carry out analyses within strata. Many other approaches are possible, including using the propensity scores directly in the analysis or as weights. These methods require the researcher to assume that all potential sources of bias are directly observed. More sophisticated methods, particularly when longitudinal data are available, permit researchers to control on unobserved sources of bias as well.

Statistical Approaches

Whether or not researchers match in some fashion, in recent years, several statistical approaches to dealing with nonequivalent comparison groups have emerged. The space available does not permit a lengthy discussion here, but two approaches bear mentioning. The first is to model

the selection process itself. Ideally, researchers look for one or more variables that determine selection but that are correlated with the outcome only via the effects on treatment. That is, the variables in the selection equation cannot have a direct effect on the outcome. Finding such variables is not easy, although not impossible. A famous example is the random selection of birth dates to determine eligibility for the Vietnam era military draft. Researchers interested in the effects of military service on later income were able to use birth date as an instrument for military service in income estimation equations. Causal estimates from models of this kind are strongly dependent on assumptions and require careful sensitivity analyses. Recent statistical work has focused on establishing upper and lower bounds for effects in these kinds of models and others.

A second approach is known as the regression discontinuity design. Suppose that selection for treatment is based on some cutoff on a continuous measure, for example access to subsidized medical care. All subjects below an income cutoff get the treatment, while those above it do not. Obviously, the cutoff is somewhat arbitrary, and those just above the cutoff are probably not a great deal unlike those just below it. As a result, a regression of the outcome variable on the selection variable is likely to show a jump (a change in the intercept) and perhaps a change in the slope of the regression line at the cutoff.

Future Implications

It is comparatively rare for a single randomized study to definitively resolve a causal question and even rarer for an observational study to do so. Studies which seek to isolate causes of effects rather than effects of causes are unlikely to ever do so. Still, as the history of research on smoking and health demonstrates, resolutions are achievable. Technical approaches to summarizing available information, such as meta-analysis, continue to grow in sophistication. So also do institutionalized means of reconciling controversial and conflicting evidence such as the U.S. Preventative Agencies Task Force and formal National Institutes of Health (NIH) consensus conferences. The process is slow and sometimes discouraging. In most cases, even for most well-designed randomized

studies, close replication is essential. Somehow, regardless of statistical niceties, researchers are generally more confident of independent replications that reach the same conclusions. With regard to observational studies, the conclusions of which tend to be assumption-dependent, supportable conclusions tend to be achieved when researchers have conducted a series of studies that reach similar conclusions in the face of a substantial variation in design and analysis rather than from exact replications. Usually, that variation occurs in an unplanned way, and thus the time to reach a consensus is longer than it might be in the face of a more systematic approach. This is unfortunate because the public finds itself buffeted by each sequence of studies that contradict previous well-publicized results, and public confidence in the research enterprise often suffers as a result. Still, a great deal of significant work in causal inference has been accomplished in recent decades, the result of which has at least been increased clarity in what needs to be done. Two things head the list: rapid and wide diffusion of techniques more appropriate than simple regression models for the analysis of observational data; and greater insistence from journal editors that authors take prior work seriously, carefully specifying how the research design and results of their own analyses differ from the best prior work.

CENTER FOR STUDYING HEALTH SYSTEM CHANGE

Founded in 1995, the Center for Studying Health System Change (HSC) is a nonpartisan policy research organization based at Washington, DC, focused on changes in the financing, delivery, and quality of healthcare in the United States, with a particular emphasis on the policy implications of these changes. The HSC strives to provide high-quality, timely, and objective research and analysis that lead to sound policy decisions, with the ultimate goal of improving the health of the American public. Instead of advocating for particular policies, the HSC serves as an honest broker of information for policymakers, the news media, employers, healthcare providers, health insurers, and the public.

All research undertaken by the HSC is consistent with the organization's mission to inform healthcare decision and policymakers about changes in the healthcare system at both the local and national levels. The HSC is funded principally by the Robert

Wood Johnson Foundation (RWJF) but also conducts research consistent with its mission for others, including foundations and government agencies. The HSC is affiliated with Mathematica Policy Research, a leader in evaluating the effectiveness of local, state, and federal, health, human services, and educational programs.

To preserve the HSC's reputation for high-quality, independent, and nonpartisan research, nurtured and sustained during the long period when the RWJF was the sole source of support, the HSC only accepts funding when it retains the right to publish all research results. Final research topic selection, methodological, and editorial decisions ultimately reside with the HSC. Guided by these principles, the HSC seeks research support from many different types of sources: government entities, foundations, and private nonprofit and for-profit organizations.

Healthcare in Communities

Ultimately, all healthcare is organized and delivered in local communities—where the HSC collects information about the changing health system. The HSC's main research tool is the Community Tracking Study (CTS), which consists of national surveys of consumer households and physicians. The HSC also conducts intensive site visits at 12 metropolitan communities selected randomly to be representative of the nation. Led by Paul B. Ginsburg, a nationally known health economist and health policy expert, the HSC researchers combine quantitative and qualitative research from the surveys and site visits to provide policymakers with a vibrant picture of changing healthcare market dynamics and the implications for healthcare policy. The HSC researchers—economists, physicians, sociologists, and public policy experts—are knowledgeable about a wide range of healthcare policy topics. Their areas of expertise include private health insurance coverage, access to healthcare by the uninsured, healthcare quality, and healthcare markets. The HSC researchers regularly publish in peer-reviewed journals, including *Health Affairs*, *The New England Journal of Medicine*, *The Journal of the American Medical Association*, *Archives of Internal Medicine*, *Inquiry*, and *Health Services Research*.

Key Policy Research Areas

The HSC's focus on local market dynamics allows it to provide targeted research that can contribute to better health policy. To assist policymakers, the HSC focuses on four key policy research areas: health insurance coverage and costs, access to healthcare, quality and healthcare delivery, and healthcare markets.

National Household and Physician Surveys

Since 1996, the HSC has conducted four national surveys of American households and physicians and is in the process of conducting the fifth survey. Approximately 46,600 people in 25,400 families take part in the household survey, which focuses on assessing whether consumers' access to healthcare is improving or declining over time. The household survey also explores patients' satisfaction with the healthcare they receive and with their health insurance coverage. Approximately 6,600 practicing physicians across the nation provide survey information about how the practice of medicine is changing. In the physician survey, they respond to questions about their ability to provide needed services for patients, how much charity care they provide, how they are compensated, and other topics.

Site Visits to Nationally Representative Communities

In 2007, the HSC completed its sixth round of intensive site visits to Boston, Massachusetts; Cleveland, Ohio; Greenville, South Carolina; Indianapolis, Indiana; Lansing, Michigan; Little Rock, Arkansas; Miami, Florida; northern New Jersey; Orange County, California; Phoenix, Arizona; Seattle, Washington; and Syracuse, New York. In each community, the HSC researchers interviewed between 50 and 100 local healthcare leaders, including employers, physicians, hospital executives, policymakers, safety net providers, and health insurers.

Additional Research Projects

Although principally funded by the RWJF, the HSC also conducts research for others consistent

with its mission. Recent and current funders include the Agency for Healthcare Research and Quality (AHRQ), the California HealthCare Foundation, the Commonwealth Fund, the Henry J. Kaiser Family Foundation, the National Institute on Aging, the National Cancer Institute, the Health Care Financing and Organization Program of the RWJF, and the U.S. Department of Health and Human Services, Assistant Secretary for Planning and Evaluation.

Timely Access to Publications and Related Data Files

The HSC is committed to providing policymakers, the news media, the public, and researchers with convenient and timely access to its survey data files and related publications. The HSC's publication series includes *Issue Briefs*, *Data Bulletins*, *Tracking Reports*, and *Research Briefs*—all of which combine to provide detailed information on survey and site-visit findings. All the HSC's publications and public-use and restricted-use data files are available on its Web site. The HSC also offers a convenient e-mail notification service to alert interested parties to its new publications and research that is available on its Web site.

CTSONline

CTSONline is an easy-to-use, Web-based tool provided by the HSC to allow policymakers and the public to quickly access and interpret data from its surveys.

CENTERS FOR DISEASE CONTROL AND PREVENTION (CDC)

The Centers for Disease Control and Prevention (CDC), which is part of the U.S. Department of Health and Human Services (HHS), is the nation's premier and largest public health organization. The CDC is composed of the Office of the Director, the National Institute for Occupational Safety and Health (NIOSH), and six coordinating centers and offices. With its headquarters in Atlanta, Georgia, the CDC employs more than 14,000 employees in 170 occupations. Most of its employees work at its headquarters, but others work in Washington, D.C., in other cities in the nation, and in more than 40 foreign countries.

History

The CDC evolved out of a World War II malaria control program—Malaria Control in War Areas

(MCWA). Formally established in July 1, 1946, the organization was originally known as the Communicable Disease Center (CDC). The CDC's early work concentrated on malaria control in the United States. However, it was soon engaged in other public health problems such as polio by providing assistance to local governments and public health departments facing epidemics and disasters. Over time, the CDC's mission continued to broaden, expanding beyond infectious diseases to include chronic diseases, nutrition, and occupational and environmental health. To reflect these changes, the organization has changed its name a number of times; however, it has always kept the same acronym, CDC. In 1970 it changed its name from the Communicable Disease Center to the Center for Disease Control, in 1980 to the Centers for Disease Control, and in 1992 to its current designation, the Centers for Disease Control and Prevention.

Goals and Strategic Areas of Focus

Currently, the CDC has four stated organizational goals. Specifically, it works to have (1) healthy people in every state of life by reducing health risks; (2) healthy people in healthy places by ensuring that all locations including where people live, work, and play are healthy environments; (3) people prepared for emerging health threats by safeguarding them and responding to threats; and (4) healthy people in a healthy world through efforts to improve global health using medical technology, international coalitions, government interventions, and behavior changes.

To reach these goals, the CDC focuses on six strategic areas: (1) health impact focus—align the CDC staff and other resources to maximize health; (2) customer-centricity—provide what people want; (3) public health research—create and disseminate healthcare knowledge; (4) leadership—use the CDC's expertise to improve health; (5) globalization—extend the CDC's knowledge around the world; and (6) accountability—sustain confidence and trust.

Organizational Structure

The current organizational structure of the CDC includes the Office of the Director, the National

Institute for Occupational Safety and Health (NIOSH), and six coordinating centers and offices: (1) Coordinating Center for Health Information and Services, (2) Coordinating Center for Health Promotion, (3) Coordinating Center for Infectious Diseases, (4) Coordinating Center for Environmental Health and Injury Prevention, (5) Coordinating Office for Terrorism Preparedness and Emergency Responses, and (6) the Coordinating Office for Global Health.

Office of the Director

The Secretary of the HHS appoints the director of the CDC. The heads of each of the CDC's six coordinating centers and NIOSH as well as the heads of nine offices directly report to the director. The reporting offices include the following: Office of Chief Science Officer; Office of Chief of Public Health Practice; Office of Chief Operating Officer; Office of Strategy and Innovation; Office of Workforce and Career Development; Office of Enterprise Communication; Office of Chief of Staff; Office of Dispute Resolution and Equal Opportunity; and the CDC Washington Office.

National Institute for Occupational Safety and Health (NIOSH)

Headquartered in Washington, D.C., with research laboratories in Cincinnati, Ohio; Morgantown, West Virginia; Pittsburgh, Pennsylvania; Spokane, Washington; and Atlanta, Georgia, and with a staff of more than 1,400 employees, NIOSH is the largest division of the CDC. NIOSH is responsible for conducting research on new safety and health problems and making recommendations for the prevention of work-related injury, illness, disability, and death. Its specific objectives include conducting research to reduce work-related illness and injuries; promoting safe and healthy workplaces; and enhancing global workplace safety and health through international collaborations.

Coordinating Center for Health Information and Services

This CDC coordinating center oversees three centers that provide the public with access to information and statistics on a variety of health topics.

The National Center for Health Marketing provides current, science-based information to the public. It conducts research in the area of health marketing and communicates and publishes the results. This center is responsible for publishing the *Morbidity and Mortality Weekly Report (MMWR)*, which reports on disease trends and outbreaks each week. The center also runs the Health Alert Network (HAN), which provides instant information regarding serious health threats to a network of public health departments across the nation. The Public Health Training Network, another service of the center, is a professional development resource for public health workers, which provides listings of conferences and workshops, satellite broadcasts, and other learning opportunities of which public health workers may avail themselves.

The National Center for Health Statistics (NCHS) collects data from a variety of sources. The data are then used to identify and address health problems. The NCHS tracks trends in births, deaths, marriages, divorces, the aging population, hospital discharges, nursing home residents, and many other topics. Its data are widely used by policymakers, researchers, and public health professionals to address various health problems.

The National Center for Public Health Informatics coordinates technology-based applications to achieve CDC's goals. The use of computers and associated applications has become increasingly important in the public health field. The center also works to support other CDC centers and offices.

Coordinating Center for Health Promotion

This CDC coordinating center oversees two centers: (1) the National Center on Birth Defects and Developmental Disabilities and (2) the National Center for Chronic Disease Prevention and Health Promotion.

The National Center on Birth Defects and Developmental Disabilities conducts research and health promotion efforts addressing the causes of birth defects and provides resources to people dealing with these conditions. The center's programs work to educate women about healthy pregnancy. It also strives to provide resources and information about developmental disabilities such

as hearing loss, cerebral palsy, mental retardation, and other conditions.

The National Center for Chronic Disease Prevention and Health Promotion focuses on preventing chronic disease conditions such as heart disease, cancer, and diabetes. Chronic diseases are among the leading causes of death in the United States, and this center coordinates research and health promotion efforts to inform interventions and target illnesses. In addition to health disease, cancer, and diabetes, the center's programs also address chronic conditions such as stroke, epilepsy, and arthritis.

Coordinating Center for Infectious Disease

This CDC coordinating center oversees four centers that target specific infectious diseases. The four centers are (1) the National Center for HIV/AIDS, Viral Hepatitis, STD and TB Prevention; (2) the National Center for Immunization and Respiratory Diseases; (3) the National Center for Zoonotic, Vector-Borne, and Enteric Diseases; and (4) the National Center for Preparedness, Detection, and Control of Infectious Diseases. Each of these centers targets a specific type of infection, such as tuberculosis, sexually transmitted diseases, and the West Nile virus, and focuses on its prevention, control, and treatment efforts.

Coordinating Center for Environmental Health and Injury Prevention

This CDC coordinating center oversees two centers: the National Center for Environmental Health/Agency for Toxic Substances and Disease Registry; and the National Center for Injury Prevention and Control.

The National Center for Environmental Health conducts research, surveillance, and education related to the interaction between humans and the environment. Its responsibilities include protecting the public from hazards in the environment. This center has three divisions: (1) the Division of Emergency and Environmental Health Services, (2) the Division of Environmental Health Hazards and Health Effects, and (3) the Division of Laboratory Sciences.

The Division of Emergency and Environmental Health Services works to develop policy initiatives

and prevention activities related to environmental public health emergencies. The programs within this division address several health issues such as the safe and healthy use of land, elimination of chemical weapons, food and water safety, sanitation, housing, lead poisoning, and the health and well-being of refugees. In relation to disease investigation, this division monitors cruise ships for cases of gastrointestinal illness.

The Division of Environmental Health Hazards and Health Effects conducts research and education relating to the interaction of humans and the environment, including activities that focus on air pollution and respiratory health, asthma, carbon monoxide, and radiation.

The Division of Laboratory Sciences investigates exposure to toxic chemicals and other substances in the environment, and their effects on human health, through the use of laboratory methods. Through the testing of blood and urine samples, scientists in the laboratory are able to measure the amounts of chemical substances in a person's system.

The Agency for Toxic Substances and Disease Registry (ATSDR) is also housed with the coordinating center. The ATSDR is 1 of the 13 federal agencies with the HHS. It is mandated by the U.S. Congress to conduct specific activities that relate to hazardous substances in the environment. The agency's responsibilities include monitoring of waste sites, health consultations, surveillance, education and training, and research. The ATSDR is one agency that responds to emergencies caused by the release of hazardous substances. It also develops information for the public regarding hazardous substances.

The National Center for Injury Prevention and Control is the lead agency in the nation's efforts to prevent unintentional injuries. This center tracks cases of injury and assesses their associated risk factors. One well-known publication of the center is a list of the 10 leading causes of death. This list, which is compiled annually by various age groups, is widely used by educators, researchers, and public health professionals in their efforts to prevent injury.

Coordinating Office for Terrorism Preparedness and Emergency Response

This office addresses emergency preparedness for natural disasters and terrorist attacks. The

office educates first responders, healthcare professionals, and the general public about the types of emergencies that may occur. It also provides information on recent outbreaks, natural disasters, and other emergency events. Additionally, state and local health agencies take their lead from this office, and the office oversees grants and support to state, local, and community preparedness efforts.

Coordinating Office for Global Health

This CDC office partners with other health agencies and works to address global public health threats. The office's International Experience and Technical Assistance Program trains public health workers at the federal level to increase experience at the international level. Its Division of Epidemiology and Surveillance Capacity Development initiative works toward improving the disease investigation infrastructure at an international level. This division provides technical assistance to foreign nations, partners with international organizations to improve surveillance for infectious diseases, and works toward disease prevention efforts. The office's Sustainable Management Development Program collaborates with global partners to provide leadership and development of public health systems worldwide. The program attempts to look beyond theory and focuses on skills-based initiatives.

Future Implications

The CDC is the nation's, and to a great extent the world's, public health department. Its public health efforts, coordinated through the NIOSH and its various coordinating centers and offices, focus on disease prevention and health promotion, disease investigation and surveillance, and emergency and disaster preparedness. Today, and in the foreseeable future, the CDC will remain the global leader in public health.

CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS)

The Centers for Medicare and Medicaid Services (CMS), formerly known as the Health Care Financing Administration (HCFA), is a federal agency within the U.S. Department of Health and Human Services (HHS). CMS is the nation's largest purchaser of healthcare, it is responsible for administering the Medicare program, and it works collaboratively with states to administer the Medicaid program and State Children's Health Insurance Program (SCHIP). Additionally, CMS also works to simplify the standards associated with the Health Insurance Portability and Accountability Act of 1996 (HIPAA), ensure quality standards in long-term care facilities through surveys and certification, and maintain clinical laboratory standards of quality through the

Clinical Laboratory Improvement Amendments (CLIA). The agency employs nearly 4,100 employees and serves approximately 92 million individuals through all its programs. The CMS headquarters is located in Baltimore County, Maryland, with an office at the Hubert H. Humphrey Building in Washington, D.C., and 10 regional offices across the country.

Overview

President Lyndon B. Johnson signed the legislation that established the Medicare and Medicaid programs into law on July 30, 1965. Initially, the Social Security Administration (SSA) administered the Medicare program, while the Social and Rehabilitation Service Administration (SRA) ran the Medicaid program under the purview of the Department of Health, Education, and Welfare (DHEW). However, because of growing healthcare costs, the HCFA was formed in 1977 to coordinate both the Medicare and the Medicaid programs under the auspices of DHEW. In 1980, DHEW was divided into the Department of Health and Human Services (HHS) and the Department of Education (DOE), with the HHS overseeing the responsibilities of the HCFA.

The agency was later renamed the Centers for Medicare and Medicaid Services in 2001 to reflect its mission better. CMS's vision is to transform and modernize the U.S. healthcare system.

Today, CMS serves the elderly and disabled through its Medicare program, the low-income population through Medicaid, and children and families through SCHIP. The Medicare and Medicaid programs combined account for nearly one third of the nation's healthcare expenditures. The agency is dedicated to administering its program as efficiently as possible. In FY2009, the estimated total benefit costs are expected to be \$703.9 billion.

Medicare

CMS has the primary responsibility of administering the nation's Medicare program. Medicare is a health insurance program for individuals aged 65 or older, individuals with certain disabilities, and

those with end-stage renal disease. Since its inception, the Medicare program has grown 130%, from 19.1 million enrollees in 1966 to 43.9 million in 2007.

In 2003, one of the most significant changes to the Medicare program since its inception was signed into law. The Medicare Modernization Act (MMA) included provisions for an outpatient prescription drug benefit for Medicare beneficiaries and several other changes to the program.

Medicaid

Medicaid is a joint state and federal program that provides healthcare coverage to certain groups of low-income individuals and families who qualify. The states administer the program, and they may set their own eligibility and benefits guidelines. To participate in the Medicaid program, certain requirements need to be met such as age, income, disability, and citizenship. The average monthly enrollee for the Medicaid program in 2007 was estimated to be 48.1 million individuals, with the largest group being children.

State Children's Health Insurance Program

In 1997, SCHIP was created to address the needs of uninsured children. SCHIP is a program funded jointly by the federal government and states and it is administered by the states. This program provides low-cost health insurance coverage to children and families. Each state determines the eligibility, benefits, design, payment level, and operating procedures for the SCHIP program within federal guidelines. Under this program, the states are given a capped amount of matching funds by the federal government.

Research

CMS collects and maintains a wealth of quantitative data on its programs and makes them available to researchers. These data include information on claims, spending, and enrollment. The agency is also involved in conducting its own research efforts, such as examining patterns in prescription drug use, risk-adjustment methods for different

payment systems, quality initiatives, and consumer assessments. In addition, CMS performs demonstration projects to examine alternative policies for healthcare coverage and delivery. The Office of Research, Information, and Development within CMS coordinates these activities.

Some of the agency's initiatives include the Consumer Assessment of Health Providers and Systems (CAHPS) Survey, Health Outcomes Survey, Hospital Compare, and pay-for-performance. CMS also publishes a subscription journal, *Health Care Financing Review*. The review is dedicated to improving the understanding of the Medicare and Medicaid programs and the U.S. healthcare system by examining delivery and financing issues.

Outreach and Education

CMS provides numerous outreach and education initiatives to assist healthcare providers, professionals, and volunteers with its programs. The Medicare Learning Network (MLN) presents educational information to fee-for-service healthcare providers and promotes the responsiveness of the agency. MLN also helps providers deal with changes in Medicare policy. The National Medicare Training Program (NMTP) provides training to professionals and volunteers to help Medicare beneficiaries make informed decisions. The Provider Communications Group at CMS develops and disseminates provider education campaigns that involve Medicare fee-for-service programs. Through these various outreach and educational efforts, CMS employs a diverse set of methods using the Internet, fact sheets, brochures, videos, and Web-based training courses.

Future Implications

The Medicare and Medicaid programs will face a number of challenges in the future. The aging of the nation's population and the demand to meet the growing entitlement has raised serious questions regarding the solvency of the programs. Despite this, the CMS continues to serve the needs of its beneficiaries by ensuring healthcare coverage to millions of Americans. Although many

challenges remain, with increased enrollment and rising healthcare costs, the agency strives to further the vision of President Lyndon B. Johnson's Great Society to provide accessible, high-quality healthcare for the elderly, disabled, and poor.

CERTIFICATE OF NEED (CON)

Certificate of need (CON) is a state-level regulatory process first established more than 40 years ago for the purpose of rationalizing the growth and distribution of hospitals, other health facilities such as nursing homes and ambulatory surgery centers, and expensive healthcare equipment and services. In this process, a hospital or other healthcare provider must establish through an analysis that a need exists in a specific service area for the new or expanded facility or proposed service. This analysis is reviewed by a state agency or appointed health services planning body, often in a formal public hearing during which sponsors and opponents of the proposed expenditure can argue their case. If a determination is made that a need actually exists consistent with the sponsor's proposal, a CON is issued that grants the sponsor permission to proceed with the project. Currently (2007), 36 states plus the District of Columbia and the Virgin Islands have CON legislation in place. CON has been controversial during most of its history, with much of the debate centering on whether it is necessary, if it actually works, and more fundamentally, if a regulatory tool is an appropriate way to plan and control aggregate health-related investment in the United States.

CON was established at a time when healthcare services in the nation were undergoing a period of profound growth, driven by the expansion of employer-sponsored health insurance and the Medicare and Medicaid programs, along with federal subsidies for hospital construction. Prior to the end of World War II, health services grew slowly, with little investment for new hospitals or modernization. At that time, all but the largest teaching hospitals were sponsored by or affiliated with a specific community, a religious denomination, or a fraternal organization. Hospital construction and modernization at that time was financed by philanthropic and community fund raising efforts. The expansion of private and public health insurance allowed hospitals to generate needed capital internally from patient revenues. Beyond this internal source, the 1946 federal Hill-Burton Act provided grants to hospitals for construction and modernization.

By the mid-1960s, the nation's total healthcare spending had accelerated to a point where the concerns about hospital bed shortages of 20 years before were replaced with concerns that the U.S. healthcare system was becoming too expensive and that healthcare costs were out of control, largely because of unregulated construction, expansion, and purchase of new technology. Since 1966, a voluntary form of health planning and CON existed in a growing number of states. Rochester, New York, piloted the concept in 1964, where a coalition of local businesses and Blue Cross established a community health planning council to evaluate hospital need. Impressed by the Rochester experiment, and spurred by the federal Comprehensive Health Planning Act (PL 89-749) of 1966, New York State, followed closely by Maryland, Rhode Island, and the District of Columbia, soon enacted CON legislation. Voluntary CON was eventually established in 29 states prior to the federal mandate. In 1974, the U.S. Congress enacted the National Health Planning and Resources Development Act (PL 93-641), making CON mandatory for all states as a condition for receiving certain federal funds. By 1978, 42 states plus the District of Columbia had enacted CON laws, with CON in place in all states except Louisiana by 1986, when federal funding for CON ended.

Rationale

The rationale behind the use of CON to control the supply of medical services was based on a belief that normal economic market forces that bring demand and supply into balance for other goods and services would not work for medical services. There were several reasons why this was believed to be true. On the demand side, unlike other goods and services in the marketplace, consumers don't make an informed decision about which medical care service they will receive. First, as medical care is highly specialized and complex and beyond the understanding of most consumers, this decision is usually made by the person's physician. Seldom will a person refuse a medical service on cost grounds alone if the physician recommends it. Second, with the growth of health insurance coverage, patients don't directly pay for

the services they receive. Third-party payment insulates patients from the costs of medical services except for those that are paid out of pocket. Third, without quality or cost information, patients usually don't comparison-shop for medical services; and, when they do, they often wait until the time when they need the services for some acute medical condition. This puts the patient at a disadvantage in being able to behave as a consumer normally would.

On the supply side, unlike the case with most other goods and services in the marketplace, healthcare providers did not compete on price. Indeed, prices of medical services were seldom made public, and patients usually never knew the price of the service they were to receive until after they (or more accurately their insurance company) received the bill for the service. In addition, the supply of medical services seemed to generate its own demand. For example, a good predictor of surgical rates in a community was the number of surgeons, regardless of population need. So if two communities of similar size and population characteristics were compared, the one with the greater number of surgeons would likely have more surgeries performed. For hospital services, this phenomenon was so pronounced that it became known as the Roemer Effect, after the researcher who first noticed the relationship where "a bed built, is a bed filled." A community with more hospital beds is likely to fill those beds, regardless of population need.

Goals

While cost containment was the overriding motivation for CON, the 1974 federal health planning legislation outlined two primary purposes. The first was restraining skyrocketing healthcare costs, which was to be done through controlling the expansion of new healthcare services and preventing underutilization and unnecessary duplication of healthcare resources, which was thought to be the primary cause of skyrocketing healthcare costs. The U.S. Congress at the time found the national need for additional hospital beds had virtually disappeared, and as of 1974, an aggregate surplus of 20,000 underused beds existed.

CON had a second primary purpose, which was to achieve equal access to quality healthcare

at a reasonable cost. This often-overlooked purpose connected CON to a common thread in prior federal health legislation, including Hill-Burton, the comprehensive health planning act, and the landmark Medicare and Medicaid legislation. This reflected a deeply rooted concern that the nation's healthcare resources should be allocated in an equitable manner. Medicare and Medicaid made healthcare services affordable to the elderly and the poor. CON was to ensure that healthcare capital investment would not bypass low-income or rural communities as the U.S. healthcare system grew. This goal was linked to cost containment in recognizing that equal access would not be possible if healthcare services were not also affordable, and so controlling healthcare inflation was required to keep costs reasonable. Achieving this second purpose presented a challenge, as while CON provided a regulatory tool to limit capital investment that was proposed, it could not compel investment in an area deemed financially undesirable to a healthcare provider. However, by having the regulatory expectation that the needs of low-income communities should be considered, CON reviews were often able to leverage consideration of these needs in proposals that otherwise would not have done so.

Scope

While hospital construction and expansion was the initial focus of CON, given the relatively high cost of hospital facilities, it was soon realized that hospital building alone was not the only driver of healthcare costs. With advances in medical technology, new services, exotic imaging devices, and sophisticated treatment modalities were also being introduced. While most of these advances were hospital based, some were being proposed for other noninstitutional sites, including freestanding facilities where the new service or technology would be provided. These included most notably diagnostic scanners (e.g., CT, MRI, PET) and radiation beam treatment devices (linear accelerators and gamma knives). At the other end of the technology spectrum, long-term care services were also becoming a significant driver of runaway healthcare cost, and so nursing homes were an early focus of CON in all states.

After 1986, the range of review of facilities, services, and equipment covered by CON varied from state to state. Currently, some states take a comprehensive approach covering upward of 30 categories of service. Most states are less comprehensive, targeting CON to those services thought to be major cost drivers. Beyond service categories, states also adopted a financial threshold approach to CON, reviewing only those proposals that exceed a dollar threshold. Since the end of federal funding, state financial thresholds have varied greatly, ranging from under a \$0.5 million to more than \$10 million. The rationale for this approach is that the more expensive proposals are likely to make the most significant contribution to rising health costs.

Regulation Versus Planning

CON is at best only a partially effective remedy for achieving access points. It was never meant to be the only tool for either controlling cost or enhancing access but was to be partnered with health planning. The 1974 act set up a nationwide network of more than 200 community-based health planning agencies or health system agencies (HSAs) whose principal function was to develop local and state health system plans that attempted to bring into balance community needs with facilities and resources required to meet those needs. In each state and region, plans were drafted by a staff of professional health planners under the direction of an agency governing body of healthcare providers, consumers, educators, insurers, and local government officials. Hospital and nursing home administrators, along with practicing physicians and other healthcare professionals, were often among agency board members. The plans developed were to provide the framework that was to guide new construction, modernization, and the introduction of new expensive medical equipment and services by hospitals and other providers in the community. CON was intended to “put teeth” into the plans and the planning process. State CON laws usually called for an initial review by the local health system’s agency prior to consideration by the state CON body. A proposal would have to be judged consistent with the local plan to get a favorable review by the local agency, and the

favorable local review was a strong consideration in the review at the state level.

The composition of the local reviewing board often gave an advantage to the projects of local providers over those proposed by outsiders. And providers were seen as having undue influence on decisions of the local planning agency, sometimes leading to rejection at the state level of locally approved proposals. This attitude that CON was better in principle than in practice, especially when applied to a well-supported hospital expansion project, was one factor that led to its eventual unpopularity, its limited effectiveness, and the repeal of the federal mandate. Nonetheless, the linking of CON with planning at a local level provided an effective context to apply CON as a tool for achieving affordable access, as well as cost containment, as proposals could be reviewed against a plan that had specified local needs and optimal service performance. The local review process provided a mechanism to negotiate how those needs could be explicitly considered in the proposal under review.

Regulation Versus Competition

Nationally, regulation and CON fell out of favor as an approach to control healthcare costs after 1980, driven by several forces. First was the growing unpopularity of CON among healthcare providers and some communities whose projects did not receive CON approval. A second factor was that, despite the existence of mandatory CON in 49 states, healthcare costs continued to rise at an alarming rate. So, at least on the surface, there was a lack of clear evidence that CON was an effective cost containment tool. Third, and perhaps most significant, was the election of President Ronald Reagan. The year 1980 marked the ascendancy of a conservative trend in American politics and, with it, a belief that market forces and competition were more appropriate than regulation, which was seen generally as a tool of big government. Managed competition and especially managed care replaced planning and CON as the hope for controlling costs. Competition held up the promise of introducing market forces into healthcare, the lack of which was the reason behind the need for planning, regulation, and CON in the first place. In response to these forces,

in 1983, the U.S. Congress repealed the 1974 Health Planning Act and with it the federal mandate for CON (a continuing resolution maintained state funding for another 3 years). Without the federal mandate, some states began to repeal and roll back their CON laws, and the network of local health planning agencies started to dissolve. However, CON was retained in some form by most states, with only a handful opting for an outright repeal.

Throughout CON's history, healthcare providers have taken a contradictory posture toward it, largely reflecting the regulatory versus competition debate. In the early years, hospitals, in particular, were generally supportive of CON, recognizing the need for some form of planning. But as healthcare services began to look more like an industry, a belief that market forces and competition should work began to take hold, and opposition to CON increased. This opposition was behind the repeal of CON laws in 14 states and the paring down of CON's scope or raising reviewability thresholds in others. But hospitals also recognized that too much competition would not be good for existing hospitals, which might find themselves competing with neighboring facilities or, worse, a new for-profit corporately owned hospital, likely with better access to capital for new constructions and the latest medical technology. Under these conditions, CON resembled a franchising mechanism for existing facilities, protecting them from unwelcome competitors. Thus, many hospitals came to support CON in principle, but always looking for ways to reduce its impact on them while using it as a barrier against competitors.

Physicians as a group were less likely to support CON and were often the force behind hospital expansion and demands for new equipment and sophisticated services such as open-heart surgery. In addition, as a profession, physicians have long been more likely to exhibit an entrepreneurial streak. With the help of creative practice managers, physicians soon saw opportunities to directly purchase new technology and offer new services in physician-owned freestanding diagnostic and treatment centers. Consequently, physicians have usually been in the lead in opposing CON, a government-sponsored program, which they saw as thwarting their private business plans.

CON Today

CON in the 36 states where it still exists varies broadly from state to state but in general seems to have shifted in some common ways. Without the existence of local plans against which to judge need or at least place the need within a local context, CON determination is now largely based on meeting state-established performance and charity standards, oftentimes divorced from their local context. In one way, CON has become an even more regulatory process despite the continued national skepticism toward government regulation. With this regulatory character, the CON process has become as much concerned over procedural issues as with the substance of need, access, and costs, and the process has become as much an arena for lawyers and economists as for health planners and regulatory analysts. Without local agencies to represent broader community interests, the CON process is often dominated by networked institutional providers, specialized medical practitioners, and their lawyers, consultants, and lobbyists, who mount well-polished presentations to support their proposals. Opposition to a proposal may be raised on technical grounds (standards and criteria) by the staff of the state planning or CON agency, but the regulators, too, can be as much concerned about procedural issues as substance. The occasional effective opposition to a proposal is usually offered by a competing provider that has the resources to mount a case. In this environment, one of the original purposes of CON, which is achieving equal cost-effective access to quality healthcare, has taken a back seat.

Yet in many states, CON still retains much of its original character and function. And more recent evidence now shows that it can be an effective tool to control costs, expand access, and enhance healthcare quality. Studies reported by the American Health Planning Association (AHPA) of healthcare costs in states where the big-three automakers have a major presence have shown that employee and overall per-person healthcare costs are lower in states with CON. Other studies have also found that states with CON have lower costs for some regulated healthcare services as well as lower mortality for certain serious, but common, surgical procedures such as coronary artery bypass. Both of these findings support the original purpose of CON.

The future of CON is likely to be determined not only by its effectiveness as a cost containment tool but also by its political support within each state and the broader national climate. CON may continue to be one part of an evolving mix of strategies aimed at improving healthcare access, increasing quality, and controlling costs.

CHARITY CARE

Charity care may be generally defined as the financially quantifiable costs of activities, services, or programs that a hospital provides for individuals and for which the hospital does not expect to be compensated, whether fully or in part. This entry examines the role of charity care for non-profit hospitals, as compared with their for-profit counterparts, the expectations, approaches, and measurement of charity care, and the legal ramifications and policy implications of charity care.

Background

During the 1980s, a period of rapidly escalating healthcare costs and changes in third-party reimbursement, nonprofit hospitals in the United States adopted a number of different strategies to reduce costs and increase revenues. Hospitals sought to increase operating or profit margins. Rather than being praised for adopting a business-like approach, however, nonprofit hospitals drew criticism for abandoning their not-for-profit charitable missions. For reasons related to the perceptions that nonprofit hospitals were focused more on profit and less on charitable services, and pressure by local governments to find new revenue sources, the concept of charity care became the operative construct in the ensuing policy debate; nonprofit facilities, which benefit from local, state, and federal tax exemptions, are expected to provide a certain level of charity care through

contributions and services made available to their local communities. If these hospitals do not offer charitable, non-revenue-generating services, should they keep their nonprofit status?

Changes in the Public's Perception

Five factors largely accounted for the change in the public's perception of the charity mission of nonprofit hospitals and the resulting quid pro quo between levels of charity care and a nonprofit hospital's tax-exempt status. These factors are the following: (1) the distancing of local hospitals from their locally supportive communities, which resulted in the erosion of credibility and trust; (2) the movement toward greater efficiencies through the elimination of loss leader services; (3) charges of unfair competition; (4) research finding few differences between nonprofit and for-profit healthcare providers; and (5) the search for new revenue sources by financially strapped municipalities. Each of these factors is discussed below in more detail.

Distancing From Local Communities

Whether hoping to realize financial efficiencies or facing the prospect of closing, many single community-based nonprofit hospitals were absorbed into large multihospital healthcare systems. Subsequently, some hospitals with long and distinguished histories of service to their local communities not only lost their identities but also traded their links to the very communities that had supported and governed them. Instead, they were now managed by entities that were geographically distant and had anonymous corporate accountability and control. Having lost ties to their local communities, these hospitals began to suffer an erosion of credibility and trust. Distance and mistrust made nonprofit hospitals easier targets for those who questioned their charitable ethos when the move to efficiency seemed to supplant charitable services.

Movement Toward Efficiency

Whether as members of large multihospital healthcare systems or as stand-alone healthcare facilities, many nonprofit hospitals tried to realize

financial efficiencies by eliminating services that were deemed loss leaders or unable to make revenues. Some of these services, such as trauma centers, burn units, and maternity units, were often high profile and attracted large numbers of people who could not pay for primary or emergent healthcare services. Public perceptions, articulated by legislators, jurists, and for-profit hospital competitors, turned sour. In their efforts to generate revenue and serve as a business, nonprofit hospitals were seen as renegeing on their charitable mission to the community and foisting additional healthcare costs for the medically indigent on already financially strapped communities.

Charges of Unfair Competition

Owners of for-profit hospitals, also suffering from rapidly escalating healthcare costs, began to question the competitive advantage nonprofit hospitals received through their exemption from a variety of local, state, and federal taxes; for-profit hospitals have to pay these taxes. Further supporting this contention were local business people who claimed that they were suffering from unfair competition from untaxed nonprofit hospitals that were trying to raise new revenues by running for-profit services such as gift shops, health clubs, and laundries that already existed in the community as for-profit enterprises.

Research Finding Few Differences

Attracted by contentions that there were few or no substantial differences between nonprofit and for-profit hospitals, health services research that examined differences between nonprofit, for-profit, and public organizations increased. During the 1980s, empirical research comparing nonprofit and for-profit hospitals was inconclusive, largely due to measurement issues. These studies found no significant differences between the two types of hospitals in areas such as levels of uncompensated care, percentages of uninsured patients served, percentages of Medicare and Medicaid patients, and the range of often unprofitable services being offered to the medically indigent. There were, however, sufficient data from reputable researchers to create doubts about the amount of charity care nonprofit hospitals were providing. This research

spurred ongoing debates about the competitive tax status of nonprofit hospitals and the expectation of charity care.

Search for New Revenue Sources

At this time, many local municipalities were encountering significant funding shortages. The federal government was withdrawing revenue-sharing funds that once supplemented funding for local projects and programs, and local legislators were also imposing caps on property and sales taxes. Many local government officials seized on the idea of generating new revenues by rolling back the generous property tax exemptions that they traditionally accorded nonprofit organizations. These officials were facing a sluggish economy and diminished federal support, and they recognized a growing lack of trust between nonprofit hospitals and the business community. As a result, they required a certain level of charity care to qualify for property tax exemptions. Nonprofit hospitals, they argued, should no longer be able to siphon off local services if they were unable to meet their charitable responsibilities to a community that privileged them with tax exemptions.

Charity Care and the Nonprofit Tax Exemption

The 1980s brought a level of public scrutiny and criticism heretofore unknown to nonprofit hospitals. Even as they evinced financial stewardship, they were criticized for becoming too businesslike at the expense of providing charity care for those who could not afford it. Local, state, and federal governments treat nonprofit hospitals differently from for-profit hospitals and other proprietary enterprises, especially in terms of tax exemption; but are nonprofit hospitals able to justify their exemptions from a variety of taxes by making sufficient contributions of charity care to their local communities?

Such scrutiny was primarily academic until 1985, when the Utah Supreme Court moved the issue from theoretical bantering to the level of law and precedent. It denied property tax exemption to two nonprofit hospitals in the Intermountain Health Care System. Specifically, the Utah Supreme

Court established a six-part test that the local tax board could use to determine whether nonprofit hospitals made charitable contributions to the community sufficient to make them eligible for tax exemptions. In addition to examining the distinctions between nonprofit and for-profit hospitals, the extent to which the two hospitals involved were supported by donations and gifts, the profit derived from operation, the charges levied on patients, and several other factors before concluding that the hospitals did not qualify as charitable institutions, the court also examined the type and scope of charity care nonprofit hospitals provided. It looked at whether nonprofit hospitals offered services at charges below the current market rate or through a substantial imbalance in the exchange between what it costs the charity and what it costs the recipient of its services or in the lessening of a government's burden through the charity's operation. This case sought to determine if these hospitals made unremunerated contributions to the community.

Lacking evidence of providing unremunerated contributions to the healthcare of the local community, the Utah Supreme Court allowed Utah County to withdraw the tax exemptions of the two hospitals. Evidence of providing charity care was key to this newly established *quid pro quo*.

In addition to this state judicial decision, federal legislators also flirted with federal income tax exemption strategies to compel nonprofit hospitals to do more for the poor and uninsured. Concerned about the enormous revenues many nonprofit hospitals were realizing in the mid-1980s during the early days of Medicare's prospective payment system (PPS), two U.S. representatives proposed legislation in 1991 to require nonprofit hospitals to provide more charity care in return for their federal income tax exemptions. This legislation was subsequently withdrawn. Although most of the policy debates about charity care and the nonprofit hospital tax exemption are at the state and local levels, this legislation, at least for a time, gave the issue national prominence.

In 2002, the tax exemption issue reverted back to the states, only this time in Illinois. In a precedent-setting ruling by the Illinois Department of Revenue, Provena Covenant Medical Center of Urbana, part of the Provena Health System, a large Catholic health organization, was stripped of its

Champaign County property tax exemption. In a decision later upheld by the state, and having national implications, the director of the Illinois Department of Revenue ruled that the hospital was providing insufficient charity care to needy people. Since 2003, the Provena Covenant hospital has paid more than \$6 million in property taxes.

In 2006, the Illinois Attorney General proposed the Tax-Exempt Hospital Responsibility Act, which would mandate Illinois nonprofit hospitals to invest at least 8% of total operating costs toward medically necessary care for uninsured Illinois residents with incomes below certain poverty levels. The care provided would be entirely free of charge or discounted. Such investments cannot be based on foregone revenues from charges but rather on costs calculated as those measured by a hospital's Medicare cost-to-charge ratio. Proposed sanctions for noncompliance would include the revocation of tax exemption and monetary penalties. As of 2008, however, no such law has been passed.

Nonprofit Hospitals' Defense of Their Charity Care Activity

These mandates and court decisions created threats to nonprofit hospitals that potentially impacted the financial situation of all tax-exempt organizations. In response, the hospitals took historical, organizational, and operational approaches to argue that they provided charity care to the community. Each approach is discussed below.

Historical Approach

Nonprofit hospitals argued that since they were founded, they were always engaged in charity care by serving the poor and the medically indigent. For example, the ill who were wealthy, at least in their earliest days, were cared for in their homes. Those individuals who lacked access to healthcare services, because of poverty, geography, or ethnic, racial, or religious discrimination, found free or subsidized care in nonprofit hospitals, whose charitable activities were supported through goodwill and local philanthropy. Using this rationale, nonprofit hospitals clearly provided charity care by serving those who could not pay at the time of their founding.

This type of charity care argument was easier to make, however, when philanthropic activity was more obvious in the fund-raising activities of members of the community. When private insurers and state and federal governments began to take a more active role in paying for and providing healthcare services, first through the Hill-Burton legislation in 1946, then through Medicare Prospective Payment in 1983, and later through Medicare and Medicaid contractual reimbursements, nonprofit hospitals began to rely more on third-party reimbursement and less on local philanthropy. Lacking such community philanthropy, nonprofit hospitals had a difficult case, ensuring that their activities were something other than maximizing revenues or selling services to people with diminishing abilities to pay.

Organizational Approach

From an organizational perspective, nonprofit hospitals argued that they were charitable through state laws of incorporation. Because they were organized to be "not-for-profit," they did not maximize profit to distribute to individual shareholders. Rather, they were required to return any excess of revenue over expenses—any "profit"—to their hospitals to provide new, better, or below-costs services to the community. Such an organizational structure, they argued, made them inherently charitable. The charitable returns they made to their hospitals, however, were asserted and not measured. Those skeptical of the activities of nonprofit hospitals began to insist on proof.

Operational Approach

Increased skepticism about a nonprofit's organizational test directed attention to the operational test in Section 501(c)(3) of the Internal Revenue Code. This section of the Internal Revenue Code, which grants tax exemption to nonprofit organizations, states that nonprofit corporations seeking tax exemptions cannot simply assert adherence to the organizational test or "non-distribution constraint," where no "part of the net earnings inures to the benefit of any private shareholder or individual." Rather, they must also be operated exclusively for charitable purposes.

Although the Internal Revenue Code does not define *charitable* specifically, a 1956 Revenue Ruling recognized the expression of a hospital's charitable purpose in "the extent of its financial ability for those not able to pay for services rendered." By 1969, however, the Internal Revenue Service (IRS) had modified this ruling and eliminated the requirement that nonprofit hospitals provide free or subsidized care.

With the advent of the Utah case, and more recently the Provena Covenant ruling, and with changes in the nation's political and economic climate, nonprofit hospitals could no longer rely on history or organizational or operational forms as arguments for or indicators of charity care. Rather, they have to begin to measure their charity care levels in order to justify ongoing favorable tax treatment.

Measuring Charity Care

Despite being a definition that relies on quantifiable costs, an operational construct of charity care is nevertheless problematic because the cost component of charity care is difficult to measure and because there is disagreement over the types of costs that should be included in measures of charity care.

A charity care definition that depends on costs, or that counts "foregone revenues" as a proxy for measuring the costs of charity care, may over- or understate charity care contributions. Despite the advent of Diagnosis Related Groups (DRGs) and better information technology, individual hospital patient costs are still difficult to calculate. Moreover, to rely on foregone revenues as proxies for measures of costs is really to rely on foregone charges. While charges are easier to measure, they are typically higher than costs because of markups. Thus, any charity care measure that depends on charges or on deductions from revenue rather than actual costs expenses would actually favor hospitals with higher markups. And hospitals with higher markups do not necessarily make larger contributions of charity care.

Despite the difficulty of calculating costs, there is still little consensus about the types of uncompensated costs that should be included in an operational measure of charity care. Some argue that a

measure of charity care should be pure, one that is based on only the upfront write-offs of care. Others maintain that a measure of charity care should include bad debts: They consider that most bad debts are really charges that the medically indigent cannot pay and that should have been, but were not, written off before service was rendered. Additionally, consideration should be given to whether to include the shortfall from Medicare and Medicaid in an operational definition of *charity care*. Such distinctions are germane, especially for those trying to justify the nonprofit tax exemption, because the picture of a hospital's charity care contributions improves dramatically—especially if measures include unreimbursed contractuals—depending on the types of costs that are included in the operational definition of *charity care*.

Pure Charity Care

The most restrictive and the easiest to quantify form of charity care, pure charity care, is not one typically advocated by healthcare providers but by governments. Attorney generals, for example, challenge that nonprofit hospitals are providing insufficient charity care when, as a charity care measure, they calculate the prior to service write-offs of all charges to patients whom a hospital has classified as being unable to pay. These write-offs, whether they are for all or part of the bill, constitute pure charity care.

Uncompensated Charity Care

Uncompensated charity care includes both pure charity care and the costs of bad debts. Bad debts are the charges for services that a hospital tries to collect from a patient but cannot. Prior to rendering services, a hospital presumes such patients are able to pay, but they do not. Because it includes a bad-debt component and reflects foregone charges rather than costs, economists, legislators, and policy analysts usually reject uncompensated care charity care measures. While uncollected debt may be construed as a reflection of poor management practices and inefficiencies, there is some evidence to suggest that some part of a bad debt may actually be charity care provided to indigent people who were below 150% of the federal poverty level. Thus, it is not clear whether including a bad-debt component in

measures of charity care actually inflates or understates a hospital's charity care contributions. Nevertheless, including bad debt as charity care does not promote good management practices.

Unreimbursed Charity Care

Measured as the sum of foregone charges of pure charity care and Medicare and Medicaid contractual allowances and shortfalls, unreimbursed charity care reflects the differences between what a hospital charges to provide a service and the rate at which the federal or state government reimburses a hospital for its services. Hospital administrators argue that the government reimburses for Medicare and Medicaid programs at substantially lower rates than what it costs to provide service, and believe that any charity care measure that does not reflect these allowances severely understate the real value of the contribution a hospital makes to society for care of the poor. In addition, they argue, such shortfalls must be made up from other revenue sources, a strategy that pushes costs on to insured patients.

Total Charity Care

The most inclusive of all measures of charity care, total charity care, includes pure charity care, bad debt, and Medicare and Medicaid contractual shortfalls. While it is the most robust, this measure can be criticized for all the reasons for which its individual components can be criticized.

Importance of a Common and Operational Definition

As the courts and legislators become more assertive in linking a hospital's nonprofit tax exemption with the level of charity care it produces, the need to measure charity care becomes more important. It does not, however, become less complex. It is easier to define charity care than to measure it. Nonprofit hospitals can make a stronger case for a tax-exempt status if courts and legislators accept more inclusive operational measures of charity care. Of all components, however, Medicare and Medicaid contractual shortfalls have the most dramatic effect on the charity care measure.

Future Implications

Proposed changes in tax exemption policy based on measures of charity care could include tying amounts of tax exemption subsidy to levels of charity care, totally revoking the nonprofit tax exemption, or targeting individual hospitals, as seems to be the current practice. Depending on the rates of subsidy, tying levels of the tax exemption subsidy to outputs of charity care is a strong incentive for nonprofit hospitals to increase their production of charity care. The complete revocation of current tax exemption policy, however, is clearly a disincentive to the production of charity. Moreover, such a policy may actually increase the financial distress of hospitals that serve large numbers of poor, underinsured, or uninsured patients or high percentages of people whose healthcare comes through Medicare or Medicaid. The current policy trend of a quid pro quo of tax exemptions for charity care suggests that both the definition of charity care and the operational components needed to measure it will, in importance, supplant prior arguments based on the historical activities of nonprofit hospitals or any IRS ruling based on organizational and operational tests.

CHASSIN, MARK R.

Mark R. Chassin is a national leader in healthcare quality, patient safety, and public policy. In 2008, he became the president of the Joint Commission, the nation's leading accrediting body in the United States.

Born in Brooklyn and reared in New York City and Long Island, Chassin earned his bachelor's degree and a medical degree from Harvard University. He went on to earn a master's degree in public policy from the Kennedy School of Government at Harvard, and a master's degree in public health from University of California, Los Angeles. He is also a board-certified internist.

Prior to joining the Joint Commission, Chassin was the Edmond A. Guggenheim Professor of Health Policy and the chairman of the Department of Health Policy at the Mount Sinai School of Medicine in New York. Chassin also was the Executive Vice President for Excellence in Patient Care at the Mount Sinai Medical Center. During his 12 years at Mount Sinai, he led an initiative to achieve excellence in all aspects of patient care including patient safety, clinical outcomes, the experiences of patients and their families, and the working environment of caregivers. In addition, he

successfully implemented Six Sigma quality-improvement methods at the hospital and medical school. His research at Mount Sinai focused on developing healthcare measures, using those measures to improve quality, and understanding the relationship of quality measurement and improvement to health policy. He also expanded intervention trials to reduce racial and ethnic disparities in healthcare.

Before joining the faculty at Mount Sinai, Chassin served as the commissioner of the New York State Department of Health from 1992 to 1994 under Governor Mario M. Cuomo. From 1988 to 1992, he was the senior vice president and cofounder of Value Health Sciences, Inc., a Santa Monica, California, private-sector company that developed computer software and systems for quality assessment and utilization review. Prior to that, he worked as a senior project director at RAND Corporation, where he led several major health services research studies on the inappropriate use of various medical and surgical procedures. From 1979 to 1981, he served as the deputy director and medical director of the Office of Professional Standards Review Organizations at the federal Health Care Financing Administration (HCFA) (now the Centers for Medicare and Medicaid Services [CMS]). At HCFA, he oversaw the development and application of federal guidelines for determining which medical procedures were inappropriate for treating Medicare patients. Before working at HCFA, Chassin practiced emergency medicine in California.

Chassin has received many awards and honors recognizing his contributions to the fields of quality measurement and improvement. He is a member of the National Academy of Sciences, Institute of Medicine (IOM). In 2001, he was selected in the first group of honorees as a lifetime member of the National Associates of the National Academies, a program of the National Academy of Sciences recognizing career contributions to the National Academies. He is the recipient of the Founders' Award of the American College of Medical Quality, and the Ellwood Individual Award from the Foundation for Accountability. He has also served as a member of the Board of Directors of the National Committee for Quality Assurance (NCQA) and AcademyHealth.

CHILD CARE

Some health services researchers examine the impact of access, cost, financing, quality, and the organization of child care on the health and medical outcomes of children. Child care consists of various care services and the education provided to children from birth to age 12. Child care can be licensed or unlicensed care. Licensed care consists of programs that meet their state government's minimum standards for health, safety, and quality. It can also be accredited by professional education associations for meeting standards of quality, and its workforce is credentialed. Those programs that do not require a license within their state are typically the paid care provided by family members, friends, and neighbors.

Background

According to the U.S. Census Bureau's Survey of Income and Program Participation of 1999, among the nation's 12.2 million children aged 5 and younger with employed mothers, 60% were in a child care arrangement with someone other than a parent. The 22 million children of age 6 to 14 with an employed mother spent an average of 22 hours per week in the care of someone other than their parents before or after school.

The same survey also found that for children 4 to 35 months of age, about 55% had mothers who were employed either part-time or full-time. About 61% of the children spent time in child care. About 38% of the children whose mothers were employed full-time spent 21 to 40 hours in child care. In contrast, children whose mothers were not employed often spent no time in child care (59%).

In 2003, 20% of all children in the nation below the age of 6 (4.7 million children) were living in poverty. In low-income families, there is a demand for child care but with limited child care facilities. Opportunities are limited for care for school-age children and adolescents. The existing range of after-school programs and activities meets only 20% of the potential demand in urban areas.

Child Care Settings

Child care offers developmental care and education for children who live at home with a parent or guardian. There are a variety of child care settings. The National Health and Safety Performance Standards, set by the American Academy of Pediatrics (AAP) and other organizations in 2002, define several types of facilities offering child care. Family Child Care Homes provide care and education in a residence that is usually, but not necessarily, the home of the caregiver. A Small Home cares for up to 6 children at one time, and a Large Home cares for 7 to 12 children at a time, including the preschool children of the caregiver. *Center-based care* refers to a facility that provides care and education to any number of children in a non-residential setting. Centers include Head Start and Early Head Start programs. A center provides care for some children for more than 30 days per year per child, which may include summer camps.

A drop-in facility provides care for fewer than 30 days per year per child on a consecutive or intermittent basis. A school-age child care facility offers activities to children before and after school, during vacations, and on nonschool days when there are teachers' in-service programs. A facility for children with special needs provides specialized care and education for children who must be accommodated in a setting with a smaller staff-child ratio, such as for children with disabilities or certain chronic illnesses. A facility for ill children provides care for 1 or more children who are temporarily excluded from care in their regular child care setting. Facilities for ill children can serve up to 6 children and be integrated in a licensed facility for well children, or they can be a special facility for ill children that cares for only ill children or for more than 6 ill children at a time. The National Health and Safety Performance Standards recommend facilities serving birth to 12 months have a child-to-staff ratio of 3 children to 1 staff member, with a maximum group size of 6 children; for children 13 to 30 months old, the recommended ratio is 4 to 1; for children 31 to 35 months old, it is 5 to 1. As children get older, the child-to-staff ratio can grow. For example, for 3-year-olds, the ratio is 7 children to 1 staff member. For 4- to 5-year-olds, it increases to 6 to 1. The recommendations suggest a child-to-staff ratio of 10 children to 1 caregiver for 6- to 8-year-olds. For 9- to 12-year-olds, the recommended ratio is 12 to 1. Ratios for facilities serving children with special health needs are significantly smaller.

During the summer, almost 30% of school-age children are in at least one child care arrangement that can be defined as an organized program (a summer program, summer school, or a before and/or after school program). According to the Urban Institute's National Survey of America's Families for 2002, 34% of children are in relative care during the summer. The remainder is in patent care. Low-income parents spend 14% of their income during the school year for child care.

Separate from state-regulated child care sites, the U.S. Department of Defense (DoD) has developed high-quality child care programs for military personnel at 800 sites worldwide. They have a comprehensive system of child care options with accountability, oversight, and mandates for accreditation, staff training and professional

development, staff wage enhancements, and parent involvement.

Child Care Policy

Though there is the National Health and Safety Performance Standards, child care is regulated at the state government level. States typically have a statute that identifies the regulatory agency and mandates the licensing and regulation of all full-time and part-time out-of-home care for children, regardless of the setting of child care. States establish regulations for child care settings and monitor compliance with those regulations. The primary goal of state licensing is to ensure basic health and safety protection for the child and child care workers. In addition, local and state public health departments have the legal responsibility to control communicable diseases in their jurisdictions.

Child Health Issues in Child Care Settings

An effective health intervention at a child care site should address nutrition services, mental health, access to health services, quality of child care services, and systems of care.

Nutrition Services

Most child care sites provide nutritional services. The National Health and Safety Performance Standards used by state licensing agencies specify guidelines for the implementation of nutrition standards to provide high-quality meals, and nutrition education programs. Two major federal nutritional programs are available to children in child care settings. The Child and Adult Care Food Program (CACFP) is a federal subsidy for meals, snacks, and nutrition education in licensed child care centers, and family and group day care homes. The program primarily serves children whose income falls below 185% of the federal poverty level. The program, administered by the U.S. Department of Agriculture (USDA), serves more than 2 million children nationally. The department also administers the Summer Food Service Program (SFSP), which is intended to serve school-age children nutritious meals at child care sites in the summer, when they do not have access to the National

School Lunch or School Breakfast Program. Individual states also may have nutrition services funding child care sites.

Mental Health

The Comprehensive Community Mental Health Services for Children and Their Families is a federal program that child care sites can use in their referral and mental health consultation to staff. The Center for Mental Health Services, Substance Abuse and Mental Health Services Administration (SAMHSA), under the U.S. Department of Health and Human Services (HHS), funds 40 comprehensive mental health systems of care throughout the nation. The Head Start program has child mental health guidelines and has established regional Technical Assistance Centers that provide consultation to Head Start Centers on mental health issues facing children and their families.

Access to Health Services

Some child care programs such as Head Start have an integrated health service access and delivery approach. Head Start Centers often partner with local child healthcare systems to provide dental services, health screening and pediatric care, and nutrition services.

Quality of Child Care Services

Quality care requires lower child-staff ratios, smaller group sizes, and developmentally appropriate activities, as well as well-trained staff to prevent the spread of infectious diseases, provide a safe environment, and provide for safe evacuation and management of emergency situations.

Quality care provides health promotion and child protection, including hygiene, sanitation, disinfection maintenance, child and staff health protection, accommodation of special medical conditions in young children, and management of illness. Quality child care settings offer nutrition education to the child and family and a nutritious food service. They also focus on the prevention and management of infectious diseases. They are settings that are sensitive to the cultural and ecological

contexts that affect early child care for ethnic minority families, including their healthcare.

Children in child care arrangements with other children experience more bouts of upper-respiratory tract illnesses between the ages of 36 months and 54 months than do those not in child care settings. Therefore, centers have developed plans for care or exclusion of the sick child. These centers have been developed to care for the sick child, allowing working parents fewer missed days of work due to a child's illness.

Systems of Care

The quality child care programs provide are linked to the local systems of healthcare, including dental services and oral health education for the child and family, and linkages with healthcare providers who offer immunizations, health screening, and preventive pediatric care and nutrition services for the child and family. There are partnerships with healthcare professionals, mental health professionals, and community social service agencies.

The Child Care Workforce

A study by the Early Child Care Research Network of the National Institute of Child Health and Human Development (NICHD) in 2002 found that regulations regarding staff training and staff-child ratios affect the quality in child care settings and ultimately child outcomes.

The National Health and Safety Performance Standards recommend that any individual with primary responsibility for child care have an official child care credential as granted by the authorized state agency. Among the standards for credentials are those of the National Association for the Education of Young Children (NAEYC) and the Child Development Associate (CDA). The national standards recommend that staff should receive ongoing training in health, psychosocial and safety issues, including information on the spread of communicable diseases and their prevention, immunization requirements for children and staff, and the management of common childhood illness, including exclusion policies. In addition, caregivers are trained in infection control and injury prevention, emergency procedures, management of a blocked

airway, rescue breathing, and other first aid procedures. Caregivers learn nutrition, medication administration policies and practices, behavior management, and how to recognize and report child abuse in compliance with state laws.

Health advocates in child care facilities, usually one of the caregivers on-site, are the primary parent contacts for health concerns, including health-related information and the provision of resources. The National Health and Safety Performance Standards recommend that the health advocate refer children without a regular source of care to a healthcare provider who offers competent routine child care services. In addition to the on-site health advocate, each center should have a health consultant who is a health professional with training and experience and expertise in child health and development. This person should be knowledgeable about the special health and safety needs of children in out-of-home care settings, the child care licensing requirements, and available health resources. Sites should have registered nurses available on-site to provide medical treatment, staff training, and ongoing supervision of the health needs and practices of staff and children, which ensures appropriate administration of health education and prescribed medical treatment.

Facilities serving children with disabilities need the off-site availability of a variety of healthcare professionals, including a physician, registered dietitian, registered nurse, psychologist, physical therapist, occupational therapist, speech pathologist, and respiratory therapist.

Caregiver training in health and safety practices, including injury prevention, infection control, and health promotion, needs to be ongoing. The CDA credential includes training in five areas: (1) the recommended immunization schedule, (2) reporting of communicable diseases, (3) techniques, (4) emergency medical services, and (5) emergency preparedness for disaster. The National Health and Safety Performance Standards recommend caregiver training in health and safety practice, including injury prevention, infection control, and health promotion. Caregivers should also receive training in cultural diversity; nutrition and healthy eating; the protocol to prevent, recognize, and correct health and safety problems; and management of illness.

Child Health Outcomes

When looking at child care centers and services, child health outcomes should be considered in terms of general outcomes, economic impact, and access to healthcare.

General Outcomes

According to studies conducted by the NICHD, children have better school readiness and language comprehension and fewer behavior problems at 36 months of age when they attended quality child care that met recommended child-staff ratios and recommended levels of caregiver training and education. According to the NICHD's Study of Early Child Care, a 10-site prospective study of more than 1,100 participants that began at birth, in addition to education and developmentally appropriate activities, sites with positive child outcomes had programs promoting and protecting children's health and controlling infectious diseases, ensuring children's nutritional well-being, and maintaining a healthy environment. Within the sample, when only poor or near-poor children were in care for at least 20 hours a week, a higher quality of care was found to be associated with more favorable developmental outcomes in the children.

Economic Impact

In another study conducted by NICHD (the Study of Early Child Care and Youth Development) using a stratified random sample of more than 1,300 children and their families from birth through first grade, researchers found that the total number of hours in child care was associated with higher maternal wages and more hours of employment when children were in first grade. There was also a reduction in the number of parent's missed days of work, industry's lost productivity, and employee absenteeism. A study by the Federal Reserve Board in Minneapolis, Minnesota, estimated that high-quality early-childhood programs could yield a 12% rate of economic return to the public and a 4% rate of return to the individual child and his or her family. To deliver this rate of return, the child care program must meet high standards of quality, which some researchers feel can be achieved through more private outlay and public investment.

Access to Healthcare

As discussed earlier, the National Health and Safety Standards recommend that the child care facility help families who have no regular health-care provider locate a resource that can meet their needs. Referral to health services should be comprehensive and range from preventive services such as immunizations, injury prevention, and nutrition, to acute treatments to referral and evaluation for potential chronic health problems. Child care centers can serve as a linkage of families to the healthcare system, and providers can assist families in obtaining information about their child's eligibility for the State Children's Health Insurance Program (SCHIP). Additionally, they can help families access a medical home and establish a regular source of care. Linkage and referral to child care resource center, county public health departments, Early, Periodic, Diagnosis, and Treatment (EPSDT) programs, and hospital and clinic pediatric departments are among the health service use outcomes.

Future Implications

Child care is vital for families, industry, and society. It affects education, childhood development, and pediatric health. In terms of health services research, there is a need for research on the benefit-to-cost ratio of preschool health services, immunizations, health screenings, and preventive care on child health status indicators. Further research is also needed on the effects of the child health standards for children with developmental delays or chronic health problems.

Health service researchers will need to focus on effective treatments and best practices that effectively address poor nutrition, infections, and exposure to environmental toxins, drugs, and other biological hazards that affect healthy brain development. More studies with using experimental and quasi-experimental designs will help establish best practices for integrating child healthcare and child care systems.

In terms of state and federal policy, quality programs must ensure that all child care settings are safe, stimulating, and compatible with developmental needs. These settings need to be made more accessible to larger numbers of the working poor

for whom the benefits are substantial. Finally, public policies that address the financing and investment in child care by government and the private sector need to be developed, proposed, and implemented.

CHIROPRACTORS

Chiropractic is America's most popular form of alternative healthcare, and more than 25 million patients annually visit chiropractors for pain relief and other benefits. Chiropractic is a healthcare profession that focuses on disorders of the musculoskeletal system and the nervous system and the effects of these disorders on general health. Chiropractic care is used most often to treat neuromusculoskeletal complaints, including but not limited to back pain, neck pain, pain in the joints of the arms and legs, and headaches.

Doctors of chiropractic—often referred to as chiropractors or chiropractic physicians—practice a drug-free, hands-on approach to healthcare that includes patient examination, diagnosis, and treatment. Chiropractors have broad diagnostic skills and are also trained to recommend therapeutic and rehabilitative exercises, as well as to provide nutritional, dietary, and lifestyle counseling.

Chiropractors are considered first-contact providers (i.e., primary-care providers) and are so defined in federal and state regulations, including within the Medicare program. For many conditions, such as lower-back pain, chiropractic care may be the primary method of treatment. When other health conditions exist, chiropractic care may complement or support medical treatment by relieving the musculoskeletal aspects associated with the condition.

Doctors of chiropractic may assess patients through clinical examination, laboratory testing, diagnostic imaging, and other diagnostic interventions to determine when chiropractic treatment is appropriate or when it is not appropriate. Chiropractors will readily refer patients to the

appropriate healthcare provider when chiropractic care is not suitable for the patient's condition or when the condition warrants comanagement in conjunction with other members of the healthcare team.

Philosophy

Doctors of chiropractic believe in a holistic “total person” approach to healing, which typifies the new and changing attitude toward health. It is based on the concept of “maintaining health” versus “treating disease.” Chiropractic philosophy includes (a) a recognition that dynamics exist between lifestyle, environment, and health; (b) understanding the cause of illness to eliminate it, rather than simply treat symptoms; (c) a recognition of the centrality of the nervous system and its intimate relationship with the capacities of the human body; (d) a patient-centered, hands-on approach focused on influencing function through structure; and (e) a focus on early intervention, emphasizing timely diagnosis and treatment of conditions that are wholly functional and reversible.

Treatment Methods

The most common therapeutic procedure performed by doctors of chiropractic is known as *spinal manipulation*, also called *chiropractic adjustment*. The purpose of manipulation is to restore joint mobility by manually applying a controlled force into joints that have become hypomobile—or restricted in their movement—as a result of a tissue injury. Tissue injury can be caused by a single traumatic event, such as improper lifting of a heavy object, or through repetitive stresses, such as sitting in an awkward position with poor spinal posture for an extended period of time. In either case, injured tissues undergo physical and chemical changes that can cause inflammation, pain, and diminished function for the sufferer. Manipulation, or adjustment of the affected joint and tissues, restores mobility, thereby alleviating pain and muscle tightness and allowing tissues to heal.

Chiropractic adjustment rarely causes discomfort. However, patients may sometimes experience mild soreness or aching following treatment (as

with some forms of exercise) that usually resolves within 12 to 48 hours.

Research

Throughout its history, the chiropractic profession has had the difficult task of justifying itself to the mainstream medical community. The chiropractic profession has undertaken an extensive amount of research to show that chiropractic provides effective treatment that is patient-focused, low-cost, low-risk, and noninvasive.

A 2007 study from the Chicago area found that patients visiting chiropractors who serve as primary-care providers have lower utilization costs and higher patient satisfaction levels than do patients treated by conventional medical physicians. Researchers found that over the course of the 7-year study, which was published in the *Journal of Manipulative and Physiological Therapeutics*, patients visiting chiropractors and other complementary and alternative medicine-oriented primary-care providers had 60% fewer hospitalizations, 62% fewer outpatient surgical cases, and 85% lower pharmaceutical costs when compared with total network HMO utilization rates and costs. The chiropractors and other complementary and alternative medicine doctors treated and managed cases ranging from upper-respiratory-tract infections and allergies to headaches, orthopedic, and other medical conditions.

A significant amount of evidence also shows that the use of chiropractic care for problems such as acute and chronic lower-back pain, neck pain, headaches, and many other neuromusculoskeletal conditions can be more effective and less costly than traditional medical care. Most recently, the report of a 2005 study in the *Journal of Manipulative and Physiological Therapeutics* concluded that chiropractic and medical care have comparable costs for treating low-back pain, with chiropractic producing better outcomes for chronic pain. In addition, the report of a 2003 study published in the medical journal *Spine* found that manual manipulation provides better short-term relief of chronic spinal pain than do a variety of medications.

A 2007 literature review in the *Journal of Manipulative and Physiological Therapeutics*

found “high-quality evidence” that patients with chronic neck pain showed significant pain-level improvements following spinal manipulation. No trial group was reported to remain unchanged, and all groups showed positive changes up to 12 weeks after treatment.

With regard to headaches, a report released in 2001 by researchers at the Duke University Evidence-Based Practice Center found that spinal manipulation resulted in almost immediate improvement for headaches that originate in the neck and had significantly fewer side effects and longer-lasting relief of tension-type headache compared with a commonly prescribed medication.

Although there have been some isolated media reports of stroke following chiropractic neck manipulation, the findings in the current research literature agree that adverse events such as stroke or stroke-like symptoms associated with cervical manipulation are extremely rare. For example, a medical review published in 2002 looked at 73 studies of chiropractic care and found no serious complications reported in any of them. Studies have also shown that when an adverse reaction does occur, it is often the result of an improperly trained person performing the procedure—rather than a doctor of chiropractic.

Origins and History

The word *chiropractic* comes from the Greek words *cheir* (meaning “hard”) and *praktos* (meaning “done”)—that is, *done by hand*. The developer of chiropractic, Daniel David Palmer (1845–1913), chose the name.

A prolific reader of all things scientific, Palmer realized that although various forms of manipulation had been used for thousands of years, no one had developed a philosophical or scientific rationale to explain their effects. Palmer’s major contribution to the health field was the codification of the philosophy, art, and science of chiropractic, which was based on his extensive study of anatomy and physiology. Palmer performed the initial chiropractic adjustment in 1895. Palmer examined a janitor who had become deaf 17 years earlier after he felt something “give” in his back. Palmer examined the area and gave a crude “adjustment” to what was felt to be a misplaced vertebra in the

upper back. The janitor then observed that his hearing improved.

From that first adjustment, Palmer continued to develop chiropractic and in 1897 established the Palmer School of Cure, now known as the Palmer College of Chiropractic in Davenport, Iowa, where it remains today. Following the first adjustment, many people became interested in Palmer's new science and healing art. Among his early students were Palmer's son, Bartlett Joshua Palmer, as well as members of the older healing arts of medicine and osteopathy.

Kansas was the first state to license chiropractors in 1913, and by 1931, 39 states had given chiropractors legal recognition. Today, there are more than 60,000 active chiropractic licenses in the United States. All 50 states, the District of Columbia, Puerto Rico, and the U.S. Virgin Islands officially recognize chiropractic as a healthcare profession. Many other countries also recognize and regulate chiropractic, including Canada, Mexico, Great Britain, Australia, Japan, and Switzerland.

Education, Licensing, and Regulation

Chiropractic education is much more regulated and extensive than most people appreciate. The Council on Chiropractic Education, an agency certified by the U.S. Department of Education, currently recognizes 15 chiropractic programs at 18 different locations.

The typical applicant at a chiropractic college has already acquired nearly 4 years of premedical undergraduate college education, including courses in biology, inorganic and organic chemistry, physics, psychology, and related laboratory work. Once accepted into an accredited chiropractic college, students receive an additional 4 or 5 academic years of professional study. Because of the hands-on nature of chiropractic, and the intricate adjusting techniques, a significant portion of time is spent in clinical training.

In total, the chiropractic curriculum includes a minimum of 4,200 hours of classroom, laboratory, and clinical experience. Compared with medical students, chiropractic students receive considerably less instruction in pharmacology and surgery; however, added emphasis is placed on biomechanics,

musculoskeletal function, and manual treatment methods.

In the United States, all aspects of chiropractic education must meet official accreditation standards, and a graduate must also complete state and national licensing board examinations before gaining the right to practice.

Furthermore, virtually all states have mandatory continuing education requirements for chiropractors to maintain or renew a license to practice. Chiropractic colleges frequently offer postgraduate continuing education programs in specialty fields ranging from sports injuries and occupational health to orthopedics and neurology. These programs allow chiropractors to specialize in a healthcare discipline or meet state relicensure requirements.

Institutional Recognition

The public's attitude toward chiropractic care has been instrumental to the profession's growth and acceptance into mainstream healthcare. A few notable examples of chiropractic integration into today's healthcare system include the chiropractic department at the National Naval Medical Center in Bethesda, Maryland, the successful Complementary and Alternative Medicine Center at the National Institutes of Health (NIH), and the doctors of chiropractic who work as consultants to the Office of the Attending Physician at the U.S. Capitol Building. Furthermore, the federal government has recognized the effectiveness and cost savings potential of chiropractic care by providing benefits to veterans, active-duty military personnel, and Medicare patients.

Insurance Coverage

Compared with complementary and alternative therapies as a whole (few of which are reimbursed), coverage of chiropractic by health insurance plans is extensive. As of 2002, more than 50% of HMOs, more than 75% of private health-care plans, and all state workers' compensation systems covered chiropractic treatment, although chiropractic trade organizations have seen other more anecdotal and informal reports that put the percentage of PPOs offering chiropractic care at around 90%.

Chiropractors can bill Medicare for select services and more than two dozen states cover chiropractic treatment under Medicaid. Chiropractic care is available to members of the armed forces at more than 40 military bases in the United States and is covered benefit for America's veterans at nearly 30 U.S. Veterans' Administration health facilities. Furthermore, the Internal Revenue Service (IRS) includes chiropractic services as a valid medical deduction.

Chiropractors in Practice

Doctors of chiropractic represent the third largest doctoral-level healthcare professionals in the United States, after medical physicians and dentists. Nearly 82% are in full-time practice, with the average chiropractor working between 40 to 52 hours per week. The majority (61%) of chiropractors work in an office in which they are the only doctor. Nearly one third (31%) share an office with one or more chiropractors, while the remaining doctors either work in a multidisciplinary setting or work in other office arrangements.

The Chiropractic Patient

The results of a 2005 survey conducted by the National Board of Chiropractic Examiners found that more than 35% of patients receiving chiropractic care were being treated for mid- or low-back problems and almost 20% were being treated for neck pain. More than half of those surveyed indicated that their symptoms were chronic. Conditions commonly treated by chiropractors included, but were not limited to, back pain, neck pain, headaches, sports injuries, motor vehicle accident injuries, and repetitive strains. Patients also sought treatment of pain associated with other conditions, such as arthritis.

CHRONIC CARE MODEL

The Chronic Care Model (CCM) is a proposal for reorganizing primary medical care to address

better the needs of patients with chronic illnesses. This proposal creates a new clinical paradigm for delivering chronic disease care, with a major emphasis on patient self-management and secondary prevention. The ideas behind the CCM were outlined in a series of landmark articles published in 2002 in the *Journal of the American Medical Association* that described a number of attempts to implement various aspects of the model in diverse healthcare delivery systems across the United States. The principles of the model were originally developed by Edward H. Wagner, from the Center for Health Studies at Group Health Cooperative of Puget Sound.

Background

During the 1970s and 1980s, with U.S. healthcare costs regularly doubling the rate of inflation, many proponents of reforming the nation's healthcare system turned to managed care. A centerpiece of healthcare expenditure increases during these decades, above and beyond the aging of the population, was the rapid increase in the "intensity" of care, particularly hospital care for older patients with chronic illnesses. Yet despite the increase in surgical procedures and hospital-based specialty care, health services researchers were simultaneously producing ample documentation of major quality problems in basic chronic disease care for all Americans.

Early policy responses included the original federal health maintenance organization (HMO) acts of 1973 and 1976, which aimed at the creation of large integrated healthcare delivery systems that combined hospital and outpatient care. Such systems offered financial incentives, such as capitation (a fixed fee per year) reimbursement for a defined population of enrolled patients, to emphasize preventive health maintenance and avoidance of preventable exacerbations of chronic diseases. Because about 10% of the sickest patients generate over two thirds of all healthcare costs, there is a major financial incentive for prepaid delivery systems to better manage their highest-risk enrollees. It was hoped that capitated payment systems would initiate a new prevention and health promotion paradigm that could reverse the often perverse financial incentives of the fee-for-service system, which restricted

reimbursement to treatment of acute, urgent medical problems.

Although the HMO movement failed to transform the nation's healthcare, several large integrated systems, such as Group Health Cooperative, Kaiser-Permanente Northern California, and the Veterans Health Administration (VHA), did develop innovative disease management approaches to providing coordinated chronic disease care. These organizations were pioneers in adopting medical management information systems that could track utilization of care across multiple episodes of illness and provide computerized clinical guideline reminders and decision support to physicians. In addition, these organizations were able to offer multidisciplinary team-based care and proactive telephone follow-up of patients—services that are generally not reimbursed in traditional fee-for-service practice settings. It was from these successful experiments in redesign of primary care for chronically ill patients that Wagner and his colleagues distilled the CCM.

Basic Principles of the Model

The CCM was developed to capitalize on the best features of primary care, defined by the Institute of Medicine (IOM) as the provision of integrated, accessible healthcare services by clinicians who are accountable for addressing a large majority of personal healthcare needs, developing a sustained partnership with patients, and practicing within the context of family and community. The CCM seeks to go beyond managed-care gatekeeper models that attempt to reduce unnecessary care (and costs) by requiring specialty referrals from primary-care physicians. Instead, recognizing that most chronically ill patients receive the bulk of their care from primary-care physicians, and that the majority of them have multiple disease conditions, the CCM advocates efficient integration of specialty care into clinical case management while preserving a "whole"-patient perspective. Six synergistic "ingredients" of the model were distilled from evaluations of successful disease management and quality improvement efforts during the 1990s. Each is discussed below.

Clinical Information Systems and Disease Registries

Healthcare organizations that seek to improve care for a particular condition must first be able to identify patients with the condition as well as relevant aspects of their care. Chronic disease registries, which ideally should include diagnostic, laboratory, and pharmacy data, are thus essential to providing clinicians with information about all patients with a particular diagnosis (e.g., diabetes) in their practice. The registry is used to further determine whether relevant evidence-based tests and procedures have been performed (e.g., regular eye and foot examinations), to notify both patients and physicians when important exceptions to guidelines are identified or clinical services are overdue, or to identify very high-risk patients requiring intensified follow-up care. Registries provide an ongoing resource for quality improvement and continuous monitoring and evaluation of therapeutic progress (e.g., hemoglobin A1c laboratory results).

Despite the potential of health information technology to improve care, less than a half of even the largest physician group practices in the nation (those with greater than 20 physicians) had even a single chronic disease registry in 2001. Far fewer of these practices had registries linked to clinical data or that extended beyond a single condition such as diabetes. Obviously, smaller medical practices, which handle the majority of all physician visits in the nation, are even less likely to currently use chronic disease registries.

Support for Patient Self-Management

Central to the CCM is the concept of behavioral interventions in the way in which patients manage their illnesses on an everyday basis. This is conceptually distinct from shared decision making in clinical encounters between clinicians and patients, which focuses on treatment planning and collaborative decisions on medical management. Rather, self-management theory stresses the psychosocial aspects of coping with chronic illness and aims at both educating patients and improving patients' self-efficacy, or confidence in their ability and skills to undertake preventive measures to limit disease progression and symptom severity. Self-management initiatives thus

go beyond traditional didactic patient education to embrace strategies for patient empowerment. These strategies focus on individually tailored action plans that are capable of overcoming barriers to lifestyle changes, based on patients' existing health beliefs and readiness to make changes. Central to such behavior change is effective management of common psychological obstacles such as anxiety, fear, fatigue, and depression that so commonly afflict patients with incurable illness (and complicate successful medical treatment regimens). Self-management must therefore build on a patient's own goals and aspirations, with clinicians playing the role of coaches, providing feedback, and assisting in practical problem solving.

There is considerable evidence that differences in the efficacy of self-management may explain much of the widely observed socioeconomic and ethnic and racial disparities in health outcomes of patients with chronic illness. One of the greatest challenges to self-management educational initiatives is limited health literacy, including the ability to read and understand medical information. Given a general lack of fee-for-service reimbursement for psychosocial interventions, there remains a major deficit in funding for proven behavioral interventions such as smoking cessation, physical activity promotion, or weight loss.

Delivery System Redesign

The CCM calls for a redesign of the traditional physician office-based visit setting with its time limitations and focus on acute care. A basic concept is multidisciplinary, proactive team care, which can be conducted outside traditional physician office visits by allied health professionals. Nurses, case managers, health educators, and even nonclinician support personnel, working in conjunction with primary-care physicians, can be employed to schedule tests and visits, provide coaching, monitoring and education, conduct telephone (or Internet) follow-up, and update chronic disease registry information. Team members could also include pharmacists, psychologists, social workers, physical or occupational therapists, dietitians, or information system specialists. One noteworthy innovation is group visits, where patients who share a chronic illness can find mutual support, problem-solving help, and role models. In

theory, group visits can provide the type of social persuasion that characterizes effective interventions such as Alcoholics Anonymous or Weight Watchers. Other potentially useful innovations include home visits (e.g., by social workers following depressed patients), physician office open to advanced access to walk-in appointments, and “one-stop shopping” visits when patients can access a full range of specialized ancillary services such as foot or vision care in a single visit.

There are many obvious barriers to implementing these redesign features in smaller, fee-for-service physician office settings. One approach to encourage redesign has been pay-for-performance reimbursement incentives. Insurers (potentially including Medicaid and Medicare) may offer physician practices additional payments for meeting goals on “reportcard” measures that rate adherence to established clinical guidelines for chronic conditions across all patients cared for by a healthcare organization. This may spur more medical practices to pursue chronic disease redesign initiatives.

Accessing Community Resources

Community resources are critical in expanding the reach of physician office care. The CCM suggests developing ongoing linkages to community institutions such as mental health centers, senior citizen centers, hospital-based educational, smoking cessation or diet programs, exercise facilities, home health care agencies, and other community support institutions. An additional function of community resources might be assisting vulnerable or lower-income patients and their families with navigating the healthcare system or helping them find sources of health insurance, low-cost drugs, transportation, and child care or adult day care or respite care arrangements.

Medical Decision Support and Guidelines Implementation

The CCM calls for readily accessible clinical data to provide physicians and other providers with timely information and reminders, including point of care reminders of the need for indicated services at the time of patient visits. In this way, clinical guidelines and protocols can be implemented with minimum burden on physicians. Such

reminders can also be directly addressed to patients outside the physician’s office when appropriate. Registries can also be used to generate aggregate clinical performance feedback or report cards on panels of patients, displaying the percentage of each physician’s patients adhering to guidelines for their care, or providing information about clinical outcomes such as blood pressure control. Efforts such as “academic detailing” (university-based educational outreach) and specialized training and staff development programs for chronic care teams are also advocated. Finally, by flagging more severely ill patients or those who require additional medical resources, decision support may improve the efficiency of specialty care referrals.

Currently, decision support capabilities are limited by the paucity of medical practices that use electronic clinical records, particularly systems that are capable of interfacing laboratory and pharmacy prescription data. While computerized clinical records can potentially improve both patient outcomes and economic efficiency, there is a large initial investment required in hardware, software, and training. Finally, the validity and reliability of physician performance measures remains controversial, and physician or practice performance measures require adjustment for higher-risk patient populations.

Healthcare Organizational Leadership

Echoing continuous quality improvement theory, the CCM requires the enthusiastic endorsement of top-level healthcare leadership to be successful. Without top leaders supporting changes required by the CCM, traditional incentives for business as usual will undermine change efforts. CCM implementation requires significant reallocation of resources from the health system infrastructure, including information systems, use of multidisciplinary personnel in new roles, and incentives for clinicians to change their practice style to accommodate new approaches. Implementation of the model will often require a major shift in organizational culture, to proactive follow-up, emphasizing behavioral medicine, cooperative teamwork, and shared decision making with patients, skills that may conflict with traditional medical education as primarily experienced by physicians in the acute care hospital setting. It

is therefore not surprising that only about half of the largest medical practices in the nation reported using case management or performance feedback to physicians for any chronic illness.

Disease Management and the Chronic Care Model

Over the past decade, many of the functions of the CCM have been adopted by disease management firms, which primarily sell their services to large managed-care organizations, insurers, and health plans. The growth of the disease management industry has come in part as a response to the failure of managed care and the HMO movement to directly transform the healthcare delivery system through intrusive and unpopular restrictions on patient access and utilization review of physicians. Instead, large health plans hope to reduce costs by changing patient behavior outside the physician practice environment. The primary difference between the emerging disease management industry and the CCM is that educational and case management services are provided directly to patients by third-party firms contracting with the patient's insurer rather than being administered directly through the patient's medical practice.

The disease management industry began with pharmaceutical benefit and behavioral and mental health management firms that negotiated carve-out contracts with large health plans to manage care for specific populations of chronically ill patients. The industry has subsequently grown to include firms that provide many of the educational, self-management, and monitoring functions associated with the CCM. Disease management firms use sophisticated data warehouses containing claims and utilization data for millions of patients and, increasingly, specialized electronic home monitoring devices and patient self-assessments provided over the Internet. These data allow the firms to identify high-risk patients for a particular insurance entity and to then provide direct-to-patient services (usually by telephone) by specialized personnel such as nurse case managers, with or without the participation of physicians. These firms may also contact physicians directly when there is evidence of a divergence from practice guidelines or optimal care. While lacking the

intimate knowledge of patients and familiarity with local conditions that might characterize a primary-care practice, disease management firms have the resources to employ highly specialized and trained personnel who are fully dedicated to providing care management services. The future interaction of disease management and the CCM remains controversial and presents a potential financial conflict as disease management firms gain revenue that might otherwise be allocated to redesigning physician practices.

Future Implications

A number of meta-analyses have found that disease management and patient self-management programs have been generally successful in improving process quality of care and clinical outcomes for patients with chronic medical conditions. The best results have been reported for programs focused on care for diabetes, hypertension, asthma, and depression, with somewhat more contradictory results for congestive heart failure and arthritis. Data on whether self-management or case management reduces direct medical care costs remain mixed and inconclusive. There are also ongoing evaluations of attempts to implement components of the CCM through support for more than 100 demonstration projects from the Robert Wood Johnson Foundation (RWJF) and the Institute for Healthcare Improvement (IHI). These evaluations have generally been positive with regards to the fidelity of the model's principles, but the depth and extent of programs varied widely among participating provider organizations. Programs differ widely in what was done, the usual care that the control groups received, and the severity of illness of the study populations.

Because the studies to date cover only partially implemented aspects of disease management and never a full CCM implementation and because the literature may suffer from publication bias favoring successful programs, little is known about which specific aspects of self-management or case management programs actually produce the best results. This ambiguity about disease management and CCM outcomes has led to several calls for more standardized reporting of evaluations. As the nation's population ages and chronic illness

becomes more prevalent, the concepts behind the CCM will undoubtedly continue to shape health policy and delivery system innovation and will remain a central focus of health services research.

CLANCY, CAROLYN M.

Carolyn M. Clancy is a health services researcher and a general internist, and she is the director of the U.S. Department of Health and Human Services' Agency for Healthcare Quality and Research (AHRQ), the federal agency that is responsible for supporting research to improve healthcare quality, reduce healthcare costs, decrease medical errors, improve patient safety, and increase access to care. Clancy served as acting director of AHRQ from March 2002 until she was appointed director in February 2003. She previously directed the Center for Outcomes and Effectiveness Research, which conducts and supports research on the outcomes and effectiveness of healthcare services and procedures, and the Center for Primary Care Research at AHRQ, where she helped develop the U.S. Public Health Service Primary Care Policy Fellowship. Prior to joining AHRQ in 1990, Clancy was an assistant professor in the Department of Internal Medicine at the Medical College of Virginia in Richmond.

Clancy received her bachelor of science degree from Boston College and a doctorate of medicine degree from the University of Massachusetts School of Medicine. After completing medical school, she did postdoctoral training at the Kennedy Institute of Bioethics Intensive Course at Georgetown University in 1989 and the Stanford Faculty Development Program in Clinical Teaching in 1988 and was a Henry J. Kaiser Family Foundation Fellow in General Internal Medicine at the Hospital of the University of Pennsylvania from 1982 to 1984.

Clancy holds an academic appointment as a clinical associate professor at the George Washington University School of Medicine in the Department of Medicine. She has edited or contributed to seven books and has published extensively in peer-reviewed medical journals. Clancy has served on various editorial boards, including those of the *Annals of Family Medicine*, *American*

Journal of Medical Quality, and *Medical Care Research and Review*, and is a senior associate editor of the journal *Health Services Research*. Clancy has also held leadership positions in many professional organizations, including the Society of General Internal Medicine. In addition, she is an elected member of the National Academy of Social Insurance and the national Institute of Medicine (IOM) and was elected a Master of the American College of Physicians in 2004. Her research interests have been strongly influenced by the field of medical decision making and currently include the various dimensions of healthcare quality and patient care, including women's health, primary care, access to healthcare, and the impact of financial incentives on physicians' decisions.

CLINICAL DECISION SUPPORT

Computer systems to augment medical decision making were introduced to the healthcare marketplace in the late 1970s and early 1980s. Healthcare organizations have been using decision support in areas of marketing, cost accounting, strategic planning, and case-mix analysis. However, despite decision support being generally considered an old technology, relatively few organizations actively use it in the delivery of clinical work though many are beginning to use this capability in various ancillary department operations.

Decision support systems involve the capacity of combining data elements into information and then transforming information into knowledge on which to base logical decisions. Decision support goes beyond "who" and "what" questions to present data in a logical way to answer "what if" and "why" questions.

Benefits

A variety of research studies on clinical decision support systems have been conducted and published in the literature. There is a general consensus that clinical decision support technologies have the potential to enhance patient care and at the very least have the potential to modify clinicians' behavior. Clinical reminders and alerts, adherence to treatment plans, and suggested patient education have been reported as effective ways of changing

clinician practices. While some may say that these are features that demonstrate the value of clinical decision support, others say that while clinicians' behavior may be shown to be modified, there is little evidence of whether the actual thinking behind the practice modifications is indeed changed. Furthermore, only limited data suggest any improvement in actual patient outcomes. This represents an opportunity for further research and study.

The increasing pressures to monitor and reduce healthcare costs and demonstrate improved outcomes are driving the national trend toward using information as a strategy. Timely data are required to reduce operational inefficiencies and enhance the delivery of patient care. Disparate systems by themselves are inadequate, and data sharing through interfaces presents often inconsistent and conflicting results. Thus, mechanisms are needed to consolidate patient data in a meaningful way to present only the requisite data to make clinical decisions.

Uses

Clinical decision support systems have previously been used for a variety of retrospective analyses. These concepts have expanded into the clinical arena so that data are then presented to clinicians at the point of care and, more important, at the precise time clinical decision making occurs. In its foundation form, the clinical decision support systems include at least one trusted knowledge source (a database of known information about a particular subject, such as drug data) and a set of software programs that establish intelligence (usually referred to as a "rules engine") to process how the data from the knowledge source may apply to a specific clinical situation. Preestablished rules and guidelines, with corresponding alerts, are developed and edited as necessary by the healthcare organizations. These rules and guidelines typically integrate a variety of clinical data from multiple sources to generate clinician alerts and other treatment suggestions.

Most of these systems have been designed to perform a specific function, such as using data from the knowledge source to validate a medication order for potential drug or therapeutic interactions or against some predetermined range of laboratory result values. Specific rules are established to fit

clinical situations, such as if the patient has "X" diagnosis, the "Y and Z" classes of drugs are contraindicated, or if "A" medication is ordered, then the patient must have laboratory values within the range of "B to C." If the preestablished rule is violated, then an alert is sent back to the prescriber before the order is processed, thus giving the prescriber the opportunity to change the order or asking for an explanation as to why the action is to be taken. Rules and subsequent alerts are usually developed and managed by the healthcare organizations.

Problems and Concerns

A number of problems and concerns contribute to the relatively limited use of clinical decision support. These problems must be overcome before clinical decision support can become a trusted and valuable tool in the delivery of patient care.

First, rules are too restrictive and the subsequent alerts are wedged into the patient care thought process. Healthcare organizations that establish too many rules restrict the thought flow of its clinicians. Clinicians complain that the time required to respond to the rules inhibits productivity; as a result, many just bypass them without paying attention to the alert. Rules that are often bypassed and retained in the system become cumbersome and time-consuming. This diminishes the overall value of the clinical decision support systems and actually may contribute to additional patient care errors and reduced quality. It is critical that the organizations establish and endorse rules that are truly meaningful to the delivery of patient care and not overburden clinicians.

Second, alerts must have meaning to the clinician. Healthcare organizations using clinical decision support systems must realize that clinicians need to be informed in a variety of specific ways if they are to derive value from these systems. Some attending physicians desire e-mail inbox or pager notification, while others may desire a direct telephone call. This requires maintenance to keep alert notification as up-to-date as possible.

Third, extensive staff time is required to research, establish, and monitor rules and alerts. A working committee must be established with executive endorsement, and staff must be assigned to maintain the clinical decision support system. In

organizations that actively use these systems, the committees meet regularly to discuss new rules while monitoring established rules for usage and exception reporting. Some committee members may be assigned research tasks and then are expected to report their findings at subsequent meetings. Other clinician members who may be assigned the responsibility of discussing often bypass rules with peers with the intent of modifying behavior or changing the rules. In some cases, a valid reason exists for bypassing rules, which may then become a new rule in itself. Regardless, this is a dynamic process that requires the organization's continual commitment if clinical decision support systems are to become a valuable clinical tool and remain a viable tool over the long term.

Last, knowledge sources may not be up-to-date. Healthcare knowledge continuously evolves and changes. Out-of-date knowledge sources may actually contribute to reduced quality and more errors. Healthcare organizations must implement processes that ensure that knowledge sources are updated as necessary to reflect current data available in the industry.

Establishing a true clinical decision support system environment has become a high priority in some healthcare organizations, but many must still implement electronic medical records and bedside medication administration applications before rules and alerts have full utility. While many healthcare organizations recognize the value of decision support, a thorough understanding of the need for foundation applications in addition to the critical success factors and the organizational commitment required to make clinical decision support a useful utility are the first steps to success.

CLINICAL PRACTICE GUIDELINES

Clinical practice guidelines are increasingly being used in the United States to reduce inappropriate care and improve patient outcomes. Several factors are fueling the use of guidelines, including the increasing costs of healthcare, new medical technology, a growing aging population, and variations in the service delivery of care by physicians, hospitals, and geographic regions. Clinical practice guidelines are broadly defined as statements that are systematically developed to assist clinicians and patients in making decisions about appropriate healthcare, given specific clinical conditions. Specifically, the major purposes for guidelines include the following: (a) assisting patients and practitioners in making clinical decisions, (b) educating individuals and groups, (c) assessing to ensure the quality of healthcare, (d) providing guidance for allocation of resources, and (e) reducing liability risk in cases of negligent care.

Primarily, clinical practice guidelines are of most value to healthcare practitioners, patients and their families, and healthcare institutions. In an effort to contain healthcare costs, public policymakers, health benefit plans, and regulators may find them useful when making specific decisions

about reimbursement. For patients, a consumer version of guidelines made available through leaflets, audiotapes, videos, magazines, newspapers, and Web sites provides a summary of the benefits and harm regarding healthcare options and potential outcomes. Guidelines empower patients to become more educated consumers, active in choices about their own health. Guidelines may also help the patient by calling attention to the need for changes in public policy regarding issues such as preventive interventions to assist neglected or high-risk groups or other areas requiring increased attention. For healthcare providers, guidelines can improve the quality of clinical decisions by providing clear directions on how to proceed with an intervention, keeping clinicians updated, improving consistency of care, and providing an authoritative base for decision making. Healthcare organizations may primarily benefit from guidelines by minimizing costs and optimizing the value of money spent through the greater standardization of care.

Despite all the perceived benefits, clinical practice guidelines have their limits. Recommendations may not apply readily to an individual patient, requiring clinicians to tailor decisions based on the patient's unique medical history and personal circumstances. Guidelines may also influence policymakers to refuse to pay for certain services. In terms of their development, guidelines may be flawed due to a lack of adequate scientific evidence, inadequate evaluation of study design flaws, the bias of the group that developed the guidelines, or a bias in favor of serving the needs of payers or special interests groups rather than with the patient's best interest. In weighing their advantages and disadvantages, guidelines may be best viewed as one option for improving the quality of healthcare.

The development of clinical practice guidelines involves three basic stages: (1) development, (2) implementation, and (3) evaluation. This process or cycle is dynamic in that the implementation and evaluation stages prompt periodic revisions when they become outdated due to new scientific evidence, when omissions are found, or when other problems are identified. Historically, most of the focus has been on the development phase. In more recent years, however, the last two stages have received growing attention.

History

While clinical practice guidelines, broadly defined, were in use for numerous aspects of healthcare for some time, a more formalized approach to guideline development began in the United States when an amendment to the Public Health Service Act in 1989 replaced the National Center for Health Services Research (NCHSR) with the Agency for Health Care Policy and Research (AHCPR). The Omnibus Budget Reconciliation Act of 1989 (PL 101-239) mandated the AHCPR to have a stronger emphasis on medical outcomes and effectiveness research and to develop, disseminate, and evaluate clinical practice guidelines. A newly created office, the Forum for Quality and Effectiveness in Health Care, was charged with this task. The AHCPR sought advice from the national Institute of Medicine (IOM) on how best to approach its newly appointed responsibilities involving clinical practice guidelines. The IOM is an advisory body of experts who provide science-based advice on critical national issues in biomedical science, medicine, and public health to the federal government and the public. The IOM appointed a study committee for technical assistance and advice on defining terms and determining key components of guidelines, implementation, and evaluation. This committee produced two reports, *Clinical Practice Guidelines: Directions for a New Program* (1990) and *Guidelines for Clinical Practice: From Development to Use* (1992).

The legislation that spawned the work of the AHCPR stemmed from a growing national concern with the high cost of healthcare, inconsistency in medical-practice patterns, and the perceived low value of some health services. The main goal of the AHCPR was to expand knowledge rather than focus on applications. The ultimate goal was to rely less on purely professional judgment and move more strongly toward a more structured approach to support healthcare decisions.

The Forum for Quality Effectiveness in Health Care was charged with arranging the development and periodic review of clinical practice guidelines. The guidelines were not to be created by the federal government but could be contracted with public and nonprofit private organization or produced by expert panels to develop and update them. The goal was to have guidelines, standards,

performance measures, and review criteria for at least three clinical treatments or conditions by 1991. Guidelines development has continued with an array of developers.

Developing Guidelines

Clinical practice guidelines are developed by many organizations, including professional societies, public agencies, healthcare institutions, and researchers. Insurers, health maintenance organizations (HMOs), and other private organizations have also been active in their development. Guidelines may be developed through single or collaborative effort.

In the medical professions, various academies, colleges, and societies have included the development of guidelines in addition to their sponsorship of peer-reviewed clinical journals for given specialties. Public agencies play a role in guideline development mainly to promote public health and welfare, to improve quality, and to control the costs associated with government-funded healthcare programs. Federal agencies such as the Agency for Healthcare Research and Quality (AHRQ) (formerly the AHCPR) and National Institutes of Health (NIH) also play key roles, with related activities occurring in the Food and Drug Administration (FDA), the Centers for Disease Control and Prevention (CDC), and the Centers for Medicare and Medicaid Services (CMS).

The large number of organizations developing clinical practice guidelines lends great breadth to the topics available and to the diversity in the manner in which they are developed. These variations, however, lead to variable quality. According to the IOM, the guidelines can vary in five key ways: (1) clinical orientation (clinical condition, technology, or process); (2) clinical purpose (screening and prevention, diagnosis, aspect of treatment, more discrete aspects of healthcare); (3) complexity (high, medium, or low as indicated by the amount of detail, complexity of logic, length of narrative or documentation); (4) format (free text, tables, if-then statements, critical pathways, decision paths, algorithms); and (5) intended users (practitioners, patients, others).

The U.S. Congress mandated that the AHCPR present clinical practice guidelines in formats

appropriate for use by practitioners, medical educators, and medical care reviewers. After the sponsoring agency or organization has created and disseminated an initial set of guidelines, the guidelines may be transformed into various other forms of presentation for various publications or groups who may benefit from them (e.g., journals, continuing medical education, specific user groups).

To encourage the developers of guidelines to use criteria to improve their processes and products, the IOM outlined eight desirable attributes of guidelines: (1) validity (including strength of evidence and estimated outcomes), (2) reliability/reproducibility, (3) clinical applicability, (4) clinical flexibility, (5) clarity, (6) multidisciplinary process, (7) scheduled review, and (8) documentation.

A concern was that guidelines published in peer-reviewed medical journals do not follow standards for guideline development, often lacking critical information to determine their validity. To address the problem, in 2002, the AHRQ supported the Conference on Guideline Standardization (COGS), which developed a checklist of components for the evaluation of the validity and usability of guidelines.

Clinical practice guidelines are generally developed through a series of steps. The first step involves initial decisions such as the selection of the topic (e.g., condition, procedure), selection of panel members (e.g., physicians, nurses, dentists, epidemiologists, statisticians), and clarification of purpose (e.g., specification of the target condition, type of patient, clinical presentations for use of the guidelines, and interventions). Next, there is an assessment of the clinical appropriateness based on clinical benefits and harms, admissible scientific evidence, and expert consensus. A summary of benefits and harms based on scientific evidence and expert consensus is generated. This summary helps determine which practices are appropriate, are inappropriate, or are of uncertain appropriateness in the clinical situation. An assessment is then made of public policy issues that affect the broader society. Considerations involve limitations in resources such as payment, opportunity, equipment, and personnel. Feasibility issues are also considered to determine if the research findings are applicable to real-world situations. Guidelines are then drafted to provide clear recommendations

and the rationale on which they are based. Content experts review the guidelines to ensure scientific and content validity. A sample of practitioners may be asked to pretest the guidelines and provide suggestions for improvements of the document. Recommendations are then made through a plan for dissemination, evaluation, and updating. Finally, guidelines outline recommended research priorities to call attention to important gaps in scientific evidence. Disclaimers and references complete the document.

Since the 1990s, with the growth of the evidence-based medicine (EBM) movement, the development of clinical practice guidelines has increasingly been based on scientific research evidence where available, but it also relies on expert consensus, especially when such evidence is lacking. Experts are selected based on expertise in the appropriate area, and credibility with the target audience by random or purposeful sampling. Members of the selected group are asked to take cues into account when making their decisions. Cues are dimensions or indicators to consider, such as a description of a situation as part of a scenario or vignette, or the severity of a condition.

When using expert consensus, clinical practice guidelines are generally developed by using one of three methods: (1) the nominal group technique (NGT), (2) the Delphi method, or (3) a hybrid of the two. The NGT aims to structure an interaction within a group. Each participant independently records his or her ideas. The facilitator then lists one idea from each participant in turn until all ideas have been recorded for the group. Each idea is discussed in turn. Participants then return to privately record their opinions and vote. The group may reconvene to discuss and vote. Group judgment is aggregated statistically from individual opinions. In contrast, the Delphi method involves no direct interactions by the participants. Initial views are collected via a mailed questionnaire. Participants are asked to suggest the cues to be used in decision making. At the next stage, another questionnaire is sent that asks for the individual's views, often using a Likert scale. The organizers then compile the results and send a summary indicating individual and group judgments. Over one or more opportunities, individuals may modify their judgment based on information provided by

the group. A third option, the modified Delphi method, asks the participants to first express their opinions by a mailed questionnaire that is sent to the group. The group then meets to discuss their opinions and records their final judgments by a questionnaire. Finally, a consensus development conference brings together a selected group of about 10 people to meet over the course of a few days. Interest groups or experts unrelated to the decision-making group present evidence. Participants disperse to determine their opinions and then reconvene to reach consensus through a chaired discussion.

Recently, systematic reviews of research have provided the foundation for guideline development. The judgment of experts has been criticized as lacking sufficient objectivity and rigor. Basing guidelines on scientific evidence rather than expert opinion has been found to be more thorough but also more costly.

Implementing Guidelines

The implementation of clinical practice guidelines involves a cultural shift in the healthcare system from one that traditionally relied on professional judgment and discretion to one that requires accountability for judgments. Formal organizational structures and management must support the use of clinical guidelines. For the guidelines to be relevant, it is important for physicians and others to develop those that are tested in actual clinical settings rather than solely in controlled clinical trials. As practitioners adopt the guidelines, more information becomes available in adapting and revising them to make them more useful for clinical outcomes.

The implementation of clinical practice guidelines is often considered more challenging than their development. Yet their true value lies in their successful use. Many of the potential users may not be aware of the existence of guidelines that could be helpful in their decision making, or they may see them as only marginally related to their practical daily work. Guidelines may be seen as a threat to professional autonomy, resulting in rejection of their use. While guidelines may be useful to patients, their implementation involves direct education to make the patients aware of guidelines that could be useful to them.

Evaluating Guidelines

Clinical practice guidelines make explicit recommendations to influence clinical decision making. They present evidence, costs, and a model for making decisions but also contain a value judgment based on the groups that produced them. Before a guideline is adopted for use, it should be evaluated for validity. For example, it is important to determine what methods were used and if the evidence was collected systematically. All reasonable practice options and potential outcomes should be considered with an estimation of how likely the outcome will occur. It is important to note if the guideline is current with recent developments by looking at the data on the guideline and the date that final recommendations were made. To account for individual value differences, it is necessary to determine if the guideline was subject to peer review and testing. The recommendations should provide practical and unambiguous advice. The strength of the recommendations should be indicated based on the literature and taxonomies that measure “levels of evidence” as deemed appropriate for the given specialty. Of utmost importance is evaluating whether the recommendations are applicable to the patient in question based on medical history, individual circumstances, or other factors.

Updating and Withdrawing Guidelines

Clinical practice guidelines need to be evaluated periodically, in terms of both content and validity, to avoid potential breakdowns in the process of care or poor patient outcomes. Guidelines may become obsolete as new scientific information becomes available. The volume of research advances, and the amount of time between reviews will determine how thorough the update needs to be. Conducting a traditional systematic literature review can be both time-consuming and costly. Most commonly, it is recommended that guidelines receive a scheduled review date. Guidelines may require an update when new information becomes available. However, the optimal timing for such an update is unclear.

Updating guidelines should occur when changes in clinical evidence make a preexisting guideline invalid, when new outcomes become important

(such as quality of life), when new interventions supersede or complement other interventions, when the gap between ideal and current practice narrows to the point that a guideline is no longer needed, when society changes values based on specific outcomes, or when increases in service delivery warrant an update. A suggestion that has received increasing favor is a model using the expert opinion of a multidisciplinary group and focused literature reviews based on target review articles, editorials, commentaries, new guidelines found in registries, and articles that reference the guidelines to determine when a guideline requires an update. Based on this method, some guidelines may remain valid, while others may become obsolete.

Locating Guidelines

Clinical practice guidelines are available through a number of agencies, organizations, and resources, including the National Guideline Clearinghouse, the Cochrane Collaborative, and several databases.

The National Guideline Clearinghouse is an initiative of the AHRQ. Hosted on the AHRQ's Web site, the clearinghouse provides a publicly available comprehensive database consisting of more than 1,000 evidence-based clinical practice guidelines. It provides structured abstracts of the guidelines and their development and links to full-text guidelines, when available, or information for ordering print copies. A guideline comparison feature is available that allows a comparison of two or more guidelines side-by-side along with other components and features noted on the Web site.

The Cochrane Collaboration provides a compilation of five databases for finding evidence to assist in deciding on the best treatment for a given condition. These include the following: (a) Cochrane Database of Systematic Reviews; (b) Database of Abstracts of Reviews of Effects; (c) Cochrane Central Register of Controlled Trials; (d) Cochrane Methodology Register; (e) Health Technology Assessment Database; and (f) the National Health Service (NHS) Economic Evaluation Database.

Clinical practice guidelines may also be found by searching the CINAHL (Cumulative Index to Nursing and Allied Health Literature) and PubMed databases. In CINAHL (available by subscription),

the phrase *practice guidelines* may be selected from the “Publication Type” menu. In PubMed (freely available from the National Library of Medicine), under the “Limits” tab, the box for “practice guideline” can be checked in the section under “Type of article.”

Institutions and centers within the NIH often post guidelines on their Web sites. These may be searchable via the Web search feature on the page by using the search terms *guidelines*, *practice guidelines*, or *clinical practice guidelines*.

COCHRANE, ARCHIBALD L.

Archibald L. (Archie) Cochrane (1909–1988) was a British physician who contributed greatly to the development of epidemiology, and he was a pioneer in evidence-based medicine. His ideas eventually led to the creation of the international Cochrane Collaboration, which tracks down, evaluates, and synthesizes the results of clinical trials and other studies in all areas of medicine.

Cochrane was born in 1909 in Scotland to a wealthy family. He began his medical studies in 1934 at the University College Hospital, London, after receiving first class honors in the Natural Sciences Tripos from King’s College, Cambridge. In 1936, he served in a field ambulance unit in the International Brigade in the Spanish Civil War. In 1938, he qualified in medicine (receiving what is equivalent to a medical degree in the United States). With the outbreak of World War II, Cochrane enlisted and served as a captain in the Royal Army Medical Corps. While on duty in Crete in 1941, he was captured and taken prisoner by the Nazis. For the rest of the war, he was as a medical officer in various prisoner-of-war camps in Greece and Germany. Many prisoners he treated suffered from tuberculosis, and he became interested in studying the disease. After the war, through a Rockefeller scholarship, he attended the Diploma in Public Health program at the London School of Hygiene and Tropical Medicine. In 1947–1948, he left Britain to study the epidemiology of tuberculosis at the Henry Phipps Institute in Philadelphia.

Returning to the United Kingdom, from 1948 to 1960, Cochrane was a member of the Medical Research Council’s (MRC’s) Pneumoconiosis Research Unit in Penarth, Wales. His work at the council included the study and classification of pneumoconiosis, a common occupational lung disease of coal miners in Wales. At his work, he

became increasingly interested in the reproducibility of all clinical and related measurements, as well as many aspects of field epidemiology, such as the standardization of collected data and the validation of diagnoses.

In 1960, Cochrane was appointed the David Davies Professor of Tuberculosis and Chest Diseases at the Welsh National School of Medicine in Cardiff. He also became the director of the Medical Research Council Epidemiology Research Unit.

In 1972, Cochrane gave the Rock Carling Lecture “Effectiveness and Efficiency: Random Reflections on Health Services,” which was subsequently published as a book. In the book, which he is best known for, Cochrane stressed the need to use the evidence from randomized controlled trials (RCTs).

In 1974, he presented the Dunham Lectures at Harvard University; and in 1975, he became an honorary fellow of the American Epidemiological Society.

Archibald Cochrane died in 1988 at the age of 79. His autobiography, *One Man’s Medicine*, written with the assistance of Max Blythe, was published in 1989.

Cochrane’s ideas were instrumental in the founding of the Cochrane Collaboration in 1993. The collaboration is an international, nonprofit, independent organization that produces and disseminates systematic reviews of healthcare interventions and promotes the search for evidence from clinical trials and other studies. Its major product is the Cochrane Database of Systematic Reviews, which is published quarterly as part of the Cochrane Library.

CODMAN, ERNEST AMORY

Ernest Amory Codman, MD (1869–1940), had a guide star for his life’s work: the *end results idea*. He argued that patients and physicians should know the end results of the medical care they receive and give so that patients can choose good care and physicians can learn from their mistakes and improve their care.

In 1889, even before he graduated from Harvard College (class of 1891) and Harvard Medical School (class of 1895), he started a yearly log of his bird-hunting efficiency. He recorded the number of shots fired (process) and birds killed (outcome or end results of hunting) and the rates of birds to shotgun shells expended (efficiency).

In those days, medical students at the Massachusetts General Hospital gave anesthesia during surgery. Codman bet his classmate and best friend, Harvey Cushing (1869–1939), who later became a renowned neurosurgeon, to see who would have better outcomes of their care. The result was the first use of anesthesia charts, graphing the patients’ pulse and respiration every 5 minutes.

Briefly Codman became the first radiologist at the Boston Children’s Hospital. He ran the fluoroscopy for the landmark physiological experiments of Walter B. Cannon (1871–1945) showing a goose swallowing a radiologically opaque button.

Codman became a junior surgeon at the Massachusetts General Hospital and followed up on the outcomes of all patients he cared for. He urged others to do the same. Unsatisfied with the

willingness of this hospital to adopt his ideas, he created his own proprietary “End Result Hospital” nearby, where he could pursue his ideas about hospital efficiency. His hospital existed from 1911 until 1918. All patients treated at the hospital were followed up after discharge, with the results reported, patient by patient, and published at Codman’s own expense for all to read.

Here is an example of what was written (Case #17): “February 10, 1912, Female, 39, Hemorrhoids Operation (EAC) clamp and cautery. Complications: none, Result Sept. 8, 1913. Well, except for annoyance from skin tabs which were not removed (E-j).” Note that for the case, the surgeon is named (Codman), the process of care is described, a post-discharge follow-up of the patient’s perception and physical condition is included, and the public recording of the surgeon’s error in judgment (E-j) is given.

His error classification is another of his many contributions. In this case, Codman decided that he had made an error in not removing the skin tabs. This brief description is as plausible to us today as when Codman wrote it.

In 1910, Codman helped start the American College of Surgeons. He chaired its Committee for Hospital Standardization, which studied hospital outcomes (end results) and how they could be improved. Eventually the committee led to the creation of the Joint Commission.

On January 8, 1915, Codman unveiled a large cartoon at a local surgical society meeting showing his colleagues as being more interested in money than end results. This was the peak of his undiplomatic outspokenness in advocacy of his end results beliefs. His colleagues were offended, his medical income fell, and his hospital was closed in 1918, when he entered military service. Codman would eventually create end result cards for all the soldiers he treated in World War I.

After the war, Codman returned to surgical practice in Boston. He started a registry of bone sarcoma, which is the forerunner of all cancer registries. In 1934, he wrote the first book ever written solely on the shoulder, which is considered a classic work in orthopedic surgery. The book’s preface contains his autobiography, while the last chapter of the book discusses the influence of economics on surgery.

Codman received no appreciation during his lifetime. He was ostracized by many of his peers,

he received no patient referrals, and he had few patients and little income. When he died, he was too poor to afford a headstone and was buried in an unmarked grave. However, Codman realized he was ahead of his time and thought that future generations would appreciate his end result ideas.

In 1996, the Joint Commission established an award in his honor. The Codman Award is awarded annually to recognize the achievements of individuals and organizations in the use of process-and-outcome measures to improve the quality and safety of healthcare.

COHEN, WILBUR J.

Wilbur J. Cohen (1913–1987) was the Secretary of the Department of Health, Education, and Welfare (DHEW) under President Lyndon Johnson, but today Cohen is often credited with a larger role in public service. He is seen as the key architect of the American social welfare system. A participant in drafting the Social Security Act of 1935, Cohen was also closely associated with the passage into law of Medicare legislation in 1965. Between those two watershed events in American welfare history, Cohen proved himself a tireless advocate of federal assistance for America's most vulnerable members.

The conditions of Cohen's early life likely contributed to his later advocacy for social welfare. The son of immigrants, Cohen grew up in Milwaukee in modest circumstances. His father was a grocer. And from an early age, Cohen was keenly aware of economic disparities. Cohen was also intelligent and a good student in school. At the University of Wisconsin–Madison, he majored in economics, influenced in his choice by the great depression that had settled on the nation in the early 1930s. There he distinguished himself as an energetic and hardworking student and, more important, made contacts that were to prove immensely helpful in launching him into a career in government.

After graduating in 1934, Cohen considered graduate school and a career in academe but instead accepted a job as a research assistant with a former professor in Washington, D.C. Edwin Witte was one of a number of academics who were drawn to Washington to assist in writing the New Deal legislation of President Franklin D. Roosevelt. Witte was then executive director of the Committee on Economic Security, working under Arthur Altmeyer (another Wisconsin alumnus), the Assistant Secretary of Labor.

Cohen arrived in Washington in 1934 and found it much to his liking, a heady place for a bright young college graduate with liberal leanings and boundless energy. Working under Witte on the Committee on Economic Security, Cohen helped write language that eventually became the basis of the nation's first social insurance legislation. In 1935, President Roosevelt signed into law the Social

Security Act, the most well-known provision of which was insurance for the elderly. Cohen, at the age of 22 years, had played a part in drafting it.

A provision of the act created the Social Security Board—later known as the Social Security Administration—and Altmeyer, a board member, offered Cohen a job. For the next 20 years, Cohen served as a staff member of the board, and in that time he worked to expand the provisions of the original Social Security Act well beyond its original coverage. In 1939, for example, he was much gratified when amendments to the act added survivor benefits to the original legislation.

As director of the Bureau of Research and Statistics within the Social Security Administration, Cohen developed a keen knowledge of the technical aspects of the Social Security programs, which he used to good effect as a congressional liaison, providing crucial assistance in drafting public policy language, statements, and scripts. Cohen was a technocrat—a technical expert—but he was by no means a minor bureaucrat only handy with statistics. Instead, he played an important part in drafting national welfare policy and persuading legislators to embrace it and make it their own cause.

In the 1940s and 1950s, Cohen played a part in advancing the idea of national health insurance, which to him seemed a logical extension of the original Social Security legislation, leading to healthcare for all Americans. While Cohen was unsuccessful in that effort, he was nonetheless able to help expand incrementally the benefits of Social Security, which by the 1950s had become a popular program receiving bipartisan support. In 1956, the U.S. Congress passed legislation that added disability benefits to the Social Security program. In the same year, Cohen made a significant career change, leaving Washington for Ann Arbor, where he became a professor of public welfare administration in the School of Social Work at the University of Michigan.

After the 1960 national elections, Cohen was invited to join President John F. Kennedy's team as Assistant Secretary for Legislation in the Department of Health, Education, and Welfare. In New Frontier Washington, Cohen set to work on national health insurance for the elderly. This was to be part of Kennedy's vision of a "second generation" of social welfare programs, and Cohen, as an expert on Social Security, was a logical choice to play a

central role in it. After President Kennedy's death, Cohen remained in Washington, a member of President Johnson's Great Society team, where he was able to continue much of the work begun under Kennedy.

Cohen threw himself into the push for Medicare. He assisted in writing legislation; he worked with legislators to get the bill through Congress; and later, he helped implement its provisions. In that effort, he was fortunate in having the support of Arkansas Congressman Wilbur D. Mills, the powerful Democratic chairman of the House Ways and Means Committee, and in securing other political alliances to ensure its passage. The year 1965 was a watershed for social welfare legislation, as Medicare became law and Medicaid expanded healthcare to the poor. It was also the high watermark of Social Security expansion, just as it was, on a personal level, among the high points of Cohen's career in Washington, second in importance to his confirmation as Secretary of the Department of Health, Education, and Welfare (DHEW) in 1968. At the swearing-in ceremony for the new DHEW Secretary, President Johnson acknowledged Cohen's "role in every piece of social legislation in the last 35 years."

When President Johnson left public office in 1969, Cohen returned to teaching at the University of Michigan. But he could not put his political agenda behind him. Settled into academe, Cohen was never far from the ongoing social welfare battles in Washington, which he viewed from a distance with a passionate interest and outspoken advocacy. Cohen retired from the University of Michigan in 1978, but he returned to the classroom 2 years later, accepting a professorship in the Lyndon B. Johnson School of Public Affairs, University of Texas at Austin. Until his death in 1987, Cohen continued to speak out in support of social welfare legislation and in defense of the Social Security programs he had done so much to build.

From Roosevelt's New Deal to Johnson's Great Society, Wilbur Cohen played a part in shaping national welfare policy. A technocrat with a keen understanding of the statistical arguments for Social Security expansion, Cohen was also a skillful salesman of the programs he promoted. He was a man with the political contacts and know-how for guiding legislation through the U.S. Congress. It is a telling comment on Cohen's lifelong passions

to note that he maintained a home near Washington after leaving federal employment in 1969. Until the end of his life, Cohen traveled to Washington from Ann Arbor and later Austin, staying at his home near the city that had been the scene of so many of his personal triumphs.

COHORT STUDIES

Cohort studies represent a type of epidemiological approach to investigating the incidence and prevalence of disease across a fixed population group over time. Using this type of approach, researchers compare outcomes between a cohort, or group, of individuals who have a risk factor (e.g., smoking) believed to be associated with a disease (e.g., lung cancer) and a group without the factor (e.g., non-smokers). Cohort studies can be conducted either prospectively or retrospectively.

Prospective Cohort Studies

Prospective cohort studies involve following a large group of individuals who are initially free of the

disease of interest over time (often years and sometimes decades). Typically, cohort studies do not employ a randomized design because of potential ethical problems. That is, it is neither ethical nor easy to randomly assign people to be exposed to a potential risk factor for the disease of interest. Instead, the individuals in the group and their various exposures to risk factors are determined, and the development of the specific disease is determined.

The advantages of prospective cohort studies are as follows: They are able to develop and test hypotheses about the cause-and-effect relationships between identified risk factors and disease outcomes because the temporal ordering of events can be determined; they can measure multiple outcomes of a single risk factor to study relatively rare exposures to risk; and they measure the absolute or true risk of the factor under study.

The disadvantages of prospective cohort studies are as follows: They take a long time to complete; they are very expensive to conduct; they require considerable monitoring and management effort; and they may have high rates of participant attrition or many individuals lost to follow-up. Prospective cohort studies are also not well suited to study rare diseases because of the limited number of potential cases and the often long time between exposure to a risk factor and the development of a disease.

The Framingham Heart Study

Because of their high costs, long-term, prospective cohort studies are relatively rare. Perhaps the best-known and most famous prospective cohort study is the Framingham Heart Study. This study, which began more than 60 years ago, is still ongoing. The Framingham Heart Study is heralded as being responsible for the discovery of the major risk factors associated with cardiovascular disease.

Originally funded by the National Heart Institute (now the National Heart, Lung, and Blood Institute) in 1948, the study recruited a cohort of more than 5,000 adults aged 30 to 62 living in the small town of Framingham, Massachusetts. These individuals, who did not have cardiovascular disease when they started the study, were studied and received medical tests every 2 years to determine the underlying factors associated with the later development of heart disease. The study's first report, which focused on

the progression of rheumatic heart disease, was released in 1956. The original cohort was studied until 1971, when a second-generation cohort was recruited. In 2002, the third cohort, grandchildren of the original cohort, consisting of 3,900 individuals, became the latest cohort to join the study.

Over the years, the Framingham Study has uncovered and popularized the major underlying risk factors of heart disease, including high cholesterol, high blood pressure, diabetes, obesity, and cigarette smoking. The study has also identified the interactions between and among these risk factors. Additionally, it has focused on the effects of social and psychological factors, such as stress and the genetic links to heart disease. The study continues to further identifying and determining a myriad biological, social, psychological, lifestyle, and genetic effects of cardiovascular disease.

The most recent results from the Framingham Heart Study, investigating the genetic links associated with cardiovascular disease, indicate that individuals with a sibling having a stroke or arterial disease have a 45% increased risk of developing the same disease.

Retrospective Cohort Studies

Retrospective cohort studies are sometimes conducted using old records of individual groups. These studies attempt to determine a group's past exposure to a risk factor and an outcome. For example, to investigate the risk of exposure to a particular chemical and the development of a disease, researchers may use the employment records of past workers at a factory to identify their exposure and medical and death records to determine the outcome.

It should be noted that the term *retrospective studies* often refers to retrospective case-control studies, which do not follow individuals over time but rather look in the past for measures of association. These types of studies are generally viewed as a subset of cohort studies. Typically, a retrospective case-control study involves using existing medical records as the primary data source. Individuals are selected for inclusion into the study based on the outcome or disease of interest (the cases). And a comparable group without the outcome is selected as a control group.

One major advantage of the retrospective case-control studies is their ability to study the effects of risk factor exposure to the development of rare diseases. This is because the case group can be identified from a broader population and because the researcher knows the subjects have the disease compared with waiting for the disease to occur after the risk exposure. Retrospective studies have become more popular as the quality and efficacy of diagnostic procedures and the quality of medical record information have improved. There are a number of additional advantages to the case-control approach. They are relatively inexpensive to conduct because they do not require as much management; they allow the study of diseases where there is a long time period between the exposure to a risk factor and the development of the disease; and they are far less time-consuming than prospective studies.

Retrospective studies, however, also have several disadvantages. First, although several risk factors can be analyzed at one time, the study can only focus on one disease. Second, since many clinical records are not specifically designed for research purposes, their completeness may be questionable. Third, exposure to extraneous factors cannot be completely controlled for using a case-control approach.

COINSURANCE, COPAYS, AND DEDUCTIBLES

Coinsurance, copays, and deductibles are utilization management tools used by health insurers to limit the extent of moral hazard. Moral hazard is the tendency of individuals to use more healthcare services because they are insured. Coinsurance is defined as the percentage of the agreed-on provider charge that the insured is obligated to pay out of pocket. A copay is a fixed dollar amount per service that the insured is obligated to pay regardless of the amount the insurer has negotiated with the health services provider. A deductible is an amount of expenditure for covered health services that an insured individual must pay before the health plan has any obligation to pay for services.

Overview

Traditionally, an insured individual was expected to pay 20% of a bill for healthcare services he or she used. Higher percentages of coinsurance are now sometimes used for out-of-plan use by the insured in preferred provider organizations (PPOs).

A copay is paid for by the insured individual at the time of the provider visit. A typical copay may be \$20 per physician office visit or \$70 for an emergency department visit.

Historically, \$250 or \$500 deductibles were common. Today, high deductible health plans often require that an insured individual incur expenditures of \$5,000 before the plan begins to pay. Deductibles are also sometimes used for specific services rather than aggregate expenditures. For example, a health plan may require that the insured individual satisfy a \$500 deductible for

hospital services if he or she chooses to use some hospitals in the community but will not require the deductible for other, preferred hospitals.

Moral hazard in healthcare occurs because people who are insured do not bear the full cost of their care. If patients are very price sensitive, meaning they are responsive to price, a small decrease in the out-of-pocket price will result in large increases in the use of the service. Analogously, if a small coinsurance rate or copay is imposed, patients substantially reduce their use of some health services. A deductible also obligates the patient to pay a portion of the bill and would reduce health services utilization.

Empirical Evidence

The key issue surrounding the use of these utilization management tools is the extent to which they actually do reduce utilization and affect health. The RAND Health Insurance Experiment continues to be the general definitive study of the effects coinsurance and deductibles have on the use of services.

The basic finding from the RAND Health Insurance Experiment is that health services, generally, have a price elasticity of about -0.2 . This means that a 10% increase in the out-of-pocket price reduces the use of services by about 2%. However, the effects of changes in price differ rather substantially across particular types of health services. Ambulatory mental health visits, for example, are much more price sensitive than are physician visits. Dental care exhibits a large transitory effect not seen with other services, and hospital care is much less price-responsive than physician services.

This has important implications for the structure of health insurance plans and the use of other utilization management techniques. It suggests, for example, that coinsurance and copays are much more likely to be used for ambulatory services, such as physician visits, prescription drugs, and mental health services, than for inpatient care. Because of this, one would expect to see other utilization management techniques used on the inpatient side. Thus, managed-care plans tend to rely on preadmission certification and concurrent review to reduce moral hazard in the inpatient hospital

setting but use differential copays and/or coinsurance for services that are more price sensitive.

The success of copays and coinsurance in limiting utilization will depend in part on the opportunity cost of the patient-consumer's time. The "full price" of a visit to a physician includes not only the amount of money the patient must pay but also the value of the time associated with getting to the physician's office, waiting to be seen, being seen, and returning to other activities. If these activities take 2 hours and the patient is an attorney who could be billing clients at \$400 an hour, the full price of the visit is \$800 plus the actual money price paid to the physician. For someone earning \$10 an hour, the full price is \$20 plus the physician's fee. If the same copay or coinsurance rates were applied to the physician's fee, it would obviously have a smaller impact on the attorney's use of services. The implication is that smaller copays or coinsurance rates may be effective in reducing the utilization of lower-income groups, whereas substantially higher amounts would be required to have the same effect on upper-income consumer-patients.

Differential or tiered copays have become common, particularly for prescription drugs, where there are different copays for generic, preferred brand, and nonpreferred brand drugs. One study by Geoffrey Joyce and associates in 2002 compared insured individuals with one regime of copays relative to another. In every tier, for each drug type, those with higher copays had lower drug expenditures. The price elasticities ranged from -0.22 to -0.40 , with the three-tier nonpreferred brand name prescriptions being the most price sensitive. The study also demonstrated expenditure reductions in moving from a one- to a two-tier drug plan or from a two- to a three-tier drug plan. The price sensitivity in the nonpreferred brand tier was greatest because it is in this tier that the patient-consumers have the greatest availability of lower-priced substitutes.

Deductibles have become a potentially more important insurance utilization management tool with the advent of consumer-driven health plans (CDHPs) and health savings accounts (HSAs). The RAND Health Insurance Experiment found that a \$4,160 family deductible (in 2006 dollars) followed by free care reduced medical care expenditures by 31%. More recent work from the

Netherlands found reductions of 28% for a similar insurance program with a \$1,280 or more deductible (in 2006 U.S. dollars). This study suggested that a family deductible of \$1,000 U.S. dollars might reduce spending by approximately 14%.

COMMITTEE ON THE COSTS OF MEDICAL CARE (CCMC)

The Committee on the Costs of Medical Care (CCMC) was the most influential health services research group in the United States during the late 1920s and early 1930s. The CCMC, which was

composed of 48 members, including physicians, dentists, public health professionals, and economists, was established to study the escalating costs of medical care, access to care problems, and distribution of health services in the nation. Starting in 1927, the committee published 27 research reports on its findings. The committee's final report, published in 1932, made recommendations for more economical and effective healthcare. It discussed health insurance mechanisms, increased national and state funding, and the role of preventive health. However, the committee could not reach a consensus, and its final report included a majority report and two minority reports. Many of the committee's recommendations regarding health insurance coverage, group medical practice, and community health centers would come to fruition in the second half of the 20th century.

History

After a meeting on medical economics at the American Medical Association's (AMA's) annual convention in 1926, where several delegates discussed healthcare reform, a small group was convened to explore these issues in greater depth. This initial group, referred to as the Committee of Five, included Winford H. Smith from Johns Hopkins Hospital; Llewellyn F. Barker from the Johns Hopkins Medical School; Walton H. Hamilton, an economics professor from the Brookings Institution; C. E. A. Winslow, a public health professor from Yale University; and Michael M. Davis, who was previously the director of the Boston Dispensary and a well-known author on the sociological aspects of healthcare. Harry M. Moore, who served as an economist for the U.S. Public Health Service, was appointed secretary, although he was not a formal member of the committee. Smith served as the chairman of this group.

This group asked Ray Lyman Wilbur, president of Stanford University and a past president of the AMA, to preside over the meeting at the 1927 annual convention of the AMA. The Committee on the Cost of Health Care (CCHC) was formed following this meeting, and Wilbur was appointed to serve as chairperson. Moore was appointed the director of research, assuming research oversight and administrative responsibilities.

The CCMC, an independent entity, received funding from private philanthropic sources for its research and administrative costs. Specifically, the Carnegie Corporation, Josiah Macy, Jr. Foundation, Milbank Memorial Fund, New York Foundation, Rockefeller Foundation, Julius Rosenwald Fund, Russell Sage Foundation, and Twentieth Century Fund contributed a total of nearly \$1 million to the committee. This financial support allowed the committee to delve into issues concerning the affordability of medical care for Americans, the training and earnings of medical professionals, and the distribution of health resources in the nation.

In 1928, Isidore S. Falk, a young medical researcher, joined the CCMC to serve as its associated director of studies. His involvement was key to the prolific nature of the committee's publications, reports, and collaborations. The committee officially changed its name in 1930, becoming the Committee on the Costs of Medical Care, this new title reflecting the multitude of financial factors beyond the expenses associated with physicians that affect medical care.

Final Report: Findings and Majority Recommendations

The CCMC's final report detailed many of its findings over the 5 years that it was in existence. The report found that in 1929, the national health expenditures totaled \$3.7 billion, representing 4% of the nation's gross domestic product (GDP) and \$30 per individual and \$123 per family. It also found that only 60% of the nation's population was responsible for these costs, the majority of which were paid directly by patients and their families; that less than 60% of the nation's counties had a hospital; that half of the population visited a physician each year; that only 20% of the population received dental care annually; that many poor Americans could not afford adequate medical and dental services; and that the middle class was not able to pay for the expenses of a major illness. The report also found that physicians' salaries varied across geographic regions and that one third of general practitioners earned less than \$2,500 per year.

In its majority report, the CCMC presented five recommendations to address the economic issues of

the nation's healthcare system. First, it advocated for group practice between physicians and dentists in a hospital setting and the development of community health centers. Second, it proposed the expansion of public health services, especially at the state and local levels. Third, it recommended group payment for healthcare, calling for health insurance coverage to be provided by private sources, government, or a combination of both; it did not specify the type of insurance mechanism because a few members advocated for universal compulsory coverage, while others endorsed voluntary insurance schemes. Fourth, it called for stronger coordination of medical and health services, proposing the establishment of state and local agencies to study and evaluate these services. Last, it proposed improving the education and training of medical professionals, including physicians, nurses, dentists, pharmacists, and healthcare administrators.

Final Report: Minority Reports

The CCMC's final report contained two minority reports. While the first minority report agreed with the majority report on extending public health services, improving medical education, and coordinating medical services better, it strongly opposed the group practice and group payment recommendations. The first minority report felt that group practice would encourage contract practice and commercialization. Moreover, several signers of the first minority report disagreed with the proposal for voluntary group health insurance because they believed that it would lead to a compulsory healthcare system. Specifically, the first minority recommendations were as follows: Limit the government's medical activities to care for the indigent, government institutions, public health, and veteran's affairs; expand government care of the indigent, relieving the burden on medical professionals to provide charity care; improve coordination of services; restore the role of the general practitioner to the center of medical practice; eliminate the corporate practice of medicine; and examine and tailor payment methods to fit institutions and practices. Eight members of the CCMC signed the first minority report, seven of whom were physicians.

The second minority report, signed by two dentists, agreed with much of the majority report but

raised issues with the development of community health centers and the inadequate understanding of problems within dental group practice.

Two members of the CCMC did not join any report; instead they wrote personal statements—one called for compulsory insurance coverage, while the other expressed dissatisfaction with the committee's ability to deal with the fundamental economic question brought before the group.

Criticism

The AMA strongly opposed the majority report's endorsements of voluntary health insurance and group medical practice, launching an attack on its efforts. The AMA supported the first minority report and encouraged its membership to do the same. In addition to mainstream media headlines calling the CCMC's stance on group payment "socialized medicine," editorials appeared in the *Journal of the American Medical Association* that described it as "Sovietism." Local medical societies also criticized the majority recommendations and endorsed the first minority report.

Future Implications

The CCMC's efforts helped the emergence of private health insurance and eventually the federal Medicare and Medicaid programs. The committee's promotion of group medical practice can also be seen in present-day managed-care organizations and the large number of community health centers in the nation. Its emphasis on the need for national data collection systems to monitor trends in healthcare will eventually be accomplished by the National Center for Health Statistics (NCHS) and other federal agencies. Finally, the committee significantly contributed to the growth of the field of health services research, training a number of distinguished health economists, healthcare administrators, and public policymakers.

COMMONWEALTH FUND

The Commonwealth Fund is a large New York City-based, private, nonpartisan foundation that supports independent research on healthcare issues and provides grants to help improve healthcare practice and policy. The Commonwealth Fund's mission is to promote a healthcare system with better access, improved quality, and greater efficiency, especially for those most vulnerable in our society—low-income individuals, children, the uninsured, minorities, and the elderly.

History

In 1918, Anna M. Harkness founded the Commonwealth Fund with the broad mandate that it should do something that would benefit the welfare of mankind. The foundation was initially

endowed with a gift of nearly \$10 million. Edward Harkness, Anna M. Harkness's son, was the fund's first president. Both Edward and his mother were committed to building a responsive and socially concerned philanthropy, donating generously to the fund's endowment over the years. In fact, between 1918 and 1959, the Harkness family endowed more than \$53 million to the fund.

From the 1920s through the 1940s, the fund helped develop the field of child guidance and supported public health departments in communities around the country, and the construction of rural hospitals. In 1925, the fund launched the Commonwealth Fund Fellowships, an international program that brought young professionals to the United States for extended studies and travel. The Commonwealth Fund Fellowships later became known as the Harkness Fellowships.

After World War II and into the 1980s, the fund concentrated on addressing the needs of communities that lacked healthcare services. It did so in several ways: The fund assisted in developing new medical schools, which addressed the issue of physician shortage, and medical school curricula. It also contributed to bringing healthcare to underserved communities, including troubled urban areas. The fund played a role in bringing attention to the problems facing elderly Americans as well as those faced by academic health centers. In addition, the fund helped stimulate several programs and movements, including youth-mentoring programs and the patient-centered care movement of the 1980s.

Since 1995, the Commonwealth Fund has focused on healthcare issues, specifically health insurance coverage, access to care, and improving healthcare quality and efficiency. Through its international base, the fund is able to encourage communication and collaborations on health policies and practices among developed countries.

As was the Harkness family's intent, the Commonwealth Fund has sought to identify promising practices and solutions that could help the United States achieve a high-performing healthcare system.

Activities

The fund operates programs in the following areas: healthcare quality improvement and efficiency,

future of health insurance, Medicare's future, high-performance health system, patient-centered primary care, state innovations, quality of care for underserved populations, child development and preventive care, quality of care for frail elders, minority health policy, and health policy and practice. Additionally, the fund administers several fellowship programs, including the Commonwealth Fund/Harvard University Fellowship in Minority Health Policy, Harkness Fellowship in Health Care Policy, Packer Policy Fellowship, Australian-American Health Policy Fellowship, and the Ian Axford Fellowship in Policy. The Commonwealth Fund also disseminates information, knowledge, and experience—all in an effort to influence policymakers to achieve the fund's goal of a high-performing healthcare system.

Grants and Publications

The Commonwealth Fund has not only been a grant maker but also a professional publisher. The fund's professional staff works with its grant recipients to develop and implement projects and communicate project results. The fund also develops and publishes books, reports, and other material that inform clinicians, healthcare administrators, and the public about the fund's research and ways to achieve a better healthcare system.

Each year, the Commonwealth Fund produces numerous scholarly publications, written by the fund's grant recipients, staff, and invited experts—all of which are available on the Commonwealth Fund Web site free of charge. In addition, each year fund staff and grantees publish articles in peer-reviewed journals. The fund ensures the quality of its publications through internal peer review and sometimes independent external peer review.

The Commonwealth Fund continues to seek out ways to improve the quality, efficiency, and access to America's healthcare system. By bringing health services research and health policy together and continuing its mission of promoting a high-performing healthcare system, the fund will likely have a sustained impact on the access, costs, and quality of healthcare for all Americans.

COMMUNITY-BASED PARTICIPATORY RESEARCH (CBPR)

Community-based participatory research (CBPR) is a collaborative research approach that directly and equitably links researchers and communities to jointly study an issue. A key feature of CBPR is the recognition that researchers and communities each bring unique strengths and perspectives to the research process, enabling a combination of

knowledge and action to achieve social change. In the health services research arena, this achievement often leads to improved health outcomes and reduced health disparities.

The CBPR model serves to establish a structure within which community and academic participants work together to achieve a balanced set of research methods, tools, and priorities. When members of communities affected by the issue being studied are invited to participate in the research process, they are given unique opportunities to influence their surroundings. As a result, the CBPR approach is a powerful means of satisfying the rigors of scientific research and addressing the needs of the communities involved—communities that often consist of underserved and marginalized individuals.

History

CBPR is rooted within social psychologist Kurt Lewin's "action research" school, which rejected traditional notions that objectivity could only be achieved by removing oneself from the community of interest. In the 1940s, Lewin's research focused on creating mutually beneficial relationships between researcher and community and helping community leaders use research data to achieve social change. Lewin's approach emphasized a continuous cycle of planning, action, reflection, and decision making that resembles a spiral of cascading steps.

In the first step, a general issue is identified. Part of what makes the action research approach inherently unique is the belief that this initial issue should come from the community of interest itself, rather than from academia. The results of this community involvement from the start include a community's sense of empowerment, trust in the research team, and investment in the project itself.

The next step is a careful examination of the issue within the context of the community, from which comes an overall plan to guide the research. Action is taken in the next step, after which an evaluation occurs. Whether formal or informal, the evaluation usually results in a revision of the plan and additional action steps, and the cycle continues with the constant reciprocation between researcher and community.

In the 1970s, early examples of participatory research in action appeared in several developing nations, where scholars such as Brazilian educator Paulo Freire rejected “colonial” research methods in favor of more community-oriented ones. Freire’s approach built on the critical pedagogy he put forward as a response to the traditional formal models of education in Latin America. Using the same continuous cycle of steps employed by Lewin, Freire examined the process of learning as a way to stimulate critical thinking and raise students’ critical awareness of their environment. Inherently political in nature, his approach triggered social changes that reduced the divide between the powerful and the marginalized.

In 1984, the Centers for Disease Control and Prevention (CDC) established the Prevention Research Centers (PRC) Program, a network of academic researchers, public health agencies, and community members that conducts applied research in disease prevention and control. The CDC set forth four core values in keeping with the fundamental goals of the CBPR: respect, trust, integrity, and accountability. Key activities of the PRC Program include establishment of multidisciplinary research teams, creation of research networks for priority health issues, generation of long-term relationships for engaging communities as partners in research, and development of public health researchers’ skills for working with communities. There are currently more than 30 PRCs located in schools of public health and medicine, enabling academic researchers to easily identify and partner with public health agencies and communities. In 1997, the Institute of Medicine (IOM) recommended CBPR as one of eight new areas in public health education.

In recent years, the focus of CBPR has shifted from disease identification and management to prevention and education. Rooted in action research and evolving through programs set forth by Freire, the CDC, and the IOM, CBPR has become a widely accepted and respected approach to health services research.

Community-Based Participatory Research Approach

CBPR is not an explicit methodology but an approach to applied research that may combine

both qualitative and quantitative components. The concept of “empowerment” within the participating community and its members is a major factor in the discrimination between CBPR and more traditional methods.

The primary principle of CBPR is that the community be actively and continuously involved in all aspects of the project. As a result of this collaborative partnership, the research belongs jointly to the researchers and the community, and all parties mutually benefit from the results. Additional core principles of the CBPR approach include reciprocal transfer of expertise among all research partners, shared resources and decision-making power, and mutual ownership of the results. These are usually facilitated by mutual respect between community and researchers, clear and open communication, adherence to ethical standards, credit for participation as appropriate, and long-term commitment to the project.

Both community and researcher must have the capacity and the empowerment to express needs and goals as they pertain to the research at hand. The true partnership required by a rigorous CBPR approach is one that combines knowledge with action to achieve the goal of improved health outcomes and reduced health disparities.

A successful CBPR project is focused locally on the relevance of the health issue at hand and the geographic, cultural, and socioeconomic contributions to it. Such a project recognizes the community’s resources and knowledge and incorporates them into the research process. In turn, the knowledge and resource bases of the community will be bolstered by participation in the project and the dissemination of its results in the interest of improving social practice and community health.

Implementation and Best Practices

As part of the reciprocation of expertise between researcher and community, a mechanism must be created for shared decision making. This often requires formation of a community advisory board, a task force, or various planning and implementation committees. These bodies develop and adhere to guiding principles for collaboration within the particular community involved.

Throughout the project, the collaboration should be evaluated by both the researcher and the

community. The research team should remain aware and respectful of the community's needs and priorities, and emergent problems and concerns should be addressed. Incorporation of feedback loops into the project's design can help ensure proper collaboration, reflection, and relevance throughout the intervention.

A CBPR project often begins with an issue or question brought forth by a community. Inviting the community to identify health-related issues of greatest importance to them may increase motivation to participate in the research process. As with most health services research projects, the issue must be one for which epidemiologic data exist or can be gathered, and funding sources must be identified. Many CBPR projects incorporate educational "workshops" during which both researchers and communities explore each other's resources and strengths. Interviews with community members may be used to discover concerns about research and participation and may also be used to alleviate those concerns.

During the study design phase, community representatives work closely with investigators to achieve an optimal balance between scientific rigor and community acceptability. Community representatives are critical to the development of participant recruitment and retention strategies as they are attuned to the needs and desires of community members. The study must also be designed to remove existing and potential barriers to community participation. Measurement instruments should be developed with continued guidance from community members to increase the reliability and validity of the measures and to present research questions in a manner acceptable and accessible to the community.

As the project is implemented, community members continue to assist researchers with determining the cultural and social relevance of the intervention. Doing so increases the likelihood of achieving social change as a result. Finally, the community is involved with the interpretation and dissemination of findings and their translation into practice.

Before submitting manuscripts or making presentations at conferences, the research team should discuss findings with the study's shared decision-making body. Results should be framed in such a way as to limit potential "blame" for any negative

findings, and results should be communicated openly, even when they may be considered undesirable.

Major Benefits and Challenges

Benefits

In many communities that are the focus of research projects—often underserved populations—contact with researchers occurs solely during data collection. As a result, communities may become resentful or distrustful of the research community, and future participation becomes unlikely. However, the CBPR approach requires that a relationship be formed on the basis of respect and trust before the research begins and be maintained throughout the process and beyond.

CBPR may also be useful in developing and testing quantitative measures for use within certain populations and cultures. Through the community's involvement in the design and testing phases of an instrument, researchers may gain an insight into the cultural sensitivities and preferences of the community, leading to more appropriately designed and implemented methods with improved internal validity. This insight is also inherently useful in the analysis and interpretation of the results due to the "insider" perspective presented by the community members involved in the project.

Another major benefit of the CBPR approach for investigators is that the results may be disseminated almost immediately and are sustainable due to the continuous involvement and feedback from community members. This unique aspect of CBPR strikes a balance between research and practice that is rarely found in a traditional empirical study.

Challenges

CBPR has gained a great deal of acceptance among public health researchers and practitioners in recent years. However, unlike more traditional research methodologies, there is a great deal of variation in methodologies and reporting requirements, leading to a gap in the ability of researchers to compare such studies.

Although the ideal start to a CBPR project is one in which a community brings an issue or problem to the attention of researchers, there are often numerous real and perceived barriers to doing so.

Many communities that may benefit from a CBPR project are distrustful of researchers or simply do not know how to access them. If the investigators broach the CBPR issue with the community, they are wise to assess the true importance of the issue within the community. Active participation is maximized when both the community and the researcher are fully invested in the issue or problem and are committed to addressing it together. To achieve this, incentives for both community members and the research team must be adequate.

Even when both parties are fully committed to the research, some degree of division between them may still exist. The researcher must overcome his or her role as an “outsider” to truly collaborate with the community. This can be a significant barrier when a community’s members are extremely marginalized and are unlikely to identify the investigators as anything but outsiders—often with perceived knowledge and power. Such barriers can be ameliorated through involvement with community leaders in the initial stages of the project. Elders, religious leaders, and others in either real or perceived roles of power within their communities provide excellent opportunities for investigators to gain a benevolent foothold in the community. Identification of appropriate representatives may also prove challenging. A selection bias may occur if participating community members are not representative of the community’s overall makeup.

As in any research endeavor, researchers and communities must concern themselves with the issues of ownership and confidentiality. Because investigators work so closely with the communities and individuals, ethical issues may arise as relationships evolve. Discussions early in the process about these issues and how they will be addressed can alleviate the tension with regard to these issues.

Because CBPR relies on robust relationships with communities, the investments of time and resources can be large for both researcher and community. Such relationships must be properly brokered, equitably managed, and carefully sustained to maintain the ideal partnership without unfairly burdening one party. Finally, because of the relatively recent acceptance of CBPR as an empirical method, funding mechanisms can be scarce and inadequate.

Examples

REACH

The CDC’s Racial and Ethnic Approaches to Community Health (REACH) program is the cornerstone of its efforts to eliminate racial and ethnic health disparities as part of the Healthy People 2010 initiative. The strategic goals of REACH are to address health disparities in critical life stages using innovative approaches within communities, healthcare settings, schools and after-school programs, and workplaces.

Communities of focus include African Americans, Alaska Natives and American Indians, Asian Americans, Hispanic Americans, and Pacific Islanders. The six areas targeted for elimination of disparities are (1) infant mortality, (2) breast and cervical cancers, (3) cardiovascular diseases, (4) diabetes, (5) HIV/AIDS, and (6) immunizations.

REACH grantees are implementing local interventions that include continuing education for healthcare providers, health education and health promotion programs that use lay health workers to reach community members, and health communication campaigns. Evaluation of the REACH program includes gathering evidence on community capacity building, targeted intervention actions, community and system changes, widespread behavior changes, and reduction in health disparities.

California’s Health Interview Survey

California’s Health Interview Survey, the nation’s largest state health survey, represents a successful combination of CBPR with traditional quantitative research. At the start of each survey development cycle, more than 145 individuals from state and local policy-making bodies, public health agencies, advocacy groups, research organizations, and healthcare organizations collaborate with survey research staff as members of advisory boards, technical advisory committees, and work groups. This collaboration shapes topics, measures, and the design of the survey, and survey results and data are provided to the communities involved.

*Environmental Justice:
Partnerships for Communication Program*

A partnership between several federal agencies led to the 1994 launch of the Environmental Justice: Partnerships for Communication Program. The program was designed to bring together community organizations, environmental health researchers, and healthcare professionals to develop models and approaches, build communication, and increase community participation in research.

More than 30 CBPR studies have been funded under the program. For example, the Partnership to Reduce Asthma and Obesity in Latino Schools focuses on developing a better understanding of the impact on asthma and obesity of the school environment and school district policies that influence this environment. The Environmental Health and Justice in Norton Sound, Alaska, is a program funded to identify, limit, and reduce the effects of harmful contaminants in the natural food sources of indigenous people in Alaska. The Community-Based Participatory Research in Environmental Health program, based at the University of Texas at El Paso, seeks to improve the capacity of the El Paso, Texas/Juarez, Mexico, binational community to participate in research on lead exposure among low-income Hispanic children.

Future Implications

As more comprehensive approaches to public health research continue to gain traction in the scientific and academic communities, attention and resources will increasingly focus on CBPR. Public health agencies, seeking to reduce health risks and improve outcomes effectively and efficiently, are calling for more participatory studies. The shift of research focus in recent years from disease identification and management to prevention and education has attracted the attention of both private and governmental organizations. These funding agencies are beginning to require community partnerships in their requests for applications and proposals. In addition, top-tier health services research journals will likely increase the number of CBPR-related articles published, continuing to lend credence to the scientific rigors of this approach.

Additional types of community partnerships and additional underserved communities will continue to be explored. A standardized set of competencies, terminologies, quality assessments, and well-defined outcome measures must be established for CBPR to remain a viable approach to rigorous research. New investigators will be educated about the CBPR approach and its applications, benefits, and challenges. Similarly, communities will be educated about the opportunities available for their participation in CBPR. Tools to help communities locate and contact potential research partners are being developed and implemented, increasing the scope of CBPR.

Expansion of CBPR policies will allow more communities to become involved with researchers in the interest of bettering the health of their members. Communities previously excluded from CBPR and traditional research will benefit from a narrow focus, which will allow specific attention and collaboration to decrease disparities and increase participation in health-related activities.

Finally, the results of CBPR must move from local dissemination and action into policy and practice. Engaging community members in the policy process will increase the joint ownership of the research, and putting the results into practice will allow similar communities to benefit from the results.

COMMUNITY HEALTH

Although community health is a popular concept, it lacks a clear working definition in research and practice. One reason is that the concept of community health belongs to multiple disciplines, including public health, medicine, and psychology. An inherently interdisciplinary concept, community health has no one home; however, common elements can be found across disciplines in terms of how it is discussed. Throughout these discussions, community health has been presented as a conceptual framework that can be applied to understand health, a process by which health interventions can be designed and implemented, and an outcome with implications for measurement.

Community Health as a Conceptual Framework

As a conceptual framework, community health offers a view of health as the product of individual

and extra-individual factors. This framework moves beyond a traditional focus on person-level factors and reframes both causes of disease and sources of health as interactions between individuals and their social and physical environments. Community health as a perspective is a relatively new concept. The time since 1980 has been cited as seeing enormous growth in the awareness of the need to attend to environmental causes of health. Rather than focusing only on modifying individual behavior, a community health perspective prescribes both behavior- and environmental-based strategies. The rise of this perspective has been credited to the acknowledgment that most public health problems are too complex to be understood simply as a product of individual behavior.

Possibly because of its interdisciplinary nature and lack of one core disciplinary home, the concept of community health is still in its formative stage. In discussing community health as a conceptual framework, researchers have referred to two similar, more established frameworks, including the socioecological model and empowerment theory. Both of these perspectives are based on the assumption that individual and environmental factors come together to influence health and illness, and both offer a set of principles guiding the approach to understanding health and disease, preventing disease, and promoting health.

The socioecological model specifies the following three assumptions: (1) environmental settings have multiple physical, social, and cultural dimensions that affect a variety of individual physical, emotional, mental, and social health outcomes; (2) individual characteristics such as genetics, psychological characteristics, and behavior affect health and, moreover, interact with the environment to affect individual outcomes; and (3) the variety of diverse settings within an individual's life interact to affect health. Community health has ecological roots and similarly views individuals as being nested within a series of embedded systems that are interrelated and interdependent. These systems range from social dynamics to physical organizations and can include families, neighborhood groups, schools, places of worship, government policies, and both explicit and unspoken prejudices. A community health perspective acknowledges the dynamic interaction between the systems in which individuals exist and acknowledges the

importance of both systems being able to effectively meet the needs of individuals, and individuals effectively accessing systems of support. A community health perspective sees the effective functioning of these systems as vital to the health of individuals.

Empowerment theory views health as the product of an individual's social, economic, and environmental condition. Using an approach slightly different from the socioecological model, empowerment theory has at its core the need for authentic involvement of community members throughout the process of understanding the contributors to health and disease, and ultimately promoting health. Empowerment theory states that different groups in a society hold different levels of power and that this power affects the control that individuals have over their own health. Under this framework, community health stems directly from the ability of individuals to be involved in decision making in their communities. Empowerment advocates for the creation of more comprehensive networks of support and views healthy relationships between a community and other effective organizations as critical—organizations such as criminal justice systems, school systems, and healthcare providers. Participation is essential to this process as community members are vital to building and maintaining relationships across healthy settings.

Though differing in their approaches to promoting health, these models demonstrate the key assumptions of a community health framework: the recognition of individual and environmental causes of health, a focus on the interaction between individual and environmental factors, and an acknowledgment of the importance of including community members in the process.

Community Health as Process

Researchers and theorists have also discussed community health as a process, specifically focusing on approaches to intervention. The presumption of health as being defined by both individual and environmental factors necessitates changing not only individual behavior but also those social factors causing disease or preventing optimum health. A community health framework positions community-level intervention as a distinct

approach to keeping individuals healthy: The environment can be a protective factor for individual health. Opportunities afforded (or not afforded) by the environment are essential to the health and well-being of an individual. In the reframing of health and disease as interactions between individuals and environments, strategies such as self-help, community development, and social action have been discussed as being key to community health practice. Central to this process is the concept of collaborative practice.

A community health framework advocates collaboration both among individual members of the community and among various community systems. The process of community health involves the mobilization of community members to work collectively on their own behalf; there is an explicit focus on capacity building, which involves the sharing of information, skills, and resources to organize community members into leadership roles. Community members are involved in the process of understanding the contributors to health and disease, as well as the delivery of health interventions. Community health acknowledges that no one knows the community better than its members; as a result, these individuals can play an important part in recognizing barriers to health in their communities as well as making decisions about how to address these barriers. These collaborations can lead to more authentic, effective, and sustainable interventions.

Collaboration among community organizations provides an overall environment of care for individuals. Because this step can appear more daunting than the task of involving individual community members in the health promotion process, efforts have often fallen short of coordinating various needed systems to create healthy systems of care. Calls have been made for better integration among community organizations as essential to facilitating the health of community members, and research has begun to demonstrate that organizational and environmental infrastructure and support are essential to the effectiveness of health-related programming. However, more needs to be done. A community health approach advocates for a series of systems that provide what is needed for a diverse group of individuals to stay healthy: healthcare systems that reach out to multiple groups of people in culturally appropriate ways,

educational systems that meet the needs of a diverse group of learners, employment and recreational opportunities for those with varying ability levels, opportunities for the building of social connections and exchange of social support, and neighborhood environments that promote physical safety and protection from environmental pollutants. To be effective, a key requirement is that these systems should work in concert with each other, offering multiple opportunities for person-environment fit, in that individual needs and resources are complemented by the multiple environments in which a person lives.

A number of efforts have been made to lay the groundwork for community health practice. For example, in the early 1990s, the Minnesota Heart Health Program developed an intervention to foster heart health in three communities. It began with a survey intended to identify community leaders who would then be asked to become members of an advisory board with government officials and health professionals to provide guidance on programs, health education campaigns, and related policy. This effort resulted in a public education media campaign and a number of programs involving multiple organizations in the community, including school curricula on smoking, exercise, and nutrition; and an annual communitywide quit smoking contest and work site smoking policy planning assistance. An evaluation of the program demonstrated greater participation in heart disease health promotion and a greater sense of "social connectedness," although more so among stable organizations whose current needs and interests were in line with the goals of the intervention.

A number of guidelines for community health promotion programs have been developed. Many emphasize the importance of understanding the relevant aspect of the social and physical environment, which can influence a variety of health outcomes, as well as the interactions between these environmental characteristics and pertinent individual factors. Once these factors and interactions are better understood, interventions can be developed to enhance the person-environment fit, which can occur when individuals enjoy a high degree of control over their environment and are able to modify it according to their needs. Interventions can therefore work to facilitate the flexibility and responsiveness of social and physical environments.

An important part of health promotion programs not mentioned is the need to teach individuals to be aware of and advocate for the types of settings and setting characteristics that they need.

Community Health as an Outcome

Community health can also be discussed as an outcome. What does a healthy community look like? Following from the above, a healthy community is free from physical violence, environmental pollutants, disease, and discrimination. Furthermore, it is one in which community members are active and involved in decision-making processes, systems of care are coordinated and accessible to all community members, and multiple opportunities are available for person-environment fit. A healthy community focuses on keeping its members healthy through disease prevention and health promotion as well as providing effective treatment for those who are sick. These are but some of the characteristics that operationalize the theory and process presented above.

In addition to discussing how to achieve these outcomes, it is also important to discuss how such outcomes can be monitored and measured. The measurement of community health presents a challenge because of the complexity of the concept. The fact that community health views health as an interaction between individual, social, and physical environmental factors necessitates the measurement of at least three constructs: (1) individuals, (2) the environment, and (3) the interaction between them. Currently, the most sophisticated measures are available for individual-level constructs. For measurements of individual outcomes, morbidity and mortality rates can be computed, which permit a picture of the health of a group of people to be obtained. For example, mortality rates from heart disease, cancer, and stroke can be used to assess the physical health of a community. Examining these rates can be helpful in understanding trends in health and disease, particularly in understanding health disparities between subgroups of the population.

Techniques related to both environmental assessment and the measurement of individual-environment interactions need further development; however, strides have been made regarding extraindividual assessment. Environmental assessments developed

to date can be divided into two broad categories: (1) those that assess the environment subjectively (i.e., from the perspective of individuals assessing that environment) and (2) those that assess the environment more objectively. Examples of the former include the variety of environmental scales developed that allow individuals to rate their satisfaction with different aspects of their environment. Such measures have been adapted to classrooms, family environments, and work settings. Examples of the latter involve counting up the number of businesses in a community with handicap-accessible entrances or the number of available health clinics in a community. Each of these broad classes of measurement provides important information about the environment, with the subjective measures actually providing some information about the interaction between an individual and his or her environment and the objective measures providing information about the environment that perhaps individual community members cannot observe or will not report. Ideally, these measurement strategies should be used to complement each other in describing the environment.

Finally, efforts must be made at assessing the interaction between individuals and the environment to understand how it affects health. In addition to the subjective environmental measures discussed above, measures of the individual and environmental components of community competence can also assist in approximating this interaction. Community competence involves two components: (1) the competence of community resources in meeting the needs of individual community members and (2) the competence of individuals in accessing these resources. Assessing the first component involves measuring the effectiveness of various social systems, for example, the healthcare, education, employment training, housing, and criminal justice systems. Evaluation research has made strides in developing methodologies for assessing the process and outcomes of such service delivery systems. Assessing the second component involves measuring an individual's ability to effectively use resources in the community. Viewing results of both types of assessments can begin to uncover the level of fit between individuals and their communities.

The task of measuring these multiple components can become overwhelming, particularly as multiple methods (e.g., surveys, observations, and

health records) are necessary for capturing the multiple components and levels of analyses involved in the health equation. How then can variables be identified for study? How can health professionals and researchers decide on a course of action in intervention? One approach is to use strategies based on "middle-range" theories of the variety of factors that contribute to and are likely to alleviate a particular health problem. Assessing and attempting to either eliminate or bolster a set of variables thought to affect the condition in question provides a productive start to understanding health.

Future Implications

The concept of community health advocates for health as the product of the individual and his or her environment. A community health approach involves enhancing the environment to become more health promoting as a way to facilitate individual health. One vehicle for action includes public health policy. Each of the different levels of community health—framework, process, and outcome—includes a number of overlapping implications for public health policy.

Working within a community health framework, public health policymakers must acknowledge and address individual and environmental factors, and the interaction between them, as the determinants of health. The community health perspective broadens what is considered "public health" policy because every aspect of society potentially affects health. Public health policy should therefore focus not only on topics that are clearly related to health but also those whose linkages may not be as explicit. Examples include promoting community development, creating safe communities with functioning resources, and allocating resources in such a way to build a solid infrastructure both within and between communities for health-promoting initiatives to thrive. Policy around the implementation of services and programs should mandate a thorough assessment of the local community resources and needs, building on the former to address the latter. Furthermore, policies across the board should promote citizen participation: Authentic opportunities for community members to be involved in making decisions about their communities should be built in as an

essential part of the process. An understanding of the relevant individual and environmental characteristics affecting health is critical to beginning any type of policy initiative.

Community health provides a conceptual framework, a set of intervention guidelines, and outcomes to target by understanding health as a product of individual and environmental factors. Because community health is a relatively new concept, the specific mechanisms by which environments interact with individual factors in affecting individual health have not been understood well. Further work must continue to identify the process by which these interactions occur and foster health promoting communities to positively affect the health of individual community members.

COMMUNITY HEALTH CENTERS (CHCs)

Community health centers (CHCs), called neighborhood health centers until 1975, were created in 1964 by the U.S. Office of Economic Opportunity (OEO) as a component of President Lyndon Johnson's "War on Poverty." These local, public or nonprofit, community-run healthcare centers serve low-income and medically underserved communities. Community health centers provide comprehensive, affordable primary care and preventive visits. Many of these centers provide services such as case management, home visits, community outreach, dental care, diagnostic laboratory and radiology services, and pharmaceutical, mental health, and substance abuse services. Currently, more than 1,000 community, migrant, and homeless health centers serve more than 15 million people in the United States, about half in rural communities and half in economically depressed inner-city communities. Two thirds of health center patients are members of racial and ethnic minority groups, and 29% are reported as best served in a language other than English. More than 90% of health center patients are low income, and 71% have family incomes at or below the federal poverty level. About 40% of patients are uninsured, and 36% are covered by Medicaid.

Early Health Centers

Precursors to CHCs included 19th-century dispensaries, turn-of-the-century settlement houses, rural outreach efforts such as the Frontier Nursing Service in eastern Kentucky, city-operated clinics, and social medicine departments of progressive institutions such as Montefiore Hospital in New

York City. During the first two decades of the 20th century, health centers, which coordinated the health, welfare, and recreational services of multiple agencies in one location, were established in many cities in the United States. They focused on preventing disease through education, maternal and child healthcare, food inspection, and immunization. By 1926, there were more than 1,000 of these health centers across the country. By offering only preventive services, they avoided competition with the therapeutic services of private practitioners. Organized medicine opposed and defeated a proposed bill in New York State in 1920 that would have established and funded health centers throughout the state to provide both preventive and therapeutic services to laborers.

In 1920, the Rockefeller Foundation formed the Committee on Dispensary Development, directed by Michael M. Davis, which gave grants to “new concepts in ambulatory care.” One of the demonstration projects was a clinic at Cornell Medical School, which employed salaried physicians in a group practice, provided comprehensive ambulatory care services, and used a sliding-scale system for payment. During the 1940s and 1950s, patients who could not afford the cost of private physicians mostly relied on hospital outpatient departments or emergency rooms.

In 1960, the Social Security Act was amended with the passage of the Kerr-Mills measure, which provided states with grant money for the medically indigent. The Migrant Health Act of 1962 called for the development of health clinics dedicated to providing a broad array of medical and support services to farm workers and their families.

Establishment of Community Health Centers

Under the Economic Opportunity Act of 1964's Community Action Program, hospitals, medical schools, community groups, and health departments received grants to plan and administer neighborhood health centers in low-income areas. Health center advocates hoped that, in addition to providing high-quality healthcare to low-income populations that lacked access to such care, health centers would serve as a model for the reorganization of healthcare services for the nation's population as a whole.

One of the early leaders of the community health center movement was H. Jack Geiger, a young physician and civil rights activist, who had studied with Sidney and Emily Kark in South Africa and witnessed how a community-oriented primary-care model had improved the health of the Zulus. In 1964, while serving as Mississippi field coordinator with the Medical Committee for Human Rights, he recruited physicians and nurses to take care of the civil rights workers as well as the local population. Count Gibson, the chair of the Preventive and Community Medicine department at Tufts Medical School, was one of the volunteers in Mississippi. Working with the OEO, Geiger and Gibson founded the first two neighborhood health center demonstration projects. The first was established at the Columbia Point public housing project in Boston in 1965, and the other was built in Mound Bayou, Mississippi, in 1967. At these model health centers, teams of health professionals provided personal healthcare in convenient locations, with a focus on community outreach, child care, transportation, attention to the economic and environmental factors that contributed to poor health, and involvement of the patients themselves in how the programs were set up and managed.

In 1966, the Office of Comprehensive Health Services was established within the Community Action Program to administer neighborhood health center grants, and an Office of Health Affairs was created within the OEO to coordinate its medical and health programs. U.S. Senator Edward Kennedy of Massachusetts, an early supporter of the idea of health centers, helped secure the addition of authorizing language to the OEO Act in April 1967 that earmarked \$51 million for health centers. During the first 4 years of the program, medical schools and teaching hospitals received the majority of grants to start health centers. By 1971, 100 neighborhood health centers had been established under the federal Economic Opportunity Act.

While the OEO was funding neighborhood health centers, the U.S. Public Health Service (PHS), part of the Department of Health, Education and Welfare (DHEW), began providing its own grants to establish comprehensive health centers in low-income areas beginning in 1968. The PHS funded 24 centers in 1968 and 1969 through section 314(e)

of the Comprehensive Health Planning and Public Health Services Act of 1966, amended in 1967 by the Partnership for Health Amendments.

Community Health Centers After 1970

Under his New Federalism program, President Richard Nixon transferred OEO's operating responsibilities to the relevant cabinet agencies and moved the entire health center program in the early 1970s from the OEO to the DHEW's Public Health Service. In 1972, DHEW issued regulations asserting that federal support was no longer needed for the health centers as they could collect reimbursements from Medicare, Medicaid, and private insurers and become self-sufficient. In 1973, Nixon asked the U.S. Congress to phase out the legislation that funded health centers. However, the General Accounting Office (GAO) determined that Medicaid only covered about one third of the nation's poor, and in many states reimbursement rates were too low to cover health center costs. Congressmen Paul Rogers and Edward Kennedy led the effort to preserve federal funding for health centers and to broaden the mandate of the centers so that comprehensive primary and preventive services were provided to all patients who sought care. DHEW's Bureau of Community Health Services developed a system of accountability for the health centers that required each health center to report on numbers and types of staff, patients, and encounters as well as revenues and expenditures. Despite a veto by President Gerald Ford, the U.S. Congress authorized the Special Health Revenue Sharing Act of 1975. Title V of this act authorized \$215 million for health center operations in 1976 and \$235 million for 1977, plus an additional \$5 million each year for planning grants.

President Jimmy Carter and his DHEW secretary, Joe Califano, were strong supporters of increased funding for health centers. In 1978, education was moved to its own cabinet department, and DHEW changed its name to the Department of Health and Human Services (HHS). By 1980, there were 872 grantees, an increase from 158 grantees in 1974.

In the early 1980s, President Ronald Reagan, relying on advice from the conservative Heritage Foundation, which distrusted health centers as

potentially leading to a nationalized healthcare system, tried to combine health centers with other health programs into a primary-care block grant. However, opposition from individual health centers, state and regional primary-care associations, the National Association of Community Health Centers (NACHC), and senators Edward Kennedy and Orrin Hatch led to the 1986 repeal of the block grant. While there were overall funding cuts in the health center program during the early years of the Reagan administration, later the program experienced some growth due to increases in regular appropriations and temporary funds to help the centers meet rising demand from the unemployed. An increase of available healthcare providers from the National Health Service Corps, a program that pays for professional education in exchange for service in underserved areas, enabled many urban sites to expand.

During the George H. W. Bush administration, Senator John Chafee of Rhode Island and the NACHC helped develop the Federally Qualified Health Centers (FQHC) legislation, which increased health center reimbursement for Medicaid in 1989 and Medicare in 1990.

President Bill Clinton's Task Force on National Health Reform proposed to replace nearly all health programs with "purchasing cooperatives" or "health alliances." A background paper on healthcare for the underserved presented conflicting views on whether health centers should continue as a separate entity or be consolidated with insurance funds run by the purchasing cooperatives. After the White House Task Force was disbanded, the HHS proposed combining federal health programs and channeling the funds through states. When health center advocates protested this proposal, which recommended block grants similar to those of the Reagan years, the Clinton Health Security Act continued separate legislative authorities for programs such as health centers. Donna Shalala, the secretary of HHS, preferred "marrying the health centers to teaching hospitals" rather than expanding services provided by the health center. Between 1995 and 2001, the U.S. Congress increased health center appropriations 65% from \$757 million to \$1.2 billion.

President George W. Bush made expansion of health centers a top priority. In 2001, he launched the 5-year President's Health Care Expansion Initiative to establish or expand 1,200 health

center sites to serve an additional 6.1 million patients annually by the end of 2006. The U.S. Congress generally supported this effort until 2005, when it cut the proposed increase from \$219 to \$116 million as part of across-the-board cuts due to rising deficits. In 2006, health centers received only a \$48 million increase despite Bush's proposed \$304 million increase. Bush cited an Office of Management and Budget (OMB) report that reviewed hundreds of HHS programs and found health centers to be 1 of only 10 deserving the highest effectiveness rating.

The Health Resources and Services Administration (HRSA), Bureau of Primary Health Care (BPHC), currently administers the health center program within the HHS. The Health Centers Consolidation Act of 1996 combined the previously separate community, migrant, homeless, and public housing authorities under Section 330 of the Public Health Service Act (PHSA) to create the consolidated health centers program. The federal Health Care Safety Net Amendments of 2002 reauthorized the consolidated health centers program through 2006.

Financing

CHCs are funded by a variety of sources. Medicaid provides the greatest part of their revenues, accounting for 36% of total funding, followed by federal 330 grants, which cover 22%. The remainder comes from state and local funding, including foundations (12%), Medicare (6%), private insurance (6%), self-pay (6%), other federal grants (4%), and other sources (8%).

Four types of FQHCs are funded under Section 330 of the PHSA: (1) CHCs, under section 330[e], receive 81.5% of program funding; (2) migrant health centers, under section 330[g], account for 8.6% of program funding; (3) homeless health centers, under section 330[h], receive 8.7% of program funding; and (4) public housing health centers, under section 330[i], receive 1.2% of program funding. Federally Qualified Health Center Look-Alikes are health centers that meet the requirements for federal funding but do not receive a grant. FQHCs and Look-Alikes are eligible to receive enhanced reimbursement from Medicaid and Medicare and to participate in the 340B program, which allows them to purchase drugs at

reduced prices. FQHCs are paid by Medicaid and Medicare for services on a per-visit basis rather than separately for each service provided when a patient visits a health center. FQHCs also have access to medical malpractice insurance through the Federal Tort Claims Act.

Federal Grant Requirements

To receive Section 330 grant funds, a CHC must be located in a federally designated medically underserved area (MUA) or serve a federally designated medically underserved population (MUP). It must also have nonprofit, public, or tax-exempt status; provide comprehensive primary healthcare services, referrals, and other services needed to facilitate access to care, such as transportation, interpreter services, and case management. Additionally, the CHC must have a governing board, with a majority of members as patients of the health center, provide services to all patients in the service area regardless of their ability to pay, and offer a sliding fee scale based on family income.

The governing board, with at least a 51% consumer majority, must meet monthly to select the CHC's services and hours, approve the CHC's annual budget, select the CHC's director, and establish general policies.

In 2004, federally funded health center grantees provided care at 3,650 sites to more than 13.2 million patients. Federal grant funding for the consolidated health centers program totaled \$1.47 billion in 2003 and \$1.57 billion in 2004. Federal grants constitute 25% of overall health center revenues.

As health center grants are given to fund direct services, HRSA limits the use of grant money for capital-related purposes. From 1978 to 1996, health centers could use grant funds for construction, renovation, acquisition, and equipment purchases. However, the U.S. Congress revised the health center statute to prohibit the use of grant dollars for construction in 1996. Currently, HRSA allows grantees to use up to \$150,000 from their first year's budget for equipment or capital alterations. HRSA also provides a loan guarantee program to grantees and funds state primary-care associations and the National Association of Community Health Centers (NACHC) to provide technical assistance to CHCs.

Organizations

In 1970, the nonprofit National Association of Neighborhood Health Centers (NANHC), with support from the OEO, was founded with a mission to enhance and expand access to high-quality, community-responsive healthcare for America's medically underserved and uninsured. The same year, the New York Association of Neighborhood Health Centers and the Massachusetts League of Neighborhood Health Centers were also founded to pool each state's respective technical resources, train board and staff members, influence the development of DHEW regulations, and negotiate with the state government about the level of Medicaid reimbursement for health centers. Both of these groups received DHEW funding. In 1973, after the transfer of all health center programs to DHEW, the state groups gave up their individual grants and became subcontractors of the national association in an attempt to encourage the creation of additional regional associations to form a network of technical assistance groups.

In 2007, the NACHC represented a network of more than 1,000 FQHCs, serving 16 million people at 5,000 sites in all 50 states, Puerto Rico, the District of Columbia, the U.S. Virgin Islands, and Guam. The NACHC serves as the major source for information, data, research, and advocacy on key issues affecting community-based health centers and the delivery of healthcare for the medically underserved and uninsured in America. It provides education, training, and leadership development to health center staff and boards to promote excellence and cost-effectiveness, and it builds partnerships to stimulate public- and private-sector investment in the delivery of quality healthcare to medically underserved communities. The NACHC works closely with state and regional organizations, including primary-care associations and health center networks.

Quality and Costs of Care

CHCs help improve access to primary and preventive care to vulnerable populations who otherwise would not have access to services such as immunizations, health education, and screening tests. Ninety-nine percent of uninsured health center users have a usual source of care compared with

75% of all uninsured people nationally. Uninsured adults who use health centers are more likely to be counseled about diet and eating habits, physical activity, smoking, drinking, drug use (55% vs. 39%), and sexually transmitted diseases than are U.S. uninsured adults. Medicaid and uninsured patients who go to CHCs are more than 50% more likely to have up-to-date pap smears and mammograms than the overall U.S. Medicaid and uninsured population. Health centers have been shown by the Institute of Medicine (IOM) and the GAO to reduce racial and ethnic disparities in infant mortality, prenatal care, rates of tuberculosis, and death rates. Ninety-nine percent of health center patients surveyed reported that they were satisfied with the care they received at CHCs.

CHCs also serve as models for diagnosing and managing chronic conditions such as diabetes, asthma, depression, cardiovascular disease, cancer, and HIV. The Bureau of Primary Care runs the Health Disparities Collaboratives (HDC), which led to improved health outcomes and lowered costs of treating patients with chronic illness. More than two thirds of CHCs participate in these HDCs, which are a model of care that supports patients in their goal of self-management by a care management team. This team may include a health educator, nurse care manager, social worker, health-care provider, and specialists such as ophthalmologists and podiatrists. More than 75,000 CHC patients with chronic diseases have been enrolled in these HDC registries for cancer, diabetes, asthma, and cardiovascular disease. A study in South Carolina showed that diabetic CHC patients in the Diabetes Collaborative had annual health costs of \$343 per patient, while diabetic patients seeing other, non-CHC providers had annual costs of \$1,600 or \$1,900 with specialists. The CHC patients in the Diabetes Collaborative registry had dropped their hemoglobin A1c or average blood sugar from 11 to 8.

Health centers provide cost-effective care, with the average annual expenditure about \$250 less per patient than at an office-based medical provider. Health centers also reduce Medicaid expenditures due to reduced specialty care referrals and fewer hospital admissions. A study conducted in 1980 found that Medicaid patients who used community health centers had a 30% to 65% lower hospitalization rate and used 12% to 48%

less total Medicaid funds than a similar group of Medicaid patients who did not use CHCs. A more recent study showed that communities served by health centers had 5.8 fewer preventable hospitalizations per 100 people over 3 years than other medically underserved communities not served by a health center. Health centers serve about 10% of all Medicaid enrollees nationally, but in actual Medicaid dollars, this amounts to less than 1% of all Medicaid payments to all providers. A 2004 study showed that FQHCs improve access to primary care for the uninsured and underinsured, and reduce emergency room visits and hospital stays.

Future Implications

CHCs provide essential healthcare services to vulnerable populations and continue to improve health outcomes for the underserved. They have a strong presence in their neighborhoods, helping bolster local business and stimulate economic growth. As the number of uninsured Americans continues to grow and health reform becomes a topic of national policy, CHCs will continue to increase access for patients, improve quality of services, and maintain affordable care for low-income populations.

COMMUNITY MENTAL HEALTH CENTERS (CMHCs)

Community mental health centers (CMHCs) offer a full array of community-based mental health services addressing problems such as depression, anxiety, and schizophrenia. They also provide support services such as stress management, support groups, and job training and placement. These centers incorporate a public health approach to prevention and the treatment of mental health problems. By doing so, they aim to reduce healthcare costs by lowering expensive inpatient hospital stays without reducing the availability and quality of services. The centers provide inpatient and outpatient services, including counseling therapy, medication management, daycare services, hospital referral, and case management of drug and alcohol problems. Physicians, psychologists, social workers, psychiatric nurses, and other mental health professionals usually work at CMHCs. And administration staff provide the organization and leadership needed to effectively coordinate the services. Together, they provide community-based services and resources that improve the general physical and social functioning of individuals, families, and communities.

History

CMHCs have been in existence in the United States since the early 1960s. President John F. Kennedy signed the Community Mental Health Services Act in 1963. With the passage of PL 88-164 (also known as the Mental Retardation Facilities and Community Mental Health Centers Construction Act of 1963), federal health policy shifted from providing mental healthcare at large state-run hospitals to community health centers across the nation. The National Institutes of Health (NIH) supports and conducts research on mental illness through its Institute of Mental Health (NIMH). At the time of the law's passage, NIMH was assigned the responsibility of offering states the opportunity to develop CMHCs instead of state psychiatric hospitals for persons with mental illness.

Most CMHCs continue to be financed by federal, state, and local government funding, while some are funded through private organizations. Currently, the Center for Mental Health Services, the Center for Substance Abuse Prevention, and the Center for Substance Abuse Treatment of the Substance Abuse and Mental Health Services Administration (SAMHSA) administer the Mental Health Services Block Grant Program and the Substance Abuse Prevention and Treatment Block Grant Program for CMHCs. These block grant programs fund CMHCs to create programs that prevent mental health and substance abuse problems as well as expand existing services for treating mental health problems. Payments from clients, private insurance, Medicare, and Medicaid, and fund-raising efforts contribute to the financing and maintenance of the centers.

Recent Trends

The *First Report of the Surgeon General on Mental Health* was published in 1999 through collaboration with SAMHSA and NIMH. This report addressed the effectiveness of mental health services and the range of services existing for mental illnesses in the nation. In 2002, President George W. Bush formed the President's New Freedom Commission on Mental Health and charged a panel of experts with conducting the first comprehensive study of the nation's public and private mental

health delivery system. Results from the study indicated that the nation's mental health system required a reexamination of health policy and systems. It was found that fragmented mental health services caused problems for both patients and providers because there was a lack of continuity of care. The study identified six national goals to transform the nation's mental health system: (1) increased education about the importance of mental health; (2) the development of consumer- and family-driven approaches to seeking services; (3) the elimination of disparities to accessing mental health services; (4) early mental health screening, assessment, and referral to services; (5) ongoing and innovative research; and (6) the development of technology to increase access to services, resources, and information. As a result of the study, community health centers are incorporating these national goals into their models of care.

The two overarching goals of Healthy People 2010 are to increase the quality and years of healthy life and eliminate health disparities. Mental health is 1 of the 28 focus areas and 1 of 10 leading health indicators. As a result, shifts in focus have occurred regarding CMHCs and services, including the increased attention to health disparities and minority populations. As a result of the President's New Freedom Commission on Mental Health, CMHCs have also been focusing more efforts on advocacy, outreach, and community mental health education. These changes have led to a concern among some mental health professionals regarding the allocation of services provided for persons with severe and persistent mental illness. Since the original purpose of the Community Mental Health Services Act of 1963 was to address the needs of persons with mental illness, a shift to the needs of the larger community may leave the most severely mentally ill persons without needed mental health services.

Future Implications

Community mental health centers often face the uncertainty of receiving ongoing financial support based on current levels of federal and state funding. Hence, an important need is to achieve and maintain organizational sustainability. Chances of success are increased when CMHCs collaborate

with surrounding institutions such as local community hospitals and universities and develop partnerships with their communities. Integration of CMHCs with community-based systems and networks allows increased commitment and follow-up with clients and families. It also facilitates the development of improved methods to measure and evaluate factors related to access, cost, quality, and the provision of mental health services.

COMPARING HEALTH SYSTEMS

Comparison is elemental and learning inevitable in life as much as in health services research. We know what something is only by reference to what it is not, while the very process of referring and distinguishing depends on patterns of classification

and categorization inherited from others and inhabited by virtue of the language we use.

Much of the rationale of comparative analysis in public policy rests on the claims it makes about learning. Ordinarily, these are of two kinds, one cast in terms of evaluation and the other as explanation. Cross-national evaluation assumes that researchers might learn from others: If they look abroad, they might examine alternative ways of doing things, alternative solutions to common problems, and new ideas that might work for them. Single-pipe financing, for example, or the flow of funds from a single source, seems to limit the growth of the cost of healthcare (simply because those standing at the pipe can turn the tap on or off).

Meanwhile, in seeking explanations of why things happen as they do, comparing two or more cases makes it possible to isolate dependent and independent variables and then to specify relationships between them. This makes for greater (and sometimes lesser) confidence in the understanding of causes and effects, inputs, outputs, and outcomes. Historians of health policy, for example, note the role of organized labor in the introduction and expansion of public coverage for the personal costs of healthcare: In some European countries, national systems were introduced by conservative regimes to meet (or at least blunt) workers' demands; in others, they were introduced by workers' parties once in power.

In both instances, evaluation and explanation, comparison constitutes a more or less elaborate appeal to scientific method to establish what works, and why. It is encouraged by demands for evidence-based policy and plays well to an assumption that good policy should be based on good science.

Yet there is a third function of comparison, one that may in fact be prior to the other two. Because it seems more ordinary, more ubiquitous, it often passes unnoticed. This is comparison as a form of exploration, of self as much as others. Researchers figure out who they are and what they do by reference to others, by association with them, and in distinction from them. As the British medical sociologist Philip Strong described in *The Ceremonial Order of the Clinic*, it was only when he watched clinical encounters in the United States that he understood how those in the United Kingdom really worked.

The origins of the cross-national, comparative investigation of health systems lie at least as far back as the University of Chicago's medical sociologist Odin W. Anderson's work of the early 1960s. But they came into vogue in the 1980s and 1990s for a number of contextual reasons. Some of these have to do with the increased availability of low-cost air travel and information technology. But it has also become clear that systems of all kinds had to find some way of managing increasing demand in the context of fixed or at least finite resources. At the same time, relations between countries were becoming more competitive, meaning that getting it right in health policy—ensuring universal access to high-quality healthcare without breaking the bank—was to get ahead both in domestic politics and in the international economy. Global trends were creating unprecedented opportunities for comparison and learning, as well as a pressing need to take them.

Survey, Case Study, and Comparison

It was the Organization for Economic Co-operation and Development (OECD) that set the terms of international comparative debate in the late 1980s as those of efficiency and cost containment. It provided its essential currency, too, in a continuously updated and elaborated comparative data set, which now includes aspects of system performance. In turn, statistical data are complemented by increasingly systematic descriptive accounts of health systems, such as those provided by World Health Organization's (WHO's) reports on health systems in transition. Processes of professionalization (of health services management, for example) and regionalization (as in the expansion of the European Union) occasion conferences and meetings at which these data and what they mean are discussed. It is now effectively impossible for health policymakers in one country to think and act without some understanding of what their counterparts in other countries are thinking and doing.

More academic research in comparative public policy has identified different types of health systems and then sought to account both for those differences and for the effect they have on the way systems develop. The health systems of

OECD countries appear to fall into three distinct types: (1) the national health services of northern and southern Europe, largely tax-financed and with a salaried profession working in facilities that are publicly owned; (2) the compulsory social insurance systems of continental Europe, with facilities in mixed public and private ownership and in which physicians' income is in some way proportionate to the amount of work they do; and (3) systems based to a much greater extent on private insurance, such as the United States, in which hospital ownership is mixed (and a higher proportion than elsewhere may be for profit), physicians' income is typically from fees, and there is no assumption that population coverage should be universal. Much comparative policy research has been essentially trichotomous, based on sampling representative cases of each of these models.

WHO's *World Health Report 2000* sought to shift the terms of cross-national policy discussion by ranking the different national health systems of the world according to their performance on selected indicators. It was an exercise in benchmarking, which refers broadly to the comparative assessment of organizational performance, undertaken to inform its improvement (benchmarking emerged in fast-developing areas of industry and commerce, where no objective standards of evaluation exist, or where those standards change quickly; it works not by the imposition of standards but by the construction and subsequent discussion and interpretation of norms). The WHO report was met with substantial technical criticism, principally for the way it used composite indicators to measure performance and for its sensitivity to different definitions and measurements of efficiency. More radical criticism was made of its purpose and implications. Nevertheless, it made for more sophisticated discussion of the principles and methodology of cross-national comparison than had existed before.

The assumption behind the data collection and dissemination activity of international agencies such as the OECD and the WHO seems to be one of essential similarity. Standardized reporting mechanisms seem to construct a common frame of reference within which transnational assessments and initiatives can be exchanged. Case-based comparisons of policy and politics, in contrast, tend to

emphasize the local specificity of health service arrangements, including their determinants, functioning and effects, and a consequent need for caution in assessing (let alone applying) comparative “lessons.”

For comparison and learning from it are more difficult than they seem in several ways. First, cross-national comparative research is a laborious and protracted activity, demanding of the researchers that they mesh more than one local wisdom with formal and generic scientific understanding. Second, the size, intricacy, and complexity of health systems, as well as the scope and scale of change to which they are subject, mean that in practice, policy lessons have been as frustratingly difficult to draw as they are to apply. Third, and perhaps even more fundamentally, this conception of comparative research is predicated on a rationalist model of the policy process. It casts comparative analysis as a technocratic activity and its purpose, in the American political scientist Aaron Wildavsky’s phrase, as speaking truth unto power. It separates knowing from doing: Where it is the business of the comparativist to go abroad in the world, to garner new knowledge and bring it home, it is that of the policymaker to take account of it. It is for research to know and for government to act.

Comparison in Practice

Meanwhile, of course, policymakers themselves are out there in an internationalized policy world, constructing and devising truths and lessons of their own. But how do they do so? What kinds of comparison do policymakers make?

What policymakers know about what is going on abroad they know from published material in journals and reports; from attending conferences; through targeted visits to other countries, regions or specific projects, and through various forms of more sustained exchange. Published research forms the apex of what has come to be termed the *hierarchy of evidence*, and policymakers frequently commission reviews of such work. Its usefulness, however, is subject to familiar qualifications. The applicability of generic research findings to different, specific local contexts is questioned, while for many issues and problems little evidence about the effectiveness of particular interventions exists.

Meanwhile, of course, public officials talk to each other, at conferences and other meetings. Significantly, too, the conference is not just a means of exchanging information but also of making contacts and forming relationships, of networking. These are sometimes consolidated by fact-finding trips, by going and seeing what others do. Government officials and their civil servants, as well as political leaders and opinion formers, often make exploratory visits to other countries that interest them. For example, Lloyd-George (then the British Chancellor) famously undertook a formative visit to Germany in 1908, during which his initial interest in a contributory pension scheme developed into the broader conception of social insurance that underpinned the landmark Liberal Reforms. In 2002 and 2003, members of the United Kingdom’s Department of Health visited California’s Kaiser Permanente healthcare organization, interested in understanding the relationship between funding mechanisms and the quality and productivity in service delivery.

The motivation may come from the host as much as the guest, in that international experts frequently act as consultants to domestic programs and projects. In 1991, in New Zealand, reform proposals were developed by a Health Services Task Force, which appointed different groups of international consultants to consider specific issues. In Sweden in 1992–1993, the findings of a controversial parliamentary commission on healthcare, *HSU 2000*, were reviewed by an international group of health policy researchers and administrators.

Sometimes, the meeting or visit may develop into a more sustained or substantial exchange, including bilateral agreements to foster partnerships between offices and organizations.

What distinguishes these various kinds of learning? What connects them to each other? What policymakers know from published research is highly mediated by the process of data collection, analysis, and dissemination. The conference setting makes it possible for the reader or listener to interrogate the researcher and for readers and listeners to ask questions of each other. In turn, the visit makes it possible for information and understanding to be acquired directly by the visitor, for him or her to engage more immediately in “situated learning.” What this means is that a nominally scientific system of knowledge (the hierarchy of evidence) is

embedded in a social one. When asked about what they learn from abroad, policymakers respond in terms of “meetings,” “study visits,” “links,” “contacts,” and “networks.” What goes on in other countries is sometimes genuinely remote, read or heard about if known at all, but it is also sometimes personal, informal, and even intimate. Here, a disjuncture begins to emerge between the models that actors consciously espouse from those they effectively use (their theory-in-use). The difference is between the rational, clinical, or scientific epistemology in which public health policymakers and practitioners are trained and the social, managerial, and political ways of knowing that are the currency of their daily practice.

Understanding Comparison in Research and Practice

There are three ways of thinking about doing comparison in health services research, and they have corollary assumptions about the relationship between research and practice, about the ways in which comparison might be a source of learning.

The first is rationalist. The researcher’s commitment is science, assuming that the sensible policymaker will take up his or her findings and use them to make more effective decisions. Comparative evidence of the extent of health inequality has clearly informed recent public health initiatives in Scotland, for example.

The policy scientist, however, will argue that what is rational for the policymaker is what fits his or her purposes and interests. This is why evidence from abroad seems so often to be used instrumentally, as ammunition in domestic policy warfare. In the United States, for example, both Canada and the United Kingdom (very different healthcare systems) can be praised for their universalism, attacked for their “socialism,” or both. The strength of commitment to existing arrangements is also partly why research that reports uncomfortable news is so vigorously attacked on methodological grounds.

The second way of thinking about doing and learning from comparison is institutionalist. There are good reasons to think that comparative research is most meaningful when sampling cases that are similar in most important respects: This is why so

much of it has focused on the OECD and within that group on selected countries in Europe and North America. There are similar reasons to think that countries might have most to learn from those like them because they share institutional, financial, or administrative arrangements or a common language and political culture and on both counts are likely to face similar problems. Note that the United Kingdom’s National Health Service (NHS) leaders sought to learn not from the United States in general but from California’s Kaiser Permanente in particular.

The policy scientist, for his or her part, would note that change is always more likely to be incremental than radical and that what policymakers know and think is shaped by the immediate environment—as is the way they interpret news from abroad and as is the news itself. The bulk of health services research is generated in the United States and the United Kingdom and/or is written in English, and is necessarily inflected in particular ways. To take up the American political scientist Herbert Simon’s famous phrase, the “rationality” of cross-national research is as “bounded” as that of policy making.

And the third way of thinking that matters here is to take seriously the idea that both research and policy paradigms are social constructs. Cross-national analysis in health policy shares many of the characteristics of what the American historian of the history and philosophy of science Thomas Kuhn’s would call “normal science”: The field is still small enough for many of its key figures to have known and worked with each other and to share assumptions about what warrants investigation and how.

One of those standard assumptions is that cases or units of comparative analysis are independent of each other (while the suspicion that they might not be is what is known as Galton’s problem, named after Sir Francis Galton). Yet researchers know that professionals and patients move between systems, as do technologies, regulations, and sometimes money—and as, too, does health services research. Policymakers cannot help but have some comparative understanding of health systems, not least as a result of the work they do. But they know much less about how that matters, about how new knowledge is interpreted, adapted, and translated in specific local contexts. Major statements and reports from the

OECD, the WHO, and others, for example, seem to serve not as evidence but as opportunities for interpretation. To the extent that health systems are complex systems, researchers may need to begin to think of relationships between them less in terms of comparison and learning than of coevolution.

What all this might mean for the comparative mission of health services research is that research in itself will make little useful difference to policy. Its significance lies in disturbing the assumptions and routines of prevailing patterns of policy making; what difference it makes depends on the arguments, interpretations—and sometimes decisions—that result. For what policymakers know about what goes on abroad is often fragmented and difficult to process: The scientific and technical knowledge they value is embedded in specific social and political contexts, while the lessons they look for seem both essential and elusive.

As a result, policymakers learn with others as much as from others, and they do so in debating what different sets of ideas, evidence, and experience might mean. They operate much closer to the third, exploratory function of comparison set out above than sometimes imagined. By the same token, of course, conditions for such a dialogue are difficult to establish. It may well be these difficulties of constructing opportunities for and making commitments to open, sustained communication across countries that set limits on the extent to which learning by comparison occurs.

COMPENSATION DIFFERENTIALS

Compensation differentials play an important role in understanding labor economics and trends in employee benefits. In equilibrium labor markets, where the supply and demand of labor intersect, people are paid what they are worth; more technically, individuals are compensated the value of their marginal product. Compensation, however, can take many forms, including money wages, vacation time, pleasant working conditions, a pension, and/or employer-sponsored health insurance. Thus, if compensation in the form of pension plan generosity is reduced, then some other element of the compensation bundle will be increased. There will be a compensating adjustment in the form of higher wages or perhaps increased job security.

Compensation differentials also help illustrate the complex nature of employer-sponsored health coverage. A growing body of empirical evidence supports the notion that workers pay a price for health coverage through their jobs, which may be reflected in lower wages or weaker pension packages.

Theory

In health services, the concept of compensation differentials is most commonly seen in discussions of employer-sponsored health insurance. The underlying concept is that if health insurance coverage is added to an employee's compensation bundle, then some other benefit will be reduced, such as money wages or pension. If this adjustment did not take place, the firm would find that it was paying more than the market clearing "price" for labor. People would be clamoring to work for the firm, and they would be willing to do so at a lower level of compensation. This argument is perfectly symmetrical. In an equilibrium labor market, if a firm decided to drop health insurance from its compensation bundle, it would have to increase some of the remaining elements in the bundle. Otherwise, current employees would resign to take jobs that offered better overall compensation.

Of course, the theory is based on equilibrium. If the demand for labor is rising, one would expect an employer to add something to the compensation bundle, be it a more generous health insurance package or more wages without removing other elements. Similarly, if the demand for labor is falling, the firm can reduce wages or cut health insurance benefits without adjusting the compensation bundle because workers are less likely to be able to find other employment.

The upshot of this theory is that workers pay for employer-sponsored health insurance in the form of lower wages and or reductions in other forms of compensation. This model has a number of implications. It implies, for example, that if a state were to require firms to provide health insurance for their workers, the workers would pay for this coverage in the form of lower wages or fewer other benefits. The theory suggests that there would be few unemployment effects unless wages could not be adjusted further downward, perhaps because of minimum wage laws. The

theory also implies that if an employer were to reduce the coverage in its health insurance plan, perhaps by raising the copays for physician visits and prescription drugs, the employer would have to improve coverage in some other dimension. Employers would have to make workers whole, by raising wages, increasing pension contributions, or expanding other forms of compensation. If this is not done by the employer, many of the employees would seek employment elsewhere. With this theory, the price of employer-sponsored health insurance to the worker is not just the out-of-pocket premium; it is the out-of-pocket premium plus the wages and other benefits given up.

Compensation differentials are one of the strongest predictions to arise from labor economics. A 2005 survey of health economists indicated that 91% of them agreed with the statement that "workers pay for employer-sponsored health insurance in the form of lower wages or reduced benefits."

Empirical Evidence

Until recently, the empirical evidence of compensation differentials in health insurance has been sparse. The difficulty has been controlling for worker productivity. For example, if a person has relatively few skills, education, or experience, he or she will not be very productive in the labor market. The worker may have a job with low wages and a modest health insurance plan. Someone with more skills, education, or experience may have both higher wages and a more generous health insurance plan. If one ignores productivity and simply compares the wages and health insurance of the two individuals, one would conclude that there is no compensation differential between wages and health insurance. Indeed, one may conclude that higher wages and generous health insurance are positively associated with one another.

Employers want to hire job candidates who are intelligent, are creative, understand the business, are able to work well with coworkers and the public, are able to take and carry out orders, are able to meet deadlines, and can provide leadership for the tasks at hand. These are the characteristics of productive workers. Finding such employees, however, is difficult. Suppose that the

only information employers had about applicants were their age, years of schooling, and perhaps the number of years of experience in the industry. When studying compensation differentials, researchers face similar challenges. Because only very crude measures of productivity are available, the resulting comparisons are biased toward positive relationships between wages and benefits. The empirical issues are compounded because a researcher would also want to control for the relevant household marginal tax rate because under current U.S. law, employer-sponsored health insurance is not considered taxable income, while money wages are taxed. This design provides incentives to shift compensation from taxed wages to untaxed health insurance benefits.

A study from 2004 provides the most straightforward analysis of compensation differentials, which examined data from 1988 through 1990 on a panel of workers, some of whom changed jobs. Researchers could have taken the standard approach to studying compensation differentials by estimating a regression equation in which wages were a function of having employer-sponsored health insurance, observable job, and worker characteristics. The problem, however, is the inability to adequately account for the unobserved differences in productivity across workers. Instead, this study estimated worker-specific changes in wages in an equation as a function of the change in the presence of employer-sponsored health insurance and changes in job and observable worker characteristics. If one can assume that worker productivity does not change much from year to year, then this change equation effectively holds productivity constant. Each person serves as his or her own control. The study found that workers who lost health insurance over the period had wage increases of 10% to 11%. This finding presents good evidence of compensating wage differentials.

In an earlier study, researchers examined the effects of the imposition of state insurance mandates for maternity benefits. In 1979, the federal government required that most group health insurance plans cover maternity care like any other covered medical condition. Before that time, only 23 states had done so. In this study, investigators undertook what is called a differences-in-differences-in-differences

(DDD) analysis. They compared the change in wages before and after the enactment date of the laws (Difference 1), in states that did and did not enact the law (Difference 2), for people who would and would not be affected by the law (Difference 3). The idea is that the wage changes in unaffected states and for similar but unaffected individuals would control for other factors at work in the states and local labor markets.

The states of New York, New Jersey, and Illinois enacted the maternity care mandate between July 1, 1976, and January 1, 1977. The states of Connecticut, Massachusetts, Ohio, Indiana, and North Carolina were used as controls because they did not enact such laws. The average wage for relevant workers in these states ranged from \$5.59 to \$6.61 in constant 1978 dollars. Affected workers were defined as married women of childbearing ages, that is, between the ages of 20 and 40. The unaffected group was defined as all individuals between 40 and 60 and all single men. The individuals excluded from the study were single women and married men aged 20 to 40. Both of these groups could have been affected by the laws, but their inclusion would only complicate the comparison.

Married women aged 20 to 40 in states that enacted the law had wage decreases of 3.4%. In states that did not enact the law, married women aged 20 to 40 had wage increases of 2.8%. The difference in these two differences was -6.2%. For the unaffected group, single men aged 20 to 40 and all people aged 40 to 60, in the states enacting the law, wages decreased by 1.1%, suggesting that there were other wage trends going on in the experimental states besides the enactment of maternity benefits laws. For the unaffected group in states that did not enact the laws, real wages declined by 0.3%. Thus, the difference-in-differences for the unaffected groups was a decline of 0.8%. The estimated effect of the laws was the difference in these two overall differences or 5.4%. This study uncovered dramatic evidence of compensating wage differentials that are borne by the affected group.

Another study from 1999 used the relationship between age and wage to identify compensating wage differentials. The investigator argued that older workers were more likely to have health insurance claims and so any compensating wage

differential for employer-sponsored health insurance should be more pronounced for older workers. Moreover, these claims should be higher in communities with higher healthcare costs. If compensating differentials exist, then older workers in communities with higher health insurance premiums should receive lower wages. This study found that wages were \$113 lower for each year of age in the high-premium markets relative to those facing lower premiums.

Last, another study used the 1989–1999 National Longitudinal Survey of Youth to examine the effects of obesity in the labor market. The researchers found that obese individuals with employer-sponsored health insurance received lower wages, while those without employer-sponsored coverage, those with nongroup coverage, and those with no health insurance coverage did not receive lower wages. The investigators' estimated wage reduction was roughly in line with the additional medical costs associated with obesity.

COMPETITION IN HEALTHCARE

Competition in healthcare refers to the interaction between healthcare providers and third-party payers. This interaction is designed to obtain the business of consumers in the form of the purchase of healthcare services or insurance. This interaction also represents the marketplace for the purchase and distribution of healthcare services.

From a normative perspective, an emphasis on competition reflects a preference for private-sector control and delivery of healthcare services. It also reflects a preference for minimum government intervention and regulation of healthcare markets. Decision making in a competitive environment is also considered to reflect rational choice based on the best available information.

In its ideal form, when healthcare markets operate properly, competition will determine the appropriate prices for medical services, the appropriate organizational forms for healthcare financing and delivery, and the appropriate range and availability for cost/quality/service trade-offs. However, there are also major tensions built into how competition operates in the healthcare system. The major tension is over whether to support competitive mechanisms within a market paradigm on the one hand and whether to preserve access and fairness through government intervention on the other hand.

Competition is thought of as determining who gets what, when, and how, and this process, in turn, influences the pace and character of policy change. However, the American healthcare system is not structured to maximize consumer choice or sovereignty. Providers and third-party payers are in a much more powerful position than consumers due to issues related to asymmetric information, economic dominance, and structural arrangements. The federal and state levels of government on the

one hand, and employers on the other, have taken on the role of an umpire whose responsibility it is to resolve tensions and provide mediated or negotiated solutions.

Competition in healthcare markets is one of the primary tools used in the United States as a strategy to contain costs, promote efficiency, and encourage innovation. Indeed, competition has been the preferred strategy for cost containment in the nation, much more so than other cost containment strategies that are prevalent in many European countries, such as the use of price setting, global budgets, and rationing of access to healthcare services. In fact, some have argued that rigorous government enforcement of antitrust regulations and the resulting protection of private innovation have allowed the healthcare industry in the nation to remain a predominantly private enterprise, as opposed to one that is government run, as in most other nations. Because of this, the United States provides many examples of how competition can work in the market for hospital care. Market-oriented health policy highlights the role of incentives in generating appropriate behavior on both the demand and the supply sides of the medical marketplace, among both consumers and providers.

The laws of competition in the United States affect the way healthcare is financed and delivered, as well as its quality and affordability, through their effects on the interaction of providers and patients within the organizational and structural framework of the healthcare industry. Competition law has traditionally focused on the process of market interactions, not necessarily on the individual actors in that process or on the outcomes—it does not concern itself with whether the outcomes that result from the operation of an efficient market accord with a particular definition of optimal social policy. However, given changing market dynamics and expectations of consumers, the framework of competition law is expanding to take into account trade-offs between price, quality, innovation, and access, which are all features of the healthcare system that consumers are demanding.

Despite this, there are a number of problems with competition in the private insurance model in the United States. The decade of the 1990s witnessed profound changes in the competitive environment of healthcare providers. A large number

of mergers and acquisitions among hospitals increased the concentration of the hospital sector, and a few large national hospital chains gained a significant market share during this time period. The hospital industry argued that these mergers offered efficiency gains that more than offset any potential anticompetitive effects they may have. Despite concerns among federal antitrust regulators, industry analysts, and the public, some empirical evidence did emerge that these efficiency gains were real. Studies of hospital competition in California and Washington suggested that increasing competition across hospitals did in fact lower costs. Evidence also shows that health maintenance organizations (HMOs) and preferred provider organizations (PPOs) nationally document significantly lower healthcare costs in regions with competitive hospitals.

Competition in the U.S. health insurance market has been primarily driven by the development of managed care since the early to mid-1990s. By 1996, 73% of those obtaining coverage through employment were in managed-care plans, compared with 27% 8 years earlier. HMOs were the most popular plan type, accounting for 31% of the market.

The benefit structure in managed-care plans included far less in the way of financial incentives for patients, which had been the norm in traditional insurance plans. This reflected a managed-care philosophy that consumers should not be called on to limit their use of services because of their ability to pay. Instead, professionals—either the patient's physician, with incentives other than fee-for-service, or clinical staff of the health plan—should take responsibility for limiting services that have a low value.

Competitive Approaches on the Consumer Side of Markets

As already indicated, competition in healthcare can be characterized as reflecting the interests and interactions among consumers, providers, and third-party payers. Consumers want to maximize their power and choice based on the best available information about their providers, about their treatment options, and about the healthcare delivery system. However, consumers operate in a context of asymmetric information. Physicians have much more

medical information and expertise than their patients, and patients rely on their provider to offer and prescribe the most effective treatment possible. Providers, in turn, as typified by the traditional physician–patient relationship, depend on the loyalty of their patients and adequate reimbursement levels provided by third-party payers. Traditionally, providers have been in a position where physicians propose and patients dispose. Under this model, patients dissatisfied with their providers may switch physicians, assuming a healthcare system in which a consumer has free choice of providers. Third-party payers, and particularly managed-care payers, play a critical role in this system because they establish rates of reimbursement and can often determine if a consumer is able to obtain the services that he or she prefers. The managed-care revolution has significantly altered these traditional relationships, particularly in the era when most Americans receive their health insurance coverage through an employer who selects the benefit plans that will be available to the consumer. Just what the consumer is able to choose in this context is unclear. This has, in turn, significantly affected the context in which competition takes place.

Consumerism and managed competition share the market paradigm that social resources, including medical care, should be allocated based on individual rather than collective decisions. Informed and price-conscious individual choices represent the values and preferences of the patient better than do the choices of even the most benevolent third party. The performance of the delivery system is enhanced by consumer and provider incentives that align the pursuit of individual self-interest with the social interest in promoting a high-quality, cost-effective system of care. Collective choice mechanisms such as regulatory agencies, professional associations, and corporate organizations find their utility in supporting, and their disutility in displacing, individual choices.

Competition and Regulation

While there have been major pushes to enhance the competitive environment in healthcare, governments at the federal and state levels have also maintained a watchdog role and intervened when there have been perceived market failures with

respect to cost, access, and fairness. The impact of the balancing between competitive approaches and government regulation has been most profound in the hospital sector in the United States. An increasingly competitive hospital market, as well as changing payment policies in both the private and public sectors, has forced hospitals to reenvision their role in the healthcare environment, and a number of structural, procedural, and financial changes have occurred.

Competition has a number of effects on hospitals, including the potential to improve quality and lower costs, but it can also undermine the hospitals' ability to engage in cross-subsidization of the cost of care between profitable and nonprofitable services or between wealthy and poor consumers. Medicare pays essentially the same price for a given health service regardless of where it is delivered. As a result, hospitals compete for the business of Medicare beneficiaries on the nonprice, system-based features that they offer. On the other hand, there are price-based and nonprice-based competitive opportunities for hospitals in the private patient/payer markets.

In the United States, hospitals operate in a regulatory environment that has developed over time at the federal and state levels. Laws and regulations have emerged to address many issues, including public financing, patient confidentiality, patient rights, risk management, medical malpractice suits, peer review activities, withdrawal of life support, advance healthcare directives, medical guardianships, institutional review boards, hospital staff privileges, contract and corporate law as applied to the healthcare industry, AIDS-testing issues, certificates of need, and others.

Hospitals are experiencing a number of price-related pressures as a result of rising costs, insurance industry trends, Medicare payment policy, and regulatory mandates. Some of the factors that affect hospital pricing and the recent rapid increases in costs include the public's demand for new and better technology, the aging of the population, shortages of hospital staff, including nurses, demands for new and broader forms of information and reporting, patient safety initiatives, rising liability insurance premiums, higher pharmaceutical costs, and increasing numbers of uninsured patients to whom they are required to provide care. Many of these factors represent new areas in

which hospitals can find competitive advantages if they perform well, but these pressures on hospitals are often augmented by the fact that they, unlike some of the newer competitors, are obligated to provide a certain amount of uncompensated care and other services under federal regulations.

Traditionally, hospitals were where people went to receive a wide range of medical services, including diagnostic, therapeutic, and rehabilitative care. They were the point of care for patients with healthcare needs that ranged from relatively minor, acute conditions to serious, life-threatening emergencies. Patients would be admitted to the hospital and would stay until they were well, which would be anywhere from a few days to weeks, up to several months. Under this model, hospitals were the recipients of the bulk of healthcare dollars. This diversification of services allowed them to cross-subsidize relatively nonlucrative services with revenues from the more lucrative services they provided. Since they were required to maintain a certain number of beds, operating rooms, and emergency departments, often with residual capacity in case of unforeseen circumstances, they depended on these cross-subsidies to maintain their financial bottom line.

Over the past two decades, however, a number of trends have emerged in the hospital sector that have altered the competitive environment in which they operate. Almost without exception, these trends have challenged the traditional role of hospitals and have forced them to compete in new ways. Outpatient surgery centers, single-specialty hospitals, rehabilitation hospitals, and outpatient diagnostic imaging centers have all cut into the revenue sources that were previously available only to general hospitals. General hospitals, in the meantime, continue to be required to maintain residual capacity in the less lucrative or more expensive areas such as emergency care, general surgery, and intensive care. This diversification in the healthcare market certainly increases competition among different types of providers, but it has also forced the hospital sector to evolve in important and profound ways.

While historically hospitals operated as independent organizations within local markets, more than two thirds of the nation's hospitals are now part of multihospital system or operate under a network of affiliated hospitals. This hospital

consolidation represents both a response to increasingly competitive hospital markets and an opportunity to compete more efficiently by reducing duplication and capitalizing on economies of scale and administrative expertise. These systems and networks range from comprehensively integrated organizations with shared licensing and ownership arrangements to loosely organized partnerships with shared governing bodies but independently operating facilities. The benefits of hospital consolidation may include a reduction of excess capacity, increased ability to assume financial risk, expansion of the hospital's delivery network, and service coordination.

There has been some concern that hospital systems have used consolidation as a tool to exert increased market power to distort the competitive environment and demand increased prices from payers. This argument stems from the observation that some hospital mergers have resulted in higher hospital prices without the concomitant increase in efficiency, such as the integration of clinical services or reduction of duplication.

Hospital payment mechanisms are complex and varied, with some hospitals billing the patient directly and others billing their insurance company. Some insurance companies require the patient to pay a copayment at the time of service and then pay the hospital directly for all costs beyond that, while other insurance plans require the patient to pay the full bill up front and reimburse the patient later for allowable expenses. Many Medicare plans require a copayment at the time of service but pay the hospital directly for the remainder of the patient's bill. The impact of Medicare payment systems on the hospital sector has been substantial and widespread since it introduced its prospective payment system (PPS) in 1983.

The nature of the hospitals with which private insurance companies contract can affect the insurance companies' ability to compete with one another. For example, marketability of insurance plans to employers and employees depends not only on the price of the coverage they offer but also on the number of hospitals where coverage is offered and on the quality, accessibility, and desirability of those hospitals. Being a "must-have" hospital may confer a significant competitive advantage to such a hospital in contract negotiations with private insurance companies.

The Centers for Medicare and Medicaid Services (CMS), the federal administrative agency of the Medicare program, clearly has a profound effect on the competitive environment in which hospitals operate, but this is primarily an indirect effect through its price-setting authority. It does not, for example, have the ability to use competitive bidding or selective contracting mechanisms to exert direct control of the providers, with which it negotiates. And there is virtually no way for Medicare to encourage nonprice competition between providers. This is what recent pay-for-performance initiatives would attempt to do by inserting quality and outcome measures into the payment policy, but such initiatives are in their infancy.

Legal Framework Affecting Competition

The major way in which the federal and state governments affects competition is through the implementation and enforcement of laws and regulations focusing on unfair competition, antitrust, and certificate of need.

Unfair Competition

Competition law has traditionally focused on the process of market interactions, not necessarily on the individual actors in that process or on the outcomes—it does not concern itself with whether the outcomes that result from the operation of an efficient market accord with a particular definition of the best social policy. However, given changing market dynamics and expectations of consumers, the framework of competition law is expanding to take into account trade-offs between price, quality, innovation, and access, which are all features of the healthcare system that consumers are demanding. Hence, under these laws, government is able to intervene to label a given practice by a provider or insurance company to be unfair and thus null and void.

Antitrust

The application of antitrust laws, regulations, and principles to healthcare services relies on the assumption that hospitals are businesses that provide medical care as a service. This is a distinct

shift from the emphasis on the independent, fee-for-service provider and has been a relatively recent occurrence. The U.S. Supreme Court first applied antitrust principles to healthcare providers in 1975, and hospitals and providers are now required to comply with federal antitrust legislation. Previous jurisprudence had held that the medical community was a “learned profession” and therefore exempt from antitrust regulation.

There are three main federal laws that govern the competitive environment of the nation’s healthcare industry: (1) the Sherman Act (1890), (2) the Clayton Act (1914), and (3) the Federal Trade Commission Act (1914).

The Sherman Act, also known as the Antitrust Act, is the predominant law in the United States that deals with issues of competition in financial and business markets. The Sherman Act is concerned with maintaining competition to ensure consumer welfare, and it generally prohibits unilateral and collective conduct that poses unacceptable dangers to competition. Generally, the act prohibits contracts, combinations, and monopolization or attempted monopolization in restraint of trade. Section 1 (codified as 15 U.S.C. §1) of the act prohibits “every contract, combination . . . or conspiracy in restraint of trade.” As such, *competition* can be defined as “a dynamic process featuring voluntary transactions between, and independent decisions by, mutually accountable buyers and sellers.” In the healthcare setting, potential anticompetitive actions that are particularly scrutinized under the Sherman Act are price fixing, market division, and group boycotts. Section 2 of the act (codified as 15 U.S.C. §2) deals with the development of monopolies, particularly when they arise or are maintained through wrongful or exclusionary means. The existence of a monopoly in the healthcare sector, such as the presence of only one hospital in a given geographic area, is not necessarily a violation of the act, but tactics by that hospital’s administration to restrict the entry of a second hospital in the region may very well violate Section 2 of the Sherman Act.

The Clayton Act (and the Robinson-Patman Act of 1936, which is a related piece of legislation) prohibits commodity price discrimination; exclusive dealing arrangements that substantially lessen competition; and mergers, acquisitions, or joint ventures that would substantially lessen competition or

create a monopoly. Section 7 of the Clayton Act (codified as 15 U.S.C. §18) prohibits mergers and acquisitions where the effect “may be substantially to lessen competition, or to tend to create monopoly.” In scrutinizing potential, or planned, arrangements that could lead to future Sherman Act violations, the Clayton Act provides an additional safeguard against the development of anticompetitive monopoly power. In the current U.S. healthcare environment, in which major national healthcare systems have been consolidating their market power, both the Clayton and Sherman Acts have been repeatedly invoked.

The Federal Trade Commission Act prohibits unfair methods of competition and deceptive acts or practices, including misrepresentations or false and misleading advertising. Section 5 of the act (codified as 15 U.S.C. §45) prohibits “unfair methods of competition” and “unfair or deceptive acts or practices in or affecting commerce.”

There is clearly an overlap between these three laws, as well as in the regulatory authority to pursue claims under the laws. The U.S. Department of Justice (USDOJ) and the Federal Trade Commission (FTC) are the primary enforcers of the laws, and state attorney generals as well as private parties can file lawsuits under competition laws.

There are some exceptions under the antitrust laws that permit certain types of hospital mergers, and not all such mergers are scrutinized as potentially anticompetitive. In fact, the FTC’s “Health Care Statement,” which outlines its antitrust enforcement policy, provides a safety zone for certain types of hospital consolidation and merger that protects them from challenges. This safety zone is designed to lessen the burden for merger activities when the merging hospitals are not major competitors before the merger. It specifically protects mergers between two general acute care hospitals where one of the hospitals has an average of fewer than 100 licensed beds and has an average daily inpatient census of fewer than 40 patients. In general, the commission and the USDOJ will also not challenge a potential merger if there are significant, demonstrable efficiencies to be gained by the merger. To be deemed procompetitive (or at least not anticompetitive) such efficiencies should be merger-specific; be verifiable; and not arise from anticompetitive reductions in output or service.

However, other types of mergers may come under greater scrutiny by the FTC or the USDOJ if they tend to create or enhance the merging hospitals’ market power in a given region. Under the 1992 Horizontal Merger Guidelines of the commission, whether the proposed merger could possibly have anticompetitive effects depends on the following: whether the merger, in light of market concentration and other factors that characterize the market, would be likely to have adverse competitive effects; whether entry would be timely, likely, and sufficient either to deter or to counteract the competitive effects of concern; whether there are efficiency gains from the merger that meet the commission’s criteria for examination; and whether, but for the merger, either party to the transaction would be likely to fail, causing its assets to exit the market. Under these guidelines, a market is defined as a product and a geographic area in which it is produced or sold, such that a hypothetical profit-maximizing firm that was the only present and future producer or seller of those products in that area would likely impose at least a small but significant and nontransitory increase in price.

The institutional status (for profit vs. not for profit) of hospitals can sometimes become an issue in antitrust analysis when mergers are proposed. Being a nonprofit hospital does not per se protect it from scrutiny under antitrust laws although some courts have been more sympathetic to nonprofits wishing to consolidate their operations with other nonprofits. Even in these cases, however, the underlying antitrust issue is whether such an institution would use its newly acquired market power in ways that would be harmful to consumers.

Medical antitrust law is complicated by the fact that federal and state governments are a major regulator and purchaser of healthcare services while antitrust laws are primarily designed to regulate the private economy. Traditional antitrust law is designed to shape the behavior of private businesses, but there is a melding of private and public actors in healthcare service funding, purchasing, and delivery. This may lead to market-distorting effects that invite unnecessary business transactions, impair organizational efficiency, and hamper the negotiation of mutually advantageous arrangement by willing buyers and sellers. Government programs such as Medicare and Medicaid have a

substantial impact on how hospitals can conduct themselves within the marketplace as competitive businesses.

Additionally, antitrust law rests on the premise of active bargaining between buyer and seller to create competition. The rise of managed care and third-party payers has all but removed the active bargaining component. Managed care has changed the bargaining market in two distinct ways: mainstreaming explicit contracting for the sale of hospital services, and creating a new group of purchasing agents (third-party payers) who negotiate prices for health services. The complex and changing healthcare market, therefore, does not always fit cleanly into the traditional antitrust regulation framework, and some commentators have argued that these regulations may actually stifle competition and drive up costs as opposed to stimulate competition and moderate costs.

Certificate of Need

Certificate of need (CON) laws are state regulations that require institutional healthcare providers to seek prior approval before adding new improvements, equipment, or facilities or replacing existing healthcare facilities. Prior approval is granted by the respective state's Department of Health and is also required for the addition of certain medical services at the facility. CON laws are designed to hold down costs by preventing duplication of medical services. Examples of facilities required to seek CON approval include new hospitals, psychiatric facilities, chemical-dependency treatment facilities, and nursing home facilities. CON requests will be approved if it is determined that the community genuinely needs the proposed service or facility.

The CON laws were developed in response to the belief that there was wasteful duplication of medical resources and facilities within the hospital sector. The feeling was that because hospital prices were relatively fixed in a geographic area, hospitals did not compete for patients based on the price of their services but rather increased their competitive edge on the basis of perceived quality of care, services, or facilities. As a result, competition was based on quality and unnecessary, wasteful expenditures to attract patients.

CON laws were initially required by federal mandate in 1974, but this mandate was later

repealed in 1982, when it was found that such regulations had little impact on the rising cost of healthcare. In fact, critics of CON argue that they have been used by hospitals to stifle competition and that the programs may actually increase healthcare costs as supply is simply depressed below competitive levels. Despite these criticisms and the repeal of the federal mandate, 36 states and the District of Columbia have retained their CON laws.

Future Implications

The competitive environment in the nation's healthcare industry will develop in response to cost pressures and consumer demand, as well as technological advances. Among the greatest pressures for competitive reforms are consumer-driven care, a demand for greater choice of providers, the changing role of the hospital sectors, and the increasing importance of Medicare and Medicaid in the private health insurance industry. In addition, the trend toward self-insurance will also have an impact on the competitive environment. Financial incentives for patients will continue to become more important, and refinements to the benefit structures that include substantial patient cost sharing will get more attention. More emphasis will be given to incentives to choose more efficient providers.

Concerns over the rising costs of healthcare and health insurance have led providers, consumers, and third-party payers to new attitudes toward healthcare reform. The concern is over a growing number of employers who cannot afford to offer health insurance as a benefit, and a growing problem of lack of access to adequate healthcare.

The current discussion about healthcare reform is influenced by the Jackson Hole Group, which in the early 1990s asserted that the nation needed to adopt a strategy of managed competition. The concept of managed competition can be characterized as a market-based policy of controlled or regulated competition among insurance carriers with incentives for insurance carriers, physicians, and other healthcare providers to improve quality, increase benefits, expand access, and control costs. It calls for "robust competition among healthcare plans" by creating large regional healthcare cooperatives or health alliances.

In the future, competitive models will likely be built around consumers' choices and some of the core concepts of managed competition. Increasing amounts of information will be available to consumers, which will allow them to compare providers and financial arrangements as they make more careful healthcare choices. Information technology (IT) will be an important part of this new competitive environment in healthcare, and consumers and providers will clearly use IT in different ways. Providers will use IT to organize and present information about their efforts to increase efficiency and improve quality and to advertise to consumers. Consumers, on the other hand, will use IT to shop for the best deal from the best provider they can find. This will force providers to improve quality and outcomes in an effort to compete for consumers' business. Of course, this will require that more and better information become available about the various providers in the marketplace.

Hospitals are likely to continue to consolidate, motivated in large part by their dwindling market share as competition increases. This will create new opportunities for hospitals to develop innovative partnerships, perhaps integrating previously for-profit hospitals with nonprofit hospitals to develop new types of multihospital systems.

Competition will certainly play an important role in the U.S. healthcare system in the future, but just what form it will take and with what restraints remain to be seen. Indeed, who will have the greatest control in shaping the future of competition in healthcare in the nation—government, providers, insurers, or citizens—remains an open question.

COMPLEMENTARY AND ALTERNATIVE MEDICINE

Constituted of multiple therapies that have their origin in cultural practices and traditional medicine, some of which have a history of thousands of years, complementary and alternative medicine (CAM) encompasses a diverse group of health-related practices and products that are viewed as existing outside mainstream medicine. The approach to healing and the wellness construct that defines each of these modalities may, in some respects, differ from the realm of conventional thought as present in the West or as is taught in the traditional medical curriculum in the United States. These CAM practices are divided into four domains by the National Institutes of Health's National Center for Complementary and Alternative Medicine (NCCAM): (1) mind-body medicine, (2) biologically based practices, (3) manipulative and body-based practices, and (4) energy medicine. The effectiveness and/or safety of some of

the modalities within these groups continue to be in question, while others are gathering strong scientific evidence in their favor.

Every year, an increasing number of Americans are using CAM therapies by means of licensed practitioners as well as through the use of over-the-counter herbal preparations. In 1997, David Eisenberg estimated that 42% of the U.S. population was using some form of alternative therapy, and another study by Nancy Elder estimated that at least 50% of primary-care patients were using some form of CAM. In 2004, the NCCAM illustrated that these numbers are rising with evidence that upward of 60% of adults in the United States are using some form of CAM. According to this survey, women more than men, people with higher educational levels, and people who have recently been hospitalized are more likely than others to use CAM. In addition, allopathic physicians are, in greater numbers, using these methods through referral or direct recommendations. Medical schools are incorporating this topic into the core curriculum, and continuing medical education courses are being offered in related topics. Also, some third-party payers are increasingly reimbursing for these services. As popularity continues to rise, expenditures dedicated toward this arena climb. CAM continues to grow in popularity within the United States and, in the process, enhances the lives of many while raising concerns of safety and regulation among others.

Whole Medical Systems

The NCCAM classifies certain fields of CAM under the heading of Whole Medical Systems as they are considered complete systems of theory and practice. There is some overlap with these medical systems and the four domains of CAM; however, historically these systems have developed independently and hold their basis within an accepted theory and often use specific modalities of practice as recognized within this framework. Traditional Chinese medicine is one of the most well-established and complete systems that have been practiced well before the first known written texts dating to 200 BCE. The maintenance of the body and spirit within a balanced state through the regulation of two opposing forces, yin and

yang, allows the proper flow of Qi, the vital energy, along meridians, pathways within the body. Traditional Chinese medicine uses acupuncture and moxibustion, the Chinese *Materia Medica* (herbal reference), and massage and manipulation as parts of its therapeutical modalities. Ayurvedic medicine, with origins in India, also places an emphasis on balance. This system attempts to restore harmony within the body, mind, and spirit through Ayurvedic treatments such as meditation, herbal therapy, massage, controlled breathing, and diet. Naturopathy, practiced mainly in the West, originated in Europe and holds six principles as its basis: (1) the healing power of nature, (2) identification and treatment of the cause of disease, (3) first—do no harm, (4) the physician as teacher, (5) treatment of the whole person, and (6) prevention. Naturopathy uses many forms of modalities, including diet modification, nutritional supplements, herbal products, hydrotherapy, massage, manipulation, and lifestyle counseling and borrows some therapies from traditional Chinese medicine, including acupuncture. Another recognized medical system is homeopathy, which uses the Law of Similars, stating that a substance causing a particular single or set of symptoms in a healthy person is viewed as a remedy in persons suffering from similar symptom(s), which can be cured in these individuals. The Law of Dilutions states that the more a remedy is diluted, the stronger it becomes. This field was formed primarily by a German physician, Samuel Hahnemann, in the 1800s and has increased in popularity since that time.

Mind–Body Medicine

The NCCAM domain of mind–body medicine is evolving, with more and more modalities being recognized as mainstream in recent years. Of note, patient support groups and cognitive-behavioral therapy are commonly used methods of counseling. Other modalities within this domain include meditation, prayer, mental healing, and creative therapy, encompassing art, music, and dance. In fact, prayer is the most common CAM practice used, with about 45% of the U.S. population practicing prayer for health-related reasons in 2002.

The importance of the mind within healing was recognized by traditional Chinese and Ayurvedic medicine, just as mind–body medicine recognizes the importance of the relationship between emotions and physical health. This, in part, is due to the interrelationship between the sympathetic and parasympathetic nervous systems and has been widely documented and often exhibited in patients through symptoms such as gastrointestinal hyperactivity, neck and shoulder pain, and headaches. These clinical manifestations have a direct relationship with increased levels of tension and stress in these individuals. Walter Cannon, in the 1920s, first drew the correlation between stress and the neuroendocrine response. Since that time, this field has continued to be extensively researched, and the importance of moral and spiritual aspects, belief, emotion, and positive thought within healing is more and more recognized. Intervention strategies used within this field include relaxation, hypnosis, visual imagery, meditation, yoga, biofeedback, tai chi, qi gong, and spirituality.

Biologically Based Practices

The biologically based practices as recognized by NCCAM include therapies such as botanicals, animal-derived extracts, vitamins, minerals, fatty acids, amino acids, proteins, and probiotics. With NCCAM estimating that about one fifth of the U.S. population use natural products, this domain encompasses a large portion of the popular usage of CAM. Herbal products are popular as they carry a perception by the general population of being more natural than pharmaceuticals as well as more gentle, having fewer side effects and being more affordable. Some of the most common herbs used in the United States include *Ginkgo biloba*, commonly used as an antioxidant and for the improvement of memory; St. John's wort, used for mild depression; ginseng, used for fatigue and weakness; garlic, used for high cholesterol; and *Echinacea*, used for the relief of common colds and respiratory infections. Some common supplements include glucosamine and chondroitin sulfate for osteoarthritis, CoQ-10 as an antioxidant to fight heart disease, melatonin for insomnia, amino acids for body building, and omega fatty acids for high blood pressure and high cholesterol.

The NCCAM survey concluded that only about 12% of those using CAM have done so through seeking care from a licensed CAM practitioner: Thus, the remaining use CAM to treat themselves. This can be alarming, as in contrast to the common perception of these products being completely safe, there are critical dosing issues with all, as well as possible dangerous herb to drug, food, or illness interactions. The Dietary Supplement Health and Education Act of 1994 exempted herbal medications and supplements from safety and efficacy requirements and regulations applied to prescription and over-the-counter medications. Because of this legislation, there can often be a problem with quality in these over-the-counter preparations. Variations in potency and biological, chemical, or pharmaceutical contamination may be present. Presently, the burden does not rest with the manufacturer. It is the responsibility of the U.S. Food and Drug Administration (FDA) to prove that a product is unsafe before it can be pulled from shelves. Therefore, practitioners and patients must strive to be well informed.

Practitioners and patients must also remain astute to avoid possible dangerous interactions. Herbs such as *Ginkgo biloba* may alter glucose levels and can be a dangerous product in persons who are diabetic. Other herbs and supplements such as ginger, garlic, and fish oils can inhibit platelet aggregation and dangerously alter the effectiveness of pharmaceutical anticoagulants commonly used in patients with arrhythmias and with a history of blood clots. There are multiple other possible dangerous interactions, and persons using these products should heed caution. Many products have been shown to be effective, but one should only use them after much study and consideration, as well as through recommendation by a medical practitioner.

Manipulative and Body-Based Practices

The manipulative and body-based practices domain includes chiropractics, osteopathy, and massage.

Chiropractics finds its origins as a profession in Davenport, Iowa, as developed in 1895 by D. D. Palmer, though historically, spinal manipulation has been a part of cultural practices for centuries throughout the world, including in ancient

Egypt. The basis of chiropractics according to modern theory is based on vitalism and proffers the tenant that normal functioning will return through joint structure restoration. Chiropractors work mostly with musculoskeletal complaints, including spinal subluxations, low back pain, neck pain, muscle strain, and tendonitis, but they may also incorporate therapy for other disorders such as asthma, upper respiratory conditions, constipation, and menstrual disorders. Through mechanical manipulation, the chiropractor is able to inhibit and reduce the pain reflex, release connective tissue, and stimulate the autonomic nervous system. Chiropractics is popular in the United States, as a discipline being the third largest health profession after medicine and dentistry, and in addition, many third-party payers will cover chiropractic services. Chiropractics is regulated in all 50 states, with 16 chiropractic colleges being accredited.

Osteopathy, developed in Kirksville, Missouri, by Andrew Taylor Still in 1874, is now considered a part of mainstream medicine. Practitioners in this field follow a curriculum similar to that of allopathic physicians, with more emphasis placed on a holistic approach with additional training in manipulation. Doctors of osteopathy continue with a residency appointment to become licensed practitioners in the field of their choice. Those who choose to remain within the realm of primary care are able to better use their additional training of a holistic approach to diagnosis and therapy.

Massage therapy is a very diverse field and holds its origins in cultural traditions throughout the world. Chinese medical texts dating back 4,000 years make reference to the benefits of therapeutic massage; the healing art of Ayurveda, originating in India, includes massage as part of its practice; and Hippocrates, as well, advocated the use of medicinal oils for massage therapy. Today, the field encompasses many categories, including relaxation or Swedish massage, neuromuscular massage, and craniosacral therapy, to name a few, and holds the intent of improving health through positively affecting relaxation, circulation, nerve responses, or energy flow through skilled manipulation of soft tissues and connective tissues. Some estimates state that more than \$4 billion is annually spent on massage by over 80 billion consumers. More than 200,000 massage therapists are licensed in the United States and practice independently as

well as within hospitals, fitness centers, primary-care offices, and intensive-care units and in conjunction with psychotherapy treatment programs and hospice.

The most common form of massage, Swedish massage, incorporates a variety of strokes, including effleurage, petrissage, tapotement, vibration, friction, and compression to aid in therapy through the relief of muscular tension. While Swedish massage generally focuses broadly on the full body, neuromuscular therapy often addresses localized areas of trigger points within the myofascial system and seeks to restore a balance with the alleviation of local and referred pain. Western massage techniques may, as well, be used for specific purposes such as sports, pregnancy, and with infants. Another classification of massage includes structural and functional movement and influences the posture and biomechanics of the body while reestablishing a balanced relationship with gravity. Forms within this classification include rolfing, Feldenkrais, zero balancing, craniosacral therapy, and the Trager Approach. Asian forms are generally referred to as acupressure and attempts to regulate Qi without the use of needles (as is used within acupuncture). The common forms within this classification include Shiatsu, Jin Shin Do, Jin Shin Jytsu, and Chinese Tuina.

Energy Medicine

The massage techniques of energetic or zone therapies are sometimes referred to as reflexology and fall within the NCCAM-defined domain of energy medicine, which includes biofield therapies such as qi gong, reiki, and therapeutic touch. Modalities not based on massage also fall within this domain and include bioelectromagnetic-based therapies such as pulsed fields, magnetic fields, and alternating-current and direct-current fields.

Acupuncture and homeopathy (described above as a whole medical system) are, as well, classified within the domain of energy medicine. Acupuncture, an art of traditional Chinese medicine dating back at least 2,500 years, uses Qi, a vital energy, that circulates in the body through pathways. Fine needles are placed at points along these pathways, also called meridians, to restore and balance the flow of energy in order to promote healing.

Licensing

Professional regulation of the CAM professions differs from state to state, with the most common CAM professionals being licensed acupuncturists (LiAcs), doctors of chiropractic (DCs), naturopathic doctors (NDs), and licensed massage therapists (LMTs). The professionals recognized by state professional license in a smaller number of states are as follows: homeopathic practitioners, therapeutic touch practitioners, reiki healers, herbalists, and aromatherapists. As concerns mainstream physicians, ideally all should have a competent working knowledge of CAM regardless of the extent to which they implement CAM into their practice. An adequate patient history should reveal utilization of CAM, thus giving warning if a certain CAM therapy possesses a contraindication or critical interaction with a proposed manner of treatment. Several estimates place the rates of patient disclosure to the primary-care physician concerning use of alternative therapies between 35% and 40%. These low rates can lead to complications and endanger patient safety. It is critical, thus, that medical curricula and continuing medical education include CAM as an important aspect of teaching.

Evidence

There is convincing scientific evidence supporting the efficacy of many of the previously mentioned therapies.

Mind-body interventions are effective for acute and chronic pain management, headaches, wound healing, and low-back pain. It has also been shown to be useful in coping with chemotherapy-induced nausea and vomiting as well as in reducing discomfort, controlling adverse effects, and improving hemodynamic stability as associated with some surgical procedures. Susceptibility to infection decreases with greater control of stress through relaxation techniques, and mind-body techniques have even been shown to assist in control of coronary artery disease. Acupuncture, for example, has been shown to be effective for the treatment of postoperative and chemotherapy-induced nausea and vomiting, nausea associated with pregnancy, postoperative dental pain, and osteoarthritis of the knee.

As concerns herbal preparations, there is some evidence that *Ginkgo biloba* in recommended doses can improve cognitive and social function in patients with dementia. Garlic has been shown to significantly lower cholesterol and lower blood pressure as shown in multiple studies. Saw palmetto is likely effective at reducing the symptoms of benign prostatic hypertrophy. Black cohosh, in addition, significantly reduces symptoms of menopause in perimenopausal women when taken over several weeks. The supplements glucosamine and chondroitin sulfate have been shown to be effective for improving joint symptoms caused by osteoarthritis. Omega-3 fatty acid, found in fish oil preparations, has been shown to be cardioprotective and will improve blood pressure control in patients taking the recommended dosages. Also, probiotics have been shown to reduce the duration of certain types of diarrhea in infants and children.

Massage therapy continues to be limited in its scope of available evidence though strong support does exist through some scientific studies. Massage has been shown to positively affect acute and chronic pain, chronic inflammation, lymphedema, anxiety, and arthritis. There is, as well, some support in consideration of the effect of massage on depression, diabetes, fibromyalgia, chronic headaches, stress, and hypertension.

The aforementioned evidence in support of specific CAM therapies should be viewed as a general overview and should not be considered to be all-inclusive. All scientific evidence should be scrutinized, with risks and benefits of the particular therapy weighed on a case-by-case basis in conjunction with discussions with a medical practitioner.

Future Implications

CAM is an extremely broad and rich field that is gaining in popularity in the United States in recent decades. Many of these health-related practices and products were developed over the course of thousands of years and often incorporate a construct of viewing disease and health that is viewed as being outside mainstream thought. An increasing number of research studies are being performed in recent years, and results are providing encouraging support for some therapies. While scientific evidence does grow in support of some

therapies and practices, patients and practitioners should continue to strive to be well informed of the interactions, contraindications, and side effects of the modalities they choose for treatment. Certain professions within this field are regulated at the state level, but many products are available over the counter, with little regulation. If used appropriately and judiciously, the practices and products within the realm of CAM can offer much in relation to health and wellness.

COMPUTERS

Computers play an important role in increasing access, lowering costs, and improving the quality of healthcare. Healthcare organizations use computers for a variety of purposes in a variety of settings. For example, computers can be used to store and retrieve electronic medical records, to assist in medical decision making, and to improve patient safety by reducing medical errors. While many healthcare organizations use computers for various purposes, relative to other large industries (e.g., financial, travel), the nation's healthcare industry lags far behind in their use and applications. For example, although some large hospitals have electronic medical records systems, very few physician offices and nursing homes have such systems. Furthermore, most hospital electronic medical record systems are not compatible, and these records cannot be transferred from one hospital to another. The Agency for Healthcare Research and Quality (AHRQ) and several private organizations are attempting to change this situation by providing grant funds for healthcare organizations to purchase and implement various computer systems.

Basic Definitions

A computer is an electronic machine that manipulates data in accordance with a set of predetermined instructions. Earlier versions of computers used vacuum tubes and required a large building to house the computer. Now, computers come in many different forms and sizes from a large mainframe to a small smart phone.

A computer contains a system board, central processing unit (CPU), memory chip, system clock, power supply, expansion slots, ports, and bus lines. A system board is a flat board that contains the CPU and a memory chip. The CPU is the center of all processing. All data manipulation and

arithmetic/logic computations are performed and controlled in the CPU. A chip has many tiny circuit boards etched on small silicon wafers. The memory chip consists of registers that are located in the control unit and arithmetic logic unit of the CPU. Memory also consists of cache memory, random access memory (RAM), and read-only memory (ROM). Cache memory is located between the RAM and the CPU for faster access. RAM is used to store temporary data or programs when the computer's power is on. ROM stores essential information permanently, and the system clock controls how often the operations will take place within the computer. The expansion slots determine the functions that can be added to the computer. Ports are where printers, keyboards, and other devices connect to an expansion board in the unit. The bus lines are an electrical pathway through which bits are transmitted between the CPU and other devices. Bits are binary information consisting of zeroes and ones.

The set of instructions that control how the computer reacts is called system software. The operating system is the official name for the system software, and it allows the computer to interact with the application software. Application software is the computer software that enables the user to perform word processing, accounting, and other specialized functions.

The size and type of computer used depend on the type of information the user needs to conduct business. Computers are machines that are used to process data into information. Data are raw facts collected during the normal daily operational functions of an organization. In contrast, information is data that have been processed to gain the intrinsic value useful to the operation and management of the organization. Computers provide the processing power to transform the raw data into information based on a set of instructions. The set of instructions differ, depending on the classification of the computer system and the intended user.

Types of Computer Information Systems

There are five general types of computer information systems: (1) executive information systems, (2) transaction processing systems, (3) decision support systems, (4) management information

systems, and (5) knowledge work systems. Only the latter three systems are used in the health-care field.

Decision support systems can be managerial or clinical in nature and use various analytical tools to facilitate and improve the outcomes. The decision support systems can provide basic report generation or sophisticated graphical or textual integration from different data storages. In expert systems, the system integrates data and knowledge based on the structure and complexity of the problem presented by the user to suggest a feasible decision and/or alternatives. Management, physicians, nurses, pharmacists, and researchers use decision support systems.

Management information systems process raw data to provide useful, complete, and timely managerial information. The information is used by managers to organize daily tasks to support organizational plans and operations. These systems provide support to the information technology department, financial operations, personnel department, and other auxiliary departments.

Knowledge work systems are systems developed for professional and technical workers. These systems are more pronounced in healthcare now and are being used by nurses and physicians in the form of handheld computers.

Use of Laptop and Handheld Computers

The national nursing shortage and the complexity of healthcare knowledge have led to a redesigning of existing automation used in the point-of-care processes that occur between nurses and patients. Handheld computers have been employed to allow nurses to capture interventions or graphically view changes in data values at the patient's bedside. System interfaces have been developed to provide nurses with decision support information on a personal digital assistant (PDA) within the confines of the patient's room or home in an effort to increase patient safety and care management. PDAs can be synchronized with the main hospital information system and other team members' PDAs and can be used to browse the Internet for the latest medical information. Thus, nurses can stay current on all new findings contained in the medical journals through the daily use of a PDA.

Physicians also use PDAs, and they can soon be expected to have access to electronic medical records on them. Currently, physicians use PDAs and laptop computers to document patient findings and to order medical tests. Information can be synchronized to the main hospital information system where wireless connections are not available for online ordering or entry into the main databases. When laptop computers are used, the hospital provides connections at the nurse's stations or along the hallway for mobile connection so that data can be updated to the main computer system. Mobile computers and handheld devices allow physicians to tailor their workflow to meet the patient workload. Thus, they can see more patients without compromising safety or care.

Case managers and pharmacists also use handheld computers. As more knowledge work system applications are developed for healthcare, the use of handheld computers will likely expand, thus allowing healthcare professionals to provide closer and more personal support to patients without having to turn their back to the patient to enter data. However, with every advantage, a disadvantage also exists. The disadvantages that arise with the increased use of laptops and handheld computers are the increase in data security and data privacy risks. The risks that will arise from the increased dependency on these computers as a means to enhance medical care are that the devices are more susceptible to be misplaced or stolen, and thus, data encryption and password policies will need to be enforced more stringently. Therefore, the data contained on these devices will need to be protected to a given degree of certainty or at an acceptable level of risk.

CONGRESSIONAL BUDGET OFFICE (CBO)

Established by the Congressional Budget and Impoundment Control Act of 1974 (PL 93–344), the Congressional Budget Office (CBO) is a non-partisan federal agency within the legislative branch of the U.S. government. The primary responsibility of the CBO is to make budgetary and cost projections of legislation proposed by the U.S. Congress. It is analogous to the White House Office of Management and Budget (OMB), which makes estimates of projected spending for the executive branch of government. However, the political appointment of many OMB officials by the president tends to result in more partisan spending projections that tend to favor the president's policy agenda. Thus, the CBO's estimates are typically considered more credible and objective than those produced by the OMB.

Leadership

The director of the CBO is jointly appointed to a 4-year term by the speaker of the House of Representatives and the president pro tempore of the Senate on recommendations of both the House and Senate budget committees. There are no term

limits, but the U.S. Congress may pass a resolution to remove the director. The director hires all other CBO staff members, and positions are filled based on professional merit, rather than political appointment.

The current director of the CBO, Peter R. Orszag, took office in January 2007. He is the seventh director of the CBO. Prior to joining the CBO, Orszag, who is an economist by training, served on President Clinton's Council of Economic Advisors and was a senior fellow and the deputy director of economic studies at the Brookings Institution. Orszag's immediate predecessor was acting director Donald B. Marron, who served in that capacity beginning in December 2005. Alice Rivlin, the first director of the CBO, holds the title of the longest tenure as head of the agency, having served from the office's inception from February 1975 until August 1983.

Organization and Structure

The majority of the CBO's annual budget, which amounted to more than \$35 million in 2007, provides salaries for its more than 230 employees, the majority of whom have graduate degrees in fields such as economics and public policy. A mix of economists, policy analysts, budget analysts, and research assistants work in one of six of the office's divisions: (1) the Budget Analysis Division, (2) Health and Human Resources Division, (3) Macroeconomic Analysis Division, (4) Microeconomic Studies Division, (5) National Security Division, and (6) Tax Analysis Division.

The CBO also confers with the Panel of Economic Advisors and the Panel of Health Advisors. These two groups of experts are responsible for reviewing the CBO's methods and forecasts in the context of the current economic and sociopolitical landscape. The panels also advise the CBO on important developments in their respective fields.

The Budget Analysis Division, the largest division within the CBO, prepares spending projections of proposed legislation currently before the U.S. Congress and the CBO's estimate of the president's annual budget. The division is subdivided into four substantive units, each with expertise in a different area: (1) health; (2) defense, international affairs, and veterans' affairs; (3) human resources; and (4) natural and physical resources.

Cost Estimates

The CBO develops projections and prepares cost estimates of proposed legislation at the request of the U.S. Congress. Nearly every bill that makes it to a congressional committee will be scored by the CBO. The cost estimates, designed to inform members of Congress about the financial implications of the legislation, should it be enacted, broadly include the following: (a) the cost of establishing new programs, (b) the projected cost of savings from altering existing programs, and (c) anticipated changes in revenues, should tax laws be changed. In cases related to proposed changes in the tax code, the CBO is legally required to use estimates prepared by the Joint Committee on Taxation. All other estimates generally attempt to project the effects of the legislation at least 5 years into the future. Ten-year and longer projections, however, are not uncommon. Included with each estimate is a narrative explaining the specific methods used and the assumptions made in calculating the final figures.

CBO's estimates, which are often revised as a bill moves through Congress and is amended, play an important role throughout the entire legislative process, from preliminary bill drafting, through the design of floor amendments, to the final bill that emerges from the conference committee for a vote. Members of Congress, as well as various governmental agencies, policy research organizations, advocates, and many others, rely heavily on the expert advice provided to them by the CBO's cost estimates to determine how to allocate a limited amount of available funds.

Additionally, the Unfunded Mandates Reform Act of 1995 requires the CBO's cost estimates to inform the U.S. Congress if a piece of proposed legislation contains federal mandates to the states. If such a mandate exists, and the estimated cost to the states exceeds a predetermined threshold, the CBO must fully estimate these state costs in its reports.

The Federal Budget

The current federal budget is more than \$2.5 trillion. Each February, the President releases a budget proposal created by the OMB, which outlines the administration's priorities for the coming

fiscal year. Ultimately, however, it is the U.S. Congress that must create and pass a budget bill. For this reason, the CBO plays an important role in the federal budget process.

The CBO's first task is to reevaluate the president's budget and create a report to Congress that contains objective nonpartisan estimates of the President's proposals. In odd-numbered years, the CBO also provides Congress with a "budget options" report that lists literally hundreds of possible budget alternatives for the Congress to consider. In the spirit of political neutrality, however, the report makes no policy recommendations.

In January, the CBO also provides an annual report to Congress titled the *Budget and Economic Outlook*, which includes an economic forecast along with 10-year projections of federal spending and revenues. This report is useful to members of Congress when considering proposed legislation (and their corresponding CBO cost estimates) as it provides a baseline against which comparisons can be made. In addition to these publications, the CBO prepares analytical papers, policy and issue briefs, monthly budget reviews, and background and working papers. All the CBO's publications are available on its Web site.

CONSUMER-DIRECTED HEALTH PLANS (CDHPs)

Consumer-directed health plans (CDHPs) are insurance plans that combine two major design features: (1) a high-deductible health plan that provides catastrophic coverage, but places the consumer at risk for substantial spending, including possible cost sharing on amounts above their deductible, and (2) a tax-advantaged employer and/or self-funded individual savings account that can be used to pay directly for healthcare expenses and can be rolled over from year to year. A central claim is that by combining higher cost sharing with savings accounts, CDHPs can encourage more price-conscious purchasing by consumers and help contain costs while mediating exposure to the risk of large direct out-of-pocket payments. Other features often associated with CDHPs include exemption of certain services such as preventive care from deductibles and access to decision support tools "empowering" consumer decision making. Interest in CDHPs is relatively new and has centered on the private sector. In 2006, only 3% to 4% of the privately insured population in the United States were enrolled in CDHPs, but this represented a substantial increase over previous years, and enrollments could grow further in the future. Important issues raised by the growth of CDHPs include their design and relationship with managed care, their potential for future growth, and the possible implications of increased enrollments for access, costs, and quality of healthcare.

Background

CDHPs have emerged against a background of rising insurance premiums, dissatisfaction with managed care, and changing consumer attitudes about involvement in their care. Managed-care plans arguably played a major role in slowing the growth of healthcare costs in the 1990s by combining selective contracting with restrictions

on consumer choice, allowing them to reduce payments to hospitals and physicians. Key features included direct controls on utilization and the use of financial incentives to steer consumers to networks of contracting providers. However, since the late 1990s, there has been a growing consumer backlash against these restrictions. This has been accompanied by a shift in enrollment toward less restrictive types of managed-care organizations (e.g., moving away from health maintenance organizations [HMOs] toward preferred provider organizations [PPOs]), a relaxation of plan constraints on choice, and a re-acceleration in the growth of health insurance premiums. The combination of rising premiums and the push back against managed care has fueled interest in CDHPs as an alternative cost containment strategy or at least as a means of shifting some of the burden of cost increases toward consumers. At the same time, there has also been growing interest among consumers in greater involvement in decisions about their care and in CDHPs as vehicles for tax-advantaged saving.

Design and Operation

Typically, CDHP insurance plans include not only a high deductible but also substantial consumer cost sharing above this deductible until the consumer reaches a maximum stop-loss cap on out-of-pocket expenditures, at which point services are usually fully covered as long as they are obtained in the network. Consequently, insurance premiums will usually be lower than for coverage with a smaller deductible and less cost sharing, but there is greater risk exposure. In the individual insurance market, this trade-off between premiums and risk is explicit. In employer-based plans, the impact on a consumer will depend on an employer's decision not only about contributions to employee spending accounts but also about premium contributions.

Two major types of savings account arrangements are currently in use for CDHPs: (1) employer-based and funded Health Reimbursement Accounts (HRAs) and (2) personal Health Savings Accounts (HSAs) funded with individual and possibly employer contributions. HRAs are offered in conjunction with an employer-sponsored

insurance plan and are employer owned and administered. Along with employer contributions to insurance premiums, expenditures made from HRA accounts are tax-exempt, subject to Internal Revenue Service (IRS) review. HRA-based plans are usually defined as a CDHP in the literature if deductibles equal or exceed \$1,000 for single coverage and \$2,000 for family coverage. HRA funds may be rolled over from year to year. However, balances are generally nontransferable and revert to the firm if an employee leaves his or her job. Consequently, an employer's actual spending may be less than the amount contributed.

Based on a Henry J. Kaiser Family Foundation/Health Research and Educational Trust survey of employers, in 2006, the average employer contribution to employee CDHP HRA accounts was \$797 for single coverage and \$1,584 for family coverage. The average total premium for insurance associated with HRA plans, including both employer and employee contributions, was \$3,666 for single coverage and \$10,482 for family coverage, which compares with average premiums of \$4,242 and \$11,480, respectively, for all types of insurance plans combined. The average deductible for HRA CDHPs was \$1,442 for single coverage and \$2,985 for family coverage, and average out-of-pocket maximum stop-loss caps were \$2,693 and \$5,230, respectively. HRA funds may be used to cover both deductibles and coinsurance. However, because there is usually a gap between the employer's contribution and the maximum stop-loss cap in the typical HRA plan, unless a consumer has rolled over sufficient funds from past years, they are at risk for direct out-of-pocket payments to bridge this gap.

HSAs are regulated under Title XII of the Medicare Modernization Act of 2003. An HSA may be established in conjunction with either a qualifying employer-sponsored insurance plan or an individual purchase of qualified coverage. In either case, HSA accounts are personally owned and fully portable. Typically administered through an outside financial institution such as a bank or an insurance company, there are no income limits on who can contribute to an HSA, and they are triply tax advantaged—contributions to HSA accounts, earnings on account balances, and withdrawals for healthcare expenditures are all tax-exempt. Subject

to payment of regular federal income tax and a 10% penalty, HSA funds may also be used for other purposes. This penalty is waived at age 65, however, and unlike most retirement plans, there are no mandatory provisions for withdrawing funds from HSAs after age 65.

In 2007, to qualify for an HSA, a consumer had to be enrolled in a health insurance plan with a deductible of at least \$1,100 for single coverage and \$2,200 for family coverage and a maximum out-of-pocket spending limit of \$5,500 or less for single coverage and \$11,000 or less for family coverage, with both limits subject to adjustment for inflation. Combined contributions from individuals and their employers were limited to a maximum of 100% of the deductible, but not more than \$2,850 for single coverage and \$5,650 for family coverage, also subject to adjustment for inflation. Again, a substantial gap may exist between the maximum allowed contribution and the maximum cap on out-of-pocket spending, placing a consumer at risk for large potential out-of-pocket payments, where by law, purchase of first-dollar supplemental coverage is prohibited.

One widely expressed concern with CDHPs is that cost sharing may lead consumers to reduce spending on “necessary” as well as “unnecessary” services, resulting in higher costs and/or poorer outcomes. At least in part, this concern may be addressed by exemptions permitting reimbursement for services even if a consumer has not reached their deductible. By law, HSAs must exempt preventive services such as screening tests, while many HRAs do so as well. Some CDHPs also exempt expenses related to the management of chronic medical conditions such as diabetes and may offer consumers incentives to enroll in disease management and wellness programs. However, beyond this, deductibles, coinsurance, and copayments are typically applied using a one-size-fits-all approach. Possible refinements include further adjustments in cost sharing based on individual clinical characteristics and possibly income.

Another important concern is that even if consumers are motivated to shop for care, they are ill equipped to do so. Proponents of CDHPs argue that this can be addressed by empowering enrollees with decision support tools, for example, Web-based tools enabling consumers to compare prices and quality information. Many plans

provide such tools, but the literature suggests continuing problems. For example, it is often difficult for a consumer to obtain accurate, timely data on the prices that they can expect to pay for specific services and how much their plans will reimburse for them, let alone the anticipated overall cost of an episode of care at different providers. In this context, developing comprehensive bundled prices combining the costs of hospital and physician services could be an important factor in facilitating shopping. On the quality side, data on performance are often rudimentary, especially for physicians, while there are important issues with their interpretation.

Illustration of Reimbursement

Consider a consumer enrolled in an employer HRA plan with a deductible of \$1,500 and a 20% coinsurance rate for expenses above this deductible up to a maximum cap of \$3,900 for total eligible expenditures. Suppose the employer’s annual HRA contribution is \$800 and that the employer’s insurance plan includes a managed-care organization network and restrictions on reimbursement for out-of-network providers. In Year 1, suppose the consumer has no major health problems and spends a total of \$600 on health-care, including \$300 for preventive services. In this case, the consumer will be at risk for 20% of the cost of eligible preventive services ($20\% \times \$300 = \60) and the full cost of the remaining services (\$300), a total of \$360. Deducting \$360 from his or her HRA, no out-of-pocket payments will be required, and a balance of $\$800 - \$360 = \$440$ will be rolled over to the next year.

In Year 2, if the employer again contributes \$800, the total HRA balance will be \$1,240, but suppose that the consumer has major health problems leading to total expenditures of \$19,000. Suppose all these services are purchased from network providers and are fully eligible for reimbursement. The consumer will owe the first \$1,500 of the cost of his or her care (the deductible). He or she will also be required to pay 20% of the cost of care above the deductible up to the point where the total out-of-pocket spending (the deductible plus coinsurance payments) equals \$3,900. The HRA will cover \$1,240, but he or she will still have to pay \$2,660 ($\$3,900 - \$1,240$) directly out

of pocket. Assume again that in Year 3, they have large expenses (\$14,000), in which case, with no funds to roll over and an employer contribution of \$800, they will spend \$3,100 out of pocket (\$3,900 – \$800). Note, however, that as long as the consumer uses network providers, this amount (\$3,100) will represent his or her maximum risk exposure since expenditures above the stop-loss cap will be fully covered. (Note, out-of-pocket spending could be substantially higher if a consumer goes out-of-network for services and incurs expenses not eligible for reimbursement. However, this situation could also occur with conventional managed care and is not unique to CDHPs.)

From this example, it is evident that a CDHP can potentially expose a consumer to substantial financial risk and that he or she may face considerable complexity in navigating a plan's provisions. In addition, this example highlights an important limitation of typical CDHP cost-sharing strategies: Once a consumer reaches his or her maximum out-of-pocket stop-loss limit (or anticipates he or she will), there is no further incentive to control costs for services eligible for reimbursement. This issue is irrelevant for the vast majority of enrollees because their spending is below maximum caps. Nonetheless, it is an important design issue because of the high concentration of health-care spending (e.g., the top 10% of patients account for nearly 70% of total expenditures). A key challenge for CDHPs is to find ways to control high dollar expenditures either through restructuring of cost sharing or through alternative mechanisms.

Relation to Managed Care

It is possible to envision a system in which consumers individually enroll in CDHPs and independently shop for their care, and the primary function of plans is to pay claims and supply decision support tools. However, proponents of this kind of approach usually link it to major restructuring of healthcare markets. Currently, consumer cost sharing in CDHPs is usually complemented by continued reliance on major features of managed care, albeit repackaged in ways that may reduce sources of tension with consumers.

Thus, CDHPs typically continue to rely on selective contracting and use of provider networks

as a cost containment mechanism. However, for expenditures below the deductible, the issue of consumer choice is typically reframed in terms of how consumers want to spend their own money. Plan rules on what expenditures are eligible for reimbursement do not explicitly become an issue until a consumer exceeds the deductible. Plan networks may still be important in determining provider choices even for low dollar expenditures because of the price discounts they offer. Furthermore, the network a CDHP offers may be a major factor in consumers' enrollment decisions. But high deductibles effectively eliminate direct issues with the reimbursement eligibility of providers for the majority of consumers.

CDHPs also typically eliminate direct controls on utilization of low dollar services, a frequent source of conflict with consumers under managed care. Instead, efforts to affect consumer behavior are usually framed in terms of incentives (e.g., eliminating deductibles for preventive services and use of incentive payments to encourage participation in disease management and wellness programs). The literature suggests that plans may complement low dollar cost sharing with the use of case management to directly control utilization of high dollar services. The extent and stringency of case management by CDHPs is not well documented. But in any case, it is likely to involve only small numbers of consumers and to be a less visible source of conflict, although issues may still arise, for example, high-profile cases regarding access to experimental services.

Enrollment Trends

Currently, CDHPs cover only a very small percentage of Americans with private health insurance, but between 2005 and 2006 estimated enrollments grew sharply, rising from about 3 million to about 5 or 6 million enrollees. In 2006, an estimated 3 million of these enrollees were in employer-sponsored HRA plans, and 2 to 3 million were in HSA plans, including plans purchased individually.

In the employer group market, a 2006 Henry J. Kaiser Family Foundation survey found that 7% of firms offering health benefits provided a CDHP as an option and that 4% of covered workers were

enrolled in such plans. However, among firms not offering CDHPs, 24% indicated that they were either somewhat or very likely to offer such a plan next year. Large firms were more likely to offer a CDHP, while when small firms offered a CDHP, it was more likely to be the only option.

Studies of enrollment patterns for CDHPs find evidence of moderately favorable selection. Enrollees tend to be more educated and have lower levels of prior healthcare utilization. The evidence on age is mixed. Retirement savings opportunities are hypothesized to be an important consideration for enrollees in HSA-qualified plans, especially for higher-income individuals. The literature indicates that when consumers have a choice, they are more likely to enroll if CDHPs actively seek to educate consumers about the plan's features.

Cost and Quality

The RAND Health Insurance Experiment (HIE) provides strong evidence that high-deductible plans can reduce utilization, primarily through effects on a consumer's decision to seek care. Simulation studies using HIE data suggest that combining high deductibles with savings accounts would mediate the effects on utilization but that reductions could still be substantial. However, findings from the HIE raise concerns that consumers may reduce the use of "necessary" as well as "unnecessary" care, especially in the case of poor, sick consumers, while in real terms, deductibles in the HIE were much greater than those currently in use by CDHPs. Studies based on actual experiences with CDHPs remain limited, and issues exist with controlling for favorable selection and tracking out-of-pocket spending. However, the available evidence is generally consistent with at least onetime savings. The evidence on the effects on quality is mixed, with at least some evidence that consumers may adopt behavior that could have adverse health consequences.

Future Implications

Continued increases in private health insurance premiums could spur growth in CDHPs, especially if CDHPs can successfully realize even modest cost

savings compared with other plans. Even if they cannot, CDHPs may still be attractive to employers (and possibly the public sector) as a framework for shifting costs toward consumers through greater financial risk bearing. Greater familiarity with CDHPs could increase consumer acceptance, especially with more consumer education. But substantial numbers of consumers may remain reluctant to assume the financial risks involved and/or greater responsibility for shopping for their care. Other potential barriers to future growth include the lack of adequate decision support tools and issues with federal and state regulations governing HSAs.

An immediate public policy concern is the effect CDHP growth could have on insurance markets. The evidence so far suggests only modest favorable selection. However, a large-scale shift of more healthy, lower-cost individuals to CDHPs could leave other types of plans with a disproportionate share of more costly enrollees, potentially driving up premiums in those plans serving individuals with the greatest need for care. In addition, to the extent CDHPs redistribute financial burdens, there are concerns that risk could be disproportionately shifted to those enrollees least able to bear them, for example, individuals with severe chronic illnesses. In the longer run, a central question is the ability of consumer-directed strategies to generate sustained cost savings while ensuring the quality of healthcare.

CONTINUITY OF HEALTH SERVICE OPERATIONS DURING PANDEMICS

The emergence of hazards related to the global transmission of pandemics presents challenges to local public health departments. It requires the planning of responses, not only with respect to the crisis itself but also with respect to the continuity of essential public health services during the crisis. Influenza pandemics have occurred several times during the 20th century, and there is a high probability that an influenza pandemic will occur again in this century. Such a pandemic will directly and indirectly affect the operations of public health departments, critical infrastructures, and private and nonprofit organizations. When the pandemic does occur, it will likely be with

little warning, and the novel flu virus may be identified in any region of the world. Experts believe that there will be 1 to 6 months’ time between the identification of the novel influenza virus and the time that widespread outbreaks begin to occur in the United States. Simultaneous clusters of disease are expected to occur throughout much of the nation, preventing the relocation of human and material resources. Multiple waves of infection are anticipated. The effects of an influenza pandemic will be relatively prolonged, occurring in estimated waves of 8 to 20 weeks’ duration.

Continuity of Operation Plans

With a possible influenza pandemic, governments at all levels must be prepared for the health crisis. The plans for the maintenance of services and the recovery of public health departmental capability after the crisis have been referred to as continuity of operations planning. Such plans describe the organization with its operational framework for continuing essential public health functions when normal operations are disrupted or otherwise cannot be conducted. At a minimum, the continuity of operation plans should meet several key objectives. The plans should identify prioritized essential functions and determine necessary resources to maintain these functions. They should also establish a command and control structure related to the management of personnel to maintain these services during the crisis. Other objectives of the plans should be to identify the triggers that would initiate the sequential phases of the continuity of operations and to list the necessary resources, such as people, equipment, and materials, to perform essential functions. Finally, the plans must establish procedures to acquire necessary supplies and support services to continue essential public health functions, as well as the capabilities to restore or reconstitute agency activities to their pre-event status.

The structure of the plans should be driven by the types of problems arising from the occurrence of pandemics and the necessity of maintaining certain services during a crisis. A public health department has to effectively reorganize its lines of authority, operations, and service provision to reflect a vastly different set of public health priorities. Plans must

be in place prior to the crisis, which define essential versus nonessential services so that nonessential services can be curtailed during the crisis. The distinction between an essential and nonessential public health service needs to be clearly understood. The designation of a nonessential service does not mean that such a service is not of vital importance to the public health of citizens. *Nonessential*, in this context, means that a service can be delayed for the period of 1 to 3 months without causing significant or immediate public health problems.

Beyond the definition of essential and nonessential services, other issues must be addressed in continuity of operation plans. The issues include the appropriate preparations to be made before the occurrence of a pandemic, such as the pre-ordering of pharmaceuticals for patients who may be unable to obtain them during the crisis. The training needs of temporarily reassigned personnel should also be considered. When preparing the plans, leaders also need to determine which changes should be made to departmental reporting and communication to allow management to create a unified situational awareness during the rapidly shifting conditions of the crisis. Finally, since a public health department depends on a network of services provided to it to function, the interactions between the department and service providers during the crisis must be addressed as changes in these interactions are expected. For example, emergency-contracting provisions may need to be created to allow the rapid ordering of urgently needed supplies.

Managerial Organization and Coordination

Continuity of operation plans need to be specified so that they are coordinated with pandemic response plans. Pandemic response plans are phased in using a number of specific trigger points. Such points may include the following: (a) activation of the Public Health Incident Command System (PHICS); (b) enhanced public health surveillance activity; (c) community containment, including quarantine and isolation, and the enactment of social distancing measures; (d) epidemiological investigation; (e) administration of pre-pandemic vaccines, and antiviral distribution; and (f) mass vaccination of the entire population.

These trigger points will initiate pandemic response actions, which will in all likelihood require the shifting of personnel in the public health department from nonessential services to the implementation of pandemic response activities. Therefore, for each of these trigger points, a parallel continuity-of-operation trigger point involving the termination of nonessential services exists.

The shifting of personnel raises a number of managerial problems within public health departments trying to respond to the pandemic. Due to the illness of key personnel, adjustments will have to be made in personnel assignments during the pandemic in order to ensure the continuity of essential services. It is likely that alternative work practices such as telecommuting will be employed more heavily during the pandemic influenza response. Such work practice changes require preparation and operational guidance to work effectively. If schools are closed, the rate of absenteeism at the department could increase significantly.

It is assumed that there will be at least a 2- to 3-week period of time prior to the diagnosis of the first case of pandemic influenza locally, when a city will have warning of the impending crisis. Preparatory action for the large-scale reassignment of personnel needs to take place. Other necessary preparatory actions may include the following: (a) pre-ordering medications for patients in anticipation of difficulties in filling prescriptions during a citywide pandemic influenza response, (b) just-in-time training for voluntary staff, (c) ensuring that computer network capacity for an increase in the use of home-based work practices exists, and (d) editing of public information alerts to be issued as nonessential services are curtailed.

The curtailment of nonessential services will require a coordinated public information program so that a coherent and consistent message is provided to the general public. Information on the damage due to the curtailment of nonessential services, such as patients not seen and health inspections postponed, will need to reside in a central location in order to assist in developing an effective postpandemic influenza recovery plan.

The maintenance of essential services during the influenza pandemic response will require an integrated command structure capable of responding to program-level problems and issues. Program managers will need to respond in a timely manner

so that specific resources cannot be made available for nonessential services during the pandemic response. This is just as important as responding positively to a program request for additional resources. Due to rapidly changing conditions, the continuity of operation management structure must be capable of significantly faster response than required in nonemergency conditions.

Defining Essential Services and Departmental Service Support

The process of defining essential services may take place by either a top-down approach or a bottom-up one. The advantage of creating a single criterion by which essential services can be defined based on interviews with upper management is that this approach will create a designation of essential services based on criteria that presumably will relate to some form of benefit cost considerations and could be easily communicated.

A bottom-up programmatic level-initiated definition of essential services will seek the views of each program manager. When each manager has input into classifying and determining essential and nonessential services during the response, the result is complex, and the process is more complicated than a single-criterion definition. A significant advantage to this approach, however, is the increased level of participation in the plan's formation by middle management and an increased level of acceptance of the plan once it is developed.

Regardless of the approach employed, the basic consideration in defining essential services is the implication for stakeholders of the damages resulting from the temporary cessation of nonessential services. The stakeholders in this case are the general public. Such damage assessments must consider not only the immediate damages due to the services postponed but also a potential difficulty in reestablishing the service after the crisis. In the assessments of essential and nonessential services, the potential development of resource constraints ultimately resulting in the curtailment of even some essential services must be considered. For this reason, even those services initially considered essential should be ranked so that adjustments to essential service levels may be made in response to shifting priorities and conditions during the crisis.

In making an assessment of essential versus nonessential services, regardless of the approach used, certain information should be collected to create continuity of operation plans. First, normal service and staffing levels should be examined. This information establishes the baseline from which the plans are developed and allows an estimate of the personnel resources released due to the cessation of nonessential services, which can be used to respond to the pandemic crisis. Next, information on the extent and severity of the impact of service cessation over different planning horizons should be considered. The number of people affected and the severity of impact will vary based on the service under consideration. The impact may also vary greatly with the length of time of the curtailment. Some services can be curtailed for short periods of time with little impact but may have significant impacts for longer periods, such as the provision of prescription drugs for chronic ailments.

Required staffing levels for essential services must also be determined. The designation of staff levels devoted to the provision of essential services during the crisis involves more than just defining the number of staff remaining in their program during the crisis. The continuance of essential services at a program may require a specific talent mix to function even at minimal service levels. Next, leaders must consider policy and practice alterations. A number of employment-related policies may have to be suspended or altered during the crisis. Personnel will be assigned to areas or jobs that do not appear in their job descriptions or to tasks for which they have not received extensive training. Different work practices may also be initiated to provide lower-quality or less resource-intensive service. The documentation of such policy and practice alterations is an integral part of defining essential services in a continuity of operation plan. Finally, information on external service requirements should be detailed. Public health departments are dependent on a variety of services from organizations within and outside the city, county, and state agencies to function under ordinary circumstances. Pharmaceutical companies, laboratory services, and information technology firms are among such support service organizations. During a crisis, this dependence continues, but it will be altered. The level of some outside

support services may decline due to the curtailment of nonessential services, while other support becomes more critical.

During this process, the pattern of dependence on agencies and organizations outside the public health department must be made explicit. Potential difficulties in maintaining support services from these organizations should be identified. Information regarding these organizations needs to be gathered as part of the continuity of operation plans. Such information may include the following: (a) the type and level of support services during noncrises conditions, (b) the impact of the pandemic on the organizations' capacity to continue to provide these services to support essential public health services, (c) the level of continuity planning that the organization has carried out to ensure continued support to the public health department, (d) the point of contact at the organization in the event of a pandemic, (e) the level and type of prepandemic preparatory plans, (f) contract or procurement issues that may arise during a crisis, and (g) preferred communication methods during the crisis.

Damage Assessment

The continuity of operation plans should not only be designed for the continuance of essential services during a pandemic, they should also lay the groundwork for the postpandemic recovery. A damage assessment at the end of the crisis will be required to determine the impact of the curtailment of nonessential services. Such an assessment requires that program managers maintain records during the crisis related to the impacts of reduced service. Some of the curtailed services will never be able to be provided after the pandemic. An extreme example of this would be a patient who died due to the reduction in normal services. A more typical case would be nonessential services that are capable of being backlogged until after the crisis, such as restaurant inspections. At the end of the crisis, each program will have to face the need both to resume normal services and to develop plans to dispose of backlogged services.

A damage assessment report should be developed that will allow upper management to make decisions regarding the allocation of

postpandemic recovery resources. The assessment will also help leaders estimate how long the process of recovery will take. The information required to make such decisions must come from program-level personnel as part of the damage report. At a minimum, the damage report should contain program-specific information regarding an assessment of the backlogged services created during the pandemic, a judgment regarding the priority of eliminating different types of backlogged services, and an estimate of the level of additional resources and time needed to eliminate the backlogged services.

Testing and Exercises

To be effective, the procedures developed in the continuity of operation plans will require the training of public health personnel. A testing, training, and exercise program includes activities to ensure that the public health organization is capable of supporting the continued execution of its essential mission and critical functions throughout the emergency response. The most effective method of training for emergency response procedures is in the form of exercises in which the personnel to be trained are presented with realistic scenarios that simulate pandemic management conditions. These exercises will also serve as a guide in the important process of maintaining the plans over time in light of changing conditions and personnel reassignments.

Future Implications

Deadly influenza pandemics have occurred in the past, and they will indeed occur in the future. To save lives and minimize economic and social disruptions, local public health departments must be prepared and ready to meet the challenge. During the pandemic, resources will have to be redirected, some services will have to be temporarily eliminated, and special attention will have to be given to essential services. To achieve the continuity of health services, public health departments will need to systematically organize, prioritize, and mobilize their efforts.

CONTINUUM OF CARE

Continuum of care is a conceptual framework to organize all the health and related services that a

person may need over the course of time to deal with his or her health condition. This includes the coordination of complex care and multiple services that a patient may need to improve his or her health outcome. Continuum of care is defined as a client-oriented system of care that comprises both services and integrated mechanisms that guides and tracks patients over time through a vast array of health, mental health, and social services that span all levels and intensity of care.

Client-oriented refers to the healthcare system being designed around a client's or patient's need and not the insurance company's authorization for services or the provider's convenience. This concept makes every continuum potentially unique as each client has individual needs. The continuum of care concept is particularly relevant for clients with chronic disease conditions and with multiple comorbidities, whose clinical condition requires the coordination of many diverse healthcare services.

Healthcare must be approached in a holistic manner, particularly for those with complex and chronic illnesses. A person's physical environment, financial status, social support, and emotional well-being all affect health status. Therefore, the intertwining of health, mental health, housing, and social services should be considered to achieve prevention, cure, or disease management.

The aspect of the continuum of care model that guides and tracks a person over time assumes that the client needs assistance to navigate the many services available and to optimize the match of services to the client's needs. Additionally, the continuum maintains an ongoing record of the client's condition and care. Baseline information, service intervention information, and service use data, as well as costs and charges and outcomes data, are all evolving as integral to the prevention and treatment of individuals and populations.

Last, all levels of care refer to the potential need of a client for more or less intensity of care as the client's condition changes over time. For example, a person with a hip fracture may need surgery in an acute-care hospital and may then move to rehabilitation for a period of several weeks. Following this, the person may be discharged to his or her residence with home care or be discharged to a nursing home for further recovery. As the client's condition progresses, the services that are needed change, and ideally, the continuum of care facilitates this change.

Although quality, efficiency, and cost-effectiveness are not explicitly stated in the definition of the continuum of care, it is inherent in the model. When a full range of services is available to a client and matched to a client's need, essential information should be shared across providers, quality of care should be maximized, transitions should be efficient, and cost-effectiveness should be achieved. Client outcomes under a model of continuum of care should be better than under a fragmented system of care.

Overview

The concept of continuum of care started in the United States in the early 2000s. The notion was to create an organized and seamless healthcare delivery system to use limited resources most effectively. Despite this, comparative outcomes data that document the value of the ideal continuum form of organization remain a challenge. Nonetheless, they will become increasingly available as electronic health records and comprehensive patient information systems provide opportunities to evaluate clinical outcomes and cost-effectiveness. The continuum is shown graphically in Figure 1.

Services

A partial list of more than 60 services of the continuum of care is presented in Table 1. These services are grouped into seven categories: (1) extended care, (2) acute care, (3) ambulatory care, (4) home care, (5) outreach services, (6) wellness activities, and (7) housing. The categories do not have a fixed order. An individual client will use a unique combination of services in a sequential or simultaneous order appropriate for the person's condition. Thus, categories of services could be arranged by location (as they are in the diagram), by type of provider personnel, by the patient's functional status, or by any of a number of other variables.

Extended Care

Extended care refers to inpatient medical or nursing care over an extended period of time.

Figure 1 Services and Integrating Mechanisms of Continuum of Care

Source: Evashwick, C. Definition of continuum of care. In *Managing the Continuum of Care*, edited by C. Evashwick and L. Weiss. Gaithersburg, MD: Aspen, 1987.

Note: The services of the continuum are coordinated by deliberate integrating mechanisms.

Nursing facilities are the dominant providers of this level of care. However, others that might provide extended care for any given individual include rehabilitation hospitals, long-term care hospitals, assisted living in a state that allows a high health-care component, and intermediate care facilities for the mentally disabled in a state that allows a strong medical component. As federal and state regulations and nomenclature have changed, the providers in this category have varied.

Acute Care

Acute care refers to acute medical or surgical services provided by a licensed hospital. Acute care implies a short period of time. However, the majority of patients in today's hospitals have underlying diagnoses of chronic disease conditions. Thus, the acute inpatient stay is often just one episode in ongoing care. Many acute-care hospitals have services for those with chronic conditions, as well as the services designed for episodic care.

Ambulatory Care

Ambulatory care refers to medical and other health services provided on an outpatient basis

Table I Services of the Continuum of Care

Extended Care	Hospice
Nursing facilities	Durable medical equipment
Sub-acute units	Outreach Programs
Intermediate care facilities	Mobile vans
Long-term-care hospitals	Telephone reassurance
Rehabilitation hospitals	Senior services
Psychiatric hospitals	Friendly visitors
Other chronic-care hospitals	Parish nurses
Acute Care	Nurses in schools
Emergency rooms	Nurses in housing complexes
General hospitals	Wellness Programs
Specialty hospitals	Health education
Ambulatory Care	Health fairs
Physicians' offices	Exercise programs
Multi-specialty group practices	Workplace wellness
Outpatient clinics	Disease management
Ambulatory-care centers	Housing
Urgent-care centers	Independent housing
Community clinics	Assisted living
Adult day care	Continuing-care retirement
Home Care	Communities
Medicare-certified home health	Board and care
Private home health	Group homes
High-tech home therapy	

Note: The full continuum includes more than 60 services, grouped into seven major categories for convenience.

to persons who are not bedridden. Hospital outpatient clinics, ambulatory-care centers, physicians' offices, urgent-care centers, nurse practitioner clinics in rural areas, physical therapy clinics, and pharmacies offering consultation by licensed pharmacists are all examples of ambulatory care.

Home Care

Home, or the place of residence, is placed in the center of the continuum of care schematic because most people prefer to be at home, with care organized under the assumption that they reside and function as independently as possible in their home. Home care ranges from informal assistance provided by friends and families to care provided by formal, government-regulated organizations such as Medicare-certified home health agencies and hospices. The majority of care in the home is provided and paid for by families.

Outreach Programs

Outreach services represent efforts by formal providers and informal support services to reach people in their homes and communities. These services are typically less medically intense than those available in facilities with sophisticated equipment and a cadre of highly trained professionals. Examples of services provided by formal healthcare organizations include mobile vans operated by hospitals, health fairs conducted in community venues, and telephone monitoring offered by for-profit companies. Informal or volunteer services include programs such as Friendly Visitor, sponsored by Area Agencies on Aging, home-delivered meals organized by church volunteers, and telephone reassurance calls by volunteers organized by local community agencies.

Wellness Programs

These services are designed to help people stay healthy. They may occur at any location, from a

formal institution to a person's home. They encompass primary, secondary, and tertiary prevention, with goals that range from initial prevention of an acute condition to disease maintenance for a chronic condition. Examples of wellness activities include free fitness centers offered on-site by employers for employees, health education lectures held at hospitals, and pharmaceutical management programs that monitor potential drug interactions provided by mail-order pharmacies.

Housing

The home environment has a critical effect on a person's health. A child living in a house with lead paint is at risk for lead poisoning; an elderly person with a broken hip cannot return home as quickly to a residence in a three-story walk-up apartment as can a person residing in a one-story, easy-access ranch house. Assisted-living facilities have emerged during the latter part of the 20th century as the intersection between promoting independence and providing an environment rich in physical accessibility, service availability, and cost affordability. Many assisted-living facilities border on extended care, and they are distinguished only by state regulations on the amount of formal care allowed under each licensing category.

Integrating Mechanisms

The services of the continuum of care do not fit easily together in the nation's healthcare system. These services arose at different times to serve populations that might have been distinct at the time. State licenses, federal regulations, payment systems, and accreditation differ for each service. Thus, the rationale for fragmentation is historic. From the client's perspective, the need to integrate services is essential to obtain comprehensive care. Four basic integrating mechanisms are incorporated into the continuum of care definition. These mechanisms include (1) care coordination, (2) integrated information systems, (3) integrated financing, and (4) interentity management and structure. Other integrating mechanisms, such as physician management and state policy, could also apply to specific situations.

Care Coordination

This refers to coordination of clinical care. As is evident from the long list of services, clients may use many services over the years. Particularly for those with complex and/or chronic disease conditions, services change over time as conditions change. Ideally, clinical information would be shared across providers over time. For example, having a baseline assessment of a person's functionality prior to a stroke gives providers a basis on which to set goals for recovery.

Clinical care may be coordinated in any of several ways. Rehabilitation uses the model of an interdisciplinary team. Primary-care physicians often view themselves as the coordinator of medical care and are officially designated by managed-care organizations as the single person with the authority to authorize care by other providers, particularly specialists.

The role of the case manager, care coordinator, or service coordinator has evolved over the past three decades as a means for dealing with the fragmentation of services in the nation's healthcare delivery system. Case managers are often registered nurses, social workers, or even people with no specific professional degree or license but people who have taken formal training by their organization to coordinate the care of clients. The profession of case management has evolved to the extent that there are now nationwide professional associations of care managers, and insurance companies pay for case management functions just as they do for the services of other healthcare professionals.

Integrated Information Systems

The sharing of client information across service providers is still in its infancy. According to the ideal framework of the continuum of care, providers of all services will be able to access client information to understand disease state, environmental/social/financial dimensions that might affect health, prior treatments, service utilization patterns, and health outcomes. Ultimately, such record sharing is essential to achieve efficiency and cost-effectiveness of care for the tens of millions of people suffering from multifaceted chronic disease conditions. However, presently, information is held by each

individual provider, with only a minimum of information shared between providers on individual request. This puts clients at risk of duplicating medical tests and ineffective services, not matching services to the comprehensive state of the person's condition, and becoming ensnarled in complicated financial accounting and payment processes. There are several examples of integrated information systems that demonstrate both the value of such management information systems (MIS) and the cost and complexity of implementation. For example, the Veterans Health Administration (VHA), the largest multihospital system in the world, has implemented a comprehensive networked electronic patient clinical record system. The U.S. military has a patient clinical record system that enables a soldier in Hawaii to get blood drawn for a test; fly to Los Angeles and get the test results and start necessary medication; and then fly on to Frankfurt, Germany, and be tested to see if the medication is working—all within 24 hours. In the private sector, Kaiser Permanente has one of the best large-scale integrated patient clinical record systems in the nation.

Integrated Financing

For services to be provided according to a person's clinical need, financing must not be a barrier to care. In the United States, however, fragmented services, differing coverage by insurance companies, and many people without any health insurance coverage at all make integrated financing of healthcare a major challenge. Managed care, originally begun as health maintenance organizations (HMOs), is the conceptual model that makes financing of care on a service-by-service basis unnecessary. Under a capitated system, a person pays a monthly fee and is entitled to the full range of services covered by the insurance. With the HMO model, a broad scope of services is available from a single, organized multiservice provider. Thus, single financing matches the single provider. Kaiser Permanente and the VHA are, once again, good models of this type of system.

Over the past two decades, however, the move toward single source providers accepting capitated financing has dissipated as the nation's consumers have insisted on an unlimited choice of providers. At the present time, state Medicaid programs are

leading the main push toward enrollment in capitated systems, each with its own variation of payment and service organization parameters. Thus, payment for the continuum of care services remains highly fragmented, with a fragmentation in the provision of services as well.

Interentity Management and Structure

A full continuum of care need not be owned by a single entity, and it will most likely draw on several organizations that are linked through a variety of formal and informal mechanisms. To pull all the services and integrating mechanisms together, an integrated organizational structure must be present. This carries the inherent authority to ensure that the various components of the system work as effectively and efficiently as intended. Within a multiservice organization, this might take the structure of a service line, such as Cardiac Care, or a center of excellence, such as a Women's Center. Across providers, this might take the form of a preferred provider network or a multispecialty group practice that has its own hospital, home-care agency, and nursing facility. Formal transfer agreements articulate patient transfer terms in detail; informal relationships between two professionals who work together frequently may be equally effective at transferring client information but must be bolstered by formal agreements pertaining to legal and financial issues.

Clients

Although the continuum of care is client-oriented, the terms used to refer to clients reflect the multiple services encompassed in the continuum and the current lack of coordination among services. Table 2 shows select services and the terms by which they refer to the users of their services.

The clients of the continuum represent a mosaic of subsets of the population. Anyone might benefit from being part of an organized system of care. A healthy individual might access preventive services, wellness programs, and health monitoring. The greatest benefit of the continuum is to those who have complex, multifaceted illnesses requiring care from several service providers either simultaneously or over time. Segments of the population

Table 2 Terminology Used for Clients of Continuum Services

<i>Service</i>	<i>Name Used for Clients</i>
Hospitals	Patient
Nursing facilities	Resident
Hospice	Patient
Home care	Client
Adult day services	Participant
Assisted-living facilities	Resident
Physicians' offices	Patient
Pharmacies	Customers

Note: Each of the services of the continuum establishes its own terminology for the people it serves.

who are likely to benefit the most from an organized continuum of care include (a) the very elderly, 85 years of age or older, who are likely to have multiple chronic disease conditions; (b) people with severe chronic mental health problems; (c) children with special healthcare needs who require attention from health, welfare, and educational systems; (d) those suffering from debilitating strokes and other neurological conditions; (e) victims of Alzheimer's disease; (f) people with major functional disabilities; and (g) people with HIV/AIDS, chronic obstructive pulmonary disease (COPD), congestive heart failure, and other systemic chronic disease conditions that require constant and complex care. In short, the users of the continuum might have a physiological or mental condition as the primary diagnosis, suffer a permanent condition or curable illness, and be experiencing an acute episode of need. The commonalities include the use of multiple services offered by different providers, and thus the need to coordinate the services for clinical, financial, and patient well-being purposes is paramount.

Future Implications

In the early 2000s, healthcare that was organized as a comprehensive and coordinated continuum of care was the exception rather than the rule. Although large healthcare systems may have many of the services that make up the continuum, the majority of routine healthcare continues to be coordinated by individuals and their families

rather than physicians or case managers. Healthcare is likely to be more coordinated for those facing traumatic, disease-specific illnesses requiring multiple services over a relatively short period of time, such as cancer treatment or hospices for the terminally ill.

The VHA and the U.S. Armed Forces medical systems have demonstrated that a fully integrated continuum of care is feasible, and Kaiser Permanente has demonstrated that the continuum of care can be cost-effective. However, integrating financial streams remains a challenge. Furthermore, integrated information systems are increasingly sophisticated and expensive, organizational structures that match clients with services run counter to the American insistence on unrestricted choice, and state and federal policies pertaining to the continuum of care remain conspicuous in their absence. As the nation's population gets older and the proportion of individuals with multiple chronic disease conditions increases, the demand for coordinated care may outstrip the social preference for independence.

Until future demand creates change, the continuum of care model remains an ideal concept that helps structure individuals' thinking about how healthcare services should fit together and what must be done to accomplish the goal of having a comprehensive, coordinated system of care that provides high-quality care efficiently and effectively.

COST-BENEFIT AND COST-EFFECTIVENESS ANALYSES

Cost-benefit and cost-effectiveness analyses are widely used tools in health services research to control health spending and efficiently allocate limited resources. The purpose of cost-benefit and cost-effectiveness analysis is to compare the cost and value of different health interventions and technologies and to evaluate whether this leads to improved health and extension of life. The term *cost-benefit analysis* is used when the impact of the health intervention is measured in monetary terms. However, cost-effectiveness analysis does not use money to measure effects. Instead, cost-effectiveness analysis typically uses health outcomes.

Both cost-benefit and cost-effectiveness analyses help manage the efficient provision of health services and resource allocation while providing an understanding of the cost and outcomes of

various health interventions. This concept has become more important as health-related costs continue to rise. The federal government reported that national health expenditures in the United States amounted to \$2.3 trillion in 2007, with per capita health spending estimated at \$7,600. These sums have been projected to rise to more than \$4 trillion and \$12,320 per capita in 2015. Better use of cost-benefit and cost-effectiveness analyses can help reduce these projections or at least help ensure that resources allocated to the healthcare sector are justified by important health benefits.

Overview

A substantial part of healthcare expenditures is financed through insurance or a third-party payer. This renders many consumers insensitive to the actual price of healthcare, and they often shop on the basis of perceived quality. Healthcare providers, in turn, want to be regarded as "top quality" and often seek the latest technology to signal excellence to the consuming public. The pharmaceutical industry, medical equipment manufacturers, and medical electronics producers, to name a few, actively seek to meet this demand with new or at least differentiated products. Some have called this a medical arms race. At the root of it is a lack of cost-saving health technologies and a lack of confidence that money is being well spent. Money may be squandered with productive inefficiency, where inputs are not producing as much output as possible, or money may be squandered by producing output that is not sufficiently valued to cover the costs, were it not for insurance contributions.

Cost-benefit and cost-effectiveness analysis are used to address these problems of inefficiency by comparing two or more interventions. The analysis can be seen as a four-part procedure.

The Procedure

First, costs must be identified and measured. Generally, all relevant costs are measured, including those for the provision of health services and indirect patient costs, such as transportation costs and the value of lost labor output due to illness. Health service costs include direct costs, those that

vary with output, and indirect production costs, such as overheads, which do not vary with output. Allocations may be included for fixed costs such as buildings and equipment. Fixed and variable costs overlap with direct and indirect costs. For example, fixed costs may be direct or indirect costs. The same is true for variable costs. Allocations for indirect production costs need to be linked to the output of health services in an efficient and fair manner. For example, custodial or heating and cooling support costs can be allocated by the proportion of square footage used to provide the relevant health services.

Costs that are spread out over multiple years should also be discounted. Discounting accounts for the opportunity cost of capital, which is theoretically given by the marginal product of capital. The discount rate is also driven by an optimal rate of time preference. Under certain conditions, the marginal product of capital and the rate of time preference are driven to equilibrium. In practice, however, determination of appropriate discount rates is problematic. In applied settings, the opportunity cost of capital is given by interest rates, and these are sometimes used as discount rates even though they vary widely with inflation and risk. Some economists have questioned whether market interest rates can be used to appropriately measure time preference, especially for a social rate of time preference. Many economists have called for the use of discount rates that are lower than prevailing interest rates. In the 1990s, a consensus panel on cost-benefit and cost-effectiveness analyses in the healthcare sector recommended the use of a real (inflation-adjusted) discount rate of 3%.

The second step in the process is to identify and measure the impact of health interventions. Sometimes, these are intermediate outcomes, such as diagnostic accuracy, timeliness of intervention, or a physiological response. Many of these measures are generated in clinical settings, especially from medical research. More general health outcomes are also used. One approach is to use quality-adjusted life years (QALYs), which weight years of life for relative health impairment. A greater level of disability leads to a lower weighting given to a year of life.

Sometimes studies that use QALYs or similar tools to measure effects of health interventions are called cost-utility analyses. There has been some

controversy about cost-utility analysis. One concern is that the relative weights used to generate QALYs implicitly use social values and subjectively impose interpersonal utility comparisons. This contravenes a fundamental tenet of neoclassical economic theory.

Cost-benefit studies discount both costs and benefits. The discounting of nonmonetary effects in cost-effectiveness analyses is more controversial. This is sometimes done to reflect a social rate of time preference. But in other cases, it is not done because there is no opportunity cost of capital at issue.

The third step is to combine the costs and benefits/effects. This is done by generating an integrated measure such as a benefit-cost ratio in cost-benefit studies or cost per QALY in cost-effectiveness studies. A single stand-alone measure is of relatively little use. Far more useful is a comparison of how one intervention compares with another. This allows one to compare the relative efficiency of two or more interventions. For cost-benefit analyses, policymakers may choose the intervention with the highest benefit to cost ratio. Cost-effectiveness results differ somewhat. Table 1 illustrates the possibilities when comparing the relative cost-effectiveness of the status quo with a new technology. The most favorable result is the lower left box, where a new technology lowers costs and improves outcomes. The least favorable result is the upper-right box, where the new technology is associated with higher costs and worse outcomes. Such results are unambiguous, and medical decision makers can easily decide if the new technology is cost-effective. More problematic are results along the principal diagonal, where, for example in the lower right box, costs increase and outcomes improve. This is common in the health sector since this is the purpose of much technical innovation. But even here, cost-effectiveness analysis can be quite helpful. It can yield measures that provide information about how much additional cost is incurred for a given improvement in health. This might be in the form of a cost per QALY. A low cost per QALY is commonly regarded as a justified expense, while a very high one is often not seen to be economically prudent. A clear-cut threshold does not exist, but numbers such as \$100,000 per QALY have been put forward for advanced economies such as the United States.

The fourth step that is typical of cost-benefit and cost-effectiveness studies is sensitivity analysis.

Uncertainty is endemic in most such studies. There may be questions about the medical effectiveness of new drugs or procedures, and there may also be doubt about the exact cost of workers or of labor productivity. Frequently, there is uncertainty about the appropriate discount rate. A robust conclusion about cost-effectiveness should stand up to a wide range of estimates for key variables. Therefore, sensitivity analysis tests for this and shows how different values for key variables affect the result. Sensitivity analysis should be done for a reasonable range of values for all variables that might drive the conclusion.

It should be pointed out that cost-benefit and cost-effectiveness analyses do not necessarily provide information about the improved efficiency from a general equilibrium standpoint. That is to say, while cost-effectiveness analysis can show how a different approach compares with the status quo, it does not account for implications beyond the narrow confines of the healthcare interventions under study. A shift to a new technology, for example, might have implications elsewhere in healthcare or outside healthcare altogether that are very profound and can skew the net welfare gains one way or the other. However, this is rarely considered.

In reporting cost-benefit and cost-effectiveness studies, it is important to identify how costs and benefits/effects are distributed. Most economists are first and foremost concerned about net gains in welfare. But political scientists and others often emphasize distributive issues. A new intervention may be relatively cost-effective, but if the benefits fall primarily on the disenfranchised or otherwise

politically weak elements in society and the costs fall primarily on influential groups, the new technology may never be integrated into the fabric of medical or public health practice. Political forces are very important in the healthcare sector, and it is often the case that good policy is trumped by what leaders regard as good politics.

Application to Health Policy

Experience with cost-effectiveness analysis in the policy arena has shown that the policy processes by which health resources are allocated are generally not amenable to the strict use of benefit-cost ratios or cost per QALY as the only means to allocate health service resources. For example, a society may put a higher value on treating one person with a severe illness associated with a high cost per QALY compared with a widespread screening or treatment of a larger group of people for a less severe problem associated with a lower cost per QALY. Health risks are not always viewed in a linear or consistent fashion in society. We may bear a much higher health risk for some activities, perhaps operating a motor vehicle, than we do for other activities such as the use of common over-the-counter medications. This lack of consistency undermines the strict use of such economic methodologies. On the other hand, cost-benefit and cost-effectiveness studies are important tools for policymakers to decide how best to allocate scarce resources.

It is also common in reporting the results of cost-benefit and cost-effectiveness studies to identify key

Table I Cost-Effectiveness Matrix

	<i>Lower Cost</i>	<i>Same Cost</i>	<i>Higher Cost</i>
<i>Worse Outcome</i>	Ambiguous	Less efficient	Less efficient
<i>Same Outcome</i>	More efficient	Ambiguous	Less efficient
<i>Better Outcome</i>	More efficient	More efficient	Ambiguous

limitations of the study. Perhaps there are doubts about the data and how it can be generalized for wider applications. The population studied may limit the study, and results may not be relevant in other settings, or perhaps technical change is so rapid that the study results may no longer be valid. A wide variety of limitations may exist, and important ones should continue to be identified.

Future Implications

As healthcare costs continue to rise, cost-benefit and cost-effectiveness analyses will continue to play an important role in controlling healthcare spending and the use of scarce resources more efficiently and prudently. As healthcare costs and the benefits of health interventions are increasingly scrutinized, cost-effectiveness and cost-benefit analyses will be central to evaluating new technologies to examine if they lead to improved health outcomes and are justified compared with the relative expenditures and other available options.

COST CONTAINMENT STRATEGIES

Cost containment can be defined as reducing the level or rate of increase in healthcare costs. During the past decades, healthcare spending in the United States has grown at a much faster rate than has the general economy. Total healthcare spending increased at rates well in excess of the nation's gross domestic product (GDP). In 2006, total healthcare spending was \$2.1 trillion, representing 16% of the nation's GDP. These figures are expected to greatly increase in the future. By 2016, with a projected average annual percentage growth of 6.9%, the nation will spend a total of \$4.2 trillion, or 20% of its GDP, on healthcare.

There are many factors increasing healthcare costs, including general inflation within the economy, inflation specific to the healthcare industry, overall population growth, the growth of the elderly, health insurance, and new medical technology. Although there is debate over which specific factor contributes the most to rising healthcare costs, it is clear that these costs must be contained in some way. And a number of different strategies have been developed and proposed to contain the costs.

Efforts to Control Healthcare Costs

The primary method of controlling rising healthcare costs is giving incentives for providers to operate with reduced or controlled financial resources. Supply factors, particularly increased national medical capacity, are believed to be more important than demand factors in explaining the high use and costs of the nation's healthcare. Efforts by the public sector to contain healthcare costs have focused mainly on controlling the levels of and increases in payments to providers. In contrast, the private sector has focused on managing and controlling access to healthcare.

Public-Sector Efforts

In the public sector, the most important cost containment strategies have focused on the Medicare and Medicaid programs and on healthcare capital spending through state Certificate of Need (CON) programs.

Medicare's Prospective Payment System

To control community hospital costs, Medicare implemented the prospective payment system (PPS). The PPS sets hospital payments rates prior to when care is given. By setting a fixed reimbursement level based on diagnosis, prospective payment provides economic incentives for hospitals to conserve the use of their input resources. Hospitals that use more resources than covered by the flat rate lose the difference, while those with costs below the rate retain the difference.

Medicare's Resource-Based Relative Value Scale

To control physician fees, Medicare implemented the Resource-Based Relative Value Scale (RBRVS), which pays physicians for the various services they provide based on the amount of expertise needed, how much time they spend with the patient, and other factors. By using the RBRVS and changing the level of payment, certain high-growth, highly profitable services, such as endoscopy and ambulatory cardiac monitoring, may be slowed and not be overused.

Medicaid

State efforts to control the costs of healthcare have focused on Medicaid, which is jointly funded by the states and the federal government. In their efforts to control costs, states have used their discretion to determine who is eligible for Medicaid, what optional benefits to provide, and how much to reimburse providers. The various state efforts at cost containment have found the following: (a) one of the most effective means of managing costs is to limit access to the program; (b) states that set broad eligibility levels often accompany them with tightly regulated provider payment rates; and (c) states that include all payers in their cost containment strategies appear more effective than states with more limited (Medicaid-only) interventions in controlling costs.

Certificate of Need

The CON program is a regulatory process that requires hospitals, nursing homes, and other healthcare providers to obtain state approval for the expansion of their facilities or for major capital equipment purchases. The CON program intends to prevent unnecessary duplication of services by selecting the best proposal among competing applicants that wish to provide a particular health service. CON may have a significant effect on the capital spending of providers. However, empirical results on the effectiveness of CON programs on controlling the costs of healthcare have been mixed.

Private-Sector Initiatives

Employers have attempted to limit the rise in healthcare costs by increasing the share of costs paid by workers; managing the supply of care; and self-insuring their companies. Efforts by employers to control costs have also focused on the management of specific health benefit programs. These efforts have relied on innovative designs to reduce unnecessary use of medical care services and to negotiate lower provider payment rates.

Cost Sharing

Insurance coverage may lead to the overuse of healthcare by the insured. Cost sharing (e.g.,

coinsurance or deductibles) can be used to reduce the demand for healthcare services and thus to reduce spending. When consumers are paying some or all the charges for healthcare services, they tend to use fewer services. The famous RAND Health Insurance Experiment (HIE) demonstrated that cost sharing can be an effective means of reducing healthcare utilization levels.

Managed Care

Managed care, typically provided by health maintenance organizations (HMOs) and preferred provider organizations (PPOs), has been viewed as a means of controlling healthcare costs. These organized delivery systems provide or arrange to provide a coordinated continuum of care to a defined population. These systems are both clinically and fiscally accountable for the outcomes and health status of the population they serve. By combining the clinical and fiscal accountability, managed care creates incentives for keeping people well by emphasizing prevention and health promotion practices. When their members become ill, they treat them in the most cost-effective manner, which often limits their hospitalization.

Consumer-Directed Health Plans

Consumer-Directed Health Plans (CDHPs) are a recent attempt at cost containment. The plans have three elements: (1) medical saving accounts (MSAs), (2) high-deductible health insurance plans, and (3) detailed information on healthcare providers. Individuals and companies make tax-free contributions, up to a certain amount, into a special savings account, which can be used to pay for medical expenses. Unused funds are carried over to the next year. To protect against the costs of a major illness or accident, the individual must also have a high-deductible health insurance plan. Last, for individuals to be wise consumers, they must have access to information on provider's costs, quality, and outcomes enabling them to "shop around" for the best services.

Increased Use of Appropriate Care

This strategy generally envisions some combination of research to identify more effective ways to

treat conditions, education to persuade physicians to use more effective care, and precertification or utilization review to prevent unnecessary care. However, there is much controversy surrounding estimates of how many procedures are medically unnecessary, and there is no evidence as to whether the proportion of unnecessary procedures has grown with time or whether medical services that are growing in frequency are more likely than others to be performed inappropriately.

Limit Coverage of Services

Private insurers limit the services they cover through specific exclusions, financial limits, or limits on coverage according to circumstances. In addition, many insurers exclude specific services that they deem to be experimental or ineffective.

Healthcare Reforms

Some health services researchers and policy analysts argue that the only effective way to control the nation's healthcare costs is through some form of major healthcare reform. These reform efforts may include the following: establishing a single payer system, the use of expenditure targets, global budgets, and rationing healthcare.

Single-Payer System

Cost savings and greater cost control may be achieved by having a single payer or a single set of rules applying to all payers. Canada and the United Kingdom both use a single-payer system. Uniformity enables the system to control costs and minimizes cost shifting and reduces the administrative costs of dealing with multiple payers. However, there is concern that a single-payer system would discourage innovation, decrease consumer choice, and limit market forces.

Expenditure Targets

This strategy relies on creating a target level for total healthcare expenditures. The target is enforced by rules that any expenditure above the target will trigger future reductions in payments per service or coverage. Such targets can be applied across all

providers or to groups or individual providers. Expenditure targets differ from global budgets in that they are a policy goal rather than an absolute limit on spending, and they trigger payment reductions that apply to future years rather than to the current year.

Global Budgets

Global budgeting approaches are common in countries where their healthcare systems operate within a national budget. Global budgets differ from expenditure targets because they contain a formal management process to ensure staying within the budget. The Clinton administration's national healthcare plan proposed using global budget caps to limit healthcare spending. The proposed plan specified that beginning in FY1999, premium amounts for regional health alliances would not be allowed to increase faster than the sum of population growth and the projected increase in the Consumer Price Index (CPI). In later years, total healthcare expenditures would be allowed to rise at the growth rate of the GDP. It was believed that managed competition alone, without global budgets, would not slow the rate of increase in healthcare costs.

Rationing Healthcare

Rationing healthcare involves planning decisions to not create or to eliminate the capacity to produce healthcare services that are currently used or demanded but are judged to be "unnecessary." This process means that patients will be denied care that either they or their physicians want. Many plans for controlling healthcare costs limit supply by restricting the funding available per person and then decentralize decision making and financial responsibility to levels such as the state (for Medicaid), and HMOs, or a health authority (United Kingdom). These strategies are intended both to provide incentives for greater efficiency and more appropriate care and to allow some local flexibility in living within a fixed budget.

Future Implications

Despite much effort, there is little evidence that cost containment strategies have been successful.

The rising health insurance premium costs suggest that managed care has largely failed. And the effects of cost sharing on health expenditure growth over time are less clear. In addition, there are growing concerns about the possible negative effects of healthcare cost containment strategies on access to care and the quality of care. Furthermore, cost containment may decrease innovations in medical technology. Nevertheless, healthcare cost containment remains one of the most significant issues facing the nation.

COST OF HEALTHCARE

In 2006, the latest year for which data are available, the United States spent \$2.1 trillion on healthcare. This is equivalent to just over \$7,000 per person and accounted for 16% of the nation's gross domestic product (GDP). National healthcare expenditures are the sum of many different types of healthcare spending, but chief among the types are hospital care (\$648.2 billion, accounting for 30.8% of the total), physical and clinical services (\$447.6 billion, 21.3%), prescription drugs (\$216.7 billion, 10.3%), and home health and nursing home care (\$177.6 billion, 8.4%).

Total healthcare spending equals the prices that people pay for specific types of medical services—the costs of healthcare—multiplied by the quantities of each specific type of care they received. Thus, while the costs of healthcare and healthcare spending are often used interchangeably, they are not the same. The common substitution of spending for costs in this context occurs in large part because total spending is a cost to individuals and to society. How much individuals spend on healthcare involves resource allocation decisions; spending on healthcare has an opportunity cost in terms of income that cannot be spent on other goods and services.

This entry begins by examining the tenuous link between healthcare costs and prices, and how prices for healthcare services are set. The discussion then shifts to why healthcare spending has been growing at rates exceeding population growth and income growth, and why that difference is viewed by many analysts and policymakers as a looming problem for the United States as well as other nations.

Healthcare Costs and Prices

The cost of anything is generally the price at which it is bought. In a competitive market, the price equals the marginal cost of producing the good or service. The cost in turn depends on the prices of the raw materials and labor and the production process that is used to create the product.

In the case of healthcare, the link between the marginal cost of producing a service and its price is loose at best. Markets for healthcare services are not competitive, in large part because information problems are significant in these markets. Most people do not have the medical knowledge necessary to diagnose what various symptoms mean; most physicians cannot keep track of all the new pharmaceuticals that are available; and health insurance shields people from asking and knowing the prices of alternative services and healthcare providers. The result is that the standard economic model of how prices are set and how they relate to costs of production is not a realistic portrayal of price setting in healthcare markets.

Healthcare prices are set primarily by negotiations between insurers and healthcare providers and by administrative decisions by insurers. Politics also affects Medicare and Medicaid decisions about how much they will pay for specific medical services. Representatives of hospitals, specialty groups of physicians, nursing home operators, and pharmaceutical manufacturers all lobby the U.S. Congress and state legislators about the Medicare and Medicaid reimbursement rates.

Setting Prices for Healthcare Services

Prices for healthcare services are set in a number of ways. Providers can be paid a fee for each service provided—what is often called fee-for-service pricing. Prices may be set as fixed amounts that will be paid for providing any necessary services for treating a person's specific disease or condition. This predetermined or prospective fee method can be expanded and a fee may be set to cover all medically necessary services for a person for a specified period of time, usually a year. This is usually referred to as a capitated payment (a payment per capita). Another method of setting prices is

known as cost-based reimbursement—this is often used when a medical service is new and so there is little information on the costs of providing the service and there is an expectation that the costs will decline over time. Finally, lump-sum payments or block grants can be used to pay providers. In this case, physicians are paid a salary, and hospitals, nursing homes, and other institutional providers are given a budget for operating costs related to an expected number of people needing their services during a year.

Fee-for-service pricing has its roots in how physicians set prices for hundreds of years: They charged a fee for each service provided. In the days when physicians did not have many options for how to diagnose or treat symptoms, the fees were generally in proportion to the length of time a visit lasted—a brief visit or a longer visit. Similarly, when hospitals began to proliferate in the late 1800s, they set prices as per diem prices. As Blue Cross and Blue Shield health insurance plans and commercial insurance grew in the 1930s, they initially sold indemnity policies that reimbursed enrollees a set amount per day in the hospital or for a surgery or physician visit. The indemnity payments were tied to norms of physician and hospital fee-for-service pricing. When Medicare began paying providers in 1966, the payments were intentionally set to follow the lead of the Blues and the commercial insurers. Medicaid and its predecessor state programs also based their payments to providers on the basis of fee-for-service pricing, but Medicaid has always discounted the fees and paid between 50% and 60% of the fees.

Prospective pricing has its roots in the managed-care movement in the nation and the original health maintenance organizations (HMOs). The initial version of prospective pricing paid groups of physicians capitated payments for taking responsibility for all the healthcare needs of a group of people during the year. During the late 1980s, as more forms of managed-care plans proliferated, many physicians were enthusiastic about being paid prospectively. They thought that they could make more money under this pricing system than with fee-for-service payment schedules. Support for it soon faded, however, as physicians realized they could be at risk for large sums of money if an

unexpected number of patients became very sick. Nonetheless, prospective payments are still used by many managed-care plans to price payments to physicians to take care of patients' predictable medical care during a year. In 1983, Medicare implemented the prospective payment system (PPS) to pay hospitals. The PPS is based on the average costs of caring for a person with a diagnosis that fits within approximately 500 Diagnosis Related Groups (DRGs). The costs are adjusted for each hospital, and adjustments are also made for the costs of labor in the geographic area where the hospital is located. Medicare has also developed a similar prospective payment pricing system for skilled-nursing facility services.

It may seem odd to discuss cost-based pricing of some medical services when the costs are so difficult to determine in healthcare markets. However, even cost-based pricing is not determined by competition; rather, the cost basis is arrived at through negotiations between providers and payers. As noted earlier, cost-based prices are generally used to set reimbursement fees for new medical or surgical procedures and new diagnostic equipment when there is an expectation that within a period of time the costs will be lower. They will decline because after a learning period, physicians will be able to perform the procedures with less time and effort, and the new machinery will become less expensive per unit as more are produced. The payments for about 40% of the Medicare DRGs are cost based rather than set prospectively.

Pricing physician time and effort is viewed by many as both problematic and unseemly. This can be particularly true when it is difficult to judge the quality of individual physicians or when a society is trying to create greater income equality. Paying physicians a salary is another way in which a price for physician expertise and time has been set. The U.S. Department of Veterans Affairs (VA), the United Kingdom's National Health Service (NHS), and a large number of countries' public health services pay physicians a salary. The salary is compensation either to take care of a number of people who live near the physician or to see patients during specified hours during a week. Similarly, operating budgets for hospitals often are determined as part of the budget determination process of countries,

counties, and municipalities. Such fixed budgets are related to the expected number of people from the surrounding area who will be hospitalized. Prospective payments, salaries, and set budgets are quite similar, but each has slightly different incentives for how care is provided and how underlying costs are minimized.

Prices Paid by Private Insurance, Medicare, Medicaid, and the Uninsured

Since the early 1980s, Medicare and commercial insurers have become more aggressive about setting the prices they will pay for a wide variety of hospital, physician, and other providers' services. The Medicare reimbursement rates have become progressively more formulaic for physician services, and prospective, fixed rates are used for most hospital and skilled-nursing facility care. The Medicare reimbursement rates take into account geographical differences in the costs of labor and other factors such as electricity and rent of offices. Commercial insurers, including nonprofit plans, have negotiated reimbursement rates that often follow the fee schedules and rates set by Medicare. Managed-care plans have experimented with various forms of prospective and capitated payments to physicians and physician groups. Starting in the early 1990s, when a majority of states started to move Medicaid recipients into managed care, the rates paid to managed-care plans have been negotiated or administratively set by the states.

For people with private health insurance or those who are covered by Medicare and Medicaid, these different reimbursement mechanisms effectively set the prices for healthcare services. The only people who pay healthcare providers' "usual and customary" stated charges, which can be set however the providers want, are the uninsured—they do not have an insurance plan administratively setting the prices or negotiating discounts off the charges.

Growth in Healthcare Spending and Its Costs

Since the 1960s, national healthcare expenditures in nominal dollars have grown from \$26.9 billion to \$2.1 trillion in 2006. If general price inflation and population growth are accounted for, healthcare

expenditures per person rose from \$960 in 1960 (in 2006 dollars) to \$7,026 in 2006. The share of GDP spent on healthcare more than tripled, rising from 5.1% to 16.0%. The growth in healthcare spending as a fraction of GDP is not without costs—it influences the allocation of the nation's resources and drives up the cost of health insurance, which affects individuals' incomes and decisions about how they spend their incomes as well as employers' decisions about sponsoring health insurance for employees.

Effects of Various Factors on the Growth in Healthcare Spending

The growth in healthcare spending per person is due to a number of factors. Although the aging of the nation's population is often raised as a factor, the best estimates are that it was responsible for only a small share (7%) of the increased spending between the 1950s and late 1980s. Since 1960, health insurance policies have covered more services, and the fraction of the population covered by insurance has increased, especially because Medicare and Medicaid were implemented. Greater insurance coverage increases the demand for healthcare, since people do not face the full cost of such care. But the best estimate is that the greater insurance coverage is responsible for only as much as 10% of the growth in per capita healthcare spending through the late 1980s. Rising incomes can also contribute to increased demand for care, and incomes have risen since the 1960s, especially for the top half of the income distribution. It is difficult to disentangle the effects of increased individual incomes from the effect of greater overall national wealth, which contributes to growth in medical technology. Nonetheless, the best estimate is that increased income accounted for something between 5% and 25% of the growth in per capita healthcare spending through the late 1980s.

Between 1960 and 1990, the federal government increased funding for medical schools and encouraged foreign physicians to emigrate to the United States so as to increase the number of physicians per capita. Some analysts believe that the increased number of physicians per capita contributed to increased spending. This explanation is often tied to a belief that physicians induce demand for their services—either to gain more income or to avoid

malpractice lawsuits. But the evidence does not support these explanations for the rate of growth in healthcare spending per person between 1960 and 2005. At most, the increase in physicians per capita accounts for a 1% increase in such spending.

Other explanations for the growth in spending include the consumer price index and the fact that productivity gains in medical care treatment are very difficult to measure. The result of the measurement problem is that it is empirically difficult to decompose the increase in medical expenditures into the share due to increases in prices and the share due to increases in quantity of services provided. In sum, all these factors appear to explain no more than half, and more likely only a quarter, of the growth in healthcare spending per person since 1960.

Technological Change and Increased Capabilities in Medicine

What then explains the remaining 50% to 75% of the increased healthcare spending per person? The explanation that most healthcare economists favor is technological change in medicine that has increased the capabilities of medical care. Proving that technological change is the primary source of the enormous growth in per capita healthcare spending is difficult; the evidence for it is primarily circumstantial. First, medicine has changed dramatically since 1960. People now survive diseases such as cancer, congestive heart failure, and renal disease that they would have died from quickly in the 1960s. The quality of life for people with a variety of non-life-threatening conditions, such as orthopedic problems, arthritis, and eye conditions, is enormously better today, with a wide variety of pharmaceuticals and joint replacement surgeries that have been developed within the past three decades. Some of these medical advancements have reduced the cost of treating some diseases (e.g., laser cataract surgery), but most have high costs. Spending has increased because the new technologies have been covered by health insurance and most people are insured.

Second, hospital care accounts for the largest share of healthcare spending—since 1960, it has accounted for between 30% and 40% of national healthcare expenditures. But the fraction of people being admitted as inpatients to hospitals has not

increased, and the average length of stay in hospitals has declined over the past five decades. Thus the 10-fold increase in inflation-adjusted total hospital spending strongly implies increased intensity and amounts of care being provided to those who are hospitalized. Hospital staffing and wages have not increased enough to explain this large an increase in spending per hospital stay; technological changes seem far more plausible. Moreover, more types of surgeries and diagnostic tests have become outpatient procedures that do not require an overnight stay in a hospital—and much of this shift has been made possible because of technological changes. The shifting of surgeries and diagnostic procedures to outpatient care has had the effect of increasing the degree of medical difficulty (the case-mix) of hospital inpatients. In spite of this, however, the average length of a hospital stay has declined, which is consistent with the hypothesis that technological change is responsible for the majority of the increase in healthcare spending.

Finally, the rate of increase in healthcare spending for managed-care plans, especially those with tighter controls on patient access to specialists, has been the same as that of health plans that paid providers on a fee-for-service basis. Similarly, the rate of increase in healthcare spending in the United States has been about the same as that of most industrialized countries, especially since the 1980s. This is in spite of very different levels of spending per capita, ratios of healthcare personnel per capita, and financing mechanisms. The similarity in rates of growth for both of these comparisons suggests that a common factor is the explanation—and improvements in medical technologies affect all these different health plans and countries.

Skewed Distributions of Healthcare Spending and Technological Change

The distribution of annual healthcare expenditures per person is very skewed—a relatively small fraction of the population is responsible for most of the spending in a year. Half of the population spends less than \$500 per year on healthcare, including one fifth who have no healthcare expenditures either because they do not get sick enough to seek care or they simply do not seek medical care. Altogether, this half accounts for only 3% of all spending. People with annual expenditures that put

them in the top 10% of the expenditure distribution are responsible for about 70% of all healthcare spending. To be in the top 10% of the population in terms of healthcare spending, a person would have had expenditures above \$15,000 in 2005. The threshold for the top 2% was \$30,000, and the threshold for the very top 1% was \$50,000.

People in the top 1% or 2% of the medical spending distribution are very sick—and new medical technologies that allow them to live are driving the expenses. The group includes people who need very costly pharmaceutical treatments to stay alive (e.g., people with rare forms of hemophilia), premature babies, people with spinal cord injuries, and people who have had organ transplants or cardiac events, including strokes. Until two or three decades ago, there was very little that medical providers could do for people with these conditions. Among the 15 most costly medical conditions in 1997, the three with the largest shares of total spending were heart disease (10%), cancer (8%), and trauma (8%). An analysis of the same 15 most costly diseases and conditions found that when the increased expenses for them between 1987 and 2000 were decomposed into spending versus treated prevalence (i.e., the number of people per 10,000 who were treated for the condition), seven had higher spending because of increased costs and not greater prevalence of treated people. The seven include the three most costly conditions (heart disease, cancer, and trauma) and pneumonia, skin disorders, hypertension, and infectious diseases. The fact that spending on these conditions increased because of significant medical advancements in treating these conditions rather than an increased prevalence of people being treated provides further support for the hypothesis that technological change is driving the increases in spending. It also contributes to the skewed distribution of healthcare spending.

Benefits and Costs of the Growth in Healthcare Spending

Technological changes and expanded medical care capabilities have improved many millions of people's lives. Improvements in many older Americans' quality of life have meant that they are not only living longer lives but they are also enjoying those years more. At the other end of the life

cycle, advances in neonatology are enabling babies to live who more than 30 years ago would have died before they were a year old. Similarly, advances in medicine's understanding of immunology, genetics, and a wide range of diseases and new engineered drugs have allowed people to be long-term survivors of diseases that were untreatable just two decades ago.

In spite of these benefits, it is not clear that the increases in spending have improved most people's lives. Americans do not have higher life expectancies than citizens of other industrialized countries. Moreover, within the United States, regions that have higher per capita spending do not have significantly better health as measured by a variety of health outcomes.

Furthermore, the pace of per capita healthcare spending has been faster than the growth in median income, general price inflation, and productivity of the average worker. The result is a fact noted earlier—national healthcare expenditures have grown faster than the GDP since 1960 and accounted for 16% of the GDP in 2006. The federal and state governments were responsible for about 45% of the total spending on healthcare (with Medicare, Medicaid, and the State Children's Health Insurance Program (SCHIP) being the largest of the public programs), and Medicaid now accounts for the largest share of many states' budgets. The Congressional Budget Office (CBO) estimates that federal spending on just Medicare and Medicaid will equal 4.6% of the GDP in 2007 (or almost a quarter of the entire federal budget). The CBO also estimates that federal spending on these programs will grow to 5.9% of the GDP in 2017—a nearly 30% increase in just a decade.

These increases in the shares of the economy and the budgets of the federal and state governments that go to healthcare are imposing a cost on the nation. They are preventing the nation from spending more on education, national defense, construction of mass transit and infrastructure, environmental cleanup, investment in alternative energy sources, and a host of other priorities.

Future Implications

New medical technologies and improvements in medical capabilities are the primary forces behind

the growth in healthcare spending. Efforts to slow the growth in healthcare spending therefore must involve incentives to innovators to create new medical technologies that reduce the cost of care and restrictions on which future medical technologies advances will be paid for by private insurance, Medicare, and Medicaid. Prestigious prizes and honors could be used as incentives for inventors to create cost-reducing technologies. Ultimately, however, restrictions on access to new technologies may be the most effective way to encourage the development of cost-saving new medical technologies.

One mechanism for restricting access to new technologies involves cost-effectiveness analysis (CEA). CEA is a method for estimating the additional cost per quality of life-year provided by a new drug or new procedure relative to the status quo way of treating a particular disease. If the additional cost is estimated to be below a threshold (often \$50,000), it is generally viewed as cost-effective; otherwise, the new treatment is usually not approved. One advantage of using CEA to determine if a new technology or drug will be covered by insurance is that it may force inventors to focus on the costs of the new technology relative to the existing treatment method.

A number of industrialized nations use CEA as part of their process for determining if new technologies and pharmaceuticals will be covered by insurance. For example, Canada, Australia, and the Netherlands use CEA in deciding whether a new drug will be covered by insurance. New Zealand and the United Kingdom use it in making not just drug coverage decisions but whether new technologies will be covered as well.

An alternative to using CEA is simply to announce that access to cost-increasing new technologies will be rationed. Rationing makes most people extremely uneasy, and therefore it could pressure inventors to search for ways to reduce the costs of new technologies. Similarly, returning to the distinction between how prices are set in healthcare markets and in competitive markets, if Medicare and private health insurers were to use their market power to set reimbursement rates for new technologies, pressure would be on innovators to find production methods that reduce the costs of the new technologies.

COST SHIFTING

Cost shifting exists when a hospital, physician group, or other provider raises prices to one set of buyers because it has lowered prices to some

other group. The term has also been applied to managed-care firms that are similarly said to have raised premiums to one set of purchasers because it had to lower premiums to some other set. Cost shifting is often confused with price discrimination. Health services providers commonly price discriminate; that is, they charge different prices to different payers. However, such differential pricing strategies are not evidence of cost shifting.

Overview

The term *cost shifting* has been commonly used in debates over healthcare reform. Some have argued, for example, that efforts to reduce Medicare expenditures by lowering payments to hospitals under its prospective payment system (PPS) or through the encouragement of managed-care plans may save money for the Medicare program, but it will increase the costs to private payers. This is said to occur because hospitals will simply raise their prices to private insurers to make up the difference for the money that is being lost from Medicare beneficiaries. Private insurers, facing higher hospital prices, will then tell employers that they have to raise health insurance premiums because they are being cost shifted against by hospitals.

Two policy prescriptions emerge from this argument. First, private insurers should support coverage for the uninsured; the costs of the subsidy will be less than they appear because the hidden cost shift will be eliminated. Second, it is sometimes argued that cost shifting requires the systemic reform of healthcare. Any piecemeal effort to control costs will ultimately be eroded by increases in costs to some other payer, with the result that costs are not controlled. While subsidizing care for the uninsured and reforming the healthcare system are important goals, however, cost shifting is unlikely to be a serious component of the rationale.

Simply charging one group a higher price than another does not constitute cost shifting. Firms in many industries routinely do this. For example, airlines routinely charge different prices to people on the same airplane. Movie theaters routinely charge different prices to adults and children. Restaurants and banks give senior citizen discounts. Hotels offer convention rates. This is known as price discrimination.

Cost shifting is different. Not only must the provider charge different prices to different payers, it must also raise prices to one group in response to lower prices from another group. To be able to do this, two things are critical. First, the provider must have market power (i.e., it must have the ability to set prices above costs). Second, and most importantly, the provider must not have already fully exercised its market power.

The first condition is straightforward. Suppose a hospital had no market power. When it attempted to raise its prices to a local preferred provider organization (PPO), the PPO would simply drop the hospital from its network and channel its subscribers to other nearby hospitals. Thus, if there is substantial hospital competition in the local market, a hospital is unable to shift its costs.

The second condition is somewhat more subtle. A profit-maximizing provider with market power takes advantage of its power. The hospital will charge Medicare according to the fixed payment schedule that the government has adopted. It sets the price to the PPO based on the marginal revenue and marginal costs of the PPO's patients. Note that the marginal cost of providing care to the PPO may not be simply the medical costs of providing the care. The true marginal costs may be the payment that Medicare would have paid for one of its patients.

Now suppose that the U.S. Congress changed the Medicare payment formula and lowered the prices it paid to hospitals. The profit-maximizing hospital cannot raise its price to the PPO and get any more money. If it could do so, it was not profit-maximizing to start with. What the economics imply is that the hospital will lower, not raise, its price to the PPO. The reason is that when Medicare lowers its price, the profit-maximizing hospital tries to shift some of its capacity away from the now less-profitable Medicare market and toward the PPO market. However, the only way it can get the PPO to use more hospital days is to lower its price. The effect of a reduction in Medicare prices is a reduction in the prices faced by private insurers. Similarly, if Medicare were to raise its payment levels, the hospital would raise its prices to private insurers. Thus, a profit-maximizing provider does not engage in cost shifting.

A non-profit-maximizing provider does not necessarily cost shift either. It all depends on the objectives of the nonprofit hospital or provider. If the

objectives are to provide care to a third group of patients, say, the indigent, then even this hospital will not cost shift. Instead, it will set its prices at the profit-maximizing level, and instead of giving the profits to the shareholders, it will use those profits to care for the indigent. If it did not set those same higher prices, it would be providing less indigent care than it could have. If this hospital were now faced with reductions in Medicare payment levels, it would do exactly what the profit-maximizing hospital did, accept the lower Medicare payments and shift capacity to the PPO. This allows it to continue to provide as much charity care as possible, given the new lower Medicare payment level. Thus, there is no cost shifting in this example either.

The only way in theory to obtain the cost shifting result is to have a hospital (or other provider) that has market power but that also “likes” insured patients in the special sense that it charges them less than it profitably could. In this sense, it has unexploited market power. Now, when Medicare reduces its payment level, the hospital finds that it has fewer revenues from Medicare with which to subsidize privately insured patients and is then forced to raise its price to them. This is cost shifting. Thus, the ability to cost shift happens when hospitals still have the ability to maximize the revenues from the remaining private payers.

Cost shifting occurs because there is a growing gap between the payments from government programs (Medicare and Medicaid) that pay only for the direct cost of care for patients in these programs and not for the full economic costs of care. Because of this, a shortfall is created and hospitals then shift the unreimbursed costs by charging a higher price to privately insured patients. In effect, cost shifting results in the privately insured patients subsidizing the cost of care for the publicly insured patients. Because of the need to cost shift, hospitals may work to reduce their costs; that can lead to greater efficiency or affect quality of care.

The ability to cost shift varies in different geographic regions based on the market power of the provider, the level of payment from the public payer (Medicare and Medicaid), and the level of uncompensated care. If cost shifting were not done, providers would not be able to maintain their physical plants and equipment.

Empirical Evidence

The empirical evidence with respect to cost shifting has been mixed. Much of the work simply misses the point because it seeks to show that different payers pay different prices for essentially the same services. This is true, but price discrimination is not cost shifting. Other work tries to use cross-sectional comparisons to test for the presence of cost shifting. This is difficult to achieve because cost shifting is a dynamic phenomenon.

There have been three studies that shed light on the presence and extent of cost shifting in health-care. Hadley, Zuckerman, and Iezzoni used a national sample of hospitals from 1987 to 1989 to examine the effects of financial pressure and competition on the change in hospital revenues, costs, and profitability. They found that hospitals with lower base-year profits increased costs less and increased their efficiency. With respect to cost shifting, the authors did not find any evidence that cost shifting strategies that might protect hospital revenues in the wake of financial pressure were successfully undertaken.

Dranove and White used 1983 and 1992 California hospital data to examine the effects of reductions in Medicaid and Medicare volume on changes in price-cost margins (net price minus average costs all divided by net price) of privately insured patients in Medicaid-dependent hospitals. The authors did not find any evidence that Medicaid-dependent hospitals raised their prices to private patients in response to Medicaid (or Medicare) cutbacks. If there was any change, hospitals likely lowered their prices. The researchers also found that service levels fell for Medicaid (and Medicare) patients relative to privately insured patients, and they fell by more in Medicaid-dependent hospitals.

Zwanziger, Melnick, and Bamezai used California hospital data from the same source over the full time period of 1983 to 1991 and reached decidedly different conclusions. They computed the average price per discharge for Medicare, Medicaid, and non-Medicare or -Medicaid (i.e., privately insured) patients. Controlling for average costs in a two-stage model, they found that lower Medicare and Medicaid prices were associated with higher private prices. A 1% point decrease in the Medicare average price was estimated to

increase private prices at nonprofit hospitals by 0.23% to 0.59%. The larger price increases were found in markets with less hospital competition. In addition, Zwanziger and associates also found evidence that for-profit-owned hospitals also engaged in cost shifting. Similar analysis by Zwanziger and Bamezai for 1993 to 2001 concluded that the cost shifting that occurred from 1997 to 2001 of Medicare and Medicaid to private payers was responsible for a 12.3% increase in private payers' prices.

It is difficult to reconcile the disparate studies. Both Dranove and White and Zwanziger and associates used the same data over essentially the same time period. Some of the differences undoubtedly have to do with Dranove and White's use of beginning and end-point observations in a change model while the latter used essentially a panel of hospitals. The studies used different methodologies. The former examined profit margins, and the latter, price per discharge (although not price per day, which may be less subject to endogenous changes in length of stay). The former looked at changes in Medicare and Medicaid volume, while the latter looked at average price changes directly. Both of the studies tried to account for service or cost differences, but did so in very different ways.

Future Implications

One must conclude that the empirical evidence is mixed and that more work reconciling existing approaches and using alternative data would be desirable. The empirical question is compounded by the variety of other factors that must be considered. What are the relevant prices? How are they to be measured, and to what extent do the inherent compromises in their construction inadvertently bias the findings? How does one account for volume, service, and quality changes that are almost certainly endogenous (arise from within the model)? How does one approximate the relevant marginal cost by payer group? And how does one address the extent of competition?

Finally, as Zwanziger and his associates ask, do we need a more sophisticated hospital (or provider) model that not only incorporates individual hospital elements but more adequately accounts for the market environment in which providers

operate? Such models may more explicitly incorporate both price and quality competition and account for the roles of private and public-sector payment systems in driving providers individually and as a group toward one or another type of competition.

CREDENTIALING

Credentialing is the process of assessing and confirming the qualifications of a licensed, registered, or certified healthcare professional. The main goal of the credentialing process is to ensure that health professionals such as physicians, dentists, registered nurses, and others are skilled and

knowledgeable about the current best practices of appropriate and effective care. To be responsible to the public and to meet legal obligations, health-care organizations must verify the competency of their staff members. Credentialing should be conducted by an independent third party to ensure the accuracy of the information obtained on the staff members. Some of the elements that are normally verified in the credentialing process include the individual's current licensure; relevant education, training, or experience; current competence; and health fitness or the ability to perform the required tasks. Requirements of credentialing, however, vary depending on specialty or area of practice. For example, an internship or residency may not be deemed necessary to ensure that a laboratory technician has the appropriate knowledge and experience to perform his or her job; surgeons, on the other hand, are required to complete lengthy and ongoing training activities.

Background

The general public's knowledge about the importance of credentialing has grown over the years. In the past, a large variation existed in what health practitioners learned in different specialty areas or schools, especially in the field of medicine. In the 19th century, the majority of medical schools in the United States were run with the focus on making a profit; they were not associated with a university or college, and curricula lacked extensive hands-on learning opportunities such as laboratory work or dissection. As a result, many poorly trained physicians entered the profession, patients suffered high mortality rates, and the public's faith in the medical field was low. Communities discovered that it was difficult to certify physicians because there were no established guidelines according to which what they had learned could be assessed.

In the early 1900s, a number of professional medical organizations advocated for the establishment of stricter, science-based, national requirements for medical education. As part of this effort, the American Medical Association (AMA) and the Council on Medical Education (CME) wanted an assessment of the current status of medical training. With funding from the Carnegie Foundation, Abraham Flexner (1866–1959), a professional

educator, was hired to conduct on-site visits to assess all medical schools in North America. Flexner compiled his findings in a landmark report, *Medical Education in the United States and Canada*, which was published in 1910. The Flexner Report, as it would become known, criticized the state of medical education and the training process, and Flexner made a number of recommendations. Specifically, he recommended that medical schools be integrated with colleges or universities, that the length of education be extended to at least 4 years, and that the curriculum content be agreed on and standardized by a reputable body. The report's findings led to significant changes in the nation's medical education, including more standardized curricula for medical students. Its findings also carried over to the areas of accreditation and credentialing.

Areas of Credentialing

Because medical knowledge is increasing daily, all health professionals need to keep abreast of new developments that affect their practices, and they must also make sure that they have adequately retained the knowledge they learned in the past, as demonstrated by the recertification requirements. All types of health professions require credentialing that matches the variety of specialties and subspecialties in medicine and healthcare. Professionals, including critical care nurses, managed-care physicians, and healthcare administrators, seek out credentialing from a specialized third-party agency. These agencies provide the professional with codes of conduct in addition to current information regarding their role or specialty, upholding the goals and furthering the mission of the credentialing body and the field. There are many credentialing organizations in healthcare, including the American Nurses Credentialing Center (ANCC), the National Commission for Health Education Credentialing (NCHEC), and the National Register of Health Service Providers in Psychology. Advances in technology have also allowed the growth of Web-based credentialing services.

Hospitals and clinics, like individual health professionals, can also be credentialed. Facilities want their staff to be credentialed and up-to-date because credentialed individuals tend to be more efficient

and productive as compared with noncredentialed staff members. Hospitals also want their staff to be credentialed to meet various legal and regulatory requirements.

Future Implications

The goal of credentialing is to ensure that patients receive high-quality and safe medical care by making sure every health professional providing care has appropriate certification and licensing. Credentialing not only ensures high standards of care and the increased quality of services but also enables patients to trust the health professionals and organizations from which they receive care. In the future, as the healthcare field continues to grow and incorporate a wider variety of workers, such as allied health professionals and complementary and alternative medicine professionals, the credentialing process will need to expand to address them.

CRITICAL ACCESS HOSPITALS (CAHs)

Critical Access Hospitals (CAHs) are small, limited-service hospitals that act as safety net providers of essential healthcare services for rural Americans. These hospitals apply to become CAH-designated under a program established by the U.S. Congress through the Balanced Budget Act of 1997. Specifically, the program was established to address the closure of a large number of rural hospitals due to increasing financial stress. The 1980s saw a high hospital closure rate nationwide, with a considerably higher rate in rural areas. By 2000, many states had fewer than 90% of the rural hospitals they had in the 1990s. With the CAH program, closure rates have slowed significantly in rural areas, and many hospitals that had closed or reduced services have reopened.

The number of CAHs in the nation has increased from 41 in 1999 to 1,283 in 2007. To date, only New Jersey and Rhode Island have not applied for the program. The number of CAHs varies from year to year as some hospitals become ineligible for designation, either by losing rural status or through nonadherence to requirements. At the same time, new facilities are added. Currently, CAHs account for about 3% of the nation's total hospital beds and about 1% of Medicare's total payments for inpatient care.

Characteristics of the Program

The Medicare Rural Hospital Flexibility Grant Program, more commonly known as the Flex Program, established a new hospital category, the CAH, designed to provide financial stability to small, rural hospitals that were losing money after changes in the prospective payment system (PPS) implemented by Medicare in 1983. The program permits designated CAHs to function as limited-service facilities with flexible staffing and service requirements not permissible in larger hospitals. It also allows simplified billing methods and offers incentives to develop local, integrated health-delivery systems, including acute, primary, emergency, and long-term care. Although targeted at very small hospitals, the program covers healthcare

facilities and issues at the national, state, and local levels.

The Flex Program consists of two components: cost-based Medicare reimbursement for designated CAHs; and a state Flex Grant Program administered by the federal Office of Rural Health Policy (ORHP) to strengthen rural healthcare systems. The ORHP, which is within the Health Resources and Services Administration (HRSA) of the Department of Health and Human Services (HHS), manages the program nationally, making funds available to state Flex Programs and providing program oversight.

CAHs, which are designated to act as nuclei of organized, local systems of care in rural areas, work to encourage the growth of collaborative rural delivery systems across the continuum of care at the community level with appropriate external relationships for referral and support. In addition to designating and supporting the conversion of hospitals to CAHs, the statutory and regulatory provisions of the national program require states to develop and maintain a State Rural Health Plan, create a CAH network that is complementary to providing a wide range of services, fostering local Emergency Medical Services (EMS) linkages with CAH networks, supporting quality improvement initiatives, and evaluating their programs within the framework of national program goals.

The Flex Program contains explicit expectations and financial incentives up to \$700,000 to encourage CAHs to engage with their communities to access community health and health system needs, as well as to develop collaborative delivery systems. Most states are now engaged in quality and/or performance improvement activities with CAHs. Using local, state-to-state, regional, and national collaborations, states and CAHs are sharing and advancing knowledge on critical issues such as performance and quality of care improvement, health information technology development, and capital planning and acquisition. All states continue to streamline the CAH designation and conversion process, and they have now directed their efforts to providing direct assistance to support and improve CAH operations. Recent changes in the Medicare Modernization Act of 2003, such as increasing the acute-care hospital bed capacity of CAHs to 25 beds, may increase CAH conversion rates in some states. The emphasis on

infrastructure support for continued CAH operations is likely to continue for years to come as states continue to build their capacity for strengthening rural health infrastructure.

Requirements and Certification Process

Eligible rural hospitals must meet conditions of certification to obtain CHA designation from state and federal agencies. About two thirds of the state Flex Programs require that hospitals applying for CAH status conduct a community needs assessment and submit the results of that assessment with their CAH application. Specifically, to be included in the CAH program, hospitals must meet specific criteria. First, the hospital must be a rural public, nonprofit or for-profit hospital, or a hospital that was closed within the past 10 years, or a rural health clinic that was downsized from a hospital. The facility must be located in a state that has established a state plan with the federal Centers for Medicare and Medicaid Services (CMS) for the Medicare Rural Hospital Flexibility Program. Additionally, it must be located more than a 35-mile drive from any other hospital or CAH (in mountainous terrain or in areas with only secondary roads available, the mileage criterion is 15 miles), or it must be certified by the state in its plan as being a necessary provider of healthcare services to area residents. The hospital must provide 24-hour emergency care services 7 days a week, have a maximum of 25 acute-care and swing hospital beds, and provide no more than 15 hospital beds for acute, hospital-level inpatient care. Finally, to be considered for the CAH program, the hospital must provide an annual average length of stay of 96 hours per patient for acute-care patients. CAHs are required to be in compliance with the federal requirements set forth in the Medicare Conditions of Participation (CoP) to receive Medicare and Medicaid payment. Surveys are conducted to determine if the CAH is in compliance, and certification is accomplished through observations, interviews, and document and record reviews.

Federal law does not require all CAHs to be open 24 hours a day, 7 days a week. Twenty-four-hour nursing is mandatory when an inpatient is present in the hospital. It is also required for a physician, physician assistant, or nurse practitioner to

be available within 30 minutes. These exceptions allow considerable reductions in the cost of hospital operations. Medicare pays CAHs on a basis of 101% of inpatient reasonable costs, as well as most outpatient costs, while the state Medicaid program covers 100% of allowable inpatient and outpatient costs. Required services are inpatient and emergency care; laboratory and radiology services; and pharmacy and some ancillary and support services, which may be provided part-time or off site. For licensure, a CAH must be in compliance with Medicare standards of participation. Individual states can set their own criteria for levels of care that are higher than stipulated federal levels.

Future Implications

The CAH program helps fulfill a long-standing national need of ensuring hospital services for rural Americans. It facilitates the financial viability of small, low-volume rural hospitals and has nearly halted hospital closures. Being designated a CAH helps these facilities receive loans and funds from diverse sources, which in turn helps them modernize and expand the services they offer. The availability of additional CAH services has likely reduced the number of rural residents who bypass these facilities to seek care at other, more-distant hospitals. ORHP has funded studies of performance quality, best practices, and community impact of CAHs. The results of these studies will indicate how the CAH program may continue to improve the quality of healthcare in rural communities.

CROSS-SECTIONAL STUDIES

Cross-sectional health studies present a snapshot of a disease, exposure, or health outcome at a specific point in time for a specific population. This snapshot often provides useful information for health services researchers and other health-care professionals. Researchers may glean useful information from conducting cross-sectional studies or by using information obtained from them. Often, the findings from cross-sectional studies help researchers identify which specific topic to pursue for more detailed investigation.

Nomenclature and Categorization

The purpose of many cross-sectional health studies is to describe the prevalence of a disease (e.g., the number of individuals with lung cancer in a community), the exposure to a particular risk factor (e.g., the number of individuals who smoke), or the

health outcome (e.g., changes in death, disease, disability, discomfort, or dissatisfaction) for a specific population; hence cross-sectional studies are also commonly referred to as *prevalence studies*. Cross-sectional or prevalence studies are also referred to as *surveys*, which emphasizes the fact that they are conducted at one time. Beyond this nomenclature is the categorization and classification of cross-sectional studies, which often differs by author. The various classification schemes are summarized below.

Most of the healthcare literature classifies cross-sectional studies as descriptive studies, along with case reports, case-series reports, and surveillance studies. Descriptive studies in general collect information from individuals (except ecological studies, which are sometimes placed in this category), and they attempt to describe the characteristics of people or a population.

Other classification schemes divide all studies into either experimental studies (where the randomized controlled clinical trial is the gold standard) or observational studies (which include cross-sectional, case-control, cohort, and ecological studies). Occasionally observational studies are subclassified into descriptive studies (i.e., case reports, case-series reports) and analytical studies (i.e., ecological, cross-sectional, case-control, and cohort studies)—where the criterion for classification is whether or not the information collected requires data analysis to develop conclusions.

Yet other classification schemes simply divide all studies into either cross-sectional studies or longitudinal studies—one point in time measurements (i.e., cross-sectional) versus repeated measures or time series measurements over a length of time (i.e., longitudinal, such as a cohort study). However, when serial cross-sectional studies of the same population are linked, such as the U.S. Census of Population for several different years, a modified form of longitudinal study is created (i.e., modified because the same people are not studied each year of the census due to migration, immigration, and births and deaths).

Uses of Cross-Sectional Studies

Cross-sectional studies are often used to determine the current health status of a population

(e.g., the total number of people with HIV/AIDS). They are often used to establish baseline information, which can be used for health services planning purposes and to make public policy decisions.

A large number of government agencies and private organizations conduct cross-sectional health studies. The federal agency that conducts the largest number of such studies is the National Center for Health Statistics (NCHS), which is part of the National Centers for Disease Control and Prevention (CDC). The NCHS conducts, for example, the National Ambulatory Medical Care Survey (NAMCS), the National Health Interview Survey (NHIS), the National Health and Nutrition Examination Survey (NHANES), the National Hospital Discharge Survey (NHDS), the National Home and Hospice Care Survey (NHHCS), and the National Nursing Home Survey (NNHS).

Health services researchers and public health workers often review information from cross-sectional studies to understand what risk factors are most common in a population for the purpose of choosing appropriate interventions. For example, when trying to prevent coronary artery disease in a population, if that population exercises and has little obesity but has a high prevalence of hypertension, an appropriate intervention may be establishing a public health program encouraging the population to lower stress and limit the use of salt. Similarly, cross-sectional studies can be used to estimate the hospital bed needs and clinic staff training needs for a population.

Clinicians also rely on information from prevalence or cross-sectional studies. Information from them is part of the diagnostic decision making in almost all the patient contacts a clinician makes. Prevalence studies help determine the likelihood that a patient with a given presentation may have a specific disease and hence the temporal order of the diagnostic work-up conducted by the clinician. For example, when carrying out an examination and tests to diagnose the cause of dyspnea (shortness of breath) in a normally healthy teenager, the clinician will consider bronchitis, pneumonia, and asthma before lung cancer, congestive heart failure, and sarcoid. Knowing the prevalence of these diseases among teenagers helps the clinician choose which diagnostic tests are needed for the dyspnic teenager.

Conducting and Analyzing Cross-Sectional Studies

Most descriptive studies address basic questions such as who, what, when, where, and why, with an implicit question of “so what?” In many cross-sectional health studies, researchers often start with a specific question (e.g., what is the relationship between smoking and lung cancer?) and then choose a population as well as which variables to study. The people in the study are chosen without regard to their exposure (e.g., smokers and nonsmokers). Cross-sectional studies collect exposure information either from all members of a population or from a sample of a population, at a single point in time. Typically, cross-sectional studies use a survey instrument or study questionnaire (either written or conducted by direct interview) and may include measurements and/or obtain biologic samples. Cross-sectional studies collect information on both the health outcome (e.g., number of individuals with lung cancer) and the exposure (e.g., smoker or nonsmoker) at the same time.

Cross-sectional studies should document and report in detail their study designs so other researchers can judge the quality of their results. The results of cross-sectional studies should provide the following: (a) a detailed description of the population studied, or if a sample of the population was used, a description of how the sampling was done, and if any weighting was used in drawing the sample; (b) when (i.e., date and time) and where (i.e., specific geographic location) the study was conducted; (c) how the comparison population was chosen, assuming the data are being analyzed for an association; (d) the source of the information used (i.e., questionnaire or biological sample—giving specific questions, or method of biological analysis) and how it was ascertained (i.e., home visit, worksite, or clinic), which includes how the exposures were ascertained (i.e., blood samples, work history, self-reporting by recall); (e) overall and specific response rates of people invited to participate in the study; (f) information on how the analysis of the study results were done; (g) what prevalence was found; (h) what associations were found; and (i) what qualification on inferences and associations need to be made.

General descriptive statistics using means and standard errors should be used in the analysis of

cross-sectional data. Often, the descriptive data from these studies are analyzed to express prevalence, such as the rate of a disease, or the proportion of the population at risk, or who had a certain exposure (the number with the disease, risk, or exposure divided by the number responding to the survey) in a population.

Besides being used for the presentation of prevalence and disease rates, cross-sectional studies are often used to develop inferences (i.e., inferring causation) or identify associations. The basic tool for analyzing cross-sectional data is a 2×2 table, where the four cells of the table are as follows: a = exposure factor and disease present, b = exposure factor and disease not present, c = no exposure factor, but disease present, and d = no exposure factor or disease present.

Often, as in the case of determining the source of a food-borne epidemic, several 2×2 tables are made to determine which food was most highly associated with the illness. From each table the prevalence odds ratios (POR), an estimate of the incident rate ratio, can be calculated. Using the cells of the table, the POR is calculated as ad/bc . The higher the POR, the stronger is the exposure or risk factor associated with the outcome or disease. In the case of the food-borne epidemic example, the highest PORs are inferred to be the foods most likely harboring the bacteria that caused the illness. To put it another way, the POR is the number of times having a specific exposure increases the risk of a disease above that of someone who has not been exposed to the risk factor. Chi-square analysis can then be used to determine if the difference between the exposure and the nonexposure is statistically significant.

Cross-sectional studies are sometimes repeated to estimate change over time in a population, but unlike cohort studies, the repeated study does not follow exactly the same population. This is called a *repeated measures design*, and generally repeated measures analysis of variance (ANOVA) is used to analyze data from this type of study.

Advantages and Limitations

Often, study methodologies are classified in terms of their ability to shed light on causality. Generally, cross-sectional studies are more useful in helping

identify possible causality than case studies, case-series, and ecological studies. However, evidence from case-control and cohort studies is considered stronger than that from cross-sectional studies, with randomized controlled clinical trials being the best or gold standard. Nevertheless, for determining the prevalence of a disease or exposure, cross-sectional studies remain an important tool for researchers.

Cross-sectional studies are useful to a wide variety of health professionals needing information for quick decisions on a low budget. Of all study methodologies, cross-sectional studies are among the most useful in acquiring information in a short time, and they are relatively inexpensive to conduct. Hence, cross-sectional studies are often referred to as “quick and dirty” assessments. They are often used to predict health service needs and the health impacts of disasters and disease outbreaks. Individuals are not deliberately exposed, treated, or left untreated, and therefore these studies rarely present ethical dilemmas. Cross-sectional studies are often used to garner the first understanding of a variety of exposures and risk factors. And they are often used to make hypotheses for further research, as seen with many large health surveys.

Although associations may be found between exposures or risk factors and health outcomes using cross-sectional studies, these studies fail in their ability to establish causality because they lack temporal information. Inferences may be made on possible causality, but they must be qualified because information gleaned from cross-sectional studies cannot clearly establish whether the outcome precedes the exposure or risk. For example, if obesity is found to be associated with lack of exercise in a cross-sectional study, it is unclear if obesity made it impossible or too painful to exercise or if obesity was caused by lack of exercise. This is an example of the antecedent-consequence bias common to all cross-sectional studies. Other studies might be developed to try to ascertain this temporal association (i.e., which comes first). However, such studies will never be as strong a support of causality as a prospective study. A clear association can be shown between exposure and a health outcome, but cross-sectional studies cannot establish causality because of loss of the temporal association between exposure (cause) and outcome

(effect), which at best relies on memory (which may be influenced by outcome).

Cross-sectional studies also have other limitations. For example, although a hospital cross-sectional, single-point-in-time survey may be used to estimate the needs of long-term care patients, the cross-sectional survey technique will likely underestimate the prevalence of short-term hospitalizations.

Another problem is using cross-sectional surveys to determine the effects of workers exposure. If a cross-sectional study is used in the workplace, workers are apt to be healthier, while others who are sick at home will not be included in the study. This is called the *healthy worker effect*. Therefore, other methodological tools may be better suited for measuring employee health.

Unless cross-sectional studies include very large populations, they are not suited for studying rare events. On the other hand, several researchers working on methodological issues in community-based health intervention trials conclude that serial cross-sectional studies, using repeated measures analysis, may be an optimal study methodology for health services research and other health research that proposes to affect the health of an entire population.

CROWD-OUT

The concept of crowd-out in the case of Medicaid and the State Children's Health Insurance Program (SCHIP) refers to the substitution of public for private health insurance coverage. This substitution is an important public policy concern because it may create unintended perverse incentives. Crowd-out may result from employers no longer offering health insurance once the public insurance expansion is implemented, from employees declining offered coverage because they opt for public coverage for which they are newly eligible, or from workers who are more inclined to take jobs with companies that do not offer health insurance coverage because they can take advantage of the publicly available alternative.

Background

A number of economic studies have investigated crowd-out in various public programs. Studies have examined crowd-out associated with the expansion of the Medicaid program in the late 1980s and early 1990s, in various state-initiated health insurance programs and in the State Children's Health Insurance Program (SCHIP), which was enacted in 1997 and initially authorized for a 10-year period. The public policy debate on whether the SCHIP should be reauthorized in 2007 focused national attention on the issue of crowd-out.

There have been many carefully conducted studies of crowd-out. In some cases, the studies defined crowd-out in different ways, reflecting both the various perspectives of the researchers conducting them and the various databases they used. Few studies have sought to identify the mechanism through which crowd-out is operating. As a result, the estimates on the extent of crowd-out can vary greatly across studies. Some studies suggest that it accounts for a very small percentage of changes in a population's health insurance coverage, while other studies put the figure as high as 60%, depending on the public program. The 2007 U.S. Congressional Budget Office's (CBO's) study of the SCHIP estimated the extent of crowd-out at 25% to 50%. In other words, for every 100 children who enrolled as a result of the program, there was a corresponding reduction in private health insurance coverage of between 25 and 50 children.

Policy Issues

For many state and national policymakers, one of the most challenging aspects of creating or expanding public insurance programs is how to provide a public health insurance option to individuals who are truly in need without distorting private behavior (crowd-out). On one hand, their goal is to increase the number of individuals covered by health insurance. On the other hand, they do not want to waste scarce public money, which merely shifts the source of funding from private to public insurance and does not result in improved access to healthcare or health status. An additional concern is that when healthy individuals shift from private to public insurance, those remaining with private insurance may be adversely affected. Risk may have to be spread over a smaller group and may trigger higher premiums.

Several factors appear to increase the likelihood of crowd-out. Expanding the eligibility of public programs to include higher income levels increases the potential for crowd-out because many individuals and families with higher incomes have private health insurance. Another factor is family eligibility: Parents are much more likely to enroll their children in a public program if they can also join it.

State public programs currently use a number of strategies to discourage crowd-out. They have

established eligibility restrictions based on current insurance states; imposed cost-sharing requirements such as monthly premiums, copayments and deductibles, and annual enrollment fees; and required a waiting period before allowing individuals to enroll in public programs.

States have also encouraged employers to begin and to continue offering health insurance to their workers' states by (a) reimbursing employers for their purchase of employer-sponsored coverage, (b) establishing purchasing cooperatives for small employers, and (c) establishing employer tax credit.

Future Implications

Much more research is needed to understand better the mechanisms, the extent, and the health impact of crowd-out. It is clear that crowd-out will occur with the creation of any new public insurance program or the expansion of an existing program. In the future, health economists will need to measure more precisely the extent of crowd-out, public health experts will need to identify the specific health impacts of crowd-out, and society will need to make a value judgment of whether and how much crowd-out in public programs is acceptable.

CULTURAL COMPETENCY

Cultural competency is an evolving concept in health services research, with no universally agreed-on definition. Although not a new concept, the term first became widely used in public health and health services in the 1990s. It remains prominent in current considerations of addressing racial/ethnic disparities in health status and access to care. With a focus on the increasing population diversity of the United States and the persistence of racial/ethnic disparities in health, public health, medicine, nursing, social work, and other health science disciplines are adapting the concept to address current issues in working with diverse population groups. The inference is that there are identifiable organizational, community, and policy strategies that facilitate or impede the delivery of services to specific cultural groups or communities. The federal Health Resources and Services Administration's (HRSA) Bureau of Health Professions (BHP) Web site offers several inter-related definitions of cultural competency across various federal agencies. An element common to

all definitions is the ability to function effectively (in healthcare or other settings) with people who are culturally different. A less widely endorsed strategy as a condition to the above is some degree of self-reflection or awareness of one's (provider, researcher, policymaker) social position, relative power status, cultural values and practices, and even worldview. Many definitions of cultural competency across federal agencies and provider groups recognize culturally competent skills as encompassing the ability to incorporate culturally defined health beliefs and practices, language and communication patterns, and health-seeking behaviors of specific groups into practice, research, and policy.

In furthering the understanding of cultural competency, it is helpful to consider the meanings of the constituent terms, *culture* and *competency*. *Culture* refers to a unique configuration of behavioral norms, beliefs, and shared understanding of the world that guides everyday life and is common to a particular population subgroup. In every cultural subgroup, there are prescriptive means to transmit culture to new group members and intuitional practices to ensure its continuity and utility in attaining individual and collective goals in life. A common language or dialect is typical of many but not all cultural groups, and although shared historical, migratory, and ancestral roots are important markers in defining group membership, there is increasing diversity within groups due to globalization (social and economic forces' contribution to population migration and bringing cultural groups into regular contact with one another) and transnationalism (cultural groups maintaining ongoing contact with the homeland of origin through media, commerce, and transportation systems). All cultural groups, (including dominant Western White groups), possess locally adapted patterns or codes of conduct or performances of daily life that are unapparent to casual observers or outsiders, making it inappropriate for practitioners or researchers to impose rigid interpretations or categorization of beliefs and behaviors on any one group. Importantly, culture provides a lens for group members to interpret illness symptoms and engage in preventive and health-seeking behaviors. *Competency*, an ill-defined term in the human

performance literature, implies skills or abilities to perform role requirements in a specific context. Burgoyne refers to "being competent" as meeting the job demands, while "possessing competencies" means having the knowledge, skills, and attitudes to perform the job. Typical applications of the concept may be found in health services delivery, community, intervention development and evaluation, provider education, and studies of patient-consumer experiences with services.

However, there is a continuum of activities beyond the provision of healthcare services where cultural competency is concerned. In addition to healthcare services, the loci of concerns include research (including needs assessment, program planning and evaluation, and health services research) and policy development. While population diversity has implications for all these activities, health services research can be most useful in identifying how personal healthcare services, population-based interventions, and public health policies are affecting the health status of population subgroups and their access to care. For example, discrepancies between population groups in receipt of recommended preventive services can be examined in terms of provider, patient, and community characteristics as well as outcomes of population-based health education and outreach, and policy initiatives. Examples of how cultural competency can be addressed across a range of public health activities, including the role of health services research, are provided in Table 1. Here, cultural competency is broken down into the related concepts: cultural sensitivity, cultural proficiency, and cultural humility.

In Table 1, "Healthcare Services" refers to clinical interventions with individuals and families in ambulatory care settings such as outpatient clinics, physician's offices, and community health centers. "Community Level Interventions" refers to health promotion practices in community settings such as churches, schools, and community-based organizations. "Health Services Research" refers to scientific inquiry designed to capture trends in healthcare services access and use, identify causal and contributing factors to access and use, and evaluate the effectiveness of clinical and community-level interventions. "Public Health Policy" refers

to the function of ensuring access to clinical and community-level services through policy initiatives, particularly for vulnerable populations. Public health policy can also address environmental conditions (air and water quality, community safety, affordable and safe housing) that foster healthful living.

Cultural Sensitivity

In terms of the range of cultural competency approaches, cultural sensitivity is perhaps the normative or most prevalent approach. It is concerned with an awareness of cultural differences between the providers of services, the culture of the supporting institution (clinic or organizational setting), and cultures of consumers or service recipients. Awareness may not necessarily lead to effective interventions, but it is a first step in recognizing potential limitations of the manner in which care is delivered and how cultural differences can translate into a “barrier” that impedes the use of health services or ability of consumers to adhere to recommendations for personal health improvement. The same can be said for awareness in community-level interventions, with little or no community control over the intervention. Health services research in this phase of cultural competency is mostly descriptive, and data and methods are not designed to capture complex cultural factors such as acculturative processes, cultural resources, beliefs, and practices. Likewise, policies are not tailored for specific subgroups and have little meaningful input of affected communities or subgroups.

Cultural Proficiency

Although no one can be truly “culturally proficient” in a culture outside one’s own, this concept refers to actively valuing and embracing cultural differences such that ongoing efforts are made to enhance the understanding of cultures encountered in practice. In healthcare services as well as in community-level interventions, the concept of community-oriented primary care is relevant here. This means that the organization or program has means to assess the health-related beliefs and

practices of the populations of interest and identify cultural and community resources (ethnic grocery stores and indigenous support groups) that can be used to complement services. At the community level, interventions are tailored to reflect local culture, often deploying cultural symbols of strength and persistence in the face of adversity (e.g., Taino petroglyphs or other symbols of ancestral heritage). Here linguistic competence is of utmost importance, and so personnel are proficient in the language. Hours and locations of services take into account how time and space are structured in the community (e.g., shift hours, safety and convenience of locations). Health services research includes cultural variables such as acculturative status, health beliefs and practices, identification of ethnic and cultural subgroups (e.g., Puerto Rican and Mexican, not just Hispanic), and characteristic of services and programs that reflect cultural competency (board members and staff reflect community of interest, and linguistic competence). Research results are shared with the community for feedback and for quality improvement. The effect of policies on access and use of healthcare as well as services effectiveness is an important role of health services research. Policies are developed with some input from cultural groups affected by the issues, and such input is facilitated by removal of language barriers to understanding and discussion (e.g., printed materials in native languages).

Cultural Humility

Cultural humility can be viewed as the highest level of attainment of cultural skills because it not only builds on cultural proficiency but also focuses on self-reflection, a critical skill in cross-cultural work, and the consequent awareness of power differences between practitioners, researchers, policymakers, and the community of interest. Moreover, there is a commitment to address these power differences across the spectrum of public health modalities. Cultural humility recognizes the privileged status and social positions that practitioners, researchers, and policymakers occupy, regardless of their own ancestral heritage. In practice, it actively seeks to understand and appreciate the local historical and social

Table 1 Cultural Competency Approaches by Public Health Modality

<i>Cultural Competency Approaches</i>	<i>Public Health Modality</i>			
	<i>Healthcare Services</i>	<i>Community-Level Interventions</i>	<i>Health Services Research</i>	<i>Public Health Policy</i>
Locus of Change or Interest	Delivering services to individuals and family members	Delivering interventions to populations, social networks and subgroups, and community-based organizations	Describing or analyzing trends in access to healthcare and services utilization	Ensuring access to services through policy initiatives
Cultural Sensitivity	Awareness of cultural differences between providers and service recipients	Awareness of cultural differences between those designing or funding the intervention and those implementing and receiving the intervention	Presenting results with awareness of the major cultural subgroups in the study	Developing policies with awareness of the cultural differences in the population
Cultural Proficiency	Valuing cultural differences; having knowledge of group-level cultural practices while acknowledging individual differences; linguistic proficiency evident in health education materials and written policies; professional and organizational development encouraged; recruitment of staff reflecting community composition	Valuing cultural differences; tailoring interventions to local cultural practices and using indigenous institutions and personnel for delivery of services; linguistic proficiency evident in health education materials and written policies	Valuing cultural differences; collaborative enquiry with members of population subgroups affected by the health issue(s) under consideration; linguistic proficiency evident in research instruments and recruitment of participants	Valuing cultural differences in appreciating how policies may differentially affect cultural subgroups; seeking input from the cultural groups most affected by the health issue(s) under consideration; linguistic proficiency evident
Cultural Humility	Awareness of power issues in delivery of care; taking action to reduce social distancing and encourage participation in care; encouraging culturally appropriate self-care and use of community and cultural resources; professional and organizational development required	Awareness of power issues; inclusion of community as an equal partner in the intervention, sharing of intervention fiscal resources; conducting training and skill building for interventions; learning and appreciating the social-historical context of community; fostering cultural revitalization; addressing the broader social determinants that affect health	Awareness of power issues; coproduction of knowledge with community members, sharing research resources; building community capacity for research; fostering cultural revitalization; using research results to foster change	Awareness of power issues; actively fostering inclusion of youth and community members in policy changes

context or worldview of communities of interest. One of the hallmarks of cultural humility is meaningful inclusion of cultural groups affected by the issue. In healthcare and community interventions, this means bringing local cultural resources into partnerships, a fair distribution of fiscal and other resources, shared decision-making about services, and conducting training and fostering community capacity for taking more initiative and control of intervention development and research. Services research employs principles of collaborative inquiry such as in community-based participatory research (CBPR). As indicated in the literature, this means community involvement in all phases of the research process from inquiry questions and instruments to data analysis, interpretations, and actions that follow from the research findings. Such processes can improve the utility of research efforts because new understandings can emerge from the coconstruction of knowledge from joint community and academic partnerships. This is particularly important in services research, where much evidence-based research is lacking that can inform future policies and practice. In policy as in services research, youth (high school and college students) can be actively involved in the processes with mentoring so that they are encouraged to consider careers in the health sciences, perhaps services research in the future. These efforts actively seek out advocacy groups (through community organizations) and support pipeline programs (for enhancing minority enrollment in health professions) for including in the research and policy processes. Last, cultural humility approaches can enhance cultural revitalization through honoring and celebrating local culture and ensuring inclusion of cultural elements in health services, health promotion messages, and practices and local health policy processes. Finally, cultural humility and participatory practices in research can also identify the small-scale culturally sensitive interventions that are often managed by indigenous groups (not outside “experts”) and investigate the mechanisms by which these unique local interventions produce outcomes in specific groups under specific conditions. These culturally sensitive interventions are often excluded from research that seeks to identify empirically supported interventions.

Limitations of Culturally Competency Approaches

Because cultural competency has not been well defined or operationalized, it has been challenging to evaluate its effectiveness. It is important to keep in mind that cultural competency is also value-based, and as such it is significant in its own right in the absence of evidence. Additionally, cultural competency in and of itself cannot address all the social determinants of health that exert influence from the broader social structure that limits opportunities for equality and health in vulnerable populations. Nevertheless, there are calls for a research agenda to critically examine the role of the cultural factors identified above in healthcare delivery systems. The evidence to date shows promise for culturally congruent services (e.g., services that take into account cultural strengths, local resources, and way of life as well as population risk and protective factors). Health services research can play a vital role through the use of mixed methods (qualitative and quantitative) that identify and measure content of services, preferences and practices of consumers, and policies. The impact of services and policies as well as the processes that foster cultural competence need to be captured with data. More specifically, identifying the conditions under which certain cultural competency approaches contribute to improved health outcomes are of great interest. To the extent that research endeavors can incorporate community-based participatory research principals and practices (itself an exercise in cultural competency), the knowledge gleaned from such research can be more useful and can potentially contribute to informing the evidence for cultural competency for practice and policy.

CULYER, ANTHONY J.

Anthony J. Culyer is a senior scientist at the Institute for Work and Health, a professor of economics (on leave) at the University of York in the United Kingdom, and an adjunct professor in the Department of Health Policy, Management and Evaluation at the University of Toronto. He is recognized internationally for his work in health economics, with special expertise in the appropriate use of health technology from both an economic and clinical perspective, and the effective translation of this knowledge into practice. His interests extend to the economics of social policy, and equity and social justice.

Culyer earned a bachelor's degree in economics from Exeter University in 1964 and received an honorary doctorate degree in economics from the Stockholm School of Economics in 1999. In 1964, he was awarded the Exeter University Leo T. Little Prize for economics, and he received a Fulbright Travel Scholarship to study and work as a teaching assistant at the University of California at Los Angeles in 1964–1965.

During his expansive career, Culyer has held academic positions in both England and Canada and has assumed administrative academic roles at the University of York. In addition, he has held visiting professor positions in Australia, Germany, and New Zealand. His editorial contributions have included being a founding coeditor of the *Journal of Health Economics*, editor of *Nuffield/York Portfolios*, advisory editor of *Social Science and Medicine*, and member of the editorial boards of numerous journals such as *The Economic Review*, *Journal of Medical Ethics*, the *British Medical Journal*, and *Clinical Effectiveness in Nursing*. He has served the health economics community extensively through his involvement in a variety of professional groups, including the Health Economists' Study Group, the Scientific Committee of the International Institute of Public Finance, the Canadian Institute of Advanced Research, and the Canadian Health Services Research Foundation (CHSRF). He has acted as an advisor, committee member, or chair for many groups, including health authorities, government agencies (in particular the United Kingdom's National Health Service [NHS]), and commissions and advisory groups for research and development. He also served as

vice-chair of the United Kingdom's National Institute for Clinical Excellence (NICE), an organization that provides national guidance on promoting good health and preventing and treating ill health in England and Wales.

Culyer has published over 200 articles, is a contributor to 28 books, and has authored or coauthored more than 35 monographs or discussion papers. His work is cited extensively. He has written on a variety of health-related topics, with many focusing on public policy and issues of efficiency, effectiveness, and equity. He is also the author of *Supporting Research and Development in the NHS* (1994), which is commonly known as the Culyer Report.

CURRENT PROCEDURAL TERMINOLOGY (CPT)

Current Procedural Terminology (CPT) is a code set that includes an array of medical, surgical, and diagnostic services tied to the financial reimbursement of physicians and healthcare services. The American Medical Association (AMA) maintains the CPT, and it is regarded as the standard for the accurate communication of medical information and procedures among physicians, government, third-party payers, and peer-review organizations.

Overview

Procedural coding by physicians has evolved from a rudimentary classification system used mostly for research purposes to a dynamic tool that reflects the rapid advancements in healthcare. The first *Physician's Current Procedural Terminology* was published by the AMA in 1966, and it was periodically revised until the fourth edition, which was published in 1977 as *CPT-4, Current Procedural Terminology—4th Edition*. Since then, the basic format has been retained, and all subsequent printings of CPT use the CPT-4 design. The revised *Current Procedure Terminology* is published annually, and the new revision takes effect each January 1. The AMA owns and develops CPT-4, and attempts by others to develop a medical procedural coding and medical nomenclature system have not been as widely recognized.

The acceptance of CPT-4 was enhanced in 1983, when the U.S. Department of Health and Human Services (HHS) signed a contract with the AMA designating CPT-4 as the standard coding system for describing physicians' and other healthcare providers' services for Medicare and Medicaid. The Resource Based Relative Value Scale (RBRVS) is based on the CPT-4 coding. The Resource Relative Value Scale is a system used to determine physician reimbursement, and numerical relative values are assigned to each CPT code. This value is multiplied by a dollar conversion factor, updated yearly by the Centers for Medicare and Medicaid Services (CMS), to determine payment levels for physician and other healthcare services. Third-party insurance companies and others have adopted

the same method of payment as the CMS based on CPT-4 coding.

The AMA/CPT Editorial Panel maintains, updates, modifies, and revises CPT-4. The AMA/CPT Editorial Panel is composed of 19 members selected by the AMA for 4- or 8-year terms. There are 13 physicians who represent selected medical and surgical specialties, in addition to a chair and vice-chair. The CMS, third-party medical insurance carriers, nonphysician providers, and the American Health Information Management Association (AHIMA) each have one member on the panel. The AMA/CPT Advisory Committee and AMA Health Care Professionals Advisory Committee also provide input into the AMA/CPT Editorial Panel. Additionally, there are 91 medical and surgical societies and 17 healthcare professional society representatives selected by the AMA for participation.

Code Categories

The CPT-4 publication divides physician services into three categories. Category I codes are based on procedures consistent with contemporary medical practice performed by many physicians in clinical practice. Category I code criteria include approval by the Food and Drug Administration (FDA) of any drug or device; the service being a distinct procedure and/or service performed by many physicians and/or practitioners; the clinical efficacy of the service and/or procedure being well established in peer-reviewed literature; the service and/or procedure being neither a fragmentation of an existing procedure or service nor currently reportable by one or more existing codes; and the suggested service and/or procedure being not a means to report extraordinary circumstances related to the performance of a service and/or procedure already having a specific CPT code. The CPT-4 coding system assigns a five-digit number to each code in Category I.

Category II codes are supplemental codes used for tracking performance measures. These codes are used to facilitate the collection of data on quality of care by coding services and/or tests that support performance measures contributing to good patient care. These four-digit codes are followed by

a capitalized letter *F* (e.g., discussion of osteoporosis prevention 4019F) and have no relative values assigned to them. CMS is presently conducting a pilot study based on the Category II codes called pay-for-performance—that is, using a reimbursement scheme based on performance measures.

Category III codes are temporary tracking codes assigned for new or emerging services and/or procedures to facilitate data collection and assessment. The criteria for Category III codes require a protocol for the study of procedures being performed, support from specialists who would use the procedure, availability of peer-reviewed literature, and a description of current clinical trials outlining the procedure's efficacy. There are no relative value units assigned to Category III codes. Category III codes are identified by four digits and followed by a capitalized letter *T* (e.g., 0052T). These codes are archived after 5 years unless the codes are promoted to a Category I code or there is a demonstrated need for further study.

Code Requests

Requests for a new code or the revision to an existing code can be submitted by anyone, and an application form can be obtained from the AMA Web site. Code requests submitted are reviewed by the AMA Editorial Research and Development Department staff. These requests are then sent to selected members of the CPT Advisory Committee for proper code placement, comment, and approval. The responses from members of the CPT Advisory Committee and others are evaluated by the AMA/CPT Editorial Panel. Sponsoring societies or individuals may request to appear before the AMA/CPT Editorial Panel during the CPT code consideration. The AMA/CPT Editorial Panel members then vote by secret ballot. The decisions of the editorial panel may be appealed prior to the completion of the yearly CPT-4 update.

Future Implications

The CPT coding system continues to evolve, and it is updated on a regular basis by the AMA in response to changing demands. It is likely that the CPT will continue to play an important role in the

future for financial, administrative, and research purposes.

D

DATA PRIVACY

Data privacy is an abstract term that, in health-care, refers to the delicate relationship among the legal rights of a person, the growing global demand for information, and the technology used in the collection, sharing, and use of data. The word *privacy* invokes thoughts of freedom from unwanted access to one's health-related information as guaranteed by federal and state laws; it is also used with or in place of the term *confidentiality* in health-care. Confidentiality refers to the right of a person to expect his or her health-related information not to be accessed without his or her permission except what is required for his or her medical care and as allowed by the laws of the land.

Laws and Rules

A recent important rule is the Privacy Rule that was issued by the U.S. Department of Health and Human Services (HHS) in 2002 with a compliance date of April 14, 2003, under the mandate of the Health Insurance Portability and Accountability Act of 1996 (HIPAA). The Privacy Rule provides standards to protect individually identifiable health information. However, the rule only sets conditions for use and disclosure of the data by health-care plans, health-care providers, and health-care clearinghouses. The rule still allows disclosure of an individual's health-related information under certain public health and legal instances.

State law can prevail when it is more stringent than the federal HIPAA Privacy Rule. These state laws vary in the protection they offer and generally pertain to the privacy protection of genetic data. Laws, especially the Privacy Rule, limit the disclosure to the minimum necessary. *Minimum necessary* restricts disclosure or use to the minimum required to accomplish an individual's healthcare or legal task that enabled the release of the information.

Privacy and the Public's Health

The term *data privacy* becomes more obscure and indistinguishable from *confidentiality* as the global demand for information grows each year. As epidemics such as bird flu affect the global population, the terms *public health* and the *common good of the community* take on new connotations. Data privacy, or the anonymity of an individual with regard to his or her medical data, is weighed against the common good of the community, such as a city, then a state, and, eventually, a nation. Now our community is the world, and the data privacy of an individual must be weighed against the common good of the global community. Therefore, health-care providers are required by law to report certain diseases and other health conditions to specific health groups or registries. The data sent to the health groups, such as the state public health department, the Centers for Disease Control and Prevention (CDC), and cancer or other registries, are in one of three forms:

(1) individually identifiable data, (2) de-identifiable data, or (3) linkable data.

Forms of Data

Individually identifiable data consist of 18 items listed within the HIPAA Privacy Rule as items that can be used to identify an individual. The items are name, zip code with some reservations, dates (birth and death, without year) and the year when the person is 89 years of age or older, and telephone number. The list also includes facsimile number, e-mail address, social security number, medical numbers, and health plan beneficiary numbers. Identifiable data also cover Web universal resource locators (URLs), account numbers, certificate/license numbers, Internet protocol (IP) address, and vehicle identifiers. Also in the list as identifying data are device identifiers and serial numbers; biometric identifiers, full-face photos; and any other unique identifying number, characteristic, or code.

The de-identifiable data have most, if not all, of the 18 items removed so that the information cannot be traced back to an identifiable individual.

Linkable data have limited identifiable information and/or a code that can be used by the holder of the information to identify the individual whose data are being used or sent to the required agency or person.

Research Uses

Medical agencies are not the only ones that require healthcare data. Researchers also require data in their pursuit of new knowledge and advance cures. While researchers are not under the jurisdiction of HIPAA unless they are employees of a healthcare provider, healthcare plan, or healthcare clearinghouse; a provider themselves; or a business associate of one of the aforementioned groups and covered by contract or business agreement, they must follow the stipulations of an institutional review board (IRB) or a privacy board. IRBs are covered under Title 45 CFR (Code of Federal Regulations) Part 46, referred to as the Research Act of 1974. IRBs oversee the use of research data and the ethical and privacy problems that may arise from that use. A privacy board is an independent

review board founded to assist researchers in meeting HIPAA privacy requirements.

Pharmaceutical companies are also in the data and knowledge acquisition race. The data that are collected from the different registries, medical agencies, researchers, and others can and do end up in computer databases.

The technological advancements in the past 5 to 10 years allow researchers and others with personal computers and a connection to the Internet to perform data-mining procedures that were once the total domain of large research companies. Data mining is the process of searching large volumes of data using collective reasoning, associative rules, and other techniques to search for data patterns within multiple databases. Some programs will assist a researcher in data-mining efforts, so expertise with this technique is not needed to accomplish it.

Future Implications

The tentative relationship among the legal rights of a person; the growing global demand for data; and the technology used in the collection, use, and sharing of data has transformed the term *privacy* into *confidentiality* in the context of the world of healthcare. To keep the data confidential, healthcare providers must ensure that all interfaced systems are properly secured and must enforce the required level of protection against loss of individually identifiable data to unauthorized persons. Researchers and others who are not covered by HIPAA will need to rely on the IRBs, the privacy boards, the policies and procedures of the healthcare entity from which the data were received, and the researcher's own professional ethics. Technology will need to follow the guidelines set down in the HIPAA Security Rule and follow the principles of best security practices to lower the level of security risk to confidential data.

DATA SECURITY

Data security refers to the requirement to ensure confidentiality, integrity, and availability of data. In security circles, confidentiality, integrity, and availability are called the *CIA triad* and are the bases for implementing data security. Confidentiality is present when disclosure of data to unauthorized personnel and/or systems is prevented from occurring. Data have integrity when they are complete, accurate, and reliable and when unauthorized alteration and/or destruction is prevented. Data security requires the active interventions of laws, management, people, and technology to ensure that the triad is active and working effectively.

Laws and Regulations

Numerous federal and common laws affect the way data are secured by individuals and within systems. A few of the federal laws that affect healthcare are the Computer Fraud and Abuse Act, the Computer Security Act of 1987, the Electronic Communications Privacy Act of 1986,

the Health Insurance Portability and Accountability Act of 1996 (HIPAA), the National Information Infrastructure Protection Act of 1996, and the Security and Freedom Through Encryption Act of 1999. In some instances where providers or hospitals offer financial plans, they are covered by the Sarbanes-Oxley Act of 2002. The main law that covers data security in the healthcare arena is HIPAA's Security Rule, Title 45 CFR (Code of Federal Regulations) Parts 160, 162, and 164, which had a compliance date of April 20, 2005.

The Security Rule applies only to covered entities—namely, healthcare providers, healthcare clearinghouses, and healthcare plans. The Security Rule requires that each covered entity institutes a security plan that meets or exceeds the security standards as set forth in the rule to protect the confidentiality, integrity, and availability of electronically protected health information and other information as set forth in the rule. The standards are divided into three categories: administrative, physical, and technical. Administrative safeguards require a risk analysis, contingency/disaster recovery plans, personnel security measures, sanctions, security policies and procedures, termination procedures, and training requirements. The physical safeguards cover media controls, physical access controls, workstation controls and procedures, and security awareness training. The technical safeguards pertain to system access controls, encryption, authorization controls, data authentication, and access authentication. These standards are either required or addressable. A required standard must be implemented. An addressable standard can be implemented as described in the rule, or the entity can justify why it chose another method to meet the standard.

The common laws that affect data security are numerous and usually are called into force through civil litigation when due diligence or due care is in question. Due diligence requires that an organization make and continue to make a valid effort to protect the confidentiality, integrity, and availability of the data. Due care requires the organization to act as any prudent and rational organization would when trying to protect the security of the data. One law that is not always enforced by court action is the law that grew from the norms, morals, and common laws of the land—ethics. Ethics

guides professionals, especially in healthcare, to do no harm and to protect the confidentiality of the patient or client.

Role of Management and Employees

Data security at a company or healthcare facility cannot be met through pain of penalty alone or with the adage “Do as I say, not as I do.” Security must be from the top down and may sometimes involve a modification of behavior within the entire organization. Management sets the tone and direction of security through policies, goals, and mission statements. The first step in building a data security program is to have top management state in writing the importance of security and determine what assets are to be protected and at what cost. It also directs and allocates resources to perform a risk analysis for determining what threats and hazards are being faced by which assets and how much it will cost to protect those assets from those threats and hazards. Management must then assume the risk or allocate resources to protect the identified assets to a level it deems appropriate. Management also is responsible for ensuring that all applicable policies and procedures are in place; even if it delegates the authority, it still maintains the responsibility.

Management cannot enforce data security in a vacuum. Employees must assist in data security or it will fail. Employees must ensure that only authorized individuals enter controlled areas where access to secure data and systems can be obtained. They also need to be observant enough to notice when someone is trying to peer over their shoulder to view the information being entered into the system. Employees must be careful of social engineering techniques and be aware enough to block the use of such security-breaking techniques. Social engineering is an act of undermining security by obtaining secure information through the use of deception. For instance, an employee may receive a telephone call from someone pretending to be the secretary of the chief executive officer (CEO) asking for secured information. The employee should realize that a secretary would not be asking for information that would not normally be released over the telephone or in person. Security awareness training can preclude or reduce the occurrence of social engineering.

Another concept related to security is called the “MOM” in security circles. It stands for means, opportunity, and motive. Workers have the means and opportunity to obtain secure data, and all they lack is the motive to cause a data security breach. But although outsiders or hackers may have the means and the motive, security controls will normally block their entry into the network. If the security controls do not block access to the network, the control might slow penetration into the network and give the network administrator a chance to notice and stop the violation. Hackers or crackers are individuals who penetrate secure networks for fun, profit, or fame or to cause havoc within the system. In the past, there was a difference in the meanings of hackers and crackers. Hackers broke into a system for fun and fame, while crackers did it for profit and to cause havoc.

With MOM and the tendency for employees to try to assist superiors over the telephone, a healthcare organization must ensure that its security policies and procedures are up-to-date and relevant. The organization must also use controls during hiring to ensure that the new recruits are trustworthy. Employees should be aware that they will face sanctions if they do not follow policies and procedures. Behavior modification can be achieved through education, observation by the management (seeing that controls apply to everyone no matter who they are), and awareness training.

Role of Technology

Technology is also necessary to ensure data security. Technical procedures and mechanisms must be put into place to control access to systems, networks, and facilities. Detection apparatuses can sense viruses and other malicious software and deny them access to vital systems and networks. Audit logs should be used to track authorized and unauthorized changes to data, but the logs need to be reviewed for inconsistency and possible security violations. Security patches and programs need to be tested before installation into a live system as the patches themselves can cause the introduction of errors or viruses. Security technology must be checked and updated regularly if security levels are to be maintained.

Data security can maintain the confidentiality, integrity, and availability of data only if the laws, management, people, and technology work together to ensure a stable but flexible security program.

DATA SOURCES IN CONDUCTING HEALTH SERVICES RESEARCH

Health services research can be defined as the multidisciplinary field of investigation that studies how social factors, financing systems, organizational structures and processes, health technologies, and personal behaviors affect access to healthcare, the costs and quality of healthcare, and, ultimately, the outcomes of healthcare. Health services research often attempts to influence health policy and the practice of medicine through the analysis of large databases.

Although the list is not exhaustive, health services research generally addresses the following areas: (a) costs, cost-benefit, cost-effectiveness, and other economic aspects of healthcare; (b) patient and population health status/health disparities; (c) outcomes of healthcare technologies and interventions; (d) practice patterns and diffusion of technologies and interventions; (e) quality assurance programs; (f) clinical guidelines, standards, and criteria for healthcare; (g) the need and demand for health services; (h) utilization patterns of health services; (i) patient satisfaction with treatments, providers, and practice settings; (j) organization and delivery of healthcare; and (k) the various means of financing healthcare.

Many federal, state, and trade associations and professional societies actively collect and disseminate data that are used for health services research. At the federal government level, examples include the Agency for Healthcare Research and Quality (AHRQ), the Centers for Medicare and Medicaid Services (CMS), and the National Center for Health Statistics (NCHS). At the state government level, they include departments of public health, departments of health and family services, and health planning and development offices. Examples of trade associations and professional societies include the American Hospital Association (AHA), American Medical Association (AMA), and National Committee for Quality Assurance (NCQA).

Major Databases

To conduct health services research, a large number of publicly accessible databases are available. Below is a brief description of some of the major databases.

Minimum Data Set (MDS)

The Minimum Data Set (MDS) is a part of the federally mandated process for clinical assessment of all residents in Medicare- or Medicaid-certified nursing homes. This process provides a comprehensive assessment of each resident's functional capabilities and helps nursing home staff identify health problems. Resident assessment protocols (RAPs) are a part of this process and provide the foundation on which a resident's individual care

plan is formulated. MDS assessment forms are completed for all residents in certified nursing homes, regardless of the source of payment for the individual resident. The MDS is available from the CMS.

Medicare Current Beneficiary Survey (MCBS)

The Medicare Current Beneficiary Survey (MCBS) is a survey of a nationally representative sample of aged, disabled, and institutionalized Medicare beneficiaries. It is the only comprehensive source of information on the health status, healthcare use and expenditures, health insurance coverage, and socioeconomic and demographic characteristics of the entire spectrum of Medicare beneficiaries. Data from the MCBS are available from the CMS.

Online Survey, Certification, and Reporting (OSCAR)

The Online Survey, Certification, and Reporting (OSCAR) system is a compilation of all data elements collected by surveyors during the inspection conducted at nursing facilities for the purpose of certification for participation in the Medicare and Medicaid programs. It is the most comprehensive source of facility-level information on the operations, patient census, and regulatory compliance of nursing facilities. Data from the OSCAR system are available from the CMS.

Healthcare Cost Report Information System (HCRIS)

The Healthcare Cost Report Information System (HCRIS) contains audited Medicare provider cost reports submitted to the CMS. The HCRIS contains five different cost reports: (1) hospital reports, (2) hospice reports, (3) home health agency reports, (4) renal facility reports, and (5) skilled-nursing facility reports. The H and the Individual Facility Cost Report Information System are available from the CMS.

Area Resource File (ARF)

The Area Resource File (ARF) is a database containing more than 6,000 variables for each of

the nation's counties. It contains information on health facilities, health professionals, measures of resource scarcity, health status, economic activity, health training programs, and socioeconomic and environmental characteristics. ARF is a collection of data from various sources, including the AHA, AMA, and the NCHS. ARF is available from Quality Resource Systems, Inc.

American Hospital Association (AHA) Annual Survey

The AHA's Annual Survey collects information on numerous characteristics of hospitals and their patients. It collects data on the organizational structure, the facilities and services offered, utilization data, physician arrangements, managed-care relationships, and hospital expenses and staffing. The annual survey is the largest and most comprehensive source of information on the nation's hospitals, including the association's member and nonmember hospitals. Data from the annual survey are available from the AHA.

Healthcare Cost and Utilization Project (HCUP)

Healthcare Cost and Utilization Project (HCUP) databases bring together the data collection efforts of state data organizations, hospital associations, private data organizations, and the federal government to create a national information resource of patient-level healthcare data. HCUP databases include the Nationwide Inpatient Sample (NIS), the Kids' Inpatient Database (KID), the State Inpatient Databases (SID), the State Ambulatory Surgery Databases (SASD), and the State Emergency Department Databases (SEDD). Data from HCUP are available from the AHRQ.

National Health Interview Survey (NHIS)

The National Health Interview Survey (NHIS) is the principal source of information on the health of the civilian noninstitutionalized population of the United States. Conducted since 1960 by the NCHS, data from the NHIS are used to monitor national trends in illness and disability and to track progress toward achieving national health objectives. Its questions have remained fairly constant over time,

although new questions are periodically added. The NHIS is available from the NCHS.

National Hospital Ambulatory Medical Care Survey (NHAMCS)

The National Hospital Ambulatory Medical Care Survey (NHAMCS) is a data set on the utilization and provision of ambulatory-care services provided in hospital emergency and outpatient departments. Findings are based on a national sample of visits to the emergency departments and outpatient departments of general and short-stay hospitals, excluding federal, military, and Veterans Health Administration hospitals. The NHAMCS is available from the NCHS.

Surveillance, Epidemiology, and End Results (SEER) Program

The Surveillance, Epidemiology, and End Results (SEER) Program collects and publishes cancer incidence and survival data in the nation. It collects data from population-based cancer registries covering about 26% of the U.S. population. The SEER Program registries routinely collect data on patient demographics, primary tumor site, tumor morphology and stage of diagnosis, first course of treatment, and follow-up for vital status. It is the only comprehensive source of population-based information in the nation that includes stage of cancer at the time of diagnosis and patient survival data. Data from the SEER Program are available from the National Cancer Institute (NCI).

Healthcare Effectiveness Data and Information Set (HEDIS)

The Healthcare Effectiveness Data and Information Set (HEDIS) is a tool used by more than 90% of health plans in the nation to measure performance on important dimensions of care and service. In total, the HEDIS consists of 71 measures across eight domains of care. It is a set of standardized performance measures related to many significant public health issues, such as cancer, heart disease, smoking, asthma, and diabetes. The HEDIS also includes a standardized survey of consumers' experiences that evaluates a health plan's performance in areas such as customer

service, access to care, and claims processing. The HEDIS is available from the NCQA.

Limitations of Available Databases

While conducting research, many health services researchers often combine several databases. This can sometimes be problematic because data sets may be collected at different times using different definitions of variables. Some data sets may have few cases, and the small numbers may make it difficult to extrapolate to the population. Another major problem is missing data. Sensitive questions may have few responders. Finally, although some data sets are given to users for free, others can cost thousands of dollars to purchase.

Ethical Issues

When using databases, health services researchers may encounter ethical challenges that arise from the tension between protecting the individual's privacy and meeting societal needs for information. The most important features of U.S. federal regulations on the protection of human subjects are institutional review boards (IRBs) and informed consent from participants in research studies. Researchers need permission to use secondary data from IRBs.

An IRB is a group that has been formally designated to approve, monitor, and review medical and behavioral research involving humans with the aim of protecting the rights and welfare of the subjects. Furthermore, informed consent is required for any research that directly involves individuals and patients. The purpose of informed consent is to provide subjects information about the research, including its purpose, procedures, risks, and anticipated benefits. It also is the investigator's responsibility to protect the subjects' privacy when conducting research involving human subjects.

DAVIS, KAREN

Karen Davis is the president of the Commonwealth Fund, a large New York City-based, private foundation that promotes healthcare. Davis is a nationally recognized health economist, with an extensive background in health services research and public policy.

A native of Oklahoma, Davis was born in 1942. Davis earned a bachelor's degree (1965) and a doctoral degree in economics (1969) from Rice University in Houston, Texas. She started her career as an assistant professor of economics at

Rice University, teaching from 1968 to 1970. In 1970, she left the university and became a research associate at the Brookings Institution in Washington, D.C. In 1974-1975, while on leave from Brookings, she was a visiting lecturer on economics at Harvard University. She returned to the Brookings Institution as a senior fellow. In 1977, she was appointed deputy assistant secretary for planning and evaluation (health) in the Office of the Secretary of the U.S. Department of Health and Human Services (HHS). In 1980, she became the first woman to ever head a U.S. Public Health Service agency when she became the administrator of the Health Resources Administration. Davis served as the administrator until the end of the Carter administration in 1981. From 1981 to 1992, she was a professor at Johns Hopkins University. She served as chairman of the Department Health Policy and Management at the School of Hygiene and Public Health from 1983 to 1992. In 1992, she left the university to become the executive vice president of the Commonwealth Fund, and in 1995, she became its president.

Throughout her career, Davis has served as a member of numerous healthcare boards and committees. These include the Congressional Budget Office (CBO), Health Advisory Panel; National Academy of Sciences, Institute of Medicine (IOM); Board of Directors of the Geisinger Health System Foundation; Baxter-Allegiance Foundation Prize for Health Services Research Election Committee; Council on the Economic Impact of Health Care Reform; Health Care Executive Forum; President's Council, Health Policy Forum, United Hospital Fund; and Kaiser Commission on Medicaid and the Uninsured.

Davis has authored or coauthored six books, numerous reports, and more than 100 journal articles. Her most recent publications address issues such as access to healthcare, the healthcare problems experienced by the uninsured, various state and national healthcare reform efforts, and the overall performance of healthcare systems.

Davis has received numerous awards and honors for her work. She received the Picker Institute Annual Award for Excellence in Patient-Centered Care and, in 2006, the Academy Health Distinguished Investigator Award. She was made an Alpha Omega Alpha Honorary Member in 2001. She was awarded an honorary doctorate in

humane letters from Johns Hopkins University in 2001. She was given the Baxter-Allegiance Foundation Prize for Health Services Research in 2000. And she received the Rice University Distinguished Alumna Award in 1991.

DAVIS, MICHAEL M.

Michael M. Davis (1879–1971) was a major figure in healthcare policy in the United States. Davis was a pioneer researcher in the economics, quality, and organization of medical care. During his career of more than 50 years, he held executive positions on the Committee on the Costs of Medical Care (CCMC), the Julius Rosenwald

Fund, the Committee for Research on Medical Economics, and the Committee for the Nation's Health.

Born in 1879 in New York City, Michael Davis earned a bachelor's degree (1900) and a doctoral degree (1906) in sociology from Columbia University. While working on his doctoral degree, Davis became interested in the social problems of New York's Lower East Side. In 1905, he had joined the staff of the People's Institute at Cooper Union. He remained at the institute for 5 years, working in social settlements, where he learned firsthand the many problems experienced by immigrants and the poor.

From 1910 to 1920, Davis was the director of the Boston Dispensary, where he investigated the organization, delivery, and financing of health services, a subject to which he was to devote his life. At the dispensary, Davis studied the management and structure of healthcare, its efficiency and evaluation methods, and the interrelations between health professionals and preventive and curative care. He also introduced the idea of a "pay clinic," where patients were charged a fee corresponding to the costs of the services rendered.

In the 1920s, Davis was instrumental in setting up the CCMC, and he served as a member of its executive committee. In 1928, he became the director of medical services at the Julius Rosenwald Fund in Chicago. His department promoted the concept of pay clinics and supported studies leading to the establishment of the Blue Cross system of prepayment of hospital costs.

From 1932 to 1936, Davis was a lecturer in sociology at the University of Chicago, where he was instrumental in establishing the first graduate program in hospital administration in the country, under the auspices of the Graduate School of Business. In 1934–1935, Davis assisted in drafting the Social Security Act.

With a grant from the Rosenwald Fund, Davis established the Committee for Research in Medical Economics in 1936. Under his leadership, the committee funded a wide variety of studies in medical economics. It also published the first journal, *Medical Care*, solely devoted to the economic and social aspects of health services. The journal was published from 1941 to 1944.

In 1945, Davis helped draft President Harry S. Truman's message advocating a national health

insurance program. And in 1946, Davis established and chaired the Committee on the Nation's Health to promote national health insurance. With the election of President Dwight D. Eisenhower in 1952, the prospects of national health insurance diminished, and the committee was eventually abolished in 1956.

Over his long career, Davis authored 12 books and more than 250 articles. Some of his most influential publications include *Dispensaries, Their Management and Development* (with Andrew R. Warner), *Immigrant Health and the Community*, *The Crisis in Hospital Finance and Other Studies in Hospital Economics* (with C. Rufus Rorem), *Public Medical Services*, *America Organizes Medicine*, *Medical Care for Tomorrow*, *America Challenges Medicine*, and "What Are We Heading for in Medical Care?"

Davis's many contributions were recognized by the American Sociological Association (ASA) and the American Public Health Association (APHA). The University of Chicago established a lecture series in his honor in 1963, which continues to the present. Davis gave the first lecture, titled "America Challenges Medicine."

DENTISTS AND DENTAL CARE

Dentistry is a branch of biomedical science addressing the prevention, diagnosis, and treatment of conditions, diseases, and disorders of the teeth, gums, jaws, oral cavity, and adjacent structures.

In most of the world, 4 years of undergraduate study and 4 years in a doctoral program are required to become a dentist. In the United States, a dentist is qualified to practice after graduating with a doctor of dental surgery or doctor of dental medicine degree. There are 56 dental schools in the United States and 10 in Canada.

The majority of practitioners are general dentists, who examine the oral cavity and diagnose and treat diseases, decay, and injuries within it. The American Dental Association (ADA) recognizes nine branches of dental specialization: (1) endodontics, which is root canal therapy, or removing the nerves of teeth; (2) oral and maxillofacial pathology, the detection and diagnosis of diseases

in the oral cavity; (3) oral and maxillofacial radiology, the radiologic interpretation of oral disease; (4) oral surgery, the treatment of oral diseases and abnormalities via surgery; (5) orthodontics, the treatment of abnormalities in tooth position and jaw relationships; (6) pedodontics, the provision of oral care to children; (7) periodontics, the treatment of gum disease; (8) prosthodontics, the creation of artificial teeth and other dental appliances; and (9) public health dentistry, the science of promoting dental health through organized public efforts.

There are other specialties as well, such as general-practice residency (hospital training), cosmetic dentistry, and geriatric dentistry (dental care for older adults).

Dentists often work with dental auxiliaries, including dental assistants (who pass instruments and retract tissues), dental hygienists (who specialize in preventive care, such as cleaning and scaling), and dental technicians (who fabricate dental appliances).

This entry briefly describes the historical development of dental treatment and then discusses the current problems for dentistry and the emerging trends and challenges that dentistry faces.

Historical Development

Historical records indicate that dental treatment existed in the Indus valley of Asia as early as 3300 BCE. In previous centuries, dentistry was not an independent profession and consisted primarily of tooth extractions, performed by everyone from general physicians to barbers.

The 17th-century French physician Pierre Fauchard is considered the father of modern dentistry, as he developed dental prostheses and dental fillings. Porcelain teeth were introduced in the 18th century, and the invention of Vulcanite rubber in the 19th century made dentures more affordable to larger numbers of people.

Nitrous oxide was introduced as an anesthetic in the 1830s. The first dental school, the Baltimore College of Dental Surgery, opened in 1840. Gold foil fillings were invented in 1855 by Robert Arthur. The first crowns were developed in 1880 by Cassius M. Richmond. Fluoridation of water, proven to prevent cavities, began in the 1930s. The

high-speed handpiece, which made dental treatment much less painful, was invented by John Borden in the 1940s.

Problems in Dentistry

There currently are approximately 199,000 dentists in the United States, and there has been no substantial change in the dentist-to-population ratio in the past three decades. However, approximately 35% of dentists are aged 50 years or older, and approximately 20% are older than 60. Although there is no shortage of dentists today, because of the aging dentist population, the number of dentists retiring is expected to exceed the number of new dentists starting in 2014.

There is a maldistribution of dentists in both the United States and Canada as dentists simply do not migrate to certain areas, according to the Academy of General Dentistry (AGD) Council on Dental Care. There also is a severe lack of dentists in rural areas; for example, California, an urban state, has 11.9 times the population of Mississippi, a rural state, but 22.9 times the number of dentists. There is one dentist for every 2,359 residents of rural South Dakota, compared with one for every 1,714 people nationally. The dentists who practice in those areas also tend to be older and close to retirement. There also is a nationwide shortage of dental hygienists.

Although American dental care is considered by some to be the best in the world, the cost of dental care is high and is accessible to, at most, only half of the population. Access to dental care is a serious problem in America today. The U.S. Surgeon General's 2000 report *Oral Health in America* reported that minority, economically disadvantaged, medically compromised, elderly, and rural persons suffered from a lack of oral healthcare. More than 100 million Americans have no dental insurance.

The federal Health Resources and Services Administration (HRSA) reports that 20% of the U.S. population resides in health professional shortage areas (HPSA). According to a Workforce Study by the ADA, 37 states report a lack of practicing dentists in one or more area of the state.

This lack of dental care has far-reaching educational, economic, and health applications. Oral

pain interferes with the daily activities of 4 to 5 million youngsters annually and is the leading cause of missed school days. The Surgeon General's report cited research showing that chronic oral infections can lead to heart and lung diseases, diabetes, stroke, premature births, and low-birth-weight infants.

Because Medicare does not pay for routine oral care, nearly a third of those over 65 years of age have untreated oral disease. More than 100 million Americans are without fluoridated water. Seniors living in rural areas are less likely to have dental insurance, less likely to visit the dentist, and more likely to be edentulous (without teeth) and to have poor dental health than their urban counterparts. With the number of seniors in the United States, currently about 35 million, expected to double by 2030, the problem of providing them with dental care will grow enormously.

Both the very young and the very old are the parts of the population most vulnerable to oral health problems, and they are the parts of the population most lacking oral healthcare.

The lack of access to care is a serious threat to the way dentistry currently is practiced. As the situation has worsened, state governments have stepped in. California and Minnesota has passed legislation allowing foreign dentists to be licensed in those states if they will treat the underserved. North Carolina provides Medicaid funds to pediatricians and nurse practitioners to conduct oral health screenings, apply fluoride varnish, and provide oral-care education to patients. In 19 states, dental auxiliaries have been granted the right to perform some procedures previously reserved for dentists.

If Medicare is altered to include oral care, it will mark perhaps the biggest change in dentistry of all, as the federal government will then be dealing directly with dentists' treatments and payments on a large scale for the first time.

Another threat to dentistry is deprofessionalization—the perception by the public and the public's representatives in government that oral healthcare is not a part of general healthcare.

That perception began in the 1960s, when the dental profession as a whole declined to participate in the Medicare system. It is reinforced today by the focus on dentistry as a business and on cosmetic dentistry in many practices. Cosmetic dentistry is a lucrative part of the profession, but the

emphasis on it confuses members of the public, linking the dentist more in their minds with the cosmetologist and the small-business entrepreneur than with the medical doctor. Such a link creates a risk of the dental profession becoming marginalized.

Still another threat to dentistry is that of the underfunding of public higher education, as many dental schools are part of public universities. After World War II and with the GI Bill, American public higher education was held up as the right of Americans. In the past 20 years, however, that view has shifted to one of higher education being a commodity that is the student's responsibility to fund, not the taxpayer's. Dental education is hit particularly hard by this change in public perception, because dental education is the most expensive of any discipline other than veterinary medicine.

Dentistry therefore runs the risk of becoming the exclusive purview of the well-to-do. If only those who already are financially secure can afford dental school, the lack of access to dental care by the underserved will only increase. Students are leaving dental school with an average debt of \$141,541, according to the ADA, and will make median annual earnings of \$129,920. That \$129,920 brings a good living, but business school or medical school can provide a graduate with an education leading to an even better living. Therefore, dentistry also is running the risk of losing the best and brightest students to other professions.

Another aspect of the crisis in dental education is the shortage in dental faculty. Three decades ago, a practicing dentist and a teaching dentist made approximately the same amount of money. Faculty salaries have not kept up with the rising salaries of practitioners, however, so there now are at least 250 vacant faculty positions around the country. Half the dental educators are over 50 years of age and are expected to retire in the next decade, making the faculty shortage even more acute.

This lack of faculty, along with aging dental school facilities requiring modernization, is expected to result in some older dental schools closing, a trend that has already begun. Some new schools are opening, but they are operating under a very different model. They often do not have a research mission like the older schools do; they charge at least \$50,000 per year in tuition, and that figure precludes them from doing much about diversity in their student population.

Hope for the Future

Yet there are positive signs on the horizon for dentistry as well. The way dentistry is taught and practiced is rapidly changing. As the solo practitioner has been replaced by group practices, and the treatment of existing dental disease has been replaced by preventive dentistry, dental school curricula have been changed as well. Discipline-based educational approaches formerly focused on surgical therapy performed by solo practitioners; now they focus on integrated preventive patient care measures and collegiality. Large lecture halls have been replaced by small-group practices within dental schools, in which students take a collaborative approach, perform Internet research, and work on patients earlier than ever.

Dental school curricula are increasingly focused on prevention, dental public health, research, community-oriented healthcare, behavioral science, cultural sensitivity, ethics, quality assurance, and practice management. In addition, many dental schools are sending students out to practice in community healthcare facilities in order to give them exposure to America's underserved populations.

American dental schools are seeing a generation of students who do not just want to make money but want to make a difference. Schools are educating more students who are interested in public health dentistry. Even those who are not willing to devote their entire career to public health dentistry are showing more interest in practicing in a community clinic a few days a week while they devote the bulk of their time to their private practices. While few young dentists are interested in becoming full-time faculty in dental schools, many are interested in giving back to the profession by teaching part-time. Dental schools are therefore creating new curricula in which a large number of part-time faculty are fulfilling the roles that full-time faculty did previously.

To bring awareness of the problems in dental education and the efforts to solve them to the public and the profession, "Dental Education: Our Legacy—Our Future," a national collaborative effort of partner organizations, has been created. It is underwritten by the American Dental Association Foundation with support from the ADA and is designed to help participating partner organizations, such as dental schools and dental societies,

raise more than \$500 million through 2014, to deal with issues such as faculty shortages, lack of diversity, aging physical and clinical facilities, lagging governmental support, and escalating costs.

The dental schools committed to research are seeking new knowledge vital not just to dentistry but also to medicine as a whole. For example, research on replicating or "cloning" teeth being undertaken at the University of Illinois at Chicago College of Dentistry will influence the replication of other body parts as well. Dentists, already familiar with making replacement body parts, are at the forefront of stem cell science at the University of Michigan.

There are programs in place to ameliorate faculty shortages. For example, the American Dental Education Association (ADEA) Academic Careers Network links potential faculty with open positions. The ADEA/American Association of Dental Research Academic Dental Careers Fellowship Program, supported by the American Dental Association Foundation, provides students who are interested in careers in academic dentistry with paid fellowships and other stipends. The federal HRSA Faculty Loan Repayment Program provides a financial incentive for health professionals from disadvantaged backgrounds to pursue academic careers. The ADA annually hosts a session for practitioners interested in learning about opportunities to join the faculty of dental schools.

There also are programs in place to increase the numbers of dentists who are willing to provide oral care to the underserved. The Robert Wood Johnson Foundation (RWJF) provides a "Pipeline, Profession, and Practice Community-Based Dental Education" grant to several dental schools to help prepare an oral healthcare workforce competent and committed to treating oral diseases in vulnerable populations. The W. K. Kellogg/ADEA Minority Dental Faculty Development Program provides grants to some dental schools to increase the number of its African American, Hispanic American, and Native American faculty.

A gender shift also is occurring in dentistry. Among the active private dental practitioners in the United States, nearly 83% are male, and slightly more than 17% are female. Among recently graduated dentists, those who earned their degrees within the past 10 years, slightly more than 65% are male, and nearly 35% are female. In addition, two thirds

of female dentists are under the age of 45. Women make up nearly 44% of all dental students.

As female dentists have traditionally shown more interest in devoting more of their time to providing oral care to the underserved, this bodes well for the profession. In addition, with women taking more and more leadership roles in organized dentistry, it is expected that dental societies will take an increasingly activist role in solving the access-to-care problem.

The practice of dentistry itself is an attractive profession. With some areas already experiencing a dentist shortage and others about to, dentists can practice just about anywhere they choose. Dentists increasingly keep flexible work schedules, achieving financial independence in a relatively independent environment. Surveys indicate that nearly 95% of dentists are glad they chose dentistry as a career. Dentists enjoy the people-to-people contact and the artistry and creativity inherent in the profession. While they often dislike business, personnel, and administrative issues, firms such as ProCare Dental Group PC have arisen to take such tasks off dentists' hands, allowing them to spend more time practicing.

A technological revolution in dentistry is allowing dentists to provide better care to more people more quickly. Digital radiography, dental lasers, cone-beam tomography, intra-oral cameras, lighting enhancements, and dental implants are some of the technologies that improve dental care every day.

Patients are more aware of and more educated about the need to maintain their dental health and to take responsibility for oral disease prevention, making the modern dentist's job easier as well. Through advertising, they are more aware of specific dental procedures and come to the dentist as educated buyers. Approximately 55% of children between the ages of 5 and 17 have had no tooth decay—another factor that makes the dentist's job easier.

Although some dentists object to it, the American Dental Hygienists Association (ADHA) is working on creating an "advanced dental hygiene practitioner" who would provide diagnosis, preventive, restorative, and therapeutic services to patients. The ADHA assures dentists that it is neither trying to compete with dental practitioners nor taking away hygienists from practitioners. In any case, the new advanced dental hygiene practitioner will

increase the availability of dental care for the public and serve as a liaison between patients and busy dentists, explaining procedures more fully on behalf of the dentist and guide patients in decision making.

Dentistry likely will change both rapidly and greatly in the future. Those educational institutions and practitioners who cannot adjust to the change will have difficulty, but those who can are likely to experience a new golden age of dentistry.

DIABETES

Diabetes mellitus, often referred to simply as diabetes, is not a single disease but a group of metabolic disorders characterized by hyperglycemia (elevated blood glucose) resulting from defects in insulin secretion, insulin action, or both. It is a major public health problem in the United States, affecting 24.1 million individuals, of whom an estimated 6.6 million are undiagnosed. From 2002 to 2007, the number of individuals in the nation diagnosed with diabetes increased from 12.1 to 17.5 million. In addition, an estimated 54 million individuals have abnormalities in glucose tolerance, which places them at high risk for developing diabetes. Approximately one third of the individuals born in the nation during 2000 are likely to develop diabetes during their lifetime. The social, economic, and personal costs of diabetes are enormous. This entry describes the classifications, complications, and risk factors of diabetes. In addition, prevention and complications are discussed, along with the social, economic, and personal costs associated with diabetes. Last, this entry addresses quality-of-life issues and policy implications.

Classification

There are four clinical classifications of diabetes: (1) Type 1 diabetes, (2) Type 2 diabetes, (3) “other specific types,” and (4) gestational diabetes mellitus (GDM). In addition, there are two categories of abnormal glucose tolerance: (1) impaired glucose tolerance (IGT) and (2) impaired fasting glucose (IFG). Type 1 and Type 2 diabetes are the most common forms of diabetes, representing approximately 10% and 90% of the diabetes population, respectively. Gestational diabetes mellitus, a form of diabetes diagnosed during pregnancy, affects 4% of all pregnancies. “Other specific types” of diabetes may result from a variety of factors, including

genetic conditions, surgery, drugs, malnutrition, and infections. IFG is characterized by elevated (though nondiabetic) fasting blood glucose levels, while IGT is characterized by elevated postmeal blood glucose levels. Individuals with IGT and IFG have a substantially increased risk of developing Type 2 diabetes.

Diabetes Complications

A variety of acute and chronic complications are associated with diabetes. The acute complications are medical emergencies and include diabetic ketoacidosis (DKA), hyperosmolar hyperglycemic syndrome (HHS), and hypoglycemia. The chronic complications include disorders associated with microvascular (small vessel) changes in the eyes, nerves, and kidneys, along with macrovascular (large vessel) changes in the heart, veins, and arteries. These changes result in retinopathy (eye disease, e.g., blindness); neuropathy (nerve disease, e.g., nerve damage affecting sensation and pain pathways in the hands and feet, nerve damage affecting the ability to digest food); nephropathy (kidney disease, e.g., end-stage renal disease requiring dialysis or renal transplantation); and premature and accelerated development of coronary heart disease (CHD), cerebrovascular disease, and peripheral vascular disease (PVD). In particular, heart disease and stroke account for 65% of deaths in people with diabetes. Diabetes-related complications are associated with excessive morbidity and mortality from heart disease, blindness, kidney failure, extremity amputations, and other chronic conditions.

Risk Factors

The development of Type 1 diabetes is associated primarily with an autoimmune destruction of the insulin-producing cells of the pancreas and is characterized by a nearly complete loss of insulin secretion. In contrast, Type 2 diabetes is characterized by insulin resistance and decreased insulin secretion. The development of both Type 1 and Type 2 diabetes is initiated by the interplay between genetics and the environment. Type 1 diabetes results when an environmental insult, in an individual genetically predisposed to the disorder, initiates

autoimmune destruction of the insulin-producing cells. The environmental factor initiating this destruction is not known and is an area of intense investigation.

Risk factors for Type 2 diabetes include genetics, age, ethnicity/race, dyslipidemia (excess levels of blood lipids or fats), obesity, hypertension (high blood pressure), prior gestational diabetes, polycystic ovary syndrome, and physical inactivity. Type 2 diabetes, a disease traditionally associated with middle-aged and older adults, has been increasing among children and adolescents. A variety of clinic-based reports and small-population studies indicate that this increased prevalence of Type 2 diabetes is highest among the youth of Native Americans, Blacks, and Hispanics. Currently, there are no large epidemiological studies of Type 2 diabetes among the youth; however, estimates from some urban clinic-based studies range from 30% to 50%.

The increased prevalence of Type 2 diabetes among minority youth is consistent with evidence that diabetes disproportionately affects the ethnic/racial minority populations of the United States. Among adults aged 20 years or older, the national prevalence of Type 2 diabetes is estimated to be 8.7% for Whites, 13.3% for Blacks, 9.5% for Hispanics, and 12.5% for American Indians/Alaskan Natives. In addition, ethnic/racial populations have higher rates of diabetes-related complications. For example, there are higher rates of retinopathy and diabetes-related renal disease in Blacks and Hispanics than in Whites. In particular, diabetes-related renal disease is 2.6 times higher among Blacks than among Whites. Diabetes-related complications among ethnic/racial minority populations are also associated with greater morbidity and mortality. During the years 1979 to 2004, diabetes death rates for Black youths were approximately twice those for White youths. In 2004, the annual average diabetes death rate was estimated at 2.46 per million for Black youths and 0.91 per million for White youths. The burden of the evolving epidemic of Type 2 diabetes, particularly among minority youths, has yet to be realized. As youths with early-onset Type 2 diabetes approach middle age, the excessive mortality and morbidity associated with diabetes-related complications will contribute to the increasing social, economic, and personal burden imposed by diabetes. The reason

why minority groups bear a disproportionate burden of diabetes is multifactorial; however, poor access to healthcare among these groups appears to be a major contributor.

Primary Prevention of Type 2 Diabetes

Weight gain and physical inactivity are the primary factors contributing to the epidemic of Type 2 diabetes. Lifestyle modification, involving change in diet, weight loss, and increase in physical activity, can slow the progression to overt diabetes. The Diabetes Prevention Program (DPP), a large research study sponsored by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), compared the effects of dietary and exercise counseling (control group), intensive dietary and exercise interventions (lifestyle group), and medications (particularly metformin, a popular antidiabetic drug) in preventing diabetes in men and women with IGT. After an average follow-up of 2.8 years, a 58% relative reduction in the progression to diabetes was noted in the lifestyle group, and a 31% relative reduction in the progression of diabetes was noted in the metformin group compared with the control group.

Prevention of Diabetes Complications

As the prevalence of diabetes increases, the complications of the disease also will increase, unless aggressive treatment strategies are implemented. The results of two research studies—the Diabetes Control and Complications Trial (DCCT) and the United Kingdom Prospective Diabetes Study (UKPDS)—clearly indicate that diabetes-related microvascular complications (retinopathy, neuropathy, and nephropathy) could be prevented or reduced by maintaining normal blood glucose levels. In addition, there is evidence that diabetes-related macrovascular complications (CHD, cerebrovascular disease, and PVD) can be reduced by factors such as blood pressure control, lipid control, smoking cessation, and aspirin use. Patients with diabetes can use intricate pharmacological regimens (along with diet and exercise) to normalize blood glucose levels. Newer insulin preparations, insulin delivery systems, oral medications, and blood-glucose-monitoring systems

have been developed to assist patients in maintaining normal blood glucose levels.

There are specific goals for glucose level, blood pressure, and blood lipid concentration. Chronic glucose control is measured periodically by hemoglobin A1C level, which correlates to average blood glucose levels over the previous 3 months. Daily self-management of diabetes requires constant vigilance and adjustment of diet, medications, and physical activity to normalize A1C levels. The best benefits can be achieved when there is a strong problem-solving relationship between the patient and the healthcare provider. This allows the patient to make adjustments to the plan of care (e.g., diet, exercise, oral medications, and/or insulin) in a supportive atmosphere.

Social, Economic, and Personal Costs

Diabetes and its related complications are associated with significant personal, social, and economic costs. National medical expenditures attributed to diabetes in 2007 were estimated at \$174 billion, including \$116 billion in medical costs and \$58 billion in indirect costs. Direct medical costs include expenditures related to hospital inpatient care, diabetes medications and supplies, retail prescriptions for diabetes complications, and physician office visits. Indirect medical costs include the costs resulting from increased absenteeism from work, reduced productivity at work and home, unemployment, disability, and loss of productivity due to premature death. Expenditures for diabetes were attributed to institutional care (\$65.3 billion), outpatient medications and supplies (\$27.7 billion), and outpatient care (\$22.7 billion). In particular, the costs were greatest for inpatient hospital stays (\$58.3 billion), physician's office visits (\$9.8 billion), diabetes medications and supplies (\$14.1 billion), and retail prescriptions (\$12.7 billion).

Individuals with diabetes have medical expenditures that are approximately 2.3 times higher than what expenditures would be in the absence of the disease. Indirect costs related to diabetes include the following: absence from work (\$2.6 billion), reduced performance at work (\$20.0 billion, or a loss of 120 million days), reduced productivity for those not in the workforce (\$0.8 billion), permanent disability (\$7.9 billion), and mortality (\$26.9 billion).

Quality of Life

Diabetes profoundly influences the lives of those affected and their families. Patients with Type 1 diabetes are treated with insulin, diet, and exercise, whereas patients with Type 2 diabetes are treated with diet and exercise and sometimes with insulin and/or oral medications. Patients may use insulin pumps or multiple insulin injections per day. Such a regimen necessitates frequent blood glucose testing with portable glucose monitors. The ability to minimize complications largely depends on the ability and willingness of patients to integrate the treatment regimens into their lifestyle. The ability of patients to integrate treatment regimens is influenced by many factors, including access to a healthcare provider, ability to pay, insurance coverage, perceptions of complication risk, and perception of treatment burden. End-stage complications, such as blindness, have the greatest perceived burden on the quality of life; however, comprehensive treatment regimens also have a high perceived burden on the quality of life. In a recent report, a small group of patients stated that they were willing to give up 8 to 10 years of life in perfect health to avoid life with treatment. The importance of understanding the factors that influence adherence to treatment regimens cannot be overestimated.

Policy Implications

The United States is in the midst of an epidemic of diabetes, which has increased exponentially over the past two decades. Diabetes is associated with a number of acute and chronic medical complications that lead to significant morbidity and mortality. Minority ethnic/racial populations in the nation disproportionately carry the burden of diabetes complications. Lifestyle modification programs, especially those incorporating intensive weight loss and physical-activity interventions, can result in the primary prevention of Type 2 diabetes. In patients with diagnosed diabetes, treatments aimed at normalizing blood glucose levels and controlling risk factors such as hypertension and dyslipidemia can delay the progression and development of diabetes-related complications. Health policy initiatives need to incorporate both primary prevention of diabetes

and prevention of secondary complications from the disease. The challenge to healthcare policy-makers is to balance the personal and societal benefits of preventing and treating diabetes with their monetary costs.

DIAGNOSIS RELATED GROUPS (DRGs)

Diagnosis Related Groups (DRGs) is a system that is used as a part of prospective payment to group cases of patients into more than 500 categories according to similar hospital resource use. DRGs have been used since 1983 by the nation's Medicare program to determine the level of payment to a hospital since patients who are grouped together under the same DRG code are expected to use approximately the same amount of resources. DRGs are important in health services research since all hospitals in the United States must code and are reimbursed by Medicare and other payers through this mechanism. Other nations have also adopted and use the DRG system.

Background

DRGs were first developed by Robert Fetter and John Thompson at Yale University in the early 1970s, with support from the federal agency Health Care Financing Administration (HCFA), now the Centers for Medicare and Medicaid Services (CMS). This system included the Medicare population in addition to newborn, pediatric, and adult populations.

DRGs were first implemented on a large scale in New Jersey in the late 1970s. The New Jersey Department of Health used DRGs as a form of prospective payment whereby hospitals were paid a fixed amount for a given patient. Since 1983, CMS has taken over the control of the Medicare DRG system as a form of prospective payment for hospitals, and the agency has been responsible for any revisions to the definitions for Medicare DRGs.

As a concept, DRGs were originally created to classify hospital admissions of patients who had similar International Classification of Disease, 9th Edition (ICD-9) codes, or ICD-9 codes, so that the relationship between the types of patients that a hospital treated could be used to better understand the costs that the hospital incurred. The general guidelines of DRGs were that they must use patient data that are routinely collected by hospitals, such as ICD-9 codes, age, and gender; they should include patients who have a similar pattern of resource use;

they should include patients with a similar clinical condition; and there should be a manageable number of DRGs that include all types of patients who are encountered as inpatients. The required data elements of a DRG include the principal and secondary diagnosis codes; procedure codes; and patient's age, gender, and discharge disposition.

DRGs are grouped in a hierarchical manner. First, DRGs are grouped into 25 major diagnostic categories (MDCs) that relate to a single organ system or etiology. HIV and multiple significant trauma were the two most recently added MDC groups. Next, MDCs are grouped as either surgical or medical categories. Last, patients in surgical categories are grouped according to the type of procedure performed, while medical patients are grouped according to their principal diagnosis. Some categories under DRGs have been designated with complications and comorbidities (CCs). This represents a condition that causes an increase in the length of stay by at least a day for 75% of patients. Age is also used to define some categories of DRGs.

The first Medicare DRG category is craniotomy with CCs for those greater than or equal to 17 years of age, while Medicare DRG category 316 relates to renal failure. Medicare DRG category 531 is for spinal procedures with CCs.

Critiques and Revisions

The Medicare DRG system has been revised over the years, and updates are generally made available on October 1 every year. In 2007, CMS implemented a significant revision to the Medicare DRG system and regrouped categories. Under version 25, the CCs have been recategorized to include the absence of CCs, the existence of CCs, and the major presence of CCs.

One criticism of the Medicare DRG system is that it does not perform well for nonelderly populations. In the late 1980s, the New York State Health Department conducted an evaluation of the Medicare DRG system and found it to be inadequate for the non-Medicare population. As a result, New York State entered into an agreement with the 3M Corporation to develop necessary revisions to the Medicare DRG system. This resulted in the All-Patient Diagnosis Related Group (AP-DRG) system that supported areas such as

organ transplants, high-risk obstetric care, nutritional issues, pediatrics, and other populations. A limitation of the AP-DRG system has been that there is no common set of formulas across states, unlike the Medicare DRG system, so therefore each state maintains its own information.

CMS has also noted that the MDC 15 does not properly capture the care that is provided to newborns and neonates and that updates to its DRG system have focused primarily on the Medicare population. As a result, CMS has encouraged others to develop or choose other DRG systems that currently exist to fit these needs. In 1986, the National Association of Children's Hospitals and Related Institutions (NACHRI) developed a Pediatric Modified DRG (PM-DRGs) for neonates and the pediatric population.

Although Medicare DRGs were initially developed primarily for payment, there was also a growing need to compare hospitals on the basis of resource use and patient outcomes, examine differences in inpatient mortality across hospitals, evaluate differences in complication rates, and identify continuous quality improvement projects, among others. Thus, the breadth and scope of DRGs needed to be expanded. From 1985 to 1993, HCFA supported two projects at Yale to expand the CCs categorization in addition to further studying severity of illness. These projects resulted in the Refined Diagnosis Related Groups (R-DRGs) and Severity Refined Diagnosis Related Groups (SR-DRGs). To date however, the SR-DRGs have not yet been implemented in practice.

In 1990, the 3M Corporation and NACHRI developed a new and enhanced DRG system that could better capture information on patients of all ages and counter some of the shortcomings of Medicare DRGs. The starting point for this project was the AP-DRGs and PM-DRGs. The expanded DRG system included subclasses for each DRG that would be indicated as minor, moderate, major, or extreme for the severity of illness as well as mortality risk. The end product of this collaboration was the All-Patient Refined Diagnosis Related Groups (APR-DRGs). The APR-DRG system is the only one to include the influence of multiple secondary diagnoses and their relation to the severity of illness and mortality. Thus, the APR-DRG system is able to assess the severity of illness of patients who have multiple comorbidities and has utility for payment

as well as quality-of-care initiatives. As of 2003, Version 20.0 of APR-DRGs has been released, and it includes 25 MDCs and 316 APR-DRG categories that classify a hospitalized patient into a mutually exclusive group. APR-DRGs are used by more than 20 states to compare hospital costs and mortality at more than 1,600 hospitals.

Future Implications

Since its development, the DRG system has been revised and updated by various parties to reflect the many changes in the way healthcare is delivered. The scope of DRGs has been expanded over the years to include reimbursement, benchmarking, and comparison of hospitals as well as other research. Additionally, prospective payment systems for various types of care have been established since the development of Medicare DRGs to include the neonatal, pediatric, long-term care, and Medicaid populations. Prospective payment continues to remain the primary method by which providers are reimbursed for care, and DRGs are the cornerstone of this mechanism.

DIAGNOSTIC AND STATISTICAL MANUAL OF MENTAL DISORDERS (DSM)

The *Diagnostic Statistical Manual of Mental Disorders (DSM)* is an authoritative and comprehensive reference book devoted to the classification of psychiatric illnesses. The main purpose of the *DSM* is to provide a categorical classification system that can be used in clinical practice, research, and administration across healthcare professions. It facilitates communication within the field of mental health by providing a nomenclature that supports the standardized identification of psychiatric symptoms for diagnosis, prognosis, treatment, research, reimbursement of services provided, and medical record keeping. It does not address the causes of mental illness but rather provides a framework for consistent descriptions of various illnesses.

Revisions

The *DSM* has been revised five times over the past 25 years. In 1952, the American Psychiatric Association (APA) published the *DSM-I*. It was 130 pages long, defined 106 separate categories of mental disorders, and contained coding systems used by earlier diagnostic manuals, such as the *Statistical Manual for Mental Diseases*, which was published in 1933. The *DSM-I* also drew from

nomenclature developed by the U.S. Army and the Veterans Administration.

In 1968, the *DSM-II* was published, and it attempted to improve consistency with the International Classification of Diseases (ICD). The ICD is published by the World Health Organization (WHO) for similar reasons that had motivated the development of the *DSM*. The ICD provides an international taxonomy that assigns numerical codes to disease conditions. In the United States, the *DSM* is used in addition to the *ICD* codes. There were many new mental disorders added to the *DSM-II*, increasing the total number of separate categories to 182. Neither the *DSM-I* nor the *DSM-II* attempted to elaborate on specific psychiatric symptoms or their manifestations. Rather, the *DSM-I* and *DSM-II* emphasized the psychological underpinnings of psychiatric disease and were less focused on the itemized symptom clusters that identified the illness. This was an important distinction beginning with the third edition of the *DSM*, *DSM-III*.

The *DSM-III* was published in 1980. It was 494 pages long, and included 265 categories. The *DSM-III* attempted to transition from an explanatory tome of mental disorders to an objective and descriptive model based on empirical data, not theories and hypotheses. The most significant change was that the manual focused on symptom-based diagnostic criteria. Further developments included a multiaxial diagnostic framework that not only included the primary diagnosis but also supplemented it with relevant clinical information on contributing medical, psychosocial, and functional distinctions.

The *DSM-III-R* was published in 1987, and it not only refined definitions of many diagnoses but also included exclusionary criteria to be considered in ruling out a disorder.

After much research, the *DSM-IV* was published in 1994. It had a major focus on empirical research gathered by extensive literature reviews. Almost half of the categories included a clinical aspect, which required specific symptoms that cause impairment in various areas of functioning such as work, school, or social interaction. Many disorders were deleted (i.e., sadistic personality disorder and passive aggressive personality disorder), and other disorders were reorganized. Disorders were also added (e.g., bipolar-II disorder), as well as culture-specific

syndromes and disorders, which focus on age-, race-, and gender-specific problems. Other small changes were made to the nomenclature, such as the renaming of multiple personality disorder to dissociative identity disorder.

The latest version of the *DSM* is the *DSM-IV-TR*. Published in 2000, it consists of minor revisions, such as updating the literature reviews, correcting factual errors, and updating *ICD* codes.

Components

Currently, the *DSM* consists of three major components: diagnostic classification, diagnostic criteria, and descriptive text. The diagnostic classification is a list of the mental disorders, paired with a diagnostic code. The diagnostic criteria consist of a summary of each disorder and include both inclusion criteria, a list of symptoms that must be present and their duration, and exclusion criteria. Diagnoses may include subtypes that further specify the symptom presentation or severity of the illness. The diagnostic criteria component was developed to provide a framework to assist in clinical assessment. The descriptive text describes the diagnostic features, subtypes, culture, age, gender, familial pattern, differential diagnosis, as well as other relevant information.

Multiaxial Framework

The multiaxial system introduced in the *DSM-III* consists of five dimensions called “axis,” used to evaluate the phenomenological aspects of a patient’s mental health. The biopsychosocial model allows for the manual to be applied across different psychiatric disciplines and theoretical orientations. The axial system provides additional information designed to make clear a more comprehensive picture of the patient’s status.

Axis I consists of all major clinical disorders, such as childhood disorders (i.e., attention deficit, disruptive-behavior disorders, and tic disorders); delirium, dementia, amnesic disorder, and other cognitive disorders; mental disorders due to a general medical condition; substance-related disorders (i.e., alcohol or drug addiction); psychotic disorders (i.e., schizophrenia, schizoaffective and delusional disorders); mood disorders (i.e., depressive

disorders and bipolar disorder); anxiety disorders (i.e., generalized anxiety disorder, obsessive-compulsive disorder, and posttraumatic stress disorder); somatoform disorders; factitious disorders; dissociative disorders; sexual and gender identity disorders; eating disorders (i.e., anorexia nervosa and bulimia nervosa); sleep disorders; impulse control disorders (i.e., pathological gambling); and adjustment disorders.

Axis II focuses on disorders that are considered less acute and less responsive to treatment with medication, such as personality disorders and mental retardation. Personality disorders are further grouped in clusters that include specific behavioral patterns. For example, Cluster A consists of paranoid, schizoid, or schizotypal personality disorders. Cluster B contains antisocial, borderline, histrionic, or narcissistic personality disorders. And Cluster C includes avoidant and dependent personality disorders.

Axis III describes general medical conditions that might affect mental illness, such as depression resulting from a cancer diagnosis.

Axis IV contains assessments of psychosocial and environmental problems. There are nine categories of problems, consisting of family, social environment, educational, occupational, housing, economic, access to healthcare, legal system, and other (i.e., disasters and war).

Axis V contains the overall functioning score obtained from the Global Assessment of Functioning Scale (GAF). The GAF rates the social, occupational, and psychological functioning of adults. Scores range from 1 to 100, with a score in the 91 to 100 range meaning that the patient has superior functioning in a wide range of activities and has no symptoms, whereas a score in the 1 to 10 range means that the patient is in continual danger of severely hurting himself or herself or others or has made a serious suicidal attempt. The *DSM-IV-TR* also has specialized scales included in the GAF for Social and Occupational Functioning, Defensive Functioning and Global Assessment of Relational Functioning.

Criticisms

Although the *DSM* is highly regarded, it has been criticized. Some feel that attaching a label to a mental illness can result in a negative social stigma.

Despite attempts to address this through the development of a multiple axial system, the medical model is believed to reduce the patient to a one-dimensional categorical, clinical impression rather than recognize the multidimensional presentations existing along a continuum, which in turn would encourage clinicians to treat the whole person, not simply the diagnosis. Others have criticized the current *DSM* as being too cumbersome. For example, under schizophrenia, there are 69 various combinations of symptoms to fulfill the *DSM-IV* Criterion A and 483 “clinical subtypes,” if seven possible outcomes are taken into account, and many of these symptoms cross criteria and subtypes.

Despite the criticisms, the *DSM* has clearly advanced the field of mental health. The *DSM* has undergone a great shift from its first publication, which consisted of a theoretical basis of the etiology of disorders, to later versions that focus on more empirical data. Inclusion of symptom-based diagnostic criteria, as well as specific inclusion and exclusion criteria, has helped standardize diagnosis of mental disorders in many disciplines worldwide. All these factors have contributed to the *DSM* being recognized and accepted as an important source of information and knowledge. The *DSM-IV* has been translated into 22 languages and is considered the quintessential reference on psychiatric disorders. The next major revision, *DSM-V*, is not expected until 2012 or later, and there is much speculation as to the direction it will take.

DIRECT-TO-CONSUMER ADVERTISING (DTCA)

In healthcare, the term *direct-to-consumer advertising* (DTCA) refers to the promotion of drugs and medical devices by their manufacturers directly to prospective users. Advertising to users via the media, such as newspapers, magazines, radio, television, the Internet, pamphlets and brochures, billboards, and direct mailing, is considered DTCA. Most discussions of DTCA, though, focus on the promotion of prescription drugs, those requiring a physician's order, through mass print and broadcast media, with growing attention to the Internet.

Before 1985, advertising of drugs available only by physician's prescription was directed only at physicians. Advertising directly to consumers is more recent and more controversial. It is legal in only two nations, the United States and New Zealand. The global pharmaceutical industry is lobbying to prevent a proposed ban of

DTCA in New Zealand and to lift bans in Europe and elsewhere.

In 2006, global drug sales totaled \$582 billion (45% in the United States and 30% in Europe), and DTCA expenditures were \$4.5 billion. If DTCA to the European Union (EU) is allowed, it is forecast to run to \$1 billion. From 1997 to 2002, DTCA expenditures in the United States more than doubled. However, the rate of growth in DTCA expenditures has slowed, and pharmaceutical firms still direct 86% of their promotional dollars toward direct marketing to physicians.

History

In the 19th century, promotion of patient medicines in the United States represented the largest print advertising spending by any industry. The federal 1906 Pure Food and Drug Act, passed in response to egregious abuses in the production and representation of food and drugs, was replaced in 1938 by the Food, Drug, and Cosmetic Act (FDCA), which gave the U.S. Food and Drug Administration (FDA) more authority to regulate the labeling of all drugs, then not distinguished as prescription and over-the-counter drugs. The FDCA prohibited "false or misleading labeling." The U.S. Congress assigned the regulation of drug advertising to the U.S. Federal Trade Commission (FTC). In 1951, the Dunham-Humphrey Act legally defined prescription drugs as distinct from those safe for consumers to purchase over the counter. In 1962, the Kefauver-Harris amendments to the FDCA moved prescription drug advertising regulation to the FDA, where it is currently handled by the Center for Drug Evaluation and Research, Division of Drug Marketing, Advertising, and Communications (DDMAC).

Until the early 1980s, prescription drugs were advertised only to physicians, primarily through detailing (company representatives who visited the physicians), sampling (provision of drug samples to physicians' offices), and professional medical journals. The 1962 amended FDCA required that advertisements not be "false or misleading," contain what it called a "brief summary" (relating to side effects, contraindications, and drug effectiveness), and have a "fair balance" coverage of risks and benefits. To supply the brief summary, drug advertisements in medical journals simply reprinted

the FDA-approved product labeling (package insert), constituting at least an entire page of very technical medical information in very small print. The mandated fair-balance requirement specified that the advertisement present an evenhanded account of all clinically relevant information and that the presentation not focus disproportionately on the benefits. Fair balance is measured not only in the quantity of information on both sides but also in quality (major vs. minor risks) and in presentation (legibility, readership, and size of font).

In 1981, after a few companies had tested direct-to-consumer advertisements in the marketplace, the pharmaceutical industry asked the FDA for permission to advertise directly to consumers, touting its educational benefits. Following a voluntary moratorium while it studied the issue, the FDA ruled in 1985 that the standards established in 1962 relating to advertisements to physicians were sufficient to protect consumers. The industry then began direct advertising. The FDA became the overseer of DTCA of the drug by its supplier via print, audio, and visual matter. The rules for DTCA were the same as they had been for advertising to physicians.

The industry quickly returned to the FDA to ask for a variance from the required brief summary, claiming it to be too long, and therefore expensive, for both print and broadcast media. Reflecting a changed political and regulatory environment, the FDA, in 1997, relaxed the requirement for broadcast advertising. It allowed the mention of both the drug's name and the condition it purported to treat (heretofore prohibited), along with a shorter version of the brief summary. In exchange for the condensed information, the advertiser had to make "adequate provision" for access to the complete required information (via Web page, toll-free telephone number, or by mail). Requirements for print advertisement remained the same. Drug advertising increased rapidly thereafter.

The FDA enforcement of its regulations does not include mandatory prescreening of advertisements. When an advertisement goes into use, the manufacturer must submit it to the FDA. If it is found to be in violation, the FDA can send warning letters and untitled letters (for less serious offenses) and occasionally, a request for corrective advertising. These letters are posted on the Center for Drug Evaluation and Research Web site. In

most cases, companies comply, so that the FDA rarely uses its seizure or injunction powers. When the latter does occur, companies become permanently obligated to prescreening of their advertisements and to other restrictions.

However, the FDA is hampered by understaffing, no ability to impose monetary penalties, and under the George W. Bush administration, by a requirement that notices of violations must clear through the Office of the Chief Counsel. Often the violation letters arrive after the natural end of the advertisement's use. The U.S. General Accountability Office (GAO) reports that many companies receive repeated notices of violations, sometimes for the same drug. In 2005, the FDA issued 60 such letters for violations of direct-to-consumer guidelines as compared with 158 in 1998.

Scrutiny and criticism of DTCA by state and local policy officials and organizations such as the APA and the AMA have steadily increased. The withdrawal of the Cox-2 inhibitor Vioxx, one of the most heavily direct-to-consumer promoted drugs in history, precipitated even more controversy. Concern over the advantages and disadvantages of DTCA led the FTC and the FDA to hold hearings in 2003 and 2005, respectively, to gather information about whether the regulations needed to be changed. Testimony ranged from requests for changed regulation regarding presentation of benefits and disadvantages, to an outright ban on all DTCA. The FDA issued more complete guidelines (without the force of law) to help advertisers know what it expected in advertisements. Numerous bills to limit DTCA have been introduced in the U.S. Congress and in the state legislatures.

In response to the heightened attention, the pharmaceutical industry adopted a "govern or be governed" approach to fend off impending government regulation. In 2005, the Pharmaceutical Research and Manufacturers of America (PhRMA), an organization of major U.S. drug companies, approved 15 voluntary guidelines (called "Guiding Principles"), an accountability office, and a panel (appointed by PhRMA) to track signatory company compliance. A total 23 companies signed on to the guidelines that took effect in 2006, but no penalties accrue for violation of the guidelines. Some critics doubt the potential success of the direct-to-consumer guidelines, pointing to the

mixed impact of earlier voluntary industry guidelines regarding physician detailing and continuing medical education. The guidelines call for, among others things, FDA compliant advertising, a clear educational focus, balance of benefits and side-effects, voluntary, pre-use submission of new television advertisements to the FDA for comment, and a delay of unspecified length on DTCA of new drugs until physicians have been educated about them. The national IOM calls for this moratorium to be 2 years (the length of time proposed in an anticipated U.S. Senate proposal), but the drug companies complain that their patent protection is too short to waste that long not advertising to consumers. The AMA's House of Delegates also called for a moratorium on new drug advertising at its 2006 meeting. However, manufacturers are circumventing the voluntary ban by use of more "news" and public relations activities to introduce new products to the public.

In recent years, about three fourths of DTCA went to television advertisements. For 2006, about 5% of DTCA budgets seems to have been diverted from television to magazine advertising. Pharmaceutical firm spending on DTCA has continued to rise but at rates slower than those seen from 1997 to 2005. Compliance with the PhRMA guidelines, changes in television viewer behavior, better-informed but cynical consumers, and the rise of the Internet as a source of information appears to explain this switch from television.

Internet DTCA spending by drug companies is estimated at 1% to 10% of their advertising budgets, and is expected to increase as they change from a scatter-shot mass media approach to one that targets patients with particular diseases. The 1997 FDCA modifications allowing less brief summary information being in broadcast advertisements, companies must make the expanded information available to consumers by telephone, mail, or the Internet. Many U.S. adults prefer the Internet to follow-up on such advertisements. Thus, the act alone feeds millions of self-selected potential patients to the drug Web pages for further information. No specific regulations exist for presentation of information in Web-based sources so those for print and broadcast advertising prevail. In addition to company or specific drug Web sites, companies also sponsor disease Web sites,

banner advertisements, pop-up ads, and e-mails as promotion and may optimize their Web sites to increase "hits." Critics point out that aspects of a Web page may resemble both print and broadcast media and may bridge the rules for labeling and for advertising. In addition, styles of information presentation may make it more or less obvious and accessible on Web pages as opposed to broadcast advertisements or print ads. For example, Web page hierarchy affects how unbiased information may be (e.g., homepage vs. a "deeper" page or number of "clicks" to access).

The EU has banned DTCA, but pharmaceutical industry pressure and, to some extent consumer demand, led observers to predict that the ban will be lifted. The WHO Criteria for Medicinal Drug Promotion says that advertising of prescription drugs should not be allowed. Meantime, as of 2008, New Zealand, the only country besides the United States with legal DTCA, has a voluntary moratorium and is considering a legal ban of such advertising. Pharmaceutical companies are lobbying to prevent a permanent New Zealand ban and to lift the current prohibitions in Europe and Canada. Currently, border crossing Internet advertising defies the bans outside the United States and New Zealand.

Controversy

A variety of issues make up the controversy regarding DTCA. Thousands of studies have failed to find consistent results examining advertising impacts on healthcare utilization and costs, on patient and physician behavior and interaction, and on health outcomes. Drug manufacturers are in favor of DTCA, but advocates and opponents are found in nearly every other stakeholder group—consumers, physicians, insurers, and policy experts. Proponents point to the educational value of advertising that informs consumers about diseases and drugs. Studies show that both consumers and physicians agree that DTCA increases physician visits and physician–patient discussions, and they have shown that some traditionally underdiagnosed disorders (e.g., depression) are found and treated as a result of this interchange. Studies show inconsistent results on the perceived value of that discussion. Consumers report that the advertisements are useful, especially if the physician actually gives

them a prescription. Some physicians like to have informed, questioning patients, while others find it burdensome to spend extra time to disabuse patients of misconceptions.

Proponents claim that the information included in advertisements is valuable to consumers, while many critics and studies show that it is biased, misleading, and confusing. Although consumers cannot actually purchase drugs directly based on advertised information, detractors claim that the quality of information is still important. Critics point out that presenting truthful and balanced information can conflict with a drug manufacturer's primary responsibility—to make money for its stockholders. Studies have shown that some consumers are appropriately skeptical of the information but that other consumers tend to concentrate on the benefits and not on the risks. Physicians report that consumers have unreasonable expectations and focus on the benefits advertised. Furthermore, many consumers assume that advertisements have been approved by a government agency and are, thus, truthful.

Critics fault the advertisements for medicalizing too many conditions (especially those better remedied with lifestyle changes), creating the false hope that there is a pill for every disorder and discounting the importance of lifestyle and behavior changes. Advertisements aimed at youthful consumers (e.g., acne preparations) are questioned, even by some proponents of DTCA. Critics also point to the possibility that advertisements create a sense of fear in consumers. Studies show that when “physicians” and celebrities promote a drug, sales increase despite the fact that the physicians are actors and the celebrities may or may not have ever used the drug. These techniques, plus the use of emotional images and words (rather than factual presentations), are decried by critics as misleading and not educational.

Most studies find that DTCA increases prescribing. Prescriptions for a class of drugs increase when a drug from that class is advertised (not necessarily for the specific drug in the advertisement). Studies are inconclusive about the extent to which the increase is due to necessary treatment of formerly undiagnosed illness or treatment of conditions that probably do not need treatment. In other words, they do not establish whether physicians are prescribing unnecessarily. Proponents point to

the advantage of patients' mentioning their concerns after an advertising prompt. Critics point out that a physician may simply act on the information by prescribing a drug instead of carefully exploring the patient's complaints, possibly resisting the patient's expectations for a drug treatment, or introducing the much harder recommendation for behavior change.

Studies find physicians split on the value of DTCA. Some welcome the more informed patient, but virtually all dislike the pressure they feel to prescribe at all or to prescribe a particular drug. Many report that convincing patients that they do not need a drug is a waste of their time, and some resent the imposition on their autonomy and questioning of their recommendations. Studies have led to recent moves to delay DTCA of new drugs because physicians report being embarrassed when asked for a drug that they have not yet studied.

Much research has explored whether DTCA has an impact on the cost of drugs or of health-care. Certainly, demand is induced by this form of advertising. Exploring the impact of DTCA on prescription drug spending, the Kaiser Family Foundation reports that a 10% increase in DTCA spending results in a 1% increase in sales for the class of drug. The Kaiser studies also found that physicians write prescriptions more for the most heavily advertised drugs. No proof of an exact cause-and-effect relationship has been established, since DTCA is usually accompanied by increased marketing to physicians. However, a 10% increase in spending on promotions to physicians resulted in only a 0.2% to 3% increase in sales as compared with 1% for DTCA. The Kaiser studies also determined that for every \$1 spent on DTCA in 2000, sales increased by \$4.20. Some studies indicate that the advertisements encourage switching to an advertised drug, which is almost always a newer, more expensive option and may also be less well established with regard to efficacy and risks. Certainly, a drug with a brand name costs more than the generic drug, which are not advertised. No evidence has been found indicating that DTCA causes increased drug prices.

Insurers and government programs such as Medicaid report pressure to add new, highly advertised drugs to formularies. Indeed, DTCA creates a “demand pull” that undermines the cost control and utilization limits of insurers and policymakers.

Professional organizations have periodically issued statements on DTCA. For example, the American College of Physicians (ACP), in 1998, supported it in principle but recognized the need for careful regulation to ensure accuracy. Among other recommendations, it suggested that physicians receive DTCA before patients so that they can be prepared. The AMA has issued guidelines for DTCA, and its 2006 House of Delegates called for a moratorium on new-drug advertising. Expressing general support of DTCA, the American Pharmaceutical Association (APhA) calls for enforcement of regulations and suggests that pharmacists be given prerelease knowledge of advertisements.

Future Implications

Most observers agree that DTCA is probably a fixture in the U.S. health marketplace and that Europe and Canada will likely approve it in some form in the future. However, nearly every stakeholder group has critics who are unlikely to go away. Critics call for more specific direction from the FDA regarding accuracy, balance, understandability, and more regulatory authority. In addition, they call for attention to the evolving varieties of advertising (including the Internet and cell phone) that do not fit within the mold of current guidelines.

DISABILITY

While there is widespread agreement that disability is a major concern in every society in the world today, there is considerable controversy about the definition, measurement, demography, healthcare requirements, costs, politics, and personal, familial, and societal consequences of disability. In 2000, the U.S. Census Bureau counted 49.5 million Americans with some type of long-lasting health condition or disability (19.5% of the nation's total noninstitutionalized population). Many individuals (12% of the population) had multiple disabilities, and more than 4% reported a mental disability. Experts think that the rate of mental illness could well be underreported. On a global basis, the World Health Organization WHO estimates that there are 600 million disabled people in the world. The United Nations (UN) estimate is 650 million. Recent global estimates conclude that by 2020, depression will be the number two cause of disability in the world.

The World Bank and other international financial institutions have taken a recent interest in disability because they see it as a major threat to economic development. Indeed, there is general agreement among experts that disability is more common in developing than in developed nations.

Disability Definitions

Disability definitions, which are culturally specific and contested, are used to signify a particular relationship of the individual to bodily norms, social role performance, and society in general. Disability is a condition where individuals are identified as not meeting the potential expected of them by society (expressed through social and cultural norms). People are judged to be disabled because of limitations in their physical and/or mental functioning, lack of social support networks, inability to perform normative social roles, and/or living in a barrier-laden environment that prevents them from fully participating in society. In this context, disability results from a maladaptive interaction between individuals and their environments. The result is often dependency, isolation, and poverty.

Disability definitions are culturally grounded. For example, in the United States, disabilities are typically determined by physicians according to diagnostic categories such as spinal cord injury, multiple sclerosis (MS), and depression. While members of some cultures will say that impotence, infertility, and diabetes are disabilities, according to the medical model, they are seldom classified as such.

Disability definitions are also strongly influenced by politics, ideology, and social policy. Physical disabilities are more likely to be diagnosed and reported than mental illness because of stigma and the added cost burden on governments and private health insurers to cover mental health services. The full effects of these differences are expressed in U.S. social policy and law. A search of federal statutory definitions of disability in the U.S. Code in 2005 revealed that disability was defined 67 times in different ways depending on whether the statute dealt with Veterans Affairs, developmental disabilities, the Fair Housing Act, Social Security Disability Insurance (SSDI), assistive technology, or employment-based legislation. In addition, the interpretation of these definitions is often constricted or relaxed depending on the

state of the economy and the availability of government resources.

Underlying these different definitions and determination of disability is a clash of paradigms used to conceptualize disability. The medical model views disability generally as a problem of the person caused by disease, trauma, or other health conditions and resulting in the need for individual medical care. Individuals are diagnosed and are generally referred to in terms of their primary medical diagnosis. Much of the medical and health services research conducted within this paradigm focuses on functional limitations, return to work, independence, and the performance of social roles.

In contrast, the social model of disability sees disability as a socially created problem. From this perspective, disability is not an attribute of the individual but results from conditions imposed on people by oppressive physical, social, work, transportation, and social policy environments. According to this argument, society has the obligation to make reasonable accommodations to disabled people so that they can be independent and live full lives. The WHO in its International Classification of Functioning, Disability and Health (ICF) has attempted to integrate these two positions by incorporating concepts and measurements of impairment, function, and communication along with those of activity, participation, and consideration of the environments within which disabled people live and perform.

More recent approaches to the understanding of disability have come from scholars such as Amartya Sen and Martha Nussbaum, who conceptualize disability in terms of human capacity and societal development. This approach has both moral and economic components, expressed in the obligations of states to all their citizens and the notion that preventing and dealing with disability will reduce dependency and improve the economic position of states. Disability and human rights advocates have also been using forms of moral arguments, human rights initiatives, and quality-of-life analyses to advance the cause of disabled people based on what is just and right in a society.

Disability as an Outcome

In health services research, disability is conceived as an outcome measured by functional status;

activity performance; role activities such as parenting, employment, and work; community involvement; connectedness in social networks; independence; and quality of life. Newer work sponsored by the Centers for Disease Control and Prevention (CDC) concentrates on the prevention of disability through programs such as enforcing the wearing of helmets when riding a motorcycle, genetic counseling, and prevention of secondary conditions such as bed sores and urinary tract infections related to spinal cord injury. Evaluation and intervention research on disability focuses on programs designed to increase mobility (e.g., wheelchairs, cut curbs, and accessible transportation), improve strength and flexibility (such as exercise and weight-bearing regimens), and keep people in school and at work.

On a familial level, disability outcomes are measured in terms of marital stability, having and raising children, economic self-sufficiency, and accommodation to roles and demands. On the societal level, disability has been measured by the “burden” that it exerts on social welfare systems and care institutions and by dependency and unemployment indices. Most recent work by medical geographers and sociologists examines disability in terms of place. Where one lives has an enormous impact on how one lives and the quality of life. Communities rich in resources and low in disruptive activities such as crime, high poverty, and unemployment can provide health and social support services and living conditions conducive to good health status, independence, and high quality of life.

Structure of Care for Disabled People

Care for disabled people is delivered through a complex set of government, not-for-profit, and private for-profit organizations in the United States. The systems are typically organized along the separate lines of physical and mental health disabilities. This causes problems for individuals who have both physical and mental health disabilities because the sources of care, services, and insurance are often different for physical and mental conditions. In 2005, Medicaid covered the medical and rehabilitation care for 14.6 million disabled and elderly recipients. In 2001, 5.7 million disabled workers received benefits through Social Security Disability Insurance (SSDI), and

1.6 million individuals received SSDI benefits as dependent family members of disabled workers. In 2004, the U.S. Department of Veterans Affairs (VA) provided disability benefits to 2.7 million veterans. In addition to these public programs, many employees have private disability insurance through their jobs and may have access to Worker’s Compensation. This is a program administered at the state level designed to provide medical, rehabilitation, and lost-time costs to injured workers. This contentious program historically has pitted labor and business against each other, with business seeking to limit coverage and costs and labor unions seeking to expand benefits. In 2006, nationally these benefits amounted to approximately \$16.1 billion. Taken together, these insurance programs and their related benefit structures are so complicated that experts suggest that anyone seeking disability benefits or dealing with disability insurance seek the counsel of healthcare experts and legal advice before applying for them. The programs and their interrelationships are not readily transparent to the consumer.

The medical and rehabilitation care structures are composed of government inpatient and outpatient services, care for the poor provided by the government through subcontracts with public and private hospitals, and care reimbursed by private insurance at community and private hospitals and rehabilitation systems and on an outpatient basis at many private rehabilitation clinics. In an effort to respond to pressures from the disability community and to cut costs, a large 5-year Medicaid demonstration project is being launched to evaluate the efficacy of providing long-term care in home and community settings rather than in nursing homes.

Access to Care by Disabled People

Disabled individuals in the United States face myriad challenges in accessing care, receiving appropriate treatment, and availing of rehabilitation services.

The first challenge for disabled people is that many do not have health insurance. According to the U.S. Census Bureau, in 2005, there were 46.6 million uninsured Americans, of whom a disproportionate number are disabled people. The number of uninsured has been growing since 2001. As a result, many disabled people fall into Medicaid by default and/or are forced to seek care for

episodic events in hospital emergency departments. Such utilization of care is crisis oriented and does not promote prevention or continuity of treatment. In an attempt to address some of these issues, Medicaid spending has been authorized to expand access to care for certain children with disabilities.

A second challenge is that there is differential access to care for disabled people depending on whether or not their primary medical diagnosis is for a physical or mental disability. Individuals find it much easier to arrange care for a physical rather than a mental disability such as posttraumatic stress disorder (PTSD) or depression. When individuals have both sorts of disabilities, the physical disability is often dealt with, while the mental disability is ignored or undertreated.

A third challenge to treatment of disability involves continuity of care. Disability and rehabilitation services are often delivered piecemeal and from different sources and programs. The result is that the program of support and care is not integrated and is frequently discontinuous. This can result in logistical nightmares for disabled persons and their families, services offered but not needed, services and support needed but not delivered, and costs involved in stopping and restarting care programs due to lapses in eligibility.

A fourth challenge to care is the bias toward institutionalizing the seriously disabled, mentally ill, and elderly. Such a bias results in a lower quality of life and increased dependency for those institutionalized. There is widespread agreement that the more humane treatment option is to keep disabled people with their families and in their communities as much as possible and to have supportive and care services delivered in this context. As a result, disabled persons can continue to work and be socially engaged with their family and friends instead of being institutionalized.

The fifth challenge to care is that the American approach to disability is strongly dominated by the medical model. In fact, physicians must determine if a person is disabled to receive benefits, they must medically treat the person, they must sign orders, and they must ascertain the person's progress from the disability. Since many physicians are focused on genetic, biological, surgical, radiation, and pharmacological interventions, the importance and expertise of assistive technology, reasonable

accommodations, universal design, social support, architectural, transportation, and diet and exercise professionals is frequently underappreciated. These elements of care may not even be integrated into the treatment plan.

A sixth challenge to care concerns the portability of health insurance. If disabled persons are fired or change jobs, they may find that they are without insurance when they are between jobs and that the prospective employer will not hire them because they are disabled. This leaves them vulnerable unless they immediately qualify for Medicaid or VA benefits. For these reasons, disabled people often remain at their jobs or end up poor.

Cost of Care for Disabled People

The economic costs of disability are enormous. The national Institute of Medicine (IOM) estimates that the total costs of disability in the United States is more than \$300 billion annually, more than 4% of the nation's gross domestic product (GDP). This sum is split about equally into direct costs associated with medical and rehabilitation care and indirect costs due to lost productivity. A critical question facing policymakers is how to allocate scarce resources across different kinds of disability conditions and situations. Current research is addressing whether costs should be considered on the individual level (treatment and support) or on the population level (burden of disability on society). The national Medical Outcomes Study relies on individual-level analysis to measure outcomes, while the Global Burden of Disease research has stressed community- and population-level analyses in describing the costs of disability to society.

On the individual level, current research shows that the costs related to specific conditions such as spinal cord injury, low back pain, ischemic heart disease, brain injury, depression, schizophrenia, and mood disorders vary considerably. Some conditions are much more expensive than others. It is clear that controlling for level of disability, more money is being spent on visible, nonstigmatized conditions such as ischemic heart disease and spinal cord injury than on less visible and stigmatized conditions such as hepatitis C, herpes, mood disorders, and depression. The cost of pharmaceuticals

is another source of high costs when evaluated in terms of desired, efficacious outcomes. Numerous studies have shown that more than 50% of patients with depression and dementia were not being treated with appropriate drugs.

On the population level, there is a tremendous disparity between how much money is being spent on diagnosis and treatment and how much is being spent on prevention and population-based interventions. Only 3% of all healthcare costs in the United States are spent on public health programs and initiatives such as exercise programs for disabled people, education and inoculation against human papillomavirus (HPV), injury prevention, nutrition education, environmental pollution, motorcycle accidents, and disabilities caused by firearms. The return on investment from each type of intervention is enormously different. Public health programs and interventions generally are much more cost-effective than treatment of individual conditions. In addition, intervening upstream is much less costly than waiting for a problem of large proportions to hit. Smoking is an example of this logic. The problem is that intervening on the population level produces heated public debates, while treating a disabled person after the problem has occurred is less contentious in the public's eye. Therefore, cost-effective solutions to disability-producing behavior and conditions and increased funding are unlikely to occur on the population level until problems reach large proportions. Much of this has to do with public values, attitudes, and perceptions and is supported by the strong lobbies of the medical and pharmaceutical sectors of the economy.

Quality of Care for Disabled People

The quality of care for disabled people in the United States is highly variable. On the one hand, care in integrated centers such as the Rehabilitation Institute of Chicago is as good as any in the world. On the other hand, care for poor disabled individuals in the inner city of large urban centers or in rural areas often fails to live up to the same standard.

The recent scandal at the Walter Reed Army Medical Center in Washington, D.C., represents the best and worst of American disability care. Veterans of the Iraq and Afghanistan wars who lost limbs in combat were treated with exemplary

care from injury on the battlefield to transportation, medical-surgical care, provision of prosthetics and assistive devices, and extensive rehabilitation. However, this quality of care is generally reserved for veterans who remain active members of the military and who have certain types of physical disabilities. There are numerous examples of veterans with brain injuries resulting from explosive devices or sniper fire, PTSD, and neurological conditions that were not properly diagnosed or treated. In fact, the rehabilitation potential of many of these veterans was underestimated.

In the civilian disability world, the quality and comprehensiveness of care is predicated on an individual's place in the social structure and on an individual's employment and insurance status. There are different experiences for the poor, the middle class, and the wealthy, for the employed and the unemployed, and for the insured and the uninsured. Hence, there is considerable room for research on health disparities in the disability arena.

Quality of care is usually measured in terms of structure (the resources of the institution, level of training and staffing, staff-patient ratios, and expertise of the providers), process (how much care, of what type, over what period of time, and how comprehensive), and outcomes (lack of complications, level of function, return to school or work, integration into the family and community, and perceived quality of life). National initiatives such as the use of the Functional Index Measure (FIM) to monitor the progress and outcomes of adults, seen at many of the physical rehabilitation units and hospitals in the United States, and similar work by the Vermont-Oxford Network to follow patient progress and outcomes of pediatric patients provide invaluable evidence-based and outcomes data useful for clinical practice and research. Such monitoring and evaluation systems to assess the quality and outcomes of disabling mental health-care are not as well developed or prominent.

Future Implications

The task of balancing costs and quality of care is a persistent topic in contemporary health services research. This theme is reflected in the rapid growth in the disability literature on evidence-based medicine (EBM) and medical outcomes. In

the disability arena, there does not seem to be a strong correspondence between cost and outcomes. For sure, disability is an expensive business, but throwing money at the problem does not necessarily yield the desired benefits. Health services research has much to contribute to disability and rehabilitation outcomes on both the individual and the population levels. These priority areas of interest concern (a) the mix and timing of services, (b) integration of care, (c) consideration of both physical and mental disabilities and their concomitant interactions, (d) reintegration of the individual into the family and community, (e) support that allow individuals to live independently in the community, and (f) reduction of health disparities among disabled people. Encouraging more interdisciplinary work involving healthcare, clinical, and social science researchers would enhance the utility of future research. Even more important, however, is including disabled people in the design and execution of research projects and in translating research into action.

DISEASE

The term *disease* encompasses a broad range of pathologic conditions and, as a concept, is primarily objective in its nature and scope. Any condition that impairs the functioning of an organism may be classified as a disease. This concept is much less complex than the seemingly opposite idea of health. The state of health is more subjective in characterization and, as defined by the World Health Organization (WHO), is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity. Thus, one cannot simply define disease as the absence of health. The presence or absence of disease may, indeed, be strongly correlated with an individual's perceived health status; however, the relationship is not intrinsically linked. There are a multitude of cultural and social influences that alter an individual's state of health as perceived by himself or herself or by his or her community.

Many different classification systems of disease exist; the ancient field of nosology is a branch of medicine that studies the classification of diseases. One common classification system categorizes disease states as extrinsic or intrinsic to the human body or of unknown origin. The extrinsic category of diseases is sometimes referred to as acquired diseases. Exogenous factors that may

contribute to this category of disease include physical, chemical, nutritional, and biological factors. The intrinsic categorization includes hereditary and hypersensitivity (immunologic) disorders.

Extrinsic Diseases

The physical factors that contribute to disease include mechanical injury, nonionizing energy (e.g., electricity, microwaves, radio waves), and ionizing energy (e.g., x-rays, gamma rays, cosmic rays). Currently, in the United States, injury accounts for about 2.3 million hospitalizations each year and is the leading cause of death worldwide in young people between the ages of 10 to 24. The chemical factors that contribute to disease include metallic poisons, nonmetallic inorganic poisons, alcohols, asphyxiants, corrosives, pesticides, medicinals, warfare agents, and hydrocarbons. Many agents within this category of chemical factors may be contributors to certain types of cancers. The nutritional deficiency factors that contribute to disease states include metals (responsible for anemia), nonmetals, proteins, and vitamins. Among the WHO's Millennium Development Goals established in 2000 is the objective to reduce by half the number of people (852 million) who suffer from daily hunger. The biological factors include plants such as tobacco, marijuana, and opium. Cigarette smoking greatly affects the health of persons around the world. Every year, at least 4.9 million people around the globe die from tobacco use. Other biological factors include bacteria, spirochetes, viruses, rickettsia, fungi, parasites, protozoa, and helminthes. Infectious diseases continue to play a prominent role in world public health. However, with the discovery of biological agents as the cause of certain diseases and subsequent medical discoveries such as vaccines and antibiotics, the world has seen significant changes in the disease burden attributable to these factors. In addition, today, biological warfare is of prime political concern in the United States and around the world, with attention being placed heavily on preparation for action by homeland security, medical and public health officials, and law enforcement authorities.

Intrinsic Diseases

Hereditary factors contribute to a sizable number of intrinsic diseases. Diagnoses categorized within this category include diseases such as phenylketonuria, Down syndrome, Turner's syndrome, and diabetes mellitus Type I. It should be noted that diabetes mellitus Type II, as well as other chronic diseases, likely have some genetic component as well. However, these disease states are multifactorial as behavioral factors contribute significantly to the manifestation and progression of these diseases. Currently, chronic diseases are the leading cause of death in the world, causing 29 million deaths worldwide in 2002, an estimated 35 million deaths worldwide in 2005, and an estimated 36.6 million deaths worldwide in 2007. Hypersensitivity factors, as well, contribute greatly to the category of intrinsic diseases, which includes diagnoses such as asthma, lupus, and rheumatoid arthritis.

Diseases of Unknown Origin

Some disease states may not have a clear cause or etiology and are, thus, included within this category. Alzheimer's dementia is an excellent example of a disease classified in this category (although some may place this disorder within a degenerative disease category under the broad classification of acquired, or extrinsic, diseases). The prevalence of Alzheimer's continues to rise in the United States and in other high-income countries.

Other Disease Classification Schemes

The field of pathology investigates the scientific mechanism of the disease process, and as this field of medicine becomes more precise, the cause of many diseases may be found to be multifactorial, and they fall within multiple categories, or they may constitute a not previously recognized categorization. Other disease categories that in more recent years are being recognized, while not adhering well to the historical categorization scheme, include occupational, psychiatric, degenerative, neoplastic (cancer), and iatrogenic diseases.

Diseases may, as well, be described in various manners. For example, some disease states may be acute (severe in symptomatology but short in duration),

while others may be periodic (recurrent) or chronic in nature (of a long duration). Diseases may also be described by organ system, such as cardiovascular, respiratory, and gastrointestinal diseases.

The Medical Approach to Disease

The medical approach to disease centers on the manifestation apparent within the patient. The initial diagnostic clues fall within a category of objective complaints, or symptoms, described by the patient to the medical practitioner. This patient history is elaborated through a series of open-ended, ideally, or closed-ended questions from the medical practitioner, providing him or her with a set of information allowing the narrowing of the differential diagnosis, or diagnostic possibilities. Objective data are obtained through a physical examination, laboratory testing, and diagnostic tests. This information is referred to as signs and allows the practitioner to advance his or her approach to the disease in question through an algorithm. After, or during the process of, a medical decision, a patient may choose to have the practitioner initiate the use of medical or surgical interventions or other therapeutic modalities. Through this method, a disease process is delineated and addressed.

Cultural and Social Aspects of Disease

Medical anthropologists and medical sociologists study the cultural and social aspects of health, illness, and disease. There are many surrounding themes that become critical in the consideration of disease in relation to these issues. The cultural and societal views of life, individualism, morality, and normality, for example, can greatly influence a particular disease state. There may be many social ramifications of being affected by, associated with, and/or even discussing a certain disease. Many disease states have been stigmatized in certain places and times, leading to societal judgments and, in some cases, fear. These types of reactions are not necessarily rational when viewed from a scientific perspective but are, nonetheless, a significant result of the disease state and continuing aspect of the individual's state of health. The impact that these factors have on the patient and his or her family can often be extraordinary. Just

as there are sometimes negative connotations associated with disease states, some cultural and social attitudes may attribute legitimization to disease states or provide social benefits to specific diseases, or disease states in general. For example, through social programs, monetary aid may accompany certain diagnoses, and work expectations are often affected, as well. Ideas of morality and ethical considerations challenge individuals as they attempt to mesh personal considerations of a disease state with societal norms and medical expectations. Bioethical considerations exploring quantity of life versus the importance of quality of life, for example, then become central in the consideration of end-of-life issues.

Disease Acquisition

Medicine is primarily concerned with the diagnosis and cure of disease states within individuals, while public health is concerned with the role that disease plays within a population. Regardless of the level of intervention and study, one aspect that both fields scrutinize is the manner in which disease states are acquired. Risk factors, at the individual or population level, are directly tied to causation. By identifying these factors and understanding the role they play, medicine and public health have a greater understanding of the disease state itself. In addition, the two fields are better equipped to prevent or combat these disease states through this understanding. Commonly recognized categories of risk factors include biologic factors (such as genetic predisposition or age), environmental factors (e.g., air and water quality), lifestyle factors, and psychosocial factors. In consideration of populations—social, economic, and cultural factors have a profound effect on disease and health status. Many factors, at a population level, have been determined to be underlying health determinants that may increase individual risk of disease acquisition and/or severity. Examples of these health determinants include social status, access to healthcare services, educational status, race, and family income. These and many other cultural and social factors influence greatly not only the manner in which disease states may be acquired but also how they are experienced and perceived, as well as the manner in which a community may respond to them.

Disparities and Disease

Individual health behavior does play a significant role in the development of diseases, but many other factors affected by inequities are central to the determination of an individual's health behavior. Addressing issues such as poverty, education, access to healthcare, and special protection for vulnerable groups allows for the possibility of healthy choices. As an example, the primary risk factors contributing to chronic diseases—unhealthy diet, physical inactivity, and tobacco use—are consistent across divisions of economic status, gender, and age. However, the availability of resources plays a key role in the ability of an individual to prevent or combat these conditions. Thus, often, low-income countries experience a “double burden” of disease, simultaneously overwhelmed with the effects of communicable and noncommunicable diseases.

Several misunderstandings surrounding chronic diseases have caused them to be neglected on a global scale, increasing their burden with the passing years. A general view holds that chronic diseases are of significant health concern only in high-income countries and that communicable diseases pose a more significant threat to low- and middle-income countries now and in the future. While the deaths attributable to infectious diseases, maternal and perinatal conditions, and nutritional deficiencies combined are projected to decline by 3% in the world over the next 10 years, deaths due to chronic diseases are projected to increase by 17%. Nearly two thirds of the currently projected 64 million people who will die in the world in 2015 will die of a chronic disease.

The poorest people throughout the world are the most at risk of developing chronic diseases and dying prematurely from them. Poverty leads to increased vulnerability due to associated greater exposure to risks, higher levels of risk behavior, decreased access to healthcare services, social exclusion, increased psychosocial stress, and unhealthy living conditions. This social determinant, thus, is consistent with an environment where healthy choices and opportunities may not be readily available. The critical importance of this fact is that poor health of the community impedes development, which in turn predicts worsening health. Worst yet, low-income countries are affected by a disproportionate share of the burden of

chronic disease, and even in high-income countries, it is apparent that the socioeconomic gap is widening. Thus, as a general rule, around the world, the effects of poverty are increasing.

The Global Burden of Disease

The WHO suggests that disease policy should be based on comprehensive and integrated public health action, intersectoral action, a life course perspective, and a stepwise implementation based on local considerations and needs. It is important to recognize individually and collectively the range of public health priorities to ensure the well-being of the world's population. These priorities include HIV/AIDS, other infectious diseases, hunger, access to healthcare, infrastructure, clean water, mother and child health, and immunizations, among others, in addition to the importance of chronic diseases. It is also critical to recognize the social determinants of health, including the social gradient, stress, early life, social exclusion, work and unemployment, social support, addiction, food, and transportation. It will be necessary in the years to come to build cohesive, comprehensive, and easily accessible health systems and resources around the world in order to address the impact of diseases on individuals, communities, and society at large.

DISEASE MANAGEMENT

Disease management is the concept of improving or sustaining the health outcomes and quality of life of populations with chronic conditions while reducing the cost of healthcare. The aim of disease management programs is to prevent and minimize the effects of chronic conditions or disease in which patient self-care plays an important role. This is achieved through a systematic, population-based approach of identifying individuals who are at risk, intervening through targeted programs, using evidence-based guidelines, and measuring the results and outcomes of these efforts. The model of disease management focuses on coordinating a continuum of care for populations with similar or the same chronic conditions. The components of disease management programs support the provider-patient relationship and the plan of care; focus on the prevention of complications and worsening of the condition through the use of clinical guidelines; and assess patient outcomes and costs on a regular basis with the goal of improving overall health. Disease management is also known by the terms *disease self-management*, *care management*, and *health management programs*.

Background

The rise in the prevalence of chronic diseases has put an enormous strain on the economy because of a reduction in worker productivity and the increase in healthcare expenditures. The rapid escalation in healthcare costs and the pressure to contain costs by the purchasers of healthcare was one of the primary forces that led the way toward disease management. Because of these growing expenditures, purchasers began to question what the relative value of healthcare was for their dollar and started to take a closer look at inappropriate use of services.

Managed-care initiatives were another factor that led the way for disease management initiatives in the late 1980s and early 1990s. Managed care, through its prepayment mechanism and risk sharing with providers, created financial incentives that encouraged the efficient and effective delivery of care as opposed to traditional fee-for-service, which rewarded providers for performing more tests and procedures. Furthermore, because of managed care’s involvement in the continuum of patient care, disease management was more feasible under this model. Based on the concept of case management, managed-care organizations began to look into disease management as an approach to address chronic conditions at the population level. Beginning in the 1990s, disease management programs began to flourish primarily because of the goal of managed care plans to offer their members a product that was of high value.

The pharmaceutical industry was another major force that shaped disease management. Because of the growth in pharmaceutical benefit managers and managed care, the pharmaceutical industry underwent rapid consolidation and integration to increase its leverage in the healthcare market. As a result, the pharmaceutical industry transformed its image from a drug manufacturer to a healthcare company with direct marketing to consumers. Pharmaceutical companies began to offer disease management programs centered on prescription drug use in order to promote patient compliance with medications. These programs often included provider education, patient information, and counseling, and they were then sold to managed-care organizations and employers.

The increased development of clinical practice guidelines also helped facilitate the growth of disease

management. Clinical practice guidelines are generally evidence based, and they represent a systematic approach to treating patients with similar conditions. Managed care's influence over the healthcare system promoted the use of clinical practice guidelines by providers to increase the probability of improved patient outcomes. Finally, research on patient outcomes and cost-effectiveness that cover a variety of conditions has allowed the development of effective disease management strategies.

Because of the several forces described above, disease management programs have gained popularity and have become an accepted method to improve the health of populations with chronic conditions. Disease management programs are designed to address a group of the population that is at risk for chronic conditions. Several aspects of disease management have been around for many years in medical practice; however, this strategy as a concerted effort has taken shape only recently. Disease management programs have not been able to become organized previously due to the fragmented nature of healthcare, minimal data collection efforts, insufficient information technologies, and lack of treatment guidelines. Only recently have disease management programs been able to accelerate in growth due to the enhancement of information technology systems, capitation reimbursement that provided financial incentives to be cost-effective, improved clinical guidelines, and increase in outcomes measurement.

The evolution of disease management programs is described as maturing in sophistication, starting from a program that began with a few services to address chronic disease care to one that focused on targeting the highest-risk patients with outreach and education. This then led to a model with a population-based approach, integrated care, and the use of evidence-based clinical guidelines, and, finally, to a model that aims to optimize health through prevention efforts. The promise and potentials of disease management programs include reduction in healthcare costs and improved patient outcomes.

Disease Management Concept

Disease management has used effective strategies to improve the health of populations with chronic conditions. The aims of disease management include

the improvement in patient outcomes, a patient-centered approach to treating and addressing multiple conditions, and lowering costs by reducing unnecessary or redundant services and costs associated with poor outcomes. Patients may have one or more chronic conditions, and therefore, the coordination of patient care is paramount to reduce duplicative and redundant efforts in disease management programs.

The concept of disease management is different from that of case management in terms of its strategies; however, there are similar shared goals between the two, such as reducing costs and improving patient outcomes through the use of interventions. Whereas case management tends to focus on an individual patient for improving a medical condition on an episodic basis, disease management is population based and is more proactive in its approach. Nursing outreach programs is a strategy that many disease management programs use to provide oversight and support to patients. The nurse typically serves as a point of contact for the coordination of patient care. Medication compliance is another example of a disease management initiative that was used by pharmaceutical companies to increase patient adherence to treatment regimens.

The Disease Management Association of America (DMAA), the organization that represents disease management professionals, has identified six components that disease management programs should contain: (1) the identification of population processes; (2) clinical guidelines that are evidence based; (3) a collaborative practice model that includes self-support providers and the physician; (4) patient education focusing on self-management; (5) performance measures of processes and outcomes, as well as evaluation and management; and (6) routine reporting.

The processes of disease management may include self-management practices, patient education, and provider training. The disease management model is designed to increase communication between patients and providers and provide feedback for necessary behavior modification, as well as to assess the effectiveness of interventions. This model, if it is structured properly, includes a comprehensive approach to patient care that goes beyond the use of medications.

Some of the chronic conditions that disease management has been developed for include

asthma, diabetes, heart failure, hypertension, and chronic obstructive pulmonary disease. Asthma was one of the first targets that disease management practices were developed for because high-cost asthmatic patients are easy to identify, through their medication refills, clinical guidelines, and outcome measures.

Disease management can be offered through different delivery models, such as a contracted carve-out model, or as primary-care case management (PCCM). In the carve-out model, patients with chronic conditions are cared for by disease management organizations that are contracted by a health plan to provide this service. A managed-care plan may contract with a disease management vendor through competitive bids. Under the PCCM model, a specialized team within a managed-care organization helps the primary-care physician to treat patients with chronic conditions. Some early examples of PCCM include Group Health Cooperative of Puget Sound, Harvard Pilgrim Health Care, and Kaiser Health Plan.

Disease Management Design

There are four main parts that constitute a disease management program: (1) claims data analysis, (2) population selection and targeting, (3) intervention, and (4) quality measurement. These components are necessary to achieve lower costs and improved patient outcomes.

Claims Data Analysis and Population Selection

The disease management process entails the substantial use of data to meet the program goals as well as to ensure its effectiveness. Claims data analyses are used to evaluate which medical condition or conditions are the most costly as well as to determine the prevalence of disease within a given population.

Disease management programs are generally designed with the intent of improving care while reducing costs in the long term. Therefore, the next step is to identify the segment of patients with the identified condition(s) who have the highest cost and utilization patterns. The results from the claims data analysis can be used to guide the selection of the patient population that will be targeted for

disease management. By analyzing patient utilization patterns, the Pareto principle generally holds that a small proportion of patients account for the vast majority of the total costs. Approximately 20% of patients are responsible for 80% of health-care expenditures; and therefore, this small group of patients can be targeted with interventions to have the greatest impact in reducing costs. Data can also be analyzed by provider service categories to identify trends in utilization and medical costs. Patient groups can be targeted based on (a) non-compliance of their treatment regimen, (b) a high probability of improved health outcomes or potential for intervention, and (c) inappropriate use of services and utilization that can be reduced. Patients from the claims analysis can also be stratified or selected into specific subgroups based on their belonging to certain categories such as Medicaid, Medicare, managed care, or long-term care.

Intervention

The intervention is the central aspect in the implementation of disease management programs and entails both provider and patient participation. Disease intervention must include both prevention and the proper treatment and management of the given condition.

The intervention goals of the provider are implemented in this phase, and education on the clinical guidelines, the monitoring plan of the patient, and the type of feedback that will be given to the patient are established. Providers are also made aware of the referral programs and case management that are available to patients.

The intervention targeted at the patient can comprise behavior modification, lifestyle change, and health education in addition to the use of medications. This phase also includes baseline assessments, risk assessments, feedback on performance and outcome goals, education on treatment compliance, patient outreach, and other case management activities. The patient intervention may incorporate the use of videos, brochures, and prescription reminders to facilitate compliance and may also include involvement of the family members and caregivers. Disease management programs must be reviewed regularly to reflect updated treatment recommendations and clinical guidelines as well as the accepted standard of care.

Patients who suffer from an acute episode, such as a heart attack, may also need continuity of care to lead to recovery. Aggressive case management may be used as a disease management tool to plan and monitor treatment across the different settings of care. The purpose of case management is to prevent complications and reduce the use of costly and inappropriate services. A recovering patient may need rehabilitation services, home health care, and other services arranged, and therefore, a managed-care organization may assign a case manager to coordinate these needs.

Performance Measurement

The growth in the sophistication of information technology capabilities has allowed disease management programs to be implemented and evaluated. The advancements in information technology systems, such as the electronic medical record, have permitted the measurement and analysis of program performance.

Disease management programs that are successful must have a form of quality measurement. It is essential that disease management programs have realistic, feasible, and measurable goals for program evaluation. Cost, quality, provider and patient satisfaction, and changes in health status should be measured to monitor and evaluate disease management programs. Measurement is an important activity to evaluate whether a disease management program is achieving its objectives.

Three specific dimensions of any disease management program that should be measured to assess quality improvement of patients are (1) structure, (2) performance (process), and (3) outcomes. Examples of structural elements are the organizational and administrative coordination of patients and the delivery of healthcare services.

Performance or process indicators include the measurement of performance and comparing it with predefined targets. To have an effective disease management program, performance indicators must be assessed regularly to track the performance of the program goals and predefined targets by comparing these results with baseline measures through the use of benchmarking. An example of a performance indicator in a diabetes disease management program is the tracking of hemoglobin A1C levels of patients over time. Since

performance measures represent the intermediate measures of an intervention, they can be used to predict patient outcomes.

Finally, outcome measures reflect the end results of a given intervention. The difficulties with outcome measures is that outcomes can take a long period to observe and measure and, as a result, are more challenging and costly to obtain. Because outcomes are frequently difficult and expensive to measure, performance indicators are generally used to assess the effectiveness of disease management programs. An example of an outcome measure in a diabetes disease prevention program is the incidence of blindness due to diabetic retinopathy.

Measurement Instruments

To properly measure if the program is meeting its intended results, appropriate tools or instruments are needed. Some of the instruments used to measure patient outcomes include patient charges, utilization of healthcare services, and patients' general and disease-specific health status.

Cost Assessments

Disease management programs should assess the total costs associated with the treatment of patients. Prior to the implementation of the disease management program, the methodologies used should be defined, and baseline assessments should be conducted to make comparisons after the program implementation. One of the methods most commonly used to assess financial outcomes in disease management programs is the total-population approach. However, the major limitation of this approach is that there is no control group because of the pretest-posttest design that could lead to errors in measurement. The major challenges that remain in evaluating the effectiveness of disease management programs include accurately determining that a program is controlling costs and utilization of services in populations with chronic conditions.

Reimbursement

Providers of disease management programs may be reimbursed through several different mechanisms. These mechanisms include flat fee, flat fee plus incentives, or performance-based reimbursement.

Flat Fee

Flat fee is a reimbursement structure where disease management vendors or providers are paid a set administrative fee, such as per member per month (PMPM), to care for a pool of patients. This fee includes all the administrative expenses related to the pool of patients for disease management activities, but it does not include the costs of direct patient care, such as physician visits or lab tests. Some of the expenses that are covered by the flat fee include patient education materials, case management services, tracking and monitoring patient outcomes, and monitoring patient and provider compliance with treatment goals.

Flat Fee Plus Incentives

The flat-fee-plus-incentives model includes the set administrative fee in addition to a financial incentive for disease management vendors or providers who meet predetermined program objectives. Some examples of these objectives could include decreasing inappropriate emergency room utilization and hospitalizations. Under this payment mechanism, the disease management organization or provider is not obligated to meet the savings goal, and the health plan is placed at financial risk if the minimum savings are not achieved.

Performance Based

Under the performance-based model, disease management organizations are placed at financial risk of repaying administrative fees to the contracted health plan if the minimum savings are not attained. Health plans may place participating disease management organizations at full financial risk if they are not meeting the program objectives and achieving cost savings that offset the administrative fee costs.

Future Implications

Disease management is a strategy that continues to be evaluated and assessed for its utility. Disease management programs have increased tremendously since the 1990s to address the growing population with chronic illnesses and its associated costs. The enhancement and growth of information technologies, evidence-based clinical guidelines,

and measurement systems have permitted the development of disease management programs. Some of the challenges that remain regarding disease management are demonstrating that these programs are actually effective in controlling utilization and costs and improving outcomes of populations with chronic conditions. The tools, technologies, and methods for disease management programs are becoming more sophisticated and hold much promise and potential for achieving this goal.

DIVERSITY IN HEALTHCARE MANAGEMENT

Diversity in healthcare management is important to the nation's healthcare system as a strategy to advance the effectiveness of healthcare organizations and help them achieve greater representation of underrepresented minorities in leadership, improve cultural competence, and decrease the ethnic and racial disparities that exist in the delivery of health services. There are many definitions of diversity. It has been defined as the total collective mixture, made up of "main" ones and "others"; it is not a function of race or gender or any other us-versus-them dyad but a complex and ever-changing blend of attributes, behaviors, and talents. Using this definition as a construct, the Institute for Diversity in Health Management (IFDHM) states that healthcare organizations represent all aspects of society, including—but not limited to—ethnicity, race, national origin, gender, age, physical ability, sexual orientation, religion, and family status. Healthcare institutions should be totally inclusive organizations, which value the differences in their staffs and recognize that diversity adds value to the organization, its mission, and the quality of its programs and services.

Background

In 1992, the American College of Healthcare Executives (ACHE), an international society of healthcare executives, and the National Association of Health Services Executives (NAHSE), an association of African American healthcare executives, conducted a joint study comparing the career attainment of their members. The study, titled *Racial Comparison of Career Attainment in Healthcare Management: Findings of a National Survey of African American and Caucasian Healthcare Executives*, documented that although African Americans and Caucasians had similar educational backgrounds and years of experience

in the field, African Americans held fewer top management positions, worked less often in hospitals, earned 13% less income, and were less satisfied with their jobs.

In 1997, the Association of Hispanic Healthcare Executives (AHHE) and the IFDHM joined ACHE and NAHSE to repeat the study, this time including their Hispanic and Asian members. The study found that ethnic and racially diverse managers earned less than their majority counterparts and felt that they received less respect than Caucasians from supervisors, received less autonomy in doing their work, experienced discriminatory acts in the workplace, and had to be more qualified than their majority counterparts to get ahead in their organizations.

In 2003, the survey sponsors conducted a follow-up study, and many of these findings revealed in the initial study remained present among ethnic and racially diverse managers. In contrast, the follow-up study showed that more than 50% of the Caucasian members did not feel that diversity and inclusion were issues and that improvements were not necessary concerning the lack of qualified minority healthcare leaders. Although some positive strides were observed nationally, it was estimated that less than 2% of all senior healthcare executives were ethnic or racial minorities.

Current Situation

The ranks of healthcare executives, physicians, pharmacists, laboratory technicians, and especially nurses are far less diverse than in the general population, and based on statistics from ACHE, American Hospital Association (AHA), and other healthcare associations, the mismatch is of staggering proportions. This means, among other things, a lack of role models and mentors for members of minority groups, a probable concern that the chances of advancement in healthcare are limited, and the strong possibility that some of the healthcare industries' "best and the brightest" will seek careers in other areas.

Caucasian men still disproportionately hold the top jobs in healthcare, and although this is a pattern common in almost all areas of American society, it has particularly negative implications for healthcare. For one thing, prospective healthcare leaders may be unwilling to commit to careers in a field that is unlikely to offer them the opportunity

to fulfill their potential. For another, succession planning will suffer if current healthcare organization leaders are not willing or able to broaden the pool of aspiring executives. In 2002, the IFDHM warned that many healthcare organizations were struggling with the fact that although they are very diverse in some areas—housekeeping, food service, and plant management, their leadership structure does not reflect the diversity in their own workforce. So when potential employees look for role models, there are none to be found, so they will look outside their own organizations for advancement. It is very important for those who want to be the provider—the employer—of choice to have diversity in leadership.

Future Implications

Societal trends and a rapidly changing demographic picture are forcing many healthcare organizations to realize that they will have to look for new insights, examples, and best practices to help them increase diversity. Frequently, they ask themselves questions regarding how an organization is to succeed in implementing a diversity program if it does not know how to build a business case for diversity. The business case for diversity is unique to each organization. The circumstance, environment, and community demographics of one organization cannot be generalized to another, and there is no one-size-fits-all solution. However, there are some common elements that should be present in designing a business case for diversity. The key components should include the healthcare marketplace, the available talent, and organizational effectiveness, which are all key drivers for the institutional investment in—and commitment to—diversity.

Successful organizations have learned that in today's very dynamic environment, diversity is a competitive advantage for their organizations. For example, the *Fortune Magazine* Top 100 Companies have found that people of color, including women, bring strategic input to their organizations and generate productive dialogue. Different ethnic and racial groups bring vital, diverse perspectives that help their companies succeed.

DONABEDIAN, AVEDIS

Avedis Donabedian (1919–2000) is considered by many to be the father of quality assurance in healthcare. Donabedian is perhaps best known for his structure-process-outcome formulation for quality assessment of healthcare. His research and writing created much of the conceptual underpinnings for quality assessment used today.

Born in Beirut, Lebanon, in 1919 to an Armenian family, Donabedian earned a bachelor's degree in 1940 and a medical degree in 1944 from the American University of Beirut. For a while, he practiced family medicine in Jerusalem but eventually left for the United States. He received a master's degree in public health from Harvard University School of Public Health in 1955. After teaching at several universities, in 1961, Donabedian

joined the faculty of the School of Public Health at the University of Michigan as an associate professor of public health economics. In 1966, he was appointed professor of medical care organization, and in 1979, he became the Nathan Sinai Distinguished Professor of Public Health. He retired from the university in 1989, although he continued to consult, teach, and write.

Donabedian authored or coauthored 11 books and more than 100 journal articles. His seminal work was "Evaluating the Quality of Medical Care." In it, he introduced the concepts of structure, process, and outcome, which to this day make up the model used to evaluate the quality of healthcare. In the model, structure (e.g., number of hospital beds, staffing levels, physician licensing) lays the foundation for process (e.g., medical procedures and surgical operations), and process leads to healthcare outcomes (e.g., complication rates, death rates, length of stays).

Other important publications of his included a large, three-volume set titled *Exploration in Quality Assessment and Monitoring, Vol. 1: The Definition of Quality and Approaches to Its Assessment, Vol. 2: The Criteria and Standards of Quality, and Vol. 3: The Methods and Findings of Quality Assessment and Monitoring: An Illustrated Analysis*. His last book was *An Introduction to Quality Assurance in Health Care*.

Donabedian was a member of a number of prestigious professional societies. Specifically, he was a member of the National Academy of Sciences, Institute of Medicine (IOM); a fellow of the American Public Health Association (APHA); a member of the Association of Teachers of Preventive Medicine; and an honorary fellow of the American College of Hospital Administrators (now the American College of Healthcare Executives,ACHE).

He received numerous awards and honors for his work. The University of Michigan established the Avedis Donabedian Distinguished University Professorship in his honor in 2000. He was awarded the Sedgwick Memorial Medal for Distinguished Service by the APHA in 1999. The Avedis Donabedian Foundation for the improvement of healthcare was created in Barcelona, Spain, in his honor in 1989. He was awarded the Baxter American Foundation Prize for Health Services Research in 1986. He also received the first Richard B. Tobins Award from the American College of Utilization Review Physicians in 1984.

DRUMMOND, MICHAEL

Michael Drummond is a well-known United Kingdom health economist and an expert in healthcare technology assessment. Drummond is a professor of

economics at the University of York and the former director of that university's Centre for Health Economics. He is a prolific writer on the economic evaluations of healthcare treatments and programs, including the following: care of the elderly, neonatal intensive care, immunization programs, services provided to people with AIDS, eye care problems, and pharmaceuticals.

Born in 1948, Drummond attended the University of Birmingham and earned a bachelor's degree in industrial metallurgy in 1970 and a master's degree in commerce and business administration in 1972. Drummond originally considered pursuing a doctoral degree in industrial relations. However, instead, he took advantage of a teaching opportunity in public-sector management at the University of Aston in Birmingham. While teaching a class in quantitative research administration, he became interested in the emerging field of health economics.

Drummond was a research fellow in health economics at the University of York from 1975 to 1978. He left to become a lecturer in health services management at the University of Birmingham. After receiving his doctoral degree in economics in 1983 from the University of York, Drummond became a visiting associate professor in the Department of Clinical Epidemiology and Biostatistics at McMaster University in Ontario, Canada. In 1984, he returned to the University of Birmingham as a senior lecturer and assistant director of the university's Health Services Management Centre. He served as the director of that center from 1986 to 1990. In 1990, Drummond accepted the position of professor of economics and became the director of the Centre for Health Economics at the University of York. He served as the director of that center until 2005.

Drummond has served as a consultant to a number of organizations, including the World Health Organization (WHO). He also was the project leader of the European Union Project on the Methodology of Economic Appraisal of Health Technology. Drummond also has served on the board of directors of the International Society of Technology Assessment in Health Care (ISTAHC) and was the president of the International Society for Pharmacoeconomics and Outcomes Research (ISPOR).

Drummond is a prolific researcher and writer. He has authored or coauthored two major textbooks

and more than 500 scientific journal articles on various topics. His most noted book is *Methods for the Economic Evaluation of Health Care Programmes*. He also serves on the editorial boards of a number of academic journals, including *Pharmacoeconomics*, *British Journal of Medical Economics*, *Journal of Evaluation in Clinical Practice*, and the *European Journal of Health Economics*.

In his long career, Drummond has received numerous awards and honors. In 2004, he was awarded the Avedis Donabedian Lifetime Achievement Award by the ISPOR—that organization's highest award. In 2008, he was awarded an honorary doctoral degree from the City University, London.

Currently, Drummond continues to work on the methods and practices of economic evaluations in healthcare. He also chairs a guidelines review panel for the United Kingdom's National Institute for Health and Clinical Excellence (NICE).

E

ECONOMIC BARRIERS TO HEALTHCARE

Economic barriers to healthcare are economic or market-based factors that impede an individual's ability to access healthcare services. These barriers increase the costs associated with accessing healthcare and may prevent an individual from obtaining necessary preventive, chronic, or acute healthcare. Economic barriers to healthcare may ultimately increase the costs of care from both the individual and the societal perspectives by increasing the likelihood of an individual becoming ill, increasing the severity of illness, or both, thereby increasing the healthcare resources needed to treat the illness. In addition, by reducing the quality and quantity of care provided, they decrease an individual's stock of health capital. Common economic barriers include lack of access to health insurance coverage and other factors such as out-of-pocket costs and income, among others. Each of these barriers may interact with others such as ethnic and racial, and geographic barriers to healthcare, thereby further intensifying the challenges in accessing needed care.

Access to Health Insurance Coverage

While health insurance coverage is not the only economic barrier to healthcare services, it is one of the most important barriers in the United States, and it is closely tied to other barriers.

Access to health insurance coverage is driven by a number of factors—whether an individual is employed full- or part-time, whether an employer offers one or more health insurance plans, whether an individual qualifies for coverage through federal or state programs, such as Medicaid and the State Children's Health Insurance Program (SCHIP), the cost of health insurance premiums, as well as enrollee cost-sharing obligations.

Employer-Sponsored Health Insurance Coverage

In the United States, obtaining health insurance coverage through an individual's employer has historically been the most common mechanism for individuals under age 65, although employment is not a guarantee of coverage. When health insurance coverage is tied to employment, recessions and economic booms can have a significant impact on access to employer-based insurance plans for those who are employed due to the effect on labor markets (e.g., a shift between full- and part-time employment) as well as an employer's provision of health insurance coverage and its contribution to health insurance premiums. Health insurance coverage is a benefit provided to employees—in times of economic prosperity, robust health insurance coverage may be an important attraction to the firm; in times of economic downturn, employers may reduce health insurance coverage as a means to reduce costs.

Even when employed, individuals face barriers to accessing health insurance coverage. For lower-wage

earners, the cost of the health insurance premium may be unaffordable relative to the wages earned. Premiums for workers employed less than full-time are often higher than premiums for workers employed full-time. In addition, employers may have a waiting period before health insurance benefits are effective. Access to employer-sponsored health insurance coverage is an important enough benefit that it is not uncommon for individuals to choose to remain employed with a particular firm simply to maintain their health insurance benefits, and this close link between employment and coverage reduces job mobility.

In employer-sponsored health insurance, employers generally subsidize the cost of the premiums, such that employees bear only a portion of the total premium cost, and since employers may be able to better spread risk as well as have a healthier worker base than that in the general population, aggregate premiums may be lower than those available in the open market. Individuals who are self-employed can purchase an individual health insurance policy through the open market; however, they bear the full cost of the premium themselves. In addition, health insurance plans available through the open market often exclude or increase the cost of premiums for individuals with preexisting medical conditions or other risk factors. Even though options are available for self-employed persons, self-employment by itself is a barrier to accessing coverage.

Government-Sponsored Health Insurance Coverage

The federal and state governments offer health insurance programs in which individuals must meet specific eligibility requirements to enroll. It is a common misperception that all low-income individuals qualify for publicly provided health insurance coverage. While nearly all adults 65 years of age or older have access to Medicare coverage, individuals under age 65 have no guaranteed coverage in the United States. Several government programs provide coverage to narrowly defined groups of individuals without access to private health insurance coverage, but many individuals are not eligible for any of these programs. For example, individuals under age 65 with permanent disabilities may qualify for Medicare. However, Medicare eligibility is tied to the eligibility for

Social Security Disability Income benefits (SSDI). Disabled adults enrolled in SSDI must wait 24 months before receiving Medicare benefits, and SSDI has strict criteria for eligibility. Low-income disabled adults may also qualify for Supplemental Security Income (SSI) and Medicaid benefits, but again, these programs have stringent eligibility requirements.

Likewise, state programs such as Medicaid and SCHIP cover certain groups of low-income individuals, and eligibility is based on various requirements, including age; whether the individual is pregnant, disabled, or blind; income and assets of the individual; and whether the individual is a U.S. citizen or a legal immigrant. As a state-administered program, each state has its own eligibility and reenrollment requirements (e.g., reenrollment every 6 months, 1 year, or 2 years; passive reenrollment vs. active reenrollment), which serve as an additional barrier to accessing health insurance coverage. Although an individual gains coverage through a public program, it does not mean that he or she is indefinitely guaranteed coverage.

The Uninsured

Individuals without health insurance coverage experience the greatest barriers to accessing the healthcare system. While a safety net of public hospitals, community health centers, and hospital emergency departments exists, obtaining care through these venues is a challenge. While an individual's out-of-pocket costs at safety net providers are minimal, long wait times for medical or surgical services or to obtain medications remain significant barriers to care. Safety net providers may not have access to the newest and most advanced technology, further limiting access to high-quality care. In addition, service cuts by safety net hospitals as cost-cutting measures can eliminate access to certain types of care through these providers.

Other Economic Barriers

Out-of-Pocket Costs

The out-of-pocket costs of healthcare are an important economic barrier to accessing services, regardless of health insurance coverage. Uninsured individuals have historically been charged more

for healthcare services than those with health insurance coverage, due to the ability of health insurers to negotiate lower rates than those charged by healthcare providers.

Out-of-pocket costs remain a significant barrier for many with health insurance coverage. While premium costs are a barrier to accessing health insurance coverage, demand-side cost-sharing mechanisms also serve as an additional barrier to insured individuals, once they have coverage. Deductibles, coinsurance, and copayment amounts are designed to discourage unnecessary utilization, thereby reducing ex post moral hazard; however, they also may be a barrier to obtaining needed care.

Health insurance products that shift more risk to the individual enrollee, thereby increasing deductibles, coinsurance, and/or copayments, also increase barriers to healthcare. While premiums may decrease as more risk shifts to the enrollee, the trade-off with an increased risk is larger out-of-pocket payments when healthcare is obtained. While these products are designed to discourage unnecessary utilization, they also prevent some from accessing needed healthcare.

Income

While income is an important factor in whether individuals can afford to enroll in a health insurance plan through either their employer or directly in the open market or qualify for coverage through a public program, income serves as an additional barrier, independent of obtaining health insurance coverage. Income relates directly to an individual's direct ability to pay the out-of-pocket costs of healthcare services (or pay the coinsurance or deductible for healthcare services). In addition, income may be a barrier in accessing healthcare due to the travel costs associated with getting to a provider. While a sufficiently low income may help qualify some individuals for publicly provided health insurance coverage, other economic barriers related to having a low income may still prevent an individual from obtaining needed care.

Implications

The implications of these economic barriers that reduce access to healthcare services are enormous. These barriers—a lack of health insurance coverage,

high out-of-pocket costs, and low income—are associated with lower health status and an increased risk of mortality.

Second, when individuals delay necessary healthcare because of any of these factors, they have an increased likelihood of exacerbating their current medical condition, becoming ill in the future, and when ill, becoming more severely ill than those who obtain needed care on a timely basis. Delays in needed care ultimately drive up healthcare costs for both the individual and society more generally.

Third, barriers to appropriate primary and preventive healthcare services, such as a lack of preventive and primary-care providers in convenient locations with evening and weekend hours to serve working people, increase healthcare costs to the system, shifting costs to hospital emergency departments, which are often already overcrowded as well as a more expensive delivery setting. Similar effects occur with barriers to specialty and subspecialty care but may also increase the need for hospitalization.

Finally, delays in care that ultimately increase the total out-of-pocket amount paid by an individual may have a collateral effect of increasing medical debt, and this medical debt may serve as a barrier to accessing healthcare in the future, either because individuals do not want to seek care at a provider to whom they owe money or because the facility will not provide services until the debt is repaid.

Future Implications

Expanding health insurance coverage is not a guarantee of access to healthcare, nor is it the single solution to eliminating economic barriers to healthcare more broadly. Even with public insurance coverage, low-income individuals continue to face barriers to accessing the healthcare system. The availability of healthcare providers who accept patients with Medicaid or SCHIP coverage in some geographic areas, for example, limits access. In addition, even with public insurance coverage, having a low income makes it more difficult to travel to a provider and to the extent that lower-income individuals work in jobs that are less flexible, for example, they face greater financial costs when seeking medical care due to the need to take vacation or sick or unpaid time from work to see a healthcare provider. In addition, individuals with health insurance coverage face

increasing out-of-pocket costs for healthcare, which affects not only lower-income individuals but also those in the middle-income bracket.

Healthcare reform proposals aim to increase health insurance coverage to a larger group of individuals, either through a single-payer system or through a combination of private and public health insurance plans, and these plans may expand coverage, particularly for lower-income adults and children who did not previously qualify for federal or state programs and lower-income workers who could not otherwise afford healthcare coverage. While expanding health insurance coverage will reduce one barrier, other barriers will continue to persist without targeted interventions. Society is not one of limitless resources—healthcare costs have historically served as a mechanism to ration healthcare. Increasing health insurance coverage through the expansion of public programs, such as Medicaid and SCHIP, for example, to a broader range of low-income adults and children will increase coverage but does not guarantee access to care. Policymakers must also consider how to ensure an adequate supply of healthcare providers who are geographically distributed in order to provide easy access to enrolled individuals. The interrelation among economic and noneconomic barriers to care must be considered in concert to ensure that solutions to reduce one barrier do not exacerbate barriers to care in other ways. Changes to the financing of healthcare, for example, must be considered in light of the effects on access to care. When considered as a system, long-lasting solutions to these barriers can be designed and implemented.

ECONOMIC RECESSIONS

Economic recessions periodically occur in all the world's economies. Despite the importance of recessions, there has been relatively little conclusive research conducted on their impact on a population's health and healthcare providers. Those few researchers who have studied the issue tend to break into two camps. In the one camp, economists and public health researchers argue that recessions and health are countercyclical; that is, as the economy deteriorates, more individuals become ill and seek out healthcare services thereby placing a strain on healthcare providers. In contrast, researchers in the other camp argue that recessions and health are procyclical; that is, as the economy deteriorates, fewer individuals have the economic resources to pursue unhealthy behaviors such as overeating, smoking, and consuming

alcohol, which lead to improved health and decreased healthcare utilization. Both camps study the issue by focusing on mortality data and/or healthcare utilization data.

Definition of Economic Recession

Economic recession is defined in macroeconomic theory as two or more calendar quarters of consecutive decline in a nation's gross domestic product (GDP). The National Bureau of Economic Research (NBER) more broadly defines recession as a significant decline in economic activity spread across the economy, lasting more than a few months. Recession may also have accompanying declines in employment rates, among other measures of a nation's economic health such as business profitability, stock market performance, and inflation.

Definition of Health and Healthcare Measures

The study of economic recession effects on a population's health includes the analysis of aggregate health outcome statistics, such as the overall population mortality and disease-specific mortality and morbidity. Most researchers have studied the relationship of unemployment and population health using mortality data, while few have studied the relationship of unemployment and morbidity.

Mortality and Morbidity

Mortality, a commonly used public health index, is a very crude measure of the health of a population. The crude death rate is calculated as the total number of deaths in a year for a geographic area divided by the average midyear population expressed per 1,000 people. There are many ways to refine mortality rates, including adjusting for the population's age (age-specific death rate), causes of death (cause-specific death rate), and the period around birth (e.g., infant mortality rate, neonatal mortality rate, maternal mortality rate).

In the study of morbidity, defined as the relative incidence of disease, the earliest attempts by

government to investigate disease occurrences were related to the need to contain serious infectious diseases, such as smallpox, diphtheria, and yellow fever. To this was added the goal of studying the distribution of diseases. In their focus on patients as individuals, practicing physicians are likely to be relatively unconcerned with their role in contributing to a community-wide network of information about disease. However, through the use of medical billing data, the incidence of disease across networks can be determined as patients present to healthcare facilities. Morbidity can therefore be analyzed by studying utilization of healthcare services and can be a useful measure of the effects of unemployment on a population's health over time.

Healthcare Utilization

The analysis of the effects of economic recession on the utilization of healthcare services generally focuses on inpatient hospitalization but may also include an analysis of outpatient services. Inpatient hospitalization (generally defined as an overnight stay in a hospital for more than 24 hours) analysis is more common given that data are uniformly and consistently gathered by hospitals through federal requirements for participating in the Medicare program. Data are captured in a uniform billing (UB) data set made available to researchers and practitioners typically through state public health departments or hospital associations. Outpatient data are less reliably captured and inconsistently reported on and therefore are not well suited for health services research.

Health Problems and Economic Recession

One of the first researchers to study the relationship between unemployment and health in the United States was M. Harvey Brenner. In the late 1960s, Brenner studied the effect of economic change on the patterns of psychiatric hospitalizations and psychopathological conditions in general. He initially studied the effects of economic change on the mental hospitalization levels of various socioeconomic groups. Brenner found that it was not necessarily the traditional poor alone who became psychiatric victims of precipitating economic stress—under sufficient economic

pressure, members of all socioeconomic stratum responded in terms of mental hospitalization. Hospital utilization—a surrogate for the incidence of disease or morbidity—in the larger population, therefore, increased during times of increasing unemployment and declining gross domestic product growth. As unemployment increased, the incidence in job-loss related stress and macroeconomic stressors increased, thereby increasing the utilization of mental health services.

Economic recession appears to increase the probability of a variety of losses and social changes that potentially threaten health in at least three ways: Poverty or lack of material resources to meet the ordinary requirements as well as the extraordinary problems of life can affect many of the unemployed and others who experience financial loss; the psychological stress associated with financial loss is potentially damaging itself, especially if it leads to withdrawal and the loss of potentially beneficial relationships; and attempts to alleviate psychological distress by medicating with alcohol or legal and illegal drugs, by overeating or under-eating, or by smoking tobacco will tend to exacerbate existing morbidity and produce additional health problems.

In a more recent mental health example, there is an emerging area of research related to the post-9/11 terrorist attack on New York City's World Trade Center and healthcare utilization. In a public health phenomenon that may be described as posttraumatic stress, for weeks after the attack, residents in New York City and other cities in the nation went to hospital emergency departments in increasing numbers with stress-related diagnoses.

Health Benefits and Economic Recession

Recent research conducted by Christopher J. Rhum and others suggests that health may actually improve during times of increasing unemployment and declining GDP growth. The driving macroeconomic theory is that during times of economic expansion, as relatively more consumers enjoy larger amounts of disposable income, consumers assume greater amounts of risk-associated buying behavior. Examples include purchasing luxury automobiles, smoking, and consuming alcoholic beverages. When this phenomenon occurs, the incidence of health-related problems

associated with the risk behavior increases. So, for example, as more consumers smoke because they have the resources to do so, the incidence of lung-related cancers increases over time. Or, similarly, as more people consume more alcoholic beverages and drive automobiles, the incidence of motor-vehicle-related fatalities increases.

In this relationship, the total mortality rate, age-specific mortality rates, as well as most specific mortality causes are procyclical or increase during times of economic expansion. Fixed-effect models are estimated using longitudinal data, with health proxied by total and age-specific mortality rates and 10 specific causes of death. The 10 causes of death included cancer (malignant neoplasms), heart disease (cardiovascular diseases), pneumonia and influenza, chronic liver diseases, motor vehicle accidents, suicide, homicide, other accidents, neonatal mortality (death within 28 days after birth), and infant mortality. These 10 conditions accounted for approximately 80% of all mortality in the United States, on average. In addition, microdata from the Behavioral Risk Factor Surveillance System (BRFSS) were used to examine how risky behaviors and time-sensitive health investments in physical activity, diet, and preventive medical care vary with the status of the U.S. economy.

It was found that health improves when the economy temporarily declines—state unemployment rates are negatively and significantly related to total mortality in 8 of the 10 specific causes of mortality, with suicides representing an important exception. The variation in death rates is strongest for those causes and age groups where fluctuations are most plausible, and there is some evidence that the unfavorable health effects of temporary upturns in the economy are partially or fully offset if the economic growth is long lasting. Consistent with these results, the microdata revealed that joblessness is associated with reduced smoking and obesity, increased physical activity, and improved diet. The number of medical problems, the prevalence of acute morbidities, and the number of reported inpatient bed-days decreased during economic recessions. A 1-percentage-point rise in a state unemployment rate, relative to its historical average, is associated with a 0.5% to 0.6% decrease in total mortality; Rhum therefore concludes that economic recessions are “good for your health.”

Effects of Health Insurance on Economic-Related Mortality

There are differences across social insurance systems where stronger procyclical fluctuations might occur in nations with relatively weak social protections if individuals have incentives to work particularly hard during good economic times to offset the effects of reduced incomes during downturns. Conversely, an employment-based system of health insurance, such as in the United States, may imply higher rates of insurance coverage during macroeconomic expansions. It has been shown that procyclical fluctuations in mortality are much stronger in nations with weak social insurance programs. These results occur despite a protective effect of income, which, not surprisingly, is more pronounced in nations with weaker social safety nets.

The Underemployed

There is another group that is affected by economic change—the underemployed. Underemployment is defined as the condition in which people in a labor force are employed at less than full-time or regular jobs or at jobs inadequate with respect to their training or economic needs. Most studies on the relationship between unemployment status and health have contrasted just two conditions, employment versus unemployment. Because the underemployed share some of the more stressful features of unemployment, such as decreased income, status, or time structure, it seems plausible that they could produce adverse effects on health similar to those reported for unemployment.

Future Implications

The question of whether health and healthcare utilization is influenced by economic fluctuations is of significant interest from a number of perspectives. The importance of clarifying the relationship between economic recession, individual health, and the health of populations is foremost among them. It is possible that a recession lowers the mortality risk for some individuals while worsening the health status of other individuals, but short of increased mortality. This need not contradict the

evidence for the negative effects of unemployment on some health aspects for at least some people. The public-policy implications of the research indicate a focus on how the negative impact of economic upturns on mortality rates can be mitigated, if not avoided. These questions have profound implications for the development of national policies that influence economic expansion/recession and, by relation, those that influence the health of the population. Clarifying the relationship between economic downturn and the effect on the healthcare delivery system as a whole is also of utmost importance. If patterns of healthcare utilization change as a result of economic recession, healthcare delivery systems must adjust to meet either increasing or decreasing demand for services.

Although the evidence is far from conclusive, recent research appears to show that there is a procyclical relationship between recession and health and that mortality decreases during economic downturns. However, much more research needs to be conducted to address the specific relationships for particular diseases and various population groups, including those who are insured, underinsured, and underemployed.

ECONOMIC SPILLOVER

Economic spillover, also referred to as an externality, is a cost or benefit that is created by an individual or a firm that also affects other parties in a way that is not captured by the price, or that spills over to other consumers or producers. Economic spillover is often classified as either a consumption or a production externality. A consumption externality is associated with the consumption of a good or service that creates costs or benefits for other members of society, and a production externality is associated with the production of a good or service that creates costs or benefits for other members of society. Externalities may be positive, generating benefits for other consumers or producers, such that the societal benefits of the transaction are greater than the private benefits borne by the producer or consumer. They may also be negative, generating costs for other consumers or producers, such that the societal costs are greater than the private costs borne by the individual producer or consumer.

Examples of Externalities in Healthcare

General Examples of Externalities

Examples of externalities abound in the healthcare market. The market for immunizations is one example of a positive externality. While an

immunization prevents or reduces the risk of an individual contracting a disease, it has an additional benefit of protecting the immunized individual from spreading the disease to other members of society. When an individual makes a decision about whether to obtain an immunization, however, he makes this decision based on his marginal cost of the immunization compared with his marginal benefit of preventing himself from contracting the disease. Because spreading the disease to others bears no cost to the individual, it is not a factor in his decision. From the societal perspective, too few people will obtain immunizations if they bear the full cost.

An example of a negative externality relates to smoking. Smoking generates secondhand smoke, which imposes health costs on others. The smoker, however, does not bear the health costs borne by others. Another type of consumption externality exists if one individual's utility or satisfaction depends on another individual's utility. Individuals may, for example, benefit from knowing that everyone in society has access to healthcare.

Medical education provides another positive externality to society, because a community benefits from the human and health capital generated by physicians. Medical education is often heavily subsidized. For example, Medicare subsidizes teaching hospitals through graduate medical education and disproportionate share payments, decreasing a teaching hospital's marginal cost of training residents and ultimately increasing the number of residents trained.

Research and Development

Research and development also generate externalities in society. Research increases the overall level of knowledge in society, and often, the results of research created by one individual or firm are freely used by other entities. Without government grants and subsidies to encourage research and development, too little research would likely be generated, since the individual or firm creating the new knowledge does not reap all the benefits of the research.

Problems With Externalities

Externalities are a concern for healthcare, because they can result in a market failure, a situation where too many or too few goods or services are produced relative to the socially optimal quantity.

Consumers and producers make decisions based on their own private costs and benefits, not the societal costs and benefits that accrue to others. Without market interventions, the quantity of a good or service with significant externalities will not be socially optimal. That is, too much or too little of the good or service will be produced.

With a positive externality, consumers or producers will underconsume or underproduce the good or service, since their decisions fail to take into account the societal benefits due to spillover to others in the market. Similarly, with a negative externality, consumers or producers will overconsume or overproduce the good or service.

Solutions to Externality Problems

Externalities exist because of the lack of well-defined property rights. With smoking, smokers claim that they have the right to smoke, while nonsmokers claim that they have the right to clean air. The government may step in and assign property rights to one party or another. In the city of Chicago, for example, an ordinance was passed that bans smokers from smoking in restaurants and bars, assigning property rights to nonsmokers (i.e., the right to clean air while dining in a restaurant).

In addition to the government assigning property rights, another common solution in healthcare is to develop mechanisms for the externality to be “internalized,” where the consumer or producer incorporates the external costs or benefits into the private costs or benefits. Taxes and subsidies as well as patents are common strategies to internalize the social costs or benefits. With positive externalities, producers or consumers may be given a price subsidy to increase the marginal benefit of producing or consuming the good, paid by those who receive a benefit from the externality, and increasing the quantity bought and sold. Likewise, one solution to negative externalities is to tax the producer or consumer of the externality, increasing the marginal private cost of producing or consuming the good or service that generates the externality. It is important to note, however, that a tax levied on the producer generally is not borne entirely by the producer but instead is shared by the producer and consumer. The price elasticities of demand and supply determine the proportion borne by each party.

A large number of positive and negative externalities have existed and will continue to exist in healthcare. While an externality can lead to market failure, a situation where goods or services are not allocated efficiently, solutions exist to mitigate these challenges when the externality is sufficiently large.

ECONOMIES OF SCALE

The notion of economies of scale in the production of healthcare goods and services is central to understanding competitive forces, the diffusion of medical

technologies, the quality of care, and regulation in the healthcare industry. Economies of scale are present when larger-scale operations lead to reductions in average operating costs. Likewise, if an increase in cost due to an increase in all inputs causes the output to rise more than proportionally, economies of scale are said to exist.

A distinction is made between internal and external economies of scale. When a company's production process is such that as the number of units produced rises, the average cost of each unit falls, internal economies of scale have been achieved. In contrast, external economies of scale occur outside a firm, within an industry. For example, sharing technology, managerial expertise, and the creation of industry standards of healthcare may lessen the burden of costly inputs. It is important to note that economies of scale can exist with respect to the physical quantity of a good, the number of patients served, or the quality of the good or service.

Economies of Scale in Healthcare

There are several avenues through which economies of scale are achieved. These include the following: high fixed costs of production, improved bargaining power for inputs, organizational design, coordination, and specialization. These factors and their applicability to the healthcare industry are discussed below.

Hospitals

Economies of scale are most likely to be found in industries with large fixed costs in production. Fixed costs are those costs that must be incurred even if production were to drop to zero. In the extreme case, high fixed costs could lead to a natural monopoly situation, in which the most efficient (least costly) market structure would be to have only one firm providing a particular kind of good or service. In the long run, economists expect only one firm to "naturally" survive even in the absence of legal regulations. Yet, in a world where the rate of technological change is extremely high, one cannot rule out a situation in which multiple firms are providing the good or service; even this would be less efficient than a single firm providing the good or service. This is part of the rationale behind

states' certificate of need (CON) laws, designed to contain costs by avoiding extensive duplication of services and redundant hospital capacity.

Studies investigating the possible existence of economies of scale in hospitals find mixed results. In part, this could be related to the large variety of services offered by individual hospitals or to demand conditions, such as transportation costs, that limit the economies of scale that can be realized. However, studies that focus on individual services characterized by high fixed costs, such as open-heart surgery facilities, CT scanner units, and therapeutic radiology facilities, often find evidence of economies of scale.

Scale economies are not limited solely to providers. Payers face long-run average costs, which incorporate capital, and other fixed set-up costs. High start-up costs in the insurance industry require many subscribers to cover those costs. The flip side is, of course, that high set-up costs represent barriers to entry, which inhibit competition. Firms in industries exhibiting economies of scale therefore tend to have market power.

Economies of scale are among the economic benefits that hospitals can reap by joining multi-hospital healthcare systems relative to being free-standing facilities. Some of these cost advantages stem from improved access to capital, while others are the result of better bargaining power versus insurers, referring physicians, and patients. Larger companies can buy supplies in bulk and centralize administrative functions as well as training and maintenance. With a larger scale of production, a company may also apply better organizational skills to its resources—such as hospitalists, physicians who specialize in the management of patients who are hospitalized. Clinical studies show that hospitalists helped contain hospital costs without compromising on quality of care.

Group Practices

Similarly, group medical practices have occasionally been touted as organizations that should yield considerable economies of scale and thus help raise output while moderating total costs. Taking advantage of scale economies may explain the shift from sole to group practice. By pooling inputs such as offices, equipment, and administrative resources, physicians could increase their productivity while lowering their costs.

Technology

Finally, the notion of economies of scale, which speaks to the behavior of costs, is closely related to the notion of returns to production, which describes technology. For example, if a technology exhibits increasing returns to production, doubling inputs will more than double output. Since doubling inputs doubles the cost, average costs (i.e., cost divided by output) will fall, hence economies of scale are achieved.

Volume-Outcome Relationship

The division of labor and specialization are two key means of achieving increasing returns to production. This is especially important in healthcare, where, to improve the skills necessary to perform their jobs, physicians and other healthcare professionals need to concentrate on a narrow set of specific tasks. These tasks can then be performed better and faster. Hence, through such efficiencies, time and money can be saved and production levels increased.

For instance, there is evidence of lower mortality rates in hospitals that perform more of a given procedure. This may be a demand phenomenon, whereby high-quality hospitals attract more patients, or a supply phenomenon, whereby quality-enhancing scale economies cause large hospitals to provide better quality of care. Therefore, scale economies can arise at the individual physician level, as learning-by-doing affects the cost structure the individual hospital faces.

The proponents of specialty hospitals, for example, assert that their “focused factory” approach enables these facilities to enjoy positive returns to experience in the production of quality, thus leading to improved efficiency and outcomes along with reduced costs.

E-HEALTH

E-health is a broad term for the diverse, evolving digital resources and practices that support health and healthcare, with the Internet and its applications at its core. Definitions of e-health vary greatly depending on its uses, stakeholders, and target areas. Some researchers define e-health as the use of emerging information and communication technology, especially the Internet, to improve or enable health and healthcare. Other researchers use a broader definition, defining e-health as including medical informatics, public health, and business, referring to health services and information delivered through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development but also a state of mind, a way of thinking, an attitude, and a commitment to networking and global thinking.

Background

The e-health revolution was ignited by the advent of Internet technology and its numerous ramifications

in the late 20th century, along with the recognition of the advantages to adapting and adopting it in healthcare delivery and research. It encompasses applications in the domains of public health, preventive medicine, patient diagnosis, management and care, consumer-oriented health awareness, healthcare business management, professional clinical informatics, electronic clinical records, consumer health informatics, and health policy formulation and implementation. E-health is an effective, fast, and convenient medium for local and global education and communication on health, healthcare delivery, health administration, and health policy issues. The backbone of e-health is a combination of the computer and the Internet, along with a number of technologies dependent on—or related to—their use, including, but not limited to, interactive communication via the World Wide Web, satellite connections, digital TV, health kiosks, wireless networks, palm technologies, CD-ROMs and DVDs, virtual reality (i.e., for remote/intercontinental surgery), and nanotechnology.

Numerous stakeholders are involved in e-health supply and use: consumers, advocacy and not-for-profit health organizations, community-based organizations, healthcare organizations such as hospitals and clinics, the health insurance industry, healthcare administrators, clinicians, developers and suppliers of e-health applications, public health programs, and public and private health policymakers and funders. The main purpose of e-health is to provide more efficient, cost-effective, convenient, interactive, interconnected, evidence-based services that benefit all parties involved.

Most e-health tools are designed for specific functions serving defined groups of people at the individual, organizational, or population level, with some overlap. Personal health functions may include the provision of health information, promotion of behavior change or prevention strategies, provision of resources for self-management of health, and formation of online communities and support groups. In healthcare provision and administration, tools are used for disease management, decision-making support, personnel and financial management, maintenance of electronic clinical records, transmission and sharing of health data and reports, and creation of interconnected networks that streamline healthcare delivery in a cost-effective manner.

Uses

E-health is not confined to healthcare delivery; it also applies to public health governance, finance, education, research, and health-related economic activities. Electronic media are increasingly used for dissemination of information for public health promotion and awareness, medical education, promotion of biomedical research and evidence-based medicine, and e-learning for healthcare professionals. Health information systems are used in disease surveillance; for maintaining databases for research and administration; and in financial, management, monitoring, evaluation, and logistical applications pertaining to healthcare. In health research, electronic databases such as population registers have galvanized epidemiological research, with immense value for health policy formulation. Informatics tools are used to guide the selection of appropriate and cost-effective priorities for policymakers. Geographical information systems are gaining popularity as tools for spatial projection and mapping of health concerns to help in making policy decisions and targeting outreach initiatives. In the field of clinical medicine and patient care, e-health has made enormous strides, particularly in developed nations, where capacity exists to support such applications. Healthcare delivery technologies support diagnostics, health decision support systems, treatment, electronic clinical communications tools (e-bookings, referrals, and discharges), electronic networks, telemedicine, teleconsultation, telesurgery, robotic surgery, and electronic medical records, among other rapidly expanding options. The pharmaceutical and nursing fields are also using systems tailored to their needs.

In the field of health education (e-learning), e-health technologies have opened up avenues for instant global exchange of health information and education at little cost. This has enabled developing countries to access evidence-based health interventions and research in order to guide their own programs for improving population health. Applications include tools for cognitive learning, computer-aided instruction and training, continuing education, and distance learning. The creation of digital libraries has revolutionized health research and learning by bringing expensive books and journals into the home and office at little or no

cost. The creation of digital knowledge bases and online dissemination of health education has broad-reaching applications in the public health sector as well as in consumer health education.

The concepts of consumer e-health and personal health management are being promoted by health policymakers and thought leaders to enable people to be responsible for their own health, signifying a shift away from the traditional paternalistic pattern of healthcare delivery. As these technologies are becoming more widespread, more people are using them to make informed, independent decisions on how, when, where, and why to access healthcare that is convenient, reliable, and affordable or to adopt healthy behaviors. The most common tools are personal health records, patient portals, and secure patient-physician e-mails. These can become important tools in promoting personal, community, and population health.

Interactive health communication (IHC) allows individuals with an electronic device or communication technology to access, transmit, or receive health information, treatment guidance, or support on an issue related to their health. This consists mostly of Web sites or technology-mediated applications that promote self-care and healthy behaviors, enable individuals to make informed decisions on health issues, promote exchange of information, or allow remote access to physician care. The application permits improved individual access to specific health information, gives wider choice in seeking and comparing treatment options, promotes user anonymity, and supports wider group involvement in health concerns and advocacy. Another advantage is the capacity for instant updates on recent advances. However, research on the quality or effectiveness of such approaches is still in its infancy. Preliminary research has revealed a low level of use and significant disparities in access to the socially disadvantaged and in ethnic and racial minorities, even if access is similar. Possible explanations for these disparities in use include differences in the quality or speed of the Internet connection; the perception of e-health as a valuable health tool; cultural preferences; wariness of the trustworthiness and privacy of sites; and the typical lag time in diffusion of innovations. Lack of reliability of sources is a cause for serious concern. Additionally, most IHC systems in the healthcare arena are provider

oriented, so a shift to providing consumer-friendly applications may portend a wider adoption of health technologies.

Healthcare business intelligence and predictive modeling are important applications of e-health. E-health provides support to clinical, financial, budgetary, and forecasting decisions based on realistic and accurate predictive modeling. It enables a self-service type of reporting for external and internal clients and organizations. In the public health sector, systems are used to evaluate population health status and develop, disseminate, and evaluate health promotion and disease management interventions. For example, applications provide HEDIS (Healthcare Effectiveness Data and Information Set) quality and performance measurements for various public health programs and insurance companies. They can be used for conducting cost-benefit analysis of alternative strategies and helping choose the best option. Technology is used extensively in maintaining data warehouses for health statistics that guide health policy and planning in both the public and the private sectors. Software is used that enables accurate and credible budgeting and forecasting based on actual, predicted, and adjusted measures of utilization and costs; reduces fraudulent or inappropriate claims billing and eligibility; and can be used for predicting future requirements and shortfalls. Excellent tools are available for human resource management in the healthcare arena, and they are increasingly being used to improve efficiency and cost savings.

Telemedicine

Telemedicine, the first and oldest form of e-health, is the interface of medicine and information and communication technologies for delivery of healthcare services where distance is a critical factor. Telemedicine applications are making rapid strides in the fields of emergency healthcare, homecare, patient telemonitoring and a variety of clinical fields such as teleradiology, -cardiology, -pathology, and -surgery. They are used to provide fast and convenient expert medical services locally, nationally, and globally, enabling two-way transmission of patient-provider information and images that permit patient or physician access to remote experts to enable prompt diagnosis and timely treatment in rural health centers, remote

areas, and inaccessible geographic locations, apart from facilitating homecare. Teleconsulting is a corollary that allows experts to consult each other or advise physicians in remote areas. Telesurgery and robotic surgery are state-of-the-art techniques that allow surgeons to perform remote-controlled procedures or guide surgeons from a distance in conducting innovative or emergency procedures. Remote satellites enable the global use of these systems.

A wide variety of services fall under the umbrella of telemedicine services: specialist referral services, patient consultations, remote patient monitoring, medical education, and consumer medical/health information. Specialist referral services usually involve a teleconsultation between one or several specialists and/or a general physician to arrive at a correct diagnosis and treatment. More than 50 specialties are successfully using it to provide local or global patient care. Patient consultations are direct, remote interactions between the patient and the health professional in which reports and other health data are interchanged to guide treatment. Remote patient monitoring, or home telehealth, transmits and collects data from remote stations (e.g., an ECG or pulse recording), usually via the Internet, which is useful in controlling the use of visiting nurses.

Delivery Mechanisms

Several types of delivery mechanisms are used in e-health: networked programs, point-to-point connections, primary or specialty care to the home, home monitoring, and Web-based e-health patient or consumer services sites. Dedicated networks link health organizations with their partners, subsidiaries, or health centers in remote areas and are used primarily for administrative purposes. Their use in public health programs is growing as e-health becomes more popular. Point-to-point connections usually link private providers such as hospitals to patients requiring telehelp or teleconsultation. Primary or specialty care to the home connects physicians and visiting nurses with patients over single-line telephone-video systems for interactive clinical consultations. Home-to-monitoring-center links are useful for remote monitoring of lung functions, fetal heart monitoring, or cardiac monitoring for patients needing extensive surveillance at home.

Only those Web-based e-health patient service sites that provide direct patient communication fall under the purview of telemedicine.

E-Health Terminology

Store-and-forward transmission of still digital images or clinical data is frequently used in radiology, dermatology, and pathology. A digital camera is used to store and transmit relevant patient pictures. *Originating site*, also known as spoke site, patient site, remote site, and rural site, is defined by the Centers for Medicare and Medicaid Services (CMS) as a site where the patient and/or the patient's physician is located during the telehealth encounter or consult. A *patient presenter* is someone with clinical skills, such as a nurse, who is trained in the use of the camera equipment and who is in attendance with the patient at the originating site to "present" the patient, manage the camera, and perform any hands-on activities requested by the remote physician to arrive at a diagnosis. A trained presenter is not necessary in all cases, as in radiology or pathology consults. *Bandwidth* signifies the capacity of a communications channel to transmit information. Broadband communications carry a wide range of frequencies that permit simultaneous transmission of several messages, as in broadcast TV and satellites. Interactive video/television permits two-way, synchronous, interactive video and audio signals to deliver e-health services: ITV, IATV, or VTC (video teleconference) are commonly used acronyms. *Firewalls* are computer hardware and software that block communication channels between an institution's computer network and unauthorized external networks.

E-Health Ethics, Confidentiality, and Safety

The ethical and legal safety norms of e-health are still not well-defined. Ethical issues cover the preservation of confidentiality, dignity, and privacy. Legislation guaranteeing these values is essential, along with liability for misuse, for all providers of e-health information. The Internet is a particularly difficult tool to control in the absence of well-defined ownership or accountability regulations that can control cyberspace activities. The unrestricted

proliferation of e-health sites has led to the release of health information that may often be undocumented, misleading, influenced by monetary or business reasons, and potentially harmful to consumers. Consumers need to be made aware of the pitfalls of using or providing personal health information to sources that do not originate from reliable sites. All users of e-health may not be able to discriminate between reliable and unreliable information, particularly as related to drugs and supplements, and may suffer from considerable personal and economic harm.

Digital Divide

The *digital divide* is the term used to describe the disparity in access to e-health tools between the rich and the poor. Most people who suffer from higher rates of preventable diseases and risk factors for those diseases have limited access to healthcare. They are also likely to have little or no access to e-health technologies, both because of economic reasons and because of the inability to understand and use these technologies even if they are made available. This is particularly true for disadvantaged populations such as the elderly, those with low literacy, people with disabilities, those who are computer and/or health illiterate, and immigrants. Public health policymakers need to seriously consider this divide while making policy decisions to divert precious funds to adopting technologies that may not benefit the underserved.

Barriers

E-health is an evolving tool that is expensive to install initially, though some systems have proved to be cost-effective over time. Research is ongoing as more organizations discover the advantages of e-health and are adopting its technologies. However, the provision of e-health that is user-friendly and accessible to all is fraught with problems. Demographic, sociocultural, economic, and linguistic barriers exist in designing e-health tools for public consumption. To use such tools, people need access to hardware, software, and an Internet connection, along with the ability to navigate the system, understand its content, and use it effectively, often described as *meaningful access*. In a multilingual society with limited health literacy, as

is common both in the United States and globally, the development of consumer-oriented tools and provision of infrastructure require the involvement of a number of stakeholders and the creation of multiple tools to ensure equitable access. As e-health is essentially a multidisciplinary tool, conflicts occasionally arise between stakeholders in deciding the best technology or software to adopt, as health is primarily a social responsibility while technology is business oriented. Besides, creating networks involves coordinating several organizations with different levels of needs, training staff in managing such systems, and overcoming economic restraints, in addition to dealing with vendors who may not be familiar with the specific demands of healthcare delivery. A thorough needs assessment involving all stakeholders is necessary before adopting such technologies. Globally, the majority of people will be unable to use e-health services because of socioeconomic reasons for many decades to come, thus increasing the health disparities.

Future Implications

In a world governed by information and communication technology, channels of e-health technology have opened up new avenues in the delivery and management of healthcare. An increasing number of decision makers in the public and private healthcare sectors are looking at e-health tools to deliver innovative ways for healthcare reform and improving personal and population health. These tools possess the potential to reduce costs, improve efficiency and quality of care, provide wide access to healthcare and education, and improve the overall capacity of healthcare organizations. However, the arena of healthcare has been slow in adopting these technologies, partly because of the various sociocultural factors that govern health as compared with the business sector. Much progress can be made in adopting e-health strategies that are efficient and cost-effective. The emphasis should be on using an interdisciplinary approach that addresses the diversity of healthcare delivery and management at all levels.

EISENBERG, JOHN M.

John M. Eisenberg (1946–2002), an early leader in the Society for Medical Decision Making, was a general internist whose early grasp of the importance of economic and other nonmedical factors in clinical decision making fueled an exceptional career that included national leadership in medicine, medical decision making, health economics, public policy, and health services research. In addition to his own career accomplishments, Eisenberg was also renowned as one of the foremost leaders in general internal medicine and a lifelong mentor of students and professionals in multiple disciplines.

Born in Atlanta, Georgia, and raised in Memphis, Tennessee, Eisenberg received his undergraduate degree from Princeton University (1968) and his

medical degree from Washington University School of Medicine in St. Louis (1972). He trained as an internist at the University of Pennsylvania and was one of the first cadres of Robert Wood Johnson Clinical Scholars, which allowed him to receive a master of business administration degree in 1976 from Wharton School, University of Pennsylvania. From 1978 to 1991, Eisenberg served as the chief of the Division of General Internal Medicine at the University of Pennsylvania, which he made one of the top divisions of this discipline in the nation. In 1991, he was one of the first general internists selected to chair a department of internal medicine, and he served in this capacity at Georgetown Medical School until 1997, when he became Administrator of the Agency for Health Care Policy and Research (AHCPR), later known as the Agency for Healthcare Research and Quality (AHRQ). In this last position, he also served as assistant secretary for health.

In addition to numerous academic achievements, Eisenberg's expertise on the impact of financial incentives on physicians' decisions led to his serving as a member in and then chairing the Congressional Physician Payment Review Commission (PPRC) from 1986 to 1994. He was the first physician president of the Society for Medical Decision Making, and he also led the Society for General Internal Medicine, the Association for Health Services Research, and served on numerous editorial boards and federal peer review groups.

Eisenberg's scientific contributions were extensive and included a strong focus on multiple dimensions of clinical decision making, including diagnostic uncertainty, cost-effectiveness and cost-benefit analysis, and sociological influences on physicians' decisions—such as the impact of the patient's race, ethnicity, and gender. His book *Doctors' Decisions and the Cost of Medical Care* was a seminal contribution to the fields of medical decision making and health economics.

In his final position, leading what is now the AHRQ, Eisenberg was preeminent in assessing health-care quality and patient safety. His efforts in response to the national Institute of Medicine (IOM) report *To Err Is Human* resulted in AHRQ's becoming the world's leading supporter of research to ensure that healthcare is reliably and predictably safe.

Eisenberg often said that he took the greatest pride in the many individuals he had trained—from

medical students to business students to residents, fellows and junior faculty members. The impact of his numerous contributions and his legacy is still unfolding.

industry. Among the terms used are *computerized patient record* (CPR), which pertained to hospitals patient records, and was used prominently from the 1960s through the 1980s; *electronic medical record* (EMR), which pertained to ambulatory care patient records and was used in the 1980s and 1990s; and *electronic health record* (EHR), the current designation that includes patient records from a variety of healthcare entities both within and outside a single healthcare system. These terms, however, are still often used interchangeably.

Function

Today's healthcare industry professionals expect electronic clinical records to provide the following: patient information such as demographic and insurance data; patient health data such as allergies, problem lists, history and physical data, advance directives, operative and other procedural summaries; access and management of test results, including laboratory, microbiology, pathology, and other examinations; patient orders; patient notes and clinician summaries; clinical decision support specific to patient parameters; medication lists; radiology and other imaged studies; diagnoses; consult summaries; patient-specific scanned documents, pictures, and sounds; chronic disease management and pathways/reminders; and access to knowledge sources.

History

While a few large hospitals first began using computers in the 1950s to support financial, billing, and administrative functions, it was not until the 1960s that EMRs were viewed as a possibility. The idea of using computers to record patient treatments was part of President Kennedy's vision for the future of the nation. Early in his term of office, President Kennedy proclaimed that the United States would land a man on the moon by the end of the decade of the 1960s. This ultimately led to increased federal funding of NASA and the development of the nation's space program.

The Lockheed Corporation, one of the major beneficiaries of government funding for space research and exploration, decided that it was in the public's interest to use the recently developed space program technology for the benefit of all citizens of

ELECTRONIC CLINICAL RECORDS

The term *electronic clinical records* encompasses a number of individual designations that have been used by the healthcare information technology

the nation. Lockheed decided to develop a computer application that would manage the patient care delivery and clinical documentation processes in hospitals. In the late 1960s, Lockheed began the project at El Camino Hospital, a community hospital in Mountain View, California. By 1973, the first patient care unit was “live” on a computer system, and the majority of the unit’s clinical processes, nursing observations and interventions, patient orders, and test results were documented and automated in the first electronic clinical record system. This live unit was tweaked and debugged during the next year, before the system was expanded to other patient care units in the hospital. By 1976, the majority of El Camino Hospital was live on the first patient care system, using a large IBM mainframe as its host computer.

By the mid-1970s, as word of the El Camino project spread, other development efforts began to take shape. These efforts were led by a number of companies, such as HBO (now part of McKesson Corporation), McDonnell-Douglas (the aircraft manufacturer whose healthcare information technology business is also now part of McKesson), ISM (product name of PCS/ADS), and SMS (now part of Siemens), among several others. However, the majority of these developments resulted in a number of limited clinical systems that only communicated orders from patient care units to other ancillary departments such as laboratory or radiology. These systems were sold, but in many cases, they were not expanded into functional CPR systems.

In the early 1980s, other companies decided to develop CPR systems. Companies such as Medicus (bought by HBO and now part of McKesson), Meditech, PHAMIS (bought by IDX and now part of General Electric), SMS, Dynamic Control (bought by Baxter, which joint ventured with IBM, then sold to HBOC, which is now also part of McKesson), and Burroughs, among others, all made large investments to develop CPR systems. A number of hospitals invested heavily and spent much time and resources to assist and serve as development sites, but in the end there was not much success. And the majority of these companies went out of this business segment, or larger companies purchased them.

In the mid-1980s, the clinical application segment of the information technology industry

began to stratify because developers and their client hospitals recognized the enormous computer-processing requirement of clinical patient record systems. These systems operating on large computer mainframes became more functional, but they still were less developed than the system developed earlier by Lockheed.

During the 1990s, computer technology advanced, and the industry began to focus on the use of large-scale communication networks and distributed computing through the use of servers and more powerful personal computers. As the cost of computing decreased, healthcare information technology companies began emphasizing client server technology using large servers and extensive communications networks. However, despite these advances, only a minority of the nation’s hospitals have a fully installed and fully used electronic clinical record system.

There has been more success in the use of EMR systems in ambulatory care. Many physician practices and outpatient clinics have been successfully implementing these systems since the early 1990s. Because patient records in these settings are less complex, computerization is more straightforward and more easily adaptable to available technology. Today, a patient is more likely to have an EMR in a physician’s office or clinic than in a large acute-care hospital.

Future Implications

In 2004, President George W. Bush issued an executive order establishing the Office of the National Coordinator for Health Information Technology (ONCHIT). Its mission is to implement EHRs nationwide within 10 years. However, many barriers exist in achieving this goal, including the cost of these systems and concerns over privacy issues. At this point, it seems unlikely that the nation’s healthcare system will become totally paperless in the foreseeable future.

ELLWOOD, PAUL M.

Paul M. Ellwood is an innovative figure in health-care. He coined the term *health maintenance organization* (HMO), and he introduced the concept to the Nixon administration as an entity that would compete on the bases of price and quality by combining insurance and health care within a single organization. In 1972, Ellwood tested the HMO concept as a pilot program with 5,000 patients at the Park Nicollet Clinic in Minneapolis, employees from General Mills and other local corporations who were enrolled in this employer-sponsored prepaid health plan. He advised the Nixon White House on the Health Maintenance Act of 1973, which was passed into law. The HMO Act requires that all companies in the nation with 25 or more employees must offer a federally qualified HMO option along with traditional indemnity insurance. The act played a significant role in shifting the direction of the nation's health care system toward managed care.

Ellwood, along with Alain C. Enthoven and the Jackson Hole Group, later went on to propose the idea of managed competition, which is a purchasing strategy for consumers and employers.

The latest idea that Ellwood has initiated is the Pathways to Healthy Outcomes (PATHOS), which calls for increased participation from the federal government in setting standards. The goal of PATHOS is to overhaul the health care system, enhance the power of patients, redefine the role of government as an agent of change and regulator, and ensure health insurance for everyone. PATHOS would accomplish these objectives through the use of the Internet to connect patients and physicians, rely on evidence-based guidelines for prevention and treatment, adopt the use of EMRs, and provide patients with better information on medical treatments and comparative information on physician performance.

Ellwood received his bachelor's degree and a medical degree from Stanford University. He then went on to complete his medical training in pediatrics and neurology at the University of Minnesota and physical medicine and rehabilitation training at the University of Washington. He worked as a consultant at the Brookings Institution for 4 years. Following this, he held various positions at Harvard University, the University of Paris, Stanford University, and the University of Rennes in France. Later, Ellwood served as the executive director of the American Rehabilitation Foundation and the Sister Kenny Institute of Minneapolis. He founded and was the chief executive officer of InterStudy, a Minnesota-based organization dedicated to introducing market forces in health care. He also founded the Jackson Hole Group in Teton Village, Wyoming, a health care reform policy think tank composed of medical, public policy, and business leaders committed to improving the nation's health care system.

Ellwood has received numerous awards and honors. The Foundation for Accountability (FACCT) established an annual award in his honor. Ellwood has also served on many local and national boards, including the national Institute of Medicine (IOM), the American Association of Rhodes Scholars, and the RAND Corporation.

EMERGENCY AND DISASTER PREPAREDNESS

Emergency and disaster preparedness is taking the necessary precautions and preparations in the event of an emergency or disaster. Medical emergencies, natural disasters (earthquakes, hurricanes, flooding), technological disasters (hazardous material incidents, nuclear power plant failures), and terrorism pose an ever-present risk to life and property. Emergencies and disasters can cause disruptions to the lives of many and can have serious and lasting effects. Being adequately prepared for emergencies and natural disasters can help minimize the confusion and impact of the aftermath. If proper precautions are taken, disastrous situations may be potentially avoided or their effects reduced. Hospitals and other healthcare providers play a critical role in emergency and disaster preparedness since they are on the front lines of responding to and caring for the ill and the injured in the event of such an occurrence.

Overview

Recent studies and government reports continue to express concerns that hospitals are not adequately

integrated into community planning. Moreover, many hospitals remain unprepared in terms of comprehensive response plans, adequate participation in drills, and resources and training. Many hospitals are also not collaborating with other agencies. Surveys of hospital emergency departments have found deficiencies in the knowledge, plans, and resources for responding to hazardous materials (HAZMAT) or radiation incidents. Recent events that were small in scale by comparison with the potential for damage have overwhelmed healthcare facilities; lack of appropriate preparedness plans or familiarity with them as well as the delayed use of personal protection equipment (PPE) have resulted in healthcare staff becoming unnecessarily exposed to toxic agents and subsequently becoming ill. Such was the case in Tokyo during the 1995 subway attacks with sarin nerve gas. Yet during the initial 2 to 3 days of a disaster, local agencies, including hospitals, are the initial responders. Therefore, hospital personnel must be able to meet the challenges of organizing and implementing a mass medical response that may require unfamiliar activities such as decontamination, which is not a part of daily routine practices.

Clearly, community emergency and disaster preparedness is a complex undertaking given the number of stakeholders and responder agencies, local vulnerabilities, disparate resources, and potential hazards. As such, it is imperative that all healthcare facilities have preparedness plans in place, practice these plans on a regular basis, and ensure that these activities are integrated with multiple agencies that are responsible for a mass casualty event.

Components of Disaster Planning

Preparing for mass casualties from natural disasters, technologic disasters, and terrorism requires a multisystem approach that involves local and federal public health agencies along with other emergency networks and healthcare facilities. The basic components of such a plan include the following: hospital incident command system (HICS), hospital personnel, network of communication, first responders, PPE, cancellation of nonessential services and procedures, obtaining necessary supplies and medications, triaging both patients and vital resources, medical surge capacity, security

issues, National Incident Management System (NIMS) compliance, and critical analysis. Each of these components is discussed further below.

Hospital Incident Command System

The HICS is a core component of the NIMS and is mandated by the Joint Commission. HICS is a standardized incident management tool that enables healthcare facilities to organize resources and staff in order to remain operational during any emergency while promoting the restoration of routine, daily functions. HICS is based on a command-and-control system. In this system, the designated incident commander oversees the operational planning, logistics, and financial aspects of the event, with the ultimate goal of minimizing chaos. The responsibilities of the incident commander include monitoring the cost of the incident, maximizing safety, using personnel efficiently, and resuming normal operations as soon as possible. The key personnel involved include the incident commander, public information officer, safety officer, liaison officer, medical specialists, operations section chief, finance/administration section chief, environmental services, and planning or logistics section chief.

Hospital Personnel

The hospital emergency department is typically the “first receiver” of an emergency or disastrous situation. Therefore, the mobilization of clinical staff is an integral aspect of an emergency response. A central labor pool may be needed to establish order for the command center and coordinate staffing requirements. Prior staff training to deal with an increase in medical surge is paramount in preparing for disasters.

Network of Communication

Communication is key to coordinate internal responses, interact effectively with multiple agencies, and deliver important information in the form of risk communications to the public and media in a timely manner.

Hospitals must work to make sure that they have a communication network setup within a regional county in the event that they run low on medical supplies or have an overflow of patients during a disaster. Hospitals must also keep active

communication with their departments so that they know how many patients can be received and also can monitor the level of essential medical supplies.

As part of the overall communication strategy, it is important to have communication plans established that include the fire department, police department, ambulance services, emergency operations, and all hospitals within a reasonable distance. A common radio frequency and interoperability of equipment should be in place. Additionally, planning for disruptions and backup strategies are necessary to keep communication channels open.

First Responders

First responders may be called on in the event of a HAZMAT, radiological, or explosive event. Therefore, the training of first responders to coordinate with healthcare facilities is essential. First responders will be transporting many patients to healthcare facilities in the event of a major emergency or disaster. As a result, healthcare facilities should be prepared to identify, triage, track, and manage the large surge of incoming patients.

Personal Protection Equipment

PPE is necessary to protect responders from becoming contaminated. PPE is designed to protect the rescuer in a disaster management scenario from becoming a victim and to prevent the delay of rescue operations. There are four levels of protective equipment. Level A provides the most protection against vapors and liquids and includes a self-contained breathing apparatus (SCBA) and an airtight suit. Level B is used when there is no danger against vapors and only a danger involving chemicals. This level of equipment includes a chemical-resistant suit and an SCBA. Level C includes a full-faced air-purifying mask respirator and a splash suit that is chemical resistant to be used by individuals who work in a triage area. Level D is used when there is no skin or respiratory hazard, and it includes work clothes that cover an individual’s regular clothing.

Cancellation of Nonessential Services and Procedures

The cancellation of nonessential services and procedures is pivotal if a healthcare facility knows

ahead of time that it will be receiving an influx of patients from a disaster. Strategies to expedite discharge of patients and cancel all elective surgeries should be considered to accommodate a surge in patients.

Obtaining Necessary Supplies and Medications

The pharmacy plays a central role during a mass casualty incident. Pharmacies should be stockpiled to treat enough patients for 48 to 72 hours or until resources can be replenished from a nearby facility. Pharmacies should also be in contact with these facilities to obtain needed supplies.

The National Pharmaceutical Stockpile (NPSP) can help ensure the rapid deployment of pharmaceuticals, antidotes, medical supplies, and equipment. It also maintains vaccines that can be made readily available in the event of a biological attack or pandemic.

Triaging Patients and Resources

In the event of mass casualties, patients may not arrive with first responders, but they may arrive on their own at hospital emergency departments after evacuating the scene of the incident. Because of this, hospitals should be prepared to expect a large number of patients and anticipate more than what is reported by responders on the scene.

Triaging patients during an overflow period should only take 30 seconds per patient, and patients should be color-coded. Red indicates that a patient is in need of immediate care. Yellow signifies that a patient is in stable condition but needs care soon. Green indicates that a patient has minor injuries and can wait a little while for treatment. Finally, black means that a patient will not survive. The goal of triage during a mass casualty event is to help the patients who will most likely survive and to treat patients with reversible pathological processes by using as few resources as possible.

Medical Surge Capacity

Medical surge capacity refers to the number of potential patient bed spaces that can be made available to triage, manage, vaccinate, decontaminate,

or accommodate patients. The surge capacity also involves the ability of a healthcare facility to manage patients who may require specialized evaluations, intervention, and treatment. The surge capacity can be accomplished by transforming certain nonclinical areas of a healthcare facility, such as a lounge, waiting area, or auditorium, to hold patients by adding gurneys or cots.

A concern regarding surge capacity is that many hospitals and healthcare facilities lack this availability as they are already overburdened with patients on a daily basis. A significant challenge to meeting the surge capacity is to determine the number of patients a healthcare facility should actually prepare for since estimation of the potential demand varies by a given scenario. A common estimation that is used for surge capacity is to prepare for 500 victims per 1 million residents above the daily capacity of the facility. This generally results in a 20% increase in capacity.

Security

Security at both the site of the disaster and the healthcare facility is essential to emergency preparedness. Crowd control is needed to prevent anarchy and the disruption of healthcare providers from carrying out their duties. Steps should be taken to contain traffic, especially at the triage area, and a lockdown of the hospital emergency department should also be planned for. Coordination and communication with local law enforcement may be needed to ensure smooth operations during a disaster.

National Incident Management System Compliance

In 2003, President George W. Bush issued the Homeland Security Presidential Directive-5 (HSPD-5), which mandates state and local adoption of the NIMS as a requirement for receipt of federal funding. The NIMS Integration Center (NIC) has been designated as the lead federal agency to coordinate NIMS compliance. The National Incident Management Capability Assessment Support Test (NIMS CAST) is a self-assessment program for organizations to assess their ability to effectively prepare for, prevent, respond to, and recover from domestic incidents.

Critical Analysis

The debriefing and critical analysis of staff performance following a major traumatic event is an essential component of any emergency preparedness plan. This process should occur once the disastrous event has passed but prior to the resumption of usual routine activities.

Implications for Healthcare Facilities

Healthcare facilities play a central role during an emergency or disaster. Without the proper plan in place and the right networks set up, healthcare facilities will be in chaos during an emergency or disaster. During and after such an event, the facilities will need to treat many more patients than they can normally accommodate. This can only be accomplished through appropriate planning, organization, and preparation. Preparedness is the key factor in being able to effectively and efficiently deal with an emergency or disaster.

EMERGENCY MEDICAL SERVICES (EMS)

The purpose of emergency medical services (EMS) is to provide the highest level of prehospital care by a trained professional until the patient is under the care of a physician or other appropriate healthcare professional. The person who provides such care is called an emergency medical technician (EMT). A paramedic is the highest level of EMT and provides the most extensive prehospital care. The primary goal of an EMT is to provide medical care out of the hospital environment or in a trauma situation, with the objective of transporting the patient in a stable medical condition to the hospital, whereupon emergency physicians will then take over. An EMT also may have to deal with environments that might not be completely safe. According to the National Association of Emergency Medical Technicians (NAEMT), EMTs transport more than 16 million patients in the United States annually.

History

The concept of out-of-hospital care can be credited to Dominique Jean Larrey (1766–1842), who was Napoleon's chief army surgeon. Larrey recognized that it was imperative to treat wounded soldiers as

quickly as possible. To accomplish this, he created the *ambulance volante* or “flying ambulance service” to rapidly transport the wounded. The concept behind the idea was to perform medical procedures as close to the battlefield and as quickly as possible. He believed that the quicker a procedure was done, the better are the chances the patient would survive. Larrey increased the mobility and improved the organization of field hospitals, establishing the first Mobile Army Surgical Hospital or MASH units. Larrey also created the concept of “triage,” which in French means “to sort.” He established rules for the triage of the wounded; treating them according to the seriousness of their injuries and the urgency of their need for medical care.

In 1865, during the American Civil War, the first civilian ambulance service was created. Four years later in New York City, ambulances were created that consisted of horse-drawn carriages staffed by physician interns to assist at the scene of the trauma and treat the patient as quickly as possible. However, it was not until the 20th century that ambulance services began to be used widely.

During World War I, the average evacuation time for combat personnel was 18 hours, resulting in a high mortality rate. Because of this, during World War II, focus was placed on the expeditious transportation of injured personnel from the frontlines to areas where physicians were available. Although many medical advancements were made during World War I and II, advancements in training EMTs and prehospital care did not occur at home in America.

It was not until the mid-1960s that prehospital care received the attention of government and the public. Many people before this time thought that all care for the sick and injured occurred in the hospital and therefore saw no reason for paramedics to be well versed in life-saving techniques, believing that hospital physicians would be able to save the patients. In addition, most EMTs were poorly trained and did not have adequate equipment. However, in 1966, all this changed with the publication of *Accidental Death and Disability: The Neglected Disease of Modern Society*, which was written by the National Academy of Sciences, National Research Council. This report was extremely influential and represented a turning point in EMTs’ responsibilities.

The report identified that there were 52 million accidental injuries in the nation, accounting for a total of \$18 billion in 1965. The report provided a number of recommendations for the development of EMS systems. It recommended greater training of EMTs to deal with various trauma situations. The report proved to be highly influential, and many initiatives were undertaken by both private and government organizations.

One of the most important results of the report was the passage of the federal National Highway Safety Act of 1966, which helped create the U.S. Department of Transportation (DOT). From 1968 to 1979, the DOT allocated more than \$142 million to help train EMTs. In 1973, the U.S. Congress passed the Emergency Medical Services Systems Act, which provided funding to help support the training of EMT facilities. In addition, the National Highway Traffic Safety Administration (NHTSA) established state-wide EMS technical assessment programs that defined the basic components of an EMS system. The components consist of the following: regulation and policy, resource management, human resources and training, transportation, facilities, communications, trauma systems, public information and education, medical direction, and evaluation.

Certification and Learning

A high school diploma is required to begin formal EMT training. There are essentially three levels of EMT training. EMT-Basic level involves training in basic stabilization and emergency skills that do not involve medications. EMT-Intermediate level may require up to 350 hours in training of advanced airway skills and limited medication use along with intravenous fluid administration. EMT-Paramedic is the most advanced level and may take up to 2 years to complete. Course work in this area involves extensive study in anatomy, physiology, and pharmacology as well as advanced resuscitative skills.

To be certified as an EMT, an individual must successfully complete a course that is in accordance with the EMT-Basic, Intermediate, or Paramedic National Standard Curriculum, which is published by the DOT. Licensure is required in all 50 states for all three levels. Generally, recertification must be accomplished every 2 years with Continuing Medical Education requirements.

Hazardous Material Teams

Today, EMTs must be ready to respond to many types of HAZMAT incidents, including terrorist attacks. EMTs may come into contact with various HAZMATs such as biological, chemical, or radiological agents. Chemical and other types of spills are foreseeable with 4 billion tons of HAZMATs being transported across the country each year. The most common route of exposure in HAZMAT incidents is via inhalation. The federal agencies that are responsible for regulating the transportation of HAZMATs are the Occupational Safety and Health Administration (OSHA) and the Environmental Protection Agency (EPA). Furthermore, the National Fire Protection Association (NFPA) has developed a set of standards for responding to HAZMAT. NFPA Standard 471 establishes guidelines and tactical objectives for HAZMAT management while NFPA Standards 472 and 473 establish responder competency for HAZMAT incidents.

A contaminated site is often classified into zones. The hot zone or red zone is where the actual spill or contamination occurred, and only professionals who have the correct protective gear should enter this area. The warm zone or yellow zone is next to the hot zone, and it is where the decontamination occurs. The cold or green zone is where no contamination occurred, and it is where the command post is located. The green zone is the safest zone, and no one should be allowed in this area unless they have been cleansed of all contaminants that they have come into contact with in the hot zone. EMT/HAZMAT personnel should approach the contaminated site upwind or uphill if at all possible. EMTs have certain responsibilities in dealing with HAZMAT incidents. These responsibilities are based on their level of training. A Level 1 responder is a first responder who can provide care in the zone outside the contamination area (cold zone) and who does not pose a risk of secondary contamination. A Level 2 responder can treat patients in the contamination zone (warm zone) and can coordinate EMS activities.

EMERGENCY MEDICAL TREATMENT AND ACTIVE LABOR ACT (EMTALA)

The federal EMTALA, also known as the Anti-Dumping Law, was passed in 1986 as part of

the Consolidated Omnibus Reconciliation Act. EMTALA requires all hospitals receiving certain federal funds to provide medical screening examinations to all persons who arrive at their emergency departments, whether they have health insurance or not.

The intent of EMTALA is to ensure patient access to emergency medical care and to prevent the practice of patient dumping. Patient dumping occurs when patients in need of emergency care are transferred to another hospital before they are medically stable. The practice was especially prevalent when hospitals thought that the patients were unable to pay for their care. Patient dumping of uninsured patients from private hospitals to public hospitals grew rapidly in the 1980s as insurance companies promoted managed-care plans, reimbursement patterns changed, and hospitals were unable to shift the costs of bad debt, charity care, and uncompensated care to privately insured patients.

EMTALA imposes duties on all the nation's hospitals receiving Medicare reimbursement. Generally, hospitals must offer an appropriate medical screening examination to any patient seeking emergency services to determine whether or not an emergency medical condition exists. If a life-threatening condition is found, the hospital must provide the patient with stabilizing treatment within the capabilities of the facility and its staff, or if the patient cannot be stabilized, the hospital must arrange for an appropriate transfer of the patient after considering the patient's condition and the risks and benefits of the transfer.

EMTALA was not intended to create a private cause of action against the hospital and physician, but it can result in fines of up to \$50,000 per violation to both the hospital and the physician and the loss of Medicare reimbursement.

Background

Prior to the passage of EMTALA, there were several laws, rules, and guidelines in place designed to protect patients against patient dumping. Passed by the U.S. Congress in 1946, the Hospital Survey and Construction Act, more commonly referred to as the Hill-Burton Act, required hospitals to treat and stabilize all emergency patients prior to discharge as a condition for receiving federal funds for construction and modernization. However, the

federal government failed to define *emergency* in the regulation; there were no punitive remedies for violations; and despite the private right of action under Hill-Burton, most patients remained unaware of their rights and remedies under the statute.

The Joint Commission has hospital guidelines that state that individuals shall be accorded impartial access to treatment or accommodations that are available or medically indicated, regardless of race, creed, sex, nationality, or source of payment for care. The American College of Emergency Physicians (ACEP) also has issued guidelines against patient dumping. However, neither of these organizations has the power to impose penalties for a hospital's failure to comply with these guidelines.

Starting in the early 1980s, a number of articles were published in medical and public health journals as well as in the popular press addressing the issue of patient dumping. Several of the articles were written by physicians from Cook County Hospital (now John H. Stroger Hospital), the large inner-city public hospital in Chicago that primarily serves the poor, detailing the large extent of patient dumping at that facility. The authors found that the majority of the transfers were patients who were unemployed or minorities, with 95% of those patients having no health insurance. The reason stated most often for the transfers was lack of insurance in 87% of the cases. And nearly 25% of the patients were found to be medically unstable at the time of the transfer.

The practice of patient dumping was not limited to Chicago. Most large cities with public hospitals were also burdened by the practice. In 1986, it was estimated that nationally about 250,000 inappropriate transfers of medically unstable patients occurred, which was thought to greatly increase the patients' morbidity and mortality.

These articles, reports by the press, and news programs profiling transfer patients contributed to the enactment of EMTALA. According to one Senator, the law was passed to send a clear signal to the nation's hospitals, public and private alike, that all Americans, regardless of wealth or status, should know that a hospital will provide whatever services it can when they are truly in physical distress.

The Statute

EMTALA imposes a number of requirements on hospitals with emergency departments that have

Medicare provider agreements. (Because Veterans Health Affairs [VA] hospitals and other military hospitals do not participate in the Medicare program, they are exempt from EMTALA.) The act imposes several duties on hospitals, which were often unclear to healthcare professionals charged with complying with these rules.

There are essentially nine legal duties imposed on hospitals by EMTALA: (1) a medical screening examination must be performed for all patients who come to the emergency room; (2) the screening must not be delayed to determine the patient's ability to pay; (3) the medical screening examination must be performed in a nondiscriminatory manner for all patients; (4) the hospital must use all available resources to stabilize the patient for transfer; (5) the referring hospital must transfer the patient in an appropriate manner; (6) the receiving hospital must accept the patient if the transfer is appropriate; (7) the patient has the right to refuse treatment and the transfer; (8) the hospital must log and document the emergency evaluation and treatment of every patient; and (9) if a receiving hospital suspects an EMTALA violation, it must be reported within 72 hours, and in return, the government provides whistle-blower protection to the reporting entities.

In 2003, the Centers for Medicare and Medicaid Services (CMS) issued the Final Rule and added some new requirement to EMTALA. The additional requirements of the Final Rule specify that hospitals providing EMS must post signs identifying the rights of individuals under EMTALA with respect to examination and treatment for emergency medical conditions and the rights of women in labor. Hospitals also are required to maintain the records related to patients transferred to or from the hospital for a 5-year period. A list of physicians who are on call for duty must also be maintained. Finally, the hospital must maintain a log of individuals who sought treatment at the emergency department and whether the patients were treated, stabilized, or discharged.

Enforcement

The Office of the Inspector General (OIG) of the U.S. Department of Health and Human Services (HHS) and the CMS jointly enforce the EMTALA regulations.

The CMS receives EMTALA complaints at its 10 regional offices. If one of the CMS offices finds an EMTALA violation, it notifies the hospital that it may be terminated from participation in Medicare unless it takes appropriate remedial action. The CMS office provides the hospital with a statement of deficiencies and a notice of termination. If a violation involves a medical issue, a quality improvement organization (QIO) reviews the medical issue from a physician's perspective.

Subsequently, the regional CMS office notifies the OIG so that it can determine whether to levy fines against the hospital. Under EMTALA, the OIG can impose a civil monetary fine of up to \$50,000 per violation or a fine of \$25,000 for small-size hospitals. In addition, physicians may be fined up to \$50,000 if they have been found to have negligently violated their duty to examine, treat, or transfer an individual to a participating hospital.

The OIG is not required to impose penalties on hospitals found to be in violation of EMTALA. However, if monetary penalties are imposed, they are subject to administrative and judicial review.

Benefits and Limitations

The most important benefit of EMTALA is that it is designed to ensure that everyone who needs emergency medical care receives it. Patients can have some peace of mind knowing that if they need emergency care, they will usually receive it. Improper and inappropriate transfers are significantly lower now than before EMTALA was enacted.

Another benefit of EMTALA is that the potential negative publicity from a violation of the legislation may be a deterrent against hospitals and physicians failing to fulfill the duties the act imposes on them.

However, the specific language of EMTALA is vague. The vague language serves to eliminate loopholes that providers may conjure up to deny necessary emergency treatment based on the patient's ability to pay, and it creates an impetus for responsible healthcare professionals to interpret the regulations broadly in their effort to satisfy all stated and implied requirements of the law. Unfortunately, the vague language also creates significant room for misinterpretations of the requirements.

A major limitation of EMTALA is that managed-care organizations (MCOs) can potentially

use the law to avoid payments for emergency medical care. Many of these organizations require pre-authorization before they agree to pay for treatment that their clients will receive. This leaves hospitals at risk of not being reimbursed for providing services for patients who actually have health insurance coverage, in addition to those patients who are uninsured, for whom hospitals are also unlikely to be reimbursed.

Another limitation of EMTALA is that it is an unfunded mandated program for hospitals. EMTALA does not provide any payments for uninsured patients who hospitals are required to treat. This is especially troublesome for inner-city, not-for-profit hospitals, which already bear a disproportionate share of uninsured patients and Medicaid recipients.

EMERGING DISEASES

Emerging diseases may be defined as any infectious or pathogenic agent that is capable of causing disease and/or has newly appeared in a population. The infectious agent may have not been previously discovered, or it may be a new variant of an existing disease. Additionally, an emerging disease may be one that has previously existed in a population but is rapidly increasing in incidence or in geographic range. An increased incidence, or the number of new cases of a disease, over the course of a 20-year period is considered to be an emerging disease by epidemiological standards.

The source of emerging diseases may vary considerably and can result from pathogenic infectious diseases caused by bacteria or viruses. Inorganic materials and carcinogens, such as asbestos and dioxins, may also be responsible for an increased incidence of autoimmune and genetic diseases, such as cancer and birth defects. Also, a preexisting disease may reemerge in a population because of developing drug resistance or a breakdown in the public health system. Although the number of deaths due to emerging diseases has been decreasing in recent years, globally about 15 million deaths each year are attributed to infectious diseases. In the United States alone, the direct cost of infectious disease totals approximately \$30 billion a year and is the third leading cause of death. Furthermore, infectious diseases are responsible for approximately 30% of all disability-adjusted life years (DALYs) worldwide, and they are a major cause of disability and poor health.

Overview

Emerging diseases have been in existence ever since historical times, and they are responsible for many deaths worldwide each year. For many centuries, however, humans remained helpless against these diseases as their causes were relatively unknown. The establishment of the germ theory eventually led to tremendous progress in the understanding of emerging diseases and of how to prevent and treat these occurrences. The discovery of penicillin, vaccines, and treatment for infectious diseases in the 1900s caused the U.S. Surgeon

General in 1967 to prematurely claim a victory in the battle against this enemy.

The battle against emerging diseases, however, is far from over as it continues to take a significant toll on human life. Acquired immune deficiency syndrome (AIDS) is likely to surpass the Black Death and the 1918 influenza pandemic as one of the world's worst killers. Other recent emerging diseases include severe acute respiratory syndrome and monkeypox. Some newly emerging infectious diseases result in chronic diseases that are caused by infectious agents. Examples of this include certain variants of the human papillomavirus that cause cervical cancer and the herpesvirus, which causes Kaposi sarcoma.

Emerging diseases have inflicted tremendous suffering, particularly among people in resource-poor areas and developing countries. In developing nations, the burden of infectious diseases predominantly affects infants and children, while in developed nations the poor and minority groups are disproportionately affected. Although there has been tremendous progress made to prevent and treat many of these pathogens, emerging diseases continue to exist throughout the world and remain a constant threat.

The majority of cases of emerging diseases can be directly linked to infectious agents and their variants. There are six major classes of agents that are commonly responsible for the emergence of infectious diseases. These classes include bacteria; viruses; fungi; protozoa; helminthes; and a newly recognized agent, prions. These six classes of infectious agents represent the majority of newly classified emerging infectious diseases, with bacteria and viruses being the most prevalent.

Emerging infectious diseases may spread through microbial traffic. Microbial traffic is the introduction of an infectious agent that already exists in a population (human or otherwise) from other species. This includes the spread of infectious agents from smaller to larger populations and/or new geographic areas, such as the avian flu and West Nile viruses. Other factors that contribute to the propagation of infectious disease are human demographics, human behavior, technology, economic development, natural disasters, commerce and trade practices, as well as the breakdown of basic public health measures, as is the case with tuberculosis in the developing countries.

One of the most common ways in which emerging infectious diseases are spread is through zoonoses or transmission from animals to humans. The mechanism of transmission for the bubonic plague was by way of an animal reservoir (rats) and a vector (fleas). In this case, fleas that live on and bite rats were infected with the bacteria and were able to transmit the bacteria to humans through the same mechanism.

During the plague epidemic, overcrowded cities, open sewers, human waste, and garbage in abundance provided an ideal breeding ground for both rats and fleas. Both the reservoir and the vector living in very close proximity to the human population allowed the widespread infection and progression from one geographic area to another.

The cause of the emergence and the reemergence of agents that may result in disease are complex, but they typically can be traced to the ability of most microbes to evolutionary adapt genetically. Natural genetic variations, recombination, and adaptations allow new strains of pathogens to appear to which the human immune system has not been previously exposed and is therefore not primed to recognize. Furthermore, human behavior plays an important role in the reemergence of diseases. The increased and sometimes imprudent use of antimicrobial drugs, including antibiotics, has led to the development of resistant pathogens, allowing many diseases that were once treatable with pharmaceuticals to reemerge with increased virulence, which allows the pathogen to reinfect exposed individuals as well as infect previously nonexposed humans. Additional behavioral issues arise when an individual is prescribed an antibiotic for an infection and fails to complete the entire regimen of the drug. This situation tends to specifically select for and propagate the hardest of bacteria.

Another contributing factor to the spread of emerging diseases is that of demographics and geography. This is due to the fact that the sustainability of an epidemic depends on a population exceeding a certain threshold density of susceptible individuals. Over the course of the past 5 years, approximately 20 million refugees and 30 million displaced peoples have been on the move worldwide, crossing borders and relocating for a multitude of reasons. This combined with modern modes of travel and decreased travel time, which

allows an individual to move between continents within the time span of a day, create unique demographic opportunities and pressures as well as increasing the amount of microbial traffic. With worldwide travel occurring in the time period of a day and becoming more frequent, the possibility for a pathogenic variant being transmitted to a completely immunologically naive population is not only possible but under certain circumstances quite probable.

HIV/AIDS

Human immunodeficiency virus (HIV) has infected more than 60 million people worldwide, and it is the leading cause of death for those aged from 15 to 59 years. This disease possibly emerged from the consumption of nonhuman primates in sub-Saharan Africa between 60 and 100 years ago. The spread of HIV likely emerged because of the vast movement of human populations from rural to impoverished urban areas combined with sexual promiscuity. The complex interactions between agent, host, and environment demonstrate how changes and movements in the population led to this pandemic.

Although many individuals in the developed nations have benefited from highly active antiretroviral therapy (HAART) to treat this condition, few people in the developing nations have been able to receive appropriate treatment. Developing a vaccine to prevent the transmission of HIV has proved to be a very difficult challenge.

Tuberculosis

Tuberculosis (TB), caused by *Mycobacterium tuberculosis*, was once a controlled disease after the discovery of isoniazid and other drugs. However, in recent years, TB has reemerged as one of the world's most lethal diseases, killing more than 2 million people each year. The reemergence of TB was propelled by the large number of immunologically suppressed individuals infected with HIV/AIDS. The inappropriate use of TB treatments has also resulted in drug-resistant strains and costly treatments, further complicating this problem. With many people in the world continuing to live in poverty, controlling TB remains an enormous challenge.

Malaria

Although once controlled, malaria has reemerged as one of the most important diseases confronting the developing world, and it has disproportionately affected children in sub-Saharan Africa. Malaria causes about 1 million deaths each year, and it has affected more than 300 million individuals in the world. Although for many years, dichlorodiphenyltrichloroethane (DDT) was used in mosquito abatement programs, the insecticide is no longer widely used because of potential health concerns and insect resistance. As a result, malaria has reemerged as a public health problem worldwide.

Influenza

In the United States, influenza causes an estimated 200,000 people to be hospitalized, and about 36,000 individuals die each year from this condition. Globally, each year, about 3 to 5 million people are infected with influenza, and it causes between 250,000 to 500,000 deaths.

Influenza has gained attention in recent years with the outbreak of the avian influenza in Southeast Asia. An estimated 42 individuals died from this highly virulent strain, which killed millions of birds and chickens. Although few cases of human-to-human transmission have been reported, this virus may infect humans from other species. The avian flu is being closely monitored to see if variants of this disease may cause transmission more easily among humans, which could result in a pandemic, such as the 1918 influenza outbreak.

West Nile Virus

West Nile virus is a reemerging disease, commonly found in Africa, West Asia, Europe, and the Middle East, that has recently made its way to the United States. This disease was first reported in New York City in 1999, where there were a total of 62 cases. West Nile virus is known to mostly affect birds; however, humans may be infected through a mosquito vector. This virus generally spreads during the warm, summer months. Currently, there are several therapies being tested to treat the disease.

SARS

Severe acute respiratory syndrome is a respiratory disease caused by the SARS coronavirus, and it results in flulike symptoms. SARS emerged in late 2002 in Asia, and it quickly spread, alerting public health officials. Although it is still considered to be a rare disease, the near pandemic of SARS resulted in 774 deaths. The rapid emergence of SARS highlights the need for public health authorities and researchers to work closely together.

Drug-Resistant Microbes

Drug-resistance viruses and bacteria are quickly reemerging and are the result of mutations and of bacteria acquiring genes through transformation or infection with plasmids. Consequently, antibiotics such as sulpha drugs, penicillin, methicillin, and vancomycin, which were once routinely used to treat bacterial infections, no longer work. *Streptococcus pneumoniae* and *Staphylococcus aureus* have now become resistant to existing lines of treatment and are causing serious concern. Because of these resistant pathogens, continued efforts must be made to find treatments that are effective against these microbes.

Bioterror Agents

Some emerging diseases may be deliberately released, as in the case of microbial warfare and bioterrorism. Deliberate release of diseases may include the use of microbes that have been genetically engineered or produced to cause extreme and severe harm—for instance, the 2001 anthrax attack targeted at U.S. congressional leaders. Because of these growing bioterror threats, the U.S. government has initiated the construction of several regional biocontainment laboratories to detect, prevent, and treat diseases that are the result of these pathogens.

Future Implications

Emerging and reemerging diseases continue to challenge public health officials, and they pose an ever-present threat to the public's health. The effects of emerging and reemerging diseases are

unpredictable, therefore a timely response is needed to detect, diagnose, and contain these threats. Coordination of international and local agencies is needed for surveillance and to adequately respond to these threats. Additionally, continued clinical and translational research into these pathogens is paramount.

Several initiatives have been started by the United States, the United Kingdom, and the World Health Organization (WHO) to increase surveillance and the early detection of emerging infectious diseases in an attempt to curtail widespread transmission and to prevent mass infections of populations at risk. Through cooperative efforts between governments, early-warning communication and countermeasures to the threats of newly emerging infectious diseases can be accomplished. These concerted efforts should provide the best possible chance of avoiding widespread epidemics and pandemics in the future.

EMPLOYEE HEALTH BENEFITS

Employee health benefits are a service that is provided by an employer to employees in addition to wages or a salary. Employer-sponsored health benefits is the most common source of health insurance coverage in the United States, and it is a major source of health insurance for the working-age population and, to a lesser extent, retirees. Most Americans receive health insurance coverage through their job or through a family member's employer. In 2005, nearly 162 million individuals, or more than 93% of all persons with private health insurance, were covered by an employer-sponsored health plan, either as direct plan participants or as the beneficiaries of a participant's plan. Employers generally use health benefits to attract and retain workers; however, the rising costs of healthcare have become an increasing concern in recent years. Many experts believe that employer-sponsored health coverage has reached a tipping point as the number of covered individuals has been declining since 2000. Because the provision of health benefits is a matter of discretion on the part of employers and plan participation is generally voluntary by employees, health insurance coverage follows a distinct pattern linked to family income: The higher the family income, the more likely the presence of benefits.

Similarly, because the U.S. tax code extends favorable economic treatment to health insurance when purchased through an employer-sponsored plan, lower-income persons—the very individuals least likely to have employer-sponsored benefits—also have no tax subsidies available to help offset the cost of securing individual coverage. Furthermore, even when individuals can find affordable plans in the individual marketplace, coverage may

be highly restricted and may contain provisions that exclude any coverage of healthcare needs deemed by the insurer to relate to preexisting conditions. As a result, access to benefits in the workplace is a significant determinative of coverage.

Overview

Employer-sponsored health insurance coverage has been referred to as the accidental system, because its origins can be traced back to a decision to exclude employer contributions to coverage from family income during World War II, when strict wage and price controls were in effect. This decision was formalized as a part of the Internal Revenue Code Amendments of 1952, following which the proportion of persons with employer-sponsored coverage began a dramatic climb, reaching its apex in the mid-1970s. Changes in labor patterns, family composition, and the underlying economy have all contributed to the slow erosion of the system, along with a more precipitous decline in the number of retirees. In the early 1990s, two thirds of all retirees had employer-sponsored coverage; by 2005, this figure had declined to one third.

Employer-sponsored benefits create several distinct advantages for covered persons and are both tangible and intangible. First, because coverage is based on a group, the cost of coverage is significantly lower and coverage is significantly more generous than coverage obtained on an individual basis. Second, under the provisions of the tax code, employer contributions to coverage are excluded when calculating taxable income, thereby greatly reducing the cost of coverage (of course, cash wages may also be lower in recognition of this contribution to income). Third, many employers have adopted tax-advantaged arrangements that permit employees to contribute toward their own premium costs—where applicable—on a pretax basis, further reducing the cost of coverage. Fourth, many employers now offer tax-advantaged savings accounts in conjunction with, or in addition to, health benefit plans, thereby further reducing employee healthcare costs by permitting employees to contribute to these accounts and purchase uncovered healthcare on a pretax basis.

Actual revenue losses to the U.S. Treasury resulting from employer-sponsored health plans are considerable, surpassing \$200 billion in FY2006 alone. Furthermore, since state tax codes generally mirror the U.S. tax code where employer-sponsored income is concerned, revenue losses actually are significantly higher.

Finally, health insurance coverage has an incalculable value to covered individuals because it protects against economic loss from both foreseeable and unforeseeable healthcare expenditures. Whereas traditional notions of insurance would limit coverage to losses related to unanticipated events (such as serious illness or injury), it is in fact customary for employer-sponsored plans to cover at least some level of preventive and primary health benefits, such as well-child care, screening mammography, and immunizations. In essence, therefore, employer-sponsored plans function as a tax-free means of supplementing family income.

In addition to health insurance coverage, employee health benefits may also include dental and vision coverage, sick leave, maternity leave, and family medical leave. Employers have also realized the cost savings potential of health-education-related programs, known commonly as employee assistance programs, that reduce the health risks of employees. As a result, employers have developed worksite health promotion programs to assist employees modify their lifestyle through, for example, cessation of smoking, increase in physical activity and weight loss, and change of diet. Research has shown that a comprehensive worksite health promotion program can have positive benefits for employee health and for the employer through reduced absenteeism and employee turnover.

Employee Retirement Income Security Act

The Employee Retirement Income Security Act (ERISA) has played a central role in protecting and standardizing employee health benefits. ERISA covers most private health plans, and it ensures the rights of employees and beneficiaries by providing protections and ensuring access to information on health plans. Employers who manage their own plans must also make sure that certain standards are met to be in compliance with ERISA.

Trends in Employer-Sponsored Insurance

The patterns of employer-sponsored insurance have generally followed the overall trends of the economy. Although the number of nonelderly with employer-sponsored insurance grew in the early to mid-1990s, the proportion of U.S. residents with employer-sponsored insurance declined from 69.1% to 63.1% between 1994 and 2005. It has been suggested that the decline in employer-sponsored insurance is due to the lack of take-up by employees. Because health plan participation by employees is generally voluntary, not everyone who is offered employer-sponsored insurance takes advantage of this benefit. The affordability of health insurance coverage is an important concern among many low-wage workers. The decision to take up health insurance may be influenced by several factors, including the level of out-of-pocket expenses, the quality of the benefits package, and the availability of insurance through alternative sources.

Regardless of the trends in employer health insurance coverage, studies have shown that sociodemographic characteristics such as race, gender, and position in the labor market are associated with the receipt of health benefits. For instance, younger and lower-income workers are less likely to be covered through employers, and full-time workers are more likely to be covered than part-time workers. Furthermore, workers in occupations that require higher skill levels and have more responsibility, such as managerial and professional services, are more likely to have employer-based health insurance coverage than workers who are in the service industry. In addition, public-sector workers are more likely to have employer-sponsored coverage than private-sector workers. Among private-sector workers, however, employees who work in larger firms are more likely to receive health benefits than those who work in smaller firms.

Health Plan Enrollment and Healthcare Costs

Over the past decade or so, the number of individuals enrolled in traditional fee-for-service plans has declined substantially. The majority of employers generally now offer their employees a managed-care plan with level-dollar contributions,

meaning that if an employee chooses a more expensive plan, he or she will have to pay for the difference in cost. The reason for the growth in managed care is because it slowed the rising costs of health insurance for employers in the 1990s.

The rapid escalating costs of health insurance are one of the largest employee health benefit concerns of employers. In 2006, of the average health insurance premium of \$4,242, employers paid approximately \$3,563, while employees paid the remainder. In the same year, both public and private employers spent roughly \$2.33 trillion on employee benefit programs, which is an almost 50% increase from 2000. Approximately 43.5% of the employee benefit payments were for health benefits. Small businesses face greater challenges in providing their employees with affordable health insurance due to the higher premiums they face because of their decreased bargaining power. As the cost of healthcare continues to increase, it is estimated that health benefits will surpass retirement benefit costs as the single largest employer expense for benefits.

To rein in costs, employers have reduced health benefits spending by increasing the level of employee cost sharing, reducing benefits, or eliminating coverage entirely. Many companies believe that they have no other option but to have employees pay for a greater portion of their health-related expenses.

Several reasons have been offered for encouraging employee cost sharing. It has been suggested that if employees shoulder a greater portion of their actual healthcare costs, they will be more sensitive to this cost and it will create financial incentives for individuals to make more cost-effective and informed decisions from the range of available options. Having employees directly contribute a greater portion of their health benefits may make individuals' behavior more cost sensitive, but it may also affect employees' ability to retain health insurance coverage. Another reason for employee contribution is that if it is required, then a company only needs to provide insurance for those employees who demand it. Therefore, the company is able to pass on any potential cost savings back to employees directly through higher wages. A consequence of this action, however, is adverse selection, where healthier and more affluent individuals benefit the most.

Employers have also been trying to implement new strategies to control costs. For example, high deductible health plans in combination with health savings accounts is a model of consumer-driven health plans that is gaining popularity but still accounts for only a relatively small portion of covered individuals. These types of consumer-driven health plans allow employees to put pretax dollars into special health savings accounts. Because of this type of arrangement, employees generally assume a larger share of their overall healthcare costs because they must decide what types of healthcare services they are willing to pay for. Again, these types of plans have been shown to result in risk selection, attracting healthier and more affluent individuals. Additionally, there are concerns that some individuals may delay seeking care and endanger their health because they are concerned about exhausting their health savings accounts.

Employers may also change the health benefits that are offered to employees by transitioning from a defined benefits package to a defined contributions package. This approach fixes the total amount that a company contributes toward an employee's benefits. Some companies have also implemented a pay-based contribution method, whereby lower-income employees receive a greater subsidy to help keep health insurance coverage affordable. Thus, employee contributions may vary according to the level of their salary or as a fixed percentage of their income. In 2005, about 8% of large employers incorporated the use of a pay-based strategy. A limitation of a pay-based strategy, however, is that it does not address the rising healthcare costs. Therefore, some employers may decide to opt out of providing insurance coverage entirely, and others may link employee contributions to lifestyle and behavior modifications that create incentives for individuals to reduce their health risks. Another extreme measure that some employers have taken includes imposing a spousal surcharge, which requires employees to pay an additional contribution to enroll their spouse, who already has available insurance coverage through another employer. Some employers may also decide to lock out spouses who have available coverage through their workplace.

As the cost of healthcare continues to rise, employer-sponsored health insurance may no

longer be financially feasible for many companies to offer since it has become extremely difficult for industries to remain competitive in a global market. Because of this, many researchers are convinced that there needs to be a fundamental shift in the way health insurance coverage is obtained in the United States.

Future Implications

Employers remain the largest source of health insurance coverage for the nation's citizens. In light of the tangible and intangible benefits that flow from employer-sponsored health plans, it should come as little surprise that health insurance reform is so difficult to achieve. The nearly 162 million persons who have employer-sponsored coverage highly value it, as measured in numerous public opinion surveys. Likewise, employers consider health benefits to be an important dimension of their employee compensation policies and an important means of attracting and retaining a competent workforce. Allegiance to employer-sponsored coverage thus has remained considerable, even as the nation has witnessed a significant decline in coverage over the past generation. The rising cost of healthcare and the economic decline have resulted in increased cost sharing by employees. To ensure access to the healthcare system, healthcare costs must be controlled and coverage must be made affordable. It is likely that any future reforms to the U.S. healthcare system will include an expansion of the current employer-based model.

EMPLOYEE RETIREMENT INCOME SECURITY ACT (ERISA)

The Employee Retirement Income Security Act (ERISA), a federal law created in 1974, provides protection to individuals who participate in

voluntary private health and pension plans. Designed to establish minimum standards for these plans, ERISA requires plans to provide participants with important information about plan features and funding and provides fiduciary responsibilities for those who manage and control plan assets. The law requires plans to establish a grievance-and-appeals process for participants to get benefits from their plans. Importantly, it gives participants the right to sue for benefits and breaches of fiduciary duty. This entry discusses the history of employee benefits in the United States, examines the development of ERISA, explores the interpretation of the federal legislation, and highlights the likely role of ERISA in future public policy development.

History of Employee Health Benefits

In the United States, employer-sponsored health benefits represent a central source of health insurance for the working-age population and, to a lesser extent, retirees. In 2005, nearly 162 million persons, more than 93% of all persons with private health insurance, were covered by an employer-sponsored health plan, either as direct plan participants or as the beneficiaries of a participant's plan. Because the provision of health benefits is a matter of discretion on the part of employers, health insurance coverage follows distinct patterns linked to family income: The higher the family income, the more likely the presence of benefits.

Similarly, because the U.S. tax code extends favorable economic treatment to health insurance only when purchased through employer-sponsored plans, lower-income persons, the very individuals least likely to have employer-sponsored benefits, also have no tax subsidies available to help offset the cost of securing individual coverage. Furthermore, even when individuals can find affordable plans in the individual marketplace, coverage may be highly restricted and may contain provisions that exclude any coverage of healthcare needs deemed by the insurer to relate to preexisting medical conditions. As a result, access to benefits in the workplace is a significant determinative of coverage.

Employer-sponsored coverage has been referred to as the "accidental system," because its origins can be traced to a decision to exclude employer

contributions to coverage from family income during World War II, when strict wage and price controls were in effect. This decision was formalized as part of the Internal Revenue Code Amendments of 1952, following which the proportion of persons with employer-sponsored coverage began a dramatic climb, reaching its apex in the mid-1970s. Changes in labor patterns, family composition, and the underlying economy have all contributed to the slow erosion of the system, along with a more precipitous decline in the number of retirees. In the early 1990s, two thirds of all retirees had employer-sponsored coverage; by 2005, this figure had declined to one third.

Benefits sponsored through employers create several distinct advantages for covered persons and are both tangible and intangible. First, because coverage is based on a group, the cost of coverage is significantly lower and coverage is significantly more generous than coverage obtained on an individual basis. Second, under the provisions of the U.S. tax code, whose roots trace back to World War II, employer contributions to coverage are excluded when calculating taxable income, thereby greatly reducing the cost of coverage. Cash wages may also be lower in recognition of this contribution to income. Third, many employers have adopted tax-advantaged arrangements that permit employees to contribute toward their own premium costs, where applicable, on a pretax basis, further reducing the cost of coverage. Fourth, many employers now offer tax-advantaged savings accounts in conjunction with, or in addition to, health benefit plans, thereby further reducing employee healthcare costs by permitting employees to contribute to these accounts and purchase uncovered healthcare on a pretax basis.

Actual revenue losses to the U.S. Treasury resulting from employer-sponsored health plans are considerable, surpassing \$200 billion in 2006 alone. Furthermore, since state tax codes generally mirror the U.S. tax code where employer-sponsored income is concerned, revenue losses actually are significantly higher.

Finally, of course, health insurance coverage has an incalculable value to covered individuals because it protects them against economic loss from both foreseeable and unforeseeable healthcare expenditures. Traditional notions of insurance would limit coverage to losses related to unanticipated events,

such as serious illness or injury, but it is also customary for employer-sponsored plans to cover at least some level of preventive and primary-care health benefits, such as well-child care, screening mammography, and immunizations. Employer-sponsored plans, in essence, function as tax-free means of supplementing family income.

In light of the tangible and intangible benefits that flow from employer-sponsored health plans, health insurance reform has been difficult to achieve. The nearly 162 million persons who have coverage value it highly, as measured in numerous public opinion surveys; likewise, employers consider health benefits to be an important dimension of their employee compensation policies and an important means of attracting and retaining a competent workforce. Allegiance to employer-sponsored coverage thus has remained considerable, even as the nation has witnessed a decline in coverage over the past generation. Between 1994 and 2005 alone, the proportion of U.S. residents with employer coverage declined from 69% to 63% in the case of the total population, and from 66% to 58% in the case of children under 18 years of age.

Table 1 illustrates the skewed nature of health insurance coverage in the United States, chiefly as a result of a system that treats health insurance as an aspect of employee compensation.

Uninsured persons show patterns that are essentially the inverse of those evident among persons with health insurance coverage. Uninsured persons, as well as their family members, are significantly more likely to be low-income workers. Most uninsured persons are uninsured for relatively lengthy periods of time, usually a year or more. Compensating public insurance benefits for lower-income uninsured persons generally are available under the Medicaid program only in the case of selected subgroups of low-income persons: low-income children under 18 years of age; low-income pregnant women; and single parents of children under 18 years of age, who are below 50% of the federal poverty level. Public coverage through Medicare and/or Medicaid may be available in the case of persons who are sufficiently physically or mentally disabled. Medicare is restricted to persons whose employment history meets the 40-quarter minimum work requirement contained in the Social Security Act, while Medicaid

is limited to persons who are poor enough to qualify for Supplemental Security Income (SSI), where earnings are at or below approximately 75% of the federal poverty level.

As a matter of federal law, the legal authority for the regulation of insurance, including health insurance, rests with the individual states. The federal law that established this authority in states is the McCarran-Ferguson Act of 1945. At the same time, ERISA, which was passed in 1974, essentially upends this proposition to a considerable extent without actually overturning the McCarran-Ferguson Act.

The States' Role in Health Insurance

Responding to a 1945 U.S. Supreme Court decision subjecting the insurance industry to federal regulation, the U.S. Congress moved rapidly to restore the primacy of states in insurance regulation through the passage of the McCarran-Ferguson Act. By the mid-1970s, all states to some degree regulated health insurance. State regulatory structures reached the financial aspects of insurance, such as plan capitalization and reserves, and the financial aspects of plan operations. State law also regulated marketplace conduct, prohibiting certain types of deceptive marketing practices. Finally, state laws regulated the content of insurance coverage through an increasing number of benefit mandates, including the requirement for coverage of at least a certain amount of inpatient mental health treatment.

These express state laws were aimed at the insurance industry and its nature, structure, and operations of insurance contracts. Numerous other state laws reached insurer behavior too. For example, state civil rights and human rights statutes prohibiting discrimination in the workplace were interpreted to prohibit employee benefit plans from reducing or eliminating disability coverage in the case of women whose disability was related to pregnancy. Similarly, by the late 1970s, many states had laws that permitted persons alleging injuries caused by the deliberate and unfair claims denial practices of insurers to bring suit for "bad faith breach of contract" and to seek compensatory and noneconomic damages as part of their remedy. A few states, most notably California, recognized that insurers could be sued for corporate medical negligence in cases in which

prospective utilization of substandard management systems and procedures could be shown to be a proximate cause of injury or death.

In sum, even as ERISA moved to establish uniformity within the world of pension plans, a broad body of state law not only regulated the structure and content of insurance contracts, as well as contract administration, but also created rights and remedies for injuries arising from the maladministration of health insurance coverage in connection with prospective utilization review.

Requirements of ERISA

Enactment of ERISA in 1974 fundamentally altered the regulatory landscape. It also affected regulations following profound shifts in the health benefits marketplace, including the spread of prospective and concurrent utilization review and the growth of plans that effectively merge coverage and care through networked provider arrangements that give plans considerable control over actual access to care.

ERISA, which applies to all private employers, had as its central purpose the establishment of

uniform, national standards for the regulation of pension plans. Prior to ERISA's enactment, employers and unions had enormous discretion over the structure and operation of pensions, and state regulation of pension plans varied from weak to nonexistent. Following a series of spectacular pension plan failures, the U.S. Congress enacted legislation that established a unified federal approach to the vesting, funding, and operation of pension plans, a mechanism for guaranteeing pensions to secure pension rights, and a strict fiduciary standard against which to measure the legality of pension plan administration.

The enactment of ERISA involved virtually no discussion of health benefits, which simply were classified as a part of employer-sponsored "welfare benefits" and thus were to be subject to the terms of the statute. Unlike its pension provisions, however, ERISA established virtually no substantive statutory terms where welfare plans were concerned, and the intervening years have seen the enactment of very little in the way of statutory minimums with respect to health plan content and structure, health plan operations, and patient and consumer protections.

ERISA Reforms

While the original legislation did not include many statutory terms for health plans, one notable exception is the continuation of health insurance coverage, which was established as part of the federal Consolidated Omnibus Budget Reconciliation Act of 1985 (COBRA). Continuation of coverage applies to employers with 20 or more full-time employees and requires employer health plans to permit persons who lose their health plan participant or beneficiary status as a result of certain qualifying reasons (e.g., the death of the covered worker, loss of job, divorce) to continue to purchase group health insurance coverage on a full-premium, unsubsidized basis.

The Health Insurance Portability and Accountability Act of 1996 (HIPAA) also provides limited health insurance protections. Portability permits individuals who amass creditable coverage under one employer, and who meet certain other conditions, to change jobs without having to satisfy preexisting requirements and waiting periods under a subsequent employer plan. These rights also permit movement by individuals into the individual insurance market following exhaustion of their COBRA benefits, without being subject to the preexisting-conditions exclusions that characterize individual policies. Portability does not, however, address the basic affordability of individual coverage or its postcoverage limitations.

A third example of ERISA reform concerning health benefits came in 2000, during a period of intense and ultimately unsuccessful legislative debate over patients rights in managed-care arrangements. That year, the U.S. Department of Labor promulgated regulations that added considerable rigor to the obligations of health plans when individuals appeal decisions denying or terminating benefits. In addition, the 2000 “full and fair” hearing regulations established important limitations on the amount of time that plans can take in making coverage determinations, in recognition of the adverse effect that prospective and concurrent utilization review can have on healthcare access. Prospective utilization management was essentially unheard of at the time of ERISA’s enactment in 1974, as was the use of network-style health insurance. At the time, 90% of the insured workforce was covered by indemnity insurance plans that, at

most, used postclaims review procedures to determine medical necessity.

Outside these few examples and a handful of additional minor requirements, ERISA is effectively devoid of structural requirements related to the structure or administration of health benefit plans offered by employers. Despite this fact, however, an obscure provision of ERISA, known as the preemption statute, allows federal law to override state regulations by preempting state laws that “relate to” employer-sponsored benefit plans.

Preemption Under ERISA

Under the preemption statute of ERISA, laws are considered preempted if they attempt to compel plan design or place a direct burden on plan administration; on the other hand, laws that create indirect economic burdens, such as a tax on healthcare services, are not considered to relate to plans for purposes of preemption.

In addition, the ERISA preemption statute “saves” state laws that regulate insurance. However, self-insured health benefit plans, which account for over half of all persons with employer-sponsored coverage, are not considered to be insurance. Thus, they are shielded from state insurance laws that apply to the health insurance industry and regulate the insurance contract.

The preemptive effects of ERISA do not end with the so-called preemption statute. ERISA also establishes an exclusive means by which individuals can challenge wrongful plan conduct. As noted, when a claim arises involving benefits that allegedly are due to a patient under the terms of the plan, the patient can seek a full and fair review by the plan and can go to court to secure his or her benefits or to enjoin a future wrongful plan conduct. But ERISA’s remedial provisions contemplate no means for recovering damages in the event of injury. When an employer-sponsored plan, whether a large self-insured plan or a smaller plan that purchases state-regulated insurance and delegates administrative powers to the insurer, makes a bad-faith or negligent coverage decision that results in injury or death, claimants are cut off from all available damage remedies under state law. In effect, ERISA shields employer-sponsored health plans from the consequences of negligent or wrongful

conduct, a fact that the U.S. Congress has attempted to address by means of legislative amendments.

ERISA's shielding powers came to light in a historic case involving the death of an infant after the mother's health plan refused to preapprove her inpatient admission prior to delivery so that her high-risk pregnancy could be managed more appropriately. Despite the fact that state law would have given her the right to seek economic and noneconomic damages arising from the loss of her baby, the federal courts ruled that ERISA's exclusive remedial provisions served to preempt all state remedies other than those specified in the ERISA statute itself. Although the plan's decision directly implicated the woman's access to healthcare itself, the conduct was held to be a function of plan administration, since prospective utilization review is simply an aspect of modern health insurance operations.

At the same time, this shield has its limits. In those situations in which an injured person can demonstrate to a court that the injuries arise out of the quality of care, as in the performance of a health professional or hospital in a health plan's provider network, the courts consider this type of claim to be one that seeks damages for the quality of the care furnished rather than for benefits that allegedly are owed under the terms of the plan.

Despite this exception for quality claims, as well as the limits of preemption in the case of state laws that have only an indirect economic impact on ERISA health benefit plans, ERISA is understood to have a broad sweep, prohibiting state health reforms that compel certain types of health plan conduct. For example, a state cannot compel an employer to offer health benefits. The State of Hawaii does so pursuant to an express waiver of ERISA, granted in consideration of the fact that the Hawaii law predated ERISA and was immediately overturned following the federal enactment. Similarly, it would appear that a state cannot compel an employer to either offer a health benefit plan or pay into a pool, although the legality of such an approach has not yet been definitively addressed by the U.S. Supreme Court.

Future Implications

The enactment of ERISA in 1974 sought to protect participants in employee-sponsored pension

and health plans. It has many implications in the health insurance marketplace, and its modification becomes a crucial consideration in national health reform, particularly in the case of reform plans that contemplate a strong state role in the establishment or regulation of employee health benefit plans. Similarly, ERISA determines the extent to which individuals who allege injury as a result of substandard plan administration in the area of coverage determinations have access to economic or noneconomic damages. A better understanding of ERISA and its interpretations will help inform any future reform efforts.

ENTHOVEN, ALAIN C.

Alain C. Enthoven is a leading figure in the field of health economics and is regarded as the father of managed competition. He was also a cofounder of the Jackson Hole Group in Teton Village, Wyoming, a healthcare reform policy think tank, which was composed of medical, public policy, and business leaders committed to improving the nation's healthcare system. Enthoven is currently the Marriner S. Eccles Professor of Public and Private Management, emeritus, at the Stanford Graduate School of Business, and a core faculty at the Center for Health Policy/Center for Primary Care and Outcomes Research at Stanford.

Enthoven was born in 1930 in Seattle, Washington. He received his bachelor's degree from Stanford University in 1952, his master's degree from Oxford University in 1954, and a doctorate degree from the Massachusetts Institute of Technology in 1956—all in economics. From 1956 to 1960, Enthoven worked as an economist at the RAND Corporation. Following this, he worked at the U.S. Department of Defense, which ultimately culminated in his appointment by President Lyndon B. Johnson as assistant secretary of defense for systems analysis in 1965. In 1969, Enthoven entered the corporate world, taking a position as vice president of economic planning for Litton Industries, and in 1971 he became the president of Litton Medical Products. In this position, he began his work in health economics. In 1973, Enthoven became a professor at Stanford University, where he currently remains.

During his distinguished career, Enthoven has received numerous awards, appointments, and recognitions for his accomplishments in the field of economics. President John F. Kennedy presented Enthoven with the President's Award for Distinguished Federal Civilian Service in 1963. Enthoven also received the Baxter Health Services Research Prize from the Association for University Programs in Health Administration (AUPHA) in 1994 for his work on managed competition. In the same year, he was awarded the Clifton J. Latiolais Honor Medical from the American Managed Care Pharmacy Association. Enthoven also received the Board of Directors Award from the Healthcare Financial Management Association (HFMA) as

well as the Paul Ellwood Award for Efforts in Health Care Accountability from the Foundation for Accountability (FACCT).

Enthoven was a Rock Carling Fellow with the Nuffield Trust of London from 1998 to 1999 and is a former Rhodes Scholar. He is also an elected member of the National Academy of Sciences, Institute of Medicine (IOM), and a fellow of the American Academy of Arts and Sciences.

Throughout his career, Enthoven has been deeply involved with healthcare policy at both the state and federal levels. In 1977, while serving as a consultant to President Jimmy Carter, he proposed a plan for universal health insurance, called Consumer Choice Health Plan, the basis of which was managed competition. He also has served as Chairman of the Health Benefits Advisory Council for the California Public Employees Retirement System and was appointed Chairman of the California Managed Care Health Improvement Task Force, which was charged with the responsibility of studying healthcare issues created by managed care.

Enthoven has published widely on issues related to the economics, management, and public policy of healthcare, both in the United States and in the United Kingdom. The major focus of Enthoven's research has been to examine the root causes of the rapid escalation in healthcare costs and national health expenditures and to investigate strategies to mitigate these increases while improving the quality of care. He is currently developing a proposal for a market-based universal health insurance system.

EPIDEMIOLOGY

The term *epidemiology* is derived from the Greek roots *epi* meaning on or upon, *demos* meaning the common people, and *logy* meaning the study of. Epidemiology is defined as the study of diseases in human populations, their causes, and their means of prevention. The term *disease* in the definition refers to a broad array of health and medical problems, including disability, injury, and death.

Epidemiology differs from clinical medicine in a number of ways. It studies groups of people, not just individuals. Epidemiology also studies both well people and people with disease to identify the crucial differences between those who are stricken and those who are spared. These differences are compared to identify the underlying causes or etiologies of disease. While the goal of clinical medicine is to diminish pain, restore function, and bring the patient back to full health, the main goal of epidemiology is to understand the causes of diseases in order to prevent them from occurring.

Epidemiology addresses many areas of public health. For example, it studies the natural history and prognosis of disease. It is used to measure the extent and burden of disease within communities, states, and nations. Epidemiology is also frequently

used to evaluate therapeutic and preventive health measures, such as determining the effectiveness and safety of health-screening programs, new drugs, and vaccines. Public policymakers, government agencies, health insurance companies, hospitals, physicians, and others increasingly rely on epidemiology as the foundation for making sound decisions to protect the public's health.

The field of epidemiology is highly interdisciplinary. It relies heavily on the concepts, knowledge, and theories of disciplines such as biology, pathology, and physiology in the health and biomedical sciences, as well as the disciplines of anthropology, psychology, and sociology in the behavioral and social sciences. Epidemiology is also very closely tied to the discipline of statistics, particularly biostatistics. Within the basic discipline of epidemiology, there are several core subfields that have emerged over time. For example, scientific progress in the field of molecular genetics has spawned a relatively new area of study called genetic epidemiology. Epidemiologists focusing their efforts in this area are concerned with determining how newly discovered genes interact with the host and environment to produce complex disease. Other subfields within epidemiology include infectious disease epidemiology, chronic disease epidemiology, cancer epidemiology, occupational epidemiology, and social epidemiology.

History

Epidemiology is a relatively new science that emerged in the 19th century. However, its historical development spans thousands of years and is best described as slow and unsteady. Over the centuries, many individuals have contributed to the establishment of the modern field of epidemiology.

The first important individual was the Greek physician Hippocrates (428–347 BCE), who is traditionally regarded as the father of Western clinical medicine. Hippocrates wrote the first epidemiologic texts *Epidemic I*, *Epidemic III* and *On Airs, Waters, and Places*. In these works, he was the first person to attempt to explain the occurrence of disease on a rational rather than a supernatural basis. Since Hippocrates recognized disease as a mass phenomenon as well as one affecting individuals, he is recognized as the first epidemiologist.

Another figure of importance was the English statistician John Graunt (1620–1674). Graunt was the first person to analyze the *Bills of Mortality*, which recorded the weekly count of births and deaths in London. In 1662, Graunt published the results of his findings in *Natural and Political Observations Made Upon the Bills of Mortality*. He found that male births consistently outnumbered female births yet males no longer outnumbered females by the time they reached childbearing age because males experienced higher mortality rates. Graunt also constructed the first life table, a statistical table that uses death rates of a cohort of persons to determine the group's average life expectancy.

James Lind (1716–1794), a Scottish naval surgeon, also helped establish epidemiology. Lind studied the great sea plague scurvy. On long naval voyages, scurvy often killed two thirds of a ship's crew. To prevent scurvy, Lind conducted the first planned controlled clinical trial, supplementing the diet of a small number of sailors with fresh citrus fruit and lemon juice (the experimental group). He then compared the incidence of scurvy among these men with that of other sailors on the same ship who ate the normal vitamin-poor naval diet (the control group). Finding that citrus fruit prevented the disease, Lind recommended dietary changes for all sailors, which ultimately resulted in the eradication of scurvy from the British navy. Hence, British sailors are still referred to as "limeys."

Edward Jenner (1749–1823), a British surgeon who practiced medicine in the small village of Berkeley in Gloucestershire, England, observed that milkmaids who developed cowpox (a mild disease) never contracted the severe and often disfiguring and deadly disease smallpox. Using matter drawn from the lesions of cowpox on the hand of a milkmaid, Jenner performed the first vaccination. In time, the practice of vaccinating for the prevention of smallpox became widespread. Today, smallpox is the only disease to ever be totally eradicated from nature. And vaccination is a widely used method to prevent the occurrence of many diseases.

William Farr (1807–1883), a British physician who worked as the first compiler of scientific abstracts at the Registrar General's Office in London, helped shape England's vital statistics

system. His most important contribution to epidemiology was the establishment of a sophisticated system for classifying the causes of death. This enabled the comparison, for the first time, of mortality rates among different demographic and occupational groups. Farr's classification system still forms the basis of the International Classification of Disease and Related Health Problems (ICD) that is in use today.

Another great pioneer in the field of epidemiology was John Snow (1813–1858). Snow, a contemporary of William Farr, was a well-respected London physician who specialized in obstetric anesthesiology. One of his patients was Queen Victoria, whom he assisted in the delivery of two of her children. Snow became interested in the cause and spread of cholera epidemics that periodically occurred in London. In 1854, when a severe cholera epidemic once again struck the city, Snow undertook an investigation. At the time, most physicians attributed the disease to miasma or "bad air" formed from decaying organic matter. Snow, however, held the radical view at the time that cholera was caused by drinking fecal-contaminated water. Snow started his investigation by plotting the geographic location of all cholera deaths in London. When he found a large number of deaths (more than 500 in a 10-day period) clustered around a public water hand pump on Broad Street in the Soho District of west London, he informed the local authorities, along with his hunch as to the cause. Although the authorities were skeptical, the next day they had the pump disabled by removing its handle. Immediately, new cases of cholera started to dwindle and then disappear. However, because cholera deaths were already declining in the city, Snow was unable to attribute the end of the outbreak directly to the removal of the pump handle. Snow doggedly continued his investigation of cholera and conducted what he called his Great Experiment. To conduct the "Experiment," Snow painstakingly documented the cholera deaths (nearly 1,400) among the subscribers of London's two independent private water companies. The Southwark and Vauxhall Company (which supplied more than 40,000 homes) drew its water from the sewage-polluted lower Thames River, while the Lambeth Company (which supplied more than 25,000 homes) obtained its water farther upriver. Snow conclusively showed that the

number and rate of cholera deaths were much higher for residents in homes served by the Southwark and Vauxhall Company, which supplied the polluted water. Using meticulously gathered data and the power of statistics, Snow brought about the beginning of the end of cholera in Britain. Because of his study methods and insights, Snow is generally regarded as the father of modern epidemiology.

Basic Concepts and Tools

Epidemiology has two fundamental assumptions. First, disease does not occur at random. Second, disease has causal and preventive factors.

Epidemiologists often use models to explain the occurrence of disease. One commonly used model views disease in terms of susceptibility and exposure factors. Specifically, for individuals to develop disease, they must be both susceptible to the disease and exposed to it. For example, for a person to develop measles (rubeola), a highly infectious viral disease that was once very common among children, he or she must both be exposed to a person who is shedding the measles virus (an active case) and be susceptible to measles because of lack of immunity to it. Immunity to measles may be derived from either previously having the disease or from being vaccinated against it.

Another commonly used model, the epidemiologic triad, views the occurrence of disease as the balance among the host, agent, and environmental factors. The host is the actual or potential recipient or victim of the disease. Hosts have characteristics that either predispose them to or protect them from disease. These characteristics may be biological (e.g., age, sex, and degree of immunity), behavioral (e.g., habits, culture, and lifestyle), or social (e.g., attitudes, norms, and values). The agent is a factor whose presence or absence is necessary for a particular disease to occur. Agents may be biological (e.g., bacteria, fungi, and viruses), chemical (e.g., gases and toxic agents), nutritional (e.g., carbohydrates, fats, and food additives), or physical (e.g., electricity and ionizing radiation). The environment includes all external factors, other than the host and agent, that influence health. The environment may be categorized as the social environment (e.g., economic, legal, and political), the

physical environment (e.g., precipitation, temperature, and weather conditions), or the biological environment (animals and plants). To illustrate the epidemiologic triad, consider a case of lung cancer. The host is the person who developed lung cancer. He or she may have had the habit of smoking for many years. The agent is the smoke, tars, and toxic chemicals contained in the tobacco. Environment may have been the workplace where smoking on the job was permitted and cigarettes or other tobacco products were readily available.

Epidemiologists classify the type of disease cases and frequency of disease occurrence within a population as being either endemic or epidemic. Endemic is defined as the usual occurrence of a disease within a population. In contrast, an epidemic is the occurrence of disease, often developing suddenly, that is clearly in excess of the level that normally occurs within a population. It may also be the first occurrence of an entirely new disease. A special type of epidemic is the pandemic, which is a rapidly emerging outbreak of a disease that affects a wide range of geographically distributed populations. Many pandemics are worldwide in scope. To illustrate these terms, a small number of people develop the flu (influenza) in a large city throughout the year, and these would be endemic cases of the disease. In contrast, the number of people contracting the flu in the same city may increase enormously in the fall, and these would represent epidemic cases. Last, if a new variety of flu emerges and people throughout the world get sick from it, they would be pandemic cases. An example of a pandemic is the great influenza outbreak of 1918, which spread throughout the world, killing an estimated 20 to 40 million people.

Epidemiologists study the morbidity and mortality caused by acute and chronic diseases. Morbidity is defined as the state of illness, symptoms, or impairments produced by a disease, while mortality is death caused by a particular disease. Acute diseases are those that strike and disappear quickly, within a month or so (e.g., chicken pox, colds, and the flu), while chronic diseases are those that are long-term or lifelong diseases, many of which are incurable (e.g., cancer, diabetes, and HIV/AIDS).

One of the most important measurement tools of epidemiology is the use of morbidity and mortality rates. Epidemiologists use rates so that the number of disease cases and deaths can be

compared with a certain number of people at risk in a population. Although strict use of the term *rate* is not always observed, a rate is a special type of proportion that includes a specification of time. Thus, a rate indicates the proportion of people in a population who experience an event during a specified period of time. Rates can be expressed in any form that is convenient (e.g., per 100 per week, per 1,000 per year, per 10,000 per year, per 100,000 per month). Infant mortality rates, for example, are often expressed per 1,000 live births, while cancer rates are often expressed per 100,000 population. Any meaningful number may be used in the denominator, however.

The following example illustrates the important role rates play in making epidemiological comparisons. Assume that City A has 10 cases of a disease while City B has 50 cases. Although in terms of absolute numbers City B has five times more cases of the disease than City A, the differences may be due to the underlying population size of the two cities. To compare the occurrence of disease in the cities on a unit population basis, rates must be calculated. If City A has a population of 10,000 and City B has a population of 50,000, the disease rates per 1,000 people would be the same for both cities. City A's disease rate is $(10/10,000) \times 1000 = 1.0$ case per 1,000 population, and City B's disease rate is $(50/50,000) \times 1000 = 1.0$ case per 1,000 population. Of course, a valid comparison here also presumes that disease occurrence is being measured over the same amount of time.

Rates may be crude, specific, or adjusted. Crude rates use the total number of disease cases and the entire population in their calculations. For example, the above rates for City A and City B are crude disease rates. Specific rates differentiate cases and populations into age, sex, race, or other subgroups. For example, if the rates for City A and City B were for persons with disease who were 25 to 34 years of age divided by the total number of people in each city who were 25 to 34 years of age, the rates would be age-specific disease rates. Specific rates can be applied to very narrowly defined segments of a population. For example, one could calculate an age/sex/race-specific disease rate (e.g., the number of persons with disease who are African American, male, and aged 25–34 years divided by the total number of people in the population who are African American, male, and aged 25–34

years). Basically, adjusted or standardized rates allow for comparison of populations that have different demographic characteristics. To calculate adjusted rates, summary adjusted rates are used to remove age, sex, or race differences in populations. For example, in the United States, the population of Florida (a state where many people go to retire) is much older than the population in Alaska. Thus, it would be inappropriate to compare the mortality rates of the two states without adjusting for the differences in their age structures.

Two measures that epidemiologists frequently use to describe the occurrence of disease include incidence and prevalence. Incidence measures the rapidity at which new cases of a disease are occurring in a population over a specified period of time. Since incidence always includes a specified period of time during which new cases occur, it is another type of rate. The incidence rate is an important measure for evaluating disease control programs; an example incidence rate could be stated as follows: 10 new cases of Disease X per 100 people per year. Epidemiologists in health departments, for example, study the incidence rates of HIV/AIDS to determine if the disease is spreading and whether AIDS prevention programs are working.

Prevalence measures the total number of *existing* cases of a disease in a population at a given point of time ("point prevalence") or sometimes within a period of time ("period prevalence"). Prevalence can be a useful indicator of the burden of disease on the medical and social systems of a geographic region. Prevalence is often expressed as a proportion. For example, if 100 people in a small town of 1,000 people had hypertension at a particular point in time, then the prevalence of hypertension in the population would be 0.1, or 10%. Epidemiologists at the World Health Organization (WHO), for example, use prevalence measures to describe the medical, economic, and social burden of AIDS in developing countries.

There is a relationship between incidence and prevalence. Prevalence directly varies with both the incidence and the duration of disease. If the incidence of a disease is low but the duration of the disease is long, such as with chronic diseases, the prevalence will be large in relation to the incidence. Conversely, if disease prevalence is low because of short duration due to migration, death, or quick

recovery, then prevalence will be small relative to incidence.

Sources of Epidemiological Data

Epidemiologists use primary and secondary data sources to calculate disease measures and conduct studies. Primary data are the original data collected for a specific purpose by or for an investigator. For example, an epidemiologist may collect primary data by interviewing people who became ill after eating at a restaurant, to identify which foods they ate. Collecting primary data is expensive and time-consuming, and it usually is undertaken only when secondary data are not available. Secondary data are data that have already been collected for another purpose by other individuals or organizations. Examples of secondary data commonly used by epidemiologists include birth and death certificates, population census records, hospital and clinic patient medical records, data from disease registries, insurance claim forms and billing records, public health department case reports, and surveys of individuals and households.

An important source of secondary data is the Centers for Disease Control and Prevention (CDC). The CDC, which is an agency of the U.S. Department of Health and Human Services, consists of 12 centers, institutes, and offices. The various centers collect a wide array of epidemiological data on problems such as birth defects and developmental disabilities, chronic diseases, infectious diseases, injuries, work-related injuries, and sexually transmitted diseases. Within the CDC, the National Center for Health Statistics (NCHS) conducts, publishes, and widely disseminates the results of numerous health surveys of individuals and healthcare organizations. Examples of NCHS surveys include the National Health Interview Survey, the National Health and Nutrition Examination Survey, the National Hospital Discharge Survey, and the National Nursing Home Survey.

Descriptive and Analytical Epidemiology

The field of epidemiology can be divided into two broad categories: descriptive epidemiology and analytical epidemiology. Descriptive epidemiology

characterizes the distribution of disease within a population. It describes the person, place, and time characteristics of disease occurrence. It specifically asks the questions “Who is getting the disease? Where is the disease occurring? When is the disease occurring?”

A typical example of descriptive epidemiology is an investigation whereby the health status of a population is determined via the administration of a health survey. Through detailed interviews, medical examinations, and the extraction of data from medical records, the epidemiologist may be able to determine a variety of characteristics of the population, such as who suffers from diabetes, hypertension, heart disease, cancer, disability, and so on. Using these data to develop hypotheses about the environmental causes of disease may be possible. These data might also be used to help policymakers decide on how to distribute resources that could best serve the population living in the area.

Analytical epidemiology, on the other hand, tests hypotheses to determine if statistical associations exist between suspected causal factors and disease occurrence. It also tests the effectiveness and safety of therapeutic and medical interventions. To accomplish these tasks, analytical epidemiology uses four major types of research study designs: cross-sectional studies, case-control studies, cohort studies, and controlled clinical trials. Each of these types of studies has strengths and weaknesses.

Cross-sectional studies examine the relationship between disease and other variables of interest as they exist in defined populations at one particular time. For example, a cross-sectional study investigating whether residential exposure to the radioactive gas radon increases the risk of lung cancer may examine the current level of radon gas in lung cancer patients' homes. Cross-sectional studies have the advantage of being inexpensive and simple to conduct. However, their main disadvantage is that they may not establish causality because exposures are only measured once disease has already occurred. To establish causation, it would be important to measure exposure over a period of time prior to the onset of disease so that exposure status could be measured and contrasted among those who did and did not develop the disease.

Case-control studies start with people who already have a particular disease (cases) and a suitable control group without the disease and then compare

the exposures that have occurred among the cases and controls. If an exposure is truly related to development of the disease of interest, then it will have occurred more frequently among the cases than the controls. These types of studies are most useful for ascertaining the cause of rare events, such as certain cancers. For example, to determine whether the use of cellular telephones causes head cancers, a group of head cancer patients (cases) would be compared with a group of individuals without head cancers (controls). The two groups would then be compared with respect to the proportion that used cellular telephones and their level of exposure (i.e., how many minutes they talked over the telephone per day). Case-control studies have the advantages of being quick to conduct and inexpensive, and they may require only a small number of cases and controls to determine an association. However, their main disadvantage is that they rely on recall or some estimate of an exposure that has already occurred in the past. These can lead to misleading and biased results.

Cohort studies are observational studies in which a defined group of people (the cohort) is followed over time and outcomes are compared for individuals who were exposed or not exposed to different levels of some factor. Cohorts can be assembled in the present and followed into the future (a prospective cohort study) or identified from past records (historical or retrospective cohort study). An example of a cohort study is the Framingham Heart Study. The Framingham study is the longest ongoing epidemiological study in the United States. Starting in 1948 with an original cohort of 5,200 adult volunteers from Framingham, Massachusetts, the study has followed the volunteers and their offspring to identify the risk factors associated with developing heart disease (e.g., cholesterol levels, smoking, obesity, and diabetes). To date, the results from this landmark cohort study have been published in more than 1,000 scientific papers. The main advantage of cohort studies is that they can establish the timing and directionality of events. However, their main disadvantages are that they require large sample sizes and a long follow-up time and they are not typically suitable for investigating rare diseases unless extremely large populations are studied.

Controlled clinical trials are studies that test therapeutic drugs or other health or medical interventions to assess their effectiveness and

safety. Controlled clinical trials compare the outcomes of new drugs or interventions given to an experimental group versus another group (control) that does not receive the same drugs or interventions. To minimize bias, individuals involved in clinical trials may be randomly assigned to the experimental and control groups. For example, to determine whether a new drug to treat breast cancer is more effective than another drug, breast cancer patients would be assigned randomly into either an experimental group that receives the new drug or the control group that receives the other drug. The outcomes of the two groups (e.g., the number of remissions and increase in survival time) would then be compared. In the United States, and many other countries, all new therapeutic drugs are subjected to rigorous controlled clinical trials before they can be provided to the public. The main advantage of controlled clinical trials is they provide unbiased results. However, their main disadvantage is that they are very expensive to conduct.

Future Implications

During the past several decades, the field of epidemiology has greatly expanded in size, scope, and influence. The number of epidemiologists has grown rapidly along with epidemiology programs in schools of public health and medicine. Today, epidemiologists investigate the outbreaks of acute diseases, such as food-borne epidemics. They also investigate the outbreaks of new emerging diseases such as SARS and reemerging older diseases such as tuberculosis. At the same time, epidemiologists study the underlying causes of many chronic diseases such as cancer, heart disease, and stroke. They also study the causes of psychiatric disorders, substance abuse, and social problems such as violence. Since the recent terrorist attacks in the United States, Europe, and Japan, many epidemiologists are involved in planning and implementing health surveillance programs to detect and prevent possible bioterrorism attacks. Epidemiologists are also just beginning to examine the determinants of health at the molecular and genetic levels. They are studying how individual genes influence the risk of developing chronic conditions such as Alzheimer's disease. And epidemiologists are beginning to develop new molecular

markers to improve the measurement of individually specific exposure and susceptibility factors.

E-PRESCRIBING

E-prescribing or electronic prescribing systems include the ability of entering prescription data intended for ambulatory use into a computer system and then either printing a copy of the prescription or, as a preferred mechanism, communicating the data elements of the prescription directly to the filling pharmacy's computer system. These systems, whether in the hospital as part of an automated medication order entry process or in the ambulatory environment through the use of a handheld technology device, provide benefits to both clinicians and patients. They provide a quicker way for prescription data to be in the pharmacy, thereby eliminating delays in prescription processing caused by illegible handwriting and data entry. This results in a reduction in medication errors and, ultimately, should reduce overall medication costs for the patient through better drug use.

Typically, e-prescribing systems permit the clinician to use the extensive drug resources supplied by software companies in order to confirm drug information, including drug availability, dosing, indications, contraindications, and drug interactions, and have access to monograph and journal article references. In more comprehensive systems, clinicians can check intended medications against the patient's current medication profile and/or insurance company drug formulary, all at the point of care. Additionally, clinicians may benefit by using the software to stay current with information on new medications, pharmacokinetics, and other treatment protocols.

Background

The Medicare Prescription Drug, Improvement, and Modernization Act (MMA) of 2003 had a profound legislative and regulatory impact on e-prescribing. The act provides a prescription drug

benefit (under Part D) to Medicare enrollees and also includes the requirement for standards to be adopted for the voluntary use of e-prescribing as well as proposed relief to antikickback laws that may support various e-prescribing arrangements. Additionally, the act tasked the National Committee on Vital and Health Statistics with recommending appropriate messaging standards for the exchange of e-prescribing data. The committee developed an initial set of recommendations for e-prescribing data standards in September 2004, and they have been through the regulatory process, with a final rule issued in November 2005.

Utility of the Systems

There are several major factors that affect the utility of e-prescribing systems in actual practice. Specifically, the data in the systems must be accurate. Clinicians will be making decisions based on the data; thus the source systems must provide accurate data through working interfaces. Second, the software must be reliable. Clinicians must be confident that the software works as intended. Medication and patient data must be readily available at the point of care when the clinicians intend to make decisions. Third, since clinicians often use acute care for discharge and emergency department prescriptions, uniform standards in both acute care and ambulatory environments must exist. The HL7 interface standard is currently used in most acute-care systems while the National Council for Prescription Drug Programs data and transmission standards are used in most retail pharmacy systems. There is a need for cross-communications to promote full interoperability of systems. Finally, the systems must be maintained with regular updates. Clinicians must be confident that all data content is regularly updated as scheduled.

Levels of Usage

According to the e-Health Initiative, there are six graduated levels of e-prescribing usage. The levels go from the basic (Level 1) to the most comprehensive (Level 6). In Level 1, the clinician uses a handheld hardware unit for basic electronic reference data, usually provided by drug reference

software without an automated prescription writing capability. In Level 2, the clinician uses a stand-alone prescription writer without integrated access to the patient's clinical data or supporting medication history. In Level 3, the clinician has the ability to access the patient's supporting data, such as demographic, allergy, formulary, and/or payer information prior to generating a prescription from a stand-alone prescription writer. In Level 4, the clinician has the ability to manage the patient's drug treatment by tracking and monitoring the patient's medication history and current medication usage. In Level 5, the clinician has the ability to communicate prescription data with pharmacies, payers to check drug formularies, pharmacy benefit managers who submit claims data, and other intermediaries. Finally, in Level 6, the clinician has full integration with a complete electronic health record that includes the ability to order and prescribe medications.

Barriers

While there is great potential for e-prescribing, the nation's healthcare industry has seen only limited adoption of these systems. According to the e-Health Initiative, in 2004, less than 20% of physicians used e-prescribing. Given the fact that there are more than 3 billion prescriptions written annually in the United States, other studies have suggested that the national savings from the universal adoption of e-prescribing systems could save as much as \$25 to \$30 billion. Some of these savings are from prevention of adverse drug events, reduced hospitalizations and ambulatory visits, use of generic drugs, and formulary compliance, with an overall reduction in the use of prescription drugs.

This limited adoption is the result of barriers that have been reported when implementing e-prescribing systems, which have prevented the full realization of their benefits. Specifically, seven major barriers have been identified.

First, e-prescribing systems are perceived to be slower than other manual systems, and clinicians complain of lower productivity. The increased time clinicians take to use electronic prescribing requires them to spend more time with each patient, which decreases the number of patients who can be seen per unit of time, thus potentially reducing overall

income. Clinicians have had substantial experience manually writing prescriptions in a matter of seconds, and most physicians will continue to hand-write prescriptions because it is perceived to be quicker than using a computer. In spite of the quality and other benefits to be realized from electronic prescribing, until the automated process is deemed quicker, this barrier will be cited.

Second, lack of connectivity with other providers, particularly retail pharmacy outlets, is limiting the full utilization of e-prescribing. Many times, handheld e-prescribing systems do not integrate with all pharmacy computer systems, resulting in manual entry for some cases and the increased possibility of medication errors in spite of the clinician's best intentions. While many of the retail pharmacies are working hard to become e-prescribing certified, this is a difficult and slow process.

Third, the purchase of e-prescribing technology is often not the only capital investment under consideration in most ambulatory medical practices and hospitals. In an environment of decreasing reimbursements, many clinicians and hospitals feel that there is limited capital and few successful business models in the literature to make this capability a high priority when considering other major projects.

Fourth, there is confusion about the available functionality of these systems in the minds of many buyers. The e-prescribing systems marketplace is still evolving, and many suppliers in this market segment are striving to make their software systems appear to be the best. This has created confusion among clinician buyers, who may not have the full opportunity or the time to assess all available options. A variety of wrong decisions have been made, resulting in less than optimal integration and usage.

Fifth, the cost of purchasing and implementing e-prescribing has become a major barrier for many clinicians in private practice. Estimates for the hardware and software costs of low-level e-prescribing systems range from \$1,500 to almost \$5,000 per clinician. Estimated costs for higher-level systems with advanced capabilities, including complex alerts and reminders, are almost \$30,000 per clinician in the 1st year and can be as high as \$5,000 to \$10,000 annually.

Sixth, in today's healthcare environment, most clinicians have had negative experiences with other information technology projects and have become

overly concerned about another experimental technology being used.

Finally, many clinicians question their investment into e-prescribing products that do not integrate with existing systems and expect that better products will be introduced into the marketplace in the near future.

EQUITY, EFFICIENCY, AND EFFECTIVENESS IN HEALTHCARE

Healthcare providers are increasingly under pressure to prove that their services are being delivered in an efficient and effective manner. Those

funding healthcare services—both third-party payers and consumers—are demanding more accountability. And policymakers are seeking measures that are objective and based on empirical evidence.

The reason for this pressure for greater accountability is that policymakers recognize that healthcare providers have an obligation to demonstrate that what they are doing is having some specific effect. In other words, it is possible to document outcomes from particular service delivery models or programs.

With rising healthcare costs squeezing profits and the growing numbers of people without health insurance pushing costs even higher, many employers are beginning to highlight healthcare costs and benefits as one of the most important issues to be addressed. At the same time, employees faced with increased cost sharing, the increased cost of health insurance, and the growing numbers of people without any kind of insurance are also pointing to healthcare as a “crisis.”

Healthcare policymakers are concerned with whether it is possible to develop measures to document improvement or change for particular medical conditions. They raise a number of questions. For example, what should be the standard for assessing whether a consumer/patient has gotten better or worse as a result of a given treatment or service delivery model? What specific outcome or set of outcomes is a treatment aimed at? It should be noted that the state of the art in terms of measuring medical outcomes is not such that one can be particularly precise about the results that have been achieved. How does one, for example, compare four units of wellness with two or three units? Can an outcome such as wellness really be measured at interval levels where one assumes that each additional unit of wellness has the same value as another unit?

More specifically, healthcare policymakers at the national, state, and local levels have demonstrated an increasing concern for equity, efficiency, and effectiveness of healthcare.

Definitions

Equity

One of the standards used to assess the delivery of healthcare services for purposes of accountability

is the extent to which these services, especially publicly funded services, are provided to the same people, to similar groups of people, or to constituencies. “Sameness” is at the heart of a standard that focuses, for example, on whether individuals or groups receiving healthcare services funded by the same health insurance plan (e.g., Medicaid) receive the same quantity and quality of services. To the extent that they are, then equity has been achieved. To the extent that they are not, then there are documented disparities, and equity has not been achieved.

Efficiency

Another standard that can be used to assess the delivery of healthcare services is the extent to which particular services have been delivered at the least possible cost to the public or to a different third-party payer. When the least possible cost has been identified, it is assumed that this represents efficiency. The standard of efficiency is most relevant when the policymaker’s goal is to compare alternatives for the investment of resources and to select the alternative that is the least costly. This standard is focused on the least costly method to achieve a particular objective.

Effectiveness

In contrast to efficiency, another standard focuses on particular goals or outputs that are to be achieved. Alternative programs or methods are compared that achieve the same output or outcome. In other words, this form of accountability involves specifying an objective or a level of desired output and identifying alternative methods that succeed in reaching the desired goal.

By identifying all alternative methods that succeed in reaching a desired level of output or outcome, policymakers may also be identifying a range of costs that are associated with this level of success. Consequently, an effective outcome may or may not be an efficient outcome. By employing effectiveness as a standard, policymakers may also be identifying inefficient options.

This discussion of different standards highlights the fact that if policymakers are looking to make health services programs more accountable, it is crucial to be clear as to what question is being

asked. If a policymaker is mainly interested in measuring quality or a particular outcome or a set of outputs, then a range of alternatives for achieving success may be identified that, in turn, have a range of costs associated with these options. However, this assessment would not necessarily provide any information about which of these alternatives is the least costly. It is only when one poses the challenge of identifying the least possible cost that one is analyzing efficiency.

From a health policy perspective, without considered attention to the efficiency dimension, the results of an analysis may be counterproductive in that inefficient options are invested in as if they were the best available. It is also clear that an analysis of neither efficiency or effectiveness will necessarily identify options that produce equity.

Context

These measures or standards of accountability should be placed in the context of a changing health services delivery and policy landscape. By understanding how the service delivery systems and models have changed, it will be possible to also understand where the demands for accountability have come from.

In the early 1990s, the dominant model for health insurance financing and delivery in the United States was the fee-for-service system. Managed care was beginning to grow in importance but still had a smaller market share. In 1994, 50.5 million Americans were enrolled in health maintenance organizations (HMOs), and in 1993, preferred provider organizations (PPOs) had approximately 60 million enrollees. By 2006, more than 70 million Americans were enrolled in HMOs, and almost 90 million were part of PPOs.

An area where this shift to managed care has been particularly influential has been in Medicaid. In 1991, 2.7 million Medicaid recipients were enrolled in some form of managed care; by 2004, 27 million Medicaid recipients were enrolled in managed care. A total of 63% of all Medicaid recipients in the nation were enrolled in managed care in 2005.

The design of the American healthcare system is such that third-party payers for health coverage are a driving force in shaping the healthcare system

and in driving the development of accountability measures. As recently as 1960, consumers paid most healthcare expenditures as out-of-pocket expenses. In 1960, 55% of all healthcare costs were paid out of pocket, but by 1998, that number had dropped to less than 20%. It may not be coincidence that healthcare expenditures, measured as a percentage of the nation's gross domestic product (GDP), have risen in line with this increase in third-party payment. It is also worth noting that prior to 1965 and the passage of Medicare and Medicaid, the public healthcare delivery system was limited to state public health departments and some public hospitals and there was no broad insurance scheme for any segment of the population.

The system of third-party payment, especially in the form called fee-for-service insurance, contains very little incentive for cost control. Neither the provider nor the patient is at financial risk in making healthcare decisions. In economic terms, the marginal cost to either of these participants in the transaction was very low, usually zero. However, the marginal benefit of extra healthcare expenditures, while diminishing, was certainly positive. Since benefits exceeded private costs, it was "rational" for the physician to order more services and tests. However, it is unlikely that benefits exceeded the overall costs to society. Regardless, the result was ever-increasing expenditures on healthcare; and from the mid-1960s through the early 1980s, healthcare expenditures rose by more than 10% per year. Much of the changes in the healthcare arena in the recent past can be traced to changes in laws and regulations related to healthcare. While some of this legislation has helped constrain healthcare costs, some of it has also contributed to rising costs in a variety of ways.

In the 1990s, growth of managed care coincided with a sharp reduction in the growth of healthcare costs. National data from that period suggest that managed care organizations (MCOs) have been substantially more efficient than traditional indemnity plans in controlling costs. The sweeping changes in the American healthcare system in the past 15 years, such as the slowdown in the rising rate of healthcare costs, cutbacks at hospitals, and the merger of hospitals and drug companies, can be attributed in large part to the spread of managed care. While a great deal of the cost savings can be attributed to discounted prices negotiated

by MCOs, the literature also suggests that in these organizations there has been a significant decrease in the use of more costly tests, which has contributed to reduced total spending. There is certainly a general consensus that managed care was successful in reducing the rate of healthcare cost growth, and it remains a powerful tool for controlling the rate of increase. In other words, MCOs have reduced healthcare expenditures in three ways: (1) by reducing the quantity of services used, (2) by reducing payments to providers, and (3) by selecting healthier patients.

The controversy surrounding managed care stems from the question of what methods were used to achieve this level of cost control. The general answer is that managed care brought new constraints to the decision making of both consumers and healthcare providers. As indicated above, a system of fee-for-service compensation has built-in incentives for overutilization as services were provided beyond the point of effectiveness or even appropriateness. Managed care brought in a new set of incentives. The “managed” part of the term meant that there would be more attention paid to medical utilization reviewing procedures as well as to provider contracts. In this managed-care system, a greater emphasis on competition was injected into the healthcare marketplace. Insurers were able to successfully negotiate terms with hospitals and other providers that resulted in significant slowdown in the rapid rise of health insurance premiums. However, these new incentives created concerns about the quality of care being provided by providers who were suddenly forced to become more cost conscious.

This quality controversy was fueled throughout the 1990s by media horror stories and a number of lawsuits alleging that managed-care plans were guilty of medical malpractice. Despite the public perception that managed care might reduce quality, the available evidence suggests that there has been no clear change in the quality of care provided under managed care, even in areas that have been specifically targeted for regulation, such as maternity care. At worst, the evidence about the quality of care provided under managed care has been mixed, with analyses reviewing more than 100 primary studies finding nearly equal numbers of examples of managed-care arrangements that increased quality as those that decreased quality.

Despite the fact that managed-care plans did succeed in controlling costs without decreasing quality, there was a significant backlash from consumers and providers to this new form of healthcare service delivery. This strong public backlash has been driven by claims that managed care has not reduced costs or increased efficiency, it has led to patient dissatisfaction, and its management techniques have resulted in adverse medical outcomes.

This dissatisfaction came to a head in the late 1990s and early 2000s, when a series of so-called anti-managed-care regulations were passed at the federal and state levels and a series of lawsuits against HMOs put the question of managed-care organization liability on the top of the health policy agenda. Between 1996 and 2002 alone, nearly 900 bills introducing some form of regulation of MCOs were introduced in legislatures across the nation, and at least one provision was enacted in every state. By 2001, all but four states had some type of comprehensive patients’ bill of rights or patient protection act.

In sum, this picture of the healthcare service landscape documents that the demands for accountability are directly related to concerns over cost control, quality, and consumer dissatisfaction.

Measures

In the public sector, standards emerged out of the Medicare program and a desire by policymakers to effectively document and control costs while maintaining high-quality services. The first measures were developed in the inpatient sector. These measures became known as the Medicare payment systems.

The impact of the Medicare payment systems on the nation’s hospital sector has been substantial and widespread since it introduced its prospective payment system (PPS) in 1983. The PPS is divided into an inpatient system (IPPS), which is based on Diagnosis Related Groups (DRGs) payments, and an outpatient payment system (OPPS), which was implemented in 2000 and is based on ambulatory payment classifications (APCs) related to the episode of care. The PPS, which replaced the previous cost-based reimbursement system, is designed to create financial incentives for hospitals to become more efficient in providing services for each episode

of care provided to Medicare beneficiaries. Medicare administrators believed that such a system would create a more competitive, market-like environment in the hospital sector. The theory was that hospitals that successfully implemented improvements in efficiency under the PPS would become more competitive vis-à-vis their counterparts who were unable to achieve efficiency gains.

First adopted by Medicare in 1983, DRGs are now used by health systems internationally as a method to control costs. Under the DRG system, medical conditions are classified into approximately 500 groups. DRGs (and the similar APCs used in the outpatient setting) represent predetermined payments based on the average cost of providing a given healthcare service, including all the ancillary services necessary to perform the service. The payments are weighted based on the median cost of providing the service in a given geographic area. Services provided within a given DRG are expected to incur similar healthcare costs and use a similar amount of hospital resources and are therefore used to set standard Medicare reimbursement rates.

Proponents argue that DRG reimbursement systems have contained hospital costs, saving nearly \$18 billion in their 1st year of implementation. Critics say that low reimbursement rates provide an incentive for private physicians to reject Medicare patients and place an undue fiscal strain on hospitals. The costs are then passed on to other insured hospital patients, raising healthcare costs overall.

One of the goals of introducing the PPS was to encourage a shift of some hospital services to less expensive outpatient settings and thereby reduce the overall costs of inpatient hospital care. There are numerous examples of this goal having been borne out empirically, including the fact that the average hospital inpatient length of stay declined rapidly after the introduction of the PPS. Within the first few years of the PPS, the number of inpatient cataract surgeries declined by more than 65%, and the number of outpatient cataract surgeries increased by almost 130%.

The PPS also had a profound but indirect, and largely unintended, consequence. In many cases, private payers have modified the PPS for their own purposes or used outright the Medicare DRGs payment structures as reference pricing for their

own reimbursement policies. The result of this development is that Medicare reimbursement policy not only affects the prices of medical care for Medicare beneficiaries, but it also creates a standard for medical care pricing for the entire healthcare industry, both public and private.

The nature of the hospitals with which private insurance companies contract can affect the insurance companies' ability to compete with one another. For example, insurance plans' marketability to employers and employees depends not only on the price of the coverage they offer but also on the number of hospitals where coverage is offered and on the quality, accessibility, and desirability of those hospitals. Being a must-have hospital may confer a significant competitive advantage to such a hospital in contract negotiations with private insurance companies.

The Centers for Medicare and Medicaid Services (CMS), the federal agency that administers the Medicare program, clearly has a profound effect on the competitive environment in which hospitals operate, but this is primarily an indirect effect through its price-setting authority. It does not, for example, have the ability to use competitive bidding or selective contracting mechanisms to exert direct control of the providers with which it negotiates. And there is virtually no way for Medicare to encourage nonprice competition between providers. This is what recent pay-for-performance initiatives would attempt to do by inserting quality and outcome measures into the payment policy, but such initiatives are in their infancy.

Hospital pricing in the United States is determined by four primary factors: (1) the amount of bulk purchasing by insurance companies, (2) price discrimination between different buyers of services, (3) cost shifting between consumers, and (4) cross subsidies between types of services. Bulk purchasing typically involves large insurance companies negotiating discounted pricing for some or all services in exchange for a guaranteed volume. Price discrimination may result from different negotiations with different insurance companies and involves charging different prices for the same services to different payers. Cost shifting occurs when a hospital raises prices for one group of purchasers while lowering the price for another group. Cross subsidizing is similar to cost shifting in that one group is charged more for certain services; but

in this case, the excess revenue is used to subsidize the price of those services for another group.

There is controversy about whether hospitals increase prices to private payers in response to reductions in payment rates from public programs—whether they engage in cost shifting. Cost shifting has its roots in community-rated insurance, which depends on “overpayments” relative to underlying healthcare costs incurred by youthful and less sick populations. These payments cover “underpayments” relative to the healthcare costs incurred by older and sicker populations. This form of cost shifting was an outgrowth of hospitals’ and physicians’ charging practices before health insurance was generally available. Most discussion of cost shifting now centers on hospitals, where, to varying degrees, public payers and self-pay patients have paid less than their costs. The financial losses incurred by hospitals in providing care to these populations have generally been cross-subsidized by revenue surpluses generated by the privately insured.

The practice of direct hospital rate setting by states has undergone a significant reduction since the introduction of managed care. In the 1970s and 1980s, it represented an experiment that fascinated health policy analysts and enjoyed wide application in 30 states by 1980. However, currently it is only applied in Maryland and West Virginia. According to one source, the decline reflects the development of managed care and capitation as alternative means to control the growth in health spending. This trend represents both an evolution in prospective payment methodology and a renewed preference for private- over public-sector price controls.

Studies indicate that rate-setting systems were effective in controlling costs per hospital admission but ineffective in controlling healthcare costs overall. These systems did not control the number of hospital admissions, nor did they regulate outpatient costs. With the rise of managed care and its broader potential to contain healthcare costs, most states turned to market-based strategies and abandoned regulatory initiatives.

Prior to 1993, some healthcare providers (physicians) chose not to participate in the Medicare program in an effort to bypass Medicare’s mandated payment rates. But since 1993, the maximum amount that a nonparticipating provider can charge over Medicare’s approved charge rate has

been limited to 15% of the approved charge. As a result, many providers have been reducing the number of patients on Medicare that they will accept or are reducing the range of services that they will provide to Medicare enrollees. This pattern increases when Medicare’s budget is cut, and this reduces the access of Medicare beneficiaries to certain healthcare providers. The effect is to reduce the choice of providers for those in the program. Successive budget reductions have operated to reduce the number of providers who are willing to see Medicare patients without limitation.

Cost shifting and cross-subsidization tend to be minimized in a highly competitive market, and the U.S. Congress has recognized certain areas in which there is perceived social value in maintaining hospitals’ ability to continue to provide those services. It has been estimated that U.S. hospitals incur costs of \$25 billion to \$50 billion annually in providing community service, primarily in the form of health professions education and standby costs. In the case of hospitals with significant teaching functions and those whose patient base is substantially poorer than average, Medicare provides a direct subsidy to support those functions. These subsidies total more than \$10 billion in direct payments annually.

Both for-profit and not-for-profit hospitals receive support from Medicare for activities related to medical education. Large academic medical centers as well as many community-based hospitals receive Medicare payments proportional to the number of trainees (medical interns, residents, and fellows, and allied health professional trainees) who are working in their system. These payments help defray the costs of medical education that these hospitals bear, which often involves incurring greater than average uncompensated-care costs because teaching hospitals tend to be in low-income areas with higher than average populations of uninsured patients. Not including charity care, the cost of health professions education has been estimated to be \$20 billion to \$25 billion annually, and as noted above, Medicare pays a substantial portion of this subsidy to hospitals. This amount is calculated as part of Medicare payments to support graduate medical education and includes the indirect costs of operating the hospitals as well as the direct costs of salaries and benefits for trainees and attending physicians.

Some hospitals also receive additional funding from the Medicaid program to support the community benefit role they perform serving low-income populations. This Disproportionate Share Hospital (DSH) program helps defray the costs of providing uncompensated, or charity, care, which many hospitals in low-income areas provide, and it represents a significant additional government input into the hospital sector. In 2002, hospitals reported a total of \$22.3 billion in uncompensated-care expenses, and the DSH program payments amounted to \$15.2 billion.

Future Implications

Overall, accountability issues focus on the need to be able to measure outcomes (acceptable or not) and the ability to measure costs, appropriately defined. While cost measurement poses few theoretical barriers, the ability to measure outcomes and to determine what is an acceptable outcome poses serious problems. This is why it is critical to understand the healthcare policy landscapes well as some of the initiatives developed by the Medicare and Medicaid programs. Not only are outcome measures not well developed, they are also not uniformly adopted or applied. There is a definite need for further development of the concepts of equity, efficiency, and effectiveness along with measures that are employed using these concepts.

ETHICS

Ethics is a branch of philosophy that studies moral values and principles. It identifies right and wrong behaviors of individuals and members of a profession. While discussing ethics in healthcare, many distinctions have to be made. There is the growing field of bioethics, at the intersection of moral inquiry and progress in the life sciences. The original field of medical ethics has been all but swallowed by this newer cousin. Many commentators make a distinction between bioethics and the smaller, but no less important, field of public health ethics. There is a nascent literature on the social ethics of health, looking at the moral values that play a role in health and healthcare policy-making. Organizational or business ethics is a burgeoning field. There is also the growing list of professional organizations that have felt the need

to develop and promulgate codes of ethical conduct. Most university courses and publications in health ethics spend quite a bit of their efforts on standards for the ethical conduct of research. This entry identifies some of the major topics being examined within each of these fields and addresses some of the more pressing issues. It also assesses the differences and similarities between these fields of study.

Protection of Human Subjects

For practitioners of health services research, probably the most important ethical questions have to do with how to conduct their work without violating customary or legal standards of behavior. In evaluating health services outcomes, it would be useful to be able to randomly assign patients to treatment and control groups, but this cannot be done without due consideration given to the rights of the people involved. The study of best practices would benefit from being able to observe the natural history of diseases, but society does not allow this to be done without the informed consent of those being observed.

There are certain touchstones that need to be acknowledged if one is interested in understanding the history of protection of human subjects of research. Among these are the Tuskegee syphilis study and the Belmont Report. In the 1930s, a group of researchers from the U.S. Public Health Service (PHS) decided that they would closely observe a group of African American men diagnosed with syphilis to determine the natural history of the disease in Black men. The men were not offered treatment, even when, a few decades into the study, modern antibiotics became available.

Today, society looks aghast at this violation of the dignity of these men, treated as not much more than animals to be observed rather than patients to be served. Failing to discuss the goals of the study and secure the participants' permission was a violation of the men's autonomy, their right to determine their own future. The researchers did not treat these men, thereby failing to provide them the beneficence that is the hallmark of healthcare. Deciding to do without life-saving treatment when it became available was an obvious violation of the value of nonmaleficence. And it is impossible to

avoid the injustice of these actions, perpetrated on an underprivileged minority; justice demands that those who might bear the risks of an experiment be among those who could benefit from the results. These four principles—autonomy, beneficence, nonmaleficence, and justice—form the basis of most contemporary discussions about the need to protect human subjects involved in health-related experiments.

In 1974, the U.S. Department of Health, Education and Welfare formed the National Commission on the Protection of Human Subjects of Biomedical and Behavioral Research. The commission held a series of meetings at the Smithsonian Institution's Belmont Conference Center, and the report that was issued in 1979 was forever referred to as the Belmont Report. The report identified three principles that need to be considered when designing and carrying out research involving human subjects: respect for persons (encompassing autonomy), beneficence (including nonmaleficence), and justice.

The report also recommended practical guidelines for achieving informed consent, assessing the risks and benefits of the research, and selecting the subjects. Under informed consent, the report discussed the following: the amount and accessibility of information that was available to potential subjects, the subjects' ability to comprehend the information presented to them about the nature of the risks, and the extent to which the subjects voluntarily undertook the risks from the research.

The Belmont Report recommends that the nature of the risks to the human subjects should be fully understood and the magnitude and the distribution of the risks and benefits of the research should be commensurate. In trying to achieve the proper balance between protecting human subjects and encouraging needed research, the report states that research on human subjects must be "justifiable" and identified a number of factors that must be considered in assessing justifiability. It states that "brutal or inhumane treatment" of human subjects is never justifiable. Risks to participants should be kept as low as possible, and the more significant the risk of serious impairment, the more closely reviewing committees must scrutinize the research protocol. If participants are drawn from vulnerable populations, the committee should consider involving them at all. In any case, researchers

and review committees should balance the relative risks and benefits to study participants and make sure that information on them be adequately conveyed in the informed consent documents.

Finally, the report states that the principle of justice requires that there be “fair procedures and outcomes in the selection of research subjects.” The application of this principle, states the report, must occur not just at the level of the subjects themselves, making sure that selection procedures are equitable, but also at the societal level, where researchers should take into account the social justice implications of having too much of the burden fall on isolated sectors of the community—for instance, where vulnerable populations are targeted as research subjects due to their relative lack of power or status.

The U.S. Department of Health and Human Services (HHS) has issued federal regulations that establish the baseline requirements for programs to protect human subjects of research. These regulations are overseen by the Office for the Protection of Research Risks. This regulation empowers an institutional review board (IRB) to review all proposals to ensure that human subjects are granted the maximum protection possible. While certain types of research are exempt from these rules, it is common to use an IRB as the body that determines the exempt status of proposed research. Hence, health services researchers must, inevitably, become adept at understanding the federal and state rules that govern their work, as well as the policies and procedures set by their employers or cooperating institutions.

Bioethics

In addition to having ethical concerns in the conduct of their work, health services researchers may be called on to do work that educates the difficult decisions faced by health professionals, organizations, and policymakers at the intersection of moral inquiry and progress in the life sciences. Once referred to as medical ethics, this field is now more broadly known as bioethics.

The number of university-based programs in bioethics has risen exponentially in the past decade. In addition, there are many government commissions, journals, blogs, international conventions,

institutes, centers, university courses, and books on the subject.

A place to begin understanding the breadth of this field is the Web site of the Kennedy Institute for Ethics at Georgetown University, Washington, D.C., aptly subtitled “Where Bioethics Research Begins.” The institute offers “quick bibliographies” on topics of bioethics concerns. The list for the 100 most recent bibliographic citations in the institute’s database gives a useful overview of the enormously wide range of topics that bioethicists address. There are ethical issues involving the practice of healthcare, such as advanced directives, patient relationships, and terminal care. There are social problems, such as abortion (subdivided into legal aspects, moral and religious aspects, and social aspects), chemical and biological warfare, and cloning. The fact that bioethics is an extraordinarily inclusive rubric is evidenced by items on this list such as codes of ethics, informed consent (both for treatment and for research), and resource allocation.

Public Health Ethics

Public health ethics is a relatively new concern. Much of the discussion in the field is focused on the research ethics questions discussed above, some of it involving health services research, some of it involving epidemiological research and randomized controlled trials. A point of view has been expressed attempting to separate public health ethics from bioethics, on the basis that public health ethics is more properly concerned with the use of societal power and its potentially coercive impact. The most commonly cited books in the field usually reflect the academic preparation of their authors, such as law or philosophy.

Another emphasis is on developing codes of ethics for administrators of local health departments. Some of the people in this field also argue that a full view of public health ethics has to include a discussion of how normative or social ethics educates public health decision making.

Normative or Social Ethics

Normative ethics is the study of what is right and what is wrong. Social ethics is less clearly defined

but usually refers to a discussion of how communities or bodies politic can achieve the “good.” The trajectories of social ethics and health services research might be seen as skewed lines, since social ethics wishes to answer just the sort of normative questions that scientifically oriented health services researchers eschew. However, most of all the problems that concern social ethicists, issues such as rights and justice and fairness, are inextricably linked with the public policy issues that health services research hopes to illuminate with its objective work. And facts, reliable conclusions, careful analyses, are all critical inputs into normative decision making.

Social ethics attempts to understand the nature of human rights and what those ideas say about the distribution of healthcare in the United States or around the world. Is healthcare a birthright that attaches to every child born? If so, then researching market-oriented health systems may be greatly missing the point. But even if healthcare is a birthright, society can never guarantee an unlimited amount of it to everyone, everywhere, and at all times. Society’s decisions on what is “best” to do, what priorities to set, and how quickly to effect change, must all be informed by sound research.

Codes of Ethics

Many of the professions, such as law, medicine, and dentistry, have early on in their development recognized the benefits of having a code of ethics. For example, the American Medical Association (AMA) has a recommended code of ethics for physicians dating back more than 150 years. This approach is becoming popular in other venues. The American Nurses Association (ANA) has a much more recent code. The American Public Health Association (APHA) also recently adopted a code of ethics. And the American College of Healthcare Executives (ACHE) has a code of personal and organizational ethics for its members.

The ACHE code identifies the ethical responsibilities that healthcare administrators owe to patients served, to the administrator’s coworkers and employees, to their organization, to their profession, and to the larger community and society that they ultimately serve. It includes a section discussing under what circumstances a healthcare

administrator has a duty to report known violations of the code. As with many of these organizational efforts, the ACHE also includes a frequently updated list of policy documents addressing specific ethical problems faced by administrators. It is not clear how successful these codes are in consistently producing ethical behavior, a potentially interesting area for health services researchers to investigate.

AcademyHealth, the professional society for health services researchers, does not appear to have a complete code of ethics. In 2004, the organization issued a thorough report titled *Ethical Guidelines for Managing Conflicts of Interest in Health Services Research*. The organization’s Ethical Guidelines Committee focused on three values that guided their development of the policy: (1) maintaining the integrity of health services research, (2) providing consistency between the ethical values of health services research and those of other health-related research, and (3) ensuring that practitioners are aware of and adhere to the ethical guidelines of the multiple disciplines that are involved in health services research. This statement recognizes that health services researchers are doing inherently interdisciplinary work and will bring with them the ethical practices of the disciplines in which they were trained. This presents a problem for newer educational programs focusing specifically on health services research, as their ethics education will need to be drawn from a variety of other sources. Certainly, such programs will need extensive coverage of the “whys” and “why nots” and the “dos” and “don’ts” of research ethics, but they may also need to identify the ways in which the ethical issues raised by health services research differ from the ethics of other types of health-related inquiry.

The AcademyHealth document does contain 14 guidelines for the ethical conduct of health services research, albeit with a focus on how they relate to preventing conflicts of interest. These guidelines emphasize that ethical concerns can arise in every phase of the researcher’s work, in initiating the research, in conducting the research, and in reporting on the research.

So not only does the health services researcher need to understand the mandated protections of human subjects, but he or she must also confront the fact that the outcome of his or her work may very

well cost a lot of people a lot of money. Any time large and powerful organizations can be affected, positively or negatively, by a researcher's work, the researcher must be vigilant against the influence that those large and powerful organizations have on the research agenda or the conduct of its efforts. To do otherwise could be considered disingenuous.

Lessons

Health ethics is a very broad topic. At best, this entry has offered a list of key words to use when exploring less limited venues and then put those key words into some perspective.

If a health services researcher were just starting to look at the ethical issues involved in his or her work, he or she would do well to start with a thorough investigation of the ethics of doing research. If there was any part of the field of ethics that every health services researcher must know about, it is the ethical concerns of doing work: involving human subjects and where powerful interests stand to gain or lose lots of money as a result of the work's conclusions. IRBs and conflict of interest reviews should be the starting point. And the interdisciplinary nature of health services research creates an added responsibility for the researcher to understand multiple perspectives.

Health services researchers should understand the larger arena in which they are operating, and they should become more familiar with the spreading field of bioethics. One way to look at the relationship between bioethics and health services research is that the latter is merely one category of the former. If that is so, then health services researchers are an integral part of the bioethics field and need to understand the terrain of their work. However, many health services researchers do not see themselves fitting neatly into bioethics, but the two worlds are multiple and complexly linked. Bioethics is, at least, the context of health services research and so ought to be studied by any health services researcher who has an expansive view of his or her research agenda.

Discussions about health are not easy to separate from discussions about moral decision making. The word *health* has as its Indo-European origin the same root as *holy*. It is not possible to discuss health ethics without addressing "right and

wrong." While this may not be an area of inquiry in which the health services researcher is trained, he or she would do well to understand the nature of this ongoing social dialogue, the role that health services research might play in informing that dialogue, and the role that this dialogue plays in shaping the future of health services research.

ETHNIC AND RACIAL BARRIERS TO HEALTHCARE

Ethnic and racial minorities, including African Americans, Hispanics/Latinos, Native Americans and Alaskan Natives, Asian and Pacific Islanders, and Native Hawaiians, comprise approximately 25% of the United States population. It has been well documented in research studies that ethnic and racial minorities face barriers to the healthcare system due to a variety of factors, including socioeconomic, healthcare coverage, geographic, cultural differences, and decreased access and availability to healthcare providers. The ethnic and racial barriers to healthcare have in turn resulted in health disparities or differences in health outcomes and health status across racial and ethnic subgroups.

Overview

The historical injustices that ethnic and racial minorities have endured in the United States are significantly intertwined with the issue of racial and ethnic barriers to healthcare. For example, Native Americans were left to care and fend for themselves after smallpox and yellow fever were brought over by the early European settlers. Additionally, this group has been historically marginalized. Within the African American community, there remains great mistrust of the healthcare system due to the Tuskegee studies, where African American males participated in research studies without any informed consent and were denied proper treatment for syphilis with penicillin. The history of segregation of African Americans still runs deep in this community, and it has created social barriers. There are similar injustices that Hispanics/Latinos, Asian and Pacific Islanders, and Native Hawaiians have endured that provide some context and background to the racial and ethnic barriers to healthcare.

There is a large body of literature documenting the inequities and disparities in the treatment that patients receive based on their race or ethnicity. A 2003 national Institute of Medicine (IOM) report *Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care* acknowledges

that minority groups generally receive lower quality of care than nonminorities, even after considering access to care, insurance status, and income. The report also noted that the causes of these disparities are widespread and complex, requiring systemic changes at many levels by various actors.

Potential Barriers to Healthcare

In addition to the biases present in the nation's healthcare system, ethnic and racial minorities may face hardships in terms of finances, transportation, and child care to get to regular healthcare visits as well as encounter possible difficulties in navigating the complicated healthcare system. Generally speaking, ethnic and racial minorities are of lower socioeconomic status and have lower education levels, which are correlated with poorer health outcomes. Furthermore, many ethnic and racial minority groups may be at greater risk of being exposed to certain environmental conditions that may adversely affect their health. Ethnic and racial minorities may also have greater geographic impediments by traveling farther distances to see a healthcare provider. As a result, ethnic and racial minorities often encounter greater barriers when accessing the healthcare system.

A 2001 study by the National Center for Health Statistics (NCHS) indicated that 27% of Hispanics did not visit a healthcare provider over a period of 1 year. Additionally, 21.4% of Native Americans and Alaskan Natives, 20.8% of Asians, and 16.4% of Blacks did not receive any healthcare over the same time period compared with 14.3% of Whites.

Additionally, the lack of health insurance coverage poses a significant barrier to many ethnic and racial minorities in receiving appropriate healthcare. Although nearly 74% of Whites are privately insured, only about 45% of Hispanics/Latinos are privately insured. Furthermore, Medicaid covers approximately 20% of African Americans, while only about 10% of Whites are covered through this publicly sponsored program. Compared with the 12% of Whites who are uninsured, about 33% of Hispanics/Latinos, 33% of Native American and Alaskan Natives, 20% of African Americans, and 17% of Asian Americans were uninsured. The reason for the disparities in terms of healthcare coverage between these groups is primarily due to

employment status, where ethnic and racial minorities are unemployed, employed in a job that does not offer health insurance, or are unable to afford the health insurance coverage offered.

There may also be differences in cultural beliefs that preclude certain ethnic and racial groups from seeking healthcare in addition to the historical mistrust of the healthcare system, resulting in minority groups having less satisfaction with their medical care. Furthermore, certain ethnic and racial groups may not believe in Western medicinal practices. There may also be linguistic barriers to receiving culturally appropriate healthcare.

Due to this recognition, the concept of cultural competence, training health professionals to deliver culturally competent healthcare, has become a popular notion as an effective means of reducing some of the barriers faced by ethnic and racial minorities. Cultural competency training has been used to make providers aware of disparities in health status and to improve provider-patient relationships by delivering tailored and appropriate care.

Future Implications

It is estimated that by the year 2050, ethnic and racial minorities will outnumber the current White majority. As the ethnic and racial minority population continues to grow, it is paramount that barriers to healthcare be properly identified and addressed. Proactive efforts should be made to eliminate ethnic and racial barriers to healthcare in addition to eliminating health disparities. Cultural competency programs are a step in the right direction of making this a tangible reality.

EVANS, ROBERT G.

Robert G. Evans is a leading Canadian health economist. His comparative studies of healthcare systems and funding strategies have greatly influenced the Canadian federal and provincial governments. He also has served as a consultant to many governments and public agencies in the United States, Europe, Asia, and the South Pacific.

Evans is a senior faculty member and professor of economics at the University of British Columbia in Vancouver, Canada. Evans is a fellow at the Canadian Institute for Advanced Research. He was previously the director of the Institute's Population Health Program from 1987 to 1997.

Born in 1942, Evans earned a bachelor's degree in political economy from the University of Toronto and a doctorate degree in economics from Harvard University. While in graduate school, Evans was a research staff member of the Ontario Committee on Taxation (the summers of 1964 and 1965) and

at the Bank of Canada (the summers of 1966 and 1967). He returned to the Ontario Committee on Taxation in 1967 and the Bank of Canada in 1968 on a part-time basis. He also worked part-time at the Ontario Hospital Services Commission in 1969. After graduating from Harvard, Evans became an assistant professor at the University of British Columbia. He quickly rose through the academic ranks of the university, becoming associate professor in 1973 and professor in 1978.

Throughout his career, Evans has served on the boards of numerous healthcare, research, and policy organizations. He was the president of the Canadian Health Economics Research Association; member of the National Health Research and Development Program, Main Advisory Committee; member of the expert advisory panel on National Health Expenditures, Canadian Institute of Health Information; member of the Commonwealth Fund Commission on Elderly People Living Alone; member of the executive board of directors of the International Health Economics Association (iHEA); and board member of the Association for Health Services Research (now AcademyHealth).

Evans has authored or coauthored more than 230 scholarly articles and books. Two of his books are considered classics: *Strained Mercy: The Economics of Canadian Health Care* and *Why Are Some People Healthy and Others Not? The Determinants of Health of Populations*. He is a frequent commentator in the journal *Healthcare Policy*. And he serves on the editorial boards of *Annals of Internal Medicine*, *International Journal of Technology Assessment*, *ISUMA Canadian Journal of Policy Research*, *Journal of Health Economics*, and *Journal of Health Politics, Policy and Law*.

Evans has received many awards and honors in recognition of his work. He is an honorary life member of the Canadian College of Health Services Executives and the Canadian Health Economics Research Association, and he is a member of the National Academy of Social Insurance in the United States. He also was a member of the British Columbia Royal Commission on Health Care and Costs in 1990, and the National Forum on Health from 1994 to 1997. He was awarded the Baxter International Health Services Research Prize in 2001 by the Association of University Programs in Health Administration (AUPHA). In 2002, he also

received the Health Services Research Advancement Award from the Canadian Health Services Research Foundation (CHSRF).

EVIDENCE-BASED MEDICINE (EBM)

Evidence-based medicine (EBM) is a fairly recent concept in the field of medicine, and it represents a major paradigm shift from the reliance exclusively on clinical expertise in healthcare decision making. EBM involves the integration of the best available research evidence with clinical

experience and patient preferences. By combining these three components, the goal of EBM is to provide the best possible healthcare and obtain the best patient outcomes possible.

EBM involves five steps: (1) generating an answerable clinical question; (2) conducting a search to find the best research studies available that can answer the question; (3) critically evaluating the studies found for validity (closeness to the truth), impact (size of the effect), and applicability to clinical practice; (4) integrating the research evidence with the clinician's expertise and experience and the patient's values; and (5) evaluating the efficiency and effectiveness of conducting Steps 1 to 4 for potential improvements the next time they are implemented. Each of these steps is discussed in more detail below.

While it is believed that by applying findings from research studies as evidence to the application of clinical practices will result in improved decision making and patient outcomes, EBM has received mixed reactions by clinicians and academics. In real-world clinical practice, it is very difficult for clinicians to keep up-to-date with the rapid expansion of healthcare information being published. When faced with clinical questions concerning a diagnosis, prognosis, treatment, or general care, the answer is typically needed rapidly. With the volume of published information, most clinicians will only have time to read a small portion of what is available on a regular basis. The hope of EBM is that in the case of some of the more pertinent clinical questions, the evidence may have already been found, critically analyzed, and packaged in a format that is readily accessible to the busy clinician. Ultimately, the goal is to have patients, clinicians, healthcare managers, and policymakers have available to them healthcare research that is scientifically valid and readily applicable to clinical situations.

History

There are accounts of evidence being used to change medical practices as far back as the 1700s. In more recent times, Sir Richard Doll (1912–2005), a world famous English epidemiologist, described evidence for medical practice in 1937 with the use of case studies as guides. The use of evidence became more scientifically controlled with the

first published randomized controlled trial (RCT) reported in 1948 by the Medical Research Council in London. Archibald L. Cochrane (1909–1988), whose work would lead to the Cochrane Collaboration, published what is considered a classic work titled *Effectiveness and Efficiency: Random Reflections on Health Services* in 1972. This text had a profound effect on medical practice and evaluation with its stress on the importance of RCTs in evaluating the effectiveness of treatments. The Cochrane Collaboration, which was named in his honor, is known worldwide for its development, evaluation, and synthesis of RCTs in all areas of medicine.

The momentum for what was to become EBM began in the 1970s. Research was increasingly showing a wide variety of practice patterns among physicians, challenging the assumption that clinical judgment or the art of medicine was sufficient. It was deemed that medical decisions were far too complex for a physician to have all the information needed to make decisions in this manner. It was also found that there was a gap between clinical research and what was occurring in clinical practice. The evidence was lacking for many important practices. As practices were studied through clinical trials, it was found that many of those being used by physicians were ineffective. Greater emphasis began to be placed on RCTs. However, it still took years for physicians to put the results of the trials into practice. In addition, with the rising cost of healthcare, a solution needed to be found.

The term *evidence-based medicine* first appeared in the 1990s. David L. Sackett, is widely regarded as one of the originators of EBM. Sackett developed the concept when he was a faculty member at McMaster University in Canada. After working at McMaster for decades, Oxford University in the United Kingdom created a chair for Sackett allowing him to establish the first center in EBM.

The original definition of EBM stressed the need for a systematic approach to analyze published research to be used for clinical decision making. Sackett later refined the definition in 1996 to stress a more evaluative and conscientious use of current research in caring for individual patients. In 1997, the Agency for Healthcare Research and Quality (AHRQ) created the Evidence-Based Practice Center program, which collects and synthesizes evidence.

Steps

The practice of EBM constitutes a five-step process: (1) formulating a question, (2) finding the evidence, (3) critically appraising the evidence, (4) integrating evidence with clinician judgment and patient values, (5) and conducting a self-evaluation of the process. A description of each of these steps is given below.

Step 1: Formulating a Question

A good question must be answerable. Sackett makes a distinction between what he calls background and foreground questions. When a clinician's experience with a condition or disorder is limited, most questions will tend to be background questions. As clinical experience and responsibility grow, questions increasingly become foreground questions but still with the need for background knowledge. Background questions involve asking for general knowledge about a disorder by using a question root (who, what, when, where, how, why) with a verb and a disorder or an aspect of it. Foreground questions ask for specific knowledge about a given disorder and contain four essential components: patient and/or problem, intervention, comparison intervention (as needed), and clinical outcomes. In contrast, foreground questions often arise as central issues in clinical work, involving clinical findings, etiology, clinical manifestations of the disease, differential diagnosis, diagnostic tests, prognosis, therapy, prevention, patient experience and meaning, and self-improvement.

Step 2: Finding the Evidence

To make informed decisions or influence change, formulating an answerable question and then starting the process of information seeking is essential. Given the multitude of scientific and medical research articles that are now published annually, it is helpful to take a systematic approach to finding the best available evidence for the type of question being asked. Some researchers suggest looking at five areas as a guide: type of question, type of information that would answer the question, type of study that would provide the information, types of information resources that would give access to the best studies, and extracting the

best information from the resources. The types of questions might be categorized as clinical findings, differential diagnosis, diagnostic tests, therapy, prevention, prognosis, cause/etiology, cost-effectiveness, harm/risk, or quality of life.

The type of information that would answer the question will depend on the type of question. While RCTs have been considered the gold standard of scientific evidence in healthcare, a range of research methodologies, including quasi-experimental and qualitative research methods, which have been borrowed from the social sciences, may be considered appropriate evidence depending on the type of question. Questions involving patient satisfaction or quality of life would involve qualitative evidence, whereas the best evidence about a therapy might tend to be more systematically gathered and involve quantitative evidence. Hierarchies or levels of evidence are often constructed in a pyramid, showing the strongest to the weakest form of evidence for a particular type of question. In the medical model, the type of study that would be considered the strongest form of evidence is the one based on RCTs. Alternatively, a systematic review or meta-analysis, synthesizing the results of a number of RCTs, would be even stronger evidence. The quickest and potentially the most efficient way to find the best evidence is to use an evidence-based clinical practice guideline. However, there may not be one available that matches a specific clinical issue, and these guidelines, which are often developed by panels of experts, may contain more bias than a systemically controlled study. Where the strongest forms of evidence are not available, one would move down the hierarchy to less robust forms of evidence, such as nonrandomized clinical trials, cohort studies, prospective studies, and so on. Under some circumstances, the best form of evidence available may be case reports, which do not have the rigor and strength of evidence of a controlled research study but nevertheless may provide helpful information. Studies and other forms of evidence may be found in various databases (i.e., MEDLINE, CINAHL, and PsycInfo), catalogs, or free resources on the Internet in the form of journal articles, trial and research registries, bulletins and newsletters, published reports, gray literature, conference proceedings, and Web sites. It is critical that the literature be carefully evaluated for its strength and applicability to the question at hand.

Step 3: Critically Appraising Studies Found

On finding a journal article that includes potentially useful evidence, the next step is to evaluate its quality. Three key issues to address include validity, results, and the relevance of results.

In health services research, most studies include six major components by which a study can be analyzed—sampling, assignment to groups, assessment, analysis, interpretation, and extrapolation to large groups, as outlined by the National Information Center on Health Services Research and Health Care Technology (NICHSR). Each of the six components is discussed below.

Sampling

Health services research questions require data from large groups of people as recommendations for things such as reimbursement rates, screening, or surgical options that apply to the larger population. A sample of the population is studied and applied to the larger group. Based on statistical methods, an appropriate sample size of people to study can be obtained, from which the results can be applied to the larger group. Descriptions of the specific type of sampling used in the study should appear in the methods section of a journal article.

Assignment

People in the sample are assigned into prespecified groups, such as smokers and nonsmokers, to observe differences based on health behaviors and other characteristics. Alternatively, people may be randomly assigned to different groups to investigate the effects of different treatments on different groups. Regardless of study design type, the people in the experimental group must be alike except for the factor being studied so that the results may be attributed to the factor and not to differences in the people. Tables in a study showing the profiles of the people in each group should be reviewed for similarity in factors such as age, gender, ethnicity and race, socioeconomic status, and health status.

Assessment

The means by which people or factors are measured is of considerable importance to the value of the study. Some potential errors in measurement include inaccurate instruments, people

dropping out of the study without follow-up, people changing their behavior because they are being observed, or investigators treating groups differently.

When analyzing studies, it is important to look at the strength of the association between variables. Estimates of strength can be reported as relative risk, which compares the potential for one group having the same outcome as another group with the presence or absence of an experience or exposure to a condition or treatment. A relative risk of 5.0 is considered very significant. However, risks in epidemiological studies tend to be lower (i.e., 2.0). This has caused some concern and controversy about the value of the relative risk statistic. Statistical significance relates to characteristics of the larger population. From studying the results from a sample of the population, one can infer what is happening with the population.

The p value is used to measure statistical significance, with a value less than .05 indicating a less than 5% chance of the results occurring if there is no relationship to the larger population. A value of .01 has the same meaning at 1% probability. Either of these values generally results in the conclusion that there is a relationship to the larger population, which, however, is not the same as cause and effect. Finally, looking at adjustment is important. When differences between two groups being studied may influence the results, these factors are called *confounders*. Confounders may be analyzed using the statistical tools of stratification and regression analysis. Factors other than those targeted for study may have influenced and therefore confounded the results of the study. These factors are often noted in the discussion of a journal article. To understand the analysis, it is necessary to have some training in the area through readings, coursework, or consultation with a statistician.

Interpretation

A study is concluded by interpreting the results from the analysis to draw conclusions about individuals in the study. An assessment is made of the strength of the association between the variables being measured and the cause-effect relationship between them. Factors that may support more confidence in assuming a cause-effect relationship

are if the risk factor occurs more often in people with the specified outcome, if it precedes the effect, or if changes in the risk factor produce the effect. Causation may also be determined by looking at the strength of association between factors as measured by relative risk, determining the consistency of the association when the study of different groups in different settings results in similar outcomes, determining that a specific factor caused an outcome due to biologic plausibility in a clinical study, and a dose-response relationship in which higher levels of a risk factor contribute more than lower levels to an outcome.

Extrapolation

Before adopting a study as evidence for a clinical or administrative need at hand, one must determine if the study is applicable to the situation in question. For example, is the population under study similar according to characteristics that were controlled for in the selection of people? Can one generalize the results to another group, form of treatment, higher or lower dose of medication, and so on?

Step 4: Integrating Research Evidence With Clinician Expertise and Patient Values

Once the found evidence has been critically appraised, in clinical practice it is important along with the best available evidence to take the client's values and preferences into account as well as the professional judgment and experience of the clinician before making a healthcare decision. Clearly, the process and outcome of this step occurs on a case-by-case basis.

Step 5: Self-Evaluation

The final step involves evaluating oneself to determine how well the process was carried out in Steps 1 to 4. Where problems have occurred, one or more steps of the process may need to be repeated to find the best available evidence. There may also be a need for the individual to engage in further education about any of the steps involved in order to ensure greater success when seeking evidence the next time.

Selected Resources for Locating Evidence

There are numerous resources available on the Internet for learning about or finding evidence to be used in clinical or policy situations. Many are based in Canada, the United Kingdom, and the United States. Some of the main resources are highlighted below.

Evidence-Based Practice Reports

The AHRQ awards 5-year contracts to organizations in the United States and Canada to be Evidence-Based Practice Centers (EPCs). These centers thoroughly review the relevant scientific and medical literature in areas of clinical, behavioral, organization of, and financing of healthcare to produce evidence reports and technology assessments. In addition, they conduct research on the methodology of systematic reviews.

National Guideline Clearinghouse

This comprehensive database is a project of the AHRQ in partnership with the American Medical Association (AMA) and America's Health Insurance Plans (AHIP). It provides structured abstracts and links to full-text guidelines, where available, or for ordering information for print copies.

Cochrane Collaboration Database of Systematic Reviews

A major product of the Cochrane Collaboration, this database provides access to quarterly produced systematic reviews. The Cochrane Collaboration is a nonprofit organization that produces and disseminates systematic reviews related to healthcare worldwide and promotes the search for evidence in the form of RCTs. Access to the Cochrane Library is available by subscription online, on CD-ROM, or by PDA, and is free in various parts of the world through sponsorships by various organizations.

Health Services Technology Assessment Text

The Health Services Technology Assessment Text (HSTAT) is a free resource on the Internet

that provides links to full-text evidence documents to support healthcare decision making. It is available through the U.S. National Library of Medicine (NLM).

PubMed/MEDLINE

The database MEDLINE is freely accessible worldwide on the Internet using the PubMed interface maintained by the NLM. Evidence can be found by using the EBM limit. More options and instructions for finding specific forms of evidence are available from the Search for the Evidence Web site, a joint project between the New York Academy of Medicine (NYAM) and the New York Chapter of the American College of Physicians (ACP).

EYE CARE SERVICES

Studying the organization and delivery of eye care services is important to the field of health services research. Vision disorders and eye diseases affect the quality of life for tens of millions of Americans, and the resulting visual impairment or blindness significantly increases the economic burden to society. Undiagnosed and untreated visual disorders and eye diseases particularly affect children and the elderly. Childhood visual disorders have the potential to impede learning, and adult age-related eye diseases constitute a large percentage of preventable blindness in the United States. Analysis by health service researchers of eye care services can lead to increasing the nation's visual and ocular health.

Organization of Care

Three types of medical practitioners provide eye care services in the nation: ophthalmologists, optometrists, and opticians. Ophthalmologists are physicians who specialize in the medical and surgical management of the eyes and the visual system. They provide a spectrum of care, including the examination of the visual system to prescribe eyeglasses and contact lenses, as well as the diagnosis and medical or surgical management of eye disorders and diseases. In addition, many ophthalmologists further specialize in a particular section of the eye or disease. Ophthalmologists are medical doctors (MD) or doctors of osteopathy (DO).

Optometrists, also called doctors of optometry (OD), diagnose and treat vision problems,

prescribe eyeglasses and contact lenses, diagnose and treat eye diseases, and prescribe medications to treat eye disorders. They do not perform surgery, but they often provide patients with pre- and postsurgical care. Sometimes ophthalmologists and optometrists work in the same practice and co-manage patients.

An optician manufactures and fits eyeglasses and, in some states, contact lenses. Many states require opticians to be licensed to deliver these services. Some opticians manufacture eyeglass lenses and contact lenses from raw materials in the laboratory. Office-based opticians cut the laboratory-created lenses to fit into the eyeglass frame. Opticians then take eye measurements to ensure proper lens placement in the eyeglass frame and verify accuracy.

Since there is some overlap in the scope of care offered by ophthalmologists and optometrists, there is no defined organization of eye care delivery. An efficient and effective model is a vertically integrated system with optometrists being the primary entry point into the system with referral to ophthalmologists for more advanced medical care or surgical treatment. This design is widely recognized in studies as showing an enhancement in both eye care delivery and cost-effectiveness of care.

There are an estimated 17,000 practicing ophthalmologists and 33,000 practicing optometrists in the nation. Eye care services provided by them represents more than 5% of the total Medicare Part B payments, or \$4.5 billion in 2005. The National Ambulatory Medical Care Survey (NAMCS), conducted by the National Center for Health Statistics (NCHS), reported an estimated 47.3 million outpatient visits to ophthalmologists in 2004. This number does not include hospitalized patients or visits to optometrists. The current supply of eye care providers meets the patient demand; however, the demand for eye care services is artificially low. The demand significantly increases when the number of patients in whom eye care is indicated but not requested is considered. Of the population that is determined to be at high risk of serious vision loss, and which should have yearly eye examinations, less than half have had a complete eye examination in the past year. This shortfall in the provision of eye care services highlights the lack of access to needed care.

Access to Eye Care

Many factors affect the accessibility to eye care services. As with most healthcare services, affordability and availability of medical and vision insurance can limit access to needed eye care. With few exceptions, traditional health insurance coverage, including Medicare and Medicaid, does not cover well-eye examinations, preventive services, or the component of the examination for the determination of eyeglasses or contact lenses. Eye examinations must have a medical diagnosis that includes the use of the International Classification of Diseases (ICD) codes to be eligible for reimbursement. All well-eye examinations, or examinations for the determination of eyeglasses and contact lenses, are covered by a separate vision care benefit policy. The U.S. Bureau of Labor Statistics (BLS) reports that only 26% of full-time employees and 9% of part-time employees working in medium and large private companies in the nation have a vision care benefit. Without a separate vision care benefit, the cost of eye care services may keep away individuals who would benefit from preventive services and correction of refractive error.

Health disparities exist in eye care services and contribute to the lack of accessibility. Race, income, and educational level all have an effect on access to eye care. Lack of understanding of the eye and visual system also limits eagerness to seek out needed eye care. The Centers for Disease Control and Prevention's Behavioral Risk Factor Surveillance System (BRFSS) identified "no reason to go" and "cost or insurance" as the top two reasons for not seeking eye care services. In response, Healthy People 2010 includes 10 objectives for vision care. Having access to a regular provider of eye care as well as receiving a physician referral for eye care increases the likelihood that a patient will have access to these services.

Children Services

Children's access to comprehensive eye care services is particularly important. At birth, a child's visual system is not completely developed, and the eye and neuronal pathways associated with vision continue to develop during childhood. Children's visual systems have plasticity during a brief period

of time between birth and approximately 5 to 9 years of age. It is during this time that the visual system develops the ability to discern fine detail. During the time of plasticity, abnormalities of the eye or visual system that are not corrected can result in permanent uncorrectable visual disorders into adulthood. Amblyopia, commonly referred to as lazy eye, is an example of a visual disorder that is present at birth or early childhood and has the potential of being reversed if treatment is received during this time of plasticity of the visual system. However, many disorders of the visual system that are present in infants and children are undiagnosed due to the lack of an eye examination. This primarily occurs because of the lack of articulation of symptoms by children and the signs of the visual disorder going unnoticed by parents. If disorders of the visual system are not treated by the age of approximately 9, the visual deficit may become permanent.

Vision disorders in children can have lasting effects. It is estimated that 80% of learning is assimilated through the visual system, and 60% of children who are identified as problem learners have undetected vision disorders. The American Optometric Association (AOA) reports that 25% of children in the nation have significant visual disorders that impede learning. Some of these vision problems can persist into adulthood and can have implications as to which career choices are available to them. An example of this would be untreated childhood amblyopia, which results in one eye, or both eyes, with poor vision as an adult. Adults with amblyopia cannot pursue careers that would require binocular, or stereo, vision. Careers that require good binocular vision are (but are not limited to) airplane pilots, commercial vehicle drivers, and surgeons. This limitation of career choice into adulthood can translate into economic implications for society.

School vision screenings have been implemented in an effort to identify children with visual impairment. However, the implementation of school vision screenings is controversial. There is no universal standardized approach for the administration or content of school vision screenings. The components of vision screenings vary widely, and there is no consensus regarding which components are the most sensitive and specific to

identify visual disorders. In addition to no agreement regarding the content of school vision screenings, there is also no consensus as to which agency should oversee the screenings and who should administer these vision screenings, which can range from an untrained teachers aid to a physician. Also, there are no nationwide mandates for when school vision screenings should take place. Only 15 states require vision screenings for preschool age children. Parents of children who fail school vision screenings are issued a letter, which explains that the child needs a comprehensive eye examination, by an ophthalmologist or optometrist. However, due to the lack of access to eye care services and parents not understanding the scope of the vision problem, many children do not receive follow-up care after the screenings. Moreover, many parents view school vision screenings as a substitute for a comprehensive eye examination. Parents of children who pass school vision screenings may have a false sense of assurance that no vision problems exist with their child. Due to variability in the content and administration of school vision screenings, as well as the sensitivity of detecting visual disorders through the screening modality, a debate exists over the cost-effectiveness of vision screening versus comprehensive eye examinations for children. A small number of states currently require a comprehensive eye examination, performed by an ophthalmologist or optometrist, to be completed before a child enters into public kindergarten. However, this can create a financial barrier to a free public education if parents do not have health insurance or lack the financial means to afford the examination.

Adult Services

As the nation's average life expectancy increases, age-related eye diseases and disorders will increase in prevalence. This increase is compounded by the aging of the baby boomer generation, those born between 1946 and 1964. Many age-related eye diseases can lead to vision impairment and blindness. The Eye Diseases Prevalence Research Group at the Wilmer Eye Institute of Johns Hopkins University estimates that more than 3.5 million Americans are affected by blindness or

visual impairment. However grim this statistic may appear, many age-related eye diseases are preventable, or may be reduced in severity, with early diagnosis and treatment. Diabetic retinopathy, cataracts, macular degeneration, and glaucoma are the leading causes of preventable blindness in the United States. As with pediatric visual disorders, adult-age-related eye diseases may be asymptomatic in the early, most treatable, phase. Issues such as lack of health insurance coverage, lack of patient and provider education and understanding, as well as affordability impede access to adult eye care services. Increased access to eye care services would reduce the number of Americans living with blindness, which could have been prevented if timely diagnosis and treatment had been given. A 2006 study by David Rein and colleagues of the economic burden of major adult visual disorders in the nation's population 40 years of age or older estimated that the total government budgetary impact was \$13.7 billion, and the economic burden, including total direct medical costs, total direct nonmedical costs, and total productivity losses, was \$35.4 billion. Another study by Kevin Frick and colleagues of the economic impact of visual impairment and blindness in the nation estimated the loss of 209,000 quality-adjusted life years. Both of these studies highlight the significant economic burden of blindness and visual impairment. Increasing access to eye care services and the understanding of age-related eye diseases is paramount in attempting to reduce the total economic burden.

Outcome Measures

Until recently, there has not been a reliable and valid survey instrument to measure the outcome effect of interventions related to eye care services. Health-related quality of life (HRQOL) is considered an important outcome measure for healthcare. The National Eye Institute (NEI) devised a survey instrument to measure changes in HRQOL caused by eye diseases and their treatment. The NEI contracted with the RAND Corporation to develop a vision-specific HRQOL survey instrument to measure the outcomes of eye disease clinical trials. The National

Eye Institute Visual Functioning Questionnaire (NEI-VFQ) was developed to identify and quantify vision-related difficulties that are experienced by the visually impaired. The results of the collected data, from the NEI-VFQ pre- and post-treatment, measure the benefits of treatments that restore visual ability. A modified and shorter version of the survey, the VFQ-25, has been developed to measure changes in the difficulty of associated tasks after vision rehabilitation. Outcome measurement of various eye-related interventions is useful in establishing the overall effect of the intervention. These outcome measurements are also useful when comparing, and justifying, the cost interventions.

F

FARR, WILLIAM

William Farr (1807–1883) had a major impact on the emergence of British social statistics, epidemiology, and demography in the mid-19th century and is considered to be a founder of medical statistics. Born in Shropshire, England, in 1807 to poor parents, Farr was effectively adopted by a local squire, Joseph Pryce, after his family moved to Dorrington. He was able to afford his medical education, receiving a licentiate from the Society of Apothecaries, through the inheritance from several benefactors. Farr married in 1833 and opened a medical practice in Fitzroy Square in London. His wife died in 1838 of tuberculosis, and he later remarried and had eight children.

During the 1820s and 1830s, Farr became interested in public health and medical statistics, and in the early 1840s, he played a key role in the development of a system of reporting the causes of death by medical personnel and the collection of these reports for local areas. Farr was also interested in comparative methods of classification of disease and causes of death; his work included comparisons of such methods in other European nations.

Farr served for many years as the Compiler of Abstracts of the Office of the Registrar General, a post that enabled him to serve as the major statistician of vital statistics for Great Britain. He was also a census commissioner for the 1861 and 1871 British censuses and served as president of the Statistical Society.

In 1849, there was a major outbreak of cholera in London that killed nearly 15,000 people. London, at the time, was one of the most populous cities in the world due to early industrialization, and as a result, the River Thames was heavily polluted with untreated sewage. While Farr was initially a proponent of the miasmatic theory of disease, the theory that diseases were airborne, his detailed mapping of disease incidence in London, including data on social class and elevation, laid the groundwork for much 19th-century public health research. Although Farr was unconvinced by John Snow's efforts to show that cholera was of water-borne origin, he provided Snow with data on individual deaths from that disease, and his geographically based orientation toward disease incidence helped lay the groundwork for the acceptance of Snow's theory of water-borne transmission.

Farr's contributions to demography are less well-known to epidemiologists. By linking accurate vital statistics to the 1841 British census, he was able to show how cross-sectional measures like the census could be linked to dynamic measures of population processes derived from age-specific birth and death rates. Lewis credits him with originating the net reproduction ratio (NRR), a summary measure of the rate at which a population is reproducing itself net of the mortality rate. Farr's work in improving the accuracy of British population and vital statistics led succeeding generations of demographers to see these as a dynamic system. This led to the development of the linked equations of general population theory and the theory of stable populations (by Lotka and Dublin in the

1920s). The fact that their mathematical model of population dynamics could be easily demonstrated by population dynamics in late-19th-century Britain led to its widespread acceptance by demographers. These models also led to the influential computer simulations of population processes of Coale and Demeny (the families of model populations) and the development of quasi-stable population models. Farr's work in showing how accurate, age-specific cause-of-death statistics could be linked to census tabulations provided epidemiologists with the ability to measure risks of incidence and death in different population groups.

FEDER, JUDITH

Judith Feder is professor and dean of Georgetown University's Public Policy Institute in Washington,

D.C. Feder is a national leader and recognized expert on healthcare policy. Her areas of expertise include national healthcare reform, the uninsured, Medicare, Medicaid, and long-term care. She frequently testifies on Capitol Hill about various healthcare policy issues.

Born in Brooklyn, New York, Feder went on to earn a bachelor's degree from Brandeis University (1968) and a master's (1970) and a doctoral degree (1977) in government from Harvard University. She started her career working at the Brookings Institution and the Urban Institute before joining the faculty of Georgetown University in 1984.

Feder has occupied a number of key leadership positions in both the U.S. Congress and the Executive Branch of the federal government. In 1989, she was the staff director of the congressional U.S. Bipartisan Commission on Comprehensive Health Care, more commonly known as the Pepper Commission. The commission addressed national long-term care policy issues.

Feder is widely recognized for setting the stage for the national healthcare reform debate of the 1990s. She served as a senior official in the Clinton administration. Feder was the healthcare director of President-Elect Clinton's Transition Team. After President Clinton's inauguration, she was appointed the principal deputy assistant secretary for planning and evaluation in the U.S. Department of Health and Human Services. In that position, she was primarily responsible for developing the Clinton Health Security Act and chairing the working groups for the President's Health Reform Task Force. She also helped shape the administration's healthcare policy by working intensively with members of Congress and the national media.

After serving in the Clinton administration, she returned to Georgetown University in 1995. She became the dean of the university's Public Policy Institute in 1999.

In 2006, Feder decided to take her policy expertise to politics and ran for Congress as the Democratic nominee in Virginia's 10th District. Despite her eventual defeat, Feder's campaign garnered national attention and gave the 13-term Republican representative Frank Wolf his closest race in nearly 25 years.

Feder is a widely published scholar. Specifically, she has authored or coauthored five books on healthcare policy and over 60 articles in various

peer-reviewed journals, including the *New England Journal of Medicine*, the *Journal of the American Medical Association*, the *Milbank Quarterly*, *Health Services Research*, and *Health Affairs*.

She is a past chair and board member of AcademyHealth. Feder is also a member of the National Academy of Sciences' Institute of Medicine (IOM), the National Academy of Public Administration, and the National Academy of Social Insurance. She is a senior advisor to the Kaiser Family Foundation's Commission on Medicaid and the Uninsured and a member of the Commonwealth Fund Task Force on the Uninsured.

FEDERALLY QUALIFIED HEALTH CENTERS (FQHCs)

A federally qualified health center (FQHC) is a type of organized healthcare provider defined by the Medicare and Medicaid statutes. FQHCs are intended to expand access to quality healthcare services for underserved and vulnerable, culturally

and linguistically diverse populations, in collaboration with other community providers.

FQHCs must provide a specific array of services to a community in which the population is found to be suffering from a lack of access to essential healthcare providers and services. They must be organized as public or private nonprofit entities. They also must be governed by an independent board of directors, the majority of whom are current consumers of healthcare from the organization who are representative of the community served by the FQHC.

The broad values enshrined in the construct of an FQHC include the following: comprehensive primary healthcare, focus on the changing needs of individuals throughout the life cycle, evidence-based medicine, responsiveness to the health status and needs of the community, and community-dominated governance. Specific program expectations are extensive and are set forth by the Bureau of Primary Health Care of the U.S. Public Health Service (PHS). Areas covered include the following: mission and strategy, approaches to underserved populations, cultural competency, strategic positioning, needs assessment and continuous quality improvement and performance, clinical program, organization of the system of care, service delivery models, contracting for health services, healthcare planning, clinical staff, consumer bill of rights and responsibilities, and clinical systems and procedures; and governance, compliance with board composition, governing board functions and responsibilities, and network and affiliations.

The key benefits of meeting the requirements and gaining FQHC status include enhanced Medicare and Medicaid reimbursement, eligibility for Section 330 and other specific federal grants and programs, medical malpractice coverage through the Federal Tort Claims Act, eligibility to purchase prescription and nonprescription medications for outpatients at reduced cost through the 340B Drug Pricing Program, access to the National Health Service Corps, and access to the Vaccine for Children Program.

Development

The health center movement that led to the development of FQHCs began with the creation of the

migrant health center program in 1962. The federal Migrant Health Act was enacted by Public Law 87-692, which added Section 310 to the Public Health Service Act (now currently authorized under Section 330G of the act). The Migrant Health Center program provides a broad array of medical and support services to migrant and seasonal farm workers and their families.

The initial success of the Migrant Health Centers was followed by the neighborhood health center demonstration projects initiated in 1965 as part of President Johnson's War on Poverty program. It was recognized that by addressing the untreated health problems of the poor, the economic burden of these communities could be reduced.

Health centers were envisioned as comprehensive health services programs oriented toward the needs of vulnerable and underserved populations. They made great strides in eliminating barriers to healthcare for the poor and underserved, ensuring continuity and quality of care, promoting the use of preventive services, and increasing community participation. Health centers also served as an economic engine for their economically disadvantaged communities by generating jobs in the local economy. Health centers were unique in providing access to a wide range of medical and nonmedical services and in their mission to serve all regardless of their ability to pay.

Despite major growth and numerous challenges over the past 40 years, the mission of health centers has remained the same—the provision of high-quality primary and preventive healthcare services to people in rural and urban medically underserved areas.

FQHCs include all organizations receiving grants under Section 330 of the Public Health Service Act, certain tribal organizations, and FQHC look-alikes. An FQHC look-alike is an organization that meets all of the eligibility requirements of an organization that receives a Public Health Service 330 grant but does not receive grant funding.

Section 330 of the Public Health Service Act defines federal grant funding opportunities for organizations to provide care to underserved populations. Types of organizations that may receive 330 grants include community health centers (Section 330E), migrant health centers (Section 330G), healthcare for the homeless

programs (Section 330H), and public housing primary-care programs (Section 330I). While the funding opportunities and sources vary, these, as well as school-based health centers (funded through the Healthy Schools, Healthy Communities Program) and FQHC look-alikes, are all related in that they all must meet the same standards and expectations set out for health centers under Section 330.

Among the many federal initiatives that have been aimed at the problem of access to healthcare services, the health center family of initiatives has enjoyed the widest and most persistent support. Throughout more than four decades of changing social, economic, and political environments, health centers have continued to receive growing federal support and attention. From their beginning as a component of President Johnson's War on Poverty program to the commitment from President George W. Bush, health centers have been viewed as an effective and appropriate means for extending the benefits of healthcare to the poor and uninsured.

In FY2002, President Bush proposed a multi-year initiative for the Federal Consolidation Health Center Program authorized under Section 330 of the Public Health Service Act. The President's initiative seeks to substantially expand and strengthen the safety net for those most in need by extending the availability of primary healthcare services to new and existing patients served by community health centers. In 2007, the federal Office of Management and Budget (OMB) ranked the health center program as one of the 10 most effective federal programs.

Current Status

By 2006, there were more than 1,000 FQHCs in the nation. They operated in each of the 50 states as well as Puerto Rico and the District of Columbia. They provided nearly 60 million healthcare encounters to more than 15 million individuals. More than 5 million of those individuals were covered under Medicaid programs, and nearly 6 million more of the patients had no insurance. In this endeavor, the health centers employed more than 97,000 full-time-equivalent employees. Health centers served approximately 12% of all the uninsured individuals (providing about 22%

of the uninsured ambulatory-care visits) in the nation and about 15% of the nation's population living below the federal poverty level (FPL). The majority of patients (59%) served were Latino or African American. The average medical cost per patient was \$117.

The National Association of Community Health Centers (NACHC) proposes that the services of FQHCs provide great potential for substantial cost savings throughout the nation's healthcare delivery system. FQHCs are particularly effective in addressing access issues that often drive patients to hospital emergency departments with noncritical health needs. This is a significant problem operationally and financially. Studies have estimated the annual cost of "wasted" or unnecessary emergency department visits in the nation to be in excess of \$18 billion. A recent study analyzing Medicaid claims data in four states concluded that Medicaid recipients relying on health centers for usual care are 19% less likely to use an emergency department for ambulatory-care-sensitive conditions than recipients using outpatient and office-based physicians for usual care. A 2004 study estimated savings to Medicaid programs of nearly \$1,000 per year per patient served in health centers as compared with other sources of care.

Overall, when compared with Medicaid patients treated elsewhere, health center Medicaid patients are between 11% and 22% less likely to be hospitalized for avoidable conditions; are 19% less likely to use hospital emergency departments for avoidable conditions; and have lower hospital admission rates, lower lengths of hospital stays, less costly admissions, and lower outpatient and other care costs. A 2006 study estimated savings of 30% to 33% in total costs per Medicaid recipient.

Future Implications

The effectiveness of FQHCs and the popularity of the community governance model within which they operate continue to make them a highly valued option in federal plans for addressing problems of healthcare access and the uninsured population.

FEE-FOR-SERVICE

Under fee-for-service payment mechanisms, the healthcare provider's income increases each time he or she renders a service. As with any form of provider payment, a decision to pay providers on a fee-for-service basis affects utilization, cost, and population health. Many healthcare policymakers and researchers argue that fee-for-service payment

mechanisms provide a strong economic incentive to overprovide services, many of which are costly, unnecessary, and may actually decrease the quality of patient care.

Economic Theory

A healthcare provider who is paid on a fee-for-service basis and who ignores patient preferences will provide services up to the point at which the fee just matches the cost of providing the service one more time. For example, as long as the fee paid for an additional dental examination exceeds the cost incurred by the dentist for providing the examination, the dentist will provide, and bill for, additional dental exams.

Whenever the fee does not reflect the value that a fully informed patient would place on receiving the service, the level of service provided will be either inefficiently low or inefficiently high. In markets for medical services, the fee might not reflect the patient's valuation because of ignorance or intermediation. Patients often do not know all the clinical risks and benefits of the services offered by providers, and they typically do not pay providers for their services directly but through an insurer. Lack of information may lead patients to underestimate the benefits of a service such as preventive care, prompting them to demand too little care, while intermediation, such as copayments and coinsurance, insulates patients from the full cost of the service, prompting them to demand too much care. By exposing patients to the full cost of a larger fraction of services than under traditional insurance, health savings accounts (HSAs) aim to eliminate the distorting effects of intermediation. The distorting effects of patient ignorance can be mitigated by education.

If the fee exceeds the patient's valuation of the service, providers will be tempted to overprovide services (supplier-induced demand), in the sense that a fully informed patient who paid out of pocket would have purchased a lower volume of the service than the provider is rendering. Nonprice mechanisms, such as implementation of treatment protocols, utilization review, and employment of gatekeepers to control the use of medical specialists, are designed to prevent the overprovision of services.

Hospitals

The problem of potential overprovision of services is perhaps most acute for hospital-based medical care because the patient typically has less ability to assess the costs and benefits of this type of service than in the case of prescription drugs, diagnostic tests, or office visits. In addition, hospital-based medical care is also more likely to be covered by the patient's health insurer than other types of medical care. While insurance reduces the patients' incentives to economize on hospital-based services, fee-for-service reimbursement reduces hospitals' incentives to control costs: As they are fully reimbursed for the cost they report, hospitals can pass on to insurers all fluctuation in cost.

Medicare, the federal health insurance program for the elderly in the United States, used a fee-for-service payment system until 1982, which encouraged hospitals to compete for patients and physicians by investing in expensive technologies, even if their clinical value had not been demonstrated. This "medical arms race" led to sharp increases in utilization and cost without commensurate benefits in health outcomes. In an attempt to slow the increase in the cost of hospitalizations among the elderly, in 1983, the Medicare program switched from a fee-for-service payment system to a prospective payment system (PPS), according to which hospitals receive a lump sum for each patient's hospital stay. This lump sum varies with the patient's classification into a Diagnosis Related Group (DRG) but does not vary with the hospital's actual resource use to treat the patient. Thus, the hospital is fully exposed to all fluctuation in cost and now has an incentive to minimize the resource use associated with each hospitalization.

Physicians

For physicians, the counterpart of prospective payment is a fixed monthly payment per enrollee (capitation payment). While capitation payment encourages physicians to avoid patients who are anticipated to require many visits or costly and time-consuming tests and procedures, physicians who are paid on a fee-for-service basis have the opposite incentive, namely, to attract patients such as the chronically ill or those with special

needs, who are expected to require many separately billable services. To increase revenue from fees, physicians paid by fee-for-service also have an incentive to underrefer patients to a colleague whose services they can perform themselves instead, even if the colleague would be a better match. Fee-for-service also creates an incentive to overrefer patients to specialty facilities in which the referring physician has a financial stake and to establish new physician-owned specialty hospitals, ambulatory surgical centers, and imaging centers.

For patients who are expected to remain with their physician for a long time, capitation payment encourages physicians to manage their patients' health proactively by providing sufficient preventive and primary-care services to reduce the incidence of disease and thus reduce costly future visits and treatment. By the same token, however, physicians paid on a capitation basis will be reluctant to test for diseases that, once diagnosed, raise the patient's number and service intensity of future visits. Physicians paid on a capitation basis will also attempt to minimize the resources spent on treating a patient's existing medical conditions. Recognition that physicians paid by capitation might underdiagnose and undertreat diseases, especially chronic conditions such as asthma, diabetes, depression, and cancer, has led some insurers to carve out of their capitation payments fee-for-service schedules for select diagnostic procedures, under which physicians' pay increases for each performance of a qualifying procedure or examination (pay-for-performance).

FLAT-OF-THE-CURVE MEDICINE

Flat-of-the-curve medicine refers to applications of healthcare resources yielding no discernable or valuable health benefits. It is a level of intensity of healthcare that provides no incremental benefit. In health economic terms, it is the consumption of medical care resources to a point that the marginal (added) benefit relative to the marginal (added) cost is at or near zero. Flat-of-the-curve medicine is of concern because it affects the cost and quality of healthcare without improving health and medical outcomes. It also has implications for issues of access, financing, reimbursement, and the organization of healthcare. Understanding this concept, why it occurs, and how it might be addressed is beneficial to health services researchers and healthcare policymakers.

Variation in the use of healthcare and health outcomes in the United States is ubiquitous. Variation in the amount of healthcare delivered has been noted many times in seemingly comparable patients in terms of their health status and social demographic characteristics and the type and depth of health insurance coverage. This observation has persisted over time. Concern has been expressed that patients receiving costly high-intensity healthcare often do not have better health outcomes than those receiving cheaper low-intensity care. This finding is not confined to

the United States. The same phenomenon has been observed in other highly developed nations. This has led some researchers to conclude that differences in the intensity of healthcare play, at most, a minor role in explaining cross-sectional differences in health outcomes. Many health services researchers and healthcare policymakers have termed this phenomenon flat-of-the-curve medicine.

What Is Flat-of-the-Curve Medicine?

Popularized by health economists such as Alain Enthoven, Robert Evans, and Victor Fuchs, the concept underlying flat-of-the-curve medicine is analogous to the economic law of diminishing marginal returns; that is, as inputs are applied to a production process in successively larger amounts, there will be successively smaller increases in outputs. At some point, additional inputs may result in zero or even negative outputs. Used frequently in economics, this law has been applied in many instances to the production of many goods and services, environment, energy production, national defense, and medicine.

Figure 1 shows a theoretical curve to explain the concept of flat-of-the-curve medicine. An example would be the length of an inpatient hospital stay for a patient with a particular diagnosis. The horizontal x -axis in the figure reflects the inputs—in this case, cost in dollars for each day. These costs may be for personnel, equipment, supplies, overhead, and so on. The vertical y -axis reflects health outcomes depicted by improved health status. Each letter (A, B, C, D, and E) represents one inpatient hospital day. The first inpatient day (A) is clearly beneficial. Likewise, the second inpatient day (B) is beneficial but less so. Inpatient Day C is beneficial but less so than either of the previous days. That is, there is an added (marginal) benefit relative to the added (marginal) cost after the first inpatient day, but this benefit accrues at a diminishing rate. Finally, Inpatient Day 4 (D) and Inpatient Day 5 (E) add marginal costs but no discernable marginal benefit. In this instance, the marginal benefit after the third inpatient day relative to costs is zero. Likewise, additional inpatient days beyond C would add only costs without any concomitant benefits.

Issues and Implications

Flat-of-the-curve medicine raises many healthcare policy issues with many implications. In the above example, flat-of-the-curve medicine does not necessarily imply that there is no benefit with each inpatient day. But it does suggest that the marginal benefit, if any benefit at all, comes at a higher marginal cost. Issues can arise at any point along the curve. At the point where the curve becomes flat, there are no additional benefits from any combination of inputs. It may even be possible for the curve to bend lower at the tail end, as in the case of a poorer outcome. In that instance, additional costs would be associated with a worse outcome, as in the case, for example, of a hospital-acquired infection or a terminally ill patient.

Flat-of-the-curve medicine raises the issue of the amount and value of the benefit relative to the units of input, often measured by the common unit of dollars. How valuable the additional benefit is at any point along the curve is often subjective and debatable in absolute or relative terms. Medical practice often is subjective. Diagnoses are subject to uncertainty. There is often a range of possible treatments, with none being “the best” with certainty. Differing opinions also may be expressed among physicians, patients, families, or payers. Benefits may include added days of life; reduced mortality, morbidity, or disability; increased ability to function; reduced pain and suffering; or improvement in the overall quality of

Figure 1 “Outcomes” and “Costs”

life. Some of the benefits are difficult to either quantify or value. Some may occur at extremely high marginal cost or may not occur at all. Sometimes one benefit may occur at the expense of others, as in the case of added days of life in a state of extreme pain and with an overall deteriorating quality of life. Benefits are not always easy to calculate, much less translate into a common unit of measurement. Also, often there is significant uncertainty in the anticipated benefit, especially when the patient is the unit of analysis. Widespread variation in health outcomes by treatment is commonplace.

The issue of flat-of-the-curve medicine becomes an important consideration depending on the source of payment. Generally, there is little or no concern if the increased intensity or cost of healthcare is knowingly borne by the individual, as expressed by his or her preferences, demonstrated by his or her out-of-pocket payment. Many individuals may not wish to get to the point where the marginal cost is zero, since any additional cost would be entirely at their expense with no proportionate benefit. A greater level of concern may arise if the source of payment is a spouse or other family member. A more difficult social problem may arise if the payment is borne collectively through private or public health insurance coverage. At this level, the scrutiny and expectation of benefit relative to cost may increase, since the cost is no longer just borne by the individual beneficiary but by a third-party payer. An individual may be much more willing to consume medical care to a point where the marginal benefit is zero when payment is by a third-party payer, whether private or public. Some individuals may not have any effective choice if they are uninsured or lack sufficient resources to pay regardless of their condition.

Why Does Flat-of-the-Curve Medicine Occur?

Several possible reasons for why flat-of-the-curve medicine occurs have been suggested. The various reasons may occur at the same time. Service volume may increase with an increase of healthcare providers in a geographic area. Or the presence of more medical specialists in an area may be reflected in a higher intensity of practice than is found in areas with a lower concentration.

Another possible explanation is that the standard of medical care in one area may be quite different from that in another. The standard of medical care in an area may be reflected by variations in length of hospital stay, the number and frequency of diagnostic tests, rates of surgical procedures, and rates of other clinical procedures. The medical school a physician attended may play a role, since medical training varies. Medical students at one institution may be trained to be more or less aggressive. The individual physician is a variable, with some willing to go much further along the curve than others. Attention to the interests of the patient, dedication to one's profession, and professional expectations can influence clinical decisions. Finally, financial considerations may influence the clinical decisions made by patients, family members, physicians, administrators, third-party payers, and others. The widespread use of third-party payment has led many to conclude that medical-care markets operate beyond the point of maximum efficiency and perverse incentives exist. Fully insured patients may want care to the point of no incremental benefit. Similarly, a physician may be inclined to provide care that provides no benefit for an insured patient but not for an underinsured or uninsured patient. Also, self-interest on the part of the physician may play a role, since one person's health spending is another person's income. A legal entitlement to a Medicare beneficiary or a Medicaid recipient is a de facto entitlement to providers. Incentives associated with fee-for-service practice or those associated with an ownership position in a medical facility may also cause clinical decisions to differ from those made by healthcare providers working under a capitation or salary arrangement.

Strategies to Deal With Flat-of-the-Curve Medicine

Several strategies have been implemented or suggested to address flat-of-the-curve medicine. For example, the nation's Medicare program in 1983 changed its policy of paying hospitals from a cost-based retrospective one, which created the incentive for hospitals to provide more care because they were reimbursed for it, to a prospective payment system (PPS), which pays hospitals a lump

sum for treating a given medical condition. The result was an immediate and sharp decline in the average length of hospital stays, with no apparent adverse medical effect. Other strategies have included increased utilization management and review, patient cost sharing, supply limits, aggregating the unit of payment (as in capitation), lump sum payments to hospitals for specific procedures, global budgeting, and efforts to increase competition. Others have suggested that flat-of-the-curve medicine be addressed by the greater use of cost-benefit or cost-effectiveness analysis and the controlled introduction of new clinical procedures and medical technology backed by clear evidence of their benefits.

FLEXIBLE SPENDING ACCOUNTS (FSAs)

Flexible spending accounts (FSAs) are tax-sheltered programs established by employers. Employees contribute pretax wages to these accounts and may use the funds to pay for qualified healthcare expenditures. These expenditures include fees for uninsured physician or dental care, for example, but may also include the copays or deductible payments associated with otherwise insured medical expenses. In addition, the accounts may be used to pay for over-the-counter medications and things such as contact lens solution.

Overview

Flexible spending accounts are paid into with pretax dollars by employees and can be used to purchase qualified healthcare-related expenses. The Internal Revenue Service (IRS) defines what constitutes a qualified healthcare expense in FSAs. The IRS does not limit the amount of money that can be set aside in an FSA. Many employers, however, do set annual limits, often in the range of \$5,000 to \$10,000, and any monies that are not spent by the end of the year (or by March 15 of the subsequent year, at the discretion of the employer) are lost to the employee. On the other hand, once an employee's FSA is created, he or she may spend the entire annual amount to be deposited. For example, an employee may choose to set aside \$100 per month in an FSA for an annual total of \$1,200. In January, the employee could spend the entire \$1,200 on uninsured orthodontic care.

Moreover, if the employee were to leave the firm later in the same year, he or she would not be required to pay into the FSA. Analogously, however, if an employee were to leave the firm with a positive balance in his or her FSA account, those monies would be lost to the employee.

The provisions of FSAs are in marked contrast to health savings accounts (HSAs). Monies that are contributed to an HSA are owned by the employee and remain with him or her upon separation from an employer. More important, unspent HSA balances roll over to the next year, whereas an unspent FSA balance is forfeited annually. In

addition, while an individual may establish an HSA, only an employer can establish an FSA. Furthermore, HSAs require the holder individually or through his or her employer to have a qualified health plan, usually a high-deductible plan. In contrast, a firm that establishes an FSA program for its employees does not need to offer any health insurance plan.

Tax Savings

The tax savings associated with the use of FSAs can be substantial. For example, suppose an individual contributes \$100 per month, or \$1,200 per year, in an FSA, these contributions are tax sheltered. Additionally, suppose one has a marginal federal income tax rate of 28%, pays Social Security and Medicare payroll taxes of 7.65%, and faces a 5% state income tax rate. The individual or the family has a combined marginal tax rate of 40.65%. By putting \$1,200 in the FSA and spending it on qualified health services that the individual would have purchased anyway, the savings would amount to \$487.80 in taxes. Even if the individual does not spend the entire \$1,200, as long as a balance of less than \$487.80 is forfeited, the individual comes out ahead monetarily.

A less well-known and appreciated feature of establishing an FSA is that it allows employee premium contributions to employer-sponsored health insurance to be paid with pretax dollars. Workers do not have to explicitly direct premium contributions to the FSA for this purpose, as it is simply a feature of establishing an FSA. Moreover, an employer can set up a premium-only plan (POP) that allows employee premium contributions to be paid with pretax wages even without establishing an FSA.

Data on the extent to which employers offer FSAs and employees use them are not routinely collected. Offer rates appear to increase with firm size. William Jack and colleagues reported that 14% of small firms, 76% of large firms, and 83% of very large firms administered FSAs in 2003. Roger Feldman and Jennifer Schultz reported that among 15 Minnesota firms offering an FSA, 19% of singles without dependents and 33% of those with family coverage took coverage. The average annual contribution (converted to 2007 dollars) was \$530 for those with single coverage and \$988 for those with family coverage.

Economic Theory

Several testable hypotheses emerge from the economics of FSAs. The first is that households facing a higher marginal income tax rate will be more likely to participate in an FSA. Feldman and Shultz examined participation among 15 Minnesota firms in 1998. Higher marginal tax rates were associated with greater participation rates among those with family coverage but not those with single coverage. An increase in the marginal tax rate from 15% to 28% resulted in a near doubling of the participation rate. The marginal tax rate also increased the size of the FSA contribution. James Cardon and Mark Showalter used data from a benefits consulting firm from 1996. They concluded that participation increased with income and was also higher for those living in states with state income taxes. Interestingly, they also found that participants tended to spend out their accounts relatively early in the year, implying that the FSA effectively provided a no-interest loan for qualified healthcare expenditures.

A second hypothesis is that tax-sheltered treatment of employee premium contributions as a result of an FSA should reduce the premium elasticity of demand for employer-sponsored health insurance. If an insurance plan has a \$1,000 annual employee premium contribution, the presence of a 40% marginal tax rate and an FSA effectively reduces the premium contribution to \$600. As a result, the same premium contribution in an FSA will result in less plan switching than in a firm with no FSA. Bryan Dowd and colleagues examined premium elasticities in a sample of large public employers and concluded that the presence of an FSA reduced elasticities by over 50%.

Finally, one should expect FSAs to lead to larger employee premium contributions. Consider the premium contribution problem in the absence of FSA provisions. The exclusion of employer-provided health insurance from federal and state income and payroll taxes means that the entire premium should be paid for by the employer in the form of lower money wages to workers. This approach takes full advantage of the tax subsidy. However, employee premium contributions also serve to sort workers into health plans that reflect their preferences for

coverage, with higher employee premium contributions used to signal more generous plans. Thus, the tax incentives and the signaling incentives work in opposite directions. The former provide incentives for little or no premium contributions, and the latter provide incentives for potentially large premium contributions. In the presence of an FSA, the employee premium contribution is paid with pretax dollars, and the tax-induced incentive for small premium contributions is removed; however, this hypothesis remains to be tested empirically.

FLEXNER, ABRAHAM

Abraham Flexner (1866–1959) made enormous contributions to the quality of healthcare by improving the education offered at medical schools in the United States and Canada. As a result of this work, Flexner is considered one of the most important health services researchers of the 20th century. His on-site assessment of medical schools resulted in a landmark report, *Medical Education in the United States and Canada*, which was published by the Carnegie Institute for the Advancement of Teaching in 1910. This report received wide attention and acclaim. So critical was Flexner of poor-quality medical schools that many closed or merged, while others were forced to implement immediate improvements. In 1909, when Flexner began his investigation, the United States had approximately 150 medical schools; by 1915, the number had dropped to 96.

Born to German Jewish immigrant parents in Lexington, Kentucky, Flexner was one of eight children. Flexner went to Johns Hopkins University, where he received his bachelor's degree in 1886. After graduation, he returned to Lexington and worked for that city's public school system as an instructor. After 4 years, he formed his own college preparatory school, where he had the freedom to try out certain theories of classroom education, and there he became convinced of the value of progressive principles of education—among them, small classes, tutoring rather than lecturing, and learning by doing, principles that later influenced him when he undertook his investigation of medical schools. After many years of teaching, Flexner left Lexington and attended Harvard University, where he received a master's degree in 1906.

In 1908, Flexner's book *The American College: A Criticism* came to the attention of Henry S. Pritchett, president of the Carnegie Foundation for the Advancement of Teaching. Pritchett was impressed by Flexner's critical ability and his forceful manner as a writer, and he felt that Flexner would be the ideal person for a new Carnegie project: a response to a request from the American Medical Association's Council on Medical Education to carry out a survey of medical schools.

Although the Council on Medical Education had completed its own survey in 1906, the results were not widely published as there was reluctance on the part of physicians to publicly criticize other members of the profession. Pritchett recognized the inherent bias in medical involvement in the survey and therefore favored hiring a competent outsider to manage the task.

The need for a survey of medical schools was widely felt. The dismal quality of many medical schools was generally known, and in the Progressive Era at the end of the 19th century and the beginning of the 20th, the reform impulse was strong. Medical schools were already feeling the heat of that momentum when Flexner accepted the charge and began his research.

What Flexner lacked in healthcare experience, he made up for with his sound grasp of educational principles and his practical, clear-thinking, analytical mind. He also had the advantage of his employer's august name as a calling card. Because Flexner represented the Carnegie Foundation, a possible funding source, medical schools opened their doors to him.

Flexner began his preparation for the project with a review of medical education in the United States and Canada—its historical record—and the available critiques of that education. He determined that the best scientific/clinical medical education could be found at the Johns Hopkins University medical school, which was based on European models, and he hypothesized that his survey of medical schools would show that most would fall short of the high Johns Hopkins standard.

During his 16 months of fieldwork, Flexner visited 155 medical schools. He collected data from each on five key areas: (1) their admission requirements, (2) the size and qualification of their faculty, (3) the amount of funds available from the endowment and fees to support the school, (4) the quality of their laboratories and the training of their instructors, and (5) the connection of the school to clinical facilities (hospitals).

Flexner had a standard of excellence clear in his mind when he visited the medical schools. His vision of medical education was an ambitious one, centered on higher admission requirements, expanded instruction in the laboratory sciences, and clinical instruction based on access both to a large number and wide variety of hospital and

dispensary patients and to clinical laboratories for analysis and diagnosis. Flexner's plan also included a full-time medical faculty, standardized hospital record keeping, and control of a modern hospital whenever possible.

After his field study, Flexner wrote his famous report, *Medical Education in the United States and Canada*. Its findings were widely publicized. Contrary to the popular notion that the report was a relentlessly harsh critique of medical schools, unsparing in its condemnation of all institutions, over half of the report is historical background information, a discussion of Flexner's methods and findings, and recommendations for reform; the balance comprises school-by-school assessments.

The immediate reaction to the report by medical schools that fared poorly was often dismissive or antagonistic, but over time, in the wider community, the consensus of opinion was highly favorable: Flexner had done a great service for medical education. It was this view that held throughout his long life. After his death, however, historians have reassessed his report. Some now question Flexner's hastily formed judgments about the medical schools. The closing of medical schools resulted in a loss of physicians to nearby communities, however suspect their training might have been. Other historians fault the science-heavy curriculum Flexner imposed on medical education, which minimized the balancing influence of humanistic studies. Last, it has been argued that Flexner's report was merely a catalyst that accelerated the pace of existing reform. And the standards he espoused were generally accepted well before his report and were already reshaping the nation's medical education.

After publishing his famous report, Flexner also conducted surveys of medical education in England, France, and Germany. In 1912, he began working for the General Education Board of the Rockefeller Foundation as an assistant to the secretary, and in 1914 he became a trustee. As a board member for many years, Flexner had a say in the distribution of grants to colleges and universities as well as to primary and secondary schools.

Later in his life, Flexner was directly involved in founding the Institute for Advanced Study in Princeton, New Jersey, the world's first think tank. He was the institute's first director from

1930 to 1939. Among his successes in bringing distinguished scholars and researchers to the Institute was his recruitment of Albert Einstein in 1933.

Abraham Flexner died in 1959 at the age of 92. During his long life, Flexner's central interest—embodied in his landmark research and criticism and the recommendations of his famous 1910 report—was in elevating and standardizing medical education and, ultimately, contributing to the improved quality of healthcare services for all Americans. This is his greatest legacy.

FOCUSED FACTORIES

C. Wickham Skinner first introduced the concept of "focused factories" in a 1974 article in the *Harvard Business Review*. In this seminal article, Skinner, a Harvard Business School professor, applied the concept of focused factories to manufacturers in the United States, which at the time were experiencing a productivity crisis. Skinner believed that the nation's manufacturers were no longer competitive because they had very broad missions and produced too many products. To correct the situation, Skinner urged the manufacturers to focus each of their factories on a limited, manageable set of products and markets. He argued that focusing each factory's entire effort to produce a particular product would lower costs, especially overhead costs, and make each of the factories a competitive weapon.

Focused Factories in Healthcare

In healthcare there have been few attempts to formally define the concept of focused factories, and no standard definition exists. Regina H. Herzlinger, a Harvard Business School professor and a leading advocate of consumer-directed healthcare, defines healthcare-focused factories as integrated, multidisciplinary teams of health professionals organized around the needs and treatments of particular chronic diseases or disabilities. For example, she envisions diabetes-focused factories having teams of health professionals entirely focused on treating and controlling that disease.

Such teams would include cardiologists, dermatologists, endocrinologists, nephrologists, podiatrists, behavioral support specialists, and others. Focused factories would deliver services wherever patients needed them—in their homes and in pharmacies, community centers, and shopping malls, as well as in community and specialty hospitals. Focused factories also would provide the patients with all the medical information they wanted. Herzlinger views focused factories as an important component of consumer-driven healthcare.

Other researchers have empirically defined healthcare-focused factories as specialty hospitals, primarily facilities that specialize in cardiac,

orthopedic, or surgical care. A few researchers also include ambulatory surgery centers as healthcare-focused factories. Most specialty hospitals are physician-owned, for-profit facilities. Physicians often establish specialty hospitals because they want greater autonomy over treatment decisions and the care environment, a selected number of medical procedures having relatively high profit margins, and a larger share of the hospital's profit margin to increase their incomes. Physicians may directly own and manage the specialty hospitals and be their sole proprietor, or they may indirectly own and not manage the hospitals by purchasing equity stakes in them from corporations. Some corporations own a number of these facilities. Currently, there are more than 100 specialty hospitals in the nation, and the number appears to be growing. The number of ambulatory surgery centers is over 3,000.

Examples

The example of a healthcare-focused factory that is most often cited is Shouldice Hospital in Ontario, Canada. The hospital, an 89-bed, for-profit facility, is named after its founder, Edward Shouldice, who developed an innovative surgical technique for repairing hernias during World War II. Shouldice Hospital's entire focus is on the surgical repair of external abdominal wall hernias without complications. Surgeons at the hospital each perform 15 to 20 hernia repairs a week, as compared with other surgeons in Ontario, who perform on average only 1 per week. Because of Shouldice Hospital's narrow focus and high degree of specialization, it achieves excellent medical outcomes and a high degree of patient satisfaction. The hospital has very low complication and infection rates and one of the lowest hernia recurrence rates in the world. Its patients have short length of stays, and nearly all of them report being extremely satisfied with the care they received. Furthermore, the overall cost of care at Shouldice Hospital is significantly lower than at other Canadian hospitals.

Other examples of healthcare-focused factories are Aravind Eye Hospitals in India, which specialize in cataract surgery and eye diseases; Coxa Hospital in Finland, which specializes in endoscopic

and joint replacement surgery; Addis Ababa Fistula Hospital in Ethiopia, which specializes in obstetric fistula surgery; and the Diagnostic Treatment Centers in England, which specialize in elective surgery.

Controversy and Public Policy Issues

The concept of healthcare-focused factories is highly controversial and raises a number of important public policy issues. Proponents of focused factories, such as Herzlinger, argue that they provide a revolutionary promise of lowering the costs of care, improving quality, increasing innovations, increasing consumer choice, and promoting needed competition in healthcare. In sharp contrast, opponents, such as Arnold Relman, a Harvard Medical School professor and the former editor-in-chief of the *New England Journal of Medicine*, contend that the very concept of focused factories is a delusion born of unfamiliarity with the realities of medical care. Relman argues that independent physician groups and facilities such as centers for kidney dialysis, imaging centers, and cardiovascular specialty hospitals already provide some specific medical treatments and procedures. He believes that it would be wrong for the nation's healthcare system to be entirely or even largely based on thousands of independent, competing focused factories that specialize in treating only one ailment. He points out that patients often suffer from multiple ailments, they develop additional ailments over time, and they may develop new ailments from being treated. And to treat all these ailments, focused factories would need other specialists and facilities, which would be wasteful of resources. Last, Relman argues that focused factories would harm the continuity of patient care and lead to fragmented, chaotic, and lower-quality care.

Community hospitals, and the hospital associations that represent them, have strongly criticized specialty hospitals. Large community hospitals, most of which are not-for-profit facilities, fear that the increasing growth of for-profit specialty hospitals will siphon off the least complicated and best insured patients, leaving the community hospitals to treat complex, high-cost, poor, and uninsured patients. Community hospitals argue that such a shift would unfairly burden them and cut into their

already tight financial margins. And if community hospitals cannot compete with specialty hospitals, they will be forced to cut back on money-losing services such as emergency department care or to negotiate higher prices from payers. They contend that specialty hospitals may add unnecessary capacity that could hurt the quality of medical care in the community by reducing the volume of cases treated at each facility. They also assert that specialty hospitals may put patients' health at risk, because very sick patients may not get the same attention they would at large community hospitals. Last, specialty hospitals, with their physician ownership, may create incentives for excess medical care.

Federal Moratorium

Because of the debate over the growth of specialty hospitals, the U.S. Congress in 2003 enacted an 18-month specialty hospital moratorium. Specifically, Congress prohibited the Centers for Medicare and Medicaid Services (CMS) from issuing Medicare provider numbers to new specialty hospitals, thus preventing them from billing Medicare. The moratorium also temporarily prohibited physician investors in these hospitals from referring Medicare patients to facilities in which they had a financial interest. The moratorium expired in 2006, and the CMS once again is issuing Medicare provider numbers to new specialty hospitals, permitting them to expand, unless they are prohibited by specific state laws.

Future Implications

There is very little empirical evidence concerning the advantages or disadvantages of healthcare-focused factories. Given this lack of evidence, it is not clear whether public policies should be developed to encourage or discourage their further development. Resolving this and other questions concerning focused factories is important because it is likely that more specialized, niche-type healthcare facilities rather than large, all-purpose community hospitals will increase in the future.

FORCES CHANGING HEALTHCARE

Healthcare in the United States is undergoing profound changes. These changes are driven by a number of demographic, economic, sociologic, and technologic forces, including population demographics; retiree healthcare benefits; payer market consolidation; patient cost sharing; transparency in costs, quality, and outcomes; value-based purchasing; globalization in healthcare; consumerism; technology; and personalized medicine. Each of these 10 forces is discussed below.

Population Demographics

A very visible force that is reshaping the nation's healthcare is the aging of the population and the workforce. The population in general is aging; those who are already elderly are living longer; and the healthcare workforce, particularly in nursing, the largest healthcare profession, is aging. This force suggests that there will be increasing demand for care, which, in turn, will increasingly tax the current diminishing workforce.

Retiree Healthcare Benefits

Many of the nation's employers have ceased to provide, or are in the process of discontinuing, healthcare benefits to their retirees. Employers continuing retiree health benefits are shifting more of the cost to retirees. The Agency for Healthcare Research and Quality (AHRQ) reports that only 13% of private-sector employers offered health benefits to their retirees in 2005, down from 22% in 1997. Even many large employers are not offering their retirees healthcare benefits. It appears that the implementation of the recent Medicare prescription drug benefit in 2006 further encouraged employers to have their retirees rely solely on public-sector healthcare benefits, despite the federal subsidy to employers maintaining their retiree plans.

Payer Market Consolidation

The nation's health insurance industry has undergone tremendous consolidation, and this can be expected to continue, albeit less rapidly, until such a time when mergers and acquisitions trigger a major reaction from government antitrust agencies. While consolidation has been under way for some time, a key turning point occurred in 2004 with the merger of Anthem and WellPoint Health Networks—the largest ever managed-care merger, which encompassed a \$16.4 billion deal that has increased the plan's membership to about 28.5 million enrollees. WellPoint, Inc., has since acquired Empire Blue Cross, Blue Shield, moving into the eastern part of the country and thereby becoming more of a national company. The United Health Group has also made major

acquisitions and become a national player. These two health insurance giants are changing the face of the health insurance market as they assume a dominant position, and thereby offer less flexibility in reimbursement to many healthcare providers.

Patient Cost Sharing

In recent years, consumer-directed healthcare (CDHC) has emerged as one of the most potent ideas in healthcare reform. However, CDHC means different things to various people. CDHC, which involves enrollment in consumer-directed health plans (CDHPs), refers to insurance that provides financial incentives for consumers to become more involved in their healthcare-purchasing decisions. Most of the literature uses the term *consumer-directed health plans* to refer to any high-deductible insurance plan. Typically, *high-deductible* denotes a plan with a deductible of \$1,000 or more. High-deductible plans are sometimes coupled with personal health savings accounts (HSAs). HSAs are tax-advantaged health savings accounts that may be used to pay for qualified medical expenses. HSAs must be paired with a health plan whose minimum deductible is \$1,000 for individuals or \$2,000 for families in 2008 and the annual out-of-pocket expenses do not exceed \$5,000 for individuals and \$11,200 for families. Health reimbursement accounts (HRAs) are similar to HSAs but are owned by employers and do not need to be coupled with a high-deductible plan.

In 2005, about 10% of privately insured nonelderly American adults were enrolled in a plan with a high deductible; about 10% of them had an HRA or HSA. One fifth of employers offering health insurance offered a high-deductible plan, and about 4% offered such a plan with an HRA and HSA option. However, demand for these plans appears to be growing. A recent survey of these plans found that enrollment had more than tripled since early 2005, reaching 3.8 million in 2007. Predictions about the future growth of the HSA market are also impressive. One recent forecast is that the market will expand to 15 to 30 million enrollees over the next 5 to 10 years. The important point is not the exact number of people enrolled in HSAs but rather that

these new insurance products are symptomatic of a more widespread movement toward shifting more of the cost—and the decision making and the wellness accountability—from businesses to consumers.

Transparency in Costs, Quality, and Outcomes

The nation is steadily moving toward a value-based purchasing healthcare economy. This has mainly been driven by the major purchasers of care, such as the Centers for Medicare and Medicaid Services (CMS), and large employers who are seeking to quantify the value of the healthcare dollars they spend. Indeed, now more than ever, there is a growing movement by the purchasers of healthcare to demand documentation on patient care quality, along with a more transparent approach to pricing, particularly in the hospital sector. In addition, large employers, labor organizations, and consumer advocacy groups are working hard to make sure that any healthcare reform includes the requirement that information on healthcare costs and quality is collected and made available to the public. Additionally, many hospitals and health systems are now beginning to share their cost and quality information with the public. A few of them have gone so far as to commit to full disclosure of their performance (via pricing and quality indicators) to consumers on the Internet and through direct mailing to consumers.

Value-Based Purchasing

It appears that the nation's health insurance plans will move much more aggressively in the next several years to both measure the quality of physicians and hospitals and reward those with better performance records and improved outcomes. In part, this movement has been stimulated by the growing recognition of the large variance across providers in quality. Widespread quality-of-care problems demonstrated that the nation is not getting the full value for its healthcare expenditures. Indeed, there is growing national evidence of inappropriate medical care and widespread and dangerous medical errors. Research studies have shown that Americans only receive about half of

the recommended care. Furthermore, healthcare spending varies greatly from region to region, with no discernible improvement in quality of care or health outcomes associated with the higher outlays.

Globalization in Healthcare

There is a growing trend toward globalization in healthcare, which is called *medical tourism*—the basic practice of traveling to a distant location or even another country to obtain healthcare services. The increase in the popularity of medical tourism appears to be the result of the uneven quality of care in local communities, the high costs of healthcare, the long wait times for procedures, the ease and affordability of international travel, and improvements in technology and standards of care in many countries of the world. Most medical tourists seek elective services such as aesthetic treatments (cosmetic surgery) or orthopedic surgery. Countries such as India, Malaysia, Singapore, and Thailand are positioning themselves as medical destinations. In general, physicians trained at the major medical centers in North America and Europe staff hospitals and clinics in those nations catering to medical tourism. Moreover, most of these physicians are board certified in the United States. Furthermore, many American medical schools are forming partnerships with Asian hospitals to penetrate this market. In the mid-1990s medical tourism did not exist; however, the number of medical tourists to India alone has tripled in the past 4 years from 150,000 to 500,000.

Consumerism

Patients are increasingly demanding a greater role in the decisions that affect their healthcare. The development of the Internet and the availability of online healthcare information have enabled patients to take a more active role in their health management. Consumerism in healthcare is based on the idea that individuals who are financially accountable for their wellness and who have better access to information as well as more control over their own healthcare will make better decisions

about treatment and provider options. If consumers could better understand and more effectively use health services, community health status could improve, the value of healthcare to the consumer could be enhanced, and the rate of increase in healthcare costs could be reduced.

To enhance consumerism, healthcare providers can take several actions. One is to provide clear communication, which means listening deeply and with an open mind, not only to the consumers but also to the full spectrum of the stakeholders. Another is to create consumer-focused systems, which involves improving internal systems and working with others to remove barriers to engaging consumers rather than focusing on the mechanics of the care. Providers should also simplify pricing, taking into account the patient's medical condition, insurance coverage, discount eligibility, and past medical history. Improving patient safety, which involves developing safe and high-quality care-delivery systems such as an electronic health record system and an underlying clinical system to support it, is another avenue for improving consumerism. Also, serving the underinsured to make consumers' needs paramount, regardless of their ability to pay, will also enhance consumerism. Last, providers should provide accountability, which involves developing explicit action plans to address community benefit and then reporting on how those plans were implemented.

Technology

Technology has far-reaching implications for changing healthcare because it affects both the processes of care and the way organizations work. Among the broad-based effects of technology is the development of health information systems and the genomics that are contributing to the biotechnical advances in care. Health information systems are increasingly being used to decrease healthcare costs by standardization and improved data capture to support both billing practices and care decisions. Information systems have the potential to reduce the rate of increase in healthcare costs, which are predicted to reach 19% of the nation's gross domestic product (GDP) by 2014. Information systems enable managers and organizations to more effectively capture cost and

quality indicators that are used to improve practice and reward performance, thereby improving the efficiency and efficacy of healthcare.

Technological advances are also affecting care itself. Less invasive procedures, increased portability of equipment and supplies, and advances in diagnosis and treatment have made it possible to change the locus and type of healthcare procedures. Technology also affects consumer expectations for healthcare. Unlike other industries, new technologies in healthcare are additive, often raising consumer and provider expectations. Both consumer and provider expectations are shaped by experiences with other, more technologically advanced enterprises, such as the travel and banking industries. Healthcare is just now beginning to develop the information systems that will improve transactions among providers, consumers, and financiers of healthcare. Technology has the potential to change healthcare delivery. As healthcare technology advances, problems previously thought to be life threatening will begin to look more like chronic diseases. Nanotechnology, genetics, and biomedical advances are changing both consumer and provider expectations for health, care, and treatment.

Personalized Medicine

Personalized medicine refers to the development and treatment of disease and disease propensity with interventions based specifically on a person's genetic profile. Advances in genomics, pharmacokinetics, and computer technology are quickly making personalized medicine a reality. A critically important challenge will involve how healthcare payers can provide a reimbursement policy that will encourage innovators to tailor drugs, biotech products, and perhaps even medical devices to the metabolism and other characteristics of different subgroups in the population, based on factors such as age, gender, and ethnicity. Different groups respond in very different ways to these products. Yet if the market is subdivided, will the payback of return on investment justify the cost of bringing "customized" products to the market?

Personalized medicine also implies that treatment will be made personal, a trend already under way. For example, patients are informed before their office visits about their care, and they evaluate

and compare the information they have obtained with that provided by their physician or caregivers. Customers expect to be a part of the planning process for their health, discussing a plan of action for their own healthcare. As patients become more knowledgeable about their healthcare, the time pressure on providers can be expected to increase. In 2004, the reported median time physicians spent with patients on an office visit was 14.7 minutes. The challenge for providers lies in applying expertise to collaborations with consumers to evaluate information from the Internet and available up-to-date scientific evidence. Just as technology is increasingly an enabler assisting caregivers in diagnosis and treatment, it is also an enabler for patients, who assume more ownership of their own health. Personalized medicine, which will likely become personalized healthcare over time, is one of the most exciting aspects of changing healthcare.

FOR-PROFIT VERSUS NOT-FOR-PROFIT HEALTHCARE

One distinctive feature of the U.S. healthcare system is its mix of nonprofit, for-profit, and public ownership of hospitals, nursing homes, and health insurers. Nonprofits dominate the hospital sector. About 53% of the nation's hospitals are nonprofit, 19% for profit, and 28% government owned, including local, state, and federal hospitals. For-profit ownership is the norm in the nation's nursing home industry, with 62% for profit, 31% nonprofit, and 7% government owned. There are more than 1,300 health insurers and health plans in the nation, the overwhelming majority being for-profits, but nonprofit insurers and health plans are among the largest and cover approximately one quarter of the privately insured population.

Within both for-profit and nonprofit sectors, ownership structures vary. For-profit ownership can include individual proprietorships and partnerships or publicly traded or privately held corporate ownership, with corporate ownership dominating the for-profit hospital, nursing home, and insurance sectors. Nonprofit organizations are restricted by law from distributing profits or net revenues to those outside the firm (the "noninurement" requirement). They may be tax-exempt at the federal, state, or local level. Nonprofit hospitals and nursing homes are generally owned by local corporations, with self-perpetuating, locally drawn boards, although a significant number are owned by or affiliated with religious orders or denominations or are part of local or regional systems.

Several issues arise in the analysis of ownership in health services research. One is why nonprofits play such a large role in providing health services and insurance. This issue can be approached from both a theoretical and a historical perspective. A second issue is whether, because of the differences

in organization, management, or incentives, the performance of nonprofits and for-profits differs in ways that should matter to patients, payers, or regulators. Extensive research has been conducted on these issues, involving both direct comparisons of nonprofit and for-profit entities and examination of cases in which nonprofits convert to for-profit status.

Theories of Nonprofit Creation and Support in Healthcare

Three broad sets of theoretical explanations have been put forward to explain the creation and ongoing support of nonprofit organizations in healthcare. The first builds on concepts of asymmetrical information, principal-agent problems, and the difficulties of monitoring performance and ensuring quality and fair dealing. Kenneth J. Arrow was among the first to present this view in his classic 1963 article, "Uncertainty and the Welfare Economics of Medical Care," in which he notes that the very word *profit* is a signal that denies a trust relationship. He goes on to say that physicians try to avoid being seen as profit maximizers in their trust relationships with patients. And from these special relationships come various forms of ethical behavior, which leads to the relative unimportance of profit making in hospitals. Henry Hansmann, in his 1996 book, *The Ownership of Enterprise*, expands on this theme, noting that because of the high costs incurred by customers of some firms, nonprofit firms such as hospitals are set up whose managers hold them in trust for them. Other reports in the literature expand on these models of nonprofits as a response to agency and trust problems.

A second explanation put forward for the creation of nonprofits is that they address consumer or charitable needs by creating organizations to deliver goods and services that are not commercially viable. This has been identified as the original impetus for the creation of nonprofit hospitals, insurers, and health plans. Nonprofits are often classified as donative, depending on contributions for support of their activities, or commercial, depending on revenues from the sale of goods or services. Many blend these two components, and over time, the mix of donations and commercial revenues can shift, as it has in the hospital industry. Furthermore,

historically it has been the case that even when opportunities for commercially viable for-profits are established, nonprofits do not cede the field but often remain active competitors in the market.

Both of these theoretical explanations for the rise of nonprofits lead to predictions regarding observable differences in the behavior of for-profit and nonprofit firms. For-profit firms are assumed to be profit maximizers (and thus cost minimizers), while nonprofits are assumed to have other goals, such as prestige, size, quality, charity, staff satisfaction, and donor satisfaction, which are to be implemented within a break-even constraint or balanced with a profit maximization thrust. There is no agreement in the literature concerning which of the other goals predominate, perhaps reflecting the fact that objectives may vary across nonprofits, even those within the same industry. Nonetheless, it is generally predicted that nonprofits in healthcare will be less efficient and have higher costs, offer lower prices, be less profitable, have higher quality (particularly when quality is hard to monitor), be more likely to provide unprofitable services and slower to adopt profitable services, provide more community benefits generally, and be less likely to close.

The third set of theoretical analyses seeks to explain the continued presence of both nonprofits and for-profits in markets, belying models that predict that one form would dominate and drive the other out. Four sets of explanations have been offered. One is that it is simply a matter of timing—that the firms coexist as markets shift from a state that advantages one form to a state in which the other form is advantaged. Another explanation put forward is that the continued presence of different firms is supported by consumer heterogeneity; that is, some consumers cannot detect agency failure and rely more on nonprofit status as a signal, while others who believe they can detect such failures are more willing to buy from for-profit firms. A third explanation is that different forms have asymmetric advantages, such as access to different sources of capital, that allow nonprofits and for-profits to occupy different market niches or exploit different advantages when competing in the same niche. In this model, institutions, once established, operate to exploit the environment and strengthen their advantages through law and regulation. A fourth explanation, which complements the third, is that

regulatory pressures, adoption of successful models from the other ownership form, and consumer or community norms and expectations encourage nonprofits and for-profits in the same markets to mirror one another, which reduces the likelihood of one or the other being pushed out of a market. This last explanation has important consequences for comparing nonprofits and for-profits, since it suggests that differences between nonprofits and for-profits may not be observed in within-market comparisons but only in cross-market comparisons structured to differentiate between nonprofit-dominated and for-profit-dominated markets.

History suggests that consumer preferences for nonprofit over for-profit hospitals, nursing homes, or health plans has not been a major element sustaining nonprofits. Rather, the evidence supports the model of donative or charitable creation and the roles of asymmetric advantage and mimicry in sustaining both nonprofits and for-profits in the same markets. The first U.S. hospitals were nonprofit institutions created for the care of the poor, supported by donations. After the invention of anesthesia and antisepsis, hospitals could offer services that could not be easily provided at home, and for-profits entered the hospital market. By 1910, for-profit hospitals were more common than nonprofits. Differential access to capital has influenced the relative growth and decline of for-profits in the U.S. hospital system over time. Many for-profits closed during the Depression, while nonprofits were sustained by community contributions and the creation of hospital insurance programs that differentially favored nonprofit hospitals. The federal Hill-Burton program created additional subsidies for the expansion of nonprofit hospitals after World War II. The establishment of Medicare in 1965, with payment rules offering benefits to for-profit hospitals, encouraged their expansion and the purchase of individual-proprietorship and partnership-owned hospitals by corporations.

Nursing homes were developed as homes for the aged or infirm, many as individual proprietorships or partnerships, some, sponsored by religious or community groups, as nonprofits. The Social Security Act of 1935 required states to develop licensure programs for nursing homes. The establishment of Medicare and Medicaid in 1965 created substantial revenue streams for nursing

homes, encouraging expansion of their numbers as well as the growth of for-profit corporations owning chains of nursing homes and differentiation of facilities by levels of service.

In the first part of the 20th century, few insurers offered health insurance, fearing adverse selection. Modern health insurance in the United States was introduced during the Depression as hospitals, facing substantial numbers of patients unable to pay, sponsored prepayment programs for hospital care. These plans were largely created under state legislation that established separate regulations and financial standards for nonprofit organizations. Similar physician plans were soon created as well. The earliest health maintenance organizations (HMO) were likewise created as nonprofits. Only once the commercial feasibility of health insurance and prepaid health plans was established did for-profit insurers enter the market in substantial numbers. The comparative advantage of nonprofit or for-profit insurers and health plans over time appears to be influenced by the regulatory advantages offered to nonprofits, the cost-based payment systems nonprofit insurers negotiate with hospitals, and greater access to capital available to for-profit firms. The 1980s saw a series of nonprofit to for-profit conversions of a significant number of health plans, a trend that continues with the conversion of several of the largest of the nation's Blue Cross and Blue Shield plans.

Public opinion surveys reinforce the judgment that donative and commercial factors, not trust and agency issues, better explain the development of nonprofit and for-profit providers of hospitals, nursing homes, and insurance services. Surveys from the 1980s and 1990s found those surveyed to be unsure about the ownership of the institutions they used and belief to be mixed about the relative quality and efficiency of for-profit and nonprofit hospitals, HMOs, and health insurers.

Comparisons of Cost, Quality, and Community Orientation

Regardless of whether public support for the creation of nonprofits is based on concerns that patients will be exploited, a significant public policy debate emerged in the 1980s and continues to the present about the desirability of for-profit

providers supplanting nonprofits, through either for-profit expansion in the marketplace or conversion of nonprofits to for-profit status. This has resulted in an extensive literature looking separately at hospitals, nursing homes, and insurers, comparing for-profit and nonprofit cost and efficiency, quality, and provision of community benefits. The community benefits examined are broad and not always clearly defined but include lower prices (i.e., failure to fully exploit local market power), charity care (or improved access for low-income populations), and maintenance of unprofitable but needed community services. Conversions from nonprofit to for-profit status have been a focal point of this debate and, as a result, have led to a significant body of research.

Below is a summary of this literature for hospitals, nursing homes, and health plans.

Hospitals

Costs and Efficiency

The relative costs and efficiency of nonprofit hospitals in comparison with for-profit hospitals has been extensively studied. This research has used a wide range of data sets, including Medicare cost reports and state hospital financial reports; alternative modeling strategies (e.g., economic cost functions, data envelopment analysis, and stochastic frontier regression); different covariates; and functional form; it has also examined different time frames. The research has been subjected to meta-analysis. The majority of studies either find no difference in costs or efficiency between nonprofits and for-profits or find that nonprofits have lower costs and greater efficiency than for-profits. The prediction from theory that nonprofits would be less efficient is not supported.

Prices and Net Revenues

Prices and net revenues (or profits) of for-profit and nonprofit hospitals have been less widely studied than the relative costs and efficiency of these forms. These studies have found either no statistically significant difference in prices or profits or higher prices or profits in for-profit hospitals. The studies do not allow the source of differences in profits or net revenues to be clearly identified, although differences in pricing, discretionary

charity care, and decisions by for-profits to locate in areas with better-insured populations have all been suggested as explanations, and there is some research to support each of these claims.

Quality of Care

Study of the quality of hospitals has been hampered by limited data. Many studies have focused on mortality differences, with varying levels of control for patient-specific risk adjustment. More recently, data on other measures of quality have become available, and studies have incorporated these measures. The most complete systematic analysis of this literature examined 25 studies looking at mortality and 13 looking at other measures of quality, including surgical complications and medication errors. It found that a majority of these studies found no statistically significant difference between for-profit and nonprofit hospitals, but it also found that those studies that were representative of the United States as a whole tended to find lower quality of care among for-profit than among nonprofit hospitals. Another study comparing hospitals using the current Centers for Medicare and Medicaid Services (CMS) Hospital Compare measures of processes of care reinforces this conclusion that for-profits have consistently underperformed nonprofit hospitals.

Community Benefits

The two most widely considered community benefits for which comparisons have been made between nonprofit and for-profit hospitals are charity care and provision of unprofitable services. While studies have found substantial variation across states in the relative provision of charity care by ownership, on average, for-profit hospitals have been found to provide less charity care than nonprofits. At least some of this difference appears to be a function of location decisions by for-profits. For-profits have also been found less likely to offer unprofitable services than nonprofit hospitals, and they are more sensitive to changes in profitability over time.

Hospital Conversions From Nonprofit to For-Profit Status

There have been several waves of conversions of nonprofit hospitals to for-profits. These

conversions or purchases have raised issues of fair valuation of the assets of the nonprofit and concerns about maintenance of charity care and services within the community. State-specific studies of conversions of nonprofits have found that, on average, they are similar to for-profits in their states in the levels of charity care they provide, although a national study concluded that charity care declined postconversion. Studies also suggest that after conversion there is no evidence of reductions in charity or services by the converted hospital. One 1997 study of conversion trends from 1980 to 1993 found that while nonprofit to for-profit conversions were the focus of public concern, there were also a substantial number of for-profit to nonprofit conversions.

Nursing Homes

Costs and Efficiency

Studies consistently find that for-profit nursing homes have lower costs than nonprofit nursing homes. Examination of the sources of cost differences has found wages and registered nurse staffing to be higher in nonprofit homes. No studies have adequately controlled for differences in quality across the two ownership types, a significant omission given that (as described below) quality has been found to be higher in nonprofit facilities. Thus, while cost differences are observed, there have been no sufficient studies of efficiency differences across the forms.

Prices

Limited studies exist of the prices charged private-pay nursing home patients, and they are mixed as to whether nonprofits or for-profits have lower charges.

Quality of Care

A large number of studies have compared the quality of care at for-profit and nonprofit nursing homes. Across a wide variety of measures—mortality, complications such as infections or bedsores, measures of processes of care, and regulatory deficiencies, for-profit nursing homes have been found to have lower quality.

Community Benefits

Nursing homes have not been expected to offer as wide a range of community benefits as hospitals. One community goal has been to ensure access to nursing homes for Medicaid patients. For-profit nursing homes have been found by researchers to be more likely to admit Medicaid patients, thus disproportionately offering benefits to the community in this area.

It was suggested above that differences between nonprofits and for-profits may not be observed in within-market comparisons but only in cross-market comparisons structured to differentiate between nonprofit-dominated and for-profit-dominated markets. There has been some research using this framework examining the nursing home industry. One study attempted this comparison, using expansion of nursing home use as a measure of increasing consumer value from nursing home services. It found higher use in communities with more nonprofit nursing homes, concluding that more quality of care per dollar could be achieved by encouraging a greater share of nonprofit nursing homes in most market areas in the nation.

Health Insurers and Health Plans

Studies of the relative performance of nonprofit and for-profit health insurers and health plans have been limited. Conversions of nonprofits to for-profits have contributed significantly to the interest in this topic, although the research specifically studying conversions has been limited.

Costs, Efficiency, Pricing, and Profitability

Comparing the costs, efficiency, pricing, and profitability of health plans is complicated because of the multiple measures that might be examined. Premium levels, percentage of collected premiums paid as benefits, and administrative costs have been examined, but the interpretation of differences can be challenging. For example, higher administrative costs have been interpreted as a sign of inefficiency and alternatively as a measure of aggressive cost and utilization management.

The evidence for greater efficiency, lower administrative costs, lower payment to providers through more aggressive negotiations or rate setting, or higher profits of one form over the other is mixed.

There is limited evidence that suggests but does not conclusively demonstrate that both payments to providers and the proportion of premiums paid to providers are lower for for-profit plans and for Blue Cross plans following conversion, this difference being associated with higher profits. Furthermore, better-controlled studies with more data are required to resolve the questions asked in this research.

Quality

The relative quality of health plans has been assessed in a variety of ways. Given the concern among consumers that insurers might skimp on needed care, issues of trustworthiness are also frequently addressed in comparing quality across plans. Studies have been conducted comparing objective measures, such as the Healthcare Effectiveness Data and Information Set (HEDIS) measures of the National Committee for Quality Assurance (NCQA), disenrollments and appeals, and patient and physician surveys. These different approaches generally find quality and patient and physician satisfaction lower in for-profit health plans. Ownership may not be the only factor influencing these scores, since there are substantial regional differences in the ages of plans and lengths of enrollment in the plans. Studies of conversions have found few or no differences before and after conversion.

Community Benefits

One of the major issues in nonprofit to for-profit conversion of health plans has been the potential loss of community benefits. Nonprofit plans have historically provided a wide range of benefits—periodic open enrollment without preexisting condition restrictions, community rating of premiums, innovation in products to provide access to insurance for low-income or vulnerable populations such as children, health services research, and public health education, among others. Some of these, most notably community rating, have come under pressure even without conversion due to competition in the market place due to risk- and age-related premiums and active medical underwriting by for-profit insurers. In the face of growing competition from for-profit insurers and health plans, Blue Cross and other nonprofit plans have been shifting from *social service models*, with their mission

defined by commitment to their communities, to *mutual company models*, where their primary commitment is to their customers. Assessing how much impact conversion has on a company's relationship with its customers, its continuation of activities with community benefits, or its day-to-day business practices requires further research.

Future Implications

This entry began by considering two questions: Why is there substantial nonprofit presence in the hospital, nursing home, and health insurance industries; and how do nonprofit and for-profit entities compare in costs and efficiency, pricing and profitability, quality, and community benefit? With respect to the first question, theory has emphasized issues of asymmetric information encouraging consumers to prefer nonprofits. Historical analysis suggests, however, that lack of functioning markets or the need for a donative business model dominated the early creation of nonprofits and that differential access to alternative sources of capital and effective competition, through mimicry or asymmetric market advantages, provide better explanations of the continued presence in the market of both forms.

Notwithstanding the limited role asymmetric information and consumer fear of exploitation have played in creating nonprofit and for-profit hospitals, there have been active and ongoing debates regarding the desirability of for-profit provision of health services and health insurance, the risk of nonprofit to for-profit conversion, and, on the other side, the justification for continued tax exemption and public benefits for nonprofit providers.

Research continues to fuel this debate. It has shown that while for-profit nursing homes are less expensive and more likely to accept Medicaid patients, their quality is lower than that of nonprofits. Contrary to theoretical expectations, for-profit hospitals appear to be no more efficient or less costly than nonprofits. Quality in for-profit hospitals appears to be comparable with or slightly lower than in nonprofits, and for-profits provide fewer community benefits. Comparisons of nonprofit and for-profit health insurers find no difference in costs, some evidence of lower quality or consumer satisfaction in for-profits, and an

erosion of community benefits as for-profit presence in insurance markets grows.

In the future, research on these issues will likely continue. One area that has only begun to be explored is examining the role of norm setting in markets by comparing the behavior of both for-profits and nonprofits as the mix of the two forms varies across markets.

FRAUD AND ABUSE

Fraud and abuse in healthcare involve threats to the integrity of reimbursement programs. The most far-reaching laws concerning these practices prohibit illegitimate means of obtaining payment from public programs, most notably Medicare and Medicaid. Similar laws in most states apply in the context of private insurance.

Prosecution of fraud and abuse is the most aggressive area of criminal enforcement in healthcare. More than 2,000 cases are brought each year, netting an estimated \$1 billion in recoveries from violators, although the full extent of improper payments that could be recovered is projected at several times this amount. However, the most significant impact of fraud and abuse enforcement may not be reflected in the sums regained from defendants but rather in the deterrent effect of these prosecutions for the much larger number of potential violators.

Health services researchers study fraud and abuse to better understand the functioning of healthcare reimbursement systems. The availability of funding from a third party to cover the costs of healthcare goods and services creates a temptation for some to use illicit means to obtain it. Without efficient safeguards to deter such behavior, reimbursement mechanisms cannot function. Nevertheless, schemes to game the system short of actual fraud and abuse are common, and they shape many healthcare financial practices. As a result, fraud and abuse laws and enforcement policies are key factors in guiding much of the business structure of healthcare and are essential components of the economics of the industry.

Definition of Terms

The term *fraud and abuse* refers to two kinds of illicit behavior. Fraud is the misrepresentation of material facts to obtain financial gain. For a

representation to constitute fraud, it must both be false and known to be false by the party making it. Common kinds of fraud in healthcare involve claims for reimbursement submitted by providers that either fabricate services that were never rendered or exaggerate the intensity of services that were rendered to obtain a higher level of payment, a practice known as *upcoding*. Since all health insurance, both public and private, requires that goods and services be necessary for medical treatment or diagnosis to be eligible for reimbursement, submission of claims for goods and services that are not necessary can also constitute fraud.

Abuse occurs when providers take advantage of their position of trust to promote inappropriate or unnecessary use of healthcare goods or services. Most commonly, this involves the exchange of payments in return for referring a patient for a product or service. Such payments can take the form of kickbacks, as when a portion of the reimbursement received is sent to the referring provider, or less obvious schemes to bestow a reward indirectly. They are considered illegal and unethical, because the opportunity for financial reward could cloud a referring provider's judgment concerning what is clinically best for the patient.

While payments in return for referring business are forbidden in healthcare, the opposite is true in many other industries. In various contexts, they are not only permitted but actually constitute common practice. For example, real estate agents receive commissions from the sellers of homes in return for arranging sales, as do stock brokers for securities and car salesmen for vehicles. The difference between these businesses and healthcare is that, unlike buyers of homes, stocks, and cars, patients are buffered by insurance from the financial consequences of their purchasing decisions. This removes the incentive to be economically prudent, a situation known as *moral hazard*. The ability of unscrupulous providers to steer patients to purchase unneeded goods and services is thereby enhanced considerably, which creates a risk to payers of overutilization that will escalate costs. Patients also must rely on the expertise of their physicians to determine which goods and services they will obtain to a much greater extent than buyers in other contexts.

Applicable Laws: The Basic Medicare Fraud and Abuse Prohibition

The most important legal directive against fraud and abuse in healthcare is contained in the federal law governing the Medicare and Medicaid programs. It was adopted in its present form in 1977 and amended to permit limited exceptions in 1987. The law contains an extremely broad set of prohibitions that cover a wide range of financial transactions. The section on fraud penalizes anyone who “knowingly and willfully makes or causes to be made any false statement or representation of a material fact” in applying for benefits. The section on abuse applies to anyone who knowingly and willfully either “solicits or receives” or “offers or pays” any remuneration in return for referring a patient for goods or services that are eligible for coverage under Medicare, Medicaid, or similar state programs such as the State Children's Health Insurance Program (SCHIP). The term *remuneration* is defined extremely broadly to include kickbacks, bribes, and rebates that are paid either directly or indirectly, overtly or covertly, in cash or in kind.

The penalties for violations can be severe, as the violations are considered felonies. Criminal sanctions include imprisonment for up to 5 years and fines of up to \$25,000 for each transaction. Short of criminal prosecution, government enforcers can pursue violators in civil proceedings for fines and can seek that they be excluded from participation in Medicare and Medicaid for up to 5 years. For physicians who see a substantial number of geriatric patients, exclusion from Medicare can effectively destroy a medical practice.

Billing fraud under Medicare and Medicaid has generated numerous well-publicized prosecutions. Large corporate hospital chains have paid settlements running into billions of dollars to resolve charges involving practices such as falsifying cost reports, performing unnecessary heart procedures, multiple billing of procedures, and billing for services that never took place. Large pharmaceutical firms have paid similarly large sums for false billing and other deceptive practices. Prosecutions have also netted settlements and convictions against academic medical centers, community hospitals, and individual physicians. Because of the complicated nature of Medicare and Medicaid billing

requirements and the ambiguity of many rules, fraud enforcement can involve highly complex litigation.

The prohibition against abuse raises even more difficult issues in its application. After the U.S. Congress enacted the sweeping law in 1977, the willingness of the courts to apply it strictly remained in doubt. Clarification came in 1985 from the federal Court of Appeals for the Third Circuit in the case of *United States v. Greber*. In that case, a cardiologist accepted referrals of patients from primary-care physicians for diagnostic tests, and he paid the primary-care physicians fees for interpreting the results of the tests. However, the cardiologist acknowledged that one purpose of the fees was to encourage referrals. The court ruled that if any intent behind a payment to a referring physician is illicit, then the entire payment is tainted, even if there is another legitimate purpose. This broad ruling established the precedent that the law against fraud and abuse is to be applied very stringently.

The breadth of the *Greber* decision gave teeth to the statute but left the status of many legitimate arrangements in doubt. There are some situations in which the exchange of funds between referring providers is not only innocuous but actually beneficial to the healthcare system. For example, emergency room physicians are paid salaries by the same hospitals where they admit patients, and staff physicians rent space in hospital-owned office buildings. Literal enforcement of the law to prevent these arrangements would produce absurd results that could severely disadvantage patients. To clarify the status of these and other beneficial business relationships, the U.S. Congress amended the law in 1987 to permit the U.S. Department of Health and Human Services (HHS), which is responsible for administering the Medicare and Medicaid programs, to designate selected practices as immune from prosecution.

Regulations issued by HHS in 1991 in response to the amendment defined 11 *safe harbors*, types of arrangements that are considered safe from enforcement. An additional 12 have since been added to the original list. Among the areas of legitimate activity that fall within safe harbors are employment of referring physicians, rental of office space at fair market value, contracting for professional services at fair market value, investment by referring physicians in large publicly traded corporations that provide medical goods

and services, and investment in smaller entities if stock ownership is not dominated by those who make referrals. Each safe harbor defines in detail the features that place a business relationship above suspicion. Arrangements that contain some but not all features of an applicable safe harbor are not necessarily considered illegal; however, they lose the automatic presumption of legitimacy that strict compliance with the regulations confers.

Applicable Laws: The Stark Amendments

Relying on a perpetrator's intent to find a violation leaves a significant enforcement gap. Some kinds of payments to physicians influence referring decisions even in the absence of a conscious intention to steer patients. These are general compensation schemes that can cement a physician's loyalty even in the absence of a clear ulterior business purpose. For example, physicians who invest in clinical laboratories may be more likely to send patients to those facilities even though the effect of the referral on their investment's value is remote. Along these lines, studies have shown higher rates of referral to radiation therapy clinics by physicians who own stock in them.

To close this perceived gap in the enforcement armamentarium, the U.S. Congress passed two companion amendments to the Medicare law in 1989 and 1993. Formally designated the Ethics in Patient Referrals Act, they are commonly known as the Stark Amendments, after Congressman Fortney "Pete" Stark (D-CA), who sponsored them. Rather than criminalizing specific transactions, this set of laws broadly prohibits Medicare or Medicaid reimbursement when the provider of a service has any kind of financial relationship with a physician who referred the patient or with a member of the physician's immediate family, regardless of the underlying intent.

The relationships to which the Stark Amendments apply include almost any that involve an exchange of economic value, including employment, rentals of space, investments, and loans. However, the law carves out exceptions for arrangements that are considered legitimate, including most of those covered by the safe harbor regulations, and HHS has issued regulations that further clarify the scope of the exceptions. The applicability of the Stark

Amendments is further limited to certain “designated” health services. The original 1989 amendment only concerned referrals to clinical laboratories. The 1993 addition listed nine other kinds of services, including diagnostic radiology, radiation therapy, physical therapy, occupational therapy, and the use of durable medical equipment.

Other Applicable Laws

Fraud in healthcare billing can also be prosecuted under a number of additional statutes that permit prosecutors to request added penalties. The federal False Claims Act imposes civil monetary fines for knowingly making false claims to federal authorities. The mail fraud statute permits prosecution for sending false claims through the mail, and the wire fraud statute does the same for claims submitted electronically. Various criminal laws broadly forbid knowingly representing false information to the federal government. Laws in many states have a similar effect with regard to state health programs, most notably Medicaid. Since private insurance is primarily regulated by the states, state-level laws address fraud in this sphere.

For many healthcare providers, the greatest enforcement threat comes not from the government but from private individuals who act as whistleblowers. Federal legislation enables them to bring civil claims for fraud committed against the government in a type of suit known as a *qui tam* action. Once such an action is filed, government prosecutors may choose to proceed, or they may leave it to the original whistleblower to do so, generally through his or her own attorney. If a claim succeeds, the claimant is entitled to a portion of the recovery equal to 15% to 25% if the government conducts the litigation and 25% to 30% if it is pursued privately. In a large prosecution, this can amount to a substantial sum. *Qui tam* actions represent an ever-present hazard for providers, as they can be initiated not only by members of the public but also by employees and competitors.

Enforcement Agencies

Two federal agencies hold primary authority for enforcing the laws against fraud and abuse. The

Office of Inspector General (OIG) of HHS issues and enforces regulations regarding the integrity of Medicare and Medicaid. It works in conjunction with another component of HHS, the Centers for Medicare and Medicaid Services (CMS), which actually administers these programs. OIG audits healthcare providers, initiates investigations when fraud is suspected, and can impose exclusions from eligibility for reimbursement. It issues regulations to guide compliance, including the safe harbor rules for fraud and abuse and interpretations of exceptions to the Stark Amendments. It also issues advisory opinions on proposed transactions and “fraud alerts” that describe suspect practices for providers to avoid.

The activities of OIG are supplemented by the U.S. Department of Justice (DOJ) when criminal or serious civil penalties are sought. DOJ attorneys also handle appeals of OIG administrative actions in the courts. The agency may initiate investigations and prosecutions through its headquarters in Washington, D.C., or through U.S. attorneys in the department’s regional offices around the country.

Providers that operate on a nonprofit, tax-exempt basis, as do many hospitals, also face fraud and abuse enforcement by the Internal Revenue Service (IRS). To be eligible for recognition of charitable status, the IRS requires that healthcare organizations refrain from letting their activities “inure” to the benefit of private individuals. Payments to induce referrals are considered to represent such private inurement. Hospitals that are found to have engaged in this practice are subject to fines and, in egregious cases, to loss of their tax-exempt status.

Various authorities at the state level enforce the fraud and abuse prohibitions concerning private insurance, Medicaid, and SCHIP. These include the departments of health, welfare, and insurance. State offices of attorneys general usually play the role of the DOJ when enforcement actions reach the courts.

Future Implications

The presence of fraud and abuse in healthcare stems from the large amount of money that is available through public and private insurance to reimburse services. This money creates a temptation for

unscrupulous providers and patients to try to obtain more than a legitimate share. Because of the complicated nature of healthcare services and of the procedures through which they are billed, the legal directives that forbid fraud and abuse and the processes through which these directives are enforced are marked by complexity and changing interpretations.

The incentive to overbill exists primarily within insurance arrangements that reimburse providers on a fee-for-service basis—that is, with a discrete payment for each healthcare service rendered. Some alternative mechanisms avoid this inducement, most notably capitation under managed care, in which a provider is paid the same amount for each patient regardless of the quantity of services that are actually provided. Under such arrangements, overtreatment, inflation of bills, and payments for referrals no longer generate financial returns. If this kind of reimbursement paradigm spreads further, fraud and abuse enforcement in its traditional form may fade in importance. However, it may be replaced with an opposite concern, that of undertreatment, and with it, new challenges for policymakers and government agencies.

Fraud and abuse enforcement policy, therefore, can be seen to reflect the underlying economic dynamics of the healthcare industry. As the industry's structure evolves, legal doctrines will, as well. The resulting interplay presents health services researchers with opportunities to better understand the relationships between financial incentives, healthcare business practices, and policy responses.

FREE CLINICS

Free clinics are community-based entities that provide healthcare services mostly to uninsured people at little or no cost to their patients. Free clinics are organized as private, nonprofit organizations (or programmatic components of nonprofit organizations). They are run by volunteer, licensed healthcare professionals who deliver basic medical services, but the clinics often have a small paid staff to support their volunteer infrastructure. Free

clinics tend to be located in permanent stand-alone facilities or mobile units or housed in borrowed or rented spaces, such as church basements or homeless shelters. They may be independent entities or part of or affiliated with another nonprofit organization (e.g., church, hospital, or social service agency). Free clinics also are supported mostly by private sources of funding.

History

The American Medical Association (AMA) shunned the free-clinic movement of the 1960s, the era when the number of free clinics grew rapidly. Since 1994, however, official AMA policy has supported free clinics. Free clinics are now a preferred model that private physicians adopt to provide care for the growing numbers of uninsured and underserved individuals. In the mid-1990s, the Robert Wood Johnson Foundation (RWJF) funded 40 projects through a \$12 million initiative to encourage private physicians to improve access to care for the uninsured and underinsured. Under this RWJF grant program, physicians in nearly one of every three projects chose a free-clinic model as a method to improve access to healthcare. Free clinics may have emerged initially to treat “outsiders” (e.g., drug addicts and runaway youth), as exemplified by the Haight Ashbury Free Clinics in San Francisco, a free medical clinic situated at the epicenter of the 1960s hippie movement, founded to serve patient populations who identified with the counterculture. However, many free clinics now serve less marginalized segments of the population, such as low-income individuals who cannot afford health insurance, and underinsured patients. Many free clinics today target their services to the so-called working poor. Thus, in the past 40-plus years, free clinics have redefined “needy” to include the medically indigent or underserved, a much broader spectrum of patients than in the past.

Over the years, the number of free clinics in the nation has grown exponentially, from 59 in the 1960s to more than 1,000 in the 2000s. However, their precise number is unknown. Free clinics are found in every state except Alaska. The number of free clinics in the states varies widely, from 1 free clinic each in Delaware, Hawaii, and Rhode Island to more than 70 free clinics in North Carolina.

Research

Despite their long history and broad geographic distribution, free clinics have received little attention from health services researchers, largely due to a dearth of publicly available data and a lack of consensus about what constitutes a free clinic. Notably, the national Institute of Medicine’s (IOM) seminal study on the nation’s safety net *America’s Health Care Safety Net: Endangered but Intact* (2000) does not even mention free clinics. Consequently, there is very little understanding about the roles that free clinics play in the nation’s ambulatory healthcare safety net.

The Uninsured and the Ambulatory-Care Safety Net

It is estimated that 47 million persons in the United States have no health insurance coverage. It is widely reported that uninsured individuals delay or forgo needed or preventive healthcare often because the cost of obtaining care is prohibitive. Free clinics are one choice among a range of other choices—including private physicians, federally qualified health centers (FQHCs), public clinics, hospital outpatient departments, academic medical centers, and hospital emergency rooms—that uninsured patients have when seeking a source of primary care. Except for free clinics, most sources of care for uninsured patients require (often substantial) cost sharing from patients. In most ambulatory-care settings, uninsured patients are charged a flat fee or an amount according to a sliding fee scale based on a family’s income. Ambulatory providers also generally bill patients. In contrast, free clinics distinguish themselves from these other primary-care providers by offering their care for free or for a nominal fee and by not billing patients. Free clinics are, therefore, one of the few viable options available to uninsured patients with limited funds.

Free Clinics Versus Federally Qualified Health Centers

To appreciate the niche that free clinics fill in the ambulatory care safety net, it is illustrative to compare free clinics with FQHCs, because they are most analogous to (and often confused with)

free clinics. Free clinics have essential features that distinguish them from these health centers.

Specifically, free clinics annually raise \$300 million in private funds to serve an estimated 3.5 million uninsured and underinsured patients, according to the National Association of Free Clinics. In 2006, the \$1.8 billion federal health center program supported roughly 1,000 health center grantees, which accounted for approximately 4,000 sites. Collectively, these health centers served 15 million patients, of whom 6 million were uninsured.

Free clinics seek to serve the uninsured. Many only see patients who are uninsured. In contrast, approximately 40% of health center patients are uninsured; the majority of patients are insured, principally by Medicaid.

Free clinics target the working poor. Many target patients who are unlikely to qualify for public health insurance programs. Often these patients have incomes between 100% and 200% of the federal poverty level. In contrast, health centers serve mostly poor patients who qualify for Medicaid.

Reportedly, free clinics do not charge patients based on their ability to pay. By comparison, health centers are required to use a sliding fee scale based on a patient's income and family size. The amount of the sliding fee scale is set by each clinic and varies widely but ranges from \$20 to about \$100.

Free clinics provide a limited range of health-care services on-site. They deliver free services on-site as well as make arrangements for patients to receive free care from formal networks of referral providers. Most free clinics provide services such as physical examinations, urgent/acute care, chronic disease management, medications, and health education on-site. Often services are available through a referral arrangement. By comparison, health centers are required to provide comprehensive primary-care services. The scope of services is specified by law and in regulations.

Most free clinics are not open full-time. Furthermore, their patients generally cannot contact a clinic provider after-hours, when the clinic is closed. In contrast, health centers are generally open full-time. Furthermore, they are expected to ensure telephone access to another health center or community provider when the clinic is closed and to have procedures in place for patients who need care to be seen.

Reportedly, free clinics do not bill patients for services. In contrast, as part of their mandate to maximize revenue from all sources, including patients who are uninsured/self-pay, health centers routinely bill patients for services.

Free clinics tend to rely mostly on private sources of funding for their operating budget. Most of the clinics receive no revenues (or very little) from government sources. By comparison, health centers receive the majority of their funding from government sources. Federal appropriations to health centers account for approximately one fifth of a health center's revenues, and Medicaid accounts for more than one third. Very few free clinics bill for third-party reimbursement from insurers.

Last, free clinics rely on volunteer, licensed health-care professionals to deliver services. A small paid staff often supports their volunteer infrastructure. In contrast, the core clinical staff members operating in health centers are paid, full-time employees.

Heterogeneity of Free Clinics

A commonly repeated saying in the free-clinic sector—"If you've seen one free clinic, you've seen one free clinic"—aptly describes the great variety of clinics that comprise the population of free clinics. Free clinics span a continuum from those that see a limited number of walk-in patients one night per week to others that provide comprehensive primary care services to thousands of patients annually with the support of full-time, paid staff and a multimillion-dollar operating budget. The considerable diversity in the free-clinic model makes it difficult to draw conclusions about the adequacy of individual free clinics to meet the needs of uninsured patients. The differences seen across free clinics suggest that the merits of these clinics must be evaluated on a case-by-case basis.

Current and Future Trends

Having existed for many decades but remaining fairly invisible, free clinics today are garnering more attention as they become more formalized. The National Association of Free Clinics, a membership organization representing free clinics, was established in 2001. State and regional free-clinic

associations predate the national association. The 24 state and regional free-clinic associations today encompass 33 states. Twenty-two states operate their own free-clinic associations. The first state association, the Virginia Association of Free Clinics, was founded in 1993. Signifying the progress toward standardization, the free-clinic association in Virginia has developed a process to certify free clinics. Virginia's certification process has been replicated, in part, by Ohio.

Free clinics' visibility also is enhanced by their increasing participation in government programs. Historically, free clinics have eschewed government involvement, and today most free clinics do not receive any funding from government sources. But in response to the Health Insurance Portability and Accountability Act of 1996 (HIPAA), which extends federal medical malpractice coverage to volunteer healthcare professionals at free clinics, more than 2,000 health professionals at 73 sponsoring free clinics have been deemed eligible for medical malpractice protection under the Federal Tort Claims Act (FTCA) as of 2007. To be eligible for FTCA coverage, free clinics must maintain a risk management system and providers must meet privileging and certification requirements. These requirements introduce bureaucratic red tape, which free clinics historically have shunned.

These recent developments suggest that the free clinics of the future may be different in important ways from those of the past. Continued monitoring of free clinics is needed to account for the changing healthcare environment and its impact on the free-clinic sector.

FUCHS, VICTOR R.

Victor R. Fuchs is a leading health economist who is perhaps best known for his work *Who Shall Live? Health, Economics, and Social Choice*, which provides healthcare professionals and policymakers with the tools to understand the economic and policy problems in healthcare that have emerged in recent decades. Fuchs is the Henry J. Kaiser, Jr., Professor Emeritus at Stanford University, senior fellow in the Freeman Spogli Institute for International Studies, and a core faculty member in the Center for Health Policy/Primary Care and

Outcomes Research at Stanford. Fuchs is also a research associate of the National Bureau of Economic Research (NBER).

Fuchs received his bachelor of science degree in business administration from New York University and a master's and a doctoral degree in economics from Columbia University. Fuchs began his professional career as a faculty member at Columbia University and New York University. He later was a program associate for the Ford Foundation Program in Economic Development and Administration, scholar-in-residence at the Rockefeller Foundation in Lake Como, Italy, and fellow at the Center for Advanced Study in the Behavioral Sciences in Stanford, California. In 1968, Fuchs joined the faculty at the Mount Sinai School of Medicine as professor of community medicine and the City University of New York Graduate Center as professor of economics and served as vice president of the National Bureau of Economic Research (NBER). In 1974, he accepted a position at Stanford University, where he continues to teach and conduct research.

Fuchs's work involves applying economic analysis to solve social problems of national concern, with an emphasis on health and medical care. He has been particularly interested in the influence of financial incentives on physician behavior and its relation to healthcare expenditures. He has published extensively on topics such as the cost of medical care and the determinants of health, with particular focus on the role of socioeconomic factors. His scholarly work has resulted in 15 books and more than 180 articles and papers.

Fuchs's contributions have been recognized through many awards and honors, including the John R. Commons Award from the Omicron Delta Epsilon, the Emily Mumford Medal for Distinguished Contributions to Social Science in Medicine from Columbia University, the Distinguished Investigator Award from the Association for Health Services Research, the Baxter Foundation Health Services Research Prize, and the Madden Distinguished Alumni Award from New York

University. He is also a past president and distinguished fellow of the American Economic Association and holds elected memberships or fellowships in the American Philosophical Society, the American Academy of Arts and Sciences, and the National Academy of Sciences, Institute of Medicine (IOM).

His current research examines the attitudes and beliefs in public support for national health insurance. He is developing a proposal for a universal healthcare voucher system in which all individuals would receive a government voucher that would guarantee coverage in a private health plan with standardized benefits.

GATES FOUNDATION

The Bill and Melinda Gates Foundation is the largest private philanthropic foundation in the world. With assets in excess of \$38.9 billion in 2007, the foundation focuses its grant-making and advocacy efforts on eliminating global inequities and increasing opportunities for those in need. In 2007, it contributed more than \$1.5 billion to programs that addressed global agricultural and economic development, medical research and public health initiatives in developing countries, and the improvement of education and access to information in the United States.

Background

Bill Gates, Microsoft's cofounder, and his wife, Melinda, established the William H. Gates Foundation in 1994, which focused its charitable giving on advancing global health and the community of the Pacific Northwest. Gates's father, William, managed the activities of this entity. Three years later, the Gates Library Foundation was created, which aimed at improving access to public libraries for low-income families in North America. It was later renamed the Gates Learning Foundation to reflect its expansion into broader education efforts.

The Bill and Melinda Gates Foundation was established in 2000 through the merger of the two Gates foundations. The original priority

programs for this new entity were global health, education, libraries, and the Pacific Northwest. In 2006, the foundation reorganized, focusing its giving on three areas: global development, global health, and the United States. The same year, the investor and philanthropist Warren Buffett made a lifetime pledge to the foundation of Berkshire Hathaway stock, valued at \$31 billion. At this time, the foundation also changed its structure, creating the Bill and Melinda Gates Foundation Trust to manage and invest the endowment assets. The foundation is based in Seattle, Washington, with offices in Washington, D.C., and Beijing, China.

Program Areas

Since 2006, the Bill and Melinda Gates Foundation has focused on three main program areas: the Global Development program, the United States program, and the Global Health program. These programs all strive to accomplish the foundation's mission to increase equity and opportunity to those populations that are most in need.

Global Development

The Global Development program, the newest of the foundation's programs, strives to eliminate extreme poverty and hunger. In its 1st year, the program's grant-making activities totaled \$170,304,000, and in 2007, the foundation paid \$308,041,000 in grants in this area.

Through strategic partnerships and grant-making activities in its agricultural development initiative, the program helps increase opportunities for farmers in developing countries, as well as researching the production of rice and flour enriched with micronutrients. The Global Development program also has an initiative aimed at increasing financial services to the poor; it funds projects that examine the effectiveness of loans, insurance, financial planning, and financial education in impoverished countries.

In addition to these two key initiatives, the Global Development program is committed to global libraries, supporting public libraries and organizations that work to increase access to information technology. Finally, the program's Global Special Initiatives awards grants to organizations that research issues of concern to the developing world, including water, sanitation, and hygiene.

United States Program

The United States program is dedicated to reducing inequities that exist in this country for low-income, minority, and vulnerable populations. The program also aims to increase opportunities for these populations. In 2007, the program paid a total of \$483,626,000 in grants.

The United States program houses the foundation's education initiative, which focuses on keeping young students from dropping out of school and better preparing high school graduates for college. This program also oversees the activities of the public libraries initiative, which strives to provide access to computers and the Internet at local public libraries; this initiative also aims to keep technology systems up-to-date for libraries and provide adequate training and support for this technology. Showing a continued commitment to the foundation's immediate community, the Pacific Northwest initiative addresses the issues of inequity and opportunity for families and children living in Washington and Oregon. This initiative's activities include supporting projects that work with at-risk youth and helping to reduce homelessness among families in the region.

Beyond these three initiatives, the United States program also includes activities for special initiatives that identify needs that fall outside the

program's established purview. These activities help shape potentially new directions for the program. The program also handles advocacy for the foundation's efforts in this country.

Global Health

The Global Health program is the largest of the Bill and Melinda Gates Foundation programs. It is committed to addressing the high mortality and morbidity rates from preventable diseases in developing countries; it focuses on funding to projects that would increase access to existing vaccines and treatments for common diseases and researching new, affordable, and practical health solutions. In 2007, the program paid \$1,220,008,000 in grants in this area.

Projects funded by the Global Health program address prevention and treatment of diseases that meet three criteria: (1) they cause widespread illness and death in developing countries, (2) they represent the greatest inequities in health between developed and developing countries, and (3) they receive inadequate attention and funding. The foundation's priority diseases and conditions are acute diarrheal disease, acute lower-respiratory infections, child health, HIV/AIDS, malaria, poor nutrition, reproductive and maternal health, tuberculosis, vaccine-preventable diseases, and other infectious diseases.

Also through the Global Health program, the breakthrough science initiative funds projects that advance health research and technologies in the developing world. This initiative supports the development of affordable and accurate medical tools. The foundation's Grand Challenges in Global Health is part of this initiative.

In addition to the disease-specific and special initiatives, the program also handles the foundation's global health advocacy efforts and global health interventions at the local community level and provides immediate support for natural disaster and emergency relief.

Future Implications

As the world's largest private foundation, the Bill and Melinda Gates Foundation is poised to make a major impact in the areas of global policy, global health, education, and access to information

technology. Since 2006, when the Bill and Melinda Gates Foundation Trust was established, the pledge from Warren Buffett was received, and the announcement was made that the charity has a set lifespan of 50 years after the deaths of its founders, the foundation has developed a strategic outlook to maximize its charitable giving. Because of criticism of its investment practices—namely, that several corporations in the foundation's portfolio are not environmentally and socially conscious and may contribute to global development and health problems, the foundation is currently reassessing its investment practices.

In July 2008, Bill Gates stepped down from his position at Microsoft to devote his efforts full-time to the Bill and Melinda Gates Foundation. With this change, the foundation may identify additional priority areas or increase its activities.

GENERAL HEALTH QUESTIONNAIRE

The General Health Questionnaire (GHQ) was developed to assess the extent of psychiatric illness in general practice. Contrary to what the name suggests, this questionnaire does not assess general health but mental health. The GHQ is

considered to be a significant advancement in psychiatric epidemiology since general practitioners did not diagnose their patients with significant psychiatric illness in the 1970s. Recognizing the need for physicians to test and assess their patients and make a tentative diagnosis of mental illness, David Goldberg at the Institute of Psychiatry, London, developed and published the GHQ.

Overview

The GHQ was designed as a self-administered screening instrument with the ability to differentiate psychiatric patients from healthy individuals within a community. However, the GHQ is not concerned with making a specific psychiatric diagnosis. The GHQ was originally developed as a 60-item instrument. Currently, there are four shortened versions available. In addition, the GHQ has been translated into 38 languages, and it has been extensively used in both research and clinical practice. Furthermore, this survey instrument has been validated cross-culturally in many adult populations across the world.

Rating Scale

Each item on the GHQ is rated on a 4-point scale: *less than usual*, *no more than usual*, *rather more than usual*, or *much more than usual*. For example, the GHQ-12 gives a total score of 36 or 12 based on the selected scoring methods. One of the most common scoring methods used is the bimodal method, where the responses are assigned the numeric values of 0-0-1-1. Another method is the Likert scoring style, which assigns the values as 0-1-2-3.

The areas of mental health that are assessed by the original version of the GHQ include depression and anxiety, social functioning, psychophysiologic symptoms, general health, and vague aches and pains. The internal consistency of the GHQ is reported to be in the range of 80% to 90%, which indicates the high reliability of the instrument. Additionally, the coefficients of correlation with global clinical assessments of psychopathology are in the range of .55 to .83, indicating high validity. The overall sensitivity has been reported to be about 68% with a specificity of about 81%.

Factors Assessed

The GHQ assessment focuses on breaks in normal functioning rather than lifelong traits. The GHQ is based on two major classes of phenomenon that occur in patients with psychiatric illness. First, it assumes that patients with psychiatric illness are not able to carry out normal healthy functions. Furthermore, it assumes that such patients have episodes of distress. The items in the GHQ concentrate on the specific spectrum between psychiatric disturbance and normal functioning, rather than ranging over the whole array of mental health from normality to severe disturbance. Respondents are not asked how long they have experienced symptoms. As a result, disorders with less than 2 weeks' duration are included. In contrast, the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*, another diagnostic instrument for assessing the severity of depression requires that symptoms be present in a respondent for at least 2 weeks to be included as a positive symptom of depression. Certain demographic variables also affect the GHQ scores, while some do not. For example, females who are divorced or separated, unemployed, or living in urban areas generally have higher scores than women who are not in the same situation. Age and social class, however, do not have a strong effect on the GHQ score.

Versions

Several versions of the GHQ are available. These include the GHQ-60, the fully detailed 60-item questionnaire; the GHQ-30, a short form without items relating to physical illness; the GHQ-28, a 28-item scaled version that assesses somatic symptoms, anxiety, insomnia, social dysfunction, and severe depression; and the GHQ-12, a quick, reliable, and sensitive short form, which is ideal for research studies.

In terms of validity, reliability, and prediction, the 60-item version has been shown to outperform the shorter counterparts. The 12-item and the 30-item versions have been more widely used in community samples because they are brief and take less time to complete. Over the past 10 years, the GHQ-28 has become a widely used questionnaire in epidemiological studies.

The GHQ has also been adapted for different populations and cultures. There are three main reasons that account for the interest in adapting this instrument to different samples and languages. First, the GHQ-28 has the advantage of being shorter, with approximately 3 to 5 minutes required for the full questionnaire to be filled out. Additionally, it can be applied to primary-care settings, where the majority of minor psychiatric disorders arise. Furthermore, apart from providing an overall assessment, the GHQ-28 contains four scales that furnish additional information.

Use

The GHQ has been used in different settings for various purposes, including within clinical-practice settings for research studies and clinical trials and in population-based epidemiological studies. The use of GHQ and its versions is protected by copyrights held by David Goldberg and the Institute of Psychiatry, London. The GL Assessment acts on behalf of the original copyright holders, and it allows researchers to use the GHQ after paying user fees and signing various legal agreements. Based on the study design and the context of use, there is also a provision to use GHQ free of cost.

Future Implications

The GHQ has been used to assess the mental health status of individuals and populations for more than three decades. The GHQ has also been translated and validated across many languages and cultures. A general note of caution should be exercised in using the GHQ or in interpreting the results from this survey in the clinic setting, because it does not differentiate between different types of mental illness. Among all the different versions of the GHQ, the 12-item short form remains a quick, reliable, and sensitive questionnaire, making it ideal for research studies. In addition, it has been shown that the use of GHQ by general practitioners can increase their ability to recognize hidden psychiatric morbidity and a new episode of illness.

GENERAL PRACTICE

General practice, also known as family practice or family medicine, and more recently termed *primary care*, is the field of medicine dedicated to caring for people of all ages. The principles and philosophy of general practice include establishing

a long-term relationship with patients; providing patient-centered, comprehensive and cost-effective care; and identifying and addressing the family and psychosocial factors that affects the health and wellness of patients. A general practitioner (GP) is a physician who practices family medicine and provides primary care to patients to treat acute and chronic illnesses, as well as providing routine preventive care and health education.

Overview

With a mission to preserve and promote the science and art of family medicine and to ensure high-quality, cost-effective healthcare for patients of all ages, the American Academy of Family Practice (AAFP) was founded in 1947. Family practice was officially recognized in February 1969 as the 20th primary medical specialty. With this new designation came added responsibility. Training and preparation for family practitioners was standardized to include a wide variety of medical disciplines, including general internal medicine, women's health and obstetrics, infectious disease, pediatrics, newborn care, emergency medicine, surgery and its subspecialties, ophthalmology, dermatology, otolaryngology, and more. Office-based training of the fledgling family practice physician became a high priority to maintain wellness and decrease rising hospitalization rates. Recently, family practice training programs have collaborated within their respective communities and academic institutions to offer more hospital-based care to their patient populations, ensuring greater continuity of care for the patients. This programmatic philosophy for more hands-on experience with inpatient care instead of training in outpatient care has been necessary because of the increasing fragmentation of the healthcare system in the United States and the rising costs associated with healthcare.

Family and general practitioners are often the first point of contact for people seeking healthcare, and these providers generally act as the traditional family physician. In general practice, a wide range of medical services is typically available, including newborn and well-child care, age-appropriate vaccinations, and care of the sick child as needed. Adolescent and young-adult care, along with

appropriate counseling tailored to this formative period in life, completes the care of children as they progress into adulthood. Most physicians in general practice also offer care to women of child-bearing age, which includes services during pre-conception and pregnancy as well as care of the newborn. Additionally, one quarter of general practitioners have incorporated obstetrical care into their practices, which involves the delivery of the newborn and immediate care of the mother following the birth. Mainstream adult care of people 25 years of age and above, along with care of the elderly, is the main purview of physicians in general practice. Comprehensive physical exams, screening tests, treatment of common and acute conditions, management of chronic disease, coordination of allied healthcare, and even home care are all a part of the routine health maintenance functions that form a common thread in general practice.

The strength of general practice lies in the relationships forged between the patient and the physician. This bond allows the patient to feel comfortable revealing confidential, discreet problems of both physical and psychological origin. This type of relationship most often helps identify medical and health concerns in their early stages, which reliably leads to a satisfactory resolution of the issue or a timely referral to specialty services if necessary. Communication between the patient and the physician and between the physician and other healthcare providers is the key to successful general practice of medicine.

The advantages of family practice and general practitioners lie in their ability to help decrease the financial burden faced by every U.S. resident. Nations that have an adequate supply of family practice physicians and general practitioners experience significant financial rewards and lower costs of healthcare. General practice is traditional medical care that is not only the most cost-effective in comparison with other medical fields but also associated with better health outcomes. Twenty-eight nations, including Cuba, New Zealand, and most of the European countries, had lower infant mortality rates than the United States. The United States also ranks fairly low in terms of overall life expectancy and has a relatively high incidence of chronic disease. Compared with other nations

such as Canada, which has a higher percentage of medical students who enter training programs in primary care, the United States spends much more on healthcare. By investing in the training and retention of general practitioners and the promotion of this field, the United States may be able to improve health outcomes and decrease health expenditures.

With the rise in medical specialties and subspecialties and financial incentives that encourage medical specialization, the number of general-practice physicians in the United States has been declining in recent years. The Bureau of Labor Statistics (BLS) estimates that about 40% of physicians are primary-care providers; however, family and general practitioners represent just over 12% of this group.

Future Implications

General practitioners play a pivotal role in the healthcare system as the primary deliverers of care. The need for general practitioners of family medicine will continue to grow as the population ages and there is a greater emphasis on preventive healthcare. Public policies that encourage increasing the number of providers of general practice are needed to address the current shortage and to ensure adequate access to healthcare for everyone.

GENETICS

Genetics is the study of the life blueprint (commonly referred to as DNA) that makes up the genes (the fundamental units of heredity), which are found in the human chromosomes. In total, there are 23 pairs of chromosomes that make up the human genome (the total package of heredity information). Human molecular genetics focuses, among other things, on discovering and understanding the inventory of human genes; their functions; the effects of variation in their distributions among different individuals; their roles in the etiology of human diseases; and how such knowledge can be used to improve the prevention, diagnosis, and treatment of human diseases.

Substantial progress has been made in the field of molecular genetics in the past several decades, and

this has translated into better prediction, diagnosis, and drug development and hence better treatment of many diseases, especially monogenic disorders such as hemophilia, cystic fibrosis, fragile X syndrome, and Huntington's disease. Unfortunately, similar medical advances remain to be seen in relation to the genetic etiology of most common human diseases, such as hypertension, diabetes, cancer, and age-related macular degeneration. As populations age, the relative burden of these conditions has generally been on the rise.

Several reasons can be given to explain this situation in which current technology-driven advances in molecular genetics have not proven to be conceptual breakthroughs. In particular, population and clinical scientists have not done enough to assess the utility of the new advances in molecular technology. The key challenge in genetics at this time is to translate the information from genotyping and sequencing studies into clinically relevant tools.

Developing an Evaluation Framework

To accurately evaluate the impact of molecular genetics on common diseases, appropriate criteria to assess the contribution to treatment and prevention must first be available. Key elements of such an evaluation framework must provide answers to questions such as the following: How do the answers provided by this new research fit with what researchers already know? Can molecular tests provide new information about prediction or risk stratification? Will it help to tailor therapy? And will it yield insights into pathogenesis and/or pathways? Answers to these and related evaluation questions will have to be provided by data from the different but dependent stages of molecular genetic research, from discovery to application, as illustrated in Figure 1.

Figure 1 Schematic of Stages in Molecular Genetic Research

A pertinent question therefore becomes, What will the payoff be from finding disease susceptibility variants or loci? The first most likely outcome is improved prediction and/or risk stratification. Experience so far suggests that prediction is an unlikely use of the knowledge of susceptibility loci. To be useful for diagnosis or risk stratification, such a genetic test must substantially increase the posttest probability and also provide supplemental and independent information beyond currently available tests. Based on the assumption that individuals known to be at high risk of developing a disease will benefit from earlier, more intensive intervention, either through lifestyle changes or drugs, risk stratification could also be an important use of the knowledge of disease susceptibility loci. However, in a situation where both exposure and susceptibility are widespread, population-wide measures are often the most effective public health strategy (e.g., smoking, high cholesterol). Likewise, measurement of the phenotype (e.g., high blood pressure) is likely to provide more information than the genotype.

Personalized Medicine

Another area where identification of susceptibility variants will potentially be of benefit to public health is tailored therapy. There are many neutral variants in the human genome that have survived evolutionary selection and are now known to alter drug metabolism or response. These variants could therefore be responsible for the large individual variation in toxicity as well as any therapeutic effect. This background variation constitutes the potential basis for tailored therapy (sometimes referred to as personalized medicine).

In addition, it is argued that in many instances susceptibility genes will mimic pathogenesis. Under this assumption, a description of the genetic basis for chronic illness will lead to a better understanding of disease processes, including new physiologic pathways that will create new opportunities for interventions through prevention or drugs. These payoffs are, however, contingent on a thorough understanding of the biology since genetic markers cannot unravel pathways. It is important to note that knowledge of pathways or mechanisms is only useful to public health if it leads to modifiable exposures or drugs.

These proposed valuable outcomes from genetic research must be evaluated in light of the current experience. In fact, up to this point, knowing the genotype has generally not been a useful guide to therapy, even for monogenic disorders including long QT syndrome, Marfan syndrome, Factor V Leiden—venous thrombosis, and hereditary hemochromatosis. The challenge remains to narrow the gap between the vision of personalized medicine and reality. This will involve making realistic estimates of the precision of individual prediction, revisiting the trade-offs of the high-risk versus population strategy in the context of how genetic screening will be used for common diseases, describing and experimentally verifying the procedures to move from anonymous genetic markers to causal variants, and describing how knowledge of pathways and mechanisms will open new preventive and therapeutic options. All these research efforts will entail potential costs. These costs could include diversion of resources within the scientific research community away from preventive interventions that already work, fostering the impression that technology will solve social problems, and a rekindling of the debate over biological determinism and racial/ethnic health disparities. However, the seduction of even larger genetic studies appears poised to cause the diversion of already declining resources in the foreseeable future.

Future Implications

Based on these considerations, molecular medicine's role is likely to remain marginal in the control of common diseases in the foreseeable future. At the same time, it is likely that a whole new dimension of biology will be learned, and this will in some instances illuminate causal processes. In some cases, prediction will be sufficiently precise. Some drug discovery will be possible, and this should have a positive impact on the ability to deliver more effective healthcare. However, there is a need for balanced and unbiased expectations of the future contribution of genetics to medicine and public health, knowing that molecular medicine relies heavily on unproven assumptions of the potential for technology to solve health problems. Some researchers argue that genomics may hold the potential to advance the claims of a science

belief system, over the pragmatic needs of the long-term movement, toward prevention through the creation of a healthier environment as the most effective means to control common diseases.

GEOGRAPHIC BARRIERS TO HEALTHCARE

Access to care can be defined as the timely use of personal health services to achieve the best possible health outcomes. Equitable access to healthcare is directly linked to the quality of life of populations. Healthcare access and outcomes

have a linear relationship relative to structural, financial, personal, and geographic barriers. Major geographic barriers to healthcare access include the following: shortage of healthcare service providers, clinics, and/or hospitals in the vicinity of a community; increased travel time to the nearest facility or provider; lack of transportation—slow, erratic or nonexistent public transportation systems; residing in public housing or mountainous, rural, snowbound, or disaster areas; physical inability to access facilities due to disability; seasonal barriers, such as excessive rainfall or snow; and poor or nonexistent road systems.

The main tenet of preventive care is that regular access to primary medical care reduces the need for acute care. Geographic barriers to care have adverse implications both before and after an individual enters the realm of healthcare delivery, which can lead to considerable health disparities. Geographic access is typically characterized as a measure of distance to care, with 30 minutes generally being viewed as the accepted maximum time to access healthcare. Access is influenced by the area of an individual's activity space; the spatial distribution of healthcare facilities; and the spatial structures, such as mountains, lakes, and rivers, that act as barriers. Distance can be measured from two different perspectives. It can be considered from the perspective of the suppliers, who look at the distance to healthcare facilities. It also can be viewed by the individuals, who determine how to obtain the services and how far to travel to receive healthcare. A number of methods are used to calculate distance, such as the linear distance across a map, road distance, travel time, perceived distance, perceived travel time, and the distance to the nearest provider. Calculating distance alone, however, does not take into account the variation in individual mobility, preferences, and spatial habits; differences in road and travel conditions; and subjective perceptions of distance—for example, younger people may be more comfortable traveling longer distances than the elderly, sick, or handicapped.

Healthcare utilization is frequently related to travel time and distance. Research has shown that long travel time due to poor transportation to or due to long distance from facilities decreases utilization. People tend to forgo preventive, acute, and chronic care when travel is cumbersome and costly and when facilities are far away, which is common

in rural areas worldwide. This distance decay effect has been well established, as increasingly smaller proportions of populations are using services at greater distances from them. The extent of distance decay depends on the type and severity of illness.

Healthcare Geography

A community's geographic location has important implications for personal healthcare and healthcare service delivery. Human geography focuses on the patterns and processes that shape human interaction with various environments and how they adapt to it. Medical geography studies the correlation between disease and disease diffusion, without explicitly considering the other aspects of human interaction. Together, human and medical geography span the structure of health services and explain how people use health services in ways that reflect and create disparities. In the context of healthcare, economic geography focuses on the location of healthcare facilities and on transportation and trade. Remote and rural areas still suffer from inadequate healthcare infrastructure and personnel; they are also lacking in public transportation systems. Using geographic mapping to set boundaries with relation to healthcare delivery and outcomes and to compare different regions is increasingly being accepted in health policy formulation and resource allotment. Geospatial mapping is now a common approach for governments to assess the availability of healthcare providers and infrastructure in relation to adjacent communities, to identify geographic barriers to care, and to institute remedial measures. However, a universally acceptable, fundamental unit of geography for measuring health and healthcare has yet to be defined.

Geographic Maldistribution of Healthcare Providers

The phenomenon of physicians and associated healthcare professionals choosing to practice in affluent, urban communities is a recognized global trend. It is referred to as the maldistribution of healthcare providers. This ongoing trend creates a shortage of healthcare providers in remote, rural,

and inner-city areas and a surplus in urban and suburban areas. Despite an increase in the overall physician-to-population ratio, this disproportionate distribution continues. The smallest and most geographically remote communities experience the greatest shortages, though almost all rural communities have comparatively fewer physicians of all disciplines, particularly specialists, than metropolitan areas. Not surprisingly, this scarcity carries over into the fields of nursing, therapy, psychology, and ancillary services. In the United States, the greatest shortages are found in remote rural communities with fewer than 10,000 people, where the physician supply has remained relatively unchanged since the 1940s. In urban areas, the physician-to-population ratio has more than doubled since 1960, while increasing by only 15% in rural areas. These trends are evident globally, in poor and rich nations, mostly due to the difficult working conditions in geographically remote areas. Factors that make the recruitment of healthcare providers difficult in rural areas include safety issues, inadequate infrastructure and supplies for effective treatment, low pay, poor housing and education for children, lack of social options, poor bonding with the local community, and significant distance from metropolitan areas.

The closure and mergers of many community and public hospitals over the past several decades has aggravated the shortage of healthcare personnel in many areas. When hospitals close, already underserved populations have to travel greater distances to access services. People who must travel farther often incur greater transportation costs, by taking off from work or due to loss of income. These factors may lead to delays in seeking treatment and adverse health outcomes, which may prove to be more costly in the long run. Pregnant women, children, the elderly, and the physically or mentally challenged are more prone to suffer from poor health outcomes due to poor access as they often need someone to accompany them to remote centers, and they may also lack transport facilities and funds.

Travel Burden

Transportation and healthcare access are directly linked to health outcomes. Travel burden is one

of the key components of conceptualizing geographic access to healthcare. Determinants of travel burden include arranging transportation and childcare, travel time, driving distance, transportation expenses, and the costs of missing work. Rural residents have the dual burden of lack of public transportation and living far from healthcare facilities. In rural America, only 1% of healthcare visits are made using public transportation. Those individuals without cars or who cannot drive must depend on family members or community resources to take them to clinics, which limits their control over appointment times and the choice of providers. Transportation barriers are also linked to a reduction in patient compliance with treatment plans, as well as limited use of preventive and public health services.

Measuring Geographic Barriers to Healthcare

Various measures of spatial accessibility and activity space are now commonly used to measure the distance between supply and demand. The healthcare sector also is adopting innovative geographic information systems (GIS) and technology to conceptualize and measure geographic access using spatial measurements. The term *spatial* refers to space on the earth's surface; spatial phenomena are concepts that can be shown on maps. Powerful computer hardware and software mapping tools are now available to project the distance between supply and demand. These tools can be used to identify geographic locations of future hospitals and clinics in order to provide equitable access to residents in that area.

Spatial accessibility combines the concepts of distance and the provision of healthcare, and it is used by health researchers in needs assessment. Spatial accessibility to healthcare can be classified into four categories: provider-to-population ratios, distance to the nearest provider, average distance to a set of providers, and gravitational models of provider influence.

Provider-to-population ratios, easily measured supply ratios, are computed within defined areas, such as counties, metropolitan areas, or health service areas. The numerator may be any indicator of health service capacity, such as the number of

physicians or hospital beds. The denominator is the population size within the area, usually computed from census files. Areas are analyzed for the relation between provider-to-population ratio values and some indicator of healthcare utilization or health status. These ratios are only useful for providing comparisons of large geopolitical areas; analysts rely on these ratios to identify medically underserved areas and minimal standards of supply.

The travel impedance, or travel cost to the nearest provider, another tool used to measure spatial accessibility, is considered to be a reliable measure for rural areas as people are most likely to visit the nearest health facility for care. Urban populations, on the other hand, often have a large number of provider options, so travel cost to the nearest provider is a poor indicator of availability.

Spatial accessibility can be better assessed by the combined measures of travel impedance and supply. Average travel impedance to providers is a combined measure of accessibility and availability, with similar points of measurement to travel impedance.

Also used as a measure of spatial accessibility, gravity models are an indicator of both accessibility and availability. They provide the most valid measures of spatial accessibility because they are applicable to both urban and rural settings.

Some drawbacks of using GIS are potential inaccuracies or incompleteness in data sources, which could lead to unjustifiable causal inferences from ecological associations. It is a reasonable assumption that improved spatial accessibility of healthcare should lead to better population health over a period of time. However, the relationship between changes in spatial accessibility of primary care and the time taken for an impact to occur is still being defined.

Activity space, defined as the local areas within which people move or travel in the course of their daily activities, measures individual spatial behavior within local environmental differences. It aims to provide a comprehensive picture of individual geographic accessibility to healthcare within an individual's sphere of movement. The number of healthcare facilities mapped inside this space indicates the degree of individual accessibility, while the number of facilities outside the given boundary represents the extra effort and expense required to gain access to care.

Telehealth

Telehealth is a resource that relies on technology to provide services, education, and medical consultations. Using telehealth to deliver services in remote areas has gained acceptance as a quick, easy method of offering timely healthcare, particularly for preventive, public health, and chronic care. However, the use of these services depends on Internet availability, access to computers, adequate literacy, and the ability to navigate the system. For struggling, low-income, or minority communities, these resources may be difficult to obtain. Also, the number of physicians willing to deliver online care is limited, as is the number of reimbursable online consultations. The ability to filter accurate online information from misleading Web content, which requires considerable health literacy skills, is an ongoing problem. Telehealth technology holds great promise as a tool for healthcare delivery and access in geographically remote areas, though, as the world is increasingly connected to the Web.

Efforts to Increase Access

In the United States, the federal government has designated Medically Underserved Areas (MUAs) and Medically Underserved Populations (MUPs) as those that face shortages of primary medical care, dental and mental health providers, and hospitals due to various reasons, including geographic barriers. MUAs and MUPs are funded to open community health centers and receive higher rates of Medicare and Medicaid reimbursable services in an attempt to address the growing health disparities due to closure of healthcare facilities. Closures particularly affect public health clinics and hospitals that provide free services to underserved populations in rural and impoverished inner-city neighborhoods, forcing these populations to travel longer distances for healthcare.

Future Implications

Geographic barriers to care exist worldwide and adversely affect health outcomes in even the most developed countries. The vast majority of people

who live in less affluent countries bear the brunt of adverse health outcomes due to these barriers. The scarcity of primary-care provision persists in spite of valiant attempts by governments to address the issue, primarily because of the lack of healthcare providers. Advances in GIS and technology have helped calculate the healthcare needs of populations. However, GIS is an expensive tool and may be unaffordable by many countries, and it cannot ensure an adequate supply of healthcare providers. Though transportation systems continue to improve in remote areas, geographic barriers to care are still responsible for persistent health disparities. Addressing these barriers is an ongoing challenge for health services researchers.

GEOGRAPHIC INFORMATION SYSTEMS (GIS)

Geographic information systems (GIS) are computer-based systems for managing, integrating, and analyzing geographic data. Geographic data are observations or measurements of objects or events referenced explicitly to their locations on the earth. Location is the basis for integrating data in a GIS. GIS tools have been available for more than two decades and are widely used to integrate and analyze many different types of spatial data, including data on health needs, healthcare providers and facilities, health services delivery and utilization, healthcare accessibility, and health outcomes.

GIS implementation involves organizing people to use computer hardware, software, and spatial databases to answer questions or solve problems. The institutional context of this implementation plays a significant role in governing system design, application development, and database design. In the case of health services, the range of institutional settings for GIS implementation is especially wide and includes both public agencies and private entities operating at local, state, national, and international levels. These settings have implications for GIS data acquisition, integration, analysis, and distribution.

Spatial Database Management, Mapping, and Analysis

GIS tools support spatial database management, visualization and mapping, and analysis. Many public and private health agencies manage databases, usually stored and viewed as tables, describing the health status and health service utilization of individuals. GIS software functions can be used to make these data mappable at a high level of geographic disaggregation. The objects—for example, patients with specific health problems and the health facilities where they receive treatment—whose attributes are described in a health database can also be assigned spatial dimensions and attributes. Objects represented as points, such as the place where a clinic or patient resides, have position in space, and these positions are recorded using longitude and latitude coordinates or coordinates

from one of many other coordinate systems used for mapping. Lines are created by connecting the points; these lines can be routes for home-delivered healthcare services and similar factors. Health-planning districts might be represented as areas, objects formed by closed, connected lines. These types of spatial data are referred to as object, or entity, data. Vector databases are collections of discrete objects modeled as points, lines, or areas whose locations and other attributes are described. Vector databases that describe property parcels are sometimes referred to as cadastral databases. These databases are often used for local public health service applications such as drinking water regulation and emergency response.

GIS software functions enable users to import tabular data and to create and edit points, lines, and areas representing objects of interest. Tables of data containing *X*, *Y* coordinates, such as longitude and latitude values, captured using global positioning system (GPS) technology can be added to a GIS and converted to point databases. The United States and other nations use address-matching geocoding tools in GIS software to map locations of cases of disease, healthcare facilities, and other points of interest. The Healthy People 2010 initiative of the U.S. Department of Health and Human Services (HHS) revised its objective for the use of geocoding in health data systems to achieve 100% nationwide use of GIS by 2010 by increasing the proportion of major national health data systems that use geocoding.

Other types of information that can be managed and integrated using GIS include network data, raster data, and imagery. Network databases describe space in terms of paths and nodes in a network. The network, however, constitutes the entire space where objects can be located or events can occur. These databases are used for modeling service areas of facilities, finding the shortest network path between an origin and a destination, or finding the facility closest to a point.

Raster data provide measurements of continuous phenomena, such as air quality or land cover, taken at discrete locations in space. Digital remote-sensing databases classified to model surface vegetation, water, and the built environment are examples of spatial data using a raster data structure. Most GIS enable users to convert data from raster to vector and vice versa. Raster data have

been more widely used in epidemiological applications of GIS, especially those involving infectious disease, than in health services applications of GIS. Imagery includes scanned maps and digital images or photographs of the earth's surface. Imagery is increasingly important in all types of GIS applications, but image files must be accompanied by files containing information to register the locations of the pixels in the image to the earth's surface.

Data integrated in a health services application of GIS are commonly drawn from many sources. Health services providers have direct access to utilization data and to information on the locations of the facilities where they deliver services, but these are likely to be only a small part of the data needed to geocode addresses, analyze health information, and map data and results. Data on the need, or demand, for health services in vulnerable populations may be drawn from national or local census databases or health surveillance databases. Because health services needs are often age and gender specific, detailed demographic information is most useful. Data on the facilities of other service providers may be more difficult for a health agency to acquire. Most GIS applications rely on foundation data layers of street networks, political and administrative boundaries, and imagery that are acquired from government agencies or geographic database vendors. Database management is one of the most expensive and time-consuming tasks in GIS implementation.

Once data have been georeferenced, they can be displayed using the mapping and visualization function of the GIS. Confidentiality remains an important issue in health services applications of GIS that involve mapping. Research has demonstrated that maps used to display individuals as points, even when published at low resolution with few geographic reference features, may reveal patient location information in a way that breaches confidentiality. The process of reverse geocoding converts points on maps to addresses, and these conversions can be accomplished with a fairly high level of accuracy.

Critics of GIS as a surveillance technology acknowledge that the development of information systems such as the centralized universal-number emergency response systems benefits those receiving emergency medical care. Additional critique also demonstrates that this infrastructure, coupled

with technological advances such as wireless communications, has led to the growth of commercial systems capable of intruding on individual privacy through the capture and integration of a wide range of information, including health data. Although there is widespread recognition of the value of assigning geographic identifiers to health data, there is little agreement on their form, assignment, reporting, or use. Legislation such as the federal Health Insurance Portability and Accountability Act (HIPAA) of 1996 restricts the disclosure of health data, and many health surveillance databases, such as the National Health and Nutrition Examination Survey (NHANES) and the Health Survey of England (HSE), distribute data primarily at the national, state, or regional level.

Even when data are aggregated spatially and mapped by area, cartographic representations of health data must be carefully designed to communicate patterns of health and disease or medical-care accessibility effectively. GIS can produce multiple views of data, which is a major advantage in using the tool. Tables, summary statistics, and multiple cartographic representations can be created using these systems, providing a complete description of a health issue. In addition, the spatial analysis functions of GIS can provide insight into how partitioning data by areas affects analyses of health services utilization and other processes.

The spatial data analysis functions of GIS software often receive less attention than the mapping and visualization functions, but they are equally important. Spatial modeling functions include techniques such as buffering and overlay. Buffering can be used to identify all areas within a certain distance of a feature such as an emergency warning alarm. Overlay operations can be used to identify the portion of an area that lies within another area, so that people living within the service area of more than one medical provider can be identified. Mathematical modeling techniques used in GIS applications account for the influence of distances between objects and the geographical positioning of objects on patterns of interaction between objects. Models of healthcare accessibility consider factors such as the distance between residential communities and healthcare facilities. Spatial statistical techniques model dependencies in data and enable analysts to investigate health outcomes in context. All these

spatial, analytic operations result in new geographic databases that can be mapped to provide insights into a range of health services issues.

Health Applications

Few applications of GIS in public health, epidemiology, or health planning appeared before the 1990s. During that decade, interest in GIS and their use in health applications increased rapidly. The term *GI Science* was coined at this time to distinguish geographic information as a research field from the technology of GIS. As in other areas, GIS applications in health services have built on the theories and methods of spatial analysis, relevant long before the innovations that made GIS possible. The health services literature of the 1960s and 1970s, and even earlier, addresses and provides methods for analyzing the location and distribution of healthcare providers, patient origin patterns, facility service areas, medically underserved areas, and health services. Some of these methods, such as the use of spatial interaction models to study health services accessibility, have been implemented, fully or partially, using GIS functions, especially those system functions that are used to measure the distance to health service sites. The availability of GIS has led to a rediscovery of many spatial analytic methods applicable to health services research. And the use of this technology is likely to encourage the development of other new methods.

The shift toward greater privatization of health services that began in the United States in the 1980s, leading to less federal and state involvement in health services planning and regulation, coincided with the development of GIS. One consequence is that data on patient origins, provider networks, and healthcare insurance coverage became a form of proprietary business information, unlikely to be published by large healthcare organizations. Additionally, this information was unlikely to be accessible to public health researchers, either as public domain or through regulatory disclosure. For this reason, it is difficult to document the use of GIS in many areas of health services delivery or planning. The growth of managed care resulted in the creation of new health-related businesses—for example, companies that manage prescription drug benefits for major health insurance companies.

These entities have access to large databases on patterns of health service utilization that could be analyzed spatially. There is evidence that health insurance companies and other corporate entities use GIS as part of their operations, but few examples of these applications appear in the health services literature.

Geographic Dimensions of Health Services Analysis

Geographic analysis of health services has five main dimensions: (1) analyzing the geographic distribution of vulnerable populations and their need for services, (2) modeling the location and distribution of health services providers and their capacities, (3) describing patterns of health services delivery and utilization, (4) analyzing accessibility to health services, and (5) investigating disparities in health outcomes. Populations are not evenly distributed across regions, and local populations differ in age, gender, culture, and other characteristics that affect health status and the need for health services. For example, mapping the number of Black women 50 years of age and above gives an indication of the need for annual routine mammography screens. Figure 1 provides an example of such a map for Connecticut.

When people are placed in their community settings, the challenge for health services delivery becomes clear. In addition to health services planning, the design of randomized control trials (RCTs) and public health interventions needs to take into account the underlying spatial distribution of the target population. GIS tools are well suited for mapping and exploring geographical variation in the need for health services.

The supply of health services can also be investigated using GIS by mapping the locations and capacities of healthcare providers. For example, many hospitals have radiology units capable of providing mammography screens. GIS can be used to display the locations of these facilities in relation to the geographic distribution of need. It would also be desirable to map the locations of other providers of mammography services, including freestanding radiology centers, women's health centers, and other facilities. The number of appointment slots, days and times when appointments can

Source: Office of Health Care Access, Connecticut Department of Environmental Protection.

be made, and other attributes of the services provided that might affect who can access care should also be recorded. Figure 2 provides an example of such a map, showing the geographic distribution of community hospitals in Connecticut.

Healthcare providers can also geocode and map the residential locations of the patients they serve. This information can be used to identify the communities that send most of their residents to particular providers, as well as the providers that treat

and serve the most number of residents of particular communities. Patient origin areas may differ widely depending on the particular service offered, even for the same healthcare facility.

In addition to measuring the attractiveness of the services and the level of competing demand for the services from patients in other communities, models of geographical accessibility to health services usually involve some measure of distance between potential patients and service sites. The network analysis functions of GIS can be used to estimate the area within a specified travel distance or travel time from a facility. Measuring travel time along a network often yields a much more accurate measure of distance than creating a simple distance buffer. Figure 3 reflects the measurement of travel time.

Modeling geographical coverage of existing healthcare facilities provides insight into areas that are not covered or are underserved by the existing supply of healthcare providers. This information can be used to plan for the redistribution of capacity across service sites, the location of new services, or the location of alternative services. It can also be used to evaluate the characteristics of populations that have different levels of access to healthcare services.

GIS tools make it possible to understand patterns of health and disease in the context of healthcare services accessibility. The geographical organization of health services, the geographical differences in accessibility to healthcare, and the geographical reach of surveillance and screening systems may act to filter the underlying distribution of health problems and influence the apparent geographical distribution of health problems mapped by health analysts. Increasingly, information on health conditions and health services is delivered through the Internet.

GIS and the Internet

Changes in computing technology were recognized as major drivers in the development and rapid diffusion of GIS to new application areas.

Figure 3 Network Analysis Identifying the Service Area Neighborhood Within 30 Minutes of Travel Time Based on 40-mph Travel Speed and a 20-Mile Buffer

Source: Office of Health Care Access and the Connecticut Department of Environmental Protection.

In the early years of GIS adoption, the use of workstations and desktop computers with larger memories and improved graphics capabilities, the availability of inexpensive and reliable printers, and the emergence of networks were among the most important developments affecting GIS. During the first decade of this century, both the Internet and wireless networks and devices are having a significant effect on geospatial information technology. The development of GIS on the Internet has the potential for broadening access to geographic data because data users do not need to have GIS software or databases on their own computers or wireless devices. GIS software companies offer Internet map server products supporting online systems. The launch of Google Earth in 2005, however, provided organizations with a different framework for delivering cartographic displays of geographic data, one that does not rely on GIS software packages.

Distributed GIS supports four main activities: (1) data sharing, (2) information sharing, (3) data processing, and (4) location-based services. Data in original format and metadata describing the geographical database may be published for downloading on an organization's Web site or through a data clearinghouse portal. The U.S. Census Bureau's

Web site distributes cartographic boundary files of census units that can be used in GIS. Similarly, government agencies such as the Health Resources and Services Administration (HRSA) participate in the government's Geospatial One Stop portal. Alternatively, organizations such as the National Cancer Institute (NCI) can use GIS to share information by publishing static maps or maintaining interactive Web-based GIS that allow users to map data. Another type of distributed system involves serving GIS analysis tools. This type of application is most commonly used within an agency to allow staff members to manage spatial databases. Location-based services enable users to access information about a location and nearby areas. A person seeking healthcare can use location-based services to find the nearest provider and determine the best route to a particular destination.

Future Implications

Although GIS technology developed outside the sphere of public health, the systematic application of computer science and information technology in public health and healthcare is not new. The same forces affecting GIS today are also fostering a population-focused, experience-based, and research-oriented approach to public health information systems in the emerging field of health informatics. GIS tools play an important role in these systems by supporting the geocoding, mapping, and spatial analysis of health and health services data.

GEOGRAPHIC VARIATIONS IN HEALTHCARE

Geographic variations in healthcare are the differences in healthcare services delivery to patients based on the location where they receive them. John E. Wennberg, a New England physician, first described the phenomenon of geographic variation in healthcare in the late 1960s after finding small area variations based on Medicare spending. Although some variation in the delivery of healthcare is justified and acceptable, unwarranted variations in the delivery of healthcare services leads to differential medical spending and treatment across regions of the nation with

no clear benefits in patient outcomes or healthcare quality. Geographic differences have been reported across the healthcare system, from the intensity of hospital use and end-of-life care to the patterns of elective surgeries. The geographic differences reported in healthcare delivery have raised many important questions for health services researchers on what and how much care is appropriate and what is the relative value of the differential spending and treatment across regions.

Overview

The use of healthcare services and the associated spending patterns vary greatly across the nation. Geographic variations in healthcare are generally measured over large areas, such as at the state level, while measurement of smaller geographic areas can focus on counties, metropolitan statistical areas, and hospital referral areas. Medicare patient data have been extensively used to study geographic variations in the United States, because of the large number of patients and the readily accessible data.

In 1967, Wennberg analyzed Medicare data to examine how this program was serving communities. Through his research, Wennberg found unwarranted differences in patient care that could not be explained by the severity of patients' illnesses, medical need, or evidence-based medicine. Over the years, Wennberg and others have found many geographic variations in healthcare. Recently, Wennberg's Dartmouth Atlas of Healthcare Project reported finding differences in hemoglobin A1C testing for Medicare patients with diabetes, ranging from 91% in Vermont to 71% in Alaska. It also reported differences in Medicare beneficiaries who have a primary-care physician as the predominant provider, ranging from 86% in Nebraska to 65% in New Jersey.

The unwarranted differences in healthcare across regions can be attributed to effective care, meaning clinically proven treatments, and patient safety; preference-sensitive care, or patient's choices in their treatment; and supply-sensitive care, or care that is associated with the healthcare system's resource capacity and supply. The majority of the geographic differences in healthcare, however, can largely be attributed to supplier-sensitive care. The

underlying theory is that because there is a lack of firm evidence to treat many medical conditions, the general assumption is that more care leads to better patient outcomes. Therefore, in areas with more healthcare resources, the tendency of healthcare providers is toward greater intensity of healthcare services.

The notion of supply-sensitive care overlaps with the concept of supplier-induced demand. Supplier-induced demand was first identified in the early 1960s by the public health professor Milton I. Roemer (1916–2001). Roemer found that when health insurance was widespread in a community, increased utilization of services resulted in an increase in the supply of hospital beds. Roemer coined the saying “A bed built is a bed filled.” This finding became known as the Roemer effect, or Roemer’s law.

Geographic differences in care can also arise from the uneven distribution of morbidity. For example, the higher rates of cardiovascular procedures in the southeastern United States may be due to the higher prevalence of tobacco use in this area. Also, certain regions may be more apt to adopt low-cost and effective healthcare practices, while other regions may maintain high-cost practices, leading to further differences across areas.

Geographic differences in healthcare also result in differences in spending across regions. For example, in 2004, the per capita spending in Utah was \$2,400 compared with \$6,700 in Massachusetts. These differences persist even at smaller geographic levels and even among providers. Research conducted by the Dartmouth Atlas of Health Care found that among Medicare beneficiaries with similar health status, those living in high-spending areas received 60% more healthcare services than those who live in low-spending areas. Some researchers predict that Medicare spending would decrease by 29% if spending in high- and medium-spending areas was equivalent to that in low-spending areas.

The geographic differences in patient care and spending that have been highlighted indicate that the healthcare system is not as efficient as it could be. There is a growing body of literature suggesting that the overuse or misuse of and increased spending on healthcare services do not produce better care or improved patient outcomes.

Overall, differences in geographic spending on healthcare have been increasing over the years; however, the variation in Medicare spending has decreased recently because of changes in its reimbursement policies. The Veterans Health Administration (VHA) has also experienced geographic differences in healthcare spending despite a national resource allocation formula.

Small-Area Variation Analysis

Small-area variation analysis, developed by Wennberg and Gittelsohn, is a tool that is used by health services researchers to understand the geographic differences in the rates of healthcare utilization and also how this varies over defined areas. Because of the substantial variation in healthcare utilization and spending across regions of the country, small-area variation analysis uses established epidemiological methods to better grasp the causes of these variations across similar communities, which can help guide healthcare decision making and resource planning. Because healthcare is provided at the local level by physicians and other providers, the differences in medical treatment at this level appear to be due to the different prevailing practices. Small-area variation analysis has become an important technique that researchers use to disentangle the disparities in healthcare utilization and treatment as well as provide further insight into whether or not more care leads to better health outcomes. Some areas of concern regarding the proper use of small-area variation analysis are accurate defining of geographic boundaries, the population at risk, case-mix adjustments, and the stability of rates across time. The further development of small-area variation analysis will entail the development of more refined measures, case-mix adjustment, and appropriate small areas to be examined.

Future Implications

It is likely that geographic variations in healthcare will continue to persist in the future given the uneven distribution of disease and of healthcare providers across the nation. Although there will always be some random geographic and regional differences in the care that patients receive, it is the clinical and statistical significance

of the disparities in care that are of concern. The wide variation in agreement regarding the risks and benefits of certain treatment options for specific diseases due to patient and provider preferences will further yield differences in care. Health services research will play an integral role in providing a deeper understanding of the underlying reasons for the unwarranted differences in care, as well as in helping ascertain the appropriate amount of care needed to yield maximum clinical effectiveness.

GINSBURG, PAUL B.

Paul B. Ginsburg is president of the Center for Studying Health System Change (HSC). Founded in 1995, the HSC conducts research to inform policymakers and other audiences about changes in the organization, financing, and delivery of care and the effects on people. Data are gathered through the Community Tracking Study, which includes surveys of households and physicians and site visits to interview health system leaders in 12 communities that are representative of the nation. The HSC is widely known for the objectivity and technical quality of its research and its success in communicating results to policymakers and the media, as well as to the research community. A sister organization to Mathematica Policy Research, the HSC is funded principally by the Robert Wood Johnson Foundation but also receives funding from other foundations and from government agencies.

Before founding the HSC, Ginsburg served as the founding executive director of the Physician Payment Review Commission (PPRC), now the Medicare Payment Advisory Commission (MedPAC). Widely regarded as highly influential, the commission developed the Medicare physician payment reform proposal enacted by the U.S. Congress in 1989. Ginsburg was also a senior economist at the RAND Corporation and served as deputy assistant director at the U.S. Congressional Budget Office (CBO). Before that, he served on the faculties of Duke and Michigan State Universities. He earned his doctorate in economics from Harvard University.

Ginsburg is a noted speaker and consultant on the changes taking place in the nation's healthcare system and its future outlook. He frequently testifies before the U.S. Congress. In addition to presentations on the overall direction of change in the healthcare system, recent topics have included cost trends and drivers, consumer-driven healthcare, provider payment, and the future of employer-based health insurance and competition in healthcare. In 2007, for the fifth time, Ginsburg was named by *Modern Healthcare* as one of the 100 most powerful people in healthcare. He recently received the first annual Health Services Research Impact Award from AcademyHealth, the professional association for health policy researchers and analysts. He is a founding member of the National Academy of

Social Insurance and a public trustee of the American Academy of Ophthalmology; he served two elected terms on the Board of AcademyHealth.

GINZBERG, ELI

Eli Ginzberg (1909–2002) was a writer, scholar, teacher, government consultant, policy analyst,

and one of the first health economists in the United States.

Ginzberg was born in and lived most of his life in New York City. He had a very long and well-respected tenure at Columbia University, where he earned his bachelor's (1931), master's (1933), and doctoral (1935) degrees. In 1935, he began his teaching career at Columbia University's faculty in the Graduate School of Business. He would go on to teach at Columbia for more than 60 years. Ginzberg's early years at the university exposed him to experiences that helped prepare him for his interests in public policy and healthcare. During World War II, he helped plan healthcare services for wounded soldiers and discharges for military physicians. In 1943, Ginzberg helped prepare for the 1944 European invasion by U.S. forces by serving as chief logistical advisor to the Surgeon General of the Army. In 1946, he returned to Columbia University and eventually retired from the faculty in 1979, although he continued teaching classes at the university.

Ginzberg served as director of the Eisenhower Center for the Conservation of Human Resources at Columbia University and director for the Revson Fellows Program on the Future of the City of New York. From 1962 through 1981, he served as chair for the National Manpower Advisory Committee. In 1982, Columbia University awarded him an honorary doctorate of letters.

Ginzberg's interests centered on people and the conditions in which they lived and worked. For example, in the 1960s, it was thought that there was a national physician shortage, and efforts and funds were directed toward building new medical schools, upgrading older programs, increasing student enrollments, and providing financial aid opportunities. Ginzberg countered the claim by declaring that the physician shortage was only in low-income and high-poverty areas, and even if the number of physicians in the graduating classes was increased, these socioeconomic areas would continue to be underserved. His solution was to train more paraprofessionals, nurse practitioners, and physician assistants as well as to restructure the manner in which the medical services were delivered to this portion of the population.

Several times throughout his career, he addressed the education and utilization of nurses. Because he thought that hospital training exploited nursing

students, he advocated for nursing education to become the responsibility of higher education. To improve the nursing profession's status, Ginzberg recommended that graduate programs include management courses in the curriculum. Addressing the various levels of education found in the nursing profession and the need to improve working conditions and job satisfaction, Ginzberg recommended tying levels of responsibilities to the nurses' education, with the more educated nurses having higher levels of responsibilities.

Acknowledging the U.S. culture of individualism and its socioeconomic structure, he stressed the need for national health insurance to provide essential medical care as well as policies addressing the health sector's shortcomings in the areas of access, costs, and quality of care.

Ginzberg, a prolific writer, was interested in the human experience and human resources. He was one of the first health economists, and his work continues to influence health policymakers.

GROSSMAN, MICHAEL

Michael Grossman is a well-known health economist, who has spent much of his long, distinguished career in two organizations: the National Bureau of Economic Research (NBER) and the City University of New York (CUNY). Grossman was one of the first economists to use the concept of human capital in healthcare research. He has greatly influenced the field of health economics through his research and the many students he has mentored and trained.

Born in 1942 in Brooklyn, New York, Grossman received his bachelor's degree from Trinity College in 1962. He attended graduate school at Columbia University, where he earned a doctoral degree in economics in 1970.

In 1966, Grossman began his long affiliation with NBER. At NBER, Victor Fuchs, a well-known health economist, hired him as a research assistant. Grossman held a number of positions at the organization, and in 1972, he became a research associate and Program Director of Health Economics Research, a position he presently holds.

In 1972, Grossman began his long affiliation with the CUNY. He started at the university as a visiting assistant professor and successfully rose through the academic ranks. In 1978, Grossman was appointed professor, and in 1988, he became Distinguished Professor of Economics, a position he presently holds. In addition to teaching, he also served as the executive officer (chairperson) of that university's doctoral program in economics from 1983 to 1995. And he has supervised nearly 100 doctoral dissertations.

Grossman has conducted research and written extensively on a wide variety of health economic topics including the following: economic models of the determinants of infant, child, and adult health; the cost of capital for tax-exempt hospital bonds; the introduction of national health insurance in Taiwan; the impact of taxes on cigarette smoking and alcohol use; and the economic factors associated with adult obesity. He has authored or coauthored four books, more than 40 academic journal articles, and numerous book chapters.

His first book, *The Demand for Health: A Theoretical and Empirical Investigation*, is considered a seminal work. The supply and demand model of healthcare he presented in the book has greatly influenced the field of

health economics and is widely cited in the literature. His most recent book, edited with Chee-Ruey Hsieh, is *The Economic Analysis of Substance Use and Abuse: The Experience of Developed Countries and Lessons for Developing Countries*.

Grossman is a coeditor of the *Review of Economics of the Household*, a series coeditor of *Advances in Health Economics and Health Services Research*, and an associate editor of the *Journal of Health Economics*. He also reviews manuscripts for many other healthcare journals.

Grossman has received numerous academic and professional honors for his work. Grossman has been a consultant to the National Institute on Alcohol Abuse and Alcoholism, the National Academy of Sciences, the National Science Foundation, and the RAND Corporation. He is included in *Who's Who in America* and *Who's Who in Economics*, and he is an elected member of the National Academy of Sciences, Institute of Medicine (IOM). In 2008, Grossman won the Victor Fuchs Lifetime Contribution Award from the American Society of Health Economists (ASHE).

H

HEALTH

The World Health Organization (WHO) defines health as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.” This definition is perhaps the most well known and also the most criticized, mainly because it is difficult to operationalize for achieving (and measuring) health. Despite its lack of specificity, however, the definition introduces the social dimension of health. For the WHO definition to be useful in health research and practice, physical, mental, and social well-being must be interpreted in specific social, political, and cultural contexts.

Different conceptualizations of health indicate different determinants of health. These determinants of health, in turn, prompt specific public policies and individual behaviors for achieving health. For example, suppose health is considered as the normal physiological functioning of the bodily organs. If contaminated water is believed to disturb the normal functioning of the organs, then social policies would regulate water quality, while individuals might choose not to drink tap water. In another example, if a society considers health as active social participation, then social policies would be in place to remove barriers to social participation, and individuals would seek out opportunities for social activities.

The various ways of conceptualizing health are reflected in social policies and individual behaviors. These conceptualizations also hold different

parties accountable. If a society conceives that good or ill health is a consequence of an individual’s discretionary behaviors (e.g., washing hands before handling food to avoid food poisoning), then individuals would be responsible for their own health. Conversely, if a society regards health as a reflection of social and political systems (e.g., increased infant mortality after community health center funding is cut), then policymakers would be held accountable. Societies and individuals have different and complex matrices of causality and accountability for various health outcomes. Some health conditions are attributed to individuals, while others to social policy or even to uncontrollable forces (e.g., fate, nature). Health services researchers and policymakers must recognize the strengths and limitations of the various conceptualizations of health that they use in studying health-related issues, shaping public policy, and providing services.

In the following sections, the philosophical underpinnings for the definition of health will be discussed, and the ways in which different views of health are reflected in various measures of health will be examined. Next, various determinants of health from a social-ecological perspective will be reviewed. Finally, the question of who is responsible for health is addressed.

Naturalist and Normativist Definition of Health

The definition of health has long been a subject of debate among philosophers. Two major, contrasting

perspectives have been proposed. Derived in the 1970s from the traditional biomedical standpoint, the *naturalist* view defines health as the freedom from disease, which, in turn, is defined as the inability of one's body to perform all the typical physiological functions with at least typical efficiency. This view places health and disease (or death) at the two poles of a continuum, and individuals find themselves somewhere between the two poles. According to this definition, for example, a person with diabetes cannot be "healthy," even if his or her condition is well managed with insulin, because his or her body is not able to perform all the typical physiological functions.

A contrasting definition of health was proposed in the 1990s. The *normativist* view defines health as a person's ability to achieve his or her vital goals given standard circumstances. Advocates of the normativist perspective suggest the possibility of people being healthy (i.e., able to achieve important life goals) despite functional limitations. Consider, for example, the athletes who compete in the Paralympics. While the normativist definition considers them healthy, perhaps healthier than many others without functional limitations, these athletes cannot be healthy according to the naturalist definition because of their physical or mental disabilities. In other words, the normativist definition allows every individual, regardless of his or her physical and mental abilities, the possibility to be healthy and become healthier.

The debate continues between the proponents of these two perspectives, which are not mutually exclusive; that is, individuals would have a better chance for achieving their vital goals if they were free from impairments in physical and mental capacities. However, having physical or mental malfunctions does not necessarily prevent people from achieving their life goals, especially with the ever-advancing medical technologies. As medical management of many diseases (i.e., physiological malfunctions) progresses, an increasing number of individuals survive and live well with their diseases. For example, about 1 in 10 adults in the United States currently has diabetes, and the 5-year survival rate for breast cancer increased from 60% to 86% between 1950 and 2000. More generally, life expectancy has been increasing in developed countries, indicating that more and more people are attaining advanced age. These

changes in society force us to consider how health and well-being may coexist with disease and functional limitations. While the naturalist definition of health is important in advancing medical research on managing disease, the normative definition of health—with its focus on wellness rather than illness—better informs health research and practice.

Measures of Health

The different perspectives on health have implications for health measurement. The naturalist definition sees a person as a physiological being; therefore, measures of health based on this definition are in fact measures of physiological functioning. The long history of medicine has provided a wide array of measures for assessing individuals' physiological functioning, from blood cell counting to magnetic resonance imaging (MRI). These measures are objective in the sense that others can judge a person's health status, often medical professionals. This is a valuable approach as some serious medical conditions can develop without outward signs (e.g., hypertension or high blood pressure). Especially for preventive purposes, not waiting for overt symptoms to appear is an important practice.

These objective measures are useful in detecting a medical condition that has a clear physiological definition (e.g., blood pressure as a measure of cardiovascular health). However, if health is more than just the absence of disease, these functional indicators may not fully capture one's health status. If health is the ability to achieve one's vital goals, a person's assessment of his or her own health can be a valid measure. A well-known example of such a measure is a simple question asking people to rate their general health status as *excellent*, *good*, *fair*, or *poor*. This measure has been found to be predictive of mortality: Studies have found that people who rate their general health status as *poor* had a nearly twofold higher mortality risk, a relationship that did not change when it was adjusted for functional status, depression, and chronic diseases. These findings imply that if functional status, depression level, and chronic-disease status are the same, those who rate their health as *excellent* were more likely to survive for a certain time period than those who rate their

health as *poor*. What is captured in this simple self-rated health question may be the normativist view of health. Despite this utility, however, the measure has a major limitation: It does not inform health services researchers or policymakers regarding which strategies would improve the person's self-rated health status. Self-rated health is, therefore, most useful as an *outcome indicator* for social policies and programs.

The objective (i.e., physiological) and subjective (i.e., evaluative) measures of health have advantages and limitations that complement each other. Therefore, using them together will provide a better description of health. Because refined observational-biomedical measures of health, which the naturalist definition of health calls for, contribute to successful interventions, such measures will help detect medical conditions in their early stages and monitor the progress of treatment. Better management of medical conditions is a way of enabling individuals to be healthy in the normativist view also (i.e., being able to achieve vital goals). It is possible, however, that sometimes the management of disease fails to enhance health in a normative sense (e.g., invasive treatment for cancer that results in isolation from the family and home environment). Evaluative measures of health capture this potential disjunction between well-being and a lack of disease.

Determinants of Health

Various factors affect health at different levels, from micro (e.g., bacteria) to macro (e.g., socioeconomic position). They do not exist in isolation: These factors are embedded in the next larger factors. For example, diabetes (a physiologically defined state) may be caused by a poor diet and a lack of exercise (behavioral risk factors), which may, in turn, reflect a lack of access to nutritious fresh food and a safe place for exercising (social factors). The social-ecological perspective promoted in public health provides a framework to integrate these different levels of health determinants.

In this section, four determinants of health with various levels of proximity to the person will be discussed. Topics discussed under each determinant are not exhaustive but, rather, are suggestive of important issues in current research and practice.

Biological Determinants

The most proximal determinants of health are often biological. Centuries of medical research have identified numerous biological, causal factors of disease and developed treatments for many of them. Although various infectious diseases have been effectively controlled, new diseases continue to emerge, some with drug resistance. Today, infectious diseases such as influenza and AIDS are listed among the leading causes of death.

Genetics is also a major biological determinant of health. Recent advances in genetic technology have identified genes responsible for diseases such as breast cancer and Huntington's disease. It is now possible to know whether a person has a specific gene mutation that will manifest itself as a disease. Genetic testing is potentially beneficial because the individual can take the necessary precautions to reduce the damage caused by the disease. However, the emotional, social, and financial consequences of knowing one's genetic predisposition must be considered. For example, growing attention has been paid to "genetic discrimination" by health insurance companies and employers against individuals with known genetic mutations that may require expensive medical intervention once the disease manifests. Because genetic predisposition is not modifiable, the social and psychological consequences of knowing it could be devastating.

Behavioral Determinants

It has been estimated that tobacco use, poor diet and physical inactivity, and alcohol consumption account for nearly 40% of all deaths in the United States. The deaths caused by these behavioral risk factors are, in theory, preventable by reducing these unhealthy behaviors. Other behaviors that have an impact on health include illicit drug use, immunization, and various safety practices (e.g., using a child seat in the car). The Center for Disease Control and Prevention (CDC) conducts the Behavioral Risk Factors Surveillance System (BRFSS) to monitor the trends in health behaviors in the United States.

Social Determinants

The significant impact of social interaction on health has been well documented. Social support is

associated with lower mortality from all causes, and the health-enhancing effect of social support is observed in relation to many health conditions (e.g., depression, cardiovascular disease, cancer, and infectious diseases).

One of the most robust social determinants of health is the individual's socioeconomic position in society. The Whitehall studies—longitudinal studies of more than 10,000 British civil servants—documented a *social gradient of health*: the higher a person's socioeconomic position, the better his or her health status. This gradient was found even between those at the top and those second to the top in the occupational hierarchy. Similar or sometimes steeper gradients by education, income, and occupational prestige are found in the United States. Many studies have found that the social gradient of health is partly explained by material deprivation, inadequate access to healthcare, and unhealthy lifestyle. However, the social gradient of health does not disappear after these factors are taken into consideration. The causal link between socioeconomic position and health is not yet well understood, but the stress associated with socioeconomic disadvantage is suspected as an explanatory factor.

The WHO has established the Commission on Social Determinants of Health (CSDH) to address societal causes for health inequalities, including poverty, social exclusion, work conditions, unemployment, and poor housing. The committee asserts that the social gradient of health reflects the gradients of two fundamental human needs: autonomy and social participation. That is, the lower a person's socioeconomic position, the less autonomy and social participation the person has, and this relative deprivation is detrimental to health.

Ecosystems

The quality of the air, water, and soil can affect the health of current and future generations. Many elements in the environment (e.g., lead, radon, nitrogen dioxide, and persistent organic pollutants) have been identified as potentially causing various health conditions ranging from skin or respiratory irritation to cancer and infertility. These identified hazards are only a fraction of the numerous chemicals released into the environment through

industrial wastes and commercial products. Most of these chemicals are not tested for the potential health effects of long-term exposure. Therefore, constant monitoring of environmental hazards is needed for identifying and controlling adverse health effects.

Although the impact of environmental hazards is a serious public health problem, in general, special attention should be given to the unequal exposure to environmental hazards experienced by people of different races and classes (i.e., *environmental injustice*). For example, hazardous waste sites are more likely to be found in racial-minority and low-income communities. This differential exposure may be responsible for health disparities. Since 1994, the U.S. Environmental Protection Agency (EPA) has launched the environmental justice strategy to reduce the unequal distribution of environmental burden.

Who Is Responsible for Health?

Each level of the determinants of health holds different entities potentially responsible. Identifying the determinants of health, therefore, has implications for health accountability. For biological determinants, an individual may feel powerless and turn to medical professionals to take charge of restoring his or her health. For behavioral determinants, individuals themselves may be held accountable for their health through maintaining healthy lifestyles. For social determinants, social institutions (e.g., schools, work organizations, health service providers, medical-insurance companies, and governments) need to be involved in reducing health-compromising factors. For preserving healthy ecosystems for all communities, all who are affected by the ecosystem should have an equal voice in environmental regulations and policies. Who is responsible for reducing health-compromising factors and increasing health-promoting factors? Who should bear the cost? Consequently, how should resources be allocated to enhance health? These questions are matters of serious debate. The answers may be different for each health condition and afflicted group.

Identifying health determinants and health accountability ultimately influences public health policy and intervention. The resources available

for public health intervention are limited. To achieve the maximum impact with the limited resources, policymakers must identify the most effective targets for change (i.e., high-impact leverage points), which may vary by different health outcomes. The social-ecological model suggests that because diverse human and environmental determinants of health are interrelated, changes in one factor potentially affect other factors and create synergetic effects. For example, a smoking ban in public space, originally intended to reduce environmental tobacco smoke, may encourage some people to quit smoking. Finding the high-impact leverage points to enhance the health of society will require a broad definition of health and a thorough understanding of its underlying causal factors.

Health is such a fundamental concept of human existence that many people intuitively believe that they know what health is. However, health services researchers and policymakers must recognize the different definitions of health as well as the consequences of adopting a certain definition over others. The conceptualization of health dictates whether or not certain factors are considered as determinants of health, which, in turn, determines policy and intervention. Social forces such as the political climate, the global and national economies, culture, and history influence this process of defining health, identifying the determinants of health, and establishing social policy. Recognizing the complexity of health as a concept is imperative for research and practice.

HEALTHCARE COST AND UTILIZATION PROJECT (HCUP)

The Healthcare Cost and Utilization Project (HCUP) is a family of healthcare databases and software tools developed to facilitate research on a broad range of health policy issues. HCUP represents the ongoing, collaborative efforts of federal, state, and private agencies and institutions to build a national information resource of patient-level healthcare data and to make these products available for use in health services research and health policy analyses. These efforts have culminated in the largest collection of longitudinal, discharge-level data on hospital care in the United States. Based on information from HCUP, quality indicators (QIs) that measure the clinical performance of hospitals have been developed to aide in quality assessment and continuous quality improvement efforts.

Development

In response to increasing concerns about health-care quality and the growing interest in tools for quality assessment, the Agency for Healthcare Research and Quality (AHRQ) initiated the HCUP in 1989. HCUP was charged with creating a national, comprehensive, and uniform data set of hospital inpatient records and developing a set of healthcare QIs that could be used with hospital administrative data for health policy analysis. Many organizations lack the resources necessary for extensive data collection and a quality measurement system for continual and comprehensive monitoring of quality. Furthermore, the definitions and formats of administrative data vary widely from state to state, making interstate comparisons difficult. HCUP was developed to address the infrastructural barriers that were hindering quality improvement by minimizing the burden on the healthcare industry and states in collecting, standardizing, and distributing national hospital data.

Since its inception, HCUP has grown in size and scope. The first release of HCUP data consisted of a statistical sampling of data on inpatient stays in community hospitals from 11 participating states. Currently, agencies and hospitals from a total of 38 states provide census hospital administrative data, representing 90% of all hospital discharges in the United States. HCUP data originally featured aspects of hospital inpatient care but now also includes outpatient care provided at U.S. community hospitals. The first products of the project were the Nationwide Inpatient Sample (NIS) data set, a statistical sampling of hospital discharge data, and a set of clinical performance measures constructed from the NIS and known as the HCUP Quality Indicators (HCUP QIs). Today, HCUP is a suite of databases, software, tools, and reporting and support systems that enable research on health outcomes and policy at the local, state, and national levels.

Databases

The HCUP maintains several databases, each of which contains encounter-level records for both insured and uninsured patients and are compiled in a uniform format. HCUP data report information

at the state and national levels on inpatient and ambulatory/outpatient care provided to adults and children in the United States from as early as 1988. The State Inpatient Databases (SID), Nationwide Inpatient Sample (NIS), State Ambulatory Surgery Database (SASD), Kids' Inpatient Database (KID), and State Emergency Department Databases (SEDD) are all included in HCUP.

HCUP Quality Indicators

Building on data from the project, HCUP QIs were constructed as a low-cost, ongoing, quality measurement resource to aide continuous quality improvement efforts. Rather than addressing dimensions of quality such as patient satisfaction or efficiency, the HCUP QIs were developed, in 1994, to measure clinical performance. HCUP QIs comprise a set of 33 measures of clinical performance to be used as a screening tool to identify quality concerns for further research and analysis. Development of these measures was performed in several phases: a review and evaluation of existing measures, the selection and specification of measures, distribution and empirical testing, and further refinement. The indicators spanned the following three dimensions of hospital care quality: (1) outcomes following surgery, including mortality and complication rates, by procedure; (2) utilization, such as the rate of cesarean section or coronary artery bypass graft; and (3) access to primary care, looking at factors such as low birth weight and vaccination rates among older patients.

Despite the methods and expertise employed in their development, careful reviews of the empirical literature and the methods employed in HCUP QI measurement revealed several limitations. The majority of HCUP QIs measured surgical-care performance and, thereby, inadequately represented the care of chronic medical conditions. Some measures were not useful in screening for real quality concerns. Moreover, some indicators were inappropriately based on hospital-level, rather than area-level populations. Last, the measures lacked adjustments for risk and severity. To address these limitations, the AHRQ sponsored new efforts to further refine the QIs. Between 1998 and 2002, select HCUP QIs were removed, and revised methods were invoked for the creation of new and

improved measures. Under its new name, the AHRQ Quality Indicators (AHRQ QIs) are a refinement of the HCUP QIs.

AHRQ Quality Indicators

Similar to HCUP QIs, the AHRQ QIs are measures of healthcare quality based on hospital, inpatient, administrative data available in the NIS. New methods, addressing the above-mentioned weaknesses of the HCUP QIs, were used to develop the AHRQ QIs. The new measures have also been reorganized into four foci of quality: (1) preventive care (Prevention Quality Indicators [PQIs]), (2) inpatient care (Inpatient Quality Indicators [IQIs]), (3) pediatric care (Pediatric Quality Indicators [PQIs]), and (4) patient safety (Patient Safety Indicators [PSIs]).

Although the AHRQ QIs represent conceptual and methodological improvements over the previous HCUP QIs, limitations remain. Development of the AHRQ QIs is based on administrative data, and the documentation of patients' medical conditions and care received differ across hospitals. Administrative data are also limited in its ability to monitor adverse events, elucidate temporal aspects of care, and distinguish preexisting comorbidities from complications resulting from care. Finally, the indicators do not account for differences in the environmental conditions that exist outside the healthcare system, such as sociodemographics or patient preferences. Nonetheless, the unique features of the AHRQ QIs are a useful resource for identifying quality concerns in healthcare at the hospital, community, state, and national levels.

Operated and maintained by AHRQ's Center for Organization and Delivery Studies and the AHRQ QI development team at the University of California at San Francisco's Evidence-Based Practice Center, downloadable AHRQ QIs are accompanied by available software, reporting tools, and technical assistance for research in quality tracking, improvement, comparative analyses, and public reporting.

HEALTHCARE EFFECTIVENESS DATA AND INFORMATION SET (HEDIS)

The Healthcare Effectiveness Data and Information Set, more commonly called HEDIS, consists of compiled reports from managed-care organizations concerning their health plan performance on a broad range of clinical and nonclinical measures. The National Committee for Quality Assurance (NCQA) developed and released the initial version of the measures in 1993. Although most participation in HEDIS is voluntary, more than 90% of U.S. health plans submit HEDIS data, in part to increase their competitiveness but

also, often, as part of accreditation or certification activities. Health services researchers also use HEDIS measures to conduct studies of the access, cost, quality, and outcome of care.

HEDIS measures are divided into eight categories: (1) effectiveness of care, (2) access to and availability of care, (3) satisfaction with the experience of care, (4) use of services, (5) cost of care, (6) health plan descriptive information, (7) health plan stability, and (8) informed-care choices. Of these, effectiveness of care is the largest category and includes measures dealing with highly specific standards of care such as appropriate medication for asthma patients and the use of medical-imaging studies for lower-back pain. Measures in other categories evaluate other aspects of patients' experiences (e.g., the number of customer service calls abandoned) and the business aspects of the health plans (e.g., financial stability). Over time, HEDIS has evolved to meet changing standards of healthcare and in response to regulatory changes, and NCQA now publishes changes to HEDIS measures on an annual basis.

Development and Evaluation of HEDIS Measures

NCQA uses an ongoing process to develop new HEDIS measures, evaluate existing ones, and retire those that have outlived their usefulness. Proposals for new measures first are examined through expert Measurement Advisory Panels (MAPs) tasked with evaluating them using three criteria: (1) relevance (e.g., health importance, cost-effectiveness, and potential for improvement); (2) feasibility (e.g., cost and ability to be audited); and (3) scientific soundness (e.g., basis in evidence and reproducibility). Once approved by an MAP, the proposed measures move through a process of technical development and field testing before being released for public comment. Measures subsequently reviewed and accepted by NCQA's Committee on Performance Measurement (CPM) are added as first-year measures in the new HEDIS set. NCQA does not provide public reporting on new measures during their first-year status, allowing time for reporting organizations to evaluate the initial results and address any technical issues. In subsequent years, MAPs evaluate the measures

under a continuous improvement process, which may result in their alteration or removal from the HEDIS set.

New Measurement Controversies

Although NCQA earns broad respect for its measurements, its processes sometimes draw criticism. For example, the 2006 addition to HEDIS (after 5 years of debate) of specific blood pressure and glycemic-control outcome benchmarks for patients with diabetes mellitus met with resistance from some areas of the medical establishment. Most clinical HEDIS measures focus on process rather than clinical benchmarks: Some felt that adding such specific measurements failed to adequately account for comorbidities and other individual patient variations.

Uses of NCQA's Published HEDIS Reports

NCQA makes HEDIS information available in a variety of forms to meet the needs and goals of its constituencies, chiefly accreditation and certification activities, delivering information to organizational purchasers of health plans, and delivering information to healthcare consumers.

Accreditation and Certification

NCQA uses HEDIS reports in many of its national accreditation and certification programs, notably for managed-care organizations, managed-behavioral-healthcare organizations, and preferred provider organizations (PPOs).

Nationally, the federal Centers for Medicare and Medicaid Services (CMS) require HEDIS reporting from all health plans seeking certification as providers for Medicare parts C (Medicare Advantage) and D (prescription drug coverage). Similarly, many states require HEDIS reporting from health plans seeking certification as Medicaid health maintenance organizations (HMOs). A few HEDIS measures only apply to plans serving Medicare or Medicaid patients (e.g., glaucoma screening in older adults is collected from Medicare plans only). Conversely, Medicare and Medicaid plans do not submit data on some measures (e.g., those evaluating clinical services not covered by Medicare).

Organizational Purchasers of Health Plans

NCQA publishes *Quality Compass* as a database-driven tool for organizational purchasers of health plans to use when evaluating competitive products, including cost and member satisfaction information. *Quality Compass* includes data from both commercial plans and Medicaid plans.

NCQA also offers a Web-based Quality Dividend Calculator, enabling commercial health plan purchasers to explore how the quality of differing health plans interacts with factors such as workforce demographics, type of industry, and number of provided sick days to predict the total impact of health plan selection on costs.

Consumer Information

On its own, NCQA uses HEDIS data to construct health plan report cards for use by consumers in making individual choices about insurance. However, NCQA's published HEDIS reports also form the basis for many tools and publications offered by employers; local, state, and federal government agencies; and the annual health plan rankings presented in *U.S. News and World Reports*.

Other Uses of HEDIS Measures

Although NCQA's data collection and reporting remain the primary uses for HEDIS measures, an indication of their general acceptance lies in their application for non-NCQA purposes, primarily in healthcare research and incentive programs.

Research

The advent and standardization of HEDIS measures has had two substantial impacts on healthcare research in addition to the quality assessments performed by NCQA. First, the HEDIS measures provide universally understood and widely accepted standards that researchers can use as benchmarks when studying the effectiveness of new or modified clinical interventions. Second, researchers can use these agreed-on benchmarks as the basis for evaluating nonclinical changes to healthcare delivery, such as those affecting patterns of use, reimbursement rates, or covered services.

Incentive Programs

Increasingly, managed-care organizations are implementing physician performance incentive programs as one of their initiatives to increase the quality of healthcare. Although different strategies for measuring performance exist, applying HEDIS measures has emerged as one of the more popular and effective means for incentivizing physician performance. For example, a study of physicians in Massachusetts found that using HEDIS measures produced performance improvements and that physicians were more likely to respond positively to evaluation systems based on HEDIS measures.

Future Implications

From its origins as a tool for competitive analysis and accreditation, HEDIS has evolved to become the gold standard of health plan quality evaluation. Given the current configuration of the U.S. healthcare system, NCQA will likely continue expanding its reach with new products and publications using HEDIS data to inform health plan selection. At the same time, with the current emphasis on healthcare quality improvement, HEDIS will likely provide the basis for an expanding array of performance initiatives.

However, in the event of substantive changes to the U.S. healthcare system, HEDIS may play an even more important role. First, in any national, healthcare reform movement that mandates individual health insurance, NCQA is well positioned to make HEDIS the foundation of a national, selection mechanism, and most managed-care organizations will likely participate because of increased competition. Second, former senator Tom Daschle and others have recently proposed the establishment of a nonpartisan, federal, healthcare board, combining aspects of the Federal Reserve Board and the defunct Office of Technology Assessment to create national standards for healthcare and health coverage. If HEDIS measures are used for some of its initial standards, NCQA might play a critical role in evaluating compliance with the new body's recommendations and rules.

HEALTHCARE FINANCIAL MANAGEMENT

The purpose of healthcare financial management is to provide both accounting and finance information that will assist healthcare managers in accomplishing the organization's purposes. There are no licensure requirements to be a practicing healthcare financial manager. Facility-accrediting

organizations, such as the Joint Commission, rarely provide requirements for healthcare financial managers but, instead, hold the organization's chief executive officer (CEO) responsible for its financial management. Formal, educational programs for healthcare financial management are not common and usually exist as postgraduate certificate programs. The chief financial officers (CFOs) of most large healthcare organizations possess a master's degree in business administration, a bachelor's degree in accounting, a certificate in public accounting, and have healthcare experience. For formal, continuing education and certification in healthcare financial management, managers can obtain membership and certification in healthcare professional associations such as the Healthcare Financial Management Association (HFMA).

General Functions

Healthcare financial management applies accounting and finance functions to healthcare organizations. It is a broad-based field, drawing from several disciplines and adapting to incorporate current trends.

Accounting

Accounting is generally divided into two major areas: financial accounting and managerial accounting. The purpose of financial accounting is to provide accounting information, generally historic in nature, to external users, including owners, lenders, suppliers, the government, and other insurers. Accounting information prepared for external use must follow the formats established by the American Institute of Certified Public Accountants (AICPA) and other similar organizations and must also follow the generally accepted accounting principles used for standardization. The 1996 *AICPA Audit and Accounting Guide for Health Care Organizations* established four basic financial statements that hospitals should prepare for external use: (1) a consolidated balance sheet, (2) a statement of operations, (3) a statement of changes in equity, and (4) a statement of cash flows. A new audit guide by AICPA was published in 2008. The new audit guide includes revenue recognition criteria, including the (a) accounting and disclosures for charity care and other uncompensated care,

(b) illustrative financial statement disclosures of activity for settlements due to or paid from third parties, (c) physician loans and guarantees, (d) affiliated receivables when collection is doubtful, (e) joint-operating agreements between not-for-profit healthcare organizations, (f) transfers of liabilities or net assets between unrelated not-for-profit organizations, (g) a separate guide for continuing-care retirement communities, (h) malpractice and insurance liabilities, (i) contributions and pledges, and (j) auditor association with cost reports.

The purpose of managerial accounting is to provide accounting information—generally, current or prospective in nature—to internal users, including managers. Such accounting information supports the planning and control management functions. In this way, managerial accounting is the link between financial accounting and the manager, and it, therefore, relies on the information provided by financial accounting. Managerial accounting, or accounting information prepared for internal use, requires no prescribed format and, therefore, varies greatly among organizations. Managerial accounting topics, such as budgeting and inventory control, require a knowledge of economics, statistics, and operations research.

Many managerial accountants believe that cost accounting, which is the study of costs, including methods for classifying, allocating, and identifying costs, is either synonymous with or a subset of managerial accounting. Some argue, however, that cost accounting includes all managerial accounting and also requires some financial accounting. Cost accounting and managerial accounting include topics that could be considered part of finance as well.

Finance

Historically, the purpose of finance has been to borrow and invest the funds necessary for the organization to accomplish its purpose. Today, the purpose of finance is to analyze the information provided by managerial accounting to evaluate past decisions and make sound decisions regarding the future of the organization. It uses techniques such as ratio analysis and capital analysis and requires knowledge of financial and managerial accounting, economics, statistics, and operations research.

Major Objectives

The purpose of healthcare financial management is to provide accounting and finance information that can assist healthcare management in accomplishing all the organization's varied objectives. Yet all organizations have at least one objective in common: to survive and grow. Organizations in other industries might refer to this as "maximizing the owners' wealth"; healthcare organizations typically refer to this as "maintaining community services." In either case, the organization will be of little use if it cannot afford to continue to operate. Therefore, the most important objective of healthcare financial management is to generate a reasonable net income (i.e., the difference between collected revenue and expenses) by investing in assets and putting the assets to work.

In addition to generating income, another major objective of financial management in healthcare is to respond to the regulations of the federal, state, and local governments. Because healthcare organizations are in a position to take unfair advantage of the sick and the elderly, regulation of the industry serves to protect individuals who cannot protect themselves. Government funding pays more than 45% of all healthcare bills and therefore has a vested interest in ensuring that the money is well spent. Healthcare organizations must also meet quasi-regulations in the form of accreditation or certification standards to qualify for reimbursement from many third-party payers and to qualify for loans from certain lenders. Therefore, the second objective of healthcare financial management is to respond to the myriad regulations in a timely and cost-effective manner.

The third objective of healthcare financial management is to facilitate the organization's relationship with third-party payers, who are agents of the patient who have agreed to pay all or a portion of the patient's bill. Third-party payers account for more than 81% of a healthcare organization's operating revenues. Financial management must be responsive to third-party payers and, in many ways, must treat them as customers—in the economic sense of the word—because the third party pays the patient's bill. At the same time, financial management must be attentive to the patient as the customer—in the service sense of the word—because the patient has influence over the third-party

payer and in some cases may be partially responsible for his or her bill.

The fourth objective of healthcare financial management is to influence the method and amount of payment chosen by third-party payers. Third-party payers are becoming increasingly aggressive in asking healthcare organizations for discounts if they represent large numbers of patients. In certain cases, healthcare organizations are discounting prices below cost to maintain their market share. Some third-party payers, such as Medicare, are asking healthcare organizations to assume part of the financial risk for the patient by agreeing to a *prospective payment*, that is, agreeing in advance to a price for providing care to the patient. Healthcare organizations lose money if they provide care that costs more than the prospective payment. Some third-party payers are asking healthcare organizations to assume substantial risk by agreeing to a *capitated price*, that is, a price per subscriber, before the subscriber actually needs care. Capitated prices put healthcare organizations at risk for the cost of care, if needed, and the extent of the use of care by the subscriber.

Healthcare financial management also strives to monitor physicians and their potential financial liability to the organization in terms of their ordering patterns and their possible negligence. In 2005, physicians and other professionals accounted for 31% of all healthcare spending in the nation, hospitals were responsible for 31%, and nursing homes accounted for 6%. Physicians, however, influence much of the healthcare spending attributable to hospitals and nursing homes. For example, physicians order the patient's admission, diagnostic testing and treatment, and discharge. Healthcare financial management must ensure—through the utilization review process—that physician-ordering patterns are consistent with what the patient needs. Regarding the possibility of physician negligence, healthcare financial management must ensure—through the credentialing process and the risk management process—that the healthcare organization has minimized its exposure to legal liability for the physician's possible, negligent actions.

The sixth major objective of healthcare financial management is to protect the organization's tax status. For-profit healthcare organizations seek ways of reducing their tax liability, and not-for-profit healthcare organizations seek ways of

protecting their tax-exempt status from the attempts of state and local governments to find new revenue sources. The more difficult objective rests with the not-for-profit organizations because most healthcare organizations are not for profit and corporate, tax-exempt status has come under increasing judicial and public scrutiny.

Value of Healthcare Financial Management

Healthcare financial management provides accounting information and financial techniques that allow managers to perform management functions and management connective processes; it, therefore, helps accomplish the organizational objectives. In addition to this important indirect value, healthcare financial management has a direct value in the performance of the management functions and management connective processes.

Management Functions

Healthcare financial management assists an organization in accomplishing its mission and goals through planning, organizing, appropriately staffing, motivating, and controlling the budget.

After the governing body completes the strategic plan and senior management completes the operating plan, financial management is often responsible for completing the operating budget and capital budget. The operating budget often provides the incentives to plan properly.

Financial management provides a chart of accounts, based on the organizational chart, that identifies revenue centers and cost centers. Together with the organizational chart, this provides the basis for *responsibility accounting*, that is, holding department managers responsible for their revenues and expenses.

Financial management often staffs a variety of departments and processes important to the healthcare organization. Departments such as medical records and information systems are currently being placed under the supervision of financial management, in addition to departments such as accounting, admitting, and materials management, which have been traditionally under financial management. The increasing importance of non-traditional departments in the billing process appears to justify this trend.

Also known as *motivating* and *influencing*, directing provides financial management with the opportunity to use both rewards and penalties to accomplish the organization's purposes.

The responsibility that is, perhaps, closest to the overall function of financial management—the control of the budget, financial reports, financial policies and procedures, and financial audits—allows financial management to monitor performance and take the appropriate corrective action when performance is unsatisfactory.

These management functions mean little without the *management connective processes* to integrate them.

Management Connective Processes

The connective processes of communicating and coordinating are important to financial management for both reporting and advising. Also important is coordinating the relationships between, for example, revenue and expenses, capital budgets and operating budgets, and volumes and prices and collected revenues.

Decision making is important to financial management as a direct measure of quality. Governing boards, CEOs, and outside sources (e.g., independent auditors) often judge the quality of financial management based on the decisions and recommendations made by financial management. The advantage of this view of quality is that it assumes rational decision making. Decisions made in healthcare financial management are often based on politics or other criteria that are unknown to the evaluator of the decision. Therefore, a decision may be evaluated as *bad* based on the known facts, but it may be evaluated as *good* based on other criteria unknown to the evaluator.

Effects of Financial Management on Changing Healthcare

One widespread view holds that financial management is the most important predictor of whether healthcare organizations will survive in the current competitive climate and beyond. According to one author, the healthcare industry entered an economic depression in the early 1990s that lasted through 2005. As in all depressions, the healthcare

depression was characterized by rapidly falling prices; restrictions on credit, including downgraded credit ratings; reduced production; numerous bankruptcies, mergers, and acquisitions; and high unemployment. Although this conclusion is not comforting, it points out that healthcare is one of several industries that society has allowed to grow beyond the industry's ability to produce efficiently. The same type of growth followed by depression occurred in agriculture during the 1970s and in oil and financial services during the 1980s; it is predicted that depression in government and education will follow the depression in the healthcare industry.

Regarding bankruptcies, the most notorious bankruptcy in not-for-profit healthcare history was the Allegheny Health Education and Research Foundation (AHERF), which occurred in 1998. The AHERF was a 14-hospital system in Pennsylvania. The AHERF bankruptcy had a chilling effect on bond ratings for most not-for-profit healthcare organizations.

There is significant evidence that the peak of the economic depression was in the late 1990s and that the healthcare industry is on the upside of economic recovery. The percent increase in hospital prices has risen steadily since its low in 1997; hospital outpatient prices have risen an average of 6.75% through 2004, and hospital inpatient prices have risen an average of 5.56% through 2004. Another indication of economic recovery is hospital merger activity, which generally continues to decline with 142 reported in 1999 compared with only 50 mergers in 2005. Most of the mergers were driven by a desire to consolidate operations, thus improving efficiency rather than financial distress.

Future Implications

Healthcare financial management will continue to evolve in the future along with the ongoing changes in government healthcare policies. The government and private insurers will increasingly demand greater accountability from healthcare organizations. Well-managed healthcare organizations will survive, and financial management will be instrumental to their survival.

HEALTHCARE FINANCIAL MANAGEMENT ASSOCIATION (HFMA)

Founded as the American Association of Hospital Accountants in 1946, the Healthcare Financial Management Association (HFMA) is a membership organization for healthcare management executives and leaders. With more than 34,000 members, ranging from chief financial officers to accountants, HFMA is a leader on the major financial trends and issues facing the nation's healthcare industry. Its members are found in all areas of healthcare, including hospitals, managed-care organizations, physician practices, accounting firms, and insurance companies.

At the chapter, regional, and national levels, the HFMA helps healthcare finance professionals meet the challenges of the ever-changing healthcare environment by (a) providing education, analysis, and guidance; (b) building and supporting coalitions with other healthcare associations to ensure accurate representation of the healthcare finance profession; (c) educating a broad spectrum of key, industry decision makers on the intricacies and realities of maintaining fiscally healthy healthcare organizations; and (d) working with a broad cross-section of stakeholders to improve the healthcare industry by identifying and bridging gaps in knowledge, best practices, and standards.

Chapter Management

The HFMA, which is headquartered in Westchester, Illinois, comprises 11 geographic regions and 68 local chapters. The local chapters are where most HFMA members make their first networking connections. Local chapters are the source for much of the guidance and support members seek and receive. And chapter leadership often is a steppingstone to national leadership. Most chapters, either individually or jointly, hold annual events designed to promote educational, career, and networking opportunities for their chapter members.

Educational Opportunities

Through national and chapter programs, HFMA annually offers its members more than 465,000 educational hours. Educational opportunities range from traditional seminars and conferences to audio Webcasts, e-learning courses, targeted forums, and communities of practice.

Traditional Education Activities

The centerpiece of HFMA's educational offerings is its Annual National Institute (ANI). Held annually in June, the ANI offers more than 80 educational sessions, keynote addresses from industry leaders, and an opportunity to network with more than 4,000 healthcare professionals in a relaxed yet focused environment. In addition, HFMA holds annual Executive Summit and Revenue Cycle Strategies Conferences.

Alternative Learning Activities

HFMA's audio Webcasts offer a convenient way for members to obtain information on healthcare finance topics. HFMA offers on-site, educational training. And e-learning offers more than 700 Web-based training courses, including avoiding claims denials, claims denial management, finance, billing, and cost control.

Career Development

HFMA offers a variety of resources to assist its members in developing their careers. Members can receive HFMA's free, biweekly newsletter, *Career Opportunities*; access free career advice; and view job openings nationwide through the HFMA job bank.

Certification Programs

Healthcare finance professionals seeking to prepare for increasingly responsible positions can complete one of HFMA's certification programs. HFMA offers certification in the designations of Certified Healthcare Financial Professional (CHFP) and Fellow of the Healthcare Financial Management Association (FHFMA). Achieving these designations

helps prepare for and demonstrate dedication to professional development.
