HFMA offers healthcare industry vendors numerous sponsorship, advertising, and exhibitor opportunities. Vendors can also have products and services reviewed through HFMA's peer review process. The peer review process is designed to provide healthcare financial managers with an objective, third-party evaluation of products and services used in the healthcare finance workplace. Peer review consists of a rigorous review by a peer review panel consisting of current customers, prospects who have not made a purchase, and HFMA members. After successfully completing the process, vendors may use a "Peer Reviewed by HFMA" mark to communicate their involvement to potential customers.

HFMA's Statements

Vision

HFMA's vision is "to be an indispensable resource for healthcare finance."

Purpose Statement

HFMA's purpose is to define, realize, and advance the financial management of healthcare by helping members and others improve the business performance of organizations operating in or serving the healthcare field.

Quality Statement

Quality is the foundation of the association and the keystone of its efforts to ensure member and customer satisfaction. HFMA's objective is to (a) consistently provide services and products that meet the quality expectations of its members, customers, and employees; (b) actively pursue a program of continuous quality improvement that enables employees and volunteers to do their jobs right the first time; (c) make quality a major, strategic association goal, lying at the heart of everything done for members

and customers; and (d) strive continually to improve the quality of services and products offered, the processes and procedures used to produce them, and the manner in which they are delivered.

Values Statement

HFMA believes (a) that service to members is our highest priority, (b) in excellence in all that we do, (c) that teamwork is essential in meeting the objectives of the association, (d) in the importance of individuals, (e) in encouraging innovation and creativity, and (f) in conducting the association with financial responsibility and a prudent approach to business.

Code of Ethics

Members of HFMA agree to endeavor to promote the highest standards of professional conduct by practicing honesty and maintaining personal integrity, including (a) avoidance of conflicts of interest with those of their employer or the HFMA; (b) striving for the objective and fair presentation of financial information; (c) fostering excellence in healthcare financial management by keeping abreast of pertinent issues; (d) maintaining the confidentiality of privileged information; (e) promoting a greater understanding of financial management issues by others in the healthcare field, and seeking increased public understanding through communication about such issues; and (f) seeking to maintain a reasonable balance between the quality and cost of healthcare.

Diversity

HFMA values and respects diversity. Individual differences are viewed as assets that promote the growth and success of HFMA and its members. In principle and in practice, HFMA encourages and supports diverse individual viewpoints and contributions. HFMA believes that a diverse membership is a quality membership.

HEALTHCARE INFORMATICS RESEARCH

Healthcare informatics is a specialty area that integrates health science, computer science, information science, decision science, and management science to manage and communicate data, information, and knowledge in healthcare practice and management. In addition, healthcare informatics facilitates the integration of data, information, and knowledge to support patients, providers, and healthcare executives in their decision making in all roles and settings. Specifically, healthcare informatics research can be defined as a systematic process of compiling, analyzing, and simulating data to produce verified and replicated findings from observed facts or phenomena.

Analytical Strategies

The analytical strategies of healthcare informatics research are shown in Figure 1. The specific strategies include the formulation of a data warehouse, data mining, the application of confirmatory statistical analysis, simulation and optimization via an interface with computer and information system technologies, and translational research.

Data Warehousing

Data warehousing is the systematic structuring of data in a theoretically informed framework

Figure 1 Analytical Strategies for Healthcare Informatics Research

Source: Adapted from T. T. H. Wan's "Healthcare Informatics Research," *Journal of Medical Systems* 30(1): 3-7, 2006.

shared by the disciplinary focus as a means to produce useful information for exploration. Analysts extract data from multiple sources; build a relational database, which is continuously maintained and updated; and classify and populate the study variables uniformly under a nosological or other classification system. A more current approach to data structuring is the reliance on a data-sharing design that enables the functioning of a pooling or pushing data system from multiple sources or units of healthcare organizations. Personal identifiers are, generally, encrypted to ensure the confidentiality and security of the shared data.

Data Mining

Data mining is the use of myriad exploratory and confirmatory statistical techniques to translate masses of raw data into valuable information for managerial decision makers. The benefits of data mining include understanding the patterns of

care or services, identifying causal paths or root causes for problems in service delivery, profiling best practice models, establishing benchmarks for continuous performance enhancement, and differentiating the mechanisms for achieving high performance in a healthcare delivery system.

Confirmatory Statistical Analysis

Confirmatory statistical analysis is the application of multivariate, statistical methods, such as structural equation modeling, to validate or confirm a theoretically constructed model. This modeling approach often involves latent variables, particularly those related to perceptions of health and the quality of care. Thus, the measurement model of the theoretical constructs is designed and evaluated to determine the validity and reliability of the measurement instrument used. Then, functional or causal relationships among the study variables are evaluated using a structural equation model to determine its goodness of fit to the data gathered from the field study. Relevant examples include nursing home quality measurement, patient care outcomes, information technology application, system integration, and hospital performance.

Simulation and Optimization Methods

Simulation and optimization methods play an important role in healthcare research regarding organizational performance, through which researchers develop interfaces between analytical modeling and operations research. For instance, the application of the data envelopment analysis (DEA) to identify the best practice in community health centers can suggest avenues for improving the centers' productivity and performance. The application of tabletop exercises to simulate disaster management and planning is another germane example. Graphical user interface (GUI) presentations should be developed so that simulated results can guide managerial and constructional decision making.

Translational Research

Translational research plays an important role in converting scientific knowledge into routine practices in the design and evaluation of healthcare

management interventions. With the aide of information and communication technology, practitioners, healthcare executives, and decision makers can rely on evidence-based knowledge to improve the effectiveness of health management interventions.

The most important use of information and communication technology is to enhance patient-centric care so that the quality of healthcare organizations can be improved and sustained. The national Institute of Medicine's (IOM's) Committee on Crossing the Quality Chasm: Next Steps Toward a New Health Care System strongly advocates that, at the point of care, the clinician and patient should review the results of the care the patient has received and then use scientific knowledge to decide together on continuing care.

Significance

The nation's healthcare system is evolving in such a way that good evidence is both available and actually used to stimulate effective performance by healthcare executives. The healthcare system's performance can benefit by integrating multidisciplinary perspectives to generate evidence-based knowledge and decision support modeling. Thus, organizational performance at both the patient care and management levels can be improved. The significance of healthcare informatics research has been highlighted in numerous proceedings published by the American Medical Informatics Association (AMIA) and the International Medical Informatics Association (IMIA). The knowledge generated and transformed by healthcare informatics research can be greatly enhanced by the effective use of information and communication technologies.

There are limited interdisciplinary training programs focusing on healthcare informatics in the United States. The National Committee on Vital and Health Statistics (NCVHS), public advisory body to the secretary of the U.S. Department of Health and Human Services (HHS), suggests that a significant amount of investment is needed to build a solid healthcare information infrastructure and to train a corps of health informatics professionals. The U.S. Congress is considering the appropriation of funds for training and research in healthcare informatics under the auspices of the National Science Foundation (NSF).

The Evidence-Based Modeling Approach

The field of evidence-based informatics is defined as the study of information science applications in the context of healthcare management to compile, manage, and process data and knowledge for improving the performance of healthcare organizations. The process of evidence-based, healthcare management modeling and simulation is presented in Figure 2. Specifically, the process begins with a formulation of the study problem that is guided by a theoretically informed framework to specify the interrelationships among the study variables. The analytical model is then specified and subsequently built iteratively with testable hypotheses.

This approach can be used as the basis for designing an empirical study that can, in effect, serve as a launching point for constructing confirmatory statistical models in which the measurement model and the causal models could be fully developed and validated. The validated or verified results form the foundation and constraints for simulation and multivariate optimization modeling. Thus, a decision support system for managerial operations can be formulated and further tested. The simulation is run and evaluated as a valid representation of the real-world system.

Upon completion of this validation, the simulation model may then be used to assess the real-world system and prescribe the implementations for the desired effects for improving the performance of healthcare organizations. In this case, the injection of artificial data emulating changes in input variables into the simulation that has been validated as predictive of better performance is used to guide the healthcare executives' decisions for performance enhancement. Empirical examples illustrating the intricacies of applied healthcare informatics research in optimizing inputs to achieve better outputs can be found in nursing home management research, nursing care staffing, and information system integration.

Future Implications

It is widely recognized that healthcare management technology is underused and underdeveloped. To achieve improvements in access, cost, and quality of care, patient-centric, information

Figure 2 Evidence-Based Modeling Approach in Healthcare Informatics

technology-based networks should be built to provide vital, medical information at the point of care to enhance patient care outcomes. Although the establishment of empirical research on healthcare management is timely, the future of healthcare informatics research and development relies on the application of knowledge to actual practices. For instance, translational research should generate evidence-based knowledge to guide the development and implementation of consumer-oriented health information technology that could be embedded in handheld devices (e.g., an iPhone). Research activities using massive amounts of clinical and administrative data should be promoted.

Another important step forward would be achieving a clearer and improved understanding of

the effects of clinical and managerial interventions on patient care outcomes through the development of evidence-based decision support systems for optimizing the performance of healthcare organizations. Currently, the field of healthcare informatics plays an important role in establishing knowledge management applications and information technology services. This role will likely broaden and greatly increase in importance in the future.

HEALTHCARE MARKETS

Healthcare markets define the set of consumers and producers that influence healthcare price and quality. Market definitions are of tremendous policy importance and have been studied extensively. These definitions have, for example, been crucial to understanding the relationship between competition and both financial and health outcomes. Understanding medical expenditure growth

and the diffusion of new technologies similarly depends on defining markets.

Although definitions vary across services, there are efforts to define healthcare provider markets on a national basis. Health Service Areas (HSAs), for example, describe the geographic area from which an individual hospital's patients originate. Similarly, Health Referral Regions (HRRs) define the larger geographic area from which patients travel for tertiary medical care (e.g., cardiac surgery). This distinction illustrates the point that healthcare markets are not uniform; rather, they depend on specific clinical services, not to mention clinical quality, and even intangibles such as bedside manner.

Although research on healthcare markets encompasses a broad literature, the following sections on hospital and pharmaceutical markets illustrate key concepts.

Hospital Markets

Hospital markets are among the most studied in health services research. As with much of healthcare, hospital markets are wrought with complexity. Insurers, for example, form networks of covered hospitals and physicians. Insurers heavily influence consumers' prices and thus influence hospital markets. Furthermore, hospitals are differentiated in both service mix and quality. Each of these factors plays a role in defining provider markets in general and hospital markets in particular.

Historically, regulatory concerns such as anti-trust laws have driven hospital market definitions. In theory, markets are the smallest group of products and the smallest geographic area in which a hypothetical monopolist could impose a small but significant nontransitory price increase (SNPI). Both the U.S. Department of Justice and the Federal Trade Commission define an SNPI as a 5% price increase. A single hospital may, of course, face different markets for different services.

In practice, hospital markets have been difficult to define. Initial efforts defined markets as a fixed radius (e.g., 15 miles) about a hospital. Fixed distances were often determined by the distance referring physicians would regularly drive to see patients. A natural alternative has been to use urbanized areas, such as metropolitan statistical areas (MSAs). Although these ad hoc definitions may be reasonable

proxies for markets, they are undoubtedly imperfect. Furthermore, analyses of markets may differ based on how they are defined.

Subsequent research used patient flow data to define markets. Examples include the aforementioned HSAs and HRRs. Markets were, essentially, defined as the geographic areas (i.e., 5-digit zip codes) from which their patients originated. Although appealing, patient flow data may underestimate the true market size by excluding patients who might otherwise choose a given hospital were its quality higher or prices lower. Conversely, such data may overestimate the market size if some patients are willing to travel long distances to reach a specific hospital. This might occur if patients are aware of hospital quality, a factor that is unaccounted for in market definitions.

Recent studies have recognized that hospitals compete not only for patients but also for insurance network inclusion. Empirical work in this literature builds on patient flow data by modeling individual patient's hospital choices. To date, these studies indicate that actual markets are effectively smaller than those suggested by raw patient flow data. These findings suggest that consumers' choices are heavily influenced by factors unobserved by researchers.

The basic principles underlying hospital market definitions likely apply to other healthcare providers as well. The markets for most providers, such as physicians and long-term care facilities, are defined by a geographic area and a clinical specialty or focus. Furthermore, insurers typically play a crucial role in forming a set of competing providers.

Pharmaceutical Markets

Pharmaceutical markets are drastically different from healthcare provider markets. These markets are characterized by tremendous research and development (R&D) costs, often exceeding \$1 billion per new product. Patents, a government sanctioned monopoly right, are issued as an incentive to firms to make R&D investments. Typically, a pharmaceutical firm is guaranteed exclusive rights to market a new chemical entity for the patent's term—that is, 20 years from the filing date.

Pharmaceutical markets comprise drugs that treat the same condition; these drugs form a *therapeutic*

category. Although there is no single universally accepted set of therapeutic categories, the intuition is clear: Cardiac drugs, for example, might be part of one market, whereas asthma drugs are part of another. Naturally, these categories may be further refined: Cardiac drugs, for example, could be subdivided into arrhythmia and high cholesterol treatments.

While under patent protection, a drug's market includes therapeutic substitutes—chemically different products that treat the same condition. Subsequent to patent expiration, competitors are free to market chemically equivalent (i.e., generic) substitutes. Generic entry plays a crucial role in the definition and function of pharmaceutical markets.

As with other healthcare markets, insurance plays an important role. Insurers can influence pharmaceutical use by effectively setting the drug prices for their beneficiaries. Insurers first define a *drug formulary*—that is, a set of drugs that are covered by the insurer. Conditional on drug formulary inclusion, insurers then set the prices paid by their beneficiaries, typically a copayment. Markets for Medicare beneficiaries, Medicaid recipients, and private insurance enrollees are typically distinct, with further subdivisions within each category.

From a geographic perspective, pharmaceutical markets are largely national, a marked difference from healthcare provider markets. Pharmaceutical markets are, however, differentiated across nations. Prices, for example, are typically much higher in affluent nations than in less advantaged nations. Two policy initiatives threaten to undermine these differences. *International reference pricing*, often used by European nations, sets one nation's price as a function of the prices used by other nations. Similarly, *reimportation* breaks down cross-nation price differences by allowing pharmaceuticals in one nation to be resold in another. Currently, reimportation is allowed within the European Union (EU) but banned between most other developed nations. These policies effectively lower prices for those who would otherwise pay the most. They may, however, raise prices for the relatively poor.

Future Implications

Further research is needed to understand the role of healthcare markets. Promising techniques from the hospital market literature hold the potential to

address many research and policy questions. Crucial questions regarding quality and competition, as well as the role of new technologies, remain to be addressed. Likewise, other markets, such as for physician services and medical devices, remain understudied.

HEALTHCARE ORGANIZATION THEORY

The scholarly field of organization studies and the empirical world of healthcare organizations have grown up together. Organizational concepts and

propositions have been applied to and tested in healthcare settings; healthcare organizations, which exhibit somewhat distinctive features, have posed special problems for researchers, who have contributed to the development of organization theory.

Background

Organization studies did not emerge as an academic discipline until the late 1950s; before that time, organizations were not very significant players in healthcare. Hospitals were the major organizational form, but most were small, nonprofit, "voluntary" structures closely connected to and embedded in the local communities they served. Physicians worked as independent professionals, billing individual clients for service, often on a sliding scale taking into account a client's ability to pay. Well into the 1950s, healthcare in the United States was a cottage industry—small in scale, decentralized, and locally governed. What structure there was came not from the government or from healthcare organizations but rather from the controls exercised by professional occupations—in particular, the American Medical Association (AMA).

Organization studies have evolved over time, moving from more micro to more macro forces and structures. Early students of organizations concentrated primarily on *organization behavior*—the behavior of individuals and groups operating within the context of an organization. Later students, during the 1960s, turned their attention to organizations as themselves objects of study, as collective actors varying in structure and operations. This work—including comparative organizational studies, the development of contingency theory, and transaction cost theory—emphasized the importance for an organization of the wider environment or context in which it was located. More recently, beginning during the mid-1970s, we witnessed the creation of a number of theoretical perspectives—resource dependence, population ecology, institutional theory—that examine the operation of larger systems of organizations, including organizational populations and organizational fields. The changing foci of scholarship are clearly reflected in the research on healthcare organizations.

Occupational Structure and Behavior Within Healthcare Organizations

The earliest studies of the organization of healthcare were conducted by students of occupations and professions. During the 1930s, scholars such as A. M. Carr-Saunders in England and Everett C. Hughes and Talcott Parsons in the United States began to examine the distinctive control systems devised by professional groups—in particular, physicians—to manage their work. Professional occupations sought control over the structure and activities of training systems through accreditation, and they fostered the creation of collegial controls both informal and formal, the latter exercised primarily through activities conducted by the professional associations. The backing of the government was secured to ensure that only licensed practitioners had access to specified titles, positions, and activities. During the 1950s and 1960s, important studies examined the structure, “power, purpose, and politics” of the AMA, which by that time had become one of the most powerful professional associations in the nation.

Gradually, scholars began to turn their attention to the interaction of occupations and organizations. Professionals were not only operating within and affected by their occupational associations but also by the organizational settings in which they increasingly trained and worked. During the early 1950s and 1960s, sociologists such as Everett C. Hughes, Howard S. Becker, and Robert K. Merton conducted insightful studies examining the nature of professional socialization and training in medical schools. How do medical students cope with the vast amount of material to be learned? How do they learn to conduct intimate physical examinations of patients or deal with pain, disability, and death? On what basis do they decide whether or not to specialize or choose which specialty to pursue?

Physicians are exposed to organizations not only in their training but, to an ever-increasing extent, in their practice settings as well. Until late in the 20th century, most physicians were solo practitioners, operating in small, private offices and looking after the health needs of their private patients. As studies by Oswald Hall during the 1940s revealed, ethnic and religious identification

were important factors in structuring a physician's location and mode of practice. Informal connections were important for obtaining patient referrals and appointment to hospitals' staffs. By the beginning of the 1950s, about 35% of physicians had moved into specialized practice, and physicians began to cluster in multispecialty, group practice settings. Studies by numerous scholars, including Joseph Ben-David, Eliot Freidson, and George Silver, examined the effects on physicians' behavior of differences in their practice settings. Such studies have, of course, become much more common as more and more physicians locate their practice in organizational settings. For example, James C. Robinson has recently examined the consequences for medical practice of variations in settings including “virtual” arrangements such as (a) Independent Practice Associations (IPAs), (b) multispecialty medical groups, (c) physician practice management systems, and (d) physician-hospital organizations. Such settings vary greatly along dimensions such as the ways in which incentives are structured, the extent to which physicians are colocated in the same work setting, the type of collegial controls exercised, and the nature and extent of managerial authority.

While physicians have received much attention in studies of healthcare organizations, an extensive body of research also exists on organizational factors affecting other types of professions, including nurses, chiropractors, pharmacists, and medical social workers.

Determinants and Consequences of Structures in Healthcare Organizations

Moving to the organizational level, far and away more scholarly attention has been devoted by organizational scholars to the study of hospitals than to any other type of organization. Informative historical investigations of changes in the nature of U.S. hospitals have been provided by Paul Starr, Rosemary Stevens, William D. White, and Charles E. Rosenberg, among others. In the early 20th century, hospitals were places where indigent patients went to die and where inquisitive physicians went to learn more about disease. However, aseptic procedures improved and medical care practice became more complex, requiring ever more expensive equipment, and by midcentury,

physicians had come to depend on hospitals for the care of their patients. Hospitals became indispensable to professional, medical practice, serving, in Herman Somers and Anne Somers's term, as "the doctor's workshop."

A Distinctive Structure

In the United States, physicians and hospitals have developed a unique structure. As Harvey Smith pointed out in 1955, American hospitals exhibited a "dual authority structure"—one administrative, the other professional. With only a few exceptions, such as pathologists, physicians did not become hospital employees. Rather, they organized themselves as a "medical staff" to exercise control over the care of their individual patients, whom they admitted for specialized treatment, as well as to govern their own members, through the formation of staff selection, tissue auditing, and other committees. Hospital administrators, rarely themselves physicians, were responsible for the oversight of the building, equipment, patient wards, housekeeping, and ancillary services. The patient received two bills: one for the hospital and the other for medical (physician's) services. The American model was exceptional: In Europe, hospitals were typically directed by physicians, employed a full-time staff of physicians, and were operated as public, not private, institutions.

In contrast to physicians, other U.S. healthcare professions—in particular, nurses and social workers—while granted circumscribed decision-making autonomy were subordinated to the administrative structure. A growing range of paraprofessionals—such as laboratory technicians, inhalation therapists, and radiological personnel—staffed hospital departments. All were subject to dual control: receiving orders and directions from physicians but being coordinated and routinely supervised by managerial personnel.

Not all organizational scholars focused their primary attention on the authority structure that had evolved in hospitals. Many conducted research in healthcare organizations to apply and test the general propositions emerging from organization theory. For example, Charles Perrow examined the way technological developments worked to shape the differentiation and structuring of hospitals as well as changing the power-dependence relations

between physicians and trustees. Other researchers, such as W. R. Scott and Ann B. Flood, examined structural sources of variation in quality of care, attending primarily to the structure of the medical staff and of the hospital wards. When, during the 1960s, the costs of healthcare services began their seemingly inexorable rise, economists attempted to assess what hospital characteristics were associated with cost differences. They examined, variously, the effect on costs of features such as services and case-mix, size, teaching status, type of ownership, and membership in a hospital system. More recently, researchers have examined the diffusion across hospitals of various management reforms, such as matrix management and the total quality management (TQM) approaches to improving quality.

Although most research attention has been devoted to hospitals, organization scholars have also examined the structure, operation, and performance of other, more specialized, healthcare organizations, including multispecialty clinics, health maintenance organizations (HMOs), skilled-nursing facilities, home health agencies, and hospices.

Healthcare Systems

From their beginnings as small, independent, widely scattered units, hospitals have grown enormously in size, complexity, and connectedness during the past several decades. As technologies have become more complex, physician services more differentiated, and economic competition more intense, hospitals have increasingly become more horizontally and vertically integrated. Initially, hospitals entered into loose affiliations with neighboring similar units—forming hospital chains—in an effort to reduce competition, increase economies of scale, and improve learning opportunities. The pioneers in system development in the United States were Catholic hospitals, but their systems largely reflected the organizational structure of the church hierarchy and had little effect on the operational relations among other hospitals.

Since the 1970s, many hospital systems have moved beyond the horizontal integration of similar organizations to build linkages among a diverse set of organizations, including outpatient clinics, extended-care services, urgent-care facilities, HMOs and other physicians groups, rehabilitation

units, home health agencies, and hospices. These connections may involve outright ownership, some sharing of equity, or contractual relations. Studies by Stephen M. Shortell, Jeffrey A. Alexander, and others point out that hospital systems vary in the loci of their integration: Some are constructed around hospitals, others around medical groups, and still others around insurance companies. They also vary greatly in their governance structures, some adopting a parent holding company model of relatively loose integration; others a more centrally integrated model, with a systemwide governance structure; and still others a full-fledged corporate model, with specialized managers overseeing strategic, financial, and marketing functions. Although compared with other industrial and service sectors in the United States, hospitals were slow in moving toward more concentrated modes of operation and adopting the corporate form of governance, in recent decades they have rapidly acquired most aspects of the modern organizational vocabulary.

Organization of the Wider Healthcare Environment

As suggested by the forgoing comments on the growth of healthcare systems, organizing processes are not confined within the boundaries of a given organization. Modern, societal structures are characterized by the elaboration of cultural and relational connections linking social actors and organizations across wider arenas. Organizational scholars have examined these developments principally in the course of research on *organization populations* and *organization fields*.

Organization Populations

An organization population is analogous to a biological species. It comprises organizations sharing roughly the same form and operating systems and reliant on the same resources. As developed by scholars such as Howard Aldrich, Joel A. C. Baum, and Michael Hannan, *organization ecology* examines the founding, growth, and decline of populations of organizations in relation to changes in their material resources and institutional environments. The focus is on the operation and effects of such basic processes as variations among, selection

of, and retention of organizational attributes as these are affected by competition among organizations in the same or related populations. Organizations of the same type not only compete but also look to one another for ideas as to how to act and, often, form associations to further their mutual interests.

The population perspective on organizations represents a fundamental shift in organization scholars' view of organizational change. Rather than stressing purposive—primarily managerial—choice, more attention is given to the presence of situational constraints (the environment) and to random and emergent factors (chance and contingency). Selection processes are emphasized over adaptation. Organizational ecologists emphasize the limits of managerial control due to both cognitive factors and organizational inertia—that is, resistance to change due to sunk costs and vested interests.

Organizations of the same type often are formed at roughly the same time, in response to some opportunity in the environment, and draw on the same types of organizing resources. Thus, as reported by Jeffrey A. Alexander and Terry Amburgey, community hospitals in the United States were founded in large numbers in the early years of the 20th century, and the basic features of their organizational structure were laid down at that time. New organizational populations emerge slowly, but when they become recognizable to their publics and are regarded as an improvement on earlier, alternative forms, they can increase rapidly, having acquired legitimacy. Sometimes, new populations result from changes in institutional rules. Thus, the emergence and rapid growth of HMOs during the 1970s was primarily the result of federal legislation supporting this form, as Douglas R. Wholey has demonstrated.

Organization Fields

An analysis of *organization fields* shifts attention to an even higher level to examine the interdependence of diverse populations of organizations working in the same arena. The concept of field exploits the insight that “local social orders” constitute the building blocks of contemporary societies. Fields are inhabited by a collection of competing and cooperating organizations together with their major suppliers and consumers and by

the regulatory and funding bodies, often at distant locations, that profoundly affect their operation.

Key components of organization fields include (a) organization archetypes, (b) relational systems, (c) governance arrangements, and (d) cultural-cognitive systems. Archetypes are models for the basic types of organizations that inhabit the field. In any given field, we find a delimited number of models for organizing. For example, there are a relatively small number of types of organizations that deliver healthcare services in the United States at the present time. The organizations in a field are connected in a variety of ways, both directly and indirectly, in relational systems. In some fields, these connections are infrequent and brittle; in others, they are routine and strong. They vary also in the extent of their fragmentation and centralization. Field-level governance systems are arrangements that support the regularized control—whether by mutual agreement, legitimate authority, or coercive power—of some subset of actors by others. These systems usually include changing combinations of public and private actors. Cultural-cognitive systems include both the cultural frames that enable actors to interpret events as well as institutional logics that provide routines and symbolic constructions defining appropriate ways to carry on work. As Paul J. DiMaggio and Walter W. Powell have pointed out, organization fields vary in the nature and degree of their *structuration*: the extent to which a small number of recognizable archetypes exists, the density of relations among them, the effectiveness of governance structures, and the degree of consensus on and coherence of the cultural-cognitive systems used.

Research by W. R. Scott and colleagues chronicles changes over the latter half of the 20th century in the field of healthcare services in the San Francisco Bay area. Although by no means a representative case in the United States, this area was often on the cutting edge of healthcare change. Moreover, although the care systems studied were limited to one geographic region, wider state and national forces were considered.

The study suggests that changes in the delivery of healthcare services are usefully partitioned into three periods or eras: (1) professional dominance, (2) federal involvement, and (3) managed care. The era of professional dominance, commencing in the 1920s and extending until the mid-1960s,

was marked by the growing number and influence of physicians in private practice, their professional associations (primarily, the AMA) and independent community hospitals. Healthcare organizations were small and unspecialized. Connections among actors were sparse, primarily informal, and local. Governance structures were dominated by professional associations, except for the state agencies that enforced licensure provisions at the behest of these associations. Primary cultural-cognitive frames stressed a nonprofit, voluntary ethos, and the central institutional logics stressed quality of care—as defined by the physician.

A surge in the number of healthcare professionals and facilities occurred following World War II. Hospitals, with the help of federal funding, grew much larger and more differentiated, and independent physicians increasingly organized themselves in multispecialty groups. Large employers subsidized healthcare coverage for their employees, and insurance companies became active and influential players in the field. After many failed attempts, the federal government, in 1965, passed Medicare and Medicaid legislation covering hospital services for the elderly and the indigent. This significant political event marked the dramatic onset of the era of federal involvement. For the first time, the nation-state was a major player, purchasing more than half of all the health services delivered. Moreover, because of rising healthcare costs, federal officials quickly found themselves engaged in a variety of regulatory and planning activities to control costs. Thus, governance structures, which had been primarily private, and professionals were forced to share control with state and federal agencies. Cultural-cognitive frames expanded to include equity and the importance of access to healthcare services, and patients began to assume a more active, consumer orientation and to explore the use of alternative healthcare providers.

Early in the 1980s, a third era opened, marked by the urgent need to curtail rising costs and a reliance on managerial and market-based instruments. Hospitals increased in size as small hospitals were closed and others expanded, often through merger or acquisition. Numerous specialized organizations appeared, including many freestanding organizations offering services—such as renal dialysis—that had formerly been performed only in hospitals. For-profit hospitals and care units

multiplied. Physicians were increasingly organized in groups, both real and “virtual,” as insurance plans enlisted independent physicians for their panels. Relations among all players in the field became more dense and complex, with employers forming coalitions to negotiate insurance rates; insurance companies contracting with physicians; and hospitals buying or contracting with specialized providers, such as extended care facilities. Managers of healthcare organizations now hold master’s of business administration (MBA) degrees and exercise broad powers in healthcare organizations. To concern about quality and access, a focus on efficiency and a faith in market-based solutions are added.

Although federal agents and corporate managers have not supplanted physicians and other health professionals, the world of healthcare organizations has undergone significant change in the past few decades. Organization forms have become more diverse, more complex, and much more significant in the delivery of healthcare. The continued productive interaction of healthcare and organization theory seems ensured.

HEALTHCARE REFORM

Families, businesses, and governments are struggling with the ever-increasing costs of healthcare. Every year, about 1 million people are added to the nation’s rolls of the uninsured, now numbering about 47 million. People with insurance are seeing their benefits dwindle and healthcare costs consume an increasing portion of their wages. Even people who have insurance find themselves unable to pay medical bills, and many are going without needed care. Given these conditions, calls for healthcare reform and reform proposals abound, including calls to secure health insurance for all Americans, sometimes called *universal coverage*. This entry lays out how the United States arrived at the mix of private and public insurance it now has, how that mix impedes reform, and the implications of healthcare reform.

Historical Choices

Political efforts to achieve national health insurance were a regular—and regularly unsuccessful—feature of social policy in the first half of the 20th century. The focus here, however, is not on explaining the failure; rather, it is on examining the strategy for achieving health insurance coverage that that failure produced—specifically, the reliance on private, employer-sponsored insurance as the primary means to cover workers and their families, and the promotion of public health insurance to fill the gaps that private insurance would inevitably create.

According to a growing body of scholarship, a variety of forces contributed to the emergence of employer-sponsored health insurance in the 1940s and 1950s: (a) the labor movement's shift from national politics to collective bargaining as the way to gain health insurance, (b) business interests' preferences for fringe benefits over government-run (or labor-organized) health insurance, (c) insurance industry capacity for and interest in providing those benefits, and (d) administrative actions, backed by legislation, establishing tax preferences (most important, the exclusion of employer-paid premiums from employee taxable income) that subsidized employer-sponsored health insurance. The result was the establishment of voluntary, employer-sponsored health insurance as the nation's primary health insurance system, at the very same time other industrialized nations established universal and public health insurance systems not linked to employers' decisions about wages and benefits.

The establishment of employer-sponsored health insurance, in turn, generated a strategy for achieving public health insurance—that is, by focusing on the nonworking population. From the 1950s, national health insurance advocates shifted their attention away from the general population and toward the elderly—a group unlikely to be covered by work-based or other private health insurance. However, the political compromise that established the Medicare program as universal social insurance for the elderly also established the Medicaid program as means-tested health insurance for certain population subgroups—specifically, low-income persons who receive care assistance based on age, blindness, disability, or (in the case of children living with single mothers) dependency status. The overall result was the creation of a public health insurance system targeted to people not expected to work and built around the private (albeit tax-subsidized) insurance system for workers and their families.

Employer-sponsored health insurance expanded dramatically to cover more and more (and a growing share of) workers and their families through the 1970s. But then growth stopped. Through the 1980s and 1990s, the numbers—and the proportion—of working-aged Americans without health insurance coverage grew steadily. Indeed, lack of health insurance among low-wage workers grew so substantially during the recession of the

late 1980s that even the subsequent, unprecedented prosperity of the mid- to late 1990s left a smaller proportion of low-wage workers covered at the end of the 1990s than had been covered a decade before. The clear lesson of the 1990s was not only that a threatened economy reduces health insurance coverage but also that a prosperous economy cannot guarantee it. At least for the time being, employer-sponsored health insurance remains successful in serving the vast majority of better-off workers. But employer-sponsored insurance inevitably excludes significant numbers of low- and modest-wage workers in both large and small firms.

The public health insurance system also grew in the second half of the 20th century. Medicare was expanded in 1972 to include disabled beneficiaries of Social Security (after a 2-year waiting period) and people with end-stage renal disease. But Medicare was not extended to insure the younger population, as some proponents had hoped it would be. Although federal legislation in the 1970s actually narrowed the population covered by Medicaid, ultimately Medicaid was expanded to reach certain groups with ties to the workforce: (a) children of lower-income workers; (b) pregnant women in working, two-parent households; and (c) persons with disabilities who are able to return to the workplace with supports. Medicaid's most substantial expansion came in the 1980s and 1990s through enactment of national, income eligibility standards (higher than cash assistance eligibility standards in many states) for children and pregnant women. In the late 1990s, the State Children's Health Insurance Program (SCHIP) provided a further, modest expansion of coverage for children. But, except for its coverage of low-income, aged, and disabled persons, Medicaid has remained a program for children and, to a much lesser extent, their mothers. States have the option to cover parents (fathers as well as mothers), but in most states, parents earning the minimum wage have too much income to qualify for Medicaid. And federal law, today as in 1965, does not extend Medicaid eligibility to low-income adults who are not the parents of dependent children. Except in a few states that operate their Medicaid programs as special, federally sanctioned demonstrations that waive traditional Medicaid eligibility restrictions, the history of targeting public protections to exclude workers, regardless of income, persists.

Overall, employer-sponsored insurance and the programs designed primarily for people outside the workforce—Medicare for the elderly and some of the disabled, and Medicaid for children and pregnant women—cover about 85% of the U.S. population. But their explicit structures mean that they exclude people who work but nonetheless are not offered health insurance coverage through their jobs and who, primarily because they work, remain outside the categories covered by public programs.

Barriers to Reform

Given the health insurance-financing system currently in place in the United States, a simple way to explain the country's failure to enact reform is that the "haves" have health insurance; it is the "have-nots" who do not. Although it is true that anyone can fall out of employer-sponsored coverage—for example, by losing one's job or getting divorced—the vast majority of Americans can count on receiving health insurance through their jobs. The roughly 15% of Americans who are uninsured are overwhelmingly workers in low- and modest-wage jobs that do not offer health insurance and working-aged adults who do not qualify for Medicaid. The primary political and policy problem that the United States faces is that it is almost impossible to insure the have-nots without, in some way, disrupting the status quo of the haves.

An obvious form of disruption comes from the need to raise the financial resources to subsidize health insurance for the economically disadvantaged uninsured. The full cost of employer-sponsored coverage of a typical family is more than \$12,000 per year. If comparable insurance were available to individuals outside employment, it would absorb more than 20% of their income for the great majority of the uninsured. Virtually every health insurance expansion proposal, regardless of its form, recognizes that the cost of health insurance is too high to expect the uninsured to purchase it without subsidies. Subsidization entails redistribution—taxing those who have health insurance to subsidize health insurance for those who do not. Historically, the need for redistribution has posed a substantial, political barrier to reform.

But equally problematic is the policy difficulty of getting health insurance to the uninsured without in some way disrupting the actual insurance of the already insured. National health insurance via a single-payer or Medicare-for-all strategy actually intends disruption—or, more accurately, replacement—of employer-sponsored insurance with what its advocates believe would be a simpler, more equitable, and more efficient system. Whether or not they are correct, the reluctance to disrupt Americans who have health insurance—specifically, to legislate both the redistribution of financing and the shift from private to public coverage that a single-payer system would entail—has inhibited many politicians and policymakers from tackling "replacement" head on.

Thus, the dilemma of reforming healthcare is to design a policy that can cover the uninsured without affecting the already insured and at the same time achieve political success, which is difficult if the already insured perceive that they will be worse off as a result. This dilemma is not limited to expansions aimed at universal coverage. Incremental-expansion proposals that focus on achieving small improvements for low-income populations not only make redistribution from the haves to the have-nots explicit (as only the latter receive new benefits), they also affect the coverage of the already insured. Except for a proposed expansion that would limit eligibility to individuals with incomes below the federal poverty level (a group in which hardly anyone has employer coverage), any coverage proposal is likely to make new, publicly subsidized benefits available not only to the uninsured but also to significant numbers of people who already have insurance. With a new coverage option available, even individuals with employer coverage might replace that coverage with free or near-free benefits provided at public expense. And should those benefits be made available, employers—particularly employers whose employees earn relatively low wages—might decide to drop the coverage they currently offer, essentially forcing their employees to find coverage elsewhere.

Since 2000, rising premiums and reduced benefits have increased concern among people who have employer-sponsored health insurance that even with insurance they are no longer assured of access to affordable, quality healthcare when

they need it. As a result, health reform is a key issue in the 2008 presidential campaign. Whether reform becomes a reality will depend on the leadership of a new president and whether most people come to have confidence that everyone—the insured along with the uninsured—have more to gain than to lose from reforming the health-care system.

HEALTHCARE WEB SITES

Healthcare Web sites are electronic pages available on the Internet that are generally designed to serve one or more of three different groups: (1) healthcare consumers, (2) healthcare practitioners, and (3) health services researchers. Many are published by government agencies, private foundations, or healthcare organizations; however, the Internet as a publishing medium is open to anyone with computer access. This freedom to publish can be a problem, especially in the case of healthcare Web sites, as people may make life-affecting medical decisions based on the information they read online. To this end, organizations exist that attempt to monitor healthcare Web sites and provide standards or quality criteria by which to evaluate sites.

Healthcare Consumer Web Sites

Many consumer Web sites aim to help people maintain healthy lifestyles through their behavioral choices. More sophisticated sites offer online tools and calculators that provide customized recommendations or advice based on one's personal data. One example is a body mass index (BMI) calculator, which determines whether someone is in a healthy weight range for his or her height. With an emphasis on preventive care, these types of consumer sites are motivated not only by a humanitarian desire to improve public health but also by the need to control healthcare costs. Accordingly, the major publishers of these types of sites are healthcare organizations such as hospitals, insurance companies, or those government agencies that finance a substantial portion of their citizen's medical care. As people publish personal health data online or their healthcare providers or insurance companies do so, privacy issues are of increasing concern. Sites that allow users to create electronic clinical records, for instance, run a risk of being hacked into and exposing patients' medical histories. Nevertheless, these sites do provide valuable services to consumers by empowering them to be more active in their own care. Some sites act as virtual, social-support networks for patients by using interactive technologies such as discussion boards or e-mail

lists to foster communication among people with similar medical conditions.

Healthcare Practitioner Web Sites

Web sites for healthcare practitioners offer types of information similar to that for consumers, though the content is written for a professional-level audience. Practitioner sites feature things such as journal article summaries, continuing-education opportunities, and reference materials from textbooks. Sites for practitioners are typically targeted to specific professions (e.g., physicians, nurses, or physical therapists) and, within those professions, to specialty areas (e.g., cardiology, geriatrics, or public health). Evidence-based practice Web sites are one type of site of particular value to busy healthcare providers who do not have time to comprehensively search the literature, read all the original research, and formulate their own conclusions to drive decision making. As with consumer sites, healthcare practitioner Web sites provide opportunities for networking.

Health Services Researcher Web Sites

Health services researchers have greatly benefited from the advances in e-health. Never before has it been so easy to obtain data on healthcare access, cost, quality, and outcome. Rather than being stored on individual computers or existing solely in summarized written records, health services data sets can be published online, downloaded by other researchers, and manipulated and recombined to elicit new information. The fact that these data sets are often assembled by government organizations means that the data are typically freely available. However, restrictions on use may apply when individuals could potentially be identified by demographic information.

Quality of Web Site Information

Although data privacy concerns are a major consideration in the development of healthcare Web sites, of highest importance is the quality of the information such sites provide. Two leaders in the

movement to monitor health information quality online are the Health On the Net (HON) Foundation and URAC. The HON Foundation is an international effort based in Switzerland and started in 1995 by a group of telemedicine experts. Its HON Code of Conduct (HONcode) lists eight principles for ensuring that healthcare Web sites publish accurate, reliable, and valid information. Sites that respect all eight items (authoritative, complementarity, privacy, attribution, justifiability, transparency, financial disclosure, and advertising policy) can apply for free accreditation, which allows the sites to display the HONcode logo and be listed in the HON search database of accredited, healthcare and medical sites. Approved sites are policed on a regular basis to ensure that they maintain the basic ethical standards set by HON.

Unlike HON, which is focused solely on online information provision, URAC offers accreditation to healthcare organizations in more than a dozen program areas; their health Web site program is only one. Developed in 2001, the more than 50 URAC standards evaluate healthcare Web sites on disclosure and linking, health content and service delivery, privacy and security, and quality oversight. Also unlike HON, URAC charges for its accreditation seal and covers only Web sites from U.S. companies. The HON and URAC online directories of accredited sites are an efficient starting point for locating reliable healthcare Web sites.

Health Information Professionals and Organizations

Health information professionals specialize in the selection and organization of both print and electronic materials. Since the early stages of healthcare Web site development, these professionals—often medical librarians—have led efforts to establish quality criteria and create virtual collections of health sites. At the forefront in the United States are the National Library of Medicine (NLM) and the Medical Library Association (MLA), a government agency and a professional organization, respectively, that have published directories of top healthcare Web sites for consumers, practitioners, and researchers.

HEALTH COMMUNICATION

According to the federal government's initiative Healthy People 2010, health communication should examine and advance communication strategies to inform and influence individual and community decisions that lead to improved health. Health communication is relevant in a variety of contexts: health literacy, dissemination of health

risk information, health professional/patient interactions, strategies for preventive health and population-based medicine, and the developing field of telehealth applications.

Background

The use of health communication dates back to Aristotle who first described it in his anthology *The Rhetoric* in the 4th century BCE. Today, the humanistic theory of Carl Rogers and Abraham Maslow has dominated the fields of health communication theory. The 20th century saw the advent of better methodologies, incorporating insights from the fields of sociology, psychology, and linguistics. Mass communication media, such as radio, television, and the Internet, have established social marketing and advertising as important tools for health communication, with ever-broadening horizons in the 21st century.

Effective communication channels are critical to the success of public health programs targeting health behavior change at the individual, community, or population level. Communicating consumer health information is vital as it enables people to be aware of their health status and needs and to make informed decisions about a variety of issues such as adopting a healthy lifestyle, seeking treatment, and choosing suitable health insurance benefits, health retirement plans, and long-term care. In a public health context, it encompasses the areas of disease prevention and health promotion to improve the quality of life as well as the formulation of the health policies that support mass communication of healthcare strategies to individuals, communities, and the public. The targets of health communication can be individuals, as in physician–patient relationships; communities or specific ethnic or racial groups, as in many local and state programs or research-based interventions; or the population in general, as in national programs such as the abstinence program. Health communication should be culturally and linguistically targeted to reach all ethnic groups and written in a way that can be easily understood.

Effective communication is also vital for a successful physician–patient relationship. The explosion of information technology and easy access to the Internet has widened the use of these portals as

providers of health information. However, as information available electronically is unregulated, it may be unreliable. Such information can be misleading and even harmful if not properly understood by lay people. People have great faith in public communication channels and tend to blindly accept what is reported.

Communication partnerships, usually forged between organizations serving similar clients and settings, create functional linkages that avoid replication of services, ensure uniformity in message creation, synergize expertise and effort, and are more cost-effective and successful.

Objectives

The objectives of health communication need to be clearly identified before designing and implementing programs. The two fundamental objectives are to promote change in individual behavior and to promote change in larger groups or the environment, such as in the workplace or at the local, state, or national level. At the individual level, two types of communication interventions are commonly used. In *informed decision making*, information is given to enable a person to make better health decisions, a method commonly used in medical care. *Persuasion-oriented communication* aims to convince people to change their health behaviors for the better. This approach is useful in public health interventions that promote well-established, evidence-based programs such as cancer and blood pressure screening, weight reduction, and the prevention of sexually transmitted infections. For the second objective of promoting change in large groups or the environment, *advocacy interventions* involve policy change or changes in the laws at various levels. Examples of these interventions are mandatory seatbelt and child seat use and improving safety and working conditions in the workplace.

Communication Theory and Health Behavior Change

Communication has several levels of interactions: (a) *intrapersonal*, or how people process information for themselves; (b) *interpersonal*, or

how two individuals influence each other; (c) *group dynamics*, where many people interact and influence one another; *organizational*, which can be public, private, or collaborative; and (d) *community or population*, where communication influences societal change on important issues.

Health behavior change models use communication theories extensively. The *health belief model* and the *theory of reasoned action* both rely heavily on communication methods to encourage individuals to adopt healthy behaviors. Other theories such as the *social cognitive theory*, *diffusion theory*, and the *transtheoretical model* are used as catalysts for health behavior change at the population level by using communication channels that influence an environmental as well as individual acceptance of better health habits. The *consumer information processing model* works on the premise that humans seek information only when motivated to do so. According to its concepts, to make health information acceptable to consumers, it must be readily available and perceived as innovative, helpful, and easily processed or adaptable.

Interpersonal communication is the common channel of communication used in health research and dissemination: Information and advice from peers or healthcare personnel about an innovation often carries more weight in a decision to change than merely reading or hearing about it from impersonal sources. This method is used in the community-based *participatory action approach* to provide successful and sustainable public health dissemination strategies.

Applied communication perspectives are used in public health to assess how communication strategies can negatively influence human behavior, exemplified by tobacco and fast food advertising, or positively influence behavior change, as seen in the success of antitobacco campaigns and the promotion of condom use. Empirical studies involve the application of scientific methods to study the effects of a communication strategy, as is frequently used in public health. Critical studies are more broad based as they apply methods of cultural, literary, or normative criticism to the study of outcomes on how health-related media content influences behavior change.

Methods

Health education, which is focused on improving individual health behaviors by providing information and instruction, is the most commonly used mode of health communication. The source of such messages can be from healthcare professionals, public and private clinics and hospitals, community health centers, libraries, school and worksite programs, television, radio, newspapers, magazines, pamphlets, brochures, and posters. Printed materials are readily found in most public health agencies, private practitioner offices, healthcare institutions, and voluntary health organizations. The use of outdoor media—billboards and signs, placards on commercial transport such as trains and buses, flying billboards, blimps, and skywriting—may have a fleeting impact. The mass media are useful tools for the transfer of information, concepts, and ideas to both general and specific audiences with the main functions of education, advocacy, and shaping public relations. However, mass media use is expensive and often sensationalizes the messages to increase the number of viewers. *Social marketing* is a large-scale activity that uses business principles to create mass media campaigns targeting population groups with messages for positive behavior change.

The triad of information, education, and communication (IEC) is a well-accepted continuum promoted by the World Health Organization (WHO) for reproductive health programs. The IEC campaigns aim to forge links with existing programs and organizations to reinforce channels of communication and incorporate local community traditions into the communication strategies to enhance acceptability. The campaigns also advocate using the audience segmentation technique—in which the audience is chosen from people with similar demographic and cultural norms—for better health communication. This approach exemplifies the use of sound, social-marketing techniques and behavioral-research strategies to craft targeted messages that are short, sharp, attention grabbing, and easy to adopt.

Telehealth is geared to support a variety of health professionals involved in health communication, including physicians, nurses, public health professionals, and health administrators. Provision

of long-distance, clinical care is gaining popularity because it is convenient and saves time and costs. *Telemedicine* (a subset of telehealth) is confined to the use of telecommunications and computer technologies in clinical care. Physicians of all specialties can use *teleconsulting* at the local, national, and global levels. Earning continuing medical-education credits through the Internet is an increasingly accepted method for healthcare professional organizations and is gaining popularity owing to its ease of accessibility.

Health communication between health professionals is just as important to maintain awareness of the latest trends and developments and the needs of the healthcare sector. Electronic communication networks form the backbone for fast, inexpensive sharing, reporting, and dissemination of public health information. These networks are particularly useful for communicating between agencies and to the public during public health emergencies such as natural disasters and epidemics.

Hallmarks of Effective Communication

Effective communication is critical to the success of programs targeting health behavior change either in individuals or at the population level. Communication strategies are cost-effective only if the desired impact is achieved. Exploratory audience research during program development will identify the incentives and barriers to be addressed in communication strategies and the most acceptable sources of information for and channels of communication to the target population. Pretesting the final products and incorporating suitable recommendations ensures that the message is consumer-friendly, culturally appropriate, and understood by most people. Audience research at the end of a program is useful in evaluating the impact of health communication, identifying shortcomings, and redesigning it for wider, more effective dissemination.

It is important that communication be reliable and based on evidence derived from formative evaluation and communication research in the targeted population. Research shows that public health information dissemination is most successful when multiple communication channels are employed. A multidisciplinary approach that uses

the media, academia, government, policymakers, private organizations, and community collaboration as vehicles for dissemination is most likely to result in positive health behavior change. Integrated efforts have a symbiotic effect and are sharply focused, more cost-effective, and more likely to have a sustainable impact. A preliminary needs assessment should be conducted, before beginning a new initiative, using a mixed methods approach to gather information on devising a communication strategy for the target audience. Ongoing process evaluation allows for suitable modifications throughout the course of a program. An outcome evaluation is conducted to assess the impact of the program in changing the patterns and attitudes of the study population during the health intervention.

Media communications has a critical role to play in public health, which aims to influence individual behaviors in large segments of the population. Because they are believed to provide factual and evidence-based information, those messages from respected and legitimate media, organizations, and academia have a huge public impact in inducing or inhibiting behavior change. Successful health promotion campaigns have communication channels that are audience oriented, gender friendly, culturally sensitive, and easily understood by the public. Creation of such strategies is possible through multidisciplinary approaches involving input from media sources, journalists, public health and medical professionals, academics, policymakers, and most important, people from all segments of the target audience.

Future Implications

In effect, health communication must play an integral role in public health and medical practice, with special attention to meeting the needs of vulnerable populations. Knowledge of health communication theories and practices is essential for healthcare professionals, health policymakers, politicians, and collective action groups seeking to develop cost-effective, consumer-oriented strategies that will have a maximal impact on personal or mass health and healthcare. Efforts are under way to enunciate certification, quality assurance, and ethical standards for people and organizations

involved in health communication practice, research, and training.

HEALTH DISPARITIES

Health disparities are major differences or inequalities in health status between majority and minority groups within a population. Health disparities

also refer to differences between groups in access to health services or treatments and in the quality of services or treatments received. They may be caused by differences in gender, race, socioeconomic status, or insurance status or by higher environmental and behavioral risks. Ethnic and racial minority groups in the United States disproportionately experience poorer health status. Health and healthcare disparities often derive from and are embedded in the larger historical, geographic, demographic, sociocultural, economic, and political context.

Barriers to Addressing Healthcare Disparities

Barriers to accessing healthcare stem from many factors: personal, financial (uninsured or underinsured), language, geographic, sociocultural, the institutional arrangements of health systems, and the legal, regulating, and policy environment. Some of these factors may produce inconvenience and frustration, while others may actually prevent people from getting the healthcare they need. These barriers vary with population, location, and political situation and should be assessed by each community, especially those with medically underserved populations.

Overview

The basic contours of socioeconomic and ethnic and racial disparities in health are wellknown. Socioeconomic status is inversely correlated with virtually all the major indicators of health status, including functional impairments, self-rated health, and disease-specific morbidity and mortality. Moreover, research demonstrates that socioeconomic position in society is linked to health through a variety of pathways, including access to care, environmental exposures, and life stressors. Race and class are codeterminants of disparities in health, each having its own additive effect. Healthcare disparities are arguably a major cause of health disparities; they include poorer access to healthcare services and poorer quality of the healthcare services received. One explanation for the relationship between access to healthcare and health status for low-income minority groups is that they have less access to and make

less use of healthcare services (including preventive care), and therefore, they suffer worse health status. For instance, minority groups may be less likely to have a usual physician or source of care, that is, a specific primary-care physician. Not having a usual physician or usual clinic for routine healthcare may be due to a variety of factors such as lack of participating medical providers, lack of knowledge or trust in the medical system, lack of understanding about the importance of preventive care, lack of financial resources, or a combination of these factors. The explanations and specific causal factors are likely to vary for each group.

Disparities in Access

Existing disparities in healthcare access based on minority status, health status, and urban versus rural status are well documented. National surveys have consistently found that Blacks, despite their lower ambulatory-care use and lower access to a usual source of care, were less likely than Whites to report problems in getting needed care and were also equally likely to report that they were very satisfied that their family could get the healthcare they needed. In contrast, Hispanics were more likely to report problems with family members getting needed treatment and less likely to report problems getting care for themselves. There are, in other words, different perceptions of access difficulties between groups.

Getting some healthcare is different from getting the healthcare the individual needs, and this is related to the issue of the quality of the healthcare received. Access to poor-quality care may still leave an individual with unmet needs and, therefore, not truly achieving access to needed care. Knowledge, health literacy barriers, and patterns of use are affected by cultural norms, and these also affect the utility of proxy measures of access (e.g., a usual source of care).

A national telephone survey in 1991 found that 16% of all respondents lacked a regular source of ambulatory care. Other national surveys between 1987 and 1996 showed a wide range, from 6% to 45%, of uninsured persons reporting problems getting needed healthcare. Between 1994 and

1997, nearly one quarter of all American families reported that it had become more difficult to get medical care, and in the same surveys, Blacks or Hispanics and young adults were more likely to report worsening access to care. Another study found that where an individual lives matters as well: Only 15% of the variation across communities in getting necessary healthcare was accounted for by differences in the characteristics of the uninsured (e.g., their health status, age, gender, family income, and ethnicity or race). Also, the pattern of variation in access for the uninsured and privately insured, in terms of their ability to obtain needed healthcare, does not correlate, meaning that the communities with relatively high levels of access problems among the uninsured do not necessarily have the highest levels of access problems for the privately insured. These studies documented disparities in access, but they did not examine what factors most highly correlate with these disparities. In addition, a lack of standardization and methodological differences in measuring access makes it virtually impossible to draw any conclusion from the various surveys about trends in unmet health needs over time.

Different populations face various combinations of barriers to accessing healthcare. For instance, members of ethnic and racial minority groups may face barriers due to stereotyping prejudice as well as distrust owing to historic and personal social conflicts or misunderstandings. Low-income populations may face difficulty with finances, child care, getting appointments, and medical debt. Underserved and rural populations may struggle to find a physician in their area or have to travel long distances to get the healthcare they need. Recent immigrants may have more difficulty navigating the bureaucratic red tape of an unfamiliar healthcare system, compounded by language and cultural barriers. A typical example is recent immigrants of an ethnic and racial minority who have low incomes and live in an underserved area. Barriers to healthcare services are a cause of healthcare disparities and are a factor in health disparities between different socioeconomic groups in a population. Healthcare disparities (differences in the amount and type of healthcare available and received) are arguably a major cause of health disparities.

Barriers to Healthcare

Barriers to access are those factors that contribute to preventing a person from using a healthcare service when needed. Although researchers have speculated on the barriers to access faced by various ethnic and racial groups, few have quantified or characterized the number and severity of the barriers faced, nor have they correlated them with the probability of achieving access to needed healthcare services. Researchers have noted that many of the existing disparities remain unexplained, presenting a challenge to the development of policies to eliminate them. While the variation in health insurance coverage is the most studied, possible explanation and a key area of emphasis for recent health policy reforms, other studies suggest that variations in health insurance coverage may be only a small part of the explanation.

Many studies have shown significant ethnic and racial differences in experience with, access to, and use of care in health plans; however, few of these studies have focused specifically on the free-clinic populations. In fact, many focus on insured populations and the disparities that persist even between people with the same insurance coverage. In addition, few studies have tried to further define or explain the cause of these differences, and those that have, have had limited success.

There have been a number of different approaches to measuring these barriers. One study did a door-to-door survey of people living in poverty asking about what they perceived to be personal barriers to accessing healthcare services. In that population, 74% reported having more than one barrier. The researchers found that the most common barriers were the lack of information about free or reduced-cost healthcare, anticipated costs, and the difficulty of accessing child care. Barriers were similar for working and nonworking residents, with the exception that transportation was more of a barrier for the nonworking. This study, however, only recorded the reported barriers and did not correlate them with any measures of access to healthcare. Other researchers have attempted to construct questionnaires to measure the barriers to healthcare faced by parents of children with chronic health conditions. One group of

researchers has developed a 41-question survey instrument that divides barriers into 5 subscales: (1) skills, (2) marginalization, (3) expectations, (4) knowledge and beliefs, and (5) pragmatics.

Other researchers have divided healthcare barriers into supply and demand sides: characterizing them and suggesting policies for addressing them as market failures. They found that while demand-side barriers may be as important as supply-side factors in deterring patients from obtaining care, relatively little attention was given, either by policymakers or researchers, to ways of minimizing their effect. These barriers are likely to be more important for the poor and other vulnerable groups, where the costs of access, lack of information, and cultural barriers impede them from benefiting from public spending. In this entry, demand-side determinants are defined as those factors that influence demand and that operate at the individual, household, or community level. Table 1 presents some examples of demand-side, demand and supply interaction, and supply-side barriers to healthcare.

Correlating Barriers and Access

There are many factors other than insurance that affect access to healthcare, and access in the United States varies between populations and by the type of care needed. The preponderance of the research to date shows that local-area economic indicators, income, and demographic characteristics are the most important factors, while level of education attained explained little about access to healthcare. It is important to understand that there are significant, noninsurance barriers to achieving access, including transportation, language, ethnicity, and immigration status. It is also important to understand that barriers have differential impacts on different populations.

Severity of Different Barriers

The severity of barriers to healthcare can also differ. These barriers include the following: finances (including cost, insurance, and debt), beliefs and knowledge, prejudice and racism, health status, and other barriers. Each of these barriers is discussed below in more detail.

Finances

Health insurance coverage is a major factor in accessing healthcare services. In 2007, there were an estimated 45.7 million uninsured Americans below the age of 65 (about 18% of the population). Specifically, 13% of Whites were uninsured, while 17% of Asians, 22% of Blacks, 33% of American Indians, 36% of Hispanics, and 15% of multiracial persons were uninsured.

Poverty and cost issues are also a major factor in accessing healthcare services. In 2005, 13% of Americans were living in poverty. The poverty rate for Whites was 8.2% in 2006, compared with 24.3% for Blacks, 10.3% for Asians, and 20.6% for Hispanics. Financial resources have a direct effect on access to healthcare, but they also have an indirect effect as they are the best proxy measure for “class” (poverty vs. middle or upper class), which is a risk factor that is highly correlated with racial disparities. A recent national survey found that 55% of the respondents who owed money for medical bills found it harder to get medical care, and 33% had been denied medical care because they owed money for past treatments.

Beliefs and Knowledge

A study in Los Angeles, California, found that homeless persons are willing to obtain healthcare if they believe that it is important, and better health outcomes were associated with having a usual source of care. In the field of emergency medicine, there is an ongoing debate regarding who should use the hospital emergency department as their usual source of care—a costly and arguably inefficient pattern of use. However, there are little accurate national data on the prevalence of such usage. One study used the National Center for Health Statistics’ (NCHS) 1998 National Health Interview Survey to estimate the number of Americans who name the hospital emergency department as their usual source of care, and compared their characteristics with those of people who have a usual source of care other than the emergency room. It found that 1.7 million or 0.9% of Americans reported that the hospital emergency department was their usual source of care. Those individuals tended to have the following characteristics: low income, lack of health insurance coverage, younger age, male gender, and a member of an ethnicity or racial minority group.

Table 1 Supply and Demand Barriers to the Utilization of Healthcare

		<i>Example of Barrier</i>
Demand side	<ol style="list-style-type: none"> 1. Information on healthcare choices and providers 2. Education 3. Indirect consumer costs <ol style="list-style-type: none"> a. distance cost b. opportunity cost 4. Household preferences 5. Community and cultural preferences, attitudes, and norms 6. Price and availability of substitute products and services 	<ol style="list-style-type: none"> 1. Lack of knowledge about providers 2. Low ability to assimilate health choices and negotiate access to appropriate providers 3a. Lengthy and time-consuming travel to care facilities b. Need for patient (and caretaker) to leave work for long periods to obtain care 4. Asymmetric control over household resources 5. Reluctance to seek healthcare for women outside the home; community resistance to using modern medical care to assist with pregnancy 6. Patients seek treatment through providers that are inappropriate for their condition, such as drug sellers
Demand and supply interaction	<ol style="list-style-type: none"> 1. Direct price of a service of a given level of quality (including informal payment) 2. Quantity rationing 	<ol style="list-style-type: none"> 1. High cost of services; large, unofficial payments to staff 2. Long waits to see medical staff
Supply side	<ol style="list-style-type: none"> 1. Input prices and input availability <ol style="list-style-type: none"> a. Wages and quality of staff b. Price and quality of drugs and other consumables 2. Technology 3. Management and staff efficiency 	<ol style="list-style-type: none"> 1a. Absenteeism, staff not attracted to the area b. Scarcity of supplies, weak cold chain 2. Inability to treat disease with given technology 3. Poor quality of management training, lack of management systems

Prejudice and Racism

Ethnic- and racial-minority populations experienced worse primary care, particularly in the first-contact aspect, than did White Americans. Their usual sources of healthcare were more likely to be hospital settings than private clinics. They faced greater barriers accessing their usual source of care, finding it more difficult to get an appointment and waiting longer during an appointment. Many of the significant differences persist even after adjustment for sociodemographic and health status characteristics.

Ethnic and racial healthcare disparities in primary-care experience are not simply a reflection

of sociodemographic and health status differences across ethnic and racial groups. Prejudice and the history of segregation persist in health disparities today: The primary care provided to Blacks and Whites continues to be, to a large extent, more separate and unequal than hospital care and may contribute to persistent disparities in referrals for diagnostic and specialized procedures.

Immigration status has a huge effect on access to healthcare services, as well: In Los Angeles, California, only 17% of native-born citizens are uninsured, while 41% of foreign-born, legal residents and citizens are uninsured, and 68% of undocumented immigrants are uninsured. One study found that racial disparities in healthcare

are not explained by the commonly cited access factors.

Interestingly, self-reported discrimination is also significantly associated with physical and mental health. In a national sample of adult Americans, persons who reported a high level of day-to-day discrimination had more than twice the odds for major depression and more than three times the odds for generalized anxiety disorders as people who did not, regardless of their race.

Health Status

Although many of the healthcare needs of individuals with disabilities are similar to those of people without disabilities, the presence of a disabling condition can place the individual at greater risk than the general population for secondary conditions, greater use of downstream services, increased need for durable medical equipment such as wheelchairs, functional decline, decreased independence, and psychological distress. A study of another at-risk population, children with special healthcare needs, showed that they have higher levels of unmet needs for medical services than the general population. In addition to the importance of insurance, children are vulnerable because of their social circumstances (e.g., poverty) and have significantly greater odds of having unmet needs for routine and specialty physician care.

Other Barriers

Barriers in areas such as communication with healthcare providers, provider availability, employee's ability to get time off from work, and the availability of child care services have not been adequately studied. Ethnic disparities in healthcare are largely explained by differences in English language fluency (e.g., between Spanish-speaking Hispanics and other non-Hispanic groups). Millions of American children also lack access to healthcare because of poor transportation systems: Their parents may not have a car, and in many locations, particularly in rural areas, there is little or no available public transportation.

Future Implications

Groups of people face health disparities, at least in part, because they face more barriers to accessing good healthcare. Therefore, by eradicating the barriers to healthcare that some groups face, society can reduce the health disparities. The important question society needs to address is, What barriers are the most severe in terms of preventing people from getting the healthcare services they need? Although much research has been done documenting the disparities in health and access to healthcare, and many surveys have asked about the barriers people face, very few have correlated these barriers with health services use, and none have looked at a correlation between the number, type, and severity of barriers faced and the probability of achieving access to needed healthcare services. Clearly, much research needs to be conducted in the future.

HEALTH ECONOMICS

Health economics is the study of the supply and demand of health and healthcare services. While there are many types of healthcare services, health economics focuses on those related to medical care even though factors such as diet and exercise may be equally or more important determinants of health. Health economics provides a framework for identifying the determinants of the supply and demand for healthcare services and describes how the structure of the market for these services interacts with the supply and demand to determine the price and quantity of healthcare services. Defining the efficient use of healthcare services and how it can be achieved is the ultimate, normative goal of health economics. The second major focus of health economics is the broader study of the supply and demand of health. Notably, there is no market for health per se, and the supply and demand for health is largely determined by individuals.

Supply and Demand of Health

A key distinction in health economics is that between health and healthcare. There is no market for “health” where health can be purchased. Instead, health is produced by individuals and families using healthcare services, time, and other market goods such as exercise. This focus on health production is the basis of the *human capital model* of health. Moreover, health is a *durable good* that yields a flow of services over time. As such, health depreciates with time as an individual grows older. Purposeful changes in health are achieved through investments in health, such as the use of healthcare services and time spent exercising. Therefore, health at any particular age is a consequence of all past investments in health and past rates of *health depreciation*.

Another important tenet of health economics is that health is simultaneously a *consumption good* and an *investment good*. As a consumption good, good health is valued by the consumer for the physical pleasure it brings and for facilitating the enjoyment of life’s other activities. As an investment good, however, good health also enhances a person’s ability to learn and earn, which leads to greater consumption of all goods. In addition, because health is a durable good that yields a flow of future services, health is similar to other types of investments that require initial outlays in return for future benefits.

The canonical model of the supply and demand for health was developed in the early 1970s. In this model, a consumer desires health and other goods and chooses the optimal amount of health and other goods depending on the price of those goods. The unique thing about health, however, is that it is not purchased. Health is produced by the consumer using medical care, time, and other goods. The price or supply of health is determined by the cost of producing health, which depends on the costs of inputs used to produce health such as the cost of a person’s time (e.g., wage), price of medical care, and productivity of inputs used to produce health. The optimal amount of health, or the optimal stock of *health capital*, is chosen to equate the *marginal benefits* to the *marginal costs* of health capital. The marginal benefits of health are the discounted lifetime benefits of an additional unit of health capital and include the psychic

value of better health and the increase in earnings resulting from better health. The marginal costs of health are the costs of investment in health.

The human capital model of health results in three main predictions that can be used to explain differences in health. These predictions relate to the relationships between the depreciation of health capital and health, wages and health, and education and health. The first prediction from the human capital model of health is that higher rates of depreciation of health capital will cause health to be lower. The rate of depreciation of health increases with age, and therefore, health decreases with age. At some point, the consumer will find it too costly to offset the growing rate of depreciation (sickness), and health will deteriorate to the point of death. Rates of depreciation may be lower because of genetic and biological factors, which are largely impervious to social intervention, or because of environmental factors, which are amenable to social intervention. For example, government programs that improve the physical and social environment of people may reduce the rates of depreciation of health and result in an increase in health. The rates of depreciation are likely to be higher and health worse in less developed countries because of harsher environments and the biological disadvantages resulting from poorer maternal health.

The second prediction is that higher wages will improve health. Higher wages increase the marginal benefits of health by increasing the value of earnings capacity resulting from better health. Therefore, persons with higher earnings capability will invest more in health and be healthier. Higher wages also imply greater lifetime wealth and better health.

Finally, education will be positively associated with health. Those with more education will be more productive at producing health, which lowers the cost of investing in health. Thus, more educated persons will be healthier. Moreover, because more education raises wages, those with more education will invest more in health because being healthy and able to work will be more valuable.

Recently, researchers have developed an alternative model of the demand for health; it emphasizes several issues that, historically, had been largely ignored by health economists. This model focuses on the *complementarities* that affect the demand for health. Most important, those with a greater life expectancy will invest more in health and be

healthier than those with a lower life expectancy. This point is most easily illustrated in the context of the differences in health between the developed and less developed countries. Persons in less developed countries have relatively low life expectancy. They are more likely to be affected by a variety of illnesses and accidents and to die at a relatively young age. Therefore, their incentives to invest in health, the benefits of which occur in later life, are lower than for persons in more developed countries with higher life expectancy. A similar dynamic occurs between ages and between diseases. Raising the expected probability of surviving childhood increases the incentive to make investments that improve health at older ages. Advancements in treating one disease increase the incentive to make investments in health that decrease the probability of contracting other diseases.

In summary, the human capital model of the supply and demand of health provides a useful framework to analyze and explain observed differences in health and the potential value of health interventions. The human capital model of health is relevant to the most salient health policy issues such as racial and ethnic health disparities and how to improve the health of developing countries. Researchers have widely used the human capital model of health to assess the importance of different determinants of health, most notably medical care and education.

Supply and Demand of Healthcare Services

The second major focus of health economics is to analyze the market for healthcare services, in particular physician services and hospital markets. Kenneth Arrow wrote the seminal article for this topic in 1963, which provides an early description of what makes the market for healthcare services unique. Several aspects differentiate the health services market from the standard economic model: (a) the uncertainty of demand caused by the uncertainty of illness; (b) the absence of free entry and exit of firms; (c) the dominance of non-profit firms, particularly in the hospital industry; and (d) the nonobservability of quality of care. In sum, these factors clearly describe the ways in which the market for health services departs from the simple, competitive model of supply and demand.

Perhaps the most important departure from the competitive model is the fact that providers have market power—that is, competition does not drive the price of healthcare to marginal cost. Market power stems from several sources, with the first being the personal relationship between the patient and the provider. Patients may be comfortable with and trust a specific physician, making them reluctant to switch providers. This gives the provider some power to price above marginal cost, as consumers do not choose providers solely on the basis of price. In addition, market power stems from the patient's lack of information about his or her health and healthcare needs. The physician has better information about the patient's illness and treatment (quality and quantity of care) than the patient. The physician is the patient's agent, and this lack of information ties a patient to a provider. The physician is likely to have better information about the nature and type of illness than even the insurer, and therefore, even third-party payers cannot obtain prices that equal marginal cost. Finally, because information is costly to obtain, search costs are significant, and third-party insurance deters patients from obtaining better information about the prices and quality of providers.

The ability of providers to price above marginal cost is one of the most widely studied issues in health economics. Some of the narrower topics of interest in this area are (a) whether providers can induce demand (i.e., get consumers to use services that are unnecessary); (b) whether physicians respond to financial incentives in ways that are not clinically appropriate; (c) understanding the effect of competition, mergers, and concentration on physician and hospital prices; and (d) understanding the effects of government regulation on the prices, quality, and quantity of physician and hospital services.

The dominance of nonprofit firms in the hospital industry is also a major concern of health economics. Few other industries in the United States are characterized by a mix of for-profit and nonprofit firms as is the hospital sector. Health economics seeks to explain this characteristic of the market. There are several prominent explanations for the dominance of nonprofit hospitals. The first arises from asymmetric information, which has promoted a greater level of trust in nonprofit hospitals than in for-profit hospitals. Because the consumer does not

know his or her diagnosis, the optimal course of treatment, or the quality of care provided, the consumer may trust a nonprofit hospital more because it does not appear to have the same financial incentives to exploit this lack of information. While nonprofit status, therefore, is a signal of trust and implies higher quality of care, this explanation is inconsistent with the for-profit physician services market where information asymmetries are equally important.

The second explanation for the dominance of nonprofits is due to their provision of a *public good*. The positive externalities or social benefits associated with medical research, public health, and uncompensated patient care requires public subsidies. This explanation suggests that for-profit firms are only interested in profit and will not undertake the production of goods beneficial to the community, whereas nonprofits can make the production of these goods goals of the organization. This is inconsistent, however, with the absence of regulatory oversight about the nature of nonprofit hospitals' output (e.g., there is no requirement that uncompensated care be provided).

Finally, *cartel theory* or *interest group theory* has also been used to explain the dominance of nonprofit hospitals. This explanation is predicated on managers, physicians, employees, or other stakeholders running the hospital for their own gain (for-profits in disguise). Nonprofit status allows surplus or profit to be larger than in for-profit enterprises because of public subsidies that lower costs. Nonprofit status makes it easier to "hide" rent due to the diffuse nature of ownership where there are no explicit shareholders.

There is still much debate over which of these explanations is the most appropriate, and research suggests that there is little difference between for-profit and nonprofit hospitals in terms of the quality of care they deliver and the amount of charity care they provide.

Health Insurance

A third major focus of health economics is examining the demand for and consequences of health insurance. The uncertainty of illness is one of the most important features that characterize choices regarding health and healthcare. The study of insurance in health economics builds on a long

tradition in economics, dating back to Arrow's study in 1963, that studies the effects of uncertainty on economic decisions.

The demand for health insurance stems from the uncertainty associated with illness and disease. It is assumed that consumers are risk averse and that people prefer a sure bet to a risky outcome even if, on average, the two alternatives would leave the consumer equally well off. Consumers are, therefore, willing to pay to reduce risk; insurance is a good that reduces the financial risk—and to some extent the physical risk—associated with illness. Health economics uses this simple theory of insurance to analyze patterns of insurance and why people do or do not have insurance. Consumers are expected to purchase more health insurance as the potential loss from illness (i.e., the severity of illness) increases, as the uncertainty of illness increases, and as an individual's level of risk aversion increases.

There are two major issues that dominate the study of health insurance: *moral hazard* and *adverse selection*. Moral hazard is the term used to describe a change in consumer behavior due to insurance. In the context of health insurance, there are two types of moral hazards, *ex ante* and *ex post*. *Ex ante moral hazard* refers to taking action that changes the probability or severity of illness. Insured persons may invest less in preventing disease or the severity of disease because health insurance will pay for the costs of treatment. There is little study of the extent of *ex ante* moral hazard on the prevalence of illness. *Ex post moral hazard* refers to actions the consumer takes after contracting a disease. Insurance may lead them to consume more healthcare services than they otherwise would. The latter type of moral hazard raises the cost of insurance, which will cause some people to be uninsured. The extent and consequences of *ex post* moral hazard is one of the most widely studied issues in health economics.

Adverse selection refers to the view that consumers pay the wrong price for health insurance. From an economics perspective, the price that the consumer pays for health insurance should reflect the true risk of illness: Those with a greater risk of illness should pay more for insurance than those with a lower risk of illness, because those with a greater risk of illness could end up using more healthcare services. The risk of illness, however, is not fully

observable and this results in pricing such that some consumers, usually the healthy, pay relatively more for insurance and other consumers, usually the sick, pay relatively less for insurance. A consequence of adverse selection is that it—in addition to other factors—causes the price of insurance to be high, which may contribute to the numbers of the uninsured. Probably the most important reason why there are uninsured persons in the United States is that the price of insurance is often too high.

Future Implications

After nearly 50 years of analysis, many of the basic questions that are central to health economics remain largely unanswered. For example, there is still much debate over what determinants of health are the most important, and therefore, what accounts for differences in population health within and between countries. Related to this is the question of how population health affects economic growth. Will improvements in population health lead to faster rates of economic growth and subsequent improvements in health? How important is population health to economic growth? Similarly, there is relatively little, credible research on the consequences of competition in physician services and hospital markets. Does hospital concentration result in higher prices and lower quality of care, or does it lead to lower costs because of greater economies of scale? And it is still not known whether nonprofit or for-profit hospitals provide better care. In the near future, research in health economics will continue to try to answer these fundamental questions. Furthermore, in the future, health economics is likely to continue to integrate advances in medical science in the areas of genetics and neuroscience to improve and expand analyses of the supply and demand of health and healthcare services. Medical science may also change the landscape for health insurance as the risk of illness becomes more knowable.

HEALTH INDICATORS, LEADING

To create national policies to alleviate health problems, it is imperative to define what constitutes a healthy population. Before evaluating

health, those who are assessing health status must develop a mutually agreed on set of measurement tools. One of the best-known and most widely used sets of health indicators are those developed by the federal government's Healthy People 2010 initiative. The initiative identified a set of *leading indicators* based on their ability to initiate action and measure progress. Specifically, it defined 10 leading health indicators with the objective of measuring the health status of all individuals in the United States over the 10-year period from 2001 to 2010. The 10 leading health indicators are (1) physical activity, (2) overweight and obesity, (3) tobacco use, (4) substance abuse, (5) responsible sexual behavior, (6) mental health, (7) injury and violence, (8) environmental quality, (9) immunization, and (10) access to health-care.

Healthy People 2010

The Healthy People 2010 initiative is a broad set of health objectives for the United States to achieve over the first decade of this century. The initiative is designed to be used by many different population groups, communities, and professional organizations. The initiative attempted to develop various programs to improve population health. Healthy People 2010 identified leading health indicators that represent the major public health concerns the nation faces in the first decade of the 21st century. Each of the leading indicators depends on the information individuals have about their health.

Development of the Leading Health Indicators

Selecting leading health indicators involved a large interagency task force from the U.S. Department of Health and Human Services (HHS). Additionally, many associations and professional organizations provided comments and analysis at various task force meetings and communicated with it via e-mail and through the Internet. The National Academy of Sciences, Institute of Medicine (IOM) conducted a study, using scientific models, to support a given set of indicators. This systematic approach in determining the

leading health indicators legitimized the importance and significance of the resultant measures of the population's health.

The 10 Leading Health Indicators

1. *Physical Activity*

Physical activity is an important leading health indicator because it is crucial for maintaining a healthy body, enhancing psychological well-being, and preventing early death. In 1997, 63% of adolescents engaged in the recommended amount of daily physical activities: about 20 minutes of vigorous physical activity, 3 or more days per week. During the same year, 15% of adults engaged in the recommended amount of activity: 30 minutes of moderate daily physical activity, 5 or more days per week. The goal is to increase the proportion of the nation's adolescents and adults who engage in daily physical activities.

2. *Overweight and Obesity*

Being overweight and obese are major contributors to many preventable diseases (e.g., heart disease, stroke, diabetes, and hypertension). Higher body weights are also associated with higher mortality rates. Objectives for the future are to reduce the proportion of children, adolescents, and adults who are overweight and obese. Efforts to maintain a healthy weight must start in childhood.

3. *Tobacco Use*

Cigarette smoking is the single most preventable cause of disease and death in the United States: Smoking results in more deaths each year than AIDS, alcohol, cocaine, heroin, homicide, suicide, motor vehicle crashes, and fires combined. Objectives for the future are to reduce smoking rates in adolescents and adults.

4. *Substance Abuse*

Alcohol and illicit-drug use are associated with many of the nation's most severe problems. Alcohol abuse alone is associated with motor vehicle crashes, homicides, suicides, and drowning deaths. A current goal is to increase the number of adolescents

and adults who have not used these substances in the past 30 days. Another goal is to reduce the number of adult binge drinkers.

5. *Responsible Sexual Behavior*

Unplanned pregnancies and sexually transmitted diseases (STDs), including infection with the human immunodeficiency virus (HIV) that causes AIDS, can result from unprotected sexual behaviors. The current objectives are to increase the proportion of adolescents who abstain from intercourse or who use protection if sexually active. Another goal is to increase the proportion of sexually active adults who use protection.

6. *Mental Health*

About 20% of the nation's population is affected by mental illness during any given year. Of all mental illnesses, depression is the most common. Although mental health issues affect people of all ages, the objective here focuses only on adults because of the large quantity of available data. Adults and older adults have the highest rates of depression. In fact, major depression is the leading cause of disability and is the cause of more than two thirds of suicides each year. Depression is treatable with medication and therapy, and the goal for this indicator is to increase the proportion of adults who receive treatment.

7. *Injury and Violence*

More than 400 Americans die each day from injuries, primarily due to motor vehicle crashes, firearms, poisonings, suffocations, falls, fires, and drowning. Many factors that contribute to injuries are also associated with violent and abusive behavior such as low income, discrimination, lack of education, and lack of employment opportunities. The goals for this indicator are to reduce homicides and deaths due to motor vehicle crashes. Although these are the main goals, the initiative also aims to reduce unintentional falls, fire deaths, abuse, and assault.

8. *Environmental Quality*

An estimated 25% of preventable illnesses worldwide are attributed to poor environmental quality.

Two indicators of air quality are the ozone level and environmental tobacco smoke. The main objective is to reduce the proportion of individuals exposed to air not meeting the U.S. Environmental Protection Agency's health standards for ozone. Another objective is to reduce the proportion of nonsmokers exposed to environmental tobacco smoke.

9. Immunization

Immunizations can prevent disability and death from infectious diseases and help prevent the spread of infections within communities. The main objective is to increase the proportion of young children who receive all recommended vaccines and to increase the proportion of noninstitutionalized adults who are vaccinated annually against influenza and ever vaccinated against pneumococcal disease.

10. Access to Healthcare

Strong predictors of access to healthcare include having health insurance, a higher income level, and a regular primary-care provider or other sources of ongoing healthcare. The goals for this leading health indicator are to increase the proportion of individuals with health insurance and a source of ongoing care. Another goal is to increase the proportion of pregnant women who start receiving prenatal care in the first trimester of pregnancy.

Policy Implications

Equipped with the leading health indicators, which identify problem areas and emphasize their underlying factors, U.S. policymakers can likely better serve the health needs of the nation. To achieve certain health outcomes and to achieve the goals and objectives of Healthy People 2010, resources must be spent efficiently, effectively, and equitably. Research involving the leading health indicators will likely shape national healthcare policies for the future.

HEALTH INFORMATICS

Health informatics is the science of evaluating, implementing, and utilizing technology to manage all information related to the patient care delivery process at all levels: clinical, financial, technological, and enterprise. It is a multidisciplinary field, drawing from health information and computer science, psychology, sociology, and engineering. The history of the term, itself, is relatively recent. The Russian engineer and information scientist Alexander I. Mikhailov (1905–1988) is credited with first defining, around 1968, the term *informatika* as the field that studies the structure and general properties of scientific information and the

laws of all processes of scientific communication. The English word *informatics* began to appear in the literature in the 1970s, and throughout the 1980s, the umbrella term *health informatics* emerged to encompass the continuum of information management, information science, and computer science focused on healthcare. When applied to a specific discipline, the application of informatics is focused on solving the problems of the discipline, such as medical informatics, nursing informatics, and public health informatics.

Types of Health Informatics

Health informatics encompasses many individual disciplines, which have further refined their foci in the field. For example, *bioinformatics* researchers develop or apply computational tools and approaches for expanding the use of biological, medical, behavioral, or health data. These tools include those used to acquire, store, organize, archive, analyze, or visualize such data. *Consumer health informatics*, on the other hand, is a subspecialty of medical informatics that studies the use of electronic information and communication to improve medical outcomes and the healthcare decision-making process from a patient or consumer perspective. Similarly, *dental informatics* expands the knowledge and understanding of the biological and biomedical processes in dentistry to improve prevention, diagnosis, treatment, and follow up of diseases through the examination of information handling and processing. Another type, *health sciences librarianship and informatics*, deals with health-related information, its structure, acquisition, and use. Health sciences librarianship and informatics are overlapping disciplines with strong conceptual links to the theoretical discipline of information science.

Also within the broad field of health informatics is *medical informatics*, the field that concerns itself with the cognitive, information processing, and communication tasks of medical practice, education, and research, including the information sciences and the technology to support these tasks. *Nursing informatics* is a related specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, and knowledge in nursing practice.

Pharmacy informatics, on the other hand, focuses on medication-related data and knowledge within the continuum of healthcare systems, including its acquisition, storage, analysis, use, and dissemination in the delivery of optimal medication-related patient care and health outcomes. Finally, *public health informatics* is the systematic application of information and computer science and technology to public health practice, research, and learning.

Role of Professional Associations

Health informatics disciplines can be understood, in part, through the interests of the membership of their professional associations. As an example, the Healthcare Information and Management Systems Society (HIMSS), established in 1961, regularly holds an annual conference with published proceedings. At the 1999 conference in Atlanta, Georgia, the HIMSS attendees' foci of interest centered on the use of healthcare information systems in healthcare organizations from a business perspective, exploring ways to extract value from these systems. The conference also looked at the emergence of a number of healthcare goals, among them patient safety. By the 2007 conference in New Orleans, Louisiana, the HIMSS had added sessions on information technology standards and building stronger connections between operations and technologies. Leadership emerged as a new theme, and initiatives appeared in public policy and community health. The scope had expanded to better represent both technological and patient care perspectives. The business process focus on quality had merged with patient safety and risk management. Other emerging topics recognized the need for research in clinical informatics to identify effective and efficient clinical practices and the need for both privacy and security measures to protect healthcare data.

The innate dynamic nature of the field has challenged its ability to define the term *health informatics*. While examining nearly 800 articles retrieved by the general search term *health informatics*, researchers found that the articles were indexed by 10 common terms. Top among them were medical informatics, computer science, information systems, and healthcare sciences and services. Researchers used a set of six keywords that included the term

health informatics, and mapped conceptual changes over a period of 10 years in the MEDLINE literature database. The study found a consistent focus on healthcare, electronic medical records, and information technology topics in general.

Training and Skills

Despite its historical roots, however, it has been the emergence of academic programs across the nation that has brought some stability to the term *health informatics*. Throughout the 1990s, the rapid growth in the field led to a dearth of qualified individuals capable of guiding the development and implementation of healthcare information systems applications. System vendors and hospitals began to create formal employee positions for informaticists. Colleges and universities struggled with the creation of new curricula because they lacked a clear definition of the knowledge and skill sets necessary for individuals to work successfully in the field. Published in 1996, an examination of informatics competencies across the disciplines appeared to support a general trend: Those individuals involved in clinical informatics appeared to deal in detail with the ongoing support and development of applications, while those in health informatics appeared more focused on how applications and technology, both existing and proposed, would affect enterprise-wide production of and access to information; on management of that access; and on optimization of the information available.

By 1998, the Pew Commission recognized the effective and appropriate use of communication and information technologies as one of its 21 essential competencies for all health professionals. In 1999, the International Medical Informatics Association's (IMIA's) Working Group 1: Health and Medical Informatics Education published its *Recommendations of the International Medical Informatics Association (IMIA) on Education in Health and Medical Informatics*. In that same year, the American Medical Informatics Association's (AMIA's) spring conference used invited panels and structured breakout discussion sessions to focus on issues and predictions for health informatics education of three groups of health informatics: (1) researchers, (2) administrators, and (3) health professionals.

At the end of that spring conference, the committee's efforts concluded in the acknowledgment of the following 10 competencies as central to this diverse group of providers: (1) software use, such as presentation graphics, word processing, simple databases, e-mail, Internet searches, decision support applications, telemedicine, and home monitoring; (2) principles of interface design and human-computer interaction; (3) principles of privacy, confidentiality, and security; (4) ethical uses of information technology and ethical decision making in the digital age; (5) knowledge of terminologies, taxonomies, standards, and communication methods; (6) the importance of user-driven clinical systems and structured data to support evidence-based practice; (7) methods of evaluating information and information technology; (8) basic methods of software development—the process and how to get involved; (9) how to critically and efficiently process information; and (10) understanding the impact of technology use (and of its lack of use) on public health.

Researchers have recently reflected on three of these competencies when they described a number of core themes in health informatics: (1) establishing standardized definitions of data elements, standard languages, and commonly accepted vocabularies; (2) establishing standards for electronic data exchange; and (3) usability.

Future Implications

There is no question that the field of health informatics has grown in complexity, matching the growth in capabilities of healthcare computing. Healthcare has depended on computer technology to make important advances in the field, commencing in the 1950s—when most computer applications were for signal processing, images, and laboratory tests—through the 1970s, when the first clinical information systems emerged. Today, the social and organizational effect of technology acceptance is a major consideration. The term *health informatics* will continue to evolve, capturing the essence of the world of healthcare and information systems and incorporating ever-increasing subtleties within its definition.

HEALTH INSURANCE

Many health services researchers study the function and nature of insurance, the various types of insurance plans, and the impact of insurance on healthcare. They also study the use of health services and the outcomes of care of the insured compared with the uninsured. Researchers use

this knowledge to develop more effective, efficient, and equitable health policies.

Health insurance plays a vital role in the U.S. healthcare system. Health insurance protects individuals and their families from the high and unexpected costs of injury and illness. It provides the insured with a measure of financial security. Health insurance may cover physician fees, hospital bills, prescription drugs, medical equipment, and long-term care expenses, as well as lost wages. Without health insurance, the costs of a serious injury or major illness could easily cause financial ruin for most individuals and families. In fact, medical debt is one of the leading causes of bankruptcy in the United States.

Health insurance is an important determinant of access to care. It enables the insured to have access to preventive healthcare services and to the early treatment of injury and illness. An overwhelming body of evidence shows that the uninsured get less medical care, get it later when it is of less value and usually more urgent, incur greater morbidity, and die younger than those with health insurance.

Health insurance is the largest source of revenue for nearly all healthcare providers in the nation. It enables healthcare providers to maintain high-quality care. Revenue from health insurance allows the providers to maintain their practices and organizations, and it enables them to purchase new advanced medical technology.

Function and Nature of Insurance

There are many definitions of insurance. Most of the definitions include such terms as *risk*, *pooling of risk*, *potential losses*, and *protection against losses*. For this entry, insurance is broadly defined as a form of risk management that transfers or shifts financial risk from an individual to a group such as a private insurance organization or a government agency, where losses are pooled and spread across the group.

Not all risks are insurable. A number of prerequisites are necessary for insurance to successfully work.

First, there must be a sufficiently large number of similar exposure units to make the losses reasonably predictable. Insurance is based on the law of large numbers. For example, it may be

impossible to predict with any certainty whether a specific individual will develop a rare disease or not, but by looking at a large population of individuals it may be possible to statistically predict the total number of individuals who will develop the rare disease.

The losses produced by the risk must be measurable in terms of its cause, time and place of occurrence, and its monetary value. The monetary value for most material things can be relatively easily determined. However, the monetary value of the loss of human life is much more difficult to estimate.

The losses must be fortuitous or accidental, and not intentional.

The losses must not be catastrophic. Insurance is based on the notion that only a small percentage of individuals will experience major losses, and that the losses will be shared across the group. If all individuals experience major losses, the insurance company would not be able to cover all the losses, and it may go bankrupt. An event such as a nuclear attack would be catastrophic and the losses it caused would be so great that it is not insurable.

Last, the cost of the insurance must be affordable. If the cost of the insurance is too high, and too few individuals can afford to purchase it, there may not be a sufficiently large group to share the possible losses.

Problems Faced by Insurance Organizations

Insurance organizations face two major problems: *adverse selection* and *moral hazard*. Adverse selection is the tendency of higher-risk persons or groups to buy and maintain insurance. For example, people with poor health may be more likely to seek health insurance coverage, while those with excellent health may not. To protect against this type of adverse selection, health insurance policies frequently exclude coverage for preexisting medical conditions. However, the federal Health Insurance Portability and Accountability Act of 1996 (HIPAA) now limits exclusions based on such conditions.

Moral hazard is sometimes divided into two categories: moral hazard and *morale hazard*. “Moral hazard” describes immoral or illegal conduct, while “morale hazard” describes

changes in attitude and behavior on the part of the insured. Submitting a fraudulent claim to an insurance organization is an example of moral hazard, while buying expensive designer frame eyeglass instead of cheaper less fashionable frames because insurance pays for them is an example of morale hazard. Morale hazard may also change the attitude of persons who are not insured. For example, a physician might hospitalize a person with a less than severe illness because the person has health insurance; but if the same person was uninsured, the physician might treat him or her on an outpatient basis, because the person could not afford the cost of hospitalization.

Major Classifications of Insurance and Key Terms

There are many types of insurance. Insurance can be broadly classified based on the particular risk it insures against (i.e., fire, flood, and wind damage) or by the nature of what it insures (i.e., auto, home, life, and health). Insurance can also be classified based on whether it is provided by a private organization or by a government agency. Insurance provided by a government agency is sometimes called *social insurance*.

A number of key terms are associated with insurance: premiums, deductibles, copayments, coinsurances, and maximum out-of-pocket expenses.

Premiums are the price of an insurance plan. In healthcare, premiums are based either on *community rating* or *experience rating*. In community rating, the premium price is based on the population or group in a geographic area, and it ignores any differences among subgroups. In contrast, in experience rating the premium price is based on differences in demographics, past healthcare utilization, medical status, and other factors of various groups. Generally, insurance premiums are cheaper under community rating.

Deductibles are the amount paid out of pocket for medical services each year before insurance begins to pay. Deductibles vary greatly. Some insurance plans have no deductibles, while others have a very high deductible.

Copayments are flat fees or percentages charged each time an individual visits a physician or uses a medical service. There may be a set amount for a

physician visit, a different amount for laboratory work, and various amounts for prescription drugs.

Coinsurances are requirements that individual policyholders must pay a percentage of the total cost of care. Individuals may have to meet deductibles before coinsurance begins.

Maximum out-of-pocket expenses are the most individual policyholder have to spend before all medical bills are covered. Out-of-pocket expenses include deductibles and copayments.

Types of Health Insurance Plans

Health insurance can be classified as being provided by either a private organization or a government agency. However, many people, especially the elderly, purchase both private as well as government health insurance coverage. The elderly often purchase private, supplemental health insurance, called *Medigap insurance*, to cover the costs or “gaps” not covered by government insurance such as Medicare. Also, some low-income elderly with limited resources are *dual eligible* and are covered by two government health insurance programs, Medicare and Medicaid. Below is a brief description of the major types of private and government health insurance in the United States.

Private Health Insurance

Private health insurance began in the nation during the Great Depression. At that time, many people could not afford healthcare, and hospitals were closing. In 1929, Baylor University Hospital in Dallas, Texas, contracted with local public school teachers to provide them with hospital care. For a prepayment of 50 cents per month, the hospital guaranteed that each teacher would receive up to 21 days of hospitalization in a semiprivate room, as needed. Similar plans began forming across the country. Ultimately, these plans became Blue Cross and Blue Shield organizations. With the growing success of the Blue Cross and Blue Shield, other commercial insurance companies also began to market health insurance. During World War II, when the federal government established ceilings on wages, many employers began offering their workers fringe benefits such as paid vacations, retirement benefits, and company-financed health

insurance. With the nation’s postwar prosperity, employers increasingly offered health insurance to their workers.

Most working Americans obtain their health insurance through their employers. Health insurance is generally part of the worker’s employment benefits package. Employers offer health insurance through the workplace because of the tax advantage of doing so, because of the increase in worker productivity that results from improved health, and because health benefits allow them to recruit and retain high-quality workers.

Most employers offer their workers a selection of health insurance plans to choose from. The plans tend to vary in their scope of coverage, the cost of the premiums, and the amount of coinsurance and deductibles they require. Employers and employees generally share the costs of the insurance. Health insurance obtained through work is typically group insurance. Group insurance usually costs less and offers more benefits than individual health insurance plans.

The health insurance plans offered by most large employers generally include indemnity insurance and various types of managed-care plans. The three major types of managed-care plans are (1) health maintenance organizations (HMOs), (2) preferred provider organizations (PPOs), and (3) point-of-service (POS) plans. And some employers are beginning to offer their workers health savings accounts (HSAs).

Indemnity or fee-for-service insurance is a traditional kind of health insurance. Today, this type of insurance is uncommon. Under this type of plan, the insured individual may go to any physician or hospital to receive care. After receiving the care, the individual or the healthcare provider sends the bill to the insurance company, which typically pays a certain percentage of the bill, after the individual meets the policy’s annual deductible. For example, fee-for-service plans may pay 80% of a medical bill, leaving 20% to be paid (coinsurance) by the individual. Most plans limit the amount that the individual must pay per year (i.e., the deductible) to, for example, \$500 per year maximum.

HMOs are prepaid health insurance plans. HMO members pay a monthly premium. In exchange, the HMO provides comprehensive care, including physician visits, hospital stays, laboratory tests, and therapy. HMOs include a variety of arrangements

but consist mainly of three types: (1) the *staff model*, (2) the *group model*, and (3) the *independent practice association* (IPA). Under the staff model HMO, healthcare services are provided by a group of physicians who are salaried employees of the HMO. Under the group model HMO, healthcare services are provided by a multispecialty group of physicians who are independent of the HMO but who contract with the HMO to provide services. Under the IPA, healthcare services are provided by private-practice physicians who contract with the HMO to provide care to HMO patients in a private office setting. In most HMOs, members are assigned or choose a physician who serves as their primary-care physician. The primary-care physician monitors the patient's health, provides basic medical care, and is also responsible for referring patients to a specialist and other healthcare professionals as needed. Most HMOs do not require a deductible each year, but they do generally require a small copayment for a visit. Because HMOs receive a fixed fee per member per month, they may provide more preventive healthcare services such as immunizations, mammograms, and physicals.

The most common type of private health insurance in the United States is the PPO. PPOs are generally less flexible than traditional health insurance plans but more flexible than HMOs. Individuals or members enrolled in PPOs may go to any physician (including a specialist) or hospital to receive care, but the coinsurance is higher for health providers who are not preferred providers. Preferred providers have contracts with PPOs, and they agree to provide PPO members discounts on the costs of their care. PPOs generally require their members to obtain prior approval before entering a hospital.

POS plans combine some aspects of HMOs and PPOs. POS plans provide a range of healthcare services. Like HMOs, POS plans use primary care physicians to coordinate patient care. Like PPOs, POS plans contract with healthcare providers to provide services to plan members. However, unlike PPOs, which require members to select a preferred provider in advance, PPOs plans allow members to choose at the time they need healthcare whether or not to seek care within the plan's network of care providers or to go outside the network for care. And like PPOs, if the member goes outside the plan, they will have to pay a higher coinsurance.

The costs of POS plans are generally higher than HMOs and PPOs, but the patient has greater freedom to choose healthcare providers.

A new type of health insurance that is beginning to be offered by employers is health savings accounts (HSAs). HSAs were signed into federal law in 2003. To open an HSA, an individual must have coverage from a qualified high deductible health plan (HDHP). The employer, the worker, or both can make contributions to HSAs. However, the total contributions are limited annually. Funds in HSAs are tax free, and they are completely portable, meaning that they can be kept if individuals change jobs, become unemployed, or change their marital status. Money in HSAs can be used to pay for routine health expenses, while the HDHP covers the costs of a serious injury or major illness. Money in HSAs can be saved for future medical expenses, and it can grow through investment earnings.

Although not generally covered by employers, another type of private health insurance is long-term care (LTC) insurance. LTC insurance covers care generally not covered by other types of private health insurance or government health insurance programs. It covers individuals with disabling injuries and illnesses such as spinal cord injuries, stroke, and Alzheimer's disease. Depending on the policy, LTC insurance can pay for home health care, adult day care, respite care, and nursing home stays. The cost of LTC insurance is typically based on the size of the policy and the age and health status of the individual. About 10% of Americans over the age of 55 have LTC insurance. In 2006, the U.S. Congress passed legislation authorizing changes in state laws allowing individuals to purchase LTC insurance that coordinates with the government health insurance Medicaid program.

Government Health Insurance

The first government health insurance program in the United States was *workers' compensation*, which was adopted by the individual states during the early 1900s. Every state has workers' compensation. Under the laws of each state, workers' compensation provides medical care and compensation, regardless of fault, for employees who are injured or disabled during the course of their employment.

The Social Security Act of 1935 established the Old Age, Survivors, and Disability Insurance (OASDI) Program, commonly known as Social Security. This comprehensive, federal benefits program includes retirement benefits, disability income, veterans' pensions, public housing, and the food stamp program. The U.S. Congress amended the Social Security Act in 1965 and included the Medicare and Medicaid programs. As part of the Balanced Budget Act of 1997 (BBA-97), Congress again amended the Social Security Act and included the State Children's Health Insurance Program (SCHIP).

Medicare (Title XVIII of the Social Security Act) is the federal healthcare program that covers almost everyone in the United States age 65 years or older, individuals under age 65 with certain disabilities, and individuals of all ages with permanent kidney failure requiring dialysis or a kidney transplant. Although Medicare coverage is comprehensive, it provides very limited LTC services.

Medicare consists of four parts: Part A (hospital insurance), Part B (medical insurance), Part C (managed-care plans), and Part D (prescription drug coverage). Medicare Parts A and B are sometimes referred to as "traditional Medicare."

Medicare Part A is hospital insurance. It helps provide basic coverage for hospital stays; posthospital, skilled-nursing facility care; home health care; and hospice care. Part A is financed by payroll taxes levied on employers and employees.

Medicare Part B is medical insurance that can be purchased by paying a monthly premium. It pays most of the basic physician and laboratory costs and some outpatient medical services, including medical equipment and supplies, home health care, and physical therapy. It also pays for some preventive services such as cardiovascular screening, diabetes screening, glaucoma tests, and prostate cancer screening for individuals joining Medicare for the first time.

Medicare Part C or Part C Medicare Advantage was formerly known as Medicare + Choice plans. Individuals with Medicare Parts A and B can voluntarily choose to receive all their healthcare services from Medicare managed-care plans, which are provided through private insurance companies.

Medicare Part D is a voluntary, prescription drug coverage program that can be purchased by paying a monthly premium. The program is

offered through private insurance companies. It helps pay the costs of prescription drugs. The Medicare Modernization Act (MMA) of 2003 established Part D for all individuals entitled to or enrolled in Medicare Parts A and B. It went into effect on January 1, 2006.

Medicaid (Title XIX of the Social Security Act) is a federal-state health insurance program for individuals and families with low incomes and limited resources. Although the federal government establishes broad guidelines for the Medicaid program, each state establishes its own eligibility standards, benefits packages, payment rates, and program administration. As a result, there are essentially 56 different Medicaid programs—one for each state, territory, and the District of Columbia.

Medicaid is the largest payer of LTC services in the nation, paying about 50% of the care being provided in nursing homes. Because Medicaid has strict financial eligibility criteria, it generally requires recipients to deplete their savings, or "spend down," before it will pay for nursing home services.

Medicaid does not provide medical assistance for all poor persons, unless they are in a designated eligibility group. All Medicaid programs are required to include certain eligibility groups, but they may also include other groups as well. All programs must include three groups: (1) the categorically needy (i.e., families who meet the states' Aid to Families With Dependent Children (AFDC) eligibility requirements, pregnant women and children under age 6 whose family income is at or below the federal poverty level, individuals receiving Supplemental Security Income (SSI), and individuals and couples in medical institutions with a monthly income with a certain monthly income level; (2) the medically needy (i.e., pregnant women through a 60-day postpartum period, children under age 18, certain newborns for 1 year, and certain protected blind persons, and special groups); and (3) special groups (i.e., Medicaid pays the Medicare premiums, deductibles, and coinsurance for certain individuals who are below the federal poverty level, qualified working disabled individuals, and LTC services for individuals who are Medicaid eligible and qualify for institutional care).

Medicaid programs generally cover physicians' services, inpatient and outpatient hospital care,

nursing facility services, prescription drugs, dental care, physical therapy, rehabilitation services, and hospice care. The programs also cover pregnancy and postpartum related services and early and periodic screening, diagnosis, and treatment (EPSDT) for children under age 21.

The State Children's Health Insurance Program (SCHIP) (Title XXI of the Social Security Act) assists states in providing healthcare services to uninsured, low-income children up to the age of 19. Like Medicaid, SCHIP is jointly financed by the federal and state governments and is administered by the states. SCHIP is designed to provide coverage to targeted low-income children. A targeted low-income child is one who resides in a family with income below 200% of the federal poverty level or whose family has an income up to 50% higher than the state's Medicaid eligibility threshold. However, states differ in terms of their eligibility requirements. In some states, SCHIP is part of the state's Medicaid program; in some states, it is a separate child health insurance program, while in other states, it is a combination of the two programs. States including SCHIP in their Medicaid programs must provide full Medicaid benefits. For states with separate SCHIP programs, the states must provide primary and preventive benefits, including immunizations, well-child care, and emergency services.

The federal and state governments offer a number of other health insurance programs, and they also provide healthcare services to specific groups. For example, the U.S. Department of Defense's TRICARE program provides healthcare services to active duty military personnel, retired members of the uniformed services, and their families. The U.S. Department of Veterans Affairs (VA) provides medical assistance to eligible veterans of the armed forces. The U.S. Department of Health and Human Services' Indian Health Service (IHS) provides healthcare services to American Indians and Alaska Natives. Many state governments operate or sponsor health insurance high-risk pools that provide coverage to those who are denied private health insurance because they have serious preexisting medical conditions (i.e., cancer, HIV/AIDS). A few states (i.e., Illinois, Maine, and Massachusetts) also have established new programs to expand health coverage to the uninsured.

Future Implications

Health insurance is important for individuals and their families, and for the nation's health-care delivery system. It protects individuals and their families from the high and unexpected costs of serious injury and major illness. Health insurance provides access to healthcare services. And health insurance is the largest source of revenue for nearly all healthcare providers. Many private organizations and government programs provide health insurance, but their insurance plans vary greatly in terms of benefits, coverage, and eligibility. In the future, as the costs of healthcare increase and the nature of American business practices continues to change, the number of employers offering health insurance will likely continue to decline. The ranks of the uninsured will increase. And federal and state government insurance programs will need to expand to cover them.

HEALTH INSURANCE COVERAGE

Health insurance coverage includes an insurance policy of covered healthcare benefits and services between an individual and an insurance company. In the United States, most individuals receive health insurance coverage through their employer or the employer of a family member; however, being employed does not guarantee

health insurance coverage. Individuals who are 65 years of age or older, disabled, or have end-stage renal disease are eligible for health insurance coverage through the federal Medicare program; certain low-income individuals, families, and the disabled may be eligible for coverage through state Medicaid programs; children and families may be eligible for coverage through the State Children's Health Insurance Program (SCHIP); and individuals may purchase private insurance coverage on their own.

Background

Health insurance is key to accessing the healthcare system. Individuals who are insured are more likely to receive preventive, primary, and specialized care. The American system of health insurance coverage includes a patchwork of private sector and publicly funded programs. Approximately 160 million individuals have employer-sponsored health insurance and about 13 million individuals purchase health insurance directly through a health maintenance organization (HMO) or insurer. Although the majority of individuals have private, employer-based coverage, a growing segment of the population is uninsured. Since employer-sponsored insurance is voluntary by employer and employees, not all businesses offer coverage, individuals may not choose to purchase or be able to afford the health insurance offered by their employer, and some workers may not be eligible for coverage.

As the nation shifts from an industrial to a service-based economy and labor patterns change, health insurance coverage is diminishing. The nation's service industry tends not to offer health insurance coverage. Additionally, employers increasingly employ workers who do not qualify for coverage, such as part-time and contract employees. Because of this trend, fewer workers have employer-sponsored insurance. Many small employers are unable to offer their employees health insurance coverage because of the rising cost of healthcare. Employers that do offer health insurance to employees generally require them to pay a larger portion of the costs for their coverage. This increased cost-sharing burden has caused many employees to forgo employer-sponsored health insurance entirely.

Health insurance coverage in the United States differs greatly from that of other developed nations. For example, Canada, Germany, and the United Kingdom have national health programs that provide healthcare to all their citizens. However, rather than adopt a socialist model in which the government provides health insurance coverage for everyone, the United States has opted for a voluntary, market-based system in which individuals must seek out their own health insurance coverage, generally through an employer-sponsored plan.

In the United States, there are six types of voluntary health insurance: fraternal societies and mutual benefit associations; contract physicians; private physician plans; county medical-bureau plans; hospital service plans; and group insurance operated by private, commercial insurance companies.

Health insurance coverage grew out of the marine, fire, and life insurance policies sold by commercial insurers. The Civil War was a major impetus for the development of injury insurance, which eventually evolved into health coverage. Several major events—including the Stock Market Crash of 1929, the Great Depression, and World War II—also had an influence on establishing a health insurance coverage system in this country. The federal and state government support for health insurance was directly related to the economic conditions in the country.

Prior to 1920, health insurance was thought to be unnecessary because it was viewed as income replacement for working people. During the growth in the economy after World War II, employers began providing health benefits to their workers: Employee wages, which had been frozen during the war by the government, began to include fringe benefits such as pensions and health insurance. For employers, there was no payroll tax on health benefits, and employees did not have to pay income tax on the benefits provided by employers; both these amounted to government subsidies for employer-sponsored health insurance.

As the nation's hospitals expanded and modernized in the early 20th century, new expensive equipment and services developed. As commercial carriers were starting to introduce health insurance to their portfolio of products, the forerunner to the nonprofit Blue Cross plans was established in Houston, Texas, in 1929. This early plan provided

health insurance coverage for local teachers. From this early beginning, the Blue Cross plans developed across the nation with the support of the American Hospital Association (AHA).

Medicare, Medicaid, and the HMO Act

The urbanization of the nation and the growth in the retiree and indigent populations led to the introduction of the Medicare and Medicaid programs in 1965. Medicare is a federally administered program that provides health insurance coverage for those 65 years of age and older, the disabled, and individuals with end-stage renal disease. The Medicare program provides coverage for hospital care and nursing home care for 100 days through Part A, physician visits through Part B, and prescription drug coverage through Part D. Medicare's Part C offers coverage through private managed-care plans.

Medicaid, a joint federal-state program, provides insurance coverage for certain low-income individuals, families, and people with disabilities. Coverage through Medicaid is based on need, and eligibility is determined by income; the state-administered programs must meet broad federal guidelines, but each establishes its own eligibility requirements and service provisions.

The State Children's Health Insurance Program (SCHIP), created in 1997 by the federal government, represents the largest expansion of health insurance coverage for children since Medicaid started. Administered by the states, SCHIP provides health insurance coverage for children and for families with low incomes who earn too much to qualify for Medicaid.

With the continued growth in the nation's healthcare expenditures, a new form of insurance was introduced through the Health Maintenance Organization Act of 1973. This legislation required employers with 25 or more employees to offer a federally certified HMO as an option alongside the traditional indemnity insurance.

The federal Employee Retirement Income Security Act (ERISA) was established in 1974. It allowed private employers to self-insure, and it required employers to publish the rules and regulations that governed their benefit plans on an annual basis and report any modifications to the benefit packages. This measure was designed to provide protection to employees.

Changes in Health Insurance Coverage

In 2007, employer-sponsored insurance covered 59% of the nation's population, while the remainder of the population was either covered through Medicare, Medicaid, individual nongovernmental programs, or were uninsured. In recent years, the number of people who are covered by employer-sponsored insurance has been steadily declining, leading to a greater number of uninsured adults and children. It is estimated that about 47 million or 16% of Americans do not have any form of health insurance coverage.

From 2001 to 2005 alone, the percentage of workers covered by employer-sponsored insurance decreased by approximately 4%. Nearly half of this decline was due to the loss of employer sponsorship. In 2005, about 15% of employees did not have the availability of employer-sponsored insurance through their work site, and nearly 70% of the uninsured did not have access to employer-sponsored insurance through their family. Although there has been an increase in the number of Medicaid recipients and of others with public coverage or private nongroup coverage, an increase in working adults without health insurance coverage still remains.

Because of the rising healthcare costs in recent years, employers have been faced with either passing these additional costs on to employees or dropping employer-sponsored insurance entirely. As a result, employees have had to pay a growing share of premiums, their wages have increased more slowly, and they have lost coverage or decided not to take up employer-sponsored insurance.

Health Insurance Concepts

Several concepts are key to understanding health insurance coverage: plan type, risk, enrollment and disenrollment, eligibility for benefits, out-of-pocket expense, in- or out-of-network use, copayment, coinsurance, deductible, limitations on coverage, dependent coverage, preexisting condition, lifetime maximum coverage, premium payments, the Consolidated Omnibus Budget Reconciliation Act (COBRA) continuation, the Health Information Portability and Accountability Act (HIPAA), consumer protection, access standards, and appeals and grievances.

Plan type defines the nature of the insurance product under which a person is covered. It includes organizational entities or products such as HMOs, preferred provider organizations (PPOs), Health Savings Accounts (HSAs), indemnity, Medicare, and Medicaid, among others.

The *risk* falls on the individual or entity that is responsible for payment when services have been delivered.

Enrollment refers to membership in an insurance product or program when premium dollars are paid, whereas *disenrollment* means a transfer to a new plan or termination of coverage because of nonpayment.

Patients must meet *eligibility for benefits* or fulfill the membership criteria to participate in an insurance product or program.

Out-of-pocket expenses are services that are not covered by an insurance product or program and are, therefore, paid by the enrollee.

Each insurance product or plan provides coverage for a range of services; there is a negotiated contract that specifies the services included in the premium payment. Those providers—such as hospitals, physicians, and ancillary providers—that are included in a contract, are considered to be *in-network*, and so preferred rates are paid for those services. When a member goes to a provider who is not under contract with the insurance company, those services are considered to be *out-of-network*. Members will commonly have to pay a financial penalty for using an out-of-network provider.

Copayment refers to a provision in an insurance plan that requires members to pay some portion of the bill at the time of service, usually a flat fee dollar amount. For example, for a hospital emergency department visit, the member might have to pay a \$50 copayment at the time services are rendered.

Coinsurance, on the other hand, is a provision in an insurance plan that pays up to a given percentage of services and care. For example, the plan will pay 80% for services rendered; the member must then pay the remaining balance.

The *deductible* refers to the portion of a member's healthcare expenses that must be paid out of pocket before the insurer will pay the balance on the bill. For example, a health plan may specify that a \$500 deductible must be met before the insurer begins to pay for services.

Services not included in the insurance benefits are called *limitations on coverage*. For example, blood and blood products may not be covered for an inpatient surgical procedure.

Any person included on the insurance plan who is not the primary beneficiary of the insurance policy has *dependent coverage*. For example, spouses and children may receive dependent coverage through a family member's insurance plan.

Preexisting conditions, or medical conditions that the member had prior to the insurance effective date, are often excluded from coverage. For example, prior treatment for fibroids that could lead to a possible hysterectomy would not be covered under a new insurance plan.

The *lifetime maximum coverage* is when an insurance plan covers services up to a given limit and then will not provide additional payments once the threshold has been reached. For example, the plan may cover a maximum of 60 days of inpatient psychiatric services for the life of the insurance contract.

Premium payments refer to payments made on a monthly or quarterly basis to continue insurance coverage.

The *COBRA continuation*, a provision in the Consolidated Omnibus Budget Reconciliation Act of 1998, allows workers who have been displaced from their jobs to purchase insurance under their former employer's group health plan. COBRA coverage is usually available for 18 months postemployment.

The Health Insurance Portability and Accountability Act of 1996 (HIPAA) prohibits a former employer from refusing to provide COBRA to a displaced worker who has a preexisting condition. The HIPAA also has important patient-confidentiality provisions on sharing patient information.

State and federal government programs and commercial insurance plans recognize the need for *consumer protection*, establishing measures and policy provisions that allow members to appeal the decisions made by the insurer.

Each insurance company should have *access standards* or guidelines on administrative-support issues such as telephone waiting times, mailing of identification cards after enrollment, scheduling physician appointments, and receipt of specialist referrals.

The terms *appeals* and *grievances* are often used, mistakenly, interchangeably. An appeal is a

provision made after the insurer makes a decision and the member wants to challenge the decision. The appeal is usually conducted internally to the insurer but at a different organizational level. A grievance can include a host of comments that the member would like to make to the insurer, which can include issues with customer service, coverage, billing, or claims payment.

Future Implications

Health insurance coverage is an integral component of the American healthcare system. Private coverage and public programs such as Medicare and Medicaid shoulder some of the financial burden of the costs for routine and specialty healthcare services. As the number of uninsured Americans grows and the costs associated with healthcare continue to rise, the structure and function of health insurance coverage will shift and change. Public policy and current economic trends will help shape the future of health insurance coverage.

HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT OF 1996 (HIPAA)

The Health Insurance Portability and Accountability Act of 1996 (PL 104–191), commonly referred to as HIPAA, is federal legislation that mandates extensive requirements for group health insurance plans and medical providers. HIPAA significantly expanded the notion of privacy and the protection of individual patient records, it expanded protection of individuals with preexisting medical conditions from being denied healthcare coverage, and it allowed for the portability or transfer of individual healthcare coverage from one employer to another.

There are two titles of HIPAA. Title I protects health insurance coverage for workers and their families when they change or lose their jobs, commonly referred to as *portability*. Title II, the Administrative Simplification provisions, requires the establishment of national standards for electronic healthcare transactions and national identifiers for healthcare providers, health insurance plans, and employers.

After passing HIPAA in 1996, the U.S. Congress instructed the Department of Health and Human Services (HHS) to issue specific privacy guidelines to protect health information that was being sent and viewed electronically. The proposed rules were first written by the Clinton administration and then edited by the Bush administration. The final rules were issued in February 2003, and they took effect on April 14, 2003.

The HIPAA standards represent a national, uniform, federal floor of privacy protections for patients' medical information. Until the standards were passed, patients' medical privacy was governed by a spotty patchwork of state laws. The federal

standards now in place override weaker state laws but do not interfere with states that have adopted more aggressive policies to protect patients.

General Provisions

HIPAA was primarily intended to reduce employee barriers to maintaining health insurance coverage by guaranteeing that most of the nation's workers who change or lose their jobs will have access to coverage. The legislation also established new, federal, patient privacy rules to give individuals more control over how their personal, health information is used and disclosed. It requires health insurance plans and medical providers to have written privacy procedures, to train employees involved in handling protected information, and to establish a grievance procedure. Providers with direct treatment relationships are required to make a good-faith effort to obtain an individual's written acknowledgment that he or she is aware of the provider's privacy practices.

Title I

Title I of HIPAA regulates the availability and breadth of group and individual health insurance plans. It amended both the Employee Retirement Income Security Act (ERISA) and the Public Health Service Act. Title I prohibits any *group* health insurance plan from creating eligibility rules or assessing premiums for individuals in the plan based on health status, medical history, genetic information, or disability. However, this does not apply to *private* individual insurance. Title I also limits the restrictions that a group health insurance plan may place on benefits for preexisting conditions. Group health insurance plans may refuse to provide benefits relating to preexisting conditions for a period of 12 months after enrollment in the plan, or 18 months in the case of late enrollment.

Title II

Title II of HIPAA defines numerous offenses relating to healthcare and sets civil and criminal penalties for them. It also creates several programs to control fraud and abuse within the healthcare system. However, the most significant provisions

of Title II are its Administrative Simplification rules. Title II requires the HHS to draft rules aimed at increasing the efficiency of the healthcare system by creating standards for the use and dissemination of healthcare information. These rules apply to *covered entities* as defined by HIPAA and the HHS.

Covered Entities

Covered entities include health insurance plans; healthcare clearinghouses, such as billing services and community health information systems; and healthcare providers that transmit healthcare data in a way that is regulated by HIPAA. The Administrative Simplification standards adopted by HHS under HIPAA apply to any entity that is a healthcare provider that conducts certain transactions in electronic form, a healthcare clearinghouse, or a health insurance plan. An entity that is one or more of these types of entities is referred to as a covered entity in the Administrative Simplification regulations.

Privacy Rule

The Privacy Rule took effect on April 14, 2003, with a 1-year extension for certain small plans. It established regulations for the use and disclosure of *protected health information*. Protected health information is any information about the health status, provision of healthcare, or payment for healthcare that can be linked to an individual. This includes any portion of a patient's medical record or payment history.

Transactions and Code Sets Rule

There are multiple electronic data interchange (EDI) provisions in HIPAA. The Electronic Health Care Claim Transaction set is used to submit healthcare claim billing information, encounter information, or both. It can be sent from the providers of healthcare services to payers, either directly or via intermediary billers and claims clearinghouses. Other EDI provisions include guidelines for (a) pharmacy claim transactions; (b) healthcare claim payment transactions; (c) benefit enrollment; (d) payroll deductions and other group premium payments for insurance products; (e) healthcare eligibility and

benefit inquiry; (f) healthcare claims status requests and notifications; (g) service review information; and (h) functional acknowledgment, which is used to define the control structures for a set of acknowledgments to indicate the results of electronically coded documents.

Enforcement

The enforcement rule sets civil, monetary penalties for violating HIPAA rules, and it establishes procedures for investigations and hearings for violations. Failure to comply with the standards may result in severe civil and criminal penalties. The penalties range from \$50,000 to \$250,000 in fines and from 1 to 10 years in prison for an offense committed with the intent to sell, transfer, or use individually identifiable health information for commercial advantage, personal gain, or malicious harm.

Effects on Research and Clinical Care

In the wake of HIPAA implementation, there have been effects on patient trust in deciding to share their medical records. This may be the result of increased awareness of the need for privacy of personal medical records. It has been shown that those patients who have less trust in researchers are more likely to recommend a more stringent process for obtaining individual consent for the release of their medical records. Furthermore, with the advent of personal digital assistants (PDAs), many clinicians now keep patient medical records in electronic format on mobile devices. Physicians can improve their access to information by downloading patient data onto their personal handheld computers, which are available whenever decisions need to be made.

Implications for Marketing

A key provision in HIPAA includes a prohibition on marketing. The privacy rules specifically set new restrictions and limits on the use of patient information for marketing purposes. Healthcare providers, health insurance plans, and other covered entities must first obtain an individual's

specific authorization before disclosing their patient information for marketing. At the same time, the rules permit physicians and other covered entities to communicate freely with patients about treatment options and other health-related information, including health screenings, immunizations, and disease management programs.

Future Implications

HIPAA has provided for the portability of health-care insurance, increased the protection of personal medical records, and allowed for the migration to a set of standards for electronic data exchange of clinical information among patients, providers, and payers. However, there have been some negative effects on patients' willingness to share their personal medical records for research purposes based on their low level of trust that information is kept strictly confidential, despite the more stringent HIPAA regulations. It can be argued that patients are now much more aware of what is being done with their personal healthcare records and are, generally, better-informed consumers as a result. Finally, HIPAA has required that healthcare providers become more vigilant in the protection of personal patient information under their care.

HEALTH LITERACY

Health literacy is considered a variation of functional literacy, and for that reason, many definitions of *health literacy* build on the definition of *literacy*: the ability to read and write and the quality of being knowledgeable in a particular subject or field. The Center for Health Care Strategies (CHCS) significantly extends the definition of literacy by adding the concepts of *understanding* and *action*; it defines health literacy as the ability to read, understand, and act on health information. The American Medical Association's (AMA's) Ad Hoc Committee on Health Literacy uses a slightly broader definition; it considers health literacy to be the constellation of skills required to function in the healthcare environment, including the ability to perform basic reading and numerical tasks such as the ability to read and comprehend prescriptions, appointment slips, and other essential health-related materials.

The national Institute of Medicine (IOM), U.S. Department of Health and Human Services (HHS), and the National Library of Medicine (NLM) define health literacy as the degree to which individuals have the capacity to obtain, process, and understand the basic health information and services needed to make appropriate health decisions. Some critics find this definition overly broad because it includes the individual's ability to obtain both health information and services. They argue

that the capacity to obtain services is more a function of resources than of literacy.

The World Health Organization (WHO) uses an even broader definition: Health literacy represents the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health. Health literacy means more than being able to read pamphlets and successfully make appointments. By improving people's access to health information and their capacity to use it effectively, health literacy is critical to empowerment. This definition emphasizes that it is not enough for people to have health information; they must also have access to healthcare. The WHO moves healthcare providers beyond providing health information to initiating the process of empowerment so that individuals can become active participants in their own healthcare.

Health literacy exists when health information and services are provided in a manner easily understandable and appropriate for their audience. An individual's health literacy skills depend on his or her culture, education, and language. Equally important are the skills of those who provide health information, such as health workers, the media, the marketplace, and government agencies. To maximize health literacy, it is crucial that those who provide health information and services align their skills, expectations, and preferences with those of the individuals who are seeking health information.

Measurement

The most commonly used measures of health literacy are the Test of Functional Health Literacy in Adults (TOFHLA) and the Rapid Estimate of Adult Literacy in Medicine (REALM). Both of these tests measure selected domains that are considered to be markers of an individual's overall capacity. The TOFHLA measures adult literacy in a healthcare setting; it assesses the individual's abilities in numeracy—the ability to use numerical information in printed materials—and reading comprehension. Its 17-item numeracy section measures an individual's ability to read and understand actual hospital documents and labeled prescription vials. The REALM is a 66-item test that measures the

domain of vocabulary. The TOFHLA and REALM are frequently used in research studies because they are relatively short and have been shown to predict knowledge, behaviors, and outcomes.

The health literacy component of the 2003 National Assessment of Adult Literacy (NAAL) survey, conducted by the U.S. Department of Education, provides a more comprehensive measure of health literacy. Twenty-eight health literacy tasks were added to the NAAL survey to measure respondents' skill in understanding and locating health-related services and information. These tasks address three domains of health and health-care information and services: clinical, prevention, and navigation of the healthcare system. The clinical domain addresses activities associated with clinical encounters, diagnosis and treatment of illness, provider-patient relationship, and medication. The prevention domain addresses activities associated with preventing disease, self-management of illness, maintaining and improving health, and engaging in self-care. Finally, the navigation of the healthcare system domain addresses activities associated with individual rights and responsibilities and understanding how the healthcare system works.

More instruments are needed to measure health literacy and to understand the skills necessary to successfully navigate the health system. This understanding will help guide efforts to educate individuals about health issues and to create health-related information better tailored to consumers. For research, instruments that more precisely measure an individual's reading fluency, without posing an undue response burden, are necessary. Additional studies are also needed to compare instruments such as the TOFHLA and REALM with more comprehensive tests such as the 2003 NAAL survey to better understand their strengths and weaknesses.

Prevalence

Limited health literacy skills are common among adults living in the United States. Results from the 2003 NAAL survey show that the majority of adults, 53% of the population, have *intermediate* health literacy; 22% have *basic* health literacy; 14% have *below basic* health literacy; and 12% have *proficient* health literacy. As defined by the

NAAL, health tasks that mapped to the *below basic* level required adults to locate straightforward pieces of information in short, simple texts or documents. Health tasks reflecting the *basic* level required finding somewhat more complex information in texts or documents that were longer. Tasks at the *intermediate* level required respondents to apply or interpret information that was presented in complex graphs, tables, or other health-related documents. Finally, health tasks that mapped to the *proficient* level required comparing and/or contrasting multiple pieces of information within complex texts or documents, drawing abstract inferences, or applying abstract or complex information from texts or documents.

Health literacy varies across demographic groups. Results from the 2003 NAAL survey show that the average health literacy score for women was 6 points greater than the average health literacy score for men. Results also showed that White and Asian/Pacific Islander adults had a higher average health literacy score than Hispanic, Black, American Indian/Alaska Native, and multiracial adults. Hispanic adults had the lowest average health literacy score of all the ethnic or racial groups assessed in the survey. The NAAL results also showed that adults who spoke only English before starting school had higher average scores than adults who spoke only a language other than English before starting school. Additionally, starting with adults who had graduated from high school or earned their GED (general equivalency degree), the average health literacy score increased with each higher level of educational attainment. Also, adults living below the federal poverty level had lower health literacy scores than adults living above the poverty level. Adults in the oldest age group, those 65 years of age and older, had lower health literacy scores than adults in any other age group.

Within the United States, a sizeable proportion of the adult population may not have the literacy skills needed to effectively use the healthcare system. Findings from the 1992 National Adult Literacy Survey showed that literacy was low among adults in the nation. An estimated 47% of the population had literacy skills that tested below the high school level, and of these adults, 40 to 45 million had trouble finding information in complex or unfamiliar texts, including medicine labels, forms, or newspaper articles. Despite these low

literacy levels, more than 300 studies of health-related materials, such as medication package inserts and informed consent forms, have shown that health-related materials are written in language that is far above the high school reading level. In fact, most of the studied materials exceeded the reading skills of the average high school graduate. Because of the disconnect between the high complexity level of health information and the low health literacy skills of its audience, a very large proportion of the nation's population is denied the full benefits of health information and services.

Effect on Health Outcomes

A number of studies have shown that low health literacy is associated with poor health outcomes. Compared with patients who have a higher health literacy level, those with limited health literacy and chronic illness have less knowledge of illness management, lower use of preventive healthcare services, and higher hospitalization rates. When compared with patients who have an adequate health literacy level, those with limited literacy have a lower adherence to anticoagulation therapy, lower self-reported health status, higher likelihood of poor glycemic control and retinopathy, and decreased ability to share in decision making about prostate cancer. Studies have also shown that low health literacy is a barrier to the treatment of sexually transmitted diseases and a potential contributor to depression.

Poor health outcomes in patients with low health literacy may be the result of inadequate disease knowledge. A study of diabetic patients in one clinic showed that 94% of the patients with adequate literacy levels knew the symptoms of hypoglycemia compared with only 50% of the patients with low health literacy levels. Similarly, women with low health literacy were found to have incorrect knowledge about the purpose of a pap smear, and pregnant women with low literacy had less knowledge and concern about smoking during their pregnancies.

Studies also suggest that low health literacy is associated with increased healthcare utilization and costs. For example, new Medicare managed-care enrollees with low health literacy were found to be twice as likely to be hospitalized as those with

adequate health literacy, increasing the demands they place on healthcare resources. Similarly, a study of a small sample of Medicaid patients found that individuals whose reading levels were at or below the third-grade level had average Medicaid charges \$7,500 higher than those of patients whose reading skills were above the third-grade level. Another study found that in 1996 there were \$29 billion in additional health expenditures attributable to inadequate reading skills, and that, if half of the individuals studied were also health-illiterate, the estimate would increase to \$69 billion.

Interventions

Several different interventions have been proposed and are under way to improve health literacy. Federal and state agencies, educational institutions, healthcare systems, professional associations, and community and advocacy groups have all attempted interventions in this area. Although many promising efforts are under way, few have been formally evaluated, and most of the interventions are single approaches that are not part of a systematic approach to increasing health literacy. To better understand which interventions are the most effective and appropriate, a greater understanding is needed of the causal relationship between health and education, the role of literacy, and the contribution of health literacy to health.

The national IOM's Committee on Health Literacy assessed the problem of limited health literacy and proposed a set of recommendations for improvement. The committee determined that health literacy is based on the interaction between an individual's health literacy skills, the healthcare system, the education system, and culture and society, and they, therefore, judged that the responsibility for health literacy improvement must be shared by these various sectors. Based on this view, it recommended an urgent increase in federal and nonfederal funds for health literacy research and the development and evaluation of new measures of health literacy.

The committee also recommended that (a) accreditation requirements for schools should mandate the implementation of National Health Education Standards and that demonstration programs should be funded to support state efforts to

achieve such standards; (b) professional healthcare schools should incorporate health literacy into their curricula and areas of competence; (c) public and private healthcare systems should develop and support demonstrations to identify the most effective ways in which the healthcare system can reduce the negative effects of limited health literacy; and (d) the National Committee for Quality Assurance (NCQA), Joint Commission, Centers for Medicare and Medicaid Services (CMS), and other accreditation bodies should incorporate health literacy into their standards.

Research

As recommended by the IOM, research to increase the understanding of health literacy and its effects on health outcomes is under way. In 2004, and again in 2006, the National Institutes of Health (NIH) and the Agency for Healthcare Research and Quality (AHRQ) released a Program Announcement with Special Review (PAR) titled "Understanding and Promoting Health Literacy." The goal of this program is to increase research on health literacy concepts, theory, and interventions. Specifically, the PAR encourages researchers to address health literacy and its relationships to chronic-disease management, patient-based healthcare, prevention, healthy living, health disparities, and cultural competence. The results of the research will help the NIH provide the public and healthcare providers with scientific health information. About \$9 million was awarded to fund 19 research projects from 2005 to 2009.

Healthcare Providers

Many proposed strategies for dealing with low health literacy focus on healthcare providers. Some approaches highlight the need for creating print materials in different languages and at varied reading levels that providers can distribute. Other approaches emphasize developing healthcare providers' skills in determining patients' health literacy levels and creating literacy-specific communication strategies that providers can adopt based on their assessments. Other solutions emphasize the role of providers in increasing awareness among all staff members about the prevalence of low health literacy among patient populations.

Providers are also recommended to adopt specific strategies to help their patients compensate for limited literacy. Such strategies include (a) asking patients to restate their understanding of the material presented; (b) identifying and using visual aids; (c) teaching in a step-by-step process, with the most important information presented first; (d) using simple words and phrases; and (e) avoiding complicated medical terms and jargon. Finally, healthcare providers are also instrumental in creating a shame-free environment in which patients with low literacy can feel comfortable admitting to their providers if and when they need help or do not understand. Training providers on the best ways to assist and approach those with limited literacy will also help patients feel comfortable with and trust their providers.

Health Information

Many interventions call for a decrease in the complexity of health information. Even individuals with strong literacy skills may have trouble obtaining and using health information and services because the signs, directions, and official documents (e.g., social service forms, public health information, informed consent forms, and health education materials) frequently use technical language and jargon that makes them very difficult to understand. The problem is worse for the estimated 90 million American adults who lack functional literacy skills. Measures can be taken to reduce the complexity of health materials and better match them to the literacy levels of the general public.

Recommendations for health literacy improvement addressed in the HHS's Healthy People 2010 initiative focus on two areas. First, health literacy can be improved by developing appropriate, written health material and by creating health communications that are culturally and linguistically appropriate; using plain language; and following the principles of organization, layout, writing style, and design used in professional publications and in federal documents. Second, it can also be achieved by improving the skills of persons with limited health literacy: by offering health literacy programs—at public and medical libraries; to voluntary, professional, and community groups; and in schools—that target skill

improvement for low-literacy individuals. By providing individuals with appropriate written materials and the training to use them, these recommendations should result in improvements in health literacy.

Education

The educational system can also play a major role in increasing health literacy. Childhood literacy education and childhood health education form a foundation for health literacy in adulthood. Although most elementary, middle, and high schools require students to take health education classes, requirements decrease, for the most part, as students get older. Nationally, 33% of schools require health education in kindergarten, 44% mandate it in the 5th grade, 10% require health education in the 9th grade, and only 2% of schools require it in the 12th grade. Without a coordinated health education program across grade levels, students likely do not learn the needed health literacy skills.

To address this issue, the Joint Committee on National Health Standards published the *National Health Education Standards* in 1995. In this publication, the committee details the knowledge and skills necessary for health literacy; the information and skills students should know and have in health education by the end of Grades 4, 8, and 11; and the framework for curriculum development and student assessment that will help achieve these standards. Although some progress has been made, these standards have not been widely achieved.

Future Implications

With its many definitions, roles, and measurement tools, health literacy influences not only understanding and communication but also health status and health outcomes. By focusing on its complex role in both medicine and public health, the nation's healthcare system can maximize health literacy's effectiveness at helping patients better manage their acute and chronic medical conditions, enable researchers to disseminate their new findings and recommendations, and allow the general public to shift its attitudes and health

behaviors. Although much progress has been made in understanding health literacy, much more work needs to be done.

HEALTH MAINTENANCE ORGANIZATIONS (HMOs)

A health maintenance organization (HMO) is a form of group health insurance that entitles enrollees to the services of participating hospitals, clinics, and physicians. While HMO premiums are usually prepaid, the structure of the provider network, method of reimbursement, and the scope of their utilization management and disease management programs can vary greatly between HMOs. Paul M. Ellwood coined the term *health maintenance organization* in 1970 as a way of describing an organization that would compete on the bases of price and quality by combining health insurance and healthcare in a single organization.

History

Health insurance began to appear in the United States around 1850. Initial coverage was limited to individuals who were disabled by accidental workplace injuries. The Western Clinic in Tacoma, Washington, began providing prepaid physician services for the lumber industry in 1910. A similar, prepaid program for providing medical care to lumber and mine workers was also started in Tacoma in 1917. However, this program was run through a county medical services bureau and not a single clinic or medical group. This program was later expanded to include 20 sites in Oregon and Washington.

With the beginning of the Great Depression in 1929, hospitals and physicians began to search for reliable methods to ensure reimbursement for their medical services. The Baylor Plan—the first Blue Cross plan—was started to provide hospital coverage for teachers in Dallas, Texas. During this period, a number of physicians pioneered the development of HMOs. For example, Michael Shadid started a rural, farmer's, cooperative health plan in Elk City, Oklahoma, in which he enrolled several hundred families for a predetermined fee and used the funds to build a hospital and provide physicians' services. Donald Ross and H. Clifford Loos (Ross-Loos Clinic) contracted with the Los Angeles Department of Water

and Power to provide comprehensive services for 2,000 workers and their families.

One of the most noted HMO pioneers was Sidney Garfield. Garfield was caring for the men building the Los Angeles aqueduct through the Mojave Desert in 1933. Many of the men did not have insurance, and payment was difficult for those that did. Garfield contracted with the insurance companies to prepay a fixed amount of five cents per day, per worker for coverage of their job-related, healthcare needs. For an additional five cents per day, non-job-related illness could also be covered. This funding mechanism also enabled Garfield to focus on maintaining health and job safety, in addition to treating illness and injury.

In 1938, as the aqueduct project was nearing completion, Garfield was asked by Henry J. Kaiser to provide care for 6,500 workers, who were building the Grand Coulee Dam in Washington, and their families. Garfield recruited a team of doctors to work in a “prepaid medical practice.”

With the outbreak of World War II, tens of thousands of new employees began working at the Kaiser Shipyards in Richmond, California. Kaiser was faced with the problem of how to meet the healthcare needs of nearly 30,000 people. Kaiser again called upon Garfield, who organized and ran a prepaid medical practice for the workers and their families. With the ending of the war in 1945, the shipyard’s employment dropped. Garfield and his physicians wanted to keep practicing their new form of healthcare delivery, and with the assistance of Kaiser, they opened the Kaiser Permanente Health Plan to non-Kaiser employees.

Throughout the 1930s and 1940s, several other prepaid, group practice plans developed across the country. Employees of the Federal Home Loan Bank organized the Group Health Association in Washington, D.C., in 1937. In 1945, unions and local supply and food cooperatives in Seattle, Washington, formed the Group Health cooperative of Puget Sound as a healthcare option. The Health Insurance Plan (HIP) of Greater New York was launched in 1947 to provide care to city employees and their families.

Each of these plans was structured and governed differently; however, each was committed to comprehensive and coordinated healthcare. Their coverage and benefits were more comprehensive than the prevailing health insurance of the time

with emphasis on preventive care, immunizations, well-child care, and other services not usually covered by other health insurance programs. In addition, enrollees were subject to few exclusions, limitations, or copayments.

Organized medicine—the American Medical Association (AMA) and state and local medical societies—were strongly opposed to prepaid plans and cooperatives. Throughout the 1930s and 1940s, organized medicine attempted to suppress the growth of group health plans and ostracized physicians who participated in them through boycotts and denial of hospital privileges. As a result, the AMA was indicted and convicted of violating the Sherman Antitrust Act for its efforts to suppress the new plans. The U.S. Supreme Court upheld this conviction in 1947. In spite of the conviction, the AMA’s campaign to impede the growth of prepaid, group practice succeeded via the passage of numerous state laws that required freedom of choice of physicians; restricted provider reimbursement methodology; and prohibited consumer-run, medical-service plans. As a result of the legal impediments and other barriers, prepaid healthcare remained a minor factor until the early 1970s when the accelerating healthcare costs and lack of access to care by the poor, minorities, and a growing number of uninsured brought cost containment and efficiency of care to the political forefront.

In 1971, just 5 years after the passage of the Medicare and Medicaid programs, the Nixon Administration announced a new health strategy to control skyrocketing healthcare costs—a strategy that would focus on preventive services and health maintenance. This led to the passage of the Health Maintenance Organization Act of 1973 (HMO Act), and was a significant attempt to change the underlying structure of the nation’s healthcare delivery system. While the goal of the legislation was to encourage integrated, prepaid, group practice, the AMA successfully lobbied for inclusion of an Individual Practice Association (IPA) Model HMO in the legislation. IPAs were loosely affiliated networks of mostly solo-practice, fee-for-service physicians that did not offer the integration of clinical services or acceptance of financial risk that characterized prepaid group practices.

The HMO Act set aside \$375 million to help develop HMOs; preempted state laws that banned prepaid groups; and required companies with at

least 25 employees to offer a federally qualified HMO, if the HMO asked to be offered. However, the HMO Act also imposed several conditions for federal qualification that placed federally qualified HMOs at a competitive disadvantage in the marketplace.

The HMO Act mandated (a) a comprehensive minimum-benefits package that included immunizations, preventive health exams, therapy services, low copayments, annual limits on the amounts patients could be charged through copayments, and no maximum lifetime benefit limitations; (b) an annual open-enrollment period, during which an HMO was required to accept all applicants, regardless of preexisting conditions (as a result, high-risk individuals had easier access to federally qualified HMOs than to any other insurer); and (c) premiums based on the cost of providing care to the entire community (*community rating*), rather than on the cost of providing care to a specific group or employer.

Although the HMO Act stimulated the growth of HMOs by providing planning grants and loan guarantees, removing legal impediments, and mandating their offering as an insurance option, their growth was inhibited by the administrative requirements and benefit mandates that placed federally qualified HMOs at a competitive disadvantage in the marketplace.

The HMO Act was amended in 1976 to limit the open-enrollment mandate to plans that had been operational for at least 5 years, had at least 50,000 enrollees, and were not operating at a financial deficit. However, community rating and generous benefit packages continued to prevent federally qualified HMOs from offering competitive rates to employers.

During the late 1970s and early 1980s, state legislatures began enacting their own HMO legislation. Most state legislation used the federal HMO Act as a foundation; however, state regulations initially imposed fewer administrative requirements (e.g., community rating), and benefit mandates (e.g., mandatory open-enrollment periods). As a result, fewer organizations sought the federal qualification status that subjected them to the restrictions of the HMO Act, electing instead to become state-licensed, prepaid health plans.

Federally qualified and state-licensed HMO membership in the early 1980s remained a small

proportion of health insurance coverage. However, their presence began to influence traditional health insurers' product design and benefit coverage. To compete with HMOs, traditional health insurers began offering coverage for preventive health services, immunizations, and pharmaceuticals. To make these plans affordable and keep costs down, insurers negotiated contractual relationships with providers that required price discounts and subjected reimbursement to preauthorizations and second opinions. These new relationships were the introduction of managed care outside traditional HMOs and led to the development of new types of health insurance programs such as preferred provider organizations (PPOs), exclusive provider organizations (EPOs), and point-of-service plans (POS).

Structures

The initial structures of HMOs were codified in the Federal Health Maintenance Act of 1973; however, to expand and remain competitive, some plans have evolved from one of the initial structures to a hybrid of several. There were three basic structures of HMOs as established in the HMO Act: the staff model, group model, and individual practice association model. However, by default there is a fourth model—the mixed or network model, which is a combination of the three basic models.

Staff Model HMO

In a staff model HMO, there is a single entity—the HMO. The HMO offers insurance to its members or enrollees. Most of the physician services are provided by physicians who are employed by the HMO and only see HMO members. Some specialty care may be provided by nonemployee specialists who are contracted by the HMO. The HMO may own and operate its own network of hospitals, or it may contract out for some or all its hospital services. There are only a handful of staff model HMOs remaining in the country. Group Health Cooperative of south central Wisconsin is an example of a local staff model health plan. For economic reasons, many of the former staff model HMOs have spun off their physicians into separate but affiliated medical groups. The medical groups

can then contract with additional payers and care for a larger patient population. Examples of former staff model HMOs would be Cigna Health Plan (originally Ross-Loos Health Plan) in California and Harvard Community Health Plan in Massachusetts.

Group Model HMO

The archetypical HMO—Kaiser Permanente—is often thought of as a staff model HMO; however, it is a group model HMO. Kaiser Permanente is a consortium of three distinct groups of entities: the Kaiser Foundation Health Plan, Inc. and its regional operating organizations Kaiser Foundation Hospitals and the Permanente Medical Groups. The health plan offers health insurance to members or enrollees. The physicians work for the Permanente Medical Group, and the Medical Group contracts exclusively with the Kaiser Foundation Health Plan to provide medical care to its enrollees. Therefore, the health plan is a group model HMO.

A group model HMO is not limited to only contracting with one medical group to form its network. A group model HMO can contract with a series of medical groups across a geographic region to form its network of physicians.

Individual Practice Association Model HMO

As discussed earlier, the Individual Practice Association (IPA) model HMO was lobbied for by the American Medical Associations as an option for private practice physicians to participate in HMOs. IPAs are loosely affiliated networks of small groups and solo-practice, fee-for-service physicians. IPA model HMOs manage care by forming virtual “medical groups” through risk pools, specialty capitation, and utilization review committees.

Mixed-Model HMO

To expand their capacity and geographic service areas, HMOs need to develop large physician networks. A mixed-model HMO is a hybrid of all the above models. The composition of its network will vary and likely include medical groups, IPAs, and independent physicians.

Reimbursement Methodologies

Any reimbursement methodology has the potential to influence behavior. Under any reimbursement strategy, there is an unstated reliance on the professional integrity of hospitals, physicians, and others to provide only medically necessary care, neither too much nor too little. However, any system of reimbursement can be manipulated to maximize financial gain for the provider, to the potential harm of the patient.

The initial method of hospital and physician reimbursement was *fee-for-service*, in which a provider was reimbursed for each service delivered. This methodology provides greater financial reward for delivering more services and does not encourage preventive care, which if effective, would ultimately lead to lower reimbursements. Fee-for-service reimbursement has the potential to encourage unnecessary medical visits, hospitalizations, surgeries, and diagnostic testing.

An alternative method of reimbursement is *capitation*, in which a provider (hospital, physician, or medical group) receives a fixed reimbursement for specified services during a defined period of time. As the reimbursement is fixed, the provider (hospital, physician, or medical group) does not receive additional payments for hospitalizations, surgeries, or diagnostic testing. Under capitation, the provider is best off financially by providing the fewest services possible and thus has the potential to encourage rationing of care or underutilization.

There has been a great deal of discussion regarding the method and timing of payment for health service coverage through HMOs. Most of the attention is focused on the prepayment of premiums or capitation for medical services. However, prepayment of premiums for insurance is the standard practice for nearly all types of insurance. The insured pays an insurer a predetermined amount of money to purchase defined insurance coverage for a specific risk or set of services (e.g., health, auto, fire, life). Prepayment of premiums by employers or individuals to health insurers has been and continues to be standard practice for fully insured (non-self-funded) products. Premiums are set based on actuarial estimates of the future year's costs of providing the health services. In the event that insurers underestimate the future costs, they incur a loss for

that year, which usually results in a larger increase in premiums the following year to compensate for the underestimate and to recoup the losses.

Although HMOs were envisioned to function as both the insurer and the provider of healthcare, very few HMOs currently operate as direct providers of healthcare. Most HMOs function exclusively as health insurers and have reverted to reimbursing physicians on a fee-for-service basis and hospitals on a case rate, percentage-of-charges, or daily-rate basis. A few HMOs continue to operate as an integrated system of insurer, hospital system, and physician group (e.g., Kaiser Permanente).

Some HMOs differ from standard health insurance in the way they reimburse healthcare providers. Staff model HMOs employ their own physicians and allocate a portion of the premium to cover the costs of providing physicians' services. In a group model HMO, such as Kaiser Permanente, the HMO (insurer) provides the medical group with a fixed monthly premium for each member to cover all the necessary physician services. If the HMO owns its own hospitals, it may allocate a portion of the premium to cover the costs of providing hospital care. If it does not own the hospitals, it may either capitate a hospital system to provide the care, or it may negotiate some other method of reimbursement, such as case rate (Diagnosis Related Group [DRG]), per-day basis (per diem) or on a percentage of billed charges.

In an IPA model HMO, networks of independent physicians organize into an IPA to accept capitated risk for physician services from an HMO. The IPA can then capitate primary-care and specialty physicians to provide care, or as an alternative, it can reimburse physicians on a discounted fee-for-service basis. The amount of the discount is adjusted based on the volume of services delivered to match the allocation of the premium—more services would require a greater discount. This model puts the IPA and independent physicians at risk for the high utilization of services and provides the potential for additional financial reward for lower utilization.

Future Implications

Since the passage of the HMO Act in 1973, there have been remarkable changes in the nation's health

insurance and healthcare. In response to competition from HMOs, health insurers expanded benefits to include preventive and pharmacy services. Kaiser Permanente attempted to expand outside its west-coast base with mixed results, but it continues to thrive. Most staff and group model HMOs that developed after the HMO Act, as well as old stalwarts such as Ross-Loos, have reorganized and been acquired by large insurance companies. Even with advances in computer technology—which allow for better coordination and analysis of medical claims, laboratory, diagnostic, and pharmacy data—there has been limited success in realizing Ellwood's vision of an HMO. Except for a handful of regional healthcare systems such as Kaiser Permanente, Intermountain Healthcare, and the U.S. Veterans Administration health system, Ellwood's vision of combining the delivery of health care with its funding to deliver improved quality and lower costs has yet to be realized.

HEALTH PLANNING

The term *health planning* refers to conscious efforts to assess the current and future health-related needs of a population and identify ways to best meet those needs effectively and efficiently with limited resources. However, there is no consensus on this definition, perhaps because planning is a practice-based discipline rather than a theory-based one. It may also be due to the uneasy association many Americans have with government planning and to preferences for incrementalism and pluralism. Although doubtful about government power, people are also duly skeptical about the ability of the market to fully meet their health needs. Planning helps mediate this conflict of views.

The United States has a lack of health planning compared with most developed nations, including most of Europe, Canada, and Japan, where healthcare has a strong centralized government element and where there are long histories of top-down, government-oriented health services planning. Furthermore, health planning in these nations is often well integrated into social and economic planning, resulting in a comprehensive approach.

The nature and organization of American health planning has varied over time. In the late 1800s, epidemics led to attempts to reduce the environmental conditions that gave rise to illness. In the early 20th century, health planning was focused on medical care. Late in that century, there was a paradigm shift from "medical care" to "health-care" and a concomitant shift from medical-care planning to healthcare planning. Although health planning still includes medical and other health services, there is a focus on community-based planning and a renewed interest in shaping the urban environment to improve health.

Sanitary Reform Movement

In the late 1800s, American cities were growing rapidly, resulting in conditions that repeatedly led to epidemics. The sanitary reform movement responded based on the "filth theory": the idea that miasmas or "bad airs" either directly gave rise to illness or were associated with contagion. Miasma could be traced to the cesspools and sinks used to store human waste. It was believed that by removing the waste, disease could be checked.

Three tools were created that facilitated health planning. First, epidemiological mapping of the environmental conditions of streets and building as they correlated to the incidence of disease set the foundation for the planning process. This technique was used most notably by the public health reformer Edwin Chadwick (1800–1890) in the England of the 1840s and by the Citizens' Association in the New York of the 1860s. The second resource was sanitary sewerage technology that allowed solid waste to be carried away through pipes and sewers. Finally, the Progressive Era political reform led to the belief that government should effectively serve the public interest by tackling issues such as public health problems.

With these tools in place, sanitary survey planning developed as a response to a yellow fever epidemic in the Lower Mississippi Valley in the late 1870s. Tennessee authorities requested that the newly created National Board of Health develop a plan for the future and conduct a complete sanitary survey. They made a comprehensive reconstruction plan based on a house-to-house survey. It suggested specific, local-area remediation; designed a sewage system; and proposed

employing a sanitary officer. It also recommended the damming of bayous, the creation of public parks, repaving streets, and the enactment of a sanitary code raising buildings off the ground.

The sanitary reform movement also shaped urban designs and plans that were intended to prevent health problems by providing access to clean air and water and by reducing organic waste, ground moisture, and congestion. Frederick Law Olmsted (1822–1903), the father of landscape architecture, was influenced by this consciousness in his design of public parks such as Central Park in New York City. This influence can also be seen in Progressive Era housing reforms and in zoning codes that used police power to regulate land use for the protection of health, safety, and public welfare.

Toward Medical-Care Planning

By the early 1900s, germ theory was institutionalized in hospitals and the medical profession, following the Carnegie Foundation's Flexner Report—a survey of American and Canadian medical schools that resulted in the eventual closure of 29 medical schools between 1910 and 1914. With these changes, the nation's hospitals and the medical profession became much more effective than before.

In line with this newfound effectiveness, the nation's voluntary hospitals greatly expanded in the 1920s, but during the Great Depression, patients were priced out and turned to the overburdened public hospitals. This gave rise to the first voluntary regional planning agencies. These agencies were representative of the wealthy classes and worked to raise funds for hospitals. Health studies done during this period, before World War II, were usually not comprehensive but were directed toward specific health problems.

After World War II, the U.S. Congress passed the Hospital Survey and Construction Act of 1946, also known as the Hill-Burton Act. This act brought about the first public-initiated, statewide, health-planning bodies and significantly funded local, areawide, health-planning bodies with matching dollars, thus marking the beginning of federally sponsored health planning.

Catchment or hospital service areas were identified, the numbers of hospital beds needed by the population were calculated, the numbers of hospital

beds available were counted, and the extent of unmet needs estimated. These estimates of unmet needs were the basis for funding hospitals, which were then required to provide some level of charity care. Amendments in 1962 required the development of regional health-planning agencies, which were generally voluntary agencies that advised states. There were 8 agencies in 1962, 33 in 1964, and increased to 50 by 1965.

Federally Funded, Comprehensive Health Planning

In the 1960s, concerns over access to healthcare gave rise to the Medicaid and Medicare programs. Government became a major payer and the high cost of medical care became a focus. As a result, the federal government expanded its role in medical-care planning. First, the 1966 Partnership for Health Action established Comprehensive Health Planning (CHP) agencies. The National Health Planning and Resources Development Act of 1967 featured the work of these agencies. The act established local Health Systems Agencies (HSAs), State Health Planning and Development Agencies (SHPDAs) and included the Certificate of Need (CON) process intended to control the development and expansion of medical-care facilities and services.

Local HSAs were the basic unit of health planning, with about 200 nationwide. Consumers were mandated to have a majority of positions on their governing bodies. HSAs were required to develop long-range plans, with open public hearings, and to review facilities every 5 years. Quantitative analysis and a systems approach were encouraged. The early focus was on inpatient and long-term care, but in 1979, amendments added a focus on prevention, home health, and alcohol and drug abuse.

SHPDAs were overseen by Statewide Health Coordinating Councils, and they were expected to hold their deliberations in public. The functions of the SHPDAs included completing a state plan, coordinating with HSA plans, implementing portions of the state plan, and assisting the Statewide Health Coordinating Councils in their reviews of medical facilities.

As part of the process, CON applications had to be submitted for proposed new or expanded health facilities, equipment, or services. These were to be

reviewed on the basis of need as identified in the plans. Initially, the CON process had little impact on the availability of facilities, services, and equipment because health planning agencies were not given the power to enforce the decisions made on CON applications. Later, however, the impact of CON varied by state, with a significant effect in some and a limited effect in others.

Federally supported, CHP came to an end when the U.S. Congress repealed the National Health Planning and Resources Development Act of 1967 in 1986. President Ronald Reagan had campaigned for a reduced, more businesslike government, and healthcare costs continued to escalate despite health-planning efforts. The planning process had few supporters.

With the end of federal support, health planning at the national level has been almost nonexistent. One exception has been Healthy People 2010, sponsored by the federal Office of Disease Prevention and Health Promotion; it identified national healthcare goals in the late 1980s and later began tracking progress toward them. Many states retained health-planning structures, and some continue to develop state health plans. Most of these entities are voluntary and have little funding or regulatory power.

Today, health planning continues in a number of different forms but not always under the rubric of planning. These include institutional planning; community-based, problem-specific planning; local, public health agency planning; and an emerging focus on health in urban planning.

Institutional Planning

Most health planning today takes place in health-care organizations rather than at the community or regional level. Hospitals in the mid-1980s faced rapidly changing environments of competition, reduced reimbursement, and declining use. Strategic planning, which had been developed by banks, was well suited to the needs of hospitals. Strategic planning involves identifying a mission and strategies for achieving that mission, given internal and external constraints and opportunities. It does not prevent hospitals from addressing community needs, but overall, strategic planning is focused on the institution. Institutional planning also takes

the form of operations planning, facility planning, budget planning, and marketing planning.

Community-Based, Problem-Specific Planning

Just as funding for comprehensive health planning began to decline, the HIV/AIDS crisis appeared. Voluntary organizations were formed to respond, including the Citizens Commission on AIDS for New York City and Northern New Jersey and the AIDS Foundation of Chicago. At about the same time, a coalition approach to funding services was being developed by the Robert Wood Johnson Foundation: Successful applicants had to ensure some level of collaboration, often in the form of a coalition. This effort facilitated a structure for community-based planning or, at the very least, service coordination.

The federal government adopted this approach in HIV Health Service Planning Councils as mandated by Title I of the Ryan White Comprehensive AIDS Resources Emergency Act of 1990 (the CARE Act). The funded HIV/AIDS agencies used a unique type of planning organization, working as community-based, participatory-planning entities. Similar models of planning also are required in maternal-child health and many other federal-grant-funded programs.

Local Public Health Agency Planning

In the 1980s and 1990s, strategic planning was recommended for local public health agencies. The Assessment Protocol for Excellence in Public Health (APEX/PH) provided by the National Association of County and City Health Organizations (NACCHOs), had some strategic-planning elements. In 2001, Mobilizing for Action through Planning and Partnership (MAPP) was developed by the NACCHOs and the Centers for Disease Control and Prevention (CDC) to help public health agencies do community health planning and programming. MAPP includes elements from both strategic planning and comprehensive health planning.

Health in Urban Planning

Health planning is becoming broader in its scope as it seeks to shape the urban environment to

promote health. In 1986, the World Health Organization Regional Office for Europe (WHO/Europe) established the Healthy Cities project, which is designed to involve local government in health promotion. In 1997, it created the health, urban-planning initiative to integrate health- and sustainable-development planning.

Physical inactivity, a cause of obesity and related chronic health problems, has been targeted by the Active Community Environments (ACES) initiative from the CDC and by the Robert Wood Johnson Foundation's Active Living by Design initiative. Both of these initiatives support the development of environments that promote physical activity.

The spatial forms of cities can lead to health problems: Urban sprawl forces hours of driving time that make people inactive, pollute the air, cause injuries, cause stress, and take people away from activities that build protective social capital. Efforts to reduce urban sprawl and improve health include the New Urbanism, a set of principles that seeks to use participatory planning to create compact, walkable communities that are connected to their surrounding regions by public transit. Similarly, Smart Growth promotes the concentration of growth in urban centers, with mixed-use development and access by public transit. Both sets of principles are intended to guide urban planning in its application of land-use tools such as building codes, zoning codes, growth management, and public transportation systems. These close ties between urban form and health have led to calls for greater collaboration between the professions of public health and urban planning.

Future Implications

Health planning had its roots in shaping the environment to improve health. Although much of the history of health planning is dominated by medical and healthcare planning, there is an increasing focus on community-based planning and a renewed interest in shaping the environment to improve health status.

HEALTH PROFESSIONAL SHORTAGE AREAS (HPSAs)

Health professional shortage areas (HPSAs) are geographic areas, population groups, or medical facilities that are designated by the Secretary of the

U.S. Department of Health and Human Services (HHS) as having a shortage of health professionals. HPSAs may be lacking primary-care, dental, or mental health providers as judged by established norms for the provision of adequate healthcare.

Types of HPSAs

There are several types of HPSAs: geographic parts of a county or a whole county; geographic service areas with portions of one or many counties; population groups, such as low-income populations; state mental hospitals; correctional institutions; Federally Qualified Health Centers (FQHCs) and FQHC look-alikes; comprehensive health centers; rural health clinics; American Indian, Alaskan Native, and Indian Health Service clinics; and “other,” including public or private nonprofit medical facilities. Additional classification criteria include geography, demographics, or institutions.

Scope of Coverage

About 20% of the population of the United States resides in primary-medical-care HPSAs. Because the demand for services exceeds the available resources, residents of these areas have inadequate access to primary-healthcare services. Approximately three of five White Americans outside metropolitan areas live in HPSAs, compared with three of four African American and Hispanic minorities. Furthermore, 84% of counties where African Americans or Hispanics constitute the majority of the population qualify as HPSAs. In 2008, there were 5,987 primary-care HPSAs, 3,951 dental HPSAs, and 2,947 mental health HPSAs in the nation.

Designation

Designation as an HPSA indicates eligibility for federal-grant funds, placement of practitioners from the National Health Service Corps (NHSC), and Medicare reimbursement bonuses to physicians in efforts to enhance healthcare provision. To bolster healthcare, foreign physicians are encouraged to practice in selected HPSAs by waiving restrictions on entry into the United States.

The Shortage Designation Branch within the Bureau of Health Professions (BHPPr), which is part of the Health Resources and Services Administration (HRSA), administers the designation of HPSAs. Different criteria are set for primary-care physicians, dentists, and mental health professionals in determining need. For population group requests, applicants must describe the barriers that the population experiences in accessing quality healthcare services in the community. Areas with low clinician-to-population ratios are also eligible for designation, along with areas where there is restricted access to services due to language or cultural barriers. The latter include areas where private practitioners do not accept Medicaid patients and areas with a high proportion of Native American residents or other population groups with limited access to care. The scoring for primary care takes four factors into account: (1) population-to-primary-care-physician ratio, (2) percentage of the population with incomes below 100% of the federal poverty level, (3) infant mortality and low-birth-weight rates, and (4) travel time or distance to the nearest available source of healthcare. Local data on the population density, travel time and distance from the population-weighted center of the primary-care service area, percentage of users living below the federal poverty level, and primary-care physicians are used to calculate the scores.

The NHSC scholarship and loan repayment programs, the NHSC Ready Responders Program, and the Federal J-1 Visa Waiver program use the HPSA scores to allocate resources. The NHSC, a component of HHS and HRSA, is dedicated to providing primary-healthcare clinicians to HPSAs. It has supplied more than 27,000 clinicians since 1972. NHSC scholars are required to fulfill their commitments by serving in HPSAs with the greatest need. For the NHSC loan repayment program, which has the largest pool of clinicians, contracts are approved in descending order of the HPSA score. Most J-1 Visa Waiver physicians are placed through the Physician Visa Waiver Program (also known as the State Conrad 30 programs, called the State 30 program because it is limited to 30 foreign-medical-graduate waivers per state), which are not subject to the scoring restrictions. Therefore, the score should have a limited impact on recruitment opportunities for most entities. All HPSA

designated entities can seek the assistance of NHSC in providing physicians, nurse practitioners, physician assistants, certified nurse-midwives, dentists, and other clinicians, with placement priority based on scoring.

Future Implications

The number of HPSAs has grown during the past 20 years, as has the ratio of practitioners-to-population in these areas. Such changes can be attributed to the efforts of the federal government to widen the scope of HPSA designation to include factors other than physician-to-population ratios, and thereby provide improved and more equitable healthcare to underserved populations. In the future, it seems likely that the number of HPSAs in the nation will continue to grow.

HEALTH REPORT CARDS

Health report cards are collections of health-related measures developed to report and highlight specific health-related information. Health report cards can include measures of individual or population health status, measures of healthcare system or healthcare provider performance, and other health-related information. The content of health report cards is typically arrayed in a manner that displays a point-in-time snapshot of health-related measures pertaining to particular health concerns, populations of interest, geographies, or healthcare providers. Current measures are usually arrayed to allow comparisons with previous time periods. In some instances, the health report cards also use defined criteria or methodologies for grading, scoring, or ranking the health information conveyed, resulting, for example, in reports of the relative healthiness of the 50 states, the relative performance of healthcare providers, the deadliest health threats or risks, or changes in health status related to established benchmarks or objectives. The scope and format of health report cards can range from basic comparative measures familiar to consumers to more advanced sets of metrics useful for health services research and public policy development. Report-card-like information sources are becoming increasingly available on the Internet, with features that include query tools for rapid, focused information retrieval.

A variety of entities have developed health report cards for numerous distinct purposes. Government agencies at the federal, state, and local levels not only collect and store health-related data but often also disseminate health-related information in report-card-like publications for the public. Advocacy and consumer groups focused on specific populations or health issues frequently use a health report card format to present information. Healthcare providers and health benefits plans provide patients and plan beneficiaries with personal reports designed to promote the patient's health and care management. Professional associations and accreditation and certification entities have also developed report cards that portray changes in measures designed to reflect the quality of healthcare.

Types of Health Report Cards

Health report cards are produced for various purposes and can include equally varied content. Report cards often include metrics developed to allow ratings, using grading schemes with standards or benchmarks, or rankings portraying a spectrum of *best to worst*. Report cards can also focus primarily on factors measured at points in time and show trends in change. Health report cards vary widely depending on the intended audience: The content and format of reports devoted to informing health services researchers, for example, are quite different from that of report cards intended to support patient awareness and consumer healthcare decisions.

Health report cards can be grouped by general types depending on the scope, purpose, and content of the report cards. These groupings include report cards focused on personal health, population health status, subpopulation health status, healthcare provider performance, and health system capacity and performance. Within each grouping, the content displayed in a particular report card can concentrate on health measures within or across geographical boundaries or portray distinctions on the basis of age, gender, ethnicity and race, level of education, income, provider type, or particular health concerns.

Personal Health Report Cards

Personal health report cards can be produced by healthcare providers and health benefit plans to depict individual health status and related health-determinant information for individual patients and health plan beneficiaries. Personal health report cards are useful tools for engaging individuals in their own healthcare decision making and health-promoting behaviors. Additional uses of personal health report cards can include advancing patient health literacy; encouraging health risk avoidance; and ensuring culturally competent, patient-centered care. An individual's health report card requires current data that reflect the health issues of concern for that particular individual: For example, body weight, body mass, blood pressure, and cholesterol levels should be augmented with prenatal care measures for an expectant mother, disease-specific measures for a person with one or

more chronic medical conditions, and appropriate measures for a person at risk of developing health problems due to their family health history.

Population Health Status Report Cards

Population health status is a common feature of many health report cards. Rates of incidence and prevalence related to morbidity, mortality, and determinants of health are frequently used to develop measures that compare and contrast population health at different points in time or in different geographical areas. These report cards are particularly useful in demonstrating progress, or the lack thereof, in meeting benchmark objectives related to population health status goals. Population health status report cards are also useful in reaching conclusions regarding the priority health issues of a population and the success or failure of public programs in protecting and improving the population's health.

Subpopulation Health Status Report Cards

Health report cards that focus on the health status and healthcare system experiences of a particular population group or groups are useful in comparing the status of that group with the status of other groups and the general population. Population groups can be segmented in terms of ethnicity and race, age, gender, place of residence, level of education, participation in particular health benefit plans, or other attributes. Such report cards can demonstrate serious disparities in health and access to appropriate healthcare and are useful in supporting public policy development and program implementation. Population subgroup report cards are often hampered by data limitations such as inadequate ethnicity, race, and gender detail and the small numbers of cases or individuals, which may prohibit the use of the available data due to accuracy and privacy concerns.

Healthcare Provider Report Cards

Health report cards that describe and compare provider performance measures have gained attention as providers focus on quality improvement, consumers focus on the relative quality of care delivered by healthcare providers, and payers focus

on maximizing value and containing costs. Development of healthcare provider report cards gained momentum during the 1990s, partly in response to the need for metrics to support the evolving managed-care and managed-competition initiatives of that decade. Currently, provider performance reporting and the availability of reports are components of the efforts to enhance transparency in the delivery of healthcare services, improve the quality of care and contain costs, and link provider payments to value-based criteria.

Common elements of healthcare provider report cards include measures designed to reflect the structures, processes, outcomes, and costs of healthcare delivery. Healthcare provider health report cards can be produced by healthcare facility trade organizations, consumer and advocacy groups, and government entities. These report cards are often presented in sophisticated Web-based formats featuring query capabilities for focusing on the performance of particular providers in specific locations during recent time periods. To maintain accuracy and equity in measuring and comparing provider performance, provider report cards should acknowledge the important distinctions in the types of providers, and they should contain explanations of the risk adjustment methodologies used to compensate for variations in the volume, severity, and complexity of the cases treated by those providers.

Health System Capacity and Performance Report Cards

Health status, both of the individual and the population, results from a complex and dynamic context of health determinants. Healthcare is an equally complicated enterprise. Broad, system-level reports and report cards are developed to support assessment of the capacity and performance of systems for facilitating the interplay of health-related programs and care providers. For example, reports based on the state, local, or national government assessment tools of the National Public Health Performance Standards are very valuable for raising awareness of public health system capacity and priority issues. Similarly, reports on the overall healthcare system of a region, state, or community are essential for identifying quality improvement concerns and informing

resource allocation decisions. The importance of health system capacity reporting has gained attention recently with the realization of system vulnerabilities and the potential surge in demands for healthcare services that would follow cataclysmic events such as a bioterrorism attack or natural disaster.

Data Sources for Health Report Cards

Health report cards rely on a variety of primary and secondary data sources. The strengths, limitations, and utility of health report cards are determined by the quality and timeliness of the data used, the underlying assumptions and techniques of any data analyses, and the methodologies employed to develop the measures included in the report. Health report cards should include disclosure of the data sources and methodologies for development of the metrics, and report card users should understand the distinction between the data and the report card's metrics, which use the data to portray changes and relationships.

All health report cards are hampered to some extent by certain data limitations. In provider performance and population health status report cards, for example, small numbers of events or categories of characteristics can lead to statistical inaccuracies and potential privacy violations. Statistical techniques to aggregate data, such as merging data collected over longer time periods, can be employed in some instances, but report cards should carefully explain the data limitations and methodologies at a level appropriate for the targeted audience.

Data for report cards pertaining to an individual's health characteristics and health status can be drawn from a patient's medical records and basic health profile, often with a focus on family health history and lifestyle choices such as smoking. Personal health report cards often include some population level data in measures used for comparison of the individual with the general population.

Population-based health report cards commonly depict information in terms of estimates, rates of disease incidence, or other measurements that require census data, such as that obtained by the U.S. Census Bureau's decennial census and intercensal-population estimates.

Survey data are another critical data resource for population health report cards; for example, the Current Population Survey, conducted by the U.S. Census Bureau, and the Behavioral Risk Factor Surveillance System (BRFSS), conducted by the states with support from the Centers for Disease Control and Prevention (CDC), are valuable sources of useful, survey-based estimates related to healthcare and determinants of health.

Most states and the federal government require extensive healthcare provider reporting of clinical and administrative data. Government entities, such as the Centers for Medicare and Medicaid Services (CMS) and the National Center for Health Statistics (NCHS), collect data on hospital discharges, claims data related to publicly funded healthcare plans, public health data such as vital statistics and reportable infectious diseases, reports of adverse health events in clinical settings, and regulatory data pertaining to providers and health insurance plans. These mandatory submissions are a rich source of data for health report cards, and many government entities produce or are developing provider report cards to inform consumers and payers.

Future Implications

The value, utility, and future evolution of health report cards depend on several factors. The primary purpose of all report cards is to translate data into understandable information and convey that information so that it becomes useful knowledge. It is essential in all cases that the underlying data be accurate; that underlying assumptions be reasonable and unbiased; and that the information, purpose, and format of the report card be comprehensible to the target audience. It is also critical that any report card contain explanations of the methods used to derive the measures portrayed and that the report card relate the measures included to the broader universe of information that is not included. The report card should also contain specific caveats detailing the limitations of the data, metrics, or general use of the report card.

Health report cards that are constructed with careful attention to accuracy, timeliness, health literacy, and cultural competency can be valuable and constructive tools for expanding useful knowledge and, ultimately, improving the health status

and healthcare of individuals and populations. Health report cards can translate complicated concepts into comprehensible information suitable for dissemination methods that favor rapid and efficient forms of communication. The utility of health report cards in decision support, education, advocacy, and continuous quality improvement will increase as data sources and data analysis methods improve.

Health report cards in a wide variety of formats will most likely continue to proliferate and become essential knowledge management tools in the years ahead, as growth in the demand for reliable, understandable health information accelerates. The demand for health information will be fueled by evolving efforts to measure, manage, and improve health status and healthcare delivery. Factors influencing this demand will include improved levels of health literacy in society, broader acceptance of the individual's growing role in decisions related to the management of his or her healthcare, and growing concern for continuous improvement and accountability in healthcare delivery. The general pressures of expanding scientific and medical knowledge, progress in technical innovation, the promise of more robust data sources, and expanding social awareness of health issues will also contribute to the demand for useful health report cards.

Numerous factors will undoubtedly continue to drive the future demand for health report cards as well as the forms those report cards will take, including the following: increasing efforts to bring transparency to the delivery of healthcare services and inform better public policies; continuing efforts to enable informed consumer choice and patient and family participation in healthcare decisions; incentives for improving the continuity and management of care, especially with regard to chronic-disease conditions; initiatives to raise the level of health literacy and promote healthy lifestyle behavior and the avoidance of health risks; and continuous work to improve the quality of healthcare.

HEALTH RESOURCES AND SERVICES ADMINISTRATION (HRSA)

The Health Resources and Services Administration (HRSA) is one of 11 agencies in the U.S. Department

of Health and Human Services (HHS), making it a component of the executive branch of the federal government. HRSA's major focus is on ensuring access to healthcare for the uninsured and other vulnerable populations and providing people with appropriate services at the appropriate times. Pursuing that mission involves funding programs to train, recruit, and retain clinicians to work in underserved areas and encouraging individuals from underrepresented groups to enter the health professions and providing the financial means for them to do so. By establishing the infrastructure to expand access to healthcare, HRSA works to eliminate health disparities.

History

With the passage of federal Titles V and VI of the Social Security Act in 1935, the federal government, through the U.S. Public Health Service, began providing grants to the states for healthcare programs. By 1943, both the Bureau of Medical Services and the Bureau of State Services were created within the U.S. Public Health Service, which at the time was part of the Federal Security Agency (FSA). A decade later, the FSA became the U.S. Department of Health, Education, and Welfare (DHEW).

By 1966, the Bureau of Medical Services and the Bureau of State Services were transformed into the Bureau of Health Services and the Bureau of Health Manpower, respectively. At the same time, the Community Health Center program was instituted, followed by the National Health Service Corps, which began in 1970.

In 1973, the Health Services Administration and the Health Resources Administration were established. In essence, the Bureau of Health Services became the Health Services Administration, while the Bureau of Health Manpower became the Health Resources Administration. Finally in 1982, the Health Services Administration and the Health Resources Administration merged to create the Health Resources and Service Administration (HRSA). This was just 2 years after the U.S. Department of Health, Education, and Welfare (DHEW) was reorganized into the U.S. Department of Health and Human Services (HHS).

Organization

Today, HRSA's staff of more than 1,600 individuals is headquartered in the Washington, D.C., suburb of Rockville, Maryland. The administrator of HRSA oversees 6 bureaus and 12 offices with an estimated fiscal year (FY) 2008 budget of \$5.8 billion. The 6 bureaus are (1) the Bureau of Health Professions (BHP), (2) the Bureau of Primary Health Care (BPHC), (3) the Healthcare Systems Bureau, (4) the HIV/AIDS Bureau, (5) the Maternal and Child Health Bureau, and (6) the Bureau of Clinician Recruitment and Service.

The BHP focuses on issues related to the healthcare workforce, including the education of underrepresented minorities in the health professions and the recruitment and retention of clinicians to work in underserved areas. This bureau houses the National Health Service Corps (NHSC) and the National Practitioner Data Bank.

The BPHC identifies underserved areas across the country and provides those areas with increased access to primary care. To this end, the most notable program housed in the BPHC is the Consolidated Health Centers Program, which includes Federally Qualified Health Centers (FQHC), Migrant Health Centers, Rural Health Centers, and others.

The Healthcare Systems Bureau leads several efforts and oversees a variety of diverse HRSA programs, including the vaccine injury compensation program; organ transplantation program; efforts to reduce the number of uninsured individuals; and support of state and local efforts at emergency management, disaster planning, and bioterrorism response.

The HIV/AIDS Bureau houses the Ryan White Comprehensive AIDS Resources Emergency (CARE) Act Program, providing funding to grantees for HIV/AIDS outreach; AIDS Drug Assistance Programs (ADAPs); and other efforts aimed at increasing access to healthcare for individuals who are uninsured or underinsured and living with HIV/AIDS.

The Maternal and Child Health Bureau (MCHB) provides national leadership on issues relating to women's and children's health, including access to healthcare, programs designed to care for children with special healthcare needs, and other similar programs. This bureau administers Title V grant

funds—to grantees at the state and local levels—that are used to fund programs such as Women, Infants, and Children (WIC).

The Bureau of Clinician Recruitment and Service (BCRS) supports the education of students and clinicians through scholarship, loan repayment, and recruitment programs.

Advisory Committees

HRSA is also involved in several committees that advise the HHS and the U.S. Congress on healthcare matters. In the area of workforce development, it is part of the Council on Graduate Medical Education, the National Advisory Council on Nursing Education and Practice, and the National Advisory Committee on the National Health Service Corps. Members of HRSA also serve on the National Advisory Committee on Rural Health and Human Services, the National Advisory Council on Migrant Health, the Advisory Committee on Organ Transplantation, the Centers for Disease Control and Prevention (CDC)/HRSA Advisory Committee on HIV and STD (sexually transmitted disease) Prevention and Treatment, the Advisory Committee on Childhood Vaccines, and the Advisory Committee on Heritable Disorders and Genetic Diseases in Newborns and Children.

Strategic Partnerships

HRSA also partners with other government agencies and organizations at the federal, state, and local levels. For instance, together with the CDC, HRSA targets preventive care for chronic diseases in underserved communities, assists in emergency preparedness and bioterrorism response planning, and strives to find solutions to the HIV/AIDS epidemic. The agency's Office of Pharmacy Affairs implements the federal 340B Drug Pricing Program to provide access to low-cost prescription drugs for federally funded grantees and other safety net providers. HRSA also works closely with the Agency for Healthcare Research and Quality (AHRQ), the Indian Health Service (IHS), and the Substance Abuse and Mental Health Services Administration (SAMHSA). At the state level, HRSA partners with public health programs such as those administered under the Title V Maternal and Child Health Block Grant and the Ryan White

CARE Act. Locally, HRSA provides grants to community-based organizations such as hospitals, health centers, and academic institutions.

Grants and Funding Opportunities

HRSA is primarily a grant-giving and oversight agency. That is, the majority of its budget goes to providing grants and other funding in support of external organizations that pursue the agency's mission through education, training, and research. These grantees include community-based organizations, colleges and universities, hospitals, local and state governments, associations, and foundations. In a typical year, community-based organizations, hospitals, and universities account for more than three fourths of the total funding disbursed by HRSA.

The various bureaus of HRSA administer a number of scholarship and loan programs to health professionals in training to encourage them to pursue a career working in an underserved area, as well as to increase the representation of minority populations and the teaching of cultural competency in health profession schools. Scholarships and loans are awarded to students in medicine, nursing, dentistry, optometry, veterinary medicine, pharmacy, podiatric medicine, public health, chiropractic medicine, the allied health professions, behavioral and mental health, and physician assistants who are from disadvantaged backgrounds. HRSA's loan repayment programs repay certain student loans in exchange for fulfilling a service obligation by working in an underserved area upon graduation. The best-known loan repayment program is part of the National Health Service Corps.

Healthcare Workforce and the Designation of Underserved Areas

One of HRSA's primary missions is ensuring that an adequate supply of clinicians exists in the country to provide needed care. Currently, there is both an absolute shortage of clinicians per capita as well as a maldistribution of clinicians across the country. To target clinician placement, HRSA's National Center for Health Workforce Analysis designates geographic areas and population groups as being medically underserved.

Receipt of such a designation is typically a prerequisite to qualifying for most grant programs administered by the agency and is also used by other programs outside HRSA. More than 34 federal programs rely on HRSA's designation of the medically underserved in making their funding decisions.

There are two general classifications: Health Professional Shortage Areas (HPSAs) and Medically Underserved Areas or Populations (MUAs or MUPs). HPSAs include urban or rural geographic areas and populations with a shortage of primary-care, dental, or mental health providers. If an area or population has more than 3,500 persons per provider, it is considered to be underserved and is classified as a HPSA. If an area has a ratio of 3,000:1 and can also demonstrate unmet need in the population, it too is classified as a HPSA.

In contrast, MUAs and MUPs rely on an Index of Medical Underservice (IMU) to determine an area's or a population's status. The IMU yields a score ranging from 0 (completely underserved) to 100 (least underserved). A score of 62.0 or below qualifies for MUA designation. The IMU itself is calculated based on the ratio of primary-care physicians per 1,000 population, the infant mortality rate, the percentage of the population below poverty, and the percentage of the population age 65 and older.

National Health Service Corps

The National Health Service Corps (NHSC) exists to ensure that healthcare providers are available to serve in the most underserved areas of the country. The NHSC acknowledges that even if a clinician is dedicated to caring for underserved populations, it can often be unfeasible for them to do so without additional incentives for a variety of reasons. To recruit clinicians to serve in these areas, the NHSC operates both a scholarship and a loan repayment program; both of these initiatives entail a service obligation upon graduation that requires the clinician to work in an underserved area for a length of time depending on how much assistance he or she received while in school. There are currently more than 4,000 active NHSC clinicians providing care to nearly 4 million U.S. residents.

Health Disparities Collaboratives

Beginning in 1998, HRSA established a national network of Health Disparities Collaboratives (HDC) to gather evidence of improved health outcomes among disadvantaged populations and to use these data to implement new evidence-based practices. Using the Chronic Care Model, the HDC seeks to address medical conditions that are the most expensive for community health centers to treat or for which a large number of patients are seen at the center. These conditions included diabetes, cardiovascular disease, asthma, cancer, and depression. More than 450 federally funded, community health centers have participated in the HDC since the program's inception.

Data Collection and Availability

HRSA maintains a variety of data—related to healthcare access, clinician workforce, and related sociodemographic factors—accessible through its geospatial data warehouse. Most notable among these are the Area Resource File (ARF), the National Practitioner Data Bank (NPDB), and the Health Centers Uniform Data System (UDS).

The ARF is a national database of county-level health resource information, combining data from more than 50 varied sources such as the American Medical Association's Physician Masterfile, the U.S. Census Bureau, and the CDC. Taken together, these data make the ARF one of the most comprehensive sources of county-level health resource data and include demographic data, indicators of need, and provider availability.

The NPDB is a national repository of information collected on clinicians, with a focus on those who are reported to HRSA as having acted without integrity in their profession. State medical boards and other entities report this information to the NPDB to identify clinicians who have behaved unprofessionally, paid an excessive number of malpractice suits, or had their license revoked and have moved from one state to another.

The UDS collects data on all the programs in the Consolidated Health Centers Program. By law, all programs receiving federal grant funding from HRSA's BPHC are required to submit annual UDS reports. The data reported include information about the health center's governing board and operating

staff, characteristics of the population served, services the program provides, and the financial performance of the organization. The bureau then uses these individual reports to compile aggregated data at the state, regional, and national levels. HRSA also uses the UDS data to monitor the performance of individual health centers and their compliance with federal laws as well as to evaluate the program as a whole in support of the annual budget requests submitted to the U.S. Congress.

Further Implications

HRSA plays an essential role in increasing access to healthcare for underserved areas and populations by funding projects; expanding opportunities for health professionals; and providing health information and data to agencies, researchers, clinicians, and the general public. In the future, the efforts of HRSA will continue to be important, especially with the federal goal of eliminating health disparities.

HEALTH SAVINGS ACCOUNTS (HSAs)

Health savings accounts (HSAs) are a relatively new phenomenon in the United States. HSAs are tax-advantaged savings accounts for individuals who are enrolled in high-deductible health plans. HSAs came into existence with the passage of the Medicare Modernization Act of 2003 (MMA). The MMA, federal legislation that introduced a pharmacy benefit for Medicare enrollees, also included provisions for private, fee-for-service health plans. These private health plans are under the consumer-directed health initiatives.

Overview

In 1984, John Goodman—the president of the National Center for Policy Analysis and an early proponent of initiatives to allow individuals to take control of their healthcare expenditures—began advocating for consumer-directed health plans. He wrote numerous newspaper articles and gave speeches at national meetings on the potential benefits of allowing private citizens to manage their own healthcare rather than ceding control to insurers and providers. He also went to the U.S. Congress and gained legislative support from both Democrats and Republicans to examine alternatives to the existing employer-sponsored health insurance plans.

In the 1990s, healthcare expenditures in the country appeared to be under control with the introduction of managed care. During this time, there were numerous commercial plans that entered the health insurance business and expanded their offerings to include managed care. Insurers soon found that healthcare was a difficult business in which to operate, and they eventually sold off their

health divisions to insurers that planned to stay in the healthcare business. Aetna, Cigna, and UnitedHealth are examples of commercial insurers that stayed in healthcare, along with the Blue Cross and Blue Shield plans.

In the late 1990s, healthcare expenditures started to rise again when health maintenance organizations (HMOs) and managed-care products fell into general disfavor. Insurance subscribers were looking for better options than the restrictions imposed by HMOs and managed care. The HSAs, included in the MMA, seemed to meet the need for cost controls that the insured person could manage, and it provided an alternative for the non-Medicare population.

Provisions of HSAs

The Internal Revenue Service (IRS) developed guidelines for HSAs in its 2004 tax year documents. To enroll in an HSA, individuals must have a trustee—either a bank, employer, or the IRS. The advantages of HSAs include (a) the ability to claim a tax deduction; (b) the ability to exclude the amount put into the HSA from gross income, if the amount is contributed by an employer; (c) the contributions can remain in the account until the money is used; (d) the interest accrued on the account is tax free; (e) the contributions are portable and can be moved, if there is a job change; (f) the monies can be transferred to an heir; and (g) the funds can be used for nonhealthcare purposes by paying income taxes.

The prospective HSA member enrolls with an IRS-designated trustee. The enrollee pays into the plan on an annual basis. The contribution is up to a given deductible amount not to exceed \$2,600 for an individual and \$5,150 for a family. The HSA member can contribute these amounts each year until the close of the tax year, which is April 15. When the HSA member files his or her taxes for the preceding year on the Form 1040 U.S. Individual Income Tax Return, he or she must also file the Health Savings Account Form 8889. When enrolling in a HSA, the enrollee must designate a beneficiary in case of death so that the account can be transferred to an heir.

As of January 2008, there were an estimated 6.1 million HSA enrollees in the nation. Health insurers see HSAs as an opportunity to expand their product lines. However, insurers are receiving competition from banks, credit unions, and money management firms; they see these accounts as a financial vehicle, and many have registered to become trustees. This competition from the financial industry has caused some insurers to purchase banks, as evidenced by UnitedHealth's acquisition of Exante Financial Services and the Blue Cross Blue Shield Association's charter of the Blue Healthcare Bank, owned by 33 Blue Cross and Blue Shield companies.

The verdict is still out on the possible success of HSAs. Patients have to pay out-of-pocket costs until they reach their deductible limit. After the deductible threshold is reached, providers then bill the HSA. Providers need the billing expertise to complete the transaction and patients need the education to use HSAs appropriately.

Some have criticized HSAs because they tend to attract a more affluent and educated population who are more willing to take responsibility for their own health. This takes a healthy population away from insurance pools leaving those who are less healthy and less willing to take responsibility for their health, which increases the premium dollars for those left in the insurance pools. While HSAs move the responsibility to the individual, the account does nothing to control healthcare costs. The individual takes advantage of the insurer's negotiated rates, but this does not address the cost escalation in healthcare. The enrollee has to manage with these predetermined rates. Yet for those HSA members who remain vigilant and mindful of their healthcare purchases, the HSA may work well.

Future Implications

In the future, the number of individuals enrolled in HSAs will likely increase. Many employers want to limit their exposure to healthcare insurance costs, and a number of healthcare proposals are being advanced to promote the private healthcare marketplace. They are concerned about the rates of obesity, diabetes, and

high blood pressure in the population that, in many cases, can be successfully managed if individuals begin to accept responsibility for maintaining their own health through wise decision making. With the support of employers, insurers, and some of the general public, HSAs may continue to expand as an alternative insurance option.

HEALTH SERVICES RESEARCH, DEFINITION

Today, health services research (HSR) is a recognized and well-respected field of investigation, supported by numerous government agencies, foundations, health plans, and insurers. The products of its research are widely used by policymakers; regulatory agencies; healthcare providers; health plans; insurers; and increasingly, by the general public. In 2001, the Association for Health Services Research, the predecessor to the AcademyHealth, adopted its currently accepted definition:

Health services research is the multidisciplinary field of scientific investigation that studies how social factors, financing systems, organizational structures and processes, health technologies, and personal behaviors affect access to healthcare, the quality and cost of healthcare, and ultimately our health and well-being. Its research domains are individuals, families, organizations, institutions, communities, and populations. (Lohr and Steinwachs, 2002, pp. 7–9)

The definition of HSR has changed and evolved over time reflecting the capacity of the field to address the increasingly complex array of health services, the role of preventive as well as curative services, and the impact of services on both individuals and populations. In 1979, a National Academy of Sciences, Institute of Medicine (IOM) report titled *Health Services Research: A Report of a Study* stated: “Health services research is inquiry to produce knowledge about the structure, processes, or effects of personal health services” (p. 14). The early and current definitions substantially overlap. The earlier definition was understandable to researchers who produced HSR but likely not very understandable to the wide range of HSR users and the public. The current definition should be clearer to users of HSR and is more encompassing, recognizing the importance of social factors and personal behaviors on the use of health services and health outcomes. The definition identifies specific characteristics of the health services that are of particular importance, including access to care, quality, cost, and their contribution to

health and well-being outcomes. These characteristics are to be examined and understood for individuals and for populations. The linkage of individual and population health forms an explicit bridge between medicine and public health and between health service interventions at both the individual and population or community levels. These changes in the definition document the changing vision for HSR and for health services.

In the following sections, a brief history of the field is provided, followed by a discussion of the basic concepts and tools of HSR.

History

Looking back over the history of the field, it can be seen how HSR has changed to reflect the growing breadth of understanding of the factors affecting health and the increasing scope and effectiveness of health services.

HSR traces its beginnings back to the 1920s and initiatives by philanthropic foundations to improve the living conditions of the poor. In the 1950s, the first legislation was passed by the U.S. Congress to support studies of health services. The name *health services research* was initially applied in the mid-1960s to a federal grants review study section awarding research funds authorized under the Hill-Burton Act. The research was to benefit hospitals by providing guidance to improve hospital operations ranging from nurse-staffing models to scheduling and patient flow models. As reported by Charles Flagle, a member of this study section, HSR was seen as the field addressing operational problems in healthcare and specifically in hospitals.

In 1967, U.S. President Lyndon B. Johnson ordered the creation of the National Center for Health Services Research (NCHSR) in the federal Department of Health, Education, and Welfare (DHEW). The name was subsequently changed to the Bureau of Health Services Research and Evaluation and then to the National Center for Health Services Research and Development (NCHSR&D). In 1989, the U.S. Congress passed legislation replacing NCHSR&D with the Agency for Health Care Policy and Research (AHCPR). This elevated HSR to the same organizational level in the Department of Health and Human Services (HHS) as the National Institutes of Health (NIH).

One of the congressional mandates for the AHCPR was to undertake outcomes research to learn what services benefit whom and under what circumstances. Also, the new agency was to integrate knowledge from health services and clinical research and develop practice guidelines for providers and patients. The goal was to improve quality and reduce the costs associated with unnecessary use and ineffective services. In 1999, when the U.S. Congress reauthorized the AHCPR, its name was changed to the Agency for Healthcare Research and Quality (AHRQ). At the same time, the U.S. Congress removed the mandate for AHRQ to develop and disseminate practice guidelines and removed the word *policy* from its name. Controversy had surrounded the AHCPR's roles in health policy reform and in disseminating practice guidelines that defined preferred treatments. These changes modified the scope of its mission.

In seeking to understand which health services work best, for whom, and under what circumstances, the AHRQ is expected to provide information that ultimately affects the practice of medicine. In the Medicare Modernization Act of 2003, the U.S. Congress gave the mandate to AHRQ to undertake comparative-effectiveness research. The goal of comparative-effectiveness research is to provide information not currently available on which alternative treatments for specific health problems are best and for whom. The findings from comparative-effectiveness studies are expected to influence medical-care choices made by providers and by healthcare consumers, and may influence coverage choices made by payers and health plans. To the extent the comparative evidence leads to winners and losers in the medical marketplace, the interpretation and robustness of the HSR data will likely be challenged. Although this may be uncomfortable for the field at times, it will signify the maturity of HSR and its growing capacity to provide timely and relevant information that can improve the quality of healthcare.

HSR has provided the tools used by healthcare policymakers to modify payment methodologies (e.g., case-mix adjustment and pay-for-performance), measure performance (i.e., quality) of providers, and regulate the healthcare industry. Advances in measurement methodologies have made it possible to restructure and refine the

incentives inherent in payment, regulatory, and quality reporting methodologies. HSR is increasingly relied on to provide the methods and measurement tools needed to evaluate the efficiency and quality of care and to provide the knowledge needed by policymakers, providers, payers, and the general public to make better-informed health-care decisions.

Basic Concepts and Tools

HSR is a field of study that draws on the theories and methods of the social and behavioral sciences, economics, medicine, public health, engineering, and mathematical disciplines. As a result, the tools used in HSR are not unique to the field. What has emerged as unique, however, is their adaptation to the understanding of health services and patient outcomes. Three research themes have dominated the HSR field: (1) controlling rising healthcare costs and improving efficiency, (2) improving the quality of healthcare services to ensure the best outcomes for patients, and (3) improving access to healthcare for disadvantaged and uninsured populations. Health services outcomes are defined broadly and include mortality, morbidity, health-related quality of life, satisfaction, and healthcare costs.

Healthcare Costs

Rising and difficult to control, healthcare costs have been a persistent public policy issue since the passage of the Medicare and Medicaid programs in 1965. Health economists have contributed to the understanding of the complexity of forces driving healthcare costs, including the lack of cost competition among providers, the design of health insurance plans in a way that protects individuals from having to make economic choices (moral hazard), and failures to provide consumers with information on cost and quality trade-offs. The classic RAND Health Insurance Experiment (HIE) of the 1970s demonstrated that increasing the level of out-of-pocket payments (coinsurance and deductibles) for healthcare reduces the average use of health services and costs. An analysis of episodes of care by Keeler and Rolph showed that the level of out-of-pocket payments was a primary influence on the decision whether or not to seek healthcare.

Once the decision to seek healthcare was made, coinsurance and deductibles had little effect on the cost of the episode of treatment. One interpretation of this finding was that once the patient was receiving healthcare, the physician and not the patient largely determined the extent of utilization.

Recognition that incentives for efficiency needed to be present for both providers (supply side) and patients (demand side) led to policy innovations using HSR tools. When the Medicare program was started, it made cost-based payments to hospitals and usual, customary, and reasonable payments to physicians. As a result, healthcare costs rose rapidly as hospitals and physicians learned how to maximize their income. In 1983, Medicare implemented a prospective payment system (PPS), paying hospitals a prospectively set rate for each admission based on the discharge diagnosis and procedures. The classification system used in this payment system, diagnostically related groups (DRG), was a product of 1970s HSR. In that the DRG payment for inpatient episodes was independent of the patient's length of hospital stay, it provided strong financial incentives for shorter hospital stays. The payment system also created a financial incentive to increase the number of admissions (episodes), to fill the beds emptied due to reductions in the average length of patient stays. To avoid paying for unnecessary admissions, Medicare instituted reviews of hospital admissions to ensure appropriateness. The review of admissions applied criteria from the Appropriateness Evaluation Protocol (AEP), a product of HSR studies.

Health maintenance organizations (HMOs) date back to the Kaiser Permanente clinics for employees in the 1930s. In 1983, the U.S. Congress passed the HMO Act, which defined the HMO in federal law. HMOs receive a fixed capitation payment for each enrollee (per person, per year) instead of being paid on a fee-for-service basis. The incentives associated with capitation payment are, clearly, to live within a budget equaling the total enrollment times the capitation rate. To balance their budgets, some consumers challenged that HMOs were sacrificing quality of care to save costs. HSR in the 1970s and 1980s examined the quality of care of HMOs compared with the fee-for-service care provided in the same communities. The findings consistently showed that HMO quality of care was equal to or better than fee-for-service care.

In the 1990s, there was rapid growth of managed-care plans that used administrative processes to manage utilization during episodes of treatment to control the costs of care (e.g., prior authorization, utilization review, and limits on the number of services). These plans generally did not impose deductibles and charged modest copayments to avoid discouraging ambulatory care utilization. Overall, utilization controls were principally supply side, where it was perceived that the greatest impact could be achieved. Public reaction to health plans controlling utilization and limiting access to some specialists and/or tests and treatments was very negative. One result was that health plans began offering insurance plan options to enrollees that allowed them to retain greater choice by paying higher premiums. The public concerns also contributed to laws in many states that required timely appeal processes, using third parties, when services were denied.

Another concern was that HMOs and managed-care plans were responding to the capitation payment method by seeking to enroll healthier people and avoiding very sick people in the community. This was a result of having capitation rates based on age and not explicitly taking into account health characteristics. HSR investigators developed and validated methods for risk adjustment. Today, these methods are being applied to adjust capitation rates based on the health characteristics of enrolled populations, better matching the capitation rate to the healthcare needs of the enrollees.

Healthcare Quality

The accepted paradigm for examining the quality of healthcare is drawn from the seminal work of Avedis Donabedian. Quality of care is influenced by the structure of the healthcare system and its resources and by the processes of diagnosis, treatment, and management. These come together to influence the health outcomes experienced by patients. The measurement of quality of care involves the measurement of structural and process of care characteristics and their influence on patient outcomes. With advances in HSR and clinical research, knowledge is growing and clarifying the contribution of specific treatments (processes) to the likelihood of alternative health outcomes.

Provider licensure and facility accreditation is required by states and payers and, for a long time, was accepted by the public as sufficient to protect their quality of healthcare. Accrediting organizations for hospitals and health plans (e.g., the Joint Commission and the National Committee for Quality Assurance [NCQA]) require healthcare organizations to meet structural standards and conduct studies to measure care processes and patient outcomes. The findings from these studies are expected to feedback into the care processes to improve patient outcomes. Quality of care, however, became a prominent public policy issue during the late 1990s. One source of concern were decisions made by managed-care plans that specific tests or procedures ordered by the patient's physician were "not deemed medically necessary" and would not be covered by the managed-care insurer. Disagreements about medical necessity between physicians and managed-care plans put the patient in the difficult position of having to decide who to believe and tested the patient's willingness to pay out-of-pocket costs for the physician-ordered tests or treatments not covered by their plan. Other sources of concerns came from HSR studies showing that only half of the time did patients receive care meeting the quality standards for their chronic health problems. And other HSR studies reported high rates of medical errors in hospitals, contributing to morbidity and mortality. The mounting evidence of these problems turned the nation's attention to the great need for more research and policy initiatives to improve the quality of healthcare.

In *Medicare: A Strategy for Quality Assurance*, the IOM defined quality of care as "the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge" (p. 21). The emphasis is on providing care that can be expected to lead to the best outcomes. However, for many this is not sufficient: Instead, the care provided should increase the likelihood of the outcomes desired by the patient. And the patient's desired outcomes may differ from the usual medical treatment goals, which would be expected to be to reduce mortality and morbidity risks. Patients, however, may be willing to incur increased mortality and morbidity risks to improve quality of life outcomes (e.g., to be able to do those

activities valued by the patient). The relationship of treatment choice to trade-offs in outcomes may be most often discussed as a consideration for end-of-life care, when treatments that may extend life may also significantly diminish quality of life for the time that remains. In routine healthcare, treatments prescribed that interfere with a patient's ability to work or carry out other usual activities may be less desired.

Starting in 1999, the IOM produced a series of reports that informed the general public and policymakers that America's healthcare was facing serious quality problems. Tens of thousands of Americans were dying each year due to medical errors and the failure to provide consistent, high-quality care. In a 2001 report titled *Crossing the Quality Chasm: A New Health System for the 21st Century*, the IOM found that the American healthcare system was fundamentally flawed. Systems of care were largely dysfunctional; not meeting the growing needs of chronically ill populations; and failing to provide continuing, coordinated, and integrated healthcare. The report concluded that to create a functioning healthcare system, it would require a fundamental transformation of the current system. The report also stated six specific goals for quality of care for the future. Specifically, patients should receive care that is safe, effective, timely, patient centered, efficient, and equitable. And increasingly, the reporting of the quality of healthcare findings is organized into these six categories. The *National Healthcare Quality Report*, mandated by the U.S. Congress, uses this framework to compare quality of care over time and across populations and diagnoses.

Access to Care

The American healthcare system differs substantially from systems in other developed nations (e.g., Canada, Germany, and the United Kingdom) by failing to provide health insurance coverage to all its citizens. The public commitment to health insurance coverage is limited. The Medicare and Medicaid programs cover the elderly, the disabled, and many, but not all, of the poor. The Veterans Administration covers those who have served in the military, with priority given to service-connected disabilities. The number of uninsured

Americans has been growing and was estimated by the Kaiser Commission on Medicaid and the Uninsured to be approximately 46.4 million in 2006. The HSR field has systematically documented the adverse health effects of being uninsured. Lack of health insurance is associated with fewer preventive services and contributes to significant delays in the receipt of necessary acute and chronic care.

In its report *Access to Health Care in America*, the IOM has defined access to healthcare as being the “timely use of personal health services to produce the best outcome” (p. 33). As a reminder of HSR measurement challenges that persist, the measurement of *timeliness* is not well developed. Early efforts to measure timeliness in ambulatory care showed that patients and physicians frequently disagreed about the timeliness of the visit. Criteria by which to judge timeliness of care do not exist for most medical conditions. Few quality standards specifically assess timeliness of care and little is known about the timeliness of most healthcare.

Improving access to care has proved to be more complex than merely extending insurance coverage to all Americans, although this is a prerequisite for access. Other barriers to access exist, including the lack of local availability of healthcare services, delays in being able to obtain visits with local healthcare providers, and limited understanding among consumers about how to use healthcare services most appropriately. Early researchers examined healthcare-seeking behaviors to understand individual decision making. The concepts of perceived health risks, the expected benefits, and overcoming the barriers to the receipt of care were conceptualized and measured. It was recognized that the failure to receive timely care may be the result of complex interactions of patient decision making, insurance coverage, availability of appointments with providers, delays in receiving tests and results, and competing demands in the patient’s life. Today, it is widely acknowledged that consumers must be educated to be able to achieve the maximum benefits from the health services available. Also, many believe that to have a responsive American healthcare system, all citizens need to have adequate health insurance coverage. The means for achieving these goals are a current priority for HSR.

Disparities in Healthcare

Among the most vexing problems in American healthcare are the extensively documented disparities in the health services received by racial and ethnic minorities as compared with the majority population. One contributor is poorer access to care among minorities. However, disparities persist even after people have entered treatment. In a groundbreaking national report *Unequal Treatment: Confronting Racial and Ethnic Disparities in Healthcare*, the IOM found that significant disparities in treatment occurred in physician’s offices and resulted in the generally lower quality of care for racial and ethnic minorities. The report described the multiple dimensions of this problem, including the extent to which disparities are associated with cultural differences, language and communication differences, increased uncertainty about best treatment, or stereotypes and biases toward ethnic and racial minorities. The evidence is convincing that disparities exist and are harmful. The future challenge for HSR is to identify ways to intervene effectively to prevent disparities in quality of care from occurring. The goal is to strengthen the capacity of the nation’s healthcare system to provide equal quality care for all.

Future Implications

The definition of HSR and associated definitions of quality of care and access to care are shaped by our understanding of the contributions of health services to disease and the health outcomes of individuals and populations. As a result, these definitions can be expected to change as we learn more. In the future, the definition of HSR may more specifically address the importance of environmental factors and their effects on health and the need for services. Changes in technology may also lead to changes in the definition. For example, as new technology makes it possible for individuals to self-diagnose and the potential for self-management or treatment becomes greater, the distinction between patient and provider may blur. Even today, we recognize that successful chronic-disease management is highly reliant on the patient and the family to manage day-to-day care. Successful chronic-disease management requires patients to be able to identify and appropriately respond to

acute exacerbations. Although the defining characteristics of HSR may change in the future, the desired outcomes are likely to remain the same: protecting and improving individual and population health and well-being.

HEALTH SERVICES RESEARCH, ORIGINS

Healthcare providers, public health officials, and others were examining access, cost, quality, and the outcomes of healthcare long before the term *health services research* (HSR) was coined. While many countries and cultures have been grappling with issues concerning the efficacy and efficiency of healthcare delivery and medical outcomes for centuries, the United States has a particularly rich history in this subject.

The field of HSR has codified diverse concepts and methods under a broad rubric within the past century. In contrast to the rapidly evolving arena of biomedical research, there was no defined field of scientific investigation that encompassed the many disciplines, methods, and problems being addressed. Instead, the field of HSR included the questions being asked about the disparate facilities, personnel, management, use, benefits, risks, costs, social and behavioral influences, and outcomes brought

to bear on the full spectrum of human health and disease. Early efforts to expand and formalize the study of HSR laid a strong foundation for the careful examination of the nation's healthcare system and the ongoing efforts to improve it.

The National Information Center on Health Services Research and Health Care Technology (NICHSR) has compiled a comprehensive history of the field, highlighting important milestones and events that helped define the area of study. This entry examines this history and the origins of HSR.

History

Early History

Many early achievements in the field of health services can be credited to England. In the 17th century, Sir William Petty (1623–1687), a physician and an economist, used quantitative reasoning when looking at physician practice and hospital care. William Farr (1807–1883) relied on statistical data on morbidity and mortality to evaluate the effectiveness of the healthcare system in the 19th century. Florence Nightingale (1820–1910), considered the founder of modern nursing, worked with Farr to develop uniform reporting procedures for British hospitals; she also was one of the first researchers to use graphics to explain and promote good hygiene practices.

The Industrial Revolution in the United States spurred the creation of many public health entities designed to promote hygiene, nutrition, and safety. These early agencies focused on assessing the health needs for many populations, as well as evaluating the success of health interventions; they relied on health services approaches to measure the outcomes of their programs. The U.S. Public Health Service (USPHS), which was established in 1798 to provide medical care to merchant seaman, expanded its role to partner with local public health departments in keeping military training bases free of disease during World War I. The American Public Health Association (APHA), which was established in 1872, examined the coordination of local public health departments in providing coverage to the whole country following the passage of the federal Social Security Act in 1935. The predecessors to the Association of American Medical Colleges (AAMC) and the

National Institutes of Health (NIH) were founded during this time, and the first issues of the *Journal of American Medicine* and the precursor of the *New England Journal of Medicine* also appeared in the 19th century.

Early 20th Century

Research on health services continued into the turn of the 20th century, with many studies addressing the role of health professionals and institutions and examining the impact of disease and disability in the United States. For example, Hull House and the Chicago Medical Society conducted a birth record study in 1908 to document the role of midwives during childbirth; the Flexner report, published in 1910, investigated the quality of 130 medical schools in North America and recommended the closure of 100 schools. Other efforts included the Report on National Vitality in 1909, surveys carried out by insurance companies, and several studies looking at social and health insurance.

The American Medical Association (AMA) surveyed the characteristics and the geographic distribution of hospitals in the nation in 1919. Ernest Codman (1869–1940) developed a system to monitor surgical outcomes; he was also a founding member of the American College of Surgeons (ACS) and its Hospital Standardization Program. The Committee on the Costs of Medical Care (CCMC) was created in 1927, and it conducted 27 different studies in the late 1920s and early 1930s before publishing its final report, *Medical Care for the American People*.

The Great Depression

The social and political conditions of the Great Depression, which started in 1929 and lasted until the beginning of World War II, prompted several policy changes and further examination of the insurance and healthcare systems. During this time, the Social Security Act was passed by the U.S. Congress; the Blue Cross and Blue Shield plans developed to insure patients for physician care and hospital care; and important studies—such as the National Health Survey and the Department of Labor, Division of Cost of Living surveys—examined health disparities, the impact of income on health status, and access to quality healthcare.

Laws passed as part of the New Deal increased the federal government's role in social programs and funding. However, private, charitable organizations still played an important role in advancing HSR. The Milbank Memorial Fund, the Commonwealth Fund, and the Kellogg Foundation all focused on improving healthcare in the country, and they helped fund the publication and dissemination of books and reports. In 1936, the Robert Wood Johnson Foundation (RWJF) was established; it would eventually become one of the largest healthcare foundations in the country. While these philanthropic entities provided essential support during the Great Depression, all of them continue with their expanded efforts today.

Federal Legislation

Following the findings of the special Committee on Medicine and the Changing Order, which was established by the New York Academy of Medicine and the American Hospital Association's Commission on Hospital Care, the U.S. Congress passed the Hospital Survey and Construction Act of 1946. Better known as the Hill-Burton Act, this federal legislation allowed for funding and conditions that expanded hospital construction throughout the country, especially in rural areas. The funding encouraged states to plan and build hospitals, which greatly increased the number of facilities and hospital beds. That same year, the U.S. Congress also passed the National Mental Health Act—which promoted research, training, and treatment centers in mental health—and the National Health Service Act, which organized local health centers to provide health services.

In 1949, the U.S. Congress recognized the need for research activities directed toward understanding and improving hospital facilities. In 1954, amendments to the Hill-Burton Act allowed for funding to support chronic-care facilities. One year later, policy was expanded to provide additional funds for research in hospital operation and administration in response to the identified need. Louis Block, a former hospital consultant, served as chief of the Research Grants Branch of the then U.S. Department of Health, Education, and Welfare (DHEW). In 1955, Block worked with John Cronin, chief of the Division of Hospital and

Medical Facilities, and U.S. Congressman John E. Fogarty to increase that year's Hill-Burton appropriation for what Block construed as medical-care research. These efforts resulted in a \$1.2 million increase in the available funds supporting research and initiatives in hospitals and other related health fields to gather information and develop new methods. They also advanced the field of HSR. Funding for this legislation ended in 1975.

Beyond the Hill-Burton legislation, the U.S. Congress passed several federal laws to expand public health and HSR. The Health Research Act of 1956 authorized increased funding for research into major diseases. In addition, the National Health Survey Act was also passed that year and provided for data collection, research, and statistical analysis on health needs, including special sickness and disability studies, by the USPHS.

The changing social climate in the United States, especially the Civil Rights movement, highlighted the issue of poverty for many Americans. The Civil Rights Act, the Economic Opportunity Act, the Comprehensive Health Planning and Services Act, and the passage of the Medicare and Medicaid programs allowed researchers to further examine issues of the medically underserved, access to services, advances in health technology, health economics, and the role of the healthcare professional. This expansion of federal policy set the stage for new laws and amendments to come in the 1970s and 1980s, much of it helping advance the role of HSR.

The Role of the National Institutes of Health

Because of the expansion of the Hill-Burton Act to include research, the NIH's Division of Research Grants (DRGs) was assigned the responsibility for reviewing new grant applications in 1955. Several NIH Study Sections existed at that time, including ones for Sanitation, Environmental Health, Public Health, and Public Health Methods. The Nursing Research Study Section was established to examine patient care. Shortly after this time, the NIH proposed the creation of the Hospital Facilities Research Study Section. These study sections were designated the Health Services Group.

After much internal debate as to the mission of the study sections and the gaps in research needs not being addressed by any one group, members of

the sections recommended expanding the role of the Hospital Facilities Research Study Section beyond the narrow scope of hospitals to include research on patient care and healthcare systems. In 1960, the NIH established the Health Services Research Study Section. It was primarily responsible for operational research in a community setting such as a health department; it was charged with the review of research grant applications in the area of community health, including needs, resources, planning, and practices of professionals, organizations, and institutions. The section was also responsible for reviewing applications for public welfare programs as they related to community health.

The Health Services Research Study Section, however, soon became focused on defining and developing its field, stimulating needed research, and improving research quality and credibility. Program development became just as important as reviewing grant applications. Kerr L. White, who gained a reputation as a health services researcher at the University of North Carolina, served as chairman of the study section from 1963 to 1965. One of his major initiatives at this time was to commission a set of articles that defined the scope, methods, standards, and applications of HSR. White organized a special symposium on medical care research in 1964. The *Milbank Memorial Fund Quarterly* published these articles in a special issue on HSR in 1967.

The leadership of the Health Services Research Study Section envisioned this new field as an amalgam of the perspectives of public health and clinical medicine, including methodology from economics, social survey research, epidemiology, biostatistics, and systems analysis. Another initiative of the group was to launch the new journal *Health Services Research*, first published in 1966. The first issue covered four topics: length of stay, statistical methods, health services utilization, and informatics. Other journals followed, such as *Medical Care Review* and *Social Science and Medicine*, offering health services researchers the opportunity to publish their studies and share their findings.

Other HSR Agencies

Although the inclusion of the Health Services Research Study Section at the NIH was key to

shaping and expanding the field, several other federal government agencies also had an important impact. The national Institute of Medicine (IOM) was established in 1970 to study policy issues that affect the health of Americans. Its work deals with quality of care, access to services, and healthcare financing and coverage systems.

The National Center for Health Services Research and Development (NCHSR&D), established by Executive Order in 1968, was created to support research, development, demonstrations, and related training directed to the improvement of the organization, staffing, delivery, and financing of health services, including the design and operation of health facilities. By 1974, that entity became the National Center for Health Services Research (NCHSR). The Veteran's Administration also started a Health Services Research and Development Office, and the U.S. Congress created the National Center for Health Statistics (NCHS) in 1974 to compile statistical information to guide policy to improve health. The Health Care Financing Administration (HCFA) was established in 1977 to oversee the Medicare and Medicaid programs; now known as the Centers for Medicare and Medicaid Services (CMS), this entity helped develop and establish the prospective payment system for Medicare recipients.

In the late 1980s, the U.S. Congress established the Agency for Health Care Policy and Research (AHCPR) from the National Center on Health Services Research (NCHSR). It was focused on patient outcomes and responsible for developing and sharing clinical practice guidelines, quality standards, medical review criteria, and performance measures. The AHCPR initiated Patient Outcomes Research Teams (PORTs), large multidisciplinary, multi-institutional projects that examined patient outcomes, treatment standards, and practice effectiveness for common chronic and acute conditions. Similarly, the AHCPR also sponsored the use of evidence-based clinical practice guidelines; through a partnership with the AMA, it set up the Web-based National Guideline Clearinghouse. In 2000, the U.S. Congress established the Agency for Healthcare Research and Quality (AHRQ) from the AHCPR.

Other federal agencies key to the promotion and growth of HSR include the Health Resources and Services Agency (HRSA), the Substance Abuse

and Mental Health Services Administration (SAMHSA), and the National Information Center on Health Services Research and Health Care Technology (NICHSR)

Private and professional organizations also play an important role in the ongoing efforts of HSR. Universities and private research centers—including the RAND Corporation, which conducted its seminal Health Insurance Experiment from 1974 to 1982—enable the field to make notable advances. The Joint Commission, a nonprofit organization originally founded in 1951, has expanded its mission to improve the safety and quality of care to the general public through rigorous accreditation of healthcare organizations and facilities. The International Society of Technology Assessment in Health Care (ISTAHC) was organized in 1985 to encourage research, education, cooperation, and the exchange of information. It became the Health Technology Assessment International (HTAi) in 2003.

The Association of Health Services Research (AHSR), founded in 1981, was a prominent group that strove to educate the public and politicians about the importance of HSR. Through a merger of the AHSR and the Alpha Center in 2000, the group is now known as AcademyHealth. Its mission is to promote interaction across the health research and policy arenas by gathering perspectives from many disciplines and professions and fostering working relationships between scientists, advocates, and policy makers. AcademyHealth partners with government offices, philanthropic foundations, and universities on a broad array of projects.

Future Implications

The middle of the 20th century proved to be a defining time for the field of HSR in the United States. Now, several subspecialties of the field have emerged, including clinical epidemiology, evaluative health sciences, evidenced-based medicine, health economics, health policy research, healthcare research, medical-care research, outcomes research, patient care research, and population health research. These areas are all concerned with improving access, cost, quality and the outcomes of healthcare.

Policymakers have taken an evidence-based approach to new legislation and regulations; they

rely on HSR to provide accurate data and strong recommendations for measures aimed at improving the nation's healthcare system. As this entry documents, the field made an impact on several social and health reforms in the past century. From helping control Medicaid costs to increasing access to care through the Medicaid and State Children's Health Insurance Programs (SCHIP), researchers have focused on assessing needs and evaluating programs. The field of HSR continues to evolve and expand to meet the changing needs of the nation.

Moving forward, health services researchers will be at the forefront of developing and implementing new healthcare reforms. As the nation continues to debate such issues as a national health insurance system, the escalating costs of healthcare, outreach efforts for chronic disease, and increased education for health promotion, its leaders will increasingly turn to the field of HSR for information and solutions.

HEATH SERVICES RESEARCH AT THE VETERANS HEALTH ADMINISTRATION (VHA)

The Veterans Health Administration (VHA) is the federal government's lead agency serving the healthcare needs of the veterans of the U.S. military services, and the largest healthcare delivery system in the United States. The VHA is part of the U.S. Department of Veterans Affairs (VA), a cabinet-level department of the federal government. The VA is composed of the VHA, the Veterans Benefit Administration, and the Cemetery Administration. The Veterans Benefit Administration administers many programs, including the GI Bill, mortgages, and compensations and pensions, while the Cemetery Administration administers 1,000 cemeteries across the nation for veterans.

Overview of the VHA

The VHA's mission includes healthcare, education, backup for the U.S. Department of Defense, and research.

Healthcare

In fiscal year (FY) 2007, the VHA comprised 155 medical centers providing inpatient and

outpatient services. The VHA operates more than 1,400 sites of care, including 872 ambulatory-care and community-based outpatient clinics, 135 nursing homes, 45 residential rehabilitation treatment programs, 209 Veterans Centers, and 108 comprehensive home care programs. The total staff of the VHA was 182,946 full-time equivalents, including 11,343 physicians, more than 50,000 nurses, and other clinical and support staff. These professionals provided care for a total of 7.9 million enrolled veterans, including 567,852 receiving acute-care inpatient services and an additional 300,000 receiving inpatient psychiatric care, nursing home, or other types of inpatient care. Enrolled veterans generated a total of 60 million outpatient visits. The VHA's total annual budget for FY2006 exceeded \$31 billion.

Education

The educational role of the VHA was initiated in 1948 with the now famous "Memorandum 2" signed by Omar Bradley, the director of the Veterans Administration, the precursor of the VA. This memorandum directed the VHA to develop affiliations with the nation's medical schools and other health-affiliated schools to develop a constant source of physicians and other healthcare workers for the VHA's healthcare mission. The VHA is currently affiliated with 107 medical schools, 55 dental schools, and more than 1,200 other schools across the nation. Each year, about 90,000 health professionals are trained in VA medical centers. More than half of the physicians practicing in the nation receive some of their professional training in the VA healthcare system.

Backup to the U.S. Department of Defense

The VHA's medical system serves as a backup to the U.S. Department of Defense during national emergencies and as a federal support organization during major disasters.

Research

One of the major strengths of the VHA is that it is a healthcare delivery system as well as

a research-granting agency. In FY2006, the U.S. Congress appropriated \$412 million for the Office of Research and Development (ORD) of the VHA. Because research is one of the main missions of the VHA, each medical facility contributes the cost of their investigators' salaries and infrastructure support for these grants, thus greatly enhancing the amount allocated by Congress. In 2006, this was an additional \$357 million from the medical-care account. Non-VA sources, such as the National Institutes of Health (NIH), other government agencies, and pharmaceutical companies, provided an additional \$882 million in funding for VA research.

VA research focuses on areas of concern to veterans. It has earned an international reputation for excellence in areas such as aging, chronic disease, prosthetics, and mental health. Studies conducted within the VA help improve medical care not only for the veterans enrolled in the VA's healthcare system but also for the nation at large. Because 7 out of 10 VA researchers are also clinicians, the VA is uniquely positioned to translate research results into improved patient care. VA scientists and clinicians collaborate across many disciplines, resulting in a synergistic flow of inquiry, discovery, and innovation between the laboratory and clinical settings.

The ORD of the VHA is divided into four services: Basic Research Service; Clinical Research (including Cooperative Trials) Service; Rehabilitation Research and Development Service; and Health Services Research and Development Service. Each of these services solicits requests for proposals in their designated areas. And each service has several study sections to review grant proposals.

Health Services Research and Development Service

The Health Services Research and Development Service (HSR&D) was initiated in 1976 with a budget of \$3.6 million. In FY2007, its budget was \$68 million. An additional \$14 million was allocated to HSR&D by Patient Care Services to administer the Quality Enhancement Research Initiative (QUERI) program.

Mission

The mission of HSR&D is to advance knowledge and promote innovations that improve the health and care of veterans and the nation. Many of the studies conducted by this service have been used within and outside the VA to assess new technologies, explore strategies for improving health outcomes, and evaluate the cost-effectiveness of services and therapies. The need for high-quality health services research (HSR) continues to grow to keep pace with and respond to the rapid changes under way within the VHA and in the healthcare community as a whole. The HSR&D carries out this mission through its various programs, including peer-reviewed research, career development, and research and resource centers.

Health Services Research

HSR in the VA examines the organization, delivery, and financing of healthcare from the perspectives of patients, caregivers, providers, and managers to improve the quality and economy of care. Specifically, the HSR&D is interested in evaluation of the structure, processes, and outcomes of care, including issues of patient safety and equity. The HSR&D is also concerned with system-level outcomes such as assessments of cost and access, as well as effective ways to translate clinical knowledge into practice. The underlying objectives of HSR in the VA are to understand and improve clinical decision making and care, inform patients, evaluate changes in the healthcare system, and inform VA policymakers.

HSR&D's projects are often multidisciplinary activities. They involve expertise in a combination of clinical fields (medicine and all its specialties, nursing, and other healthcare professions), social sciences (especially psychology, sociology, economics, and organization theory), and multiple research approaches and methods (experimental and quasi-experimental studies, survey research, database analyses, biostatistics, psychometrics, econometrics, and modeling techniques).

HSR&D's Components

The HSR&D has six components: (1) investigator-initiated research (IIR), (2) service-directed research,

(3) career development for clinicians and nonclinicians, (4) research centers, (5) resource centers, and (6) QUERI.

Investigator-Initiated Research

The largest component of HSR&D's budget is allocated to the IIR program. The HSR&D Service has active solicitations in 11 priority areas: (1) access and rural health; (2) complex, chronic condition care; (3) equity and health disparities; (4) health services genomics; (5) health informatics; (6) implementation and management research; (7) long-term care and care giving; (8) mental health; (9) postdeployment health; (10) research methodology; and (11) women's health.

Research proposals in these areas may request up to 4 years of funding and up to \$900,000; however, projects that can produce useful findings, either intermediate or final, in a shorter time frame are encouraged. The research designs used in the research studies are expected to be appropriate and efficient, with all budget categories well justified. All proposals are reviewed by a scientific-merit review board made up of experts in the area from within and outside the VA. Proposals must receive a high priority score to be considered for funding.

Service-Directed Research

The emphasis in service-directed research is on applied, action-oriented research that uses established evidence to create and document real change within an organizational unit. Projects respond rapidly to organizational needs, favor active facilitation over passive observation, modify approaches in midstream through formative evaluations, and share resources from VHA operational entities. Service-directed projects adopt the implementation framework used by the VA's QUERI. Principal investigators are encouraged to integrate their work with the QUERI program and to address conditions of high priority to the VHA because of prevalence, burden, urgency, or special emphasis populations.

Project proposals are solicited through announcements to VA's QUERI Centers, HSR&D's Centers of Excellence, or announcements to all the VA. On approval of a concept paper, a full project pro-

posal is requested from the investigator. Proposals are peer reviewed by an expert panel of reviewers, and if approved, are considered for funding.

Career Development for Clinicians and Nonclinicians

The Career Development Program is intended to attract, develop, and retain talented researchers working in areas of particular importance to improving the health and care of veterans. The program is open to clinicians and nonclinicians. Specifically, it includes the career development award one (CDA-1), career development award two (CDA-2), career development transition award (CDTA), and career development enhancement award (CDEA).

The CDA-1 is an entry-level career development program open to both clinicians and nonclinicians. It emphasizes mentorship and career development planning with full salary support for up to 2 years.

The CDA-2 is a midlevel program open to both clinicians and nonclinicians who must outline a 3- to 5-year agenda of career development and research activities. It includes full salary support for 3 to 5 years.

The CDTA is only open to clinicians who have submitted a merit review proposal that has been approved. This award provides up to 3 years of transition funding to ensure that their research career is well established.

Last, the CDEA supports established clinical and nonclinical scientists by providing the opportunity for a research sabbatical of up to 6 months to learn new research skills. To be considered for this award, an individual must have been an independent investigator in the VA for a minimum of 6 years. During the award period, the individual must devote 100% of his or her time to research.

Research Centers

There are 13 HSR&D Centers of Excellence located throughout the nation. In addition, HSR&D's Research Enhancement Award Program (REAP) supports nine other research centers.

HSR&D provides core funding for its Centers of Excellence. Each center develops its own research agenda, is affiliated with a VA medical center, and collaborates with local schools of public health

and universities to carry out its mission. The research at each center serves to energize the facility and network with which they are affiliated and provides a constant source of innovation, creativity, and support. Centers of Excellence are competitively awarded and must compete for renewal every 5 years.

Current Centers of Excellence include the following: Center for Clinical Management Research, located in Ann Arbor, Michigan; Center for Health Quality, Outcomes and Economic Research (CHQOER) in Bedford, Massachusetts; Center for Organization, Leadership, and Management Research (COLMR) in Boston, Massachusetts; Center for Health Services Research in Primary Care in Durham, North Carolina; Center for Management of Complex Chronic Care in Hines, Illinois; Houston Center for Quality of Care and Utilization Studies (HCQCUS) in Houston, Texas; Center for Excellence on Implementing Evidence-Based Practice in Indianapolis, Indiana; Center for Research in the Implementation of Innovative Strategies and Practice (CRIISP) in Iowa City, Iowa; Center for Chronic Disease Outcomes Research (CCDOR) in Minneapolis, Minnesota; Center for Health Care Evaluation (CHCE) in Palo Alto, California; Center for Health Equity Research and Promotion (CHERP) in Pittsburgh and Philadelphia, Pennsylvania; Northwest Center for Outcomes Research in Older Adults in Seattle, Washington; and Center for the Study of Healthcare Provider Behavior in Sepulveda, California.

The HSR&D also provides core support for nine REAPs, located at VA medical centers and not affiliated with a Center of Excellence but which already have a history of HSR&D research and a minimum number of funded investigators. They are to develop a core program of investigators, statisticians, and other social scientists to support and facilitate the development of HSR&D research projects and the training and mentoring of new HSR&D investigators. REAP sites are smaller than Centers of Excellence but may compete to become a Center of Excellence when appropriate. REAP sites are competitively awarded and must compete for renewal every 5 years.

The current REAP sites include the following: Deep South Center on Effectiveness, located in Birmingham, Alabama; Colorado REAP to Improve Care Coordination for Veterans (CRICC) in Denver,

Colorado; Center for Healthcare Knowledge Management in East Orange, New Jersey; Rehabilitation Outcomes Research Center for Veterans with Neurological Impairment in Gainesville, Florida; Center for Mental Healthcare and Outcomes Research (CeMHOR) in Little Rock, Arkansas; Columbia Center for the Study of Chronic Comorbid Mental and Physical Disorders in Portland, Oregon; Veterans Evidence-Based Research Dissemination and Implementation Center in San Antonio, Texas; Program to Improve Care for Veterans with Complex Comorbid Conditions in San Francisco, California; and the VA Outcomes Group in White River Junction, Vermont.

Resource Centers

HSR&D provides core funding to three resource centers that support its management and investigators by providing data, consultation, and focused research on management issues, health economics, and informatics systems. The three centers are the Health Economics Resource Center (HERC), VA Information Resource Center (VIREC), and the Center for Information Dissemination and Education Resources (CIDER).

The HERC, located in Menlo Park, California, assists VA researchers in assessing the cost-effectiveness of medical care, evaluating the efficiency of VA programs, and providing and conducting high-quality economics research.

The VIREC, in Hines, Illinois, supports VA researchers using databases and information by creating a knowledge base of factual and evaluative information about the VA and select non-VA data. It disseminates information via a help desk, publications, a Web site, research user guides to select data sources, and a HSRData Listserv. The center also represents the interests of VA researchers using databases and information systems through formal and informal liaisons within the VA and with other healthcare agencies and organizations.

The CIDER, in Boston, Massachusetts, manages the HSR&D's national dissemination efforts. Specifically, the center manages the national HSR&D and QUERI Web sites. It coordinates HSR&D's cyber seminars, and it develops and contributes to HSR&D's research and development publications and other VA and non-VA publications and products.

Quality Enhancement Research Initiative

The HSR&D's QUERI is a multidisciplinary, data-driven, quality improvement program designed to ensure excellence in all places where the VHA provides healthcare services, including inpatient, outpatient, and long-term care settings. QUERI is designed to translate research discoveries and innovations into better patient care and systems improvements. It focuses on nine high-risk or highly prevalent diseases or conditions among veterans: chronic heart failure, diabetes, HIV/hepatitis, ischemic heart disease, mental health, polytrauma, spinal cord injury, stroke, and substance use disorders. QUERI aims to identify best practices, systematize their use, and provide the ongoing feedback necessary to maintain ongoing improvement.

Today and the Future

The VHA, through the active involvement and support of all its services, including HSR&D, leads the nation in healthcare quality indicators, such as the administration of beta-blockers to heart attack patients, breast and cervical cancer screening, immunizations, and diabetic care. It exceeds the national average in quality scores from the Joint Commission. It has set the benchmark in patient satisfaction for hospital services in the American Customer Satisfaction Index, an indicator developed by the University of Michigan Business School. And the VHA is widely recognized as an industry leader for patient safety. Other healthcare systems in the United States, as well as foreign nations, are studying the VHA's success and are trying to duplicate it.

HEALTH SERVICES RESEARCH IN AUSTRALIA

Australian healthcare appears to operate effectively, compared with other countries. Australians live longer than their counterparts in New Zealand, Canada, the United Kingdom, and the United States. Healthcare in Australia accounts for close

to 10% of the nation's gross domestic product (GDP). While this percentage is lesser than for Canada, France, Germany, and the United States, it is higher than for the United Kingdom or New Zealand. Australia's healthcare system ensures universal coverage for medical services, hospital care, and pharmaceuticals.

Nonetheless, Australia faces challenges, with rapidly increasing health service costs, lack of coordinated care particularly for chronic and continuing health problems, failures in safety and quality, and poor health outcomes for some population groups, most particularly indigenous Australians. In the future, advances in medical technology, a growing proportion of elderly, and population health changes such as the rise in obesity may continue to stretch health service delivery and the nation's capacity to finance the growing demands on the healthcare sector. Health services research (HSR) helps assess these issues, develop interventions, and inform policy change.

Background

Australia has a federal system of government in which both the national government and the States and Territories hold responsibility for healthcare. In addition, the system is a complex set of interactions between the public and private sectors in both healthcare finance and delivery. Most Australians live in urban centers along the southeastern coastline. Service delivery to the rural populations has to contend with large distances, remote centers, extremes of climate, shortages of healthcare workers, limited access to specialist and referral services, as well as the social and economic problems of remote communities.

The importance of Australian HSR has been recognized by many national reviews of health and medical research funding, acknowledging that reforms in health funding, financing, and the delivery of healthcare require solutions that are tailored to the Australian culture, history, and organization. There are several areas in which Australian research has made significant contributions. Australia was the first country in the world to introduce the requirement that the cost-effectiveness of new drug therapies be considered explicitly before new pharmaceuticals are added to the subsidized list. The use

of health technology assessment approaches to proposals for new government funding, particularly public health programs, has been evident over a longer period. Australian researchers have made significant contributions to the development of case-mix classification. HSR has also been used to develop and assess new methods of funding, though this has not been applied consistently, and many new funding schemes have been established with little or no independent research. In the important area of health workforce, there has been little independent or investigator-initiated research, although government inquiries and planning agencies have generated substantial activity. There is continued interest in the development of research that will ensure a suitable evidence base for policy development.

In addition, the Health Services Research Association of Australia and New Zealand (HSRAANZ) holds its major scientific meeting every 2 years. This active group represents the significant history and promising advances in this field.

Pharmacoeconomics

The Pharmaceutical Benefits Scheme (PBS) provides universal access to prescription medicines outside public hospitals and funds around 90% of prescriptions. Patients are charged a set copayment. Pharmaceutical manufacturers apply for a product listing on the PBS for specified indications. The submission is required to provide evidence of the drug's safety, effectiveness, and, since 1993, cost-effectiveness according to detailed guidelines. The evidence is reviewed and may be reworked by an independent advisory committee assisted by a team of independent evaluators. This requirement has generated a great deal of interest and work in pharmacoeconomics, though much of it occurs in the private sector and under commercial, in-confidence provisions. As a result, relatively little of it appears in the public domain.

Pharmaceuticals currently account for around 15% of Australia's total healthcare spending, but this has been the fastest growing component of the health budget for several years. The rationale for this approach is delivering value for money in new drug treatments rather than a focus on cost savings. Drug costs have continued to rise since 1993 and various cost-saving strategies, such as encouraging the use of generic drugs, have been adopted.

Economic evaluations submitted to the Pharmaceutical Benefits Advisory Committee (PBAC) use consistent methods, and a schedule of standardized costs is provided as a part of the submission guidelines. Although the committee favors the use of patient-relevant final outcomes, such as quality-adjusted life years (QALYs), a wide range of outcome measures are used. Although international clinical trials are considered rigorous evidence of safety and effectiveness, economic evaluation of Australian service delivery patterns and costs is also required so as to be relevant to the nation's context. The committee has largely made decisions that are consistent with the incremental cost-effectiveness result. The rigor of the evidence, the extent of uncertainty inherent in the evidence, the severity of the condition being treated and the availability of alternative treatments, equity, and the financial impact all depend on the scheme, and government health service funding more broadly can be considered.

Health Technology Assessment

A similar approach to health technology assessment is applied more broadly than to pharmaceuticals. Medical services provided elsewhere than in public hospitals, either in private hospitals or outpatient settings, are funded by a government rebate plus variable patient copayments, according to a schedule of specified services known as the Medical Benefits Schedule (MBS). The MBS covers primary care, surgical procedures, anesthesiology, pathology, and radiology. Since 1998, to be included on the MBS and to be recommended for public funding, new technologies and procedures must have evidence of safety, clinical effectiveness, and cost-effectiveness. Applications may be made by the manufacturers of devices or equipment, by provider groups, or by any interested party and should conform to the submission guidelines. The evaluations are conducted by teams working under the guidance of a specialist panel established by the Medical Services Advisory Committee (MSAC). These may extend or revise the original submission, both to ensure an adequate comparator for the incremental analysis and to incorporate Australian costs and other contextual factors. At this stage, MSAC guidelines only require a full economic evaluation if the proposed service is

expensive or likely to be widely used and are less prescriptive than PBAC about the type of analysis performed. The analyses are published as a series of MSAC reports.

In addition to the scientific evidence on safety, clinical effectiveness, and cost-effectiveness, the MSAC can also take into consideration access and equity; the prevalence and burden of the disease; the availability of alternative treatments; and the financial impact on the MBS, the public and private healthcare sectors, and society as a whole. Over time, these analyses have become increasingly sophisticated.

Nonpharmaceutical health technology assessment, however, preceded the development of the MSAC. Policymakers often commission substantial evaluations of new procedures as part of the consideration of new funding proposals. Although these efforts were in part under the auspices of some national technology assessment committee, the methodological approach adopted was not standardized across projects. Similarly, major public health programs, such as breast, cervical, and bowel cancer screening, have generally been required to demonstrate feasibility through pilot programs, which are evaluated for acceptability, effectiveness, and costs.

Many investigator-initiated projects work to evaluate a range of healthcare interventions, including public health programs, new methods of service delivery, and new procedures and diagnostic technologies. These studies can be funded from multiple sources, with variable impact on healthcare policy and practice, and where the objective may be more about knowledge creation or development of methods rather than immediate policy impact.

Case-Mix Classification

Interest in case-mix classification emerged in the 1980s, primarily from academic involvement in the development of a measurement tool, which could explain variations in lengths of stay and costs. The initial work was based on the Diagnostic Related Groups (DRGs) system developed at Yale University, but concerns about the relevance of this coding to Australian clinical practice provided the impetus for the development of a specific Australian classification system. Features of the Australian approach are the adoption of a national strategy,

involving both the federal and state health authorities with the commitment of substantial funding and other support, under the guidance of a committee of clinical experts, which has comprised medical, nursing, and allied health professionals. This undertaking produced a revised classification known as the Australian National Diagnosis Related Groups (AN-DRGs). The AN-DRGs were reviewed yearly and updated through three versions, increasingly encompassing a wider range of clinical factors such as age, malignancy, complications, and comorbidities as indicators of severity. A complete review of the classification structure was undertaken, prompted by the change to the International Statistical Classification of Diseases and Related Health Problems, 10th Revision (ICD-10). The result was the development of an Australian clinical modification of ICD-10, the ICD-10-AM, which is now in its fifth edition, and the Australian Classification of Health Interventions. The DRG system was renamed the Australian Refined Diagnostic Related Groups (AR-DRGs, Version 4.0). The Australian case-mix classification has been adopted by many other countries, including New Zealand, Ireland, and Germany.

The development of the Australian disease and intervention classifications and AR-DRGs represents a great deal of clinical and health services research. The research was given great impetus by the adoption of case-mix funding of public hospitals in the state of Victoria in 1993 and, subsequently, followed by most of the other states. Ongoing developments are managed by the Federal Department of Health and Ageing. This involves a 2-year cycle of clinical input, HSR, and widespread consultation around revisions to the classification system, as well as the preparation of cost weights from morbidity and cost data supplied by all public and private Australian hospitals. In addition to providing an indicator of hospital efficiency, these data form a schedule of standard costs which are used in pharmacoeconomics, health technology assessments, and other evaluations.

Healthcare Workforce

The training of the healthcare workforce is primarily determined by the government provision of funding for training and education and by the regulatory requirements for safety and quality; their

employment is provided, or heavily subsidized, by the public purse. Australian governments—both the federal, as the major funder of healthcare delivery, and the states, as providers of public hospital services—have a long-standing interest in ensuring the adequacy of the future healthcare workforce. A national structure to undertake healthcare workforce planning has been in place since 1995, initially covering the medical workforce. These efforts have since been extended to nursing and allied health professions. Under the auspices of these various committees, a number of reviews and reports have been completed and published. Further work has been commissioned by various inquiries, also initiated by the government or parliament.

The workforce-planning approach relies on a projection of future demand—based on population growth, changes in age-sex composition, and current patterns of use—with adjustment for the extent to which the current workforce is meeting current demand, and the projections of supply—looking at current training and entry, as well as expected retirements. The success of this approach in ensuring an adequate workforce is far from assured; Australia, like many other countries, is facing severe shortages of trained nurses, physicians in primary care and some medical specialties, and allied health professions. The planning strategy does not take into account changes in productivity, alterations in work patterns, or shifts in workforce participation. For example, although the number of medical graduates has increased more rapidly than the population growth, physicians have been working shorter hours, thus resulting, effectively, in an undersupply.

Development of an adequate workforce is likely to involve increasing productivity, more flexible approaches to professional roles and the delineation of responsibilities, varied approaches to education and training, and reform of payment mechanisms. This view is not readily encompassed by traditional workforce planning methods nor by government-led planning mechanisms. However, there has been little research activity beyond the government-sponsored process.

Funding Reforms

Australia has, alongside universal public health insurance, a substantial private health insurance

sector. Private health insurance covers private treatment in hospitals, alongside universal coverage for free public hospital treatment. It also covers a range of ancillary services such as dental care, physiotherapy, and other allied health services that are not provided in the public system. Since 1996, the government has introduced a number of insurance incentives, including a 30% subsidy on health insurance premiums, which is not means tested. This strategy has resulted in the rapid growth of health insurance to cover around 45% of the population, an increase of 15%. Researchers investigating the effectiveness of several incentives have found that the results of reform on the private sector reduced the pressure on public hospitals, and to a lesser extent, improved the comparative efficiency of public and private facilities.

Prior to the private health insurance incentives, the major change in financing was the move from voluntary but government-subsidized private insurance to universal, tax-financed, insurance covering both hospital treatment and out-of-hospital medical services. The first, universal, public scheme was introduced in 1976 as Medibank, dismantled by a subsequent government then reestablished in 1984 as Medicare. The scheme's architecture was developed from the independent research of two university economists, John Deeble and Richard Scotton.

Notions of managed competition and the separation of purchasers, providers, and funders did not gain traction with Australian policymakers nor, for that matter, with health services researchers. The split in funding responsibilities across levels of government has long attracted critical comment, and not surprisingly, pooling these separate entitlements into a common budget seemed to offer an opportunity for improvement. This approach was tested through a series of demonstration projects known as the Coordinated Care Trials in the mid-1990s. Evaluation results were equivocal, both in terms of health outcomes and costs, with some trial programs facing national bankruptcy.

Data Sources

The Australian Institute of Health and Welfare (AIHW) is the national agency for health and welfare statistics and information. It is a statutory authority responsible to the federal

government, and it works closely with state and territory health agencies. Although it does not directly collect health data, it serves as a repository, playing a major role in ensuring standard definitions and consistent approaches and in making data readily available. National data standards have been developed by the AIHW in conjunction with all government health agencies and the Australian Bureau of Statistics. A comprehensive electronic repository of national data standards, known as METeOR, is accessible through the AIHW Web site.

The Australian Bureau of Statistics is responsible for a number of regular as well as occasional population surveys. There are also many administrative databases, including data on the Medicare services and the operation of private health insurance funds. Data sets are also kept by other agencies for specific purposes such as for medical audits. However, access to such data is often at the discretion of the data custodians, and the protocols for release of data vary widely.

Australia has been slow to develop ongoing population panels—in which a representative population sample is followed over time—but a few have been initiated in recent years and are starting to provide data. There is also increasing interest in the ability to link individuals across data sets. Arrangements in Western Australia have allowed data linkage for many years and have demonstrated the role of this linkage in supporting high-quality HSR.

Research and Policy Links

As evidence-based medicine has become influential in clinical decision making, so there have been calls for an evidence base for policy. The health services development program was established in the 1970s to develop further reforms following the introduction of national, public, health insurance. Alongside a major HSR program, it was established but was subsequently allowed to decline. Although other developed countries have invested in building such programs over the past 20 years, Australia has failed to make such investments.

Public health departments and other agencies regularly commission research: generally through a competitive tendering process, with very specific outputs required and often within short time frames.

The major, national, health research funding agency, the National Health and Medical Research Council (NHMRC), has attempted to develop ways of encouraging research in areas identified as priority health problems that would meet rigorous research standards and policymakers' needs. Many of these efforts have met with limited success as funds have been spread thinly and research priorities have been developed with little consideration given to research feasibility. Overall, researchers have been subject to many short-lived funding programs.

More recently, the NHMRC has established a Health Services Research Funding Program that provides more substantial and longer-term funding. Development of this initiative was strongly influenced by policymakers. Initially, this program identified the priority topic of healthcare financing, then priority approaches or disciplines such as the social sciences. Subsequently, it became less clearly targeted.

Future Implications

The future, though less clear at the moment, is promising. The Australian NHMR is now committed to implementing many of the recommendations of the most recent review of research funding and has been given substantial additional funding to support these efforts. The new strategy should encompass additional funding for IIR; new approaches to developing interactions between policymakers and researchers in defining priority topics; and the development of centers of excellence that ensure innovation in methodological approaches, continued development of skilled researchers, critical mass, and research infrastructure.

HEALTH SERVICES RESEARCH IN CANADA

Health services researchers and policymakers in the United States and Canada often contrast and

compare the two nation's healthcare systems. In the United States, those advocating a national health insurance system point to Canada as evidence that such a system works better than our own. In Canada, there is much discussion about the future of its healthcare system, and the U.S. system is often cited either in support of or as evidence against the privatization of care. This entry presents a brief overview of Canada's national health insurance system, and it discusses the structure and activities of health services research in Canada.

Canada's Healthcare System

Canada's national health insurance system has evolved over the past six decades. Saskatchewan was the first province to establish universal, public hospital insurance in 1947. By 1961, all the country's provinces and territories had established public insurance plans that provided universal access without user fees for hospital services. By 1972, the plans were extended to include physician services. Over the years, various laws were passed, including the Canada Health Act in 1985.

The most basic objective of Canada's healthcare system has been to provide universal coverage for necessary medical care to all Canadians, without imposing financial barriers such as out-of-pocket expenses, deductibles, or administrative costs. Canada's provinces and territories provide 13 interlocking, publicly funded health systems that meet the common criteria of Canada's Health Act. The first criterion is that of public administration. This establishes a single-payer insurance system administered by each provincial or territorial Ministry of Health for all services covered under the act. The second criterion is universality, requiring that all Canadian residents be eligible for insured health services. The third is accessibility, which ensures that there are no financial barriers, such as user fees. The fourth is portability, which allows health coverage for hospital and physician services for Canadian residents who are traveling in other provinces or countries. Finally, comprehensiveness refers to coverage for all hospital and physician services.

Seventy-one percent of the total funding for Canada's healthcare system comes from taxation. The federal government imposes the principles of

the Canada Health Act through fiscal transfers to the provinces. Portions of these tax-based transfer payments may be withheld, or financial penalties imposed, if any of the criteria in Canada's Health Act are violated. Provided they meet the criteria, provincial and territorial governments have exclusive powers over virtually all aspects of health delivery and organization, including, for example, control of hospitals, establishment of quarantine, organization of health services, regulation of the practice of medicine, formation of health professionals, creation of health insurance programs, regulation of the production and marketing of nutritional products, adoption of health and safety standards with respect to work and companies under provincial/territorial jurisdiction, and the system of indemnities for work-related injuries.

A Focus on Population Health

Since 1974, when the Lalonde Report—a new perspective for improving the health of Canadians—was presented in the House of Commons, Canadian health planners have adopted a broad, population-based view of health and illness, which emphasizes the social determinants of health. An important impetus for this perspective came from the realization that significant socioeconomic gradients in health status persisted even after the development of universal access to medical care. Further improvements in the health of Canadians would require a perspective that went beyond the healthcare system to the prevention of environmental and behavioral risks and the promotion of health. It gave rise to the “health field concept,” which considered health determinants from four perspectives: (1) human biology, (2) environment, (3) lifestyle, and (4) healthcare organizations. This framework gave impetus to national and international initiatives in health promotion and health protection.

In 1990, two Canadian researchers, Robert Evans and Greg Stoddart, published a highly influential article that placed emphasis on the determinants of health and illness, including the social environment. The healthcare system was identified as one component in a network of interrelated factors affecting population health. By the mid-1990s, federal, provincial, and territorial Ministers of Health had all endorsed a population approach to healthcare. A decade later, a survey of senior

federal and provincial civil servants revealed that virtually all (94%) were quite familiar with population-based determinants of health. Population health ideas have similarly percolated through policy and planning documents at the level of local health delivery systems.

Decentralization and Regionalization of Healthcare Delivery

Perhaps the most revolutionary change to occur in the Canadian healthcare system since its inception has been the move to population-focused regional systems of care. Currently, there are 108 geographically defined health regions across Canada. The boundaries and specific responsibilities of regions have been established by their respective provincial Ministries of Health. Each health region is administratively responsible to its respective provincial or territorial government for the provision of defined, publicly funded health services to residents of their respective geographic area. In recognition that the needs and demands of regional populations will differ, health regions typically have the responsibility to assess, prioritize, plan, and offer the suite of services that best meets the health needs of their respective populations.

Primary Care and Health System Renewal

Between 1975 and 1991, healthcare spending in Canada grew at an average annual rate of 3.8%. In September 2000, after a decade of fiscal restraint, deep cost cutting, and considerable loss of public confidence, the Ministers of Health of Canada's provinces agreed on an action plan for health system renewal. They agreed that primary care should be the cornerstone for health system renewal. Primary healthcare builds on the broad principles underlying the population health approach. Foremost, it is an approach to health, rather than healthcare, that goes beyond the provision of treatment-oriented services to include the full spectrum of prevention and health promotion. Primary-healthcare services will be the first point of contact with the health system. A key feature will be a shift away from general practitioners, who have typically worked in solo practices, to multidisciplinary teams of providers who are to be held accountable for providing services to a defined client population.

Primary-healthcare teams are to include prevention and treatment services, basic emergency care, referrals to specialists, and coordination of care that may be required at other levels in the health system (such as hospital, palliative, or rehabilitation services). As well as improvements in the management of health and illness, primary-healthcare teams are to build capacity to undertake evaluations, so that system performance may be monitored. Information technology, such as electronic clinical records, will play an important role in supporting the development of a culture of accountability and performance measurement.

Health Information

In Canada, the provision of population-based statistical information is a responsibility of the federal government. Statistics Canada is the federal agency responsible for this function. Statistics Canada collects data on Canada's population, its economy, society, culture, and health through population censuses, cross-sectional surveys, and longitudinal (panel) data. Microdata files are made available to researchers through university-linked research data centers, which are located throughout the country. The centers are staffed by Statistics Canada employees and operated under Canada's Statistics Act.

The Canadian Institute for Health Information (CIHI) is an independent, not-for-profit organization that captures health system information from hospitals, regional health authorities, medical practitioners, and government (through billing information). The institute publishes analytical documents and special studies on a wide range of topics, including healthcare services, healthcare spending, human resources, and population health. It also develops and promotes health indicators (such as life expectancy and per capita health spending) to compare health status and health system performance across provincial and territorial health systems and regional health authorities. Microdata are made available to researchers under strict privacy and data protection policies.

Health Services Research in Canada

In Canada, academic researchers occupy salaried positions in universities (paid from university

operating budgets), where they compete in national and other peer-reviewed funding competitions for the funds required for conducting their research. Competition for operating funds is stiff. In a 2007 open grants competition from the Canadian Institutes of Health Research (CIHR), for example, more than 2,000 operating grant applications were received, and less than 1 in 5 were funded.

Significant health system reform, including an increased emphasis on evidence-based care, health system accountability, and performance measurement, created a demand for health services research that quickly outstripped Canada's research capacity. New funding structures were required to support the clinical, population, and health services research needed to support health system restructuring and reform.

In 1996, the federal budget announced funding to establish what would become the Canadian Health Services Research Foundation (CHSRF) to facilitate evidence-based decision making in health. From the beginning, the foundation identified managers and decision makers as the primary audiences for its work and adopted an overall strategy that promoted linkage and exchange between research and decision maker communities, including incorporating decision makers (making up 50% of each committee) into the review process for operating grants. Since 2000, the foundation has de-emphasized open grants competitions (transferring this portion of their budget to be administered by another federal research funding agency) so as to consolidate its activities around capacity development and knowledge transfer.

In further recognition of the need for a broadened health research mandate in Canada, a new federal health research agency was created: the CIHR. This new structure includes 13 theme-based institutes, including an institute devoted to health services and policy research. The CIHR replaced the Medical Research Council as Canada's main health-research-funding agency. In addition to incorporating the biomedical mandate of the Medical Research Council, the CIHR was given a broadened mandate to foster clinical research, health system and services research, and population health research. By incorporating these four pillars of research under a single umbrella funder, the goal was not only to increase research in each of these areas but also to foster cross-pillar research

within and across institutes and to promote a multidiscipline approach. Under this new structure, funding for health services research grew 20-fold between 1999 and 2005. Typically, 30% of funding is reserved for strategic initiatives organized through the institutes, and the remaining 70% is reserved for open grants competitions. Currently, the CIHR funds more than 10,000 academic researchers and trainees across Canada with expenditures that total more than \$800 million.

Finally, in 2000, to build research capacity, the Canadian government created a national program to provide salary and infrastructure support to universities to attract and retain researchers—the Canada Research Chairs Program. Under the program, researchers receive salaried positions from the government in contrast to regularly awarded operating grants in which researchers do not receive salary support. Universities are each allocated a number of Chair positions and nominate researchers whose work complements their respective strategic plans. Some \$300 million per year is spent on all Chair positions with 26 Health Services Research Chairs having been funded to date.

With stable sources of salary funding, and increased spending on operating grants, the field of health services research in Canada has begun to blossom, evidenced by the development of the Canadian Association of Health Services and Policy Research (CAHSPR); a peer-reviewed academic journal entirely devoted to the topic, *Healthcare Policy* (launched in 2005); and 13 university-based centers across the country devoted to health services and policy research.

However, despite a growing and vibrant field, the 13 university-based health policy research centers in Canada face a number of important challenges, which attest to their still precarious position. The most important of these is how to maintain stable core funding for infrastructure. Most are funded through their respective provincial ministries of health, making funding unpredictable and subject to periodic renegotiation. For more than a decade, Canadian universities have operated under serious funding shortages, making them an unlikely source of stable funding for these centers. A second challenge is to maintain a balance between research that is of interest to Ministry funders (which may not translate into an academic product) and research that results in suitable academic publications.

Although the culture is beginning to change, Canadian universities still diminish the worth of applied research that does not result in academic publications. Certainly there is mounting pressure on university academics to produce research that is relevant and timely. While there is still a long way to go, universities are beginning to respond by recognizing the academic role of applied research and the importance of building capacity in this field so that it can be used in policy making.

Cross-National Health Services Research

In the context of health reform, much has been written about the Canadian versus the American healthcare system. While not all of it has been flattering or even correct, the ensuing debates have fostered considerable cross-national research examining patterns of healthcare utilization and health system outcomes. Despite widely divergent paths to healthcare delivery and reform in Canada and the United States, Canadians regularly monitor U.S. policies and practices and have imported American policy innovations and system strategies. The CIHR offers several funding programs to support international collaborations involving Canadian researchers and has supported strategic initiatives with U.S. granting bodies.

Future Implications

Health services research continues to place an emphasis on partnerships between researchers and policymakers in an effort to address key healthcare issues in Canada. The CHSRF has identified the following research themes for the coming years: workforce and the work environment; quality and patient safety; value-based decision making and public engagement; change management for improved practice and improved health; nursing leadership, organization, and policy; and primary healthcare.

HEALTH SERVICES RESEARCH IN DENTISTRY AND ORAL HEALTH

Research on oral health and related issues and conditions differs from research in dentistry, which may include clinical interventions and outcomes. The two domains share numerous common characteristics and overlap in some subject areas, but they also represent distinct and different points of reference in research.

The oral health domain includes the dimensions of eating, taste, drinking, speech, personal self-image, appearance, social interaction, employment and employability, attitudes and knowledge regarding oral health, effects across the age span, disease prevention and risk factor analysis, and studies of the oral health status of populations, among many others. In contrast, research in dentistry includes all aspects of clinical care and evidence-based assessments of its outcomes, instrumentation, methods, materials, patient management and satisfaction, diseases, immune disorders, and injuries, to name a few.

This entry begins by discussing recent research topics relating to oral health, dentistry and the overlap between the two. Next, this entry addresses health services research specifically and the various factors that affect such research. Finally, this entry touches on the future directions of health services research for dentistry and oral health.

Recent Research Topics

Recent studies have shown associations between chronic oral infections and heart and lung diseases, stroke, and low-birth-weight and premature babies. Additionally, several associations have been found between chronic and severe periodontal (gum) disease and diabetes. Injury and oral wound healing are also significant research topics. Wound healing in the oral cavity (the mouth) is accomplished in a unique environment of moisture, temperature, and bacteria. Injury can occur in various sports and through falls, motor vehicle collisions, and violence. Devices to protect against oral injury are also subjects for further investigation.

Research that cuts across these two domains and shares common facets include the following:

the impact of professionally applied fluorides, in addition to fluoride rinses, varnishes and gels, and community water fluoridation; financing of dental care; unmet needs in dental care; health literacy; and workforce studies. Behaviors and habits that affect oral health, including smoking and other tobacco uses, and dietary practices, are also important subjects for researchers. Dental care and service utilization; health disparities; issues specific to women's oral health, such as osteoporosis; and oral health concerns of people with disabilities are active areas of research.

Research in oral health also focuses on microbial elements, anatomical systems and their function, tissue and nerve systems, and cellular and molecular genetics. Many bacterial, viral, and fungal entities contribute directly to the onset of a variety of dental diseases. Understanding the effects of these agents is critical to disease prevention and health protection. Examples of research regarding anatomical systems include chewing and swallowing, and muscle and joint functioning. Other research areas include tissue and nerve systems; the structures and fluids of the oral cavity, such as teeth, saliva, mucosa, bone, and the tongue; as well as tissue regeneration and engineering. Current research shows promise that new teeth and new bone can be "grown" for replacement of missing or damaged segments of the jawbone (mandible). Research involving nerves and nerve signaling also includes studies regarding pain, its derivation and modulation, and the response to and coping with pain.

Saliva and, to some extent, tissue cells from the inside of the cheek (buccal mucosa) are increasingly being studied due to their potential diagnostic value. Saliva, as a serum exudate of blood, has been shown to be an effective diagnostic aid for a wide range of systemic health conditions, including human immunodeficiency virus (HIV) and hepatitis A and B, as well as for various drugs and environmental toxins. The use of saliva as a source for host DNA has facilitated detection of a wide range of viral and bacterial infections whose presence is difficult to detect. This has become an important area of ongoing research because obtaining saliva samples is relatively simple, noninvasive, and inexpensive.

Comprehending the genetic code for bacteria and other microbial entities that cause oral diseases, such as cavities in the teeth or gum

(periodontal) disease, is fundamental to the ability to protect against these conditions. These oral flora also form colonies on oral structures, resulting in the development of biofilms. The composition, mechanisms of actions, and adhesion capacity of these biofilms are important areas of research because of their importance in oral health and their broad application to other aspects of health beyond the oral cavity.

Health Services Research

Health services research entails multidisciplinary approaches that may include economics, political science, and medical sociology, to identify the most effective ways to deliver health services, document quality, reduce medical errors, and improve patient safety. Identifying effective ways to organize and manage health services, analyzing healthcare financing and costs, determining methods to improve access to and utilization of care, and ultimately improving the outcomes of care are among the inquiry domains of health services research.

Biological, behavioral, and psychological facets of health services research provide important views to better understand health needs and utilization of services, as well as the health disparities experienced by various populations. In effect, the evidence base derived from studies focused in these directions should serve to inform public policy on health issues and improve the systems of health services.

Health services research in dentistry has made significant contributions to the scientific literature despite the many difficulties encountered in conducting this type of research. At the same time, health services research in the field of dentistry is still in its developmental stages. Societal issues that affect oral health and, conversely, oral health conditions that affect societal issues, have received sparse attention.

However, it is in these areas that dental researchers are most challenged in their attempts to advance health services research. Large-scale population studies are expensive and time-consuming. Studies that require direct observation must include dentists, support staff, and appropriate clinical facilities. People, as study subjects, must be scheduled for examination and assessment. Finally,

dental records must be reviewed and summarized and pertinent data recorded. The latter step usually entails data coding of some sort. Consequently, large-scale population studies of this type are possible only when federal agencies undertake the study as a unique investigation or combined within a larger study.

Large-scale population opinion and information surveys have been employed effectively to conduct health services research regarding oral health issues. Surveys are somewhat less expensive than research based on direct observation. They can be conducted in person, by telephone, via mail, and through the Internet. Through surveys, issues such as patient satisfaction, access to care, and experiences in healthcare settings can be assessed.

Secondary Data Sets

The government, using various health-related population surveys conducted by federal agencies, and health insurance plans are also sources of data. These secondary data sets provide reliable information to facilitate health services research. For example, the federal National Center for Health Statistics (NCHS) conducts the National Health and Nutrition Examination Survey (NHANES) and the National Health Interview Survey (NHIS). Such surveys have been conducted periodically on a national sample and contain oral health status; dental-care-related observations; and questions regarding utilization of services, access to care, cost of care, patient satisfaction, and perceptions of quality of care received. When these types of surveys include direct clinical observations, it becomes possible to conduct research that validates patients' perceptions regarding quality of care.

Other sources of federal data with useful applications for health services research in dentistry include the Centers for Medicare and Medicaid Services (CMS), the Health Resources and Services Administration (HRSA), the Agency for Healthcare Research and Quality, and the Bureau of Labor Statistics (BLS). Other sources of data include the Health Plan Employer Data and Information Set (HEDIS), the Employee Benefit Research Institute (EBRI), and the National Association of Dental Plans (NADP).

Medicaid Data

Medicaid data from states that cover dental care are also available for analysis. Medicaid covers approximately 40 million people in the nation, mainly children and single mothers. However, there are limitations to the utility of these sources of secondary data. Not all states cover dental care under their Medicaid programs. A few states cover services for adults, and the types and range of services vary substantially among those states. Over three decades ago, federal legislation established a guarantee of dental care to Medicaid-eligible children through the Early Periodic Screening, Diagnostic, and Treatment (EPSDT) benefit. Even so, state Medicaid authorities have shown that fewer than 20% of the practicing dentists surveyed provided care that was paid for through their state program. Other analyses have shown that only about 20% of EPSDT-covered children receive dental care in a given year. Furthermore, as states elect to purchase dental care for Medicaid eligible individuals through managed-care organizations, rather than pay providers directly, additional barriers to accessing Medicaid service data from these intermediary sources have developed.

Dental Insurance Data

There are approximately 140 million people in the nation who have dental-care benefits through their place of employment or who purchase dental coverage separately from a variety of dental-insurance plans. Dental-insurance carriers include major national commercial plans, regional and state-specific companies, as well as carriers organized as Delta Dental Plans and Blue Cross Blue Shield Plans. Within this spectrum of plans, there is substantial variation in the manner in which dentists are structured to provide care. These variations include managed-care options such as preferred provider organizations (PPOs) and dental health maintenance organizations (DHMOs), indemnity plans, discount plans, and reduced-fee plans, among others. However, data indicated only a 50% to 70% annual utilization rate for persons with these forms of dental-insurance benefits. For the approximately 50% of Americans

who have no form of dental-insurance coverage, there are no reliable data sources pertinent to their utilization of dental care.

While select data can be obtained from dental-insurance carriers, the data may be limited due to the proprietary nature of the insurer's business interests, among other reasons. Furthermore, such data may have been collected and organized in such a manner that it may not be comparable with data sets from other private-insurance entities. In any case, since private health insurance is available for only a segment of the population, data from such sources cannot be generalized to the entire population.

Data From Public Health Departments

Oral health services may be provided within state and local public health departments; however, such services typically relate to disease prevention, health promotion, and health protection. In some instances, care for needy and underserved populations is also provided. In addition, population surveys are part of the public health function of these organizations. However, such surveys are conducted infrequently, are undertaken in the context of specific interests within a particular public health jurisdiction, and may not be conducted in a manner that allows for generalization to the entire population. Consequently, these surveys generally have marginal value for health services research.

Data on Dentists

The American Dental Association (ADA) conducts periodic and special surveys of dentists. These surveys tend to relate to various aspects of dental practice and experience, finance, and practice trends. The American Dental Education Association (ADEA) conducts surveys of dental schools and students pertinent to the process and outcomes of training and education of dentists.

Within dental practice settings, there are unique challenges in accumulating data necessary and sufficient for purposes of health services research. There are nearly 160,000 actively practicing dentists in the United States. The vast majority, more

than 90%, are in private practice. Of those dentists in private practice, 80% are general practitioners. The other 20% are specialists in one or more of the nine formally recognized dental specialty disciplines (orthodontics, oral and maxillofacial surgery, oral and maxillofacial radiology, periodontics, pediatric dentistry, endodontics, prosthodontics, dental public health, and oral and maxillofacial pathology). In medical practice, many physicians tend to practice in groups and congregate their practices and services in hospital practice settings. However, nearly 70% of dentists practice solo, another 20% practice with one partner, and the remainder (about 10%) practice in groups of three or more.

Dental Clinical Records

Within dental practice, there is no single, or even dominant, standard office protocol or format for data collection. There have been efforts to develop agreed-on data sets applicable to all patient services based on a common record format. However, there has been limited success in this regard. As noted previously, there are numerous dental health insurance plans. Among the plans, there is wide variation in claim formats, forms, data requirements, and information configurations. There are 56 dental schools in the United States; however, they use and teach different formats and methods for obtaining patient clinical records, history taking, and general aspects of data collection. Consequently, there are few persuasive external influences to achieve more uniformity in record keeping and data collection in dental practice.

Fees and payment for dental services, whether private and out of pocket or paid by some form of dental insurance, are based on procedures rather than diagnoses. Diagnostic codes are being developed and are used increasingly in dental practices; however, they are not the current norm. Data sets centered on diagnoses, and dental services provided in the context of those diagnoses, would be a valuable addition to the capacity of health services research in dentistry. The standards and criteria for diagnoses in dentistry can be readily defined and confirmed. The treatment response consistent with the diagnosis can vary based on many considerations. Consequently, health services research in

dentistry suffers from a lack of standardized starting points, such as diagnoses, and must rely essentially on service data independent of diagnosis. It also follows that outcome data are difficult to assess from a health services research perspective when there is no clear indication of the diagnostic starting point and the association between services rendered and disease conditions is unclear.

Further challenges are encountered in the relative lack of electronic clinical records in dental practice. While electronic clinical records are becoming more common, they are not ubiquitous among dental practices. Abstracting and summarizing data from paper records is time-consuming and expensive.

The Role of the Health Information Portability and Accountability Act

The Health Information Portability and Accountability Act (HIPAA) is an important hurdle to health services research in dentistry. This federal legislation was enacted in 1996 and obligates researchers to obtain specific permission from patients prior to accessing any patient-related information. This restriction applies to hospitals, medical and dental offices, clinics, and any other sources of healthcare service. As an example, this requirement presents a challenge in attempts to link data sets such as insurance claims and census data, where a patient's name or some other specific identifier is needed to link the data sets. However, once that is accomplished, the data can be structured in a manner that ensures that no individual patient can be identified by means of the resultant information.

Patient Care Options

Dental care is also affected by a relatively high degree of individual patient and provider options and preferences within a range of possible treatment approaches for particular situations. For example, there are choices among types of restorative materials (amalgam, gold, porcelain, resin) as well as options among the types of restorative procedures. This variation among treatment options and procedures adds to the complexity

of determining the outcomes, among other aspects, of health services research in dentistry. Differences in service patterns may be functions of provider preferences, patient preferences, cost considerations, true differences in patient health status, or cultural differences among population groups.

Obtaining Agreements to Conduct Research

The solo and independent nature of private dental practice also poses challenges to health services research regarding obtaining agreements from dentists to participate in research. For the most part, dentists are not engaged in research of this nature, nor were they trained in health services research while in dental school. Substantial effort is required to obtain the participation of private dentists in research projects. The significance of the research, the dentist's unique contribution to its completion, and the time involved in participation are a few of the many issues that must be resolved to the dentist's satisfaction.

Future Implications

As the field of health services research in dentistry develops and matures, new steps are being taken in support of these research efforts. In 2005, the National Institute of Dental and Craniofacial Research, at the National Institutes of Health (NIH), awarded \$75 million for three 7-year grants to develop practice-based research networks. These networks involve dentists in practice and establish a more "real-world" setting in which to assess dental practice and procedural issues with greater scientific rigor. Over the 7-year period, each network will conduct 12 to 20 short-term studies comparing the benefits and different outcomes of various and alternative treatment options, dental materials, and disease prevention strategies under a wide range of patient and clinical conditions.

Research in dentistry, and particularly in health services research, could be enhanced by dental schools increasing their emphasis on research as part of the curriculum. Dentistry and dentists would benefit from more involvement in

research. Increased utilization of electronic clinical records in dental practice would enhance opportunities and simplify the process of collecting data. Efforts to create greater uniformity for examination of records and developing more common data fields would also facilitate data collection and analysis.

HEALTH SERVICES RESEARCH IN EASTERN EUROPE

Health services research investigates the relationship between the factors of access, cost, quality, and the organization of care and health and medical outcomes. This entry describes how health services research has developed in the Eastern Europe region. The region consisted of eight socialist countries at the time of the fall of the Soviet Union in 1991: Bulgaria, Czechoslovakia, Hungary, the German Democratic Republic, Poland, Romania, the Soviet Union, and Yugoslavia. After significant social and political change, these eight countries now represent 25 independent nations. Fifteen of them are successor states of the former Soviet Union: Armenia, Azerbaijan, Belarus, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Moldova, the Russian Federation, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan. Ten other countries comprise the rest of the region: Bulgaria, Croatia, Czech Republic, Hungary, the former Yugoslav Republic of Macedonia, Poland, Romania, Serbia and Montenegro, Slovakia, and Slovenia. The Czech Republic, Hungary, Poland, Slovakia, and Slovenia joined the European Union (EU) in 2004. Bulgaria and Romania followed in 2007.

Healthcare During the Socialist Period

After World War II, from 1945 to 1990, Europe was divided by the Iron Curtain into two distinctive regions: the capitalist countries of Western Europe and the socialist countries of Eastern

Europe. The two regions followed very different patterns of development in their economies, public health, and healthcare. The 45-year socialist period can be viewed as one of the largest experiments in European history.

During the socialism period, the healthcare systems of the Eastern European countries were dominated by the Soviet Union and the rule of the state. The state became responsible for organizing, managing, delivering, and financing all healthcare services. In many Eastern European countries, healthcare coverage became universal, based on citizenship, and most healthcare services were provided officially free of charge. However, informal, under-the-table payments by patients to physicians were common. The informal payments were common because of the very low salaries of physicians. The number of physicians and hospital beds were high compared with Western European countries.

In terms of public health, the gap in life expectancy between the Eastern European and Western European countries was closing during the 1950s and early 1960s. However, from the mid-1960s, the health status in Eastern European countries stagnated or deteriorated, whereas in Western European countries it improved steadily. The age-standardized mortality rates rose in Eastern European countries and fell in the Western European countries. The gap in life expectancy was widening steadily, and the divergence had become even larger during the first half of the 1990s.

The economics of the healthcare systems of Eastern and Western European countries followed a similar pattern. The gap in healthcare expenditures between Eastern and Western European countries widened from 1960 to 1990. Healthcare expenditures, expressed in terms of purchasing-power parity, were comparable between the Eastern and Western European countries around 1960. In 1987, however, Western European countries spent four times more public funds on healthcare than Eastern European countries. Three years later, this gap became even larger. Healthcare expenditures decreased in the Eastern European countries from 1987 to 1990, just before the beginning of the social and political changes.

The widening gap in healthcare expenditures between the Eastern and Western European countries may have contributed to the significant gap in life expectancy. The problem, however, was not

only the smaller amount of money spent on healthcare but also the ineffective spending and the distribution across sectors. The former policy-makers of Eastern European countries attached great importance to demonstrating the power of socialist healthcare in terms of quantity. They emphasized hospital care instead of primary care, and thus they increased the total number of hospital beds and physicians, instead of focusing on the effectiveness and the quality of healthcare. Around 1990, the number of physicians per 1,000 population was 2.52 in Western European countries compared with 4.07 in Eastern European countries. The number of hospital beds per 1,000 population was 37% higher in Eastern European countries. These policies decreased the already limited resources in areas such as public health, health promotion and prevention, and health information systems. And it became clear that this approach did not lead to better health outcomes.

Before 1990, hospitals in Eastern European countries were financed through global budgets, which were calculated or based on historical costs and many other noneconomic factors. There were no financial incentives for cost containment or cost-effectiveness. The first formal steps toward healthcare reform occurred around 1990. At the time, it was recognized that the social security functions of retirement pensions and health insurance could not be reformed without restructuring the entire healthcare system of each country.

Restructuring the Healthcare Systems

After the fall of the Soviet Union, a peaceful revolution took place in Eastern European countries. Social and political changes were accompanied by two phenomena: the economic performance, including net material production and industrial output, fell markedly, which led to a decrease in the gross domestic product (GDP), and the health status of the population declined.

After 1990, many Eastern European countries decided to return to the Bismarckian tradition of solidarity based on social insurance of their healthcare system. Leaving behind the former Soviet-type system, compulsory health insurance schemes were introduced. The application of purchaser-provider

approaches resulted in the separation of healthcare providers, including general practitioners, outpatient care, hospitals, and healthcare-financing agencies, such as health insurance funds. Countries such as Hungary and Slovenia decided to establish a single healthcare financing agency, while other Eastern European countries preferred to allow many types of health insurance. Countries with multiple-payer systems include the Czech Republic, Poland, and Slovakia. In Hungary, the former National Institute of Social Security was divided into the National Health Insurance Fund Administration and the National Pension Fund Administration, while the Social Insurance Fund's budget was divided into the Health Insurance Fund and the Pension Insurance Fund.

Under the past socialist system, the Eastern European countries' primary method of healthcare financing was through global budgets. After the political shift, many of the countries introduced novel payment mechanisms for healthcare financing, including fee-for-service, Diagnostic Related Groups (DRG), and capitation.

In the past, the former policymakers of the Eastern European countries had little interest in the effectiveness of health services interventions. Important tools of health policy decision making were not used in healthcare systems. During the past two decades, however, efforts have been made in many Eastern European countries to strengthen the institutional resources and tools of health policy decision making.

The Development of Health Services Research: The Case of Hungary

After the fall of the Soviet Union, Hungarian researchers were sent to foreign universities to receive formal academic training in health services research. At the time, this was the only way for many young researchers in Eastern European countries to obtain advanced degrees in health services research, because health services research topics were not included in their educational systems. The cost of education for these researchers was covered mainly by a World Bank loan. A few years ago, after evaluating various projects in Hungary, the World Bank concluded that the most successful and sustainable project was the one that invested in human infrastructure. By

2000, this effort successfully produced a corps of highly trained Hungarian experts with internationally acknowledged qualifications and experience in health services research. However, because of the lack of appropriate academic and governmental institutions, many highly qualified researchers decided to stay abroad, and they were lost to the Hungarian healthcare system. Furthermore, many of those researchers who did return to Hungary have been employed in the private sector.

Some of the researchers who returned to the country after receiving their advanced degrees abroad became the core team that further developed health services research in Hungary. They helped form a number of academic institutions and departments, including the Health Services Management Training Centre at Semmelweis University in Budapest, the School of Public Health at the University of Debrecen in eastern Hungary, the Health Economics and Health Technology Assessment Unit at Corvinus University in Budapest, and the Department of Health Insurance and Health Policy at the University of Pecs in southern Hungary. Later, the Health Economics Research Centre was established at Eotvos Lorand University in Budapest and the Institute of Health Economics at the University of Szeged in southern Hungary.

A key issue of Hungarian healthcare policy was the introduction of cost-effectiveness concepts and methods into the decision-making process. The first step toward achieving greater cost-effectiveness was the establishment of methodological standards published by the Hungarian Ministry of Health. These standards regulate the guidelines for conducting economic evaluations. The aim of the guidelines is to encourage rational, transparent public-healthcare-spending decisions. The guidelines are continuously being refined and evaluated every 2 years.

The Hungarian Health Economics Association was founded in 2003 and has a current membership of about 100 individuals. The association holds monthly meetings where presentations are made on various health economic topics. The meetings serve as an interdisciplinary forum for healthcare professionals in the field of health economics, health services research, and health technology assessment.

The Hungarian National Health Insurance Fund Administration launched a program for monitoring the quality of hospital care in 2002. This quality indicator program, a pay-for-performance type of program, helps the national insurance fund strengthen its purchasing role of obtaining high-quality health services. The fund has decided to develop this indicator system for measuring and evaluating the quality of health services to support overall quality improvements. The national insurance fund seeks to ensure, in all possible ways, that everyone can find the evaluation points adequate to their field of interest—that is to say, that the financial point of view is not dominant in the development of the indicator system.

As a requirement for membership in the EU, which Hungary joined in 2004, the country was required to have a transparent, accountable coverage process applied by the national health insurance fund for the pricing and reimbursement of pharmaceuticals. To meet the EU transparency requirements, Hungary passed the appropriate legislation in April 2004. Since that time, anyone who wants to be reimbursed for the cost of certain drugs must submit a formal application according to the EU directives.

Perhaps the most important change resulting from EU membership has been the increased professionalization of Hungary's decision-making process. It has resulted in the application of scientific evidence in coverage decisions, equity, cost-effectiveness, publicity, transparency, accountability, and the consideration of budget constraints.

In 2004, the National Institute for Strategic Health Research was established to guide Hungary's governmental health policy decision making by undertaking activities in four areas: (1) health informatics and information policy, (2) health economics, (3) health services and health system research, and (4) the health technology assessment and coverage policy. The establishment of the institute was an important step toward the inclusion of health services research into the governmental decision-making process. The institute serves as an important resource for the Ministry of Health and the National Health Insurance Fund Administration.

During the development of health services research in Hungary, researchers studied the healthcare systems of a number of countries,

including Australia, Sweden, the Netherlands, the United Kingdom, and the United States. They also studied the published international literature, particularly focusing on health insurance coverage policies, prescription drug pricing and reimbursement, healthcare technology assessment, price/volume agreements, Diagnosis Related Groups, evidence-based guidelines, and performance measurement. Subsequently, these studies have made a significant impact on Hungarian health policy decision making.

Hungarian health services researchers are currently addressing topics such as (a) the overall access to healthcare, (b) inequalities in access and utilization of health services, (c) cost containment strategies, (d) quality-of-care improvements, and (e) the efficiency of resource allocation.

Future Implications

After the fall of the Soviet Union, the former socialist countries of Eastern Europe underwent fundamental social and political changes, which greatly influenced their healthcare systems. One of the greatest challenges faced by these countries was the restructuring of their Soviet-type socialist state healthcare systems into modern health insurance-based systems. Since that time, there has been a gradual development of health services research in the Eastern European countries. This development included the training of professionals, the establishment of academic departments, the development of new public policies and recommendations in line with those of the EU and other international organizations, the strengthening of public institutions, and the inclusion of health services research and related fields in the government decision-making process. These achievements serve as a strong base for the future development of health services research activities and projects, especially in the field of international collaborations.

HEALTH SERVICES RESEARCH IN GERMANY

Health insurance plays a vital role in the supply and demand of healthcare. Health services researchers in Germany and the United States study the function and nature of health insurance, the various types of insurance plans, and the impact of insurance on healthcare. The German healthcare system provides valuable lessons for the United States and other countries that are trying to develop health insurance programs that are universal in scope and comprehensive in coverage. Furthermore, the growing literature on comparative health insurance policies suggests that nations are learning from each other.

Background

Germany pioneered national health insurance. It was the first nation in the world to enact

compulsory health insurance legislation. In 1883, the conservative politician and German Chancellor Otto von Bismarck (1815–1898) devised a system of health insurance coverage, as well as accident insurance and old-age pensions. Specifically, he established the Statutory Health Insurance System and other programs to improve the situation of the country's large working class, to coopt similar socialist proposals, and to win an upcoming election.

Traditionally, the German population has enjoyed a very high degree of free access to both healthcare providers and healthcare insurers. In 2007, the Statutory Health Insurance System was composed of about 240 fiscally autonomous sickness funds, which insures about 86% of the total German population. These funds are compulsory for those earning less than 3,975 euros a month and for individuals who are unemployed, students, disabled, pensioners, poor, and homeless. Contributions to the funds are based mainly on wages and salaries and are obtained through a payroll tax. In 2006, the average contribution rate was 13.25%.

Individuals with a salary above the income level or who are self-employed can either voluntarily remain in the social healthcare system or opt out of it and purchase comprehensive risk-related private health insurance coverage. In 2007, a little more than 10% of the population was enrolled in a plan from 1 of 52 private health insurance companies. Until the most recent government reform, private health insurance companies increased their reserves to guarantee lower premiums for insuring older individuals. Thus, it became less attractive to switch from one to another private insurer the longer the individual stayed in a particular plan.

Miners, sailors, farmers, and soldiers may enroll in other social insurance programs, so that altogether the entire German population is insured against the risk of illness and they have comprehensive healthcare benefits.

Infrastructure and Government Reform Efforts

Compared with other industrialized nations, Germany's healthcare infrastructure is well developed, providing easy access to physicians, nurses,

pharmacists, and other healthcare providers. The ratio of healthcare providers to population in Germany is above the average of Organization for Economic Co-operation and Development (OECD) countries.

In terms of utilization, the German population tends to overutilize healthcare services. Therefore, government policymakers have recently introduced a number of measures to restrict and limit utilization of services and provide stronger guidance for patients. For example, in 2004, for the first time in the German health systems' history, a government reform introduced user fees to curb the utilization of outpatient healthcare services.

The latest government reforms, the Statutory Health Insurance Modernization Act of 2004 and the Statutory Health Insurance Competition Strengthening Act of 2007, promoted more coordination of care by restricting patient choice and helped patients to better navigate the healthcare system. The 2007 reform significantly changed the system by encouraging competition among healthcare providers and health insurers.

An earlier reform, the Health Care Structure Act of 1993, introduced for the first time free choice among the sickness funds for the majority of the insured. Since then, the German healthcare system has increasingly become more competitive.

Both the Coalition Government of Christian Democrats and the Liberal Party (1982–1998), and the coalition of Social Democrats and The Greens (1998–2005) were faced with increasing healthcare expenditures and felt pressured to apply stricter healthcare cost containment measures. Thus, various government reforms during the past 20 years have steadily increased both the level of copayments and the number of copayments imposed on prescription drugs and health services.

The *Social Code Book V*, the legal framework for the German Social Health Insurance System, stipulates that the system must provide all medically necessary services. Compared with other OECD countries, the German system provides a broad set of benefits. For example, it covers outpatient and inpatient services, medications, dental care, and rehabilitation services. Some services, however, are excluded from coverage, but they have not caused any access problems so far. The specific healthcare services offered by the sickness funds are determined by law. And the funds offer

95% of all required services. The sickness funds, inpatient and outpatient healthcare providers, and the Federal Joint Committee jointly determine which services are reimbursable. The Federal Joint Committee is a decision-making body comparable with the United Kingdom's National Institute for Health and Clinical Excellence (NICE).

The importance of integrated-care contracts has continually grown over the years. Most of these contracts are regional in scope and cover certain diseases and treatments (e.g., heart disease and artificial hips).

Some of Germany's healthcare organizations have changed over the past decades. For example, polyclinics were frequent providers of healthcare in the former German Democratic Republic (GDR/East Germany). After the German reunification in 1990, most of these polyclinics closed and were replaced with outpatient care centers organized as in the western German states. Today, only about 30 polyclinics still exist, and most of the former polyclinics now operate as outpatient care centers. The 2004 government reform led to a renaissance of outpatient care centers in the entire country. On average, the new outpatient care centers, which are generally managed by physicians or hospitals, have a staff of four physicians.

Future Implications

The German healthcare system will likely continue to evolve. It may incorporate cost and quality-of-care concepts from other countries, including the United States, and other nations, including the United States, may attempt to expand insurance coverage similarly as the German system.

HEALTH SERVICES RESEARCH IN SUB-SAHARAN AFRICA

Health services research in sub-Saharan Africa differs from its North American and European counterparts in several ways. It is often referred to as logistics research or operations research, and care delivery is severely resource constrained. The shortage of staff, transportation, supplies, and equipment leads to differences in the types of care provided. Health services research in literature from sub-Saharan Africa is focused on the major diseases and health conditions confronting this part of the world. Thus, this type of research is largely organized and funded around major health conditions, such as malaria, tuberculosis, measles, meningitis, diarrhea, HIV/AIDS, infant and child health, and maternal mortality/morbidity.

Health Conditions

In 2006, more than 65% of the total people in the world who suffer from HIV/AIDS (the human

immunodeficiency virus) are found in sub-Saharan Africa. This erosion of the immune system results in tuberculosis and pneumonia, which are the immediate cause of death. Major risk factors for HIV/AIDS in this region are unprotected sex, multiple sex partners, and the transfer of the virus from the mother to the fetus during pregnancy. In sub-Saharan Africa, women aged 15 to 24 years are considered to be at high risk of contracting HIV/AIDS. Currently three quarters of the documented cases are found among this group. Almost 6 million people in sub-Saharan Africa are in need of medical treatment. Organizations such as the Joint United Nations Programme on HIV/AIDS (UNAIDS) and the World Health Organization (WHO) are working to provide antiretroviral treatment to 3 million individuals. Additional goals may be set by other organizations to support the initiative.

Malaria is predominately spread by the female anopheles mosquito and accounted for more than 1 million deaths in 2005. Between 350 and 500 million cases are reported worldwide each year. More than 80% of the world's malaria deaths occur in Africa. The disease accounts for 18% of all child deaths in the sub-Saharan region. The major prevention strategies for malaria control include the use of insecticide-treated mosquito nets and indoor insecticide sprays. Some African mosquitoes have developed resistance to many antimalarial medications, making treatment more difficult and the costs of care more expensive.

A total of 7.7% of deaths in Africa were caused by diarrhea and its related complications in 2006. Diarrhea is a symptom of infection from bacterial, viral, and parasitic organisms primarily spread through contamination of water and food. Most deaths result from dehydration, and children are at higher risk than adults. The majority of treatments include oral rehydration, which is a low-cost therapy.

Tuberculosis (TB) is a frequent killer of the individuals who suffer from HIV/AIDS. It is estimated that more than half of the people living with HIV/AIDS will contract TB during their lifetime. In some regions of sub-Saharan Africa, up to 70% of individuals with sputum smear-positive pulmonary tuberculosis are HIV-positive. About 8 million new cases develop each year in the world. Symptoms of tuberculosis include a

chronic cough, high fever, weakness, and drastic weight loss. It is spread through indirect contact, mostly through coughing or sneezing. Treatment includes the use of Bacille Calmette-Guerin (BCG), which is commonly used as a preventive measure against TB in Africa. One of the major approaches to the treatment of TB is Directly Observed Therapy Short-Course (DOTS). Under DOTS, health workers closely monitor the treatment to ensure that patients complete the full course of medication, preventing the development of new, drug-resistant strains of TB. The DOTS strategy has proven to be an effective medical approach.

Africa accounts for more than a third of the world's annual deaths associated with measles. This virus causes approximately 345,000 deaths worldwide each year, mostly among children. More than 20 million people are affected with this virus every year. Measles can cause blindness and brain damage, and it also induces children's susceptibility to pneumonia and diarrhea. It is highly contagious and spreads mostly through coughing and sneezing. Vaccination is extremely effective against the disease. Since the cost of immunization is approximately \$1 for each child in Africa, the Measles Initiative and the World Health Organization/United Nations Children's Fund (UNICEF) Strategy for Sustainable Measles Mortality Reduction aim to reduce measles deaths with comprehensive vaccination programs. Since its implementation in Africa in 1999, there has been an overall drop of 60% in all documented measles cases.

Tetanus in sub-Saharan Africa leads to 84,000 deaths every year and a total of 2 million deaths worldwide. Tetanus is a potentially fatal disease of the central nervous system. It most commonly originates in wounds that become infected with bacteria. Neonatal tetanus passes from the mother to the fetus.

The "Meningitis Belt" has the world's highest rates of patients infected with the disease. This geographical region includes Senegal in western Africa, stretching to Ethiopia in the east. Meningitis, a frequently fatal bacterial disease, infects the membranes of the brain and spinal cord. Burkina Faso was the first African country to experience an epidemic of a new strain of meningitis known as W135. In 2005, the world price of the vaccine

ranged from \$4 to \$50, which is unaffordable in many African nations. The WHO and other global health organizations are currently negotiating to lower the price of the vaccination, making it more affordable.

Health Services Research Activities

As a result of concentrating on specific disease conditions, health services research in sub-Saharan Africa is often published and presented in disease-specific journals and conferences, as opposed to health services research-specific publications and events. These conferences include the Union World Conference on Lung Health and the International AIDS Conference. Additional health services research from the region can be found in the gray literature of unpublished dissertations, government briefs, and the reports of nongovernmental organizations (NGOs). Problems that are of great focus include issues related to poverty, vulnerable populations, distance traveled, shortage of healthcare workers, lack of supplies, and irregularity of available medications. Research studies conducted in sub-Saharan Africa tend to collect primary data on a small group of individuals, relying on hundreds of respondents and subjects as opposed to thousands. Large computerized longitudinal databases and secondary data analyses are not typically used in the sub-Saharan African health services research. Survey instruments often require translation into local languages, and there is an identified need for repositories of such translations.

A large portion of health services research in the region is underwritten by international agencies and nongovernmental organizations. Frequent topics include the cost-effectiveness of scarce resources applied to treatment. Vulnerable populations are the main area of focus, with nearly half of the published articles in the medical literature addressing women and about 40% focusing on children. Communicable disease control is another major area of focus in the developing world, reflected in the health services research articles coming out of sub-Saharan Africa, which are overwhelmingly disease specific. AIDS is the primary focus of these articles, representing more than 16% of works. Primary care, poverty, bioethics, malaria, TB,

cancer, and vaccines represent the remaining articles, in descending order of frequency.

Professional society membership, dedicated journals, focused-funding organizations, large libraries, and dedicated faculty positions define the social structure of health services research in North America. These structural elements are lacking in sub-Saharan African health services research. Relevant journals such as *East African Journal of Medicine* are not easily accessed, especially in electronic versions. Researchers are often unaware of the work of others and are unlikely to cite coexisting research in the area, making it difficult to locate relevant articles through citations and citation scores. In spite of these barriers, there is a rich, high-quality body of health services research from this region. A recent examination of scientific articles showed that from a total pool of 44,000 articles worldwide, approximately 1,300 articles dealt with topics in sub-Saharan Africa.

Future Implications

The field of health services research in this area of Africa has some advantages. This research can be carried out at low cost and often with high response rates. Some health interventions have low costs and large health benefits. Perhaps because of this, cost-benefit analysis is a more acceptable analytical method. Graduate education in this area of study is available in sub-Saharan Africa—for example, at Makerere University in Uganda. Local faculties prefer to assign articles that include authors and coauthors from the region. Local researchers are well aware of their health problems and are interested in studies that show how to improve them. There is a need for a core, accessible group of excellent articles on health services research to be available for teaching purposes.

HEALTH SERVICES RESEARCH IN THE PEOPLE'S REPUBLIC OF CHINA

During the past 25 years, the People's Republic of China has undergone tremendous social change and economic growth. China's healthcare system, however, has failed to keep pace with many of these changes. As a result, China has a growing need to improve its delivery of healthcare to its people in both rural and urban areas. Health services research has begun to play an important role in guiding this effort, with its emphasis on the issues of access, cost, quality, and the outcomes of healthcare.

History

Researchers from the United States introduced health services research to the People's Republic of China in the early 1980s. Specifically, in 1981, the Shanghai Medical University, School of Public

Health, conducted the first health services research in China. This initial research examined the utilization and provision of healthcare in Shanghai using a household interview survey. Based on the results obtained, a comparison of health outcomes between Shanghai and Washington, D.C., revealed that the health status of these two cities was similar. The results suggested that the similarity of health outcomes in China was due to the wide coverage of basic healthcare services provided by a healthcare system that was composed of the government's welfare plan, labor insurance, and the collective health systems. The comparison with Washington, D.C., also revealed that Shanghai spent substantially less on health expenditures.

Since the 1980s, Chinese health services research has proliferated, and it has been applied to many projects at both the local and the national levels. The original Shanghai Household Interview Survey assessed past episodes of illness, the use of health services in the past 2 weeks, and the number of hospitalizations in the past year, as well as surveying outpatient use. Since then, these initial assessments have been expanded to include various types of healthcare services. China has also developed the National Health Service Survey, which has been conducted in the years 1993, 1998, and 2003 throughout the various regions of the country.

Current Research

Over the past decades, health services research in China has focused on the growing unmet healthcare needs of the country, healthcare utilization, financing, costs, quality, access to care, and healthcare reform. Currently, China is considering whether its healthcare system should be more of a free-market system or a revised, centrally planned system. Health services research is helping the government to make this decision.

One critical issue China is facing is the rapidly rising healthcare costs. This increase is a result of more severely ill patients seeking healthcare, the use of new medical technologies, and the overprescribing of medications. The high cost of healthcare in China has made it unaffordable for many of the poor, resulting in a decrease in the demand for healthcare.

Another important issue of concern is the underutilization of healthcare providers in China due to reduced patient demand. As the number of healthcare providers has increased, patient case-load and occupancy at township hospitals has decreased. As a result, provider productivity has declined accordingly.

Health services research studies have shown that China, like other countries, has a limited system to monitor and ensure the quality of its healthcare. The skill level of healthcare practitioners has been found to be low, especially at the village level. Additionally, a large body of evidence suggests that some level of wasteful, inefficient, and/or inappropriate care is being delivered in China, particularly in the overprescribing of medications. Although evidence shows that healthcare quality in China has been improving, the improvements are mostly restricted to large urban areas. Furthermore, despite the general satisfaction with providers' attitudes and service delivery, dissatisfaction with physician communication concerning patients' health status, as well as conflict between providers and family members, appears to be common.

Inequities in the delivery of healthcare between urban and rural areas and across income groups further complicates China's healthcare system. Currently, the healthcare delivery system in urban areas is far more developed than in rural areas, and the gap in the quality of care between these areas continues to grow.

The reasons for the Chinese healthcare system's shortcomings continue to be investigated. Some analysts blame China's health service deficits on the country's movement away from a centrally planned healthcare system, while others look to decentralization and the adoption of a market economy as a much needed remedy. These counterperspectives have important implications for healthcare reform, especially as China debates the merits of competition versus government intervention in healthcare. Research assessing the consequences of competition between providers, as well as across and within markets, would be useful in informing this controversy and in setting future policy.

China's current fee-for-service payment structure and third-party payer system has resulted in the overprovision of services in more profitable areas of care. Additionally, because reimbursement

for simple noninvasive care is set below cost and high-tech diagnostic care is set above cost, the former is generally underprovided, while the latter is overprovided. As a consequence, healthcare costs have escalated in concurrence with the rapid adoption of new medical technologies. Provider incentives that encourage longer patient hospitalization have also contributed to the rising costs.

Other health services research studies on provider performance in China have shown that providers respond to changes in payment arrangements. A study that examined prospective payment in Hainan Province hospitals found that the average expenditure for admission decreased to below the level of other hospitals that were paid on a fee-for-service basis and the growth in spending on high-tech services declined. Another study showed that when the city of Shanghai switched payments for its government insurance program to capitation for outpatient care, escalation of costs slowed.

China's transition from a referral-based system to one that allows patients to choose the level of provider that they can afford has caused the overutilization of higher-level provincial and county hospitals, mostly by high-income patients. Meanwhile, lower-level township hospitals typically are underutilized and used mostly by indigent patients. Furthermore, studies have found that the decentralization of China's healthcare system has created greater inequity between richer and poorer regions. It also has led to overlapping and fragmented services.

Some of the issues highlighted above regarding China's healthcare system are due to inappropriate, unnecessary, or lack of government intervention. Other issues also reflect the government's concern with taking an active and positive role in healthcare service delivery. The overall findings of health services research studies have led to a greater understanding of the system and provided the basis for policymakers and program managers to continue to monitor, evaluate, and improve the effects of China's healthcare reform efforts.

Future Implications

Although the People's Republic of China has made significant progress in certain areas of its healthcare system, such as in reducing infant

mortality and increasing life expectancy, improvements in other areas are needed. The lack of funding of needed healthcare programs and the lack of access to affordable and high-quality care are of concern. Because of the various shortcomings in China's healthcare delivery system, a growing need exists for more well-designed health services research studies to guide the ongoing healthcare system reform efforts in rural and urban areas. Health services research has begun to play a pivotal role in improving the quality of life of the Chinese people, and it will continue to play an integral role in the ongoing transformation of China's healthcare system.

HEALTH SERVICES RESEARCH IN THE UNITED KINGDOM

In the United Kingdom, health services research is seen as being research that, from its inception, aims to improve the quality and efficiency of health services. In turn, a high-quality health service is seen as one that is effective, humane, and equitable. The concerns of health services research in the United Kingdom differ somewhat in emphasis from those in the United States, reflecting differences in the history of its development. To understand the role of health services research, consideration must be given to its development, current organization, funding opportunities, academic efforts, literature, and research capacity and training. Despite major achievements in this area over the past two decades, challenges and opportunities still exist. Although many of the key features of health services research are similar in all four jurisdictions in the United Kingdom, this account focuses on the largest, England.

History

Researchers at the London School of Hygiene and Tropical Medicine were the first in England to formally adopt the term *health services research*, starting a discussion on the topic in 1988. Research on health services, however, has a long history in the United Kingdom. In the mid-19th century, Florence Nightingale (1820-1910) was not only proposing how hospitals and nursing should be organized, but as a statistician, she was also assessing the performance of providers and comparing the outcomes of London hospitals. By the end of the century, Henry Burdett, a leading hospital administrator, was systematically collecting data on the resources and activities of hospitals and dispensaries throughout the country, which he compiled in extensive annual reports. In the early 20th century, E. A. Groves, a surgeon in Bristol, was advocating the need for standardized reporting of clinical cases such that comparisons of the effectiveness of care could be undertaken.

While such individual contributions were important, they represented isolated initiatives without any systematic support. In 1913, the government

established the Medical Research Council (MRC) to support and promote medical research. Although this effort included some limited funding for what is now called *health technology assessment*, its interests extended no further into health services research. The most significant early achievement of the MRC was the funding of the first randomized controlled trial (RCT) in the world, which dealt with the treatment of tuberculosis. It represented a major challenge to the traditional notion of “evidence,” which had been based largely on physicians’ observations and experiences. Other RCTs followed, culminating in 1972 with the publication of the seminal book *Effectiveness and Efficiency*, written by Archibald L. Cochrane (1909–1988), a medical epidemiologist, and funded by the Nuffield Provincial Hospitals Trust. Meanwhile, a more radical challenge to medical knowledge was being developed by a medical demographer, Tom McKeown, who, in his book *The Role of Medicine*, suggested that healthcare had made only a modest contribution to improvements in population health compared with environmental, nutritional, and social changes.

Although both Cochrane and McKeown had practiced clinically, they focused on public health or social medicine rather than clinical medicine. Unlike the United States, where health services research had its origins largely in internal medicine, in the United Kingdom, work on evaluating healthcare and challenging the established tenets of medicine was housed in public health. This persists to the present day and has influenced the focus of British health services research. The focus in the United Kingdom has also differed from that in the United States in two other ways. First, there is less concern about cost and cost containment, reflecting the existence of a global, capped budget and a greater focus on effectiveness and cost-effectiveness (reflecting not only the field’s origins in public health epidemiology but also the existence and acceptance of mechanisms for explicit rationing). Second, there is less focus on the influence of race and ethnicity on equity and more focus on socioeconomic status.

The development of health services research during the 1970s and 1980s was fairly piecemeal. The English Department of Health recognized its importance by establishing and supporting some research units, in particular at St Thomas’ Hospital

Medical School in London and at the University of Sheffield. The MRC continued to provide some funds, though it principally supported laboratory and clinical research. Despite this, it was the latter that the House of Lords Select Committee on Science and Technology were more concerned about when they deliberated on the country’s research needs in 1986. The Lordships’ conclusion was that the National Health Service’s (NHS) greatest need was for research on health services and, to a lesser extent, public health. In 1991, the NHS Research and Development Programme was established under its first director, Michael Peckham, a medical oncologist with management experience in academic medicine.

The following 5 years were extraordinarily productive and exciting for the field of health services research in the United Kingdom. The Cochrane Collaboration, an initiative led by a medical epidemiologist, Iain Chalmers, was established built on a pilot project in obstetrics and neonatal care. The initial aim of the Collaboration was to assemble all the RCT evidence on the effectiveness of healthcare and to synthesize it to produce policy and practice recommendations. Although it initiated in the United Kingdom, the Cochrane Collaboration rapidly expanded to become one of the largest, most comprehensive initiatives ever undertaken in the healthcare field.

Meanwhile, in England, new commissioned research programs were being established. For the first time, researchers, managers, and lay people were contributing to identifying research priorities and commissioning studies in areas that had often been neglected. Starting in 1992 with mental health and learning disability, seven national programs were established over the following 3 years. In time, these were replaced with two major programs focused on health technology assessment (HTA) in 1994 and service delivery and organization (SDO) in 1999. In addition, reviews of a wide range of methods needed in health services research were commissioned, which resulted in a series of monographs, an extensive textbook, and a shorter handbook providing state-of-the-art accounts for researchers.

Those early initiatives culminated in the first Scientific Basis of Health Services conference in London in 1995, an international gathering that subsequently traveled the world, including

Amsterdam, Toronto, Sydney, and Washington, D.C., with biannual meetings over the following decade. Meanwhile, the NHS Research and Development Programme flourished, with both the HTA and SDO programs growing in size and stature. The SDO programs addressed the methodological challenges in conducting research on the organization of services, published two books, and have increasingly encompassed the challenge of knowledge transfer to managers and policymakers.

After a few years of consolidation and stability, the NHS Research and Development Programme was redesignated as the National Institute of Health Research (NIHR) in 2006. While the funding streams and support for the field were unchanged or enhanced, leaders called for greater central direction and more transparency of the funds that had traditionally been allocated to NHS providers, mostly hospitals, to support research infrastructure and medical academic posts. Even while these changes were being introduced, the government, and in particular the Treasury, became increasingly concerned about the division of responsibility for health research between the NIHR and the MRC. This concern culminated in 2007 with proposals to move the NIHR away from the Department of Health (DH), creating an independent agency while at the same time ensuring that it pursued a coordinated policy with the MRC under an umbrella body, the Office for Strategic Coordination of Health Research (OSCHR). The impact of these changes is awaited.

Funding

The debate as to whether the responsibility for public funding of health services research should lie with the DH or the MRC has been going on for several decades. The compromise solution had been for the DH to fund the more applied, policy-oriented studies, leaving the MRC to fund micro, evaluative research with a particular focus on the clinical effectiveness and cost-effectiveness of specific healthcare interventions. Another difference has been that the DH has mostly used its funds to commission research, while MRC funds have been devoted to responsive or investigator-led studies. The DH has also funded research units, including—in addition to the two mentioned earlier—the

Primary Care Research and Development Centre in Manchester, the Nursing Research Unit in London, and the Centre for Health Economics in York. And from the start of the NHS Research and Development Programme in the early 1990s, regional research and development support units were established in the NHS to try to spread research activity away from the “centres of excellence” in leading universities and to encourage the uptake of research evidence into clinical practice.

With the establishment of a single research fund in 2007, the NIHR has become the lead organization responsible for coordinating all public funding of health services research, including that provided by the MRC Health Services and Public Health Research Board. The only element of public funding not included is the Economic and Social Research Council (ESRC), which provides some support for social science research on health services. In addition to public funding, some charities and foundations also provide funding, in particular the Nuffield Trust and The Health Foundation.

Organizations, Journals, and Training

Although quintessentially a multidisciplinary and multiprofessional activity, health services research in the United Kingdom continues to be fragmented intellectually. Researchers have tended to retreat to the safety and confines of their own disciplinary organization: the epidemiologists to the Society for Social Medicine, sociologists to the British Sociological Association Medical Sociology Group, and economists to the Health Economics Study Group. This has been unsatisfactory for several reasons. First, it has discouraged multidisciplinary research and exchange. Also, within each disciplinary organization, attention to health services research has inevitably been diluted by other, more dominating interests of each discipline. It has impeded the development of a higher profile for the field. In addition, this area of study has been fragmented between key areas of healthcare. Too often, researchers have focused their energies exclusively in topic- or profession-oriented organizations such as the Health Services Research and Pharmacy Practice Group, the United Kingdom’s Federation of Primary Care Research Organizations, and the Royal College of Nursing Research Society.

After at least two decades of unsuccessful attempts to establish an organization to unify the field in the United Kingdom, the Health Services Research Network was established in 2005. Nested within the main membership organization that represents NHS bodies, both purchasers and providers, it has similar aims to those of AcademyHealth in the United States. The development of a more coordinated and coherent presence for health services research has also been enhanced by the decision by the Higher Education Funding Councils to designate, for the first time, health services research as one of the 67 areas that make up the whole of academia for the all-important Research Assessment Exercise in 2008. This assessment is held every 7 years.

In the United Kingdom, the field depended largely on generalist journals, such as the *British Medical Journal* and the *Lancet*, for publishing its output until the 1980s. Research of a clinical nature could also be published in specialist medical journals. While encouraging the interest of clinicians, this practice may have exacerbated the fragmentation of health services research. The alternative for researchers has been single-disciplinary journals, such as the *Journal of Epidemiology and Community Health*, *Journal of Health Economics*, *Social Science and Medicine*, and *Sociology of Health and Illness*. American subject-specific or generalist journals have rarely been interested in research from the United Kingdom. However, over the past 20 years, the situation has improved with the establishment of some subject-specific journals in the United Kingdom, including *Health Services Management Research*, *Quality and Safety in Health Care*, *Journal of Health Services Research and Policy*, and *Journal of Evaluation of Clinical Practice*.

The capacity to conduct health services research has steadily increased. There are now many relevant Masters' level courses available, some providing a broad, multidisciplinary introduction and others focusing on one of the relevant disciplines. And with the development of research units and departments in universities, opportunities for doctoral studies have grown. Like other areas, funding for students remains the limiting factor. Fellowships, particularly doctoral and postdoctoral, are provided by the two principal sources of public funding, the MRC and the NIHR. In addition, the

Health Foundation has targeted particular groups such as nurses and allied health professionals.

Major Achievements

The profound impact that health services research has had on health services in the United Kingdom is not sufficiently recognized. Despite all the challenges that the field has faced and its low level of resources and support compared with biomedical and clinical research, it has had an immense influence on healthcare policy and the way health services are organized, managed, and regulated. The key features of the NHS have largely been driven by the challenges thrown down by leaders in the field in the 1970s and the subsequent research carried out since the 1980s that revealed unjustifiable variations in the performance of healthcare providers. This research provided policymakers and managers with the confidence to challenge established, unquestioned medical views and to require providers to be publicly accountable. These measures have included demands for rigorous demonstration of the effectiveness, humaneness, and equity of care, which is the basis of contemporary performance management and regulation. In parallel, requirements to justify the rapidly increasing expenditure on healthcare resulted largely from economic research on the cost-effectiveness of interventions and on financial management.

Some of the main achievements of the NHS Research and Development Programme have been mentioned: (a) a shift in emphasis from responsive to commissioned research to meet the priorities and needs of the health service; (b) establishment of the Cochrane Collaboration, which has mapped out what is known and what is not known about what works in healthcare; (c) support for methodological research to enable health services research to become more rigorous and heighten its scientific status; and (d) recognition of the need for research not only on health technologies but also on the way services are delivered and organized.

Other key achievements have been the adoption of the field as a distinct unit of assessment in the universities' most recent Research Assessment Exercise and the development of high-quality clinical databases in some key areas of healthcare, including critical care, cardiac surgery, acute

myocardial infarction, that provide a productive base for research, planning, and patient management. The creation of the National Institute for Health and Clinical Excellence (NICE) and National Service Frameworks also arose from health services research's demonstration of variations in inputs, processes, and outcomes.

Future Implications

The field of health services research has historically faced the challenge of persuading both colleagues in biomedical and clinical research of its scientific worth and managers and policymakers as to its practical value. In addition, in the United Kingdom, there are several other challenges to be met. First, there is increasing focus in the NHS on the research needs of the pharmaceutical industry, which is seen as creating wealth for the country, rather than on improving the health of the public. Second, the field must learn to cope with the increasing diversity of healthcare providers as the government encourages greater competition. Third, there is a need for research to reflect the increasing integration of health and social care. Fourth, researchers have to gain sufficient political knowledge to handle the government's political ideology, which is decreasingly tolerant of research that questions its beliefs. Finally, there is the challenge of dissuading authorities of the need for inappropriate bureaucratic restraints on health services research in the name of protecting the ethical rights of the patients and the staff.

Given these potential obstacles, health services research can respond in several ways: (a) by enhancing patient/public involvement in research policy and priority setting, (b) by demonstrating the value of such research to health services and research funders, (c) by improving the transfer of research-based knowledge to policymakers and managers, (d) by assisting in improving the commissioning of healthcare, (e) by exploiting high-quality clinical databases for research, (f) by increasing clinician involvement in the field, and (g) by getting more involved in deploying rigorous methods in quality improvement initiatives. Given these opportunities, the future for health services research in the United Kingdom has much potential.

HEALTH SERVICES RESEARCH JOURNALS

Access to peer-reviewed journal literature is an important part of health services research. Two resources that help identify key journals in health services research are the Core Public Health Journals Project—Health Services Administration and the Institute for Scientific Information's annual *Journal Citation Reports (JCR)*. Most of these journals are indexed in the U.S. National Library of Medicine's PubMed database, and specialized queries are available to focus on the health services research literature.

Core Public Health Journals Project

In 2001, the Core Public Health Journals Project began with the purpose of identifying a list of core public health journals that every library in the field should have. Compiled and reviewed by public health librarians and public health professionals, this list will result in a database that helps the Association of Schools of Public Health in its accreditation process. The Public Health/Health Administration Section of the American Library Association (ALA) supports this ongoing and collaborative project. The list of core journals serves as a starting point for researchers performing systematic reviews of the health services literature. It is regularly updated, and the project plan calls for a new version of the list to be produced every 2 years. In 2006, the Core Public Health Journals Project received the Medical Library Association's Louise Darling Medal for Distinguished Achievement in Collection Development in the Health Sciences.

Modeled after the Brandon-Hill list, the Core Public Health Journals Project categorizes journals into three groups: (1) those journals that are essential for a library that has specialization in

public health and health administration, (2) publications that are important for research gathering but not essential to the library collection, and (3) publications that are of interest to practitioners. These core categories provide comprehensive coverage for journals and other publications that serve health service researchers and public health practitioners. The database also includes links to additional information about the journals, such as the International Standard Serial Number (ISSN), pricing, indexing of the journal articles within the PubMed database, and links to publishers' Web sites. Most of the journals in the list are indexed within PubMed. Health services researchers would be most interested in the core list subject of Health Services Administration.

Essential Core Publications

The Core Public Health Journals Project identifies those publications that are considered essential for libraries specializing in the field of public health and health administration. The 2006 Essential Core list for the subject of Health Services Administration includes the following: *Administration and Policy in Mental Health*, published by Springer 6 times a year; *American Journal of Managed Care*, a monthly journal published by Medical World Communications; *Health Affairs*, published 6 times a year by the University of Pennsylvania; *Health Care Financing Review*, a subscription quarterly journal of the Centers for Medicare and Medicaid Services (CMS); *Health Care Management Review*, a bimonthly publication from Lippincott, Williams & Wilkins; *Inquiry*, a quarterly journal published by Excellus Health Plan; *International Journal of Technology Assessment in Health Care*, a quarterly journal from Cambridge University Press; *Joint Commission Journal on Quality and Patient Safety*, published monthly by Joint Commission Resources; *Journal for Healthcare Quality*, the bimonthly journal for the National Healthcare Quality Association; *Journal of Health and Human Services Administration*, published by Southern Public Administration Foundation 4 times a year; *Journal of Health Care Finance*, a quarterly journal from Aspen Publishers; *Journal of Health Politics, Policy, and Law*, published 6 times a year by Duke University Press;

Journal of the American Medical Directors Association, a monthly publication from the American Medical Directors Association; *Medical Care*, published by Lippincott, Williams & Wilkins 12 times a year; *Medical Care Research and Review*, a bimonthly journal of Sage Publications; and *Milbank Quarterly*, published 4 times a year by the Milbank Memorial Fund and Blackwell Publishing.

Research Level Core

The Research Level Core list is important for comprehensive library collections, helping researchers and graduate students in a particular field. The 2006 Research Level Core list for Health Services Administration includes the following: *American Journal of Law & Medicine*, published 3 times a year by the American Society of Law, Medicine & Ethics; *American Journal of Medical Quality*, a bimonthly journal of Sage Publications; *Cost Effectiveness and Resource Allocation*, an online journal published by BioMed Central; *European Journal of Health Economics*, published by Springer-Verlag 4 times a year; *Evaluation and the Health Professions*, a quarterly journal from Sage Publications; *Evidence-Based Healthcare & Public Health*, a quarterly journal from Elsevier that is not indexed in PubMed; *Frontiers of Health Services Management*, published quarterly by the Health Administration Press; *Health Care Analysis*, published 4 times a year by Springer; *Health Economics*, a monthly journal from John Wiley & Sons; *Health Policy*, published by Elsevier 15 times a year; *Health Policy and Planning*, a bimonthly journal of Oxford University Press; *Health Research Policy and Systems*, an online journal published by BioMed Central; *International Journal for Quality in Health Care*, a bimonthly journal of Oxford University Press; *International Journal of Health Services*, published 4 times a year by Baywood Publishing Company; *Joint Commission: The Source*, a monthly publication from Joint Commission Resources that is not indexed for PubMed; *Journal of Ambulatory Care Management* and *Journal of Behavioral Health Services & Research*, each published quarterly by Lippincott, Williams & Wilkins; *Journal of Health Administration Education*, a publication of the Association

of University Programs in Health Administration; *Journal of Health Care for the Poor and Underserved*, a quarterly journal from Johns Hopkins University Press; *Journal of Health Economics*, published by Elsevier 6 times a year; *Journal of Health Law*, a publication of the American Health Lawyers Association; *Journal of Healthcare Information Management*, a quarterly journal of the Healthcare Information and Management Systems Society; *Journal of Healthcare Management*, published bimonthly by the Health Administration Press; *Journal of Healthcare Risk Management*, a publication of the American Hospital Association; *Journal of Law, Medicine & Ethics*, a quarterly journal of American Society of Law, Medicine & Ethics; *Journal of Legal Medicine*, published quarterly by Taylor & Francis; *Journal of Nursing Administration*, published 11 times a year by Lippincott, Williams & Wilkins; *Journal of Public Health Management and Practice*, a bimonthly publication of Lippincott, Williams & Wilkins; *Journal of Public Health Policy*, published quarterly by Palgrave Macmillan; *Managed Care Quarterly*, a publication of Aspen Publishers; *Medical Decision Making*, published 6 times a year by Sage Publications; *Mental Health Services Research*, a publication from Springer that is not indexed by PubMed; *PharmacoEconomics* published 12 times a year by Adis International; and *Value in Health*, a bimonthly journal published by Blackwell Publishing.

The Gray Literature and Others

Besides the Essential Core and the Research Level Core lists, the Core Public Health Journals Project also categorizes the gray literature, which includes newsletters, annual reports, and other publications that may be of interest to practitioners. For the subject of Health Services Administration, the 2006 list includes the following: *AHA (American Hospital Association) News Online*, *Environment of Care News*, *Healthcare Executive*, *Healthcare Financial Management*, *Hospitals and Health Networks*, *Joint Commission Benchmark*, *Joint Commission Perspectives on Patient Safety*, *Modern Healthcare*, and the state's and surrounding states' medical association journals.

Journal Citation Reports

The Institute for Scientific Information (ISI) produces the annual *Journal Citation Reports* to provide citation data on journals, as well as calculations of the journal's impact factor, immediacy index, cited half-life, citing half-life, and source data. These are quantitative methods for determining the relative importance of journals within subject categories. *JCR* is only available through a subscription. Most academic research libraries provide licensed access to this resource.

JCR is produced annually as two editions: the *JCR Science Edition*, which covers more than 5,900 journals on science and technology, and the *JCR Social Sciences Edition*, which covers another 1,700 journals in the social sciences. Health services research journals can be found in both editions. The *JCR Science Edition* covers the category Health Care Sciences and Services. This edition has journals that cover health services, hospital administration, healthcare management, healthcare financing, health policy and planning, health economics, health education, history of medicine, and palliative care. The *JCR Social Sciences Edition* covers the category Health Policy and Services. The journals listed in this edition include those that cover healthcare systems, including healthcare provision and management, financial analysis, healthcare ethics, health policy, and quality of care. Because the target audience of each edition is different, a health services administration journal may be listed in either with different data for impact factor, immediacy index, cited half-life, and citing half-life. When using either editions of the *JCR*, it is important to use the appropriate subject category and edition to review the data for a journal.

An often-cited measure of a journal's importance is its impact factor. Although *JCR* is a subscription-based resource, most publishers will list the journal's impact factor from their Web site. This measure refers to the frequency with which a typical article in a journal has been cited within a particular year or period of time. The impact factor, however, should not be the sole basis for judging the prestige of a journal. Information from the *JCR* is intended to complement information from other journal resources.

Health Services Literature Searches

Each year, more than 3,000 articles and reviews are published in more than 40 health services research journals. Additional health services research articles can be found in other health sciences journals, such as the *American Journal of Public Health*, the *Journal of the American Medical Association*, and the *New England Journal of Medicine*. Most of the journal literature is indexed within online databases produced by the U.S. National Library of Medicine (NLM). From 1994 to 2000, the NLM and the AHA jointly produced HealthSTAR (Health Services Technology, Administration, and Research), an online database focused on the clinical and non-clinical aspects of healthcare delivery. HealthSTAR contained citations and abstracts from the journal literature as well as monographs, technical reports, and other research materials from 1975 onward. Topics covered in HealthSTAR included evaluation of patient outcomes; effectiveness of procedures, programs, products, services, and processes; administration and planning of health facilities, services, and manpower; health insurance; health policy; health services research; health economics and financial management; laws and regulation; personnel administration; quality assurance; licensure; and accreditation.

Although the NLM no longer offers HealthSTAR as a separate database, the health services journal literature continues to be indexed and included in PubMed. PubMed provides free access to MEDLINE (Medical Literature Analysis and Retrieval System Online), NLM's premier biomedical database, containing more than 15 million journal citations. Most of the core health services research journals are included in PubMed, and the citations include links to the full-text versions of journal articles at participating publishers' Web sites.

Specialized PubMed search queries on healthcare quality and costs are available via the Pilot Health Services Research (HSR) Filters Project from the National Information Center on Health Services Research and Health Care Technology (NICHSR) Web site. These specialized PubMed queries can be used to identify journal citations that correspond to a specific health services research study category with a broad or narrow scope. The health services research study categories are appropriateness, process assessment, outcomes assessment, costs,

economics, and qualitative research. These specialized PubMed search queries were designed as tools to assist researchers, clinicians, health policy analysts, and planners. For comprehensive searches, researchers can use PubMed directly to further search the health services research journal literature.

Future Implications

Health services researchers rely on the scientific literature to make advances in the field. Several mechanisms and clearinghouses help make these peer-reviewed journals and other publications accessible and organized for the use of researchers and other health administration professionals. The databases, which are updated regularly, will continue to grow, capturing publications and information that will further health services research.

HEALTH SURVEYS

Health surveys are one of the methods most commonly used in health services research for obtaining measures of various indicators of health knowledge, attitudes, behaviors, and demographic characteristics. They collect data by self-report, whereby participants (called *respondents*) reply to questions presented in a self-completion questionnaire or by an interviewer via telephone or face-to-face. Health services researchers conduct health surveys or use the findings from health surveys conducted by others (called *secondary analysis*) to perform needs assessments, develop cross-sectional profiles of populations, monitor populations or cohorts longitudinally, or collect pretest and/or posttest measures in studies using experimental or quasi-experimental designs.

Health surveys are an effective and efficient method for estimating the characteristics of large populations using data collected from representative samples, analyzing comparisons across various study units (most often, these are individuals, but they also can be groups such as households or organizations), and/or analyzing comparisons within study units over time. This is attributable to three key features.

First, most health surveys are conducted with large numbers (usually several hundred and sometimes thousands) of participants, who are selected using random (probability) sampling procedures. Random sampling avoids potential selection bias that might be present—for example, if participants were recruited by soliciting volunteers through advertising. Second, health surveys collect data in a structured, standardized manner from each respondent. This is accomplished by presenting each question to each respondent using the same mode of delivery, to the extent possible in a similar setting and under similar conditions, and using the same question wording, question order, and response choices. Third, almost all responses to health

survey questions are recorded in a quantitative format, such as counts of persons or events; numerical positions on rating scales; or by assigning numerical codes to nominal, categorical responses such as types of health insurance. This precoded response aspect facilitates data processing and analysis, especially when combining similar responses and comparing responses across and within respondents (in the case of a longitudinal design).

Advantages

There are numerous advantages or strengths of health surveys that make them useful for conducting health services research. The following points generally are characteristic of health surveys, but they do not necessarily apply to all health surveys.

First, as was already mentioned, health surveys, especially those conducted by U.S. federal governmental agencies such as the National Center for Health Statistics (NCHS) and Centers for Disease Control and Prevention (CDC), usually collect data from large, randomly selected samples. Random sampling avoids selection bias and enables health services researchers to apply inferential statistical procedures when estimating population characteristics (called *parameters*).

Second, the previously mentioned structured, standardized manner in which health surveys collect primarily quantitative data facilitates data collection, processing, and analysis. This also enhances the ability of health services researchers to replicate previous health surveys with different populations and/or to study the same populations or cohorts longitudinally.

Third, health surveys are a very flexible research method that can be used to collect data about various study units (e.g., individuals, households, organizations). They can be implemented in a wide variety of settings, ranging from a respondent's home to external sites such as schools, work sites, and health clinics. Finally, they can be used to study populations that are distributed broadly across large geographic areas, such as cities, counties, states, and countries.

Fourth, the self-report aspect of health surveys enables health services researchers to collect information about variables that are not observable directly. For example, most health surveys ask questions

about respondents' health knowledge and health attitudes/beliefs, which are not measurable reliably except by self-report. Health surveys also are often used to collect information about respondents' behaviors for which there are no records or the reliability of existing records is unacceptable, or in cases where it is difficult or not possible to gain access to records. Finally, when appropriate strategies are used, health surveys can be effective in collecting sensitive information. For example, anonymous strategies may be used to ask about attitudes, such as racial prejudice, that most respondents are reluctant to express publicly. Also, similar strategies may be used to ask about private behaviors, such as sexual practices, or about illegal behaviors, such as illegal use of drugs and other forms of substance abuse.

A final area of strength is that health surveys are efficient in terms of time and financial resources. They enable health services researchers to collect large data sets quickly and at relatively low cost per unit of information. Health surveys typically collect data from large numbers of respondents and measure large numbers of variables per respondent. Moreover, they do so much faster than is possible with most other data collection methods, especially for a study of the same size and design complexity. Although data collection time varies depending on the data collection mode, sample size, design complexity, and staff resources, the data collection phase for most relatively large health surveys ranges from about 4 to 12 weeks. Combined with the efficiency derived from using a structured, standardized data collection protocol in which almost all responses are precoded in a quantitative format, health surveys may collect and analyze large, complex sets of data in a very timely manner. This enables health services researchers to avoid or minimize potential historical influences that may threaten the interpretation of the data. It also enhances health services researchers' ability to be responsive to time-sensitive data applications, such as in making decisions about initiating, revising, or terminating health programs, or advocating health policies or legislation.

Cautions About Health Surveys

While they are efficient, the total financial resources required to conduct health surveys effectively,

especially large, complex ones, can be relatively high. Moreover, while they enable health services researchers to collect data quickly, all surveys require a substantial amount of time for planning and preparation. This time varies with the size and complexity of the survey, but it almost always is several times as much as is required for the survey data collection phase (also called the *field* phase).

Conducting any health survey effectively requires a well-trained, experienced, and supervised research team. It is feasible for small, simple surveys to be conducted by a small research team—for example, by an experienced survey researcher training and supervising staff, who are available within or through an organization that is sponsoring or collaborating on a survey. However, virtually all large, complex health surveys are conducted by health services researchers collaborating with experienced, professional academic or commercial survey research organizations.

Health Survey Data Collection Modes

Health survey data are collected by two basic strategies, whereby respondents are asked to reply to questions presented in self-completion questionnaires or read aloud by interviewers. There are several ways in which these strategies may be employed, either individually or in combination. Selecting the one most appropriate for a particular health survey requires considering several aspects regarding relative administrative feasibility and data quality.

Self-Completion Questionnaires

Self-completion (also called *self-administered*) questionnaires generally are the least expensive and easiest to implement survey data collection mode, placing the smallest demand on staff, equipment, and other resources. The most widely used application of self-completion questionnaires is in mailed surveys, whereby a questionnaire and a letter are sent via standard mail to a sample of persons whose names and addresses are available. The respondents are asked to complete the questionnaire and return it to the researchers using a postage-paid, preaddressed return envelope that is enclosed with the questionnaire.

Another common application of this strategy is for members or agents of the research team to distribute, in person, self-completion questionnaires to persons in the survey sample. The sample members are asked to complete the questionnaire and return it directly to the person from whom they received it, place it in a collection box, or send it to the researchers via standard mail, using a postage-paid, preaddressed return envelope that is provided along with the questionnaire. This strategy may be employed with individuals, such as samples consisting of clinic patients waiting to see health services providers, or with groups, such as samples consisting of students in classrooms or teams of workers at work sites.

Technological advances have led to the introduction of several computer-based strategies for conducting self-completion questionnaire health surveys. The most prevalent of these are e-mail surveys, Internet surveys, and computer-assisted self-interviews (CASIs), which is the most expensive of these strategies.

E-mail surveys are conducted by sending e-mail messages to samples of persons for whom e-mail addresses are available, such as college students or members of professional associations. They are asked to complete and return via e-mail a questionnaire that is attached to or embedded in the e-mail message or that may be downloaded from a Web site.

Internet surveys are conducted in two ways. One strategy is to send e-mail messages to the sample members (again, e-mail addresses must be available) inviting them to participate in the survey by visiting a Web site where a questionnaire may be completed online. The second strategy is to invite survey participation via pop-up windows presented to Web site visitors, for example—persons who visit Web sites for health information clearinghouses or health services providers.

CASIs are conducted by arranging for research team members to meet with respondents in person. Respondents are asked to complete a questionnaire that has been programmed into a laptop/notebook computer. The computers are provided by the research team members, who explain and monitor the respondents' use of the computer to complete the questionnaire using the keyboard to enter code numbers corresponding to their responses to the questions. Another form of this data collection

mode is audio computer-assisted self-interviews (A-CASI), whereby the respondents complete the questionnaire using a laptop/notebook computer supplemented by a synchronized recording of an interviewer reading aloud the instructions, the questions, and the response choices.

Interview Surveys

Health surveys use two basic strategies to collect data by conducting interviews. These are telephone interviews and face-to-face interviews (also called *personal interviews*). In both these modes, survey respondents are asked to reply to questions and response choices that are read aloud by interviewers. Telephone interviews are the most widely used mode for conducting survey interviews because of their versatility, data quality, and time and cost efficiency. While face-to-face interviews generally are the most expensive and time-consuming survey data collection mode, they are also generally considered to provide the best data quality among all survey modes. However, in most cases, this is not a substantial advantage over conducting interviews via telephone.

Prior to recent technological developments, most interview surveys were conducted by interviewers reading questions and response choices from paper copies of survey questionnaires and recording responses directly on the questionnaires. This paper-and-pencil-interview (PAPI) format is still used effectively for small-scale, low-budget interview surveys. However, technological advances have led to the widespread use of computer-assisted strategies for conducting interview surveys. Although there are many variations of these and new ones continue to be developed, the most prevalent strategies are very similar to the CASI described earlier. In fact, CASI strategies were derived from the interview technologies that were first developed for telephone interview surveys and then were applied to face-to-face interview surveys.

Computer-assisted telephone interviews (CATI) and computer-assisted personal interviews (CAPI—face-to-face interviews previously were called “personal” interviews, thus the *P* in *CAPI*) are conducted by interviewers reading aloud questions and response choices displayed on monitors by computers into which the survey questionnaire has been programmed. The interviewers use keyboards

to enter code numbers corresponding to the responses to the questions, which are stored directly into databases for processing and analysis. While various configurations of desktop or laptop/notebook computers may be used for CATI surveys, which usually are conducted at survey interviewing centers, CAPI interviewers are equipped with laptop/notebook computers for ease of portability in the field.

Telephone Interview Surveys

Telephone interview surveys are conducted by trained and supervised interviewers who call the persons in the sample on the telephone to interview them using the survey questionnaire as the interview guide. This requires that the sample members have current telephone access, and there must be a means for the researchers to obtain their telephone numbers. Although some members of the U.S. population do not live in households with telephone access, U.S. Census reports routinely indicate that more than 90% of the population have telephone access, providing the most thorough means of contacting of this large and geographically dispersed population at the least expense. One strategy for obtaining telephone numbers for sample members is to use appropriate existing lists, such as directories, for example, for employees of certain companies, or lists compiled from records, for example, for patients who have used services at certain health clinics during particular time periods.

A second strategy is to use one of several forms of specialized random sampling, referred to generally as random-digit dialing (RDD). This is employed when appropriate lists of telephone numbers for sample members are not available and, usually, the identity of the sample members is also not known to the researchers. For example, this describes the situation health services researchers confront when planning telephone interview surveys with random samples of all adults living in the United States. This strategy also is used for telephone interview surveys with samples of populations in smaller geographic units, such as cities, counties, and states.

Unfortunately, there are no master directories of telephone numbers for all U.S. households with telephone service that may be used as sampling

frames from which to select random samples. Even for smaller geographic units such as cities, many households with telephone service are not included in telephone directories because they have requested their numbers to be unpublished or unlisted. Also, new residents who have been assigned a telephone number since the publication of the most recent directories will not be included in them. These exclusions may result in unrepresentative samples due to substantial sample coverage bias and lead to errors in estimating population characteristics.

In its most comprehensive form, RDD would randomly select a set of all 10 digits constituting a telephone number (3-digit area code + 3-digit prefix code + 4-digit line code) to compose a sample of n telephone numbers to be called in conducting a survey. However, this procedure is never used because it is very inefficient in that most of the telephone numbers it generates will not be useful for the intended survey. Some numbers will not be in service, some will be assigned to businesses or institutions rather than to households, and some will be assigned to households located outside the city or other geographic area designated as the survey target.

In practice, alternative RDD strategies address these problems through multiple-stage sampling designs using information about groups of numbers that are known to be in service in the target population. These designs greatly improve efficiency by reducing the proportion of telephone numbers that will be called that are not in service or are not assigned to members of the survey target population. For example, the first stage might consist of selecting some or all the area code + prefix code combinations known to be in service in the target population. This information is combined with one of several alternative strategies for obtaining all or part of the 4-digit line code to create a sample of n telephone numbers to be called in conducting a survey. This is a simple illustration of an RDD sampling design. Several alternative RDD strategies are available, some of which are quite complex and require specialized expertise and resources.

For large-scale RDD telephone interview surveys, it is virtually essential for health services researchers to contract for the services of experienced survey professionals. RDD samples may be purchased directly from professional

sampling firms, usually via the Internet. However, most researchers will be served best by collaborating with experienced professional academic or commercial survey research organizations providing a full range of telephone interview survey services.

Face-to-Face Interview Surveys

Face-to-face interview surveys are conducted by trained and supervised interviewers who interview survey sample members in person, using the survey questionnaire as the interview guide. In most cases, these interviews are conducted in respondents' homes, but they also may be done at schools, clinics, work sites, and other appropriate locations.

In the most straightforward situation, face-to-face interviews are conducted in respondents' homes with a random sample selected from a list that includes the sample members' residential addresses. For example, the sample may be selected from a directory, such as one of employees, or from records, such as for health clinic patients.

Face-to-face interview surveys are very expensive in terms of time and money when the sample is selected from the general population, such as all adults residing in a large city. This is because, similar to the problem described regarding sampling for telephone interview surveys, no adequate list of names and addresses is available to serve as a sampling frame. The usual procedure for such surveys is to select a sample using a multistage cluster sampling design called *area probability sampling*.

This involves randomly selecting a series of increasingly smaller geographic units, then randomly selecting individual dwelling units, and then randomly selecting one eligible person within each dwelling unit. For example, for a survey of adult residents of a large city, the sampling design might first select a random sample of neighborhoods, then randomly select census tracts within those neighborhoods, and then randomly select city blocks within selected census tracts. At the block level, usual practice calls for sending research staff members into the field to develop on-site maps of the selected blocks and list the addresses of all dwelling units on those blocks. Then a random sample of dwelling units is selected using this information. Finally, interviewers are sent to the selected dwelling units to interview one person at

each unit. When more than one eligible person resides at a dwelling, the interviewer randomly selects one of them to interview. Virtually all surveys that involve this type of complex sampling design are conducted by health services researchers collaborating with experienced professional academic or commercial survey research organizations.

HEALTH SYSTEMS AGENCIES (HSAs)

Health systems agencies (HSAs) were regional health-planning organizations. They were established under the authority and funding of the National Health Planning and Resource Development Act of 1974 (PL 93–641), which was signed into law by President Gerald R. Ford in January 1975. This act, repealed in 1986, created Title XV and Title XVI of the Public Health Service Act, which addressed health planning and resource development.

Background

Voluntary health-planning efforts began in the mid-1940s, involving community, business, and health provider leaders who were usually associated with community chests or the United Way. They conducted health planning, coordination, and studies in local communities using local funding.

During the Great Depression and World War II, there was very little hospital construction in the nation. Existing hospitals became obsolete, and more than 40% of the nation's counties had no hospitals at all. To address this problem, the U.S. Congress passed the Hospital Survey and Construction Act (PL 725) in 1946, better known as the Hill-Burton Act (named after the bill's sponsors Senators Lister Hill [D-AL] and Harold H. Burton [R-OH]). The act established a program that provided states with federal matching funds for the construction and modernization of health

facilities. The Hill-Burton program required states to develop medical facilities plans in order to guide the allocation of federal funds. The Hill-Burton program was amended in 1962 so that planning at the regional level could be supported using federal funds in selected areas of the country. HSAs continued the history of federally sponsored health planning at the regional level that began with the amendments to the Hill-Burton program and provided support for substate planning for medical facilities.

When the Social Security Act was amended in 1965 to include the Medicare and Medicaid programs, a concern emerged that the demand for medical services by elderly and poor populations might be overwhelming and that health planning was required. The Comprehensive Health Planning Act of 1966 (PL 89-749) was passed, which created state health-planning agencies, area-wide comprehensive health-planning agencies, funding for health planning education and consumer training, block grants to states, and funding for demonstration programs.

The areawide comprehensive health-planning agencies, known as “b” agencies because they were funded under section 314(b) of the act, were the predecessors of the HSAs. A system of about 200 regional comprehensive health planning organizations developed plans for health and, in many cases, assisted state governments in regulating capital investments by health facilities. These “b” agencies were required to have boards of directors with a consumer majority.

In 1972, amendments to the Social Security Act reflected a national concern over growing healthcare costs. These amendments included Section 1122, which placed limitations on federal participation in unnecessary capital expenditures by requiring, in the states where an agreement existed with the federal government, that a designated state-level health-planning agency review and approve proposed capital expenditures by health facilities. Failure to receive approval could result in reimbursement being excluded for depreciation and interest expense associated with the “unnecessary” capital investment under the federal Medicare, Medicaid, and Maternal and Child Health programs.

During this period, a few states initiated Certificate of Need (CON) programs through legislation or executive order that required approval

by the health-planning agencies or proposed capital expenditures or changes in services by health facilities. The programs were also called Determination of Need, or DON. These policy initiatives strengthened the area of health planning because state health-planning agencies, with the involvement of “b” agencies, engaged in CON, Section 1122 reviews, or both.

Under the Comprehensive Health Planning Program, there were no resources allocated to meet the needs identified in plans for health, and healthcare costs continued to increase at rates higher than the overall inflation. During the early 1970s, the hospital industry initiated the voluntary effort, or VE, to contain costs, but that effort failed.

Establishment and Role of HSAs

These historical factors set the stage for the passage of PL 93-641, the Health Planning Act. Title XV of the Public Health Service Act established state health-planning and development agencies (SHPDAs), statewide health coordinating councils (SHCCCs), HSAs, and centers for health planning (CHPs), for technical assistance and research.

Under this legislation, states were required to establish CON programs or risk losing federal funds. Each state also defined the geographic boundaries of health service areas; HSAs were established to conduct health planning and implementation activities for each health service area by developing health systems plans (HSPs) and annual implementation plans (AIPs). The federal government, as part of this policy, issued national guidelines for health planning for use by SHPDAs and HSAs. In addition, HSAs reviewed the proposed uses of federal funds in their health service areas, as well as the appropriateness of existing services.

Like the “b” agencies, HSA boards required a consumer majority. The consumers on the boards had to be representative of the socioeconomic, linguistic, and racial characteristics of the health service area.

Title XVI of the Public Health Service Act called for an area health development fund, requesting \$1.00 per capita as seed money toward implementation. However, this federal funding was not appropriated during the history of the National Health Planning Act.

Current Status

Federal support for health planning ended in 1986, just 11 years after the National Health Planning Act was enacted. At the time, under the Reagan administration, leaders examined health-care cost containment strategies, debating the effectiveness of government regulation versus that of free-market competition. The blend of health planning with regulation through the CON program made the implementation of health plans by HSAs difficult and fueled opposition to the program by health providers.

While HSAs are no longer funded, health planning at the local level, in some form, continues without federal support in most states. This planning is accomplished through the assessment and health-planning activities conducted by local public health departments and their partners.

HEALTH WORKFORCE

Healthcare in the United States is delivered by a variety of providers. Some of these individuals hold licenses to practice within a discipline that is regulated by some state entity, while others are considered to be unlicensed support personnel. Collectively, those individuals who are healthcare professionals and those who work in healthcare facilities are referred to as the health workforce. The size and characteristics of the health workforce can be viewed from the perspective of both health professions and healthcare facilities. In 2006, 17.3 million individuals made up the health workforce, constituting 11.8% of the nation's total workforce, making it one of the largest employment sectors in the country.

The health workforce is diverse in terms of the educational preparation required for employment. Some jobs require only limited on-the-job training, some require college preparation at the associate and baccalaureate levels, others require postgraduate-level college preparation. Most professions that require licensure require at least a college degree at the associate degree level.

Health Professions and Occupations

The health professionals traditionally included in the health workforce are physicians, nurses, dentists, pharmacists, chiropractors, optometrists, podiatrists, physical therapists, occupational therapists, speech-language pathologists, and audiologists. Each of these professions requires practitioners to hold a license to practice. Some of the licenses are issued to cover practice in a single jurisdiction, usually a state; others may provide multistate licensure. Most require some form of national standardized pre-licensure examination.

The title "physician" is reserved for either doctors of allopathic medicine (MD) or doctors of osteopathy (DO). Both of these professions require formal postgraduate preparation beyond the baccalaureate degree and formalized professional practice or residency after licensure before independent practice is permitted. The area of practice selected will determine the number of years of residency training required.

Nurses represent the largest segment of the health professional workforce. Graduates of programs leading to the associate, baccalaureate, or entry master's degree may be eligible to take the licensing examination required to become registered nurses (RNs). Advanced education in nursing occurs at the master's and doctoral-degree levels. Advanced-practice licensure is available to nurse practitioners, nurse anesthetists, nurse midwives, and clinical nurse specialists in some states. Nurses holding advanced-practice licensure have an expanded scope of practice over that of RNs. The scope is defined in state statutes and through professional accreditation and certification bodies.

Dentists are educated primarily at the postbaccalaureate level, with 4 years of professional education leading to either the doctor of dental science (DDS) or the doctor of dental medicine (DMD) degree. The curricula for both degrees are essentially the same, preparing the practitioner to coordinate oral healthcare for patients. Both degrees are considered first professional degrees with postgraduate clinical specialization and advanced internships and fellowships available.

Pharmacists are trained to distribute drugs prescribed by physicians and other health practitioners and provide information to patients about medications and their use. The scope of practice for pharmacists is established at the state level and has been expanded in some states to include prescriptive authority and administration of immunizations. Education for pharmacy, once at the 5-year baccalaureate level, has moved to the 6-year doctoral level based on a 1989 decision by the American Council of Pharmaceutical Education (ACPE). As in medicine, the doctoral degree in pharmacy (PharmD) is an entry-into-practice degree. An internship is also generally required. Pharmacists holding licensure prior to the change in educational requirements remain eligible to practice within their discipline unless state law precludes it. Some, however, see the former baccalaureate-level-prepared pharmacists forced to return to school to remain competitive in the workforce.

Chiropractors, podiatrists, and optometrists are also educated with doctoral degrees that are considered first professional degrees. Doctors of chiropractic (DC) practice a drug-free, hands-on approach to healthcare that includes patient examination, diagnosis, and treatment. While the

baccalaureate degree is not a requirement for admission to schools of chiropractic medicine, the professional education is usually 4 years, with extensive clinical practice. Doctors of podiatric medicine (DPM) focus on care and management of conditions of the foot and ankle. Like the chiropractor, the podiatrist is educated in a 4-year first professional degree program, with extensive clinical work accompanying the education. Podiatrists may choose to complete additional postgraduate training in order to expand their medical and surgical skills. Doctors of optometry (OD) also engage in 4 years of professional education to receive the degree. Although many of the schools offering optometry do not require the baccalaureate degree as a condition of admission, it is important to know the regulation of the state licensing boards with practice jurisdiction. In some states, licensure is contingent on completion of not only the first professional degree but also the foundation education.

Physical therapists provide services that help restore function, improve mobility, relieve pain, and prevent or limit permanent physical disabilities of patients suffering from injuries or disease. They restore, maintain, and promote overall fitness and health. Physical therapy education has moved from the baccalaureate level to the graduate level in the past 15 years, with the last baccalaureate-level physical therapists graduating before 2002. Just as in 1999, when the decision was made to move physical therapy education to the graduate level, the professional association is now considering establishing the entry physical therapy degree as the professional doctorate. As of January 2007, 167 of the 210 programs offering physical therapy preparation were at the doctor of physical therapy level. This number has grown from 67 offering the practice doctorate in 2002.

Occupational therapists help people improve their ability to perform tasks in their daily living and working environments. They work with individuals who have conditions that are mentally, physically, developmentally, or emotionally disabling. They also help them develop, recover, or maintain daily living and work skills. As in physical therapy, occupational therapy education has moved from the baccalaureate level to a required graduate degree, with the last programs converting in 2005.

Speech-language pathologists, sometimes called speech therapists, assess, diagnose, treat, and help prevent speech, language, cognitive-communication, voice, swallowing, fluency, and other related disorders. They work with people who cannot produce speech sounds, or cannot produce them clearly; those with speech rhythm and fluency problems, such as stuttering; people with voice disorders, such as inappropriate pitch or harsh voice; those with problems understanding and producing language; those who wish to improve their communication skills by modifying an accent; and those with cognitive-communication impairments, such as attention, memory, and problem-solving disorders. They also work with people who have swallowing difficulties. In 2005, 47 states required speech-language pathologists to be licensed if they worked in a healthcare setting, and all states required a master's degree or equivalent.

Audiologists assist people who have hearing, balance, and related ear problems. They examine individuals of all ages and identify those with the symptoms of hearing loss and other auditory, balance, and related sensory and neural problems. They then assess the nature and extent of the problems and help the individuals manage them. The educational preparation for audiologists has moved from the master's degree to the clinical doctoral degree, and it is expected to become the new standard for licensure in the 49 states where audiology practice is regulated. Several states are currently in the process of changing their regulations to require the doctor of audiology (AuD) degree or its equivalent.

Allied Health Professions

Several fields constitute the allied health disciplines or professions. The types of occupations included under the allied health umbrella vary, but often include, dental hygienists, respiratory therapists, physician assistants, radiologic- and nuclear-medicine technologists and technicians, ultrasonographers, medical- and clinical-laboratory technicians and technologists, medical-records and health information technologists, medical-office assistants, emergency medical technicians and paramedics, and licensed practical nurses.

Dental hygienists remove soft and hard deposits from teeth, teach patients how to practice good oral

hygiene, and provide other preventive dental care. Although most education preparing dental hygienists is at the associate-degree level, some programs award certificates, associate degrees, and even master's degrees. Licensure is required to practice dental hygiene, and a dentist must supervise that practice.

Respiratory therapists evaluate, treat, and care for patients with breathing or other cardiopulmonary disorders. Practicing under the direction of a physician, respiratory therapists assume primary responsibility for all respiratory-care therapeutic treatments and diagnostic procedures. Most of this practice occurs in the hospital setting. Respiratory therapists complete at least an associate degree; however, most are required to hold a baccalaureate degree for practice as therapists.

Physician assistants (PA) emerged as a distinct health profession in the 1970s. As the name implies, these professionals work with physicians across all specialty areas and practice settings. PAs are formally trained to provide diagnostic, therapeutic, and preventive healthcare services, as delegated by a physician. Educational preparation for the role varies, but the professional training is usually at least 26 months in length.

Radiologic technologists and technicians take X rays and administer nonradioactive materials into patients' bloodstreams for diagnostic purposes. Some specialize in diagnostic imaging technologies, such as computerized tomography (CT) and magnetic resonance imaging (MRI). Graduation from an accredited program is generally required for licensure, although the length of education varies from certificate to degree.

Nuclear-medicine technologists administer radiopharmaceuticals to patients and then monitor the characteristics and functions of tissues or organs in which the drugs localize. Education for this field varies from 1 to 4 years, with preparation at the certificate, associate-degree, or baccalaureate-degree level. About 70% of the jobs in this field are in hospitals.

Diagnostic medical sonographers, also known as ultrasonographers, use special equipment to direct nonionizing, high-frequency sound waves into areas of the patient's body. Sonographers operate the equipment, which collects reflected echoes and forms an image that may be videotaped, transmitted, or photographed for interpretation and diagnosis by a physician. Training for this field is similar

in length to that required for radiologic-medicine technologists and nuclear-medicine technologists, although beginning in 2005, at least an associate degree was required to be registered. Unlike most of the other professions described, a license to practice is currently not required. More than 50% of those employed in the field work in hospitals.

Medical- and clinical-laboratory technologists and technicians perform complex chemical, biological, hematological, immunologic, microscopic, and bacteriological tests. The usual requirement for an entry-level position as a clinical-laboratory technologist is a bachelor's degree with a major in medical technology or in one of the life sciences. Registration and licensure are required in some but not all states.

Medical records and health information management professionals are responsible for the data storage, archiving, and retrieval of health information. Education for this occupation occurs at both the associate- and the baccalaureate-degree levels. As attention has been directed to the privacy concerns relating to electronic medical records and the federal Health Insurance Portability and Accountability Act (HIPAA), the complexity of health information management has increased.

Medical-office assistants perform administrative and clinical tasks to keep the offices of physicians, podiatrists, chiropractors, and other health practitioners running smoothly. The job responsibilities vary vastly based on the setting. Formal education, if required, is usually at the vocational and technical levels, requiring 1 to 2 years of training.

The specific responsibilities of emergency medical technicians (EMTs) and paramedics depend on their level of qualification and training. These health professionals provide field emergency assistance in incidents such as automobile accidents, heart attacks, drowning, childbirth, gunshot wounds, and disaster management, where immediate medical attention is required. EMTs have additional advanced training to perform more difficult prehospital medical procedures. Completion of a specialized training and certification process is required, and most states require that EMTs and paramedics get recertified every 2 years.

Licensed practical nurses (LPNs), or licensed vocational nurses (LVNs), care for the sick, injured, convalescent, and disabled under the direction of physicians and RNs. Although LPNs and LVNs

work under supervision, licensure is required in all 50 states and the District of Columbia. To obtain a license, an individual must graduate from an approved program and pass a standardized test (NCLEX-PN). Most educational programs are 1 to 2 years in length, some leading to a certificate of completion or diploma, and others leading to an associate degree.

Other Personnel

There are a variety of other support personnel included in the estimated 4.5 million individuals who are classified as part of the healthcare workforce because they work in healthcare settings. The list of categories of personnel classified as other support changes as new fields in healthcare are developed, new ways of delivering healthcare are created, and workforce specialization continues to develop. These other individuals include patient services support staff, such as nursing assistants, orderlies, and technicians; non-patient-care services, such as food services and janitorial/cleaning personnel; and administrative staff.

Healthcare Settings

Just as there is great variety and diversity in the healthcare professions and occupations, there also is great variety in the places where healthcare workers are employed. Although hospitals, including acute-care, psychiatric, and specialty facilities, employ the largest segment of the health workforce, there are other types of healthcare settings. These other types of facilities include nursing and personal-care facilities; home health care organizations, offices, and clinics; and medical and dental laboratories. More than 13 million members of the health workforce, or 8.9% of the overall workforce, work in designated healthcare facilities.

Hospitals collectively account for 41% of the total health workforce employed in healthcare settings in the nation. The second largest segment of employment is in nursing and personal-care facilities, where an additional 21% are employed. Offices of physicians, dentists, and other health professionals combined employ approximately 26%, with the remainder spread between ambulatory-care facilities, laboratories, and home health care.

The size of the health workforce in hospitals is one of the major reasons why attention is directed toward issues identified as effecting hospital care delivery. For example, as the largest employer of nurses, the reported vacancy rates and the length of time required to fill RN positions have driven workforce development initiatives to improve the supply of nurses. Strategies to increase the number of RNs as direct-care providers, including the use of patient simulation, have significantly influenced the education of nursing students.

There is significant regional variation in which type of healthcare entities employ the health workforce. For example, ambulatory-care settings, including offices, clinics, and similar facilities, employ significantly more of the health workforce in the western states and Florida, while hospitals are even larger employers in the northwest mountain states.

Other Employment Settings

The health workforce also comprises more than 4 million health professionals who work in settings that are not traditionally counted as healthcare facilities. Almost all health professionals working in these alternative settings hold professional degrees. In most cases, they also have licenses to practice within their discipline. Some of these settings include consulting firms, educational settings, insurance companies, pharmaceutical and equipment sales, and law firms. Some health professionals work in other settings where their educational preparation is not related to their role. As shortages in many professions grow, more attention is being directed to reengaging some of these workers in health services settings.

HEALTHY PEOPLE 2010

Healthy People 2010 is the latest in a once-per-decade series of reports produced by the federal government to chart the state of America's health. The principal purpose and long-standing theme of *Healthy People* is to promote health and prevent illness, disability, and premature death. The extensive report is composed of 467 health objectives organized into 28 focus areas under 2 overarching goals: (1) increase quality and years of healthy life and (2) eliminate health disparities. While very comprehensive and seemingly daunting in scope, *Healthy People 2010* is intended to be used by a variety of public health, professional, and community audiences and is formatted into three parts, each providing a different focus and level of content detail. Available as a document, *Healthy People* is most accessible in an electronic format on the Internet.

Purpose

In its 25-plus-year history, *Healthy People* has served several interrelated purposes. First, it is a strategic plan for improving health presented

through a comprehensive array of related health objectives that set measurable targets for health improvement efforts by all levels of government as well as the private sector and community healthcare agencies. Most states and many localities, along with nongovernmental agencies, have adopted the Healthy People objectives in their own plans and programs or have used these objectives as the underlying rationale for their efforts.

Second, it is a compendium of summary health statistics on the leading causes of death, illness, and disability arrayed by race/ethnicity, age, and socioeconomic status, and for multiple time periods. *Healthy People* is one of the most frequently referenced data sources by health services researchers, policy analysts, planners, and health administrators in presenting baseline information on various health conditions.

Third, *Healthy People* establishes a framework for understanding the determinants of health placed within a broad systems context that recognizes that health is more than the presence or absence of medical care. The health of individuals and communities is determined by a variety of factors, including individual biology and behavior, the physical and social environment, broader policies and interventions that improve community health, along with access to quality healthcare services. *Healthy People* and this framework have been widely included in public health textbooks, graduate-level courses, and professional-education programs.

Fourth, *Healthy People* is a report card that can be used to gauge progress and establish performance standards and accountability for the vast American healthcare enterprise of public health and health services delivery. Its cradle-to-grave approach reports the state of the nation's health from infant mortality to the chronic conditions and causes of death most often associated with old age. At least two national reports issued by the federal government, one for 1990–2000 and the other after the year 2000, reported on progress of the nation in meeting the Healthy People objectives. Both reports scored the nation's efforts, noting both progress and deficiencies, and used the results to exhort policymakers in the public-health and medical-care arenas toward greater action. Myriad other reports have graded the effectiveness

of state, local, and private-sector efforts against Healthy People targets.

Finally, Healthy People establishes, as national policy, efforts that improve population health by increasing quality and years of healthy life and eliminating health disparities, the two goals of *Healthy People 2010*. Indeed, Healthy People is as close as the United States has ever come to a national policy on health.

Origins

The original, *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention*, was released by U.S. Surgeon General Julius Richmond in 1979 to focus the nation on health promotion and illness prevention at a time when the federal government was increasingly concerned about the decade-long unabated rise in national healthcare spending. As the vast bulk of this spending was on medical care to treat illness and disability, it was believed that a greater emphasis on promoting health and preventing illness might slow the growth in healthcare costs. At the time, the United States was experimenting with national health planning as a way to better coordinate a fragmented and pluralistic healthcare system, which is composed of thousands of independent private and public healthcare providers, each determining individually what services would be provided to which populations or market areas. Unlike other industrialized countries, market forces are the primary organizing mechanism, with government, mainly involved at the state and local levels, playing little role beyond minimal regulation of quality, life safety, or professional standards. National health planning introduced a mechanism for coordinating health services at the local level, with strong guidance of these efforts from the states and by the federal government. National objectives for the availability of medical-care services had been set, and the state and local health-planning agencies were charged with using these standards to plan more effective and less expensive state and local healthcare systems.

Healthy People was an extension of these efforts, moving beyond goals for access to healthcare services to goals for reducing the illnesses and

health conditions underlying the need for these services. Taking a life-stage approach, *Healthy People 1979* set 15 specific goals and subgoals for reducing morbidity and mortality in five stages of life—infancy, childhood, adolescents/young adults, adults, and, finally, older adults. In addition to these specific targets, another 15 recommendations were offered, organized around preventive health services, health protection, and health promotion.

A National Health Improvement Plan

The 1979 Surgeon General's Report was more an agenda and a statement of national health policy than an implementable plan. And in 1980, a companion piece—*Promoting Health/Preventing Disease: Objectives for the Nation*—set forth 226 specific, measurable health objectives in a plan of action for reaching the Healthy People goals. These objectives, referred to as “the 1990 health objectives,” called for improvements in health status, risk reduction, public and professional awareness, health services and protective measures, along with surveillance and evaluation.

Development of the 1980 report involved consultations with and comments from more than 500 individuals and organizations from the private and governmental sectors. This highly participative development process was followed in the two subsequent versions of *Healthy People*, which involved as many groups as possible in the early stages, including comments from the public. This participatory process was formalized into the Healthy People Consortium as the organizational vehicle for the development of *Healthy People 2000* and the 2010 report.

Achievement of the 1990 Healthy People objectives was mixed, with success in areas such as hypertension, childhood infectious diseases, and injury prevention. Progress toward other objectives was slower, and new health challenges emerged. It was clear by middecade that an updated *Healthy People* for the year 2000 would be needed. This version expanded the scope of the effort to 339 objectives organized into 21 priority areas, including new areas such as cancer and HIV infection. The emphasis on prevention was increased, with inclusion of more screening to detect diseases before symptoms appeared. Specific

attention was also given to improving the health status of population groups demonstrating higher risk for a particular disease or condition. Feasibility of achievement was more explicitly taken into account in setting objective targets to make the objectives for the year 2000 more realistic, and a workbook was developed to facilitate implementation of the objectives at the state and local levels.

HOME HEALTH CARE

Home health care usually consists of formal, skilled healthcare provided by licensed professionals in a patient's home on the advice of a physician. Originally applicable to only posthospitalization patients, it now encompasses care for people of all ages at risk for institutionalization. The aim of home care is to enable the sick and the disabled to live independently with dignity in the comfort of their homes during recovery and rehabilitation, close to the support of family and friends. Home care is generally used for patients who have been discharged from the hospital and need skilled care and rehabilitation, older adults with functional limitations, children with special needs, people with severe physical or mental disabilities, veterans, and people with HIV/AIDS.

History

Home health care provided by non-family members emerged as an option in the United States during the early 20th century. Efforts to reduce costs and improve conditions for the acutely ill and newborn babies and their mothers were spearheaded by the Metropolitan Life Insurance Company in 1909. The Voluntary Nurses Association (VNA), now in existence for more than a century, provided home care to the sick. When a shortage of physicians stimulated the expansion of home-based nursing services during World War II, home care was transformed to its present form. The federal government became involved in home care following the Kerr-Mills recommendations to give aid to medically needy Americans 65 years of age or older; benefits were extended in 1965 to include disabled and dependent children. The 1988 *Duggan v. Bowen* court case expanded coverage criteria for home health

benefits. And a U.S. Supreme Court ruling in the 1999 *Olmstead v. LC* case, which determined that institutionalization should be the last resort for people with mental disabilities, has also increased the demand for home health care.

Types of Services Provided

Home health care covers a broad spectrum of diagnostic, therapeutic, and social support services. The medical component of home health care is advised by a physician and is usually administered by a physician assistant or nurse practitioner. It includes the professional services of a physician, nurse, dentist, podiatrist, rehabilitation specialist, psychologist, dietitian, optometrist, and social worker at home. In terms of Medicare, a single episode of home health care cannot exceed more than 60 days. While the number of subsequent episodes is unlimited, each has to be certified by the caring physician as required for reimbursement purposes. Skilled care in nursing, speech therapy, and physical/occupational therapy are provided by trained medical professional staff, who administer, monitor, and evaluate healthcare. Other services include medical-social services and assistance from a home health aide (reimbursable only when recommended for people receiving skilled care). The duties of the home health staff are to follow the physician's orders, adhere to prescribed routines, monitor general health and medications, teach informal caregivers and patients themselves to ensure continuity of care, and arrange all aspects of prescribed care. It is the responsibility of Medicare-certified agencies to keep the attending physician up-to-date on the patient's condition and requirements; other agencies are exempt from this requirement.

The services provided by home health care agencies can be broadly classified into five groups: (1) medical/skilled nursing, (2) equipment and/or medications, (3) personal-care services, (4) therapeutic services, and (5) psychosocial services. In 2004, about 75% of Medicare home health care patients received skilled nursing care, while less than 2.5% received physician care. Total personal care, composed of continuous home care, a companion, homemaker/household (including

meals-on-wheels) services, transportation, and respite care, is received by nearly 45%. Therapeutic-care services, in the form of dietary and nutritional services; physical, occupational, respiratory, or speech therapy; and other high-tech care, is received by nearly 37% of home health care patients. Nearly 13% were recipients of durable medical equipment (DME) and medications, and psychosocial services, consisting of counseling and psychological, social, or spiritual care, were provided to about 12% of total home care patients.

High-tech home health care is a growing component, constituting nearly 25% of total home care spending. It has allowed early discharge of seriously ill patients who need intermittent or continuous skilled nursing care, with hospices providing the bulk of care. Close coordination between physicians, nurses, pharmacists, equipment suppliers/technicians, home health care agencies, and family members provides 24-hour care and monitoring of patients, devices, and drugs. Perceived as more cost-effective than hospitalization, more health insurance companies and employer-based benefit plans have made high-tech home health care reimbursable.

Home Health Care Agencies

The federal Balance Budget Act of 1997 significantly curtailed Medicare reimbursements of home health care agencies, resulting in the closure of nearly one third of the nation's agencies, particularly in underserved and rural areas. Medicare's hospital prospective payment system (PPS), which was implemented in 1983, caused a shift of service provision away from VNAs and local health departments to the hospital and insurance sectors, which formed their own agencies and links to streamline posthospitalization care.

National statistics from 2004 show that 8,100 Medicare-certified home health care agencies provided care to nearly 2.4 million disabled and elderly people. The majority (57%) of these agencies were voluntary nonprofit organizations, 34% were for-profits, and the rest were government owned. About two thirds of them have affiliations with hospitals, corporations, or health maintenance organizations (HMOs). A disparate number

of agencies exist in rural areas, where just 21% of home health care agencies are located. In urban areas, the average length of service was 312 days, with a median of 76 days, while rates in rural areas were about 1.5 times higher. The maximum length of service was reported by for-profit agencies, with the shortest service by voluntary nonprofit agencies. Median lengths of service provided to those older or younger than 65 years of age were similar, though the average duration of care for women was 1.25 times longer than for men.

Staffs of home health care agencies are primarily composed of professional and vocational nurses (45%) and home health aides (39%), with the remainder consisting of physical, occupational, and speech therapists, and social workers.

Accreditation and Licensure

Accreditation is a voluntary process in which home health care agencies seek a "stamp of approval" from respected nonprofit organizations certifying that the agency meets national standards of care. Licensure and certification are issued by a government agency (federal or state) and are usually necessary to seek reimbursements for home health care. Licensure and certification requirements may vary by state. Often, licensure regulations are minimal and may not require an on-site survey. Different standards apply to agencies certified by Medicare and private agencies, with Medicare having more stringent standards requiring a larger investment.

Profile of Patients and Demand

The majority of individuals receiving home health care are elderly. At least 2 million individuals in the nation, half of whom are 65 years of age or older, are permanently homebound; millions more are temporarily homebound with illness or injury; and they all need home health care of some kind, whether intermittent, part-time or continuous, skilled or unskilled. The great increase in the aging and disabled populations due to increased longevity as a result of advances in medicine and technology will continue to fuel a demand for home health care in the years to come. According to the 2000 U.S. Census of Population, nearly two

thirds of the 1.3 million individuals receiving home health care were females. Detailed data from 2004 show that more than 1 million individuals receiving home health care were White, compared with 200,000 who were Black, Asian, Pacific Islander, or other racial group combined. Marital status influences the services used for home health care. Widowed individuals accounted for 35% of patients seeking the maximum Medicare benefit, while married people represented 32%. Only 18% of those who were single or never married were provided services, and the rest have unknown marital status. About two thirds of the individuals receiving home health care live with family members, less than a third live alone, while the remaining live with nonfamily members or have unknown living arrangements. More than 80% have a primary caregiver, typically a spouse or child/child-in-law. About 10% rely on paid help, and the remaining 5% rely on friends and neighbors or others.

Patients' Rights

Individuals who use home health care services from accredited Medicare and other agencies have certain patients' rights. They have a right to choose their own recognized agency, be treated with respect, appoint family or guardians to act on their behalf, receive a copy of their planned care itinerary, complain about inefficient services, and expect continuity of care. Home health care agencies are responsible for ensuring competency and continuity of care.

Costs, Funding, and Eligibility

The total national costs for home health care were nearly \$40 billion in 2000. Of the total costs, \$30 billion was spent on providing skilled and unskilled care, while the remaining \$10 billion accounted for expenditures on home respiratory (\$3.5 billion) or infusion therapy (\$4.5 billion) and DME. The total national costs of home health care are projected to be nearly \$60 billion by 2010.

Payments for home health care are covered by a variety of providers. The government pays for more than half the total national home health care costs. Medicare accounts for nearly 30% of

payments, while private insurance pays about 25%, and Medicaid and out-of-pocket payments each account for about 20%.

Medicare regulations require that a licensed physician, who also certifies the need for intermittent skilled-nursing and/or rehabilitation care, declare enrollees "homebound." Being homebound implies that leaving home requires a considerable effort; is usually performed only with supportive devices, special transportation, or another person; and occurs infrequently. To be eligible for Medicaid coverage, the individual must meet financial eligibility criteria and other parameters that differ significantly from state to state. Provision of long-term care services is mandatory in all states for individuals who are Medicaid eligible and qualify for institutional care. Similar criteria are in place for most private and public agencies that pay for home health care. Government insurance programs severely restrict the extent of home health care services, treating them as a complement to family care. Seeking reimbursable home care is generally a cumbersome, long-winded process.

Problems in Home Health Care

Home health care agencies are governed by their own rules and regulations. Personnel are usually available only on weekdays between 9 a.m. and 5 p.m., and there is no assurance that the same individuals offer treatment, to build patient confidence and ensure continuity of care. Rescheduling is not uncommon, which may disrupt family routines and clash with the schedule of other caregivers. Retention and lack of qualified staff, particularly nurses who provide the bulk of services, in this sector is a frequent problem. Delays in payment from government agencies are the norm, making it difficult for agencies to meet financial deadlines. Meeting the regulatory guidelines of Medicare and Medicaid, which are major suppliers of home health care, involves extensive paperwork and multiple billings. Quality assurance and accountability of noncertified agencies is nonexistent. Access to home health care agencies may be difficult, particularly outside urban areas. Medicaid recipients must often "spend down" to meet eligibility criteria. Disparities exist, with the uninsured and poor consuming fewer services. Overall, home

health care is labor intensive, and the out-of-pocket costs may not be sustainable for long even among the relatively affluent population.

Future Implications

Home health care is likely to increase in the future as people increasingly live longer but do not retain the ability to lead independent lives due to infirmities of normal aging coupled with disabilities due to chronic diseases. In an era where families are smaller, more nuclear, and living further apart, traditional family caregivers are becoming scarce. Currently, state and private agency support is inadequate to provide sustenance to all the needs of chronically disabled individuals. Home health care is an attractive alternative to institutionalization as it promotes independence, provides better quality of life, and is more cost-effective than prolonged hospitalization. Though Medicare and Medicaid strive to meet these needs, more must be done, such as health services researchers focusing on this aspect of providing equitable long-term healthcare.

HOSPICE

Hospice is a philosophy as much as it is a concept. It is a fundamental belief in a peaceful and rational end of life directed by the person and not by healthcare or payment systems, or laws. Hospice, as a concept, is the treatment for pain and suffering, with the recognition and acceptance that cure is not possible. Multidisciplinary teams, often including volunteers, join patients, their families, and friends in creating a peaceful end-of-life experience. Medicare and Medicaid benefits are now available for hospice care, making it a more viable choice for many. In 2007, the number of Medicare- or Medicaid-approved hospice facilities in the nation totaled 3,078. These facilities provided services to more than 1.3 million individuals and their families.

History

In ancient times, “hospitium” was a concept that dictated that travelers, passing through, were given hospitality, including clothing and entertainment in private homes. Hosts and travelers knew each other or were part of a family known to the host. More public hospitality, perhaps between two cities rather than families, was seen in ancient Roman times. During the Middle Ages across Europe, travelers might find hospitium in hospitia, buildings attached to monasteries. Hospitia came to serve travelers making holy pilgrimages and the sick. Essentially, the hospitia were guesthouses offering shelter, food, and comfort for the weary. As in the past, the modern-day hospice provides care and comfort to the weary traveler. Only today, the journey is to the end of life.

Modern-day hospice began in England during the mid-1960s, when Dame Cicely Saunders, a physician, established St. Christopher's Hospice in London. It was a facility characterized by light, gardens, small groupings of patients, and areas for families to gather. The care received in this environment translated the philosophy into modern practice. Florence S. Wald, the dean of the Yale School of Nursing, opened the first hospice in the United States in Connecticut in 1974.

Definition

The word *hospice* originates from the Latin *hospitium*, meaning a guesthouse. This origin perpetuates the confusion that hospice is always a unique and specific place. While there are facilities that are either partially or entirely used for hospice care, the place is not the most important component. The essential components of hospice as a philosophy are the unwavering commitment to relief of pain and suffering when a person is diagnosed with a life-limiting disease, an unyielding belief in the irreducible wholeness of personhood that addresses the meaning of life and death, the quality of life and death, an understanding of spirituality, and a steadfast dedication to the right to make choices and decisions about one's own care at the end of life.

Hospice is not about suicide, euthanasia, or absence of care; nor is it about the prolonging of life or the quickening of death. It is about providing comfort and palliative care at the end of life, when the treatment of a disease is no longer appropriate or possible. Palliative care is defined as the relief of pain, suffering, and stress caused by illness and disease. Services are directed at both the individual and the family. The individual is assured that relief of pain and suffering are paramount in all endeavors. The family is comforted by the attention to the relief of the pain and suffering and supported through the grieving process that accompanies a rational and dignified end of life.

Hospice Philosophy and Services

The overarching goal of hospice is to ensure comfort and dignity to the dying individual and the

family as a unit. As a philosophy of care, it can be implemented in a variety of settings. Individuals can receive hospice services in their own homes, a nursing home or other residential facility, a hospital, or a freestanding hospice facility. Most recipients obtain care in their own home or in nursing homes. The care team consists of family, physician, registered nurse, patient-care assistant, chaplain, social worker, psychologist, dietitian, volunteer, and bereavement counselors for the loved ones.

An individual's family or friends may refer the individual to a hospice, but a physician must document the diagnosis and life expectancy of the individual. Persons with less than 6 months to live are eligible for hospice benefits through Medicare, and Medicaid in 43 states. Many private health insurers also offer hospice coverage. Hospice recipients, with physician input, may receive more than 6 months of hospice services when they live beyond the original life expectancy.

In terms of national statistics (2006), the average length of service in a hospice is 59 days, and the median length of service is 21 days. Most recipients obtain care in their own homes (47%) or in nursing homes (22%). Most of those in hospice have a cancer diagnosis (44%), followed by heart disease (12%) and those with dementia (10%). Other medical conditions include, but are not limited to, lung, liver, or kidney disease, HIV/AIDS, stroke, or motor neuron diseases. The majority (81%) of hospice recipients are Caucasians, followed by African Americans (8%), and Asians, Hawaiians, or Pacific Islanders (2%). Most hospice recipients are 65 years of age or older (81%). Specifically, 65- to 74-year-olds account for 17% of the total admissions, 75- to 84-year-olds for 31%, and 85-year-olds and older for 33%.

Components of Hospice

Prior to a hospice admission, a meeting occurs with the individual, the physician, the hospice representative, and the family (as appropriate). In this meeting, discussions about the diagnosis, goals of care, and types of support occur. Specifically, hospice focuses on the physical, psychosocial, and spiritual needs of its recipients. Emphasis is placed on the relief of symptoms (pain, shortness of breath, and muscle spasm), thereby promoting

comfort for the individual. The individual, as long as possible, directs the care provided; and when no longer able to direct this care, his or her wishes are followed until death occurs.

If individuals move into a facility wherein hospice, as a philosophy of care, is practiced, they are encouraged to create a home environment with their own furniture, linen, photographs, and music. Individuals determine their visitors and visiting hours and use their own clothing, and family or friends are encouraged to prepare food, especially the patient's favorite foods. The goal of creating a hospice facility is to make the environment like an individual's home while providing the expert care needed to alleviate pain and suffering.

After death occurs, hospice provides loved ones with bereavement counseling. This has a variety of forms, from personal telephone calls to letters, support groups, and individual counseling, to annual services that honor all who have died in a specific hospice.

The Hospice Association of America (HAA), an affiliate of the National Association for Home Care and Hospice (NAHC), developed a *Hospice Patient's Bill of Rights* that is based on dignity and respect for all recipients; the ability to make decisions regarding care, privacy, and confidentiality; knowledge of financial charges and payments; and the right to the highest quality of care. These rights are embraced widely by the nation's hospices.

Advanced Directives

As the hospice philosophy and practices gained acceptance, there emerged a need to have a resource to guide the family and caregivers when individuals were no longer able to speak for themselves or to make decisions. Thus, advanced directives were created. By definition, an advanced directive is a statement of what healthcare an individual wishes to receive or not receive when that person no longer possesses the capacity to make a healthcare decision and/or is not able personally to address the issue. In 1990, the U.S. Congress passed legislation that created the Patient Self Determination Act. This act mandates that healthcare providers and healthcare agencies ensure that patients have information and education about advanced directives. Furthermore, any agency that accepts federal funds (i.e., Medicare

and Medicaid) for care provided must abide by an individual's advanced directive. All 50 states recognize the legality of advanced directives. However, each state uses its own version, but all are essentially the same.

An advance directive is created before the need arises. A living will and a durable power of attorney (for healthcare, as separate from all other arenas) are two major components. Individuals create living wills to address the type and amount of healthcare to be provided at the end of life and/or when they cannot communicate their wishes, such as in a healthcare emergency. A durable power of attorney is another document that identifies the person who the patient authorizes to make decisions when he or she is unable, for example, to execute the terms of the living will. Each state has specific regulations and laws as to what a durable power of attorney can and cannot authorize with regard to an individual's healthcare, but the key is that a specific person is designated by the individual in advance of the need. The individual makes the decision to appoint the said individual freely and without any type of coercion. The person so designated speaks on the individual's behalf when he or she is no longer able to, advocates the plans the individual made and documented in the living will, and is the decision maker when healthcare consent is required.

While advanced directives are legal documents, there is no requirement that attorneys create them. There are no specific forms or formats required, although forms are readily available. An adult-age individual with decision-making capacity may create and/or change a living will at any time and designate a person who will have durable power of attorney in healthcare matters. In most states, the advance directives need to be witnessed by two parties. The signatures affirm that the person signing the living will is indeed whoever it states it is, that this person is of sound mind at the time of the signature, and that the documents are signed freely. Both the living will and the durable power of attorney documents should be shared with the individual's loved ones and healthcare providers so that they are available when the need arises.

Advance directives are the legal system's way of assisting an individual in determining the quality of life at the end of life. Like hospice, advance directives neither prolong life nor hasten death.

They provide healthcare providers with the treatment wishes of individuals at the end of life.

Future of Hospice

In an era of growing consumerism in the United States, individuals are increasingly educated about their bodies and their medical conditions. Most individuals want to be fully informed and actively involved in decisions about and for them. To many, quality of care is as important, if not more important, than the quantity of care. At the same time, pain and suffering are unacceptable, and all efforts must be made to alleviate them. Additionally, death and conversations about death and dying often are feared and delayed. Discussions typically occur only when faced with major decisions and in a highly emotional context.

Hospice as a philosophy encourages quality of life at the end of life. It promotes neither artificial prolongation of life nor artificial hastening of death. Hospice is about determination and choice, quality of life and not quantity, advocacy for self and others, relief of pain and suffering at the direction of the individual, and a rational and peaceful end to life as we currently know it.

HOSPITAL CLOSURES

As the nation's healthcare system continues to evolve, the role and need for hospitals is changing. Sophisticated patient care technology is no longer the exclusive domain of hospitals. Some of the most advanced breakthrough technology does not require traditional healthcare settings. The pharmaceutical sector has grown, basing its economic justification on the ability to prevent hospital care. Physicians and a variety of commercial ventures have become competitors for the business of healthcare that once routinely went to hospitals. As a result of these changes, many hospitals may be at risk of closing in the future. Therefore, it is important for health services researchers to assess both the factors associated with hospital closures and the effect that those closures have on the community a hospital serves.

There have been several evaluations of the determinants associated with hospital closings. There is also some literature concerning the impact of hospital closings on other available institutional services, as well as the economic impact of hospital closings on the community. However, there is very little literature evaluating the specific health impacts of hospital closings on the populations remaining in their former service areas.

This entry begins by presenting recent hospital trends and defining hospital closure. Then, it discusses the roles of hospitals and the causes and implications of hospital closures.

National Hospital Trends

The number of community hospitals in the nation and their beds has steadily declined since 1975. In

1975, there were nearly 5,900 community hospitals with nearly 950,000 beds. In 2005, however, there were fewer than 5,000 community hospitals (a 15% drop) with about 800,000 beds (a 16% drop). Yet the number of patients admitted to the nation's community hospitals during this time period increased from 33.4 million in 1975 to 35.2 million in 2005 (a 5% increase). Despite the increase in the number of patients admitted during this same time period, there was a dramatic decline in the average length of inpatient hospital stays. In 1975, community hospitals accounted for more than 250 million inpatient days of care. In contrast, in 2005, the number had declined to fewer than 200 million days of care (a 25% drop).

At the national level, changes in technology and economics have altered the demand for inpatient hospital care, and hospital closings have not been as rapid as the changes in the marketplace. The resulting occupancy rate of community hospitals in the nation declined from an average of 75% in 1975 to 67.3% in 2005. While this brief view of national statistics would seem to alleviate concern that hospital closures are a troublesome phenomenon, the issue is, in reality, more complex. Local variations, in several metropolitan areas, have demonstrated the impact of hospital bed reductions on increasing bypass hours to trauma centers, loss of emergency service capacity, and the spreading instability of charity care that moves from closed hospitals to remaining neighboring hospitals.

Defining Hospital Closure

Hospital closure can be defined in two ways. It can be defined as the decommissioning of a physical facility that has routinely provided inpatient health services for a community. Such a hospital is simply no longer there. Hospital closure can also be defined as the elimination of all available beds in a facility that have been designated for the type of care the facility has routinely provided. Such a hospital building may still remain standing, but the services it provided no longer exist. For example, a community hospital may be replaced by a skilled-nursing facility or a behavioral-health facility. In either case, the elimination of hospital beds serving the original purpose has taken place. The

effect of each type of hospital closing is not entirely the same, and to understand the significance of the closure, one must recognize the various roles and the impact of a hospital on its community.

Hospital Roles

The effects of closures are best understood in relation to the hospital's role in the community. When a hospital closes, the community served by that hospital loses both a valuable community resource as well as an access point to the healthcare delivery system.

One important role of a hospital in the community is to serve as a point of access to healthcare. Hospitals vary significantly with respect to the specific types of care they provide. Thus, a community hospital may provide access to care ranging from acute emergency care to tertiary-level specialty care. Consequently, when a hospital closes, access to each type of care rendered by the facility no longer exists for that community. The community must therefore rely on accessing these needed services via another local hospital (if one is accessible), which may or may not provide an equitable level of access.

As a community resource, a hospital is also often an important source of employment for a community. In many communities, the hospital is the single largest employer. Consequently, the hospital plays an important role in the local economy by injecting money into the community. For example, a study of hospital closures in rural communities between 1990 and 2000 indicated that in communities for which there were no alternative hospitals, the closing of a hospital resulted in a 1.6% increase in the unemployment rate and a 4% decrease in per capita income.

Often, hospitals actively sponsor community outreach programs that, in effect, contribute to the overall wellness of the community. Such outreach initiatives may include health education, mobile prevention units, ambulance services, health fairs, screenings, and first-aid training sessions. A hospital closure, therefore, means the elimination of these community outreach services, which can be a significant loss to communities that depend on such services. Some hospitals, such as government or not-for-profit organizations, may have fiscal

obligations that lead them to provide charitable care for uninsured residents of their community. Such organizations often provide large amounts of uncompensated care for a community and draw additional funds from the state or federal government to pay for the cost of that care.

An often overlooked role of the hospital is that of player in the healthcare market affiliated with the community. Often, communities are served by more than one hospital, and the relationship between these facilities in terms of services rendered, payer mix, market share, and so on is extremely important to the viability of each facility. When a hospital closes, the healthcare market changes, and this change affects the business of other hospitals in the market. A study of the effect of rural hospital closures on neighboring hospitals examined this issue. It concluded that a rural hospital closure resulted in a statistically significant increase in patient volume for neighboring hospitals. However, this volume increase did not translate to predicted improvements in the profitability of the neighboring hospitals. Other studies of urban hospital closures have found that when a hospital closes, uninsured patients disproportionately shift to the nearest hospitals, endangering their survival.

Finally, hospitals are crystallizing forces, bringing healthcare resources into a community and focusing the activity of professionals on the needs of the community. When the hospital closes, the attention of those professionals dissipates, and the community residents lose their services.

Reasons for Hospital Closures

Most hospital closures are associated with circumstances in which a facility is no longer able to meet its financial obligations. However, it must be noted that not all financially stressed hospitals close. Studies have identified a number of other factors associated with hospital closures.

In assessing the research on factors associated with hospital closures, several recurring themes appear. One study of hospital closures in New York indicated that facilities that closed had significantly fewer hospital beds and lower occupancy rates than those facilities that remained open. This study asserted that small, low-occupancy hospitals tend to close because they

lack the diversity in services and the overall strategic planning resources necessary to survive an evolving market and because there is often less community opposition to closing these facilities than to closing larger hospitals. This study also indicated that the racial composition of a hospital's community was an important factor in assessing the potential for a hospital to close, especially for a voluntary hospital. Hospital closure rates were shown to increase significantly for communities with higher percentages of African American residents.

A study of urban hospital closures between 1980 and 1987 concluded that hospitals that invested in technology that will allow them to offer a variety of services either as a standalone facility or as a part of a multihospital system are less likely to experience closure. On the other hand, the study also concluded that hospitals located in communities with higher percentages of African American residents were significantly more likely to experience closure.

Other studies have examined the determinants of hospital closure as they related to mergers and acquisitions, and the effects of Medicare's prospective payment system (PPS). One study indicated that strategic and institutional variables such as diversification, occupancy rate, and for-profit status were critical determinants of hospital viability. The study also concluded that environmental factors such as per capita income, physician-to-population ratio, and hospital-bed-to-population ratio may also influence hospital viability.

Future Implications

While hospital closures have occurred as a result of changing technology and the economics of healthcare, the impact of the closures has not been studied in the context of the nonroutine roles that hospitals fulfill in their communities. At the national level, hospital closures seem to be consistent with changes in demand for hospital services, yet there are significant local anomalies that have resulted in displacements of vital emergency services and access to service for uninsured patients. More research is needed to address these and other issues.

HOSPITAL EMERGENCY DEPARTMENTS

The nation's hospital emergency departments (EDs) provide critical care to those in need, day

and night, regardless of an individual's ability to pay for the care he or she receives. However, EDs are experiencing many problems, and they are said to be at breaking point. ED patient volumes are on the rise, and they are increasingly being used to evaluate and treat nonemergent conditions. This has led to EDs that are increasingly overcrowded and overwhelmed, often resulting in poor patient outcomes and struggles for sustainability. The challenges faced by hospital EDs need to be addressed as they are an essential means of healthcare delivery for many and an integral part of the nation's healthcare system.

Background

Hospital EDs, often colloquially referred to as emergency rooms (ERs), developed over the 20th century in response to the need to rapidly assess, stabilize, and treat critically ill patients. Recent data show that 10% of all ambulatory-medical-care visits now occur in EDs. Many patients are evaluated in EDs and discharged; however, EDs are also often used as a bridge to inpatient admissions.

Prior to the 1970s, hospital EDs were staffed primarily by internists, surgeons, and other physicians on a rotating-call schedule. With the increasing number of patients seen in EDs and the recognition of a need for skills to treat high-acuity patients, the specialty of emergency medicine (EM) was developed and officially established in 1979. The first emergency medicine residency training programs were started in the 1970s, and these programs have rapidly expanded, with 146 accredited programs as of 2008. With the development of the specialty, emergency-residency-trained and board-certified emergency medicine physicians are increasingly staffing hospital EDs.

Characteristics

Modern hospital EDs are open 24 hours a day and are attached to hospitals with inpatient facilities. In 2005, a national survey conducted by the National Center for Health Statistics (NCHS) found that most EDs (65%) were operated by voluntary nonprofit hospitals. Four of 10 were located in nonmetropolitan areas, and many were

in hospitals with fewer than 100 beds (57%). However, hospital EDs in metropolitan areas see 86% of all patient admissions, with two thirds of nonmetropolitan EDs seeing fewer than 30 patients per day and two thirds of metropolitan EDs seeing 50 to 200 patients per day. EDs in nonmetropolitan areas typically have 10 treatment spaces, while those in metropolitan areas have 10 to 50.

Hospital EDs see patients on a “walk-in” basis (patients who arrive independently) or by arrival via ambulance. In 2005, nearly 18 million patients (16%) arrived by ambulance, up 25% from 1997. Patients are triaged on arrival, which is usually a brief assessment by a nurse, after which patients are categorized according to their level of acuity. Triage criteria include vital-sign abnormalities or specific chief complaints (primary presenting symptoms) that identify the patients that might have more urgent needs, who are given priority for physician evaluation. In 2005, the leading chief complaints were abdominal pain, chest pain, fever, and cough, which accounted for 20% of all visits.

Higher utilization rates were seen in some population subgroups, which included infants, person 75 years of age or older, Medicaid recipients, Asians or Pacific Islanders, and African Americans. The highest per capita utilization rates were for persons living in nursing homes (147.2 per 100 individuals). Other high utilization rates were for infants under 12 months of age (91.3 visits per 100) and homeless persons (62.7 visits per 100).

Private insurance was the most frequent form of payment, accounting for 40% of visits. Medicaid or State Children’s Health Insurance Program (SCHIP) accounted for 25% and Medicare for 17%. No insurance represented another 17% of visits. Utilization rates were highest for Medicaid patients at 89.4 per 100 individuals, followed by Medicare (51.0 per 100 individuals), no insurance (45.9 per 100), and private insurance (23.8 per 100).

Hospital EDs are staffed by physicians and nurses and sometimes by technicians, emergency medical service (EMS) personnel, nurse practitioners, or physicians’ assistants. Most EDs (65%) use outside contracts to provide physicians. Physicians evaluate patients in the EDs, and those requiring admission are assigned to an on-call primary-care physician (family practice, internist, or pediatrician) or occasionally to specialty services such as cardiology, general surgery, or orthopedic

surgery. In 2005, about 12% of ER visits resulted in hospital admission. The average total length of stay for those admissions was 5.2 days, with the leading hospital discharge diagnosis being nonischemic heart disease. Most ERs have specialists on call for consultations, which may be over the telephone or require the specialist to come to the ED, depending on the circumstances.

A broad variety of diagnostic tests and tools are available at EDs. In 2005, diagnostic and screening services were provided for 71% of visits. Blood tests were performed for 38% of visits and imaging studies done for 44% of visits. Medical procedures were performed for 47% of visits, and medications were given or prescribed for 77% of visits.

Some hospital EDs have dedicated laboratory services; more often, laboratory tests for ED patients are conducted by hospital laboratory services but earmarked as “stat” and given priority over other inpatient or outpatient laboratory processing. Results from laboratory tests performed in the ED are generally expected to be available within 30 to 90 minutes in order to assist in the timely diagnosis, treatment, and disposition of ED patients. Most EDs have limited “bedside” testing, including urine pregnancy tests and urine dipstick testing (with results available in minutes); but many EDs are now incorporating some stat bedside blood tests to assist in treating severely ill patients and to improve efficiency.

Radiologic imaging is typically available in EDs. Plain radiographs (X rays) are routinely available, and most EDs have the use of hospital computed tomography (CT) scanners, with a growing number having dedicated ED CT scanners. Ultrasound services are often available for specific emergency conditions, and bedside ultrasounds performed by emergency medical physicians are becoming increasingly common.

Many hospital EDs have separate “urgent-care” or “fast-track” areas that are dedicated, usually only during the highest-patient-volume hours, to streamline the care of patients with simple low-acuity complaints. These are generally patients who require minimal diagnostic testing and can be rapidly assessed and treated. Typical complaints treated in these areas include cough and cold symptoms, rashes, lacerations, minor wounds, minor fractures, and abscesses.

Some hospital EDs have rooms designated as resuscitation areas, which have some space and specialized supplies and are reserved for the most severely ill patients. Some EDs also have areas specifically designed for particular types of patients, such as psychiatric patients or asthmatics. Additionally, there are pediatric areas in some EDs, as well as dedicated pediatric EDs, which are generally found in large urban areas and associated with pediatric hospitals.

Many hospital EDs double up as “trauma centers.” In certain institutions, trauma patients (individuals suffering from physical injury) are seen in an area separate from other ED patients. In 2005, hospitals designated as trauma centers saw 37% of visits. In 2002, there were 1,154 trauma centers in the nation. Trauma center designation varies on a state-by-state basis and is not uniform. Some states designate only Level I or Level II centers, while others use a four- or five-tiered system and designate every ED as a trauma center at some level. In general, trauma centers are ranked according to certain standards, including the availability of hospital intensive-care units, operating rooms, and surgeons and some specialists, including orthopedic surgeons and neurosurgeons.

Growth in Visits

The annual number of hospital ED visits in the nation has increased 20% from 1995 to 2005 (96.5 million to 115.3 million). This is equivalent to 219 visits every minute to the nation’s EDs, or an average of 30,000 visits annually per ED. While ED visits are on the rise, the number of hospital EDs has decreased over this same time period from 4,176 to 3,795 (a decline of 9%), which has caused the average number of visits per ED to increase by 31%. Moreover, from 2000 to 2006, there has been a 12% decrease in short-term acute-care beds, while the total area of EDs has increased 15%. These statistics all demonstrate how EDs are taking on an increasingly larger share of the healthcare burden, which has led to numerous problems.

While most of the increase in hospital ED visits is attributed to the growth in the nation’s population, more than one third is accounted for by the growth in per capita use over that time period. In

2005, one fifth of all Americans made one or more ED visits, making the ED utilization rate 39.6 visits per 100 individuals. EDs are increasingly being used by the uninsured, for their ease of access and convenient hours. Additionally, many patients are sent to EDs by their primary-care providers for tests or procedures that cannot be easily performed in outpatient office settings. While many outpatient physicians in the past would directly admit patients who required hospitalization, it is now commonplace in many hospitals to admit those patients via the ED for stabilization, facilitation of testing, or ease, or because of lack of beds for direct admission. In some rural areas of the nation as well as some inner-city areas, the ED may be the primary source of healthcare for a large percentage of residents. Also, EDs are increasingly being used for public health surveillance and for disaster preparation and response.

With the passage of the federal Emergency Medical Treatment and Active Labor Act (EMTALA) in 1986, all patients presenting at the ED are required to receive a medical-screening examination and subsequent stabilization of any emergency conditions found. The purpose of this law was to prevent patients with emergency conditions from being turned away based on their ability to pay for services. Ironically, EMTALA has been criticized as actually decreasing access to care by forcing the closure of many EDs and trauma centers and creating incentives for hospitals to tolerate long waiting times and divert ambulances to other hospitals while continuing to accept elective admissions.

Problems

The National Academy of Sciences, Institute of Medicine (IOM), published a series of reports in 2006 that identified key ED problems. They include the following: (a) many EDs and trauma centers are overcrowded, (b) emergency care is highly fragmented, (c) critical-care specialists are often unavailable to provide emergency and trauma care, (d) the emergency care system is ill prepared to handle a major disaster, and (e) EMS and EDs are not well equipped to handle pediatric care. This section discusses these and other problems that EDs face.

Overcrowding

During the past 20 years, more than 100 medical articles have been published addressing the issue of overcrowding in the nation's hospital EDs. National data from 2004 estimated that 40% to 50% of EDs overall experienced crowding, with two thirds of metropolitan EDs reporting crowding. Overcrowding is often estimated by surrogate markers such as boarding times, time spent on diversion, and left-without-being-seen (LWBS) numbers. "Boarding" patients are those who are ready for admission but are waiting in the ED for an inpatient bed to become available. Diversion is the practice of diverting ambulances that bring patients to particular hospitals to other, presumably less crowded hospitals. When a hospital is "on diversion," the ED still sees walk-in patients but is temporarily relieved of the burden of also receiving ambulance runs. LWBS patients are those who present to the ED but leave before being evaluated by a physician. In 2004, an estimated 2% of patients were LWBS. Most of these patients leave due to frustration with wait times, and a significant proportion of these have been found to be acutely ill and are subsequently admitted to the hospital.

The nation's hospital EDs report boarding 22% of patients, with 73% of them boarding two or more inpatients. Almost half of the EDs report boarding patients for an average of 8.9 hours for more than 4 days per week. Due to overcrowding, EDs have been forced to make creative use of space. Fifty-nine percent report routinely using halls for housing patients, 38% double patients in rooms, and 47% use nonclinical space for patient care. With overcrowding, nurses and physicians are burdened with taking care of more patients, with an average of 4.2 patients per nurse and 9.7 patients per physician.

In 2003, there were more than half a million diversions, an average of one per minute. A 2004 survey reports that approximately one third of U.S. hospitals reported going on ambulance diversion sometime in the previous year, and 12% of hospitals in metropolitan areas reported having spent between 5% and 19% of their operating time in diversion status. Diversions can create problems by increasing ambulance transit times and disrupting patterns of care (forcing patients to

be seen at different hospitals from where their physicians and records are located).

More overcrowding has been found in hospitals in areas with larger populations, higher population growth, or higher percentages of people without health insurance coverage. The factor most commonly associated with overcrowding is ED boarding. In particular, hospitals with this problem cite difficulty in moving patients to critical care or telemetry-monitored beds. The reasons given by hospital administrators for not having enough inpatient beds are primarily economic. It is more profitable to staff only a sufficient number of beds that are likely to be occupied (which can limit the capacity to staff up for occasional spikes in admissions), and there is competition for available beds among scheduled admissions, such as surgery patients (who are generally considered more profitable than ER admissions).

Overcrowding leads to long wait times, decreased physician productivity, poor patient satisfaction, poor outcomes for patients, lengthened ambulance runs, and lessened ability of hospitals to respond to public health emergencies. In 2005, patients spent an average of 56.3 minutes waiting to see a physician and 3.3 hours for the full duration of the ED visit. Steps to address overcrowding include increasing capacity (often increasing the number of ED beds, using observation units, or adding personnel) and improving efficiency. However, these are generally methods of managing crowding problems rather than reducing them.

Emergency Medical Services

Hospital EDs are often used in conjunction with EMS. EMS are prehospital services usually provided by paramedics; emergency medical technicians (EMTs); or sometimes firemen, who provide on-site treatment of patients and transport them with ambulances to EDs. EMS vary greatly; within a community, many services may exist with some volunteer, some paid, some based in fire departments, and some operated by hospitals or other private companies. Additionally, in some geographic regions, services are divided into basic life support (BLS) or advanced life support (ALS), which differ in skill levels of providers and available supplies. Due to the great variation in EMS, the national IOM has identified fragmentation of

services as a problem. It cites poor communication between EMS workers and police and fire departments as well as between EMS and EDs. The IOM also notes a lack of uniformity in 911 agencies and lack of standards and certification for training EMS personnel.

Primary-Care Burden

Hospital ED have increasingly been used for non-urgent conditions. An estimated one third to one half of all ED visits are for nonurgent conditions that probably could have been seen in a primary-care outpatient setting. Several reasons have been postulated for this trend, including ease of access, lack of health insurance coverage, and erroneous patient perceptions of “urgent” and “emergent” conditions. One study showed that of patients with nonurgent conditions who presented to the ED, 27% reported that they used it for all their medical care, 66% reported that they didn’t know where else to go for their current problem, and almost half rated the ED better for unscheduled care. Approximately one third of ED have been classified as high-safety-net-burden providers (seeing many uninsured or underinsured patients), with hospitals located in the South more likely (61%) to have this designation. High-burden EDs see a higher percentage of nonurgent cases that are primary-care treatable.

Lack of On-Call Specialists

Many specialty physicians do not want to be on call for EDs because of the difficulty in getting reimbursed for services with many uninsured patients presenting to EDs. Also, many specialists perceive additional liability risks for working with ED patients, who may need high-risk procedures and with whom they don’t have an established relationship. Insurance premiums can be higher for specialists who offer on-call services to ED. Being on call can be disruptive to the specialists’ personal lives, and providing night and weekend services in addition to regular practice hours can be physically demanding. Due to these constraints, many EDs report a lack of on-call specialists, which could delay treatment of emergent conditions, some of which could be life threatening. Of all on-call specialists, the services of plastic and hand

surgeons have been most frequently reported as somewhat difficult to obtain (49%).

Pediatric Care

Children make up 27% of all ED visits, but only 6% of the nation’s ED have all the necessary supplies for pediatric emergency care. Deficiencies have also been noted in prehospital equipment and in EMS training for pediatric patients. Improved pediatric preparedness is found in hospitals with inpatient pediatric services, with higher pediatric volume, with teaching-hospital status, located in particular geographic regions, and with higher per capita income in the community.

Lack of Language Translation Services

Non-English-speaking patients face significant barriers to care when translation services are not available. Miscommunications can lead to misdiagnoses and can impair a patient’s ability to understand his or her medical condition, follow up as directed, and comply with recommended treatment. One study found that only 52% of non-English-speaking patients were satisfied with their ED care compared with 71% of English-speaking patients. Many EDs don’t have translation services available or don’t have services provided in a timely manner. Often, family members (especially children) are relied on to translate, which can lead to problems of inaccuracy, conflicts of interest, or compromised patient confidentiality.

Finances

Since hospital EDs are required to provide sophisticated services at all hours, operation costs are high. Services are not designed for nonurgent care, and increased use for these purposes creates unnecessary costs. Additionally, increased use of EDs by underinsured patients who cannot pay their bills leads to increased uncompensated care. The American Hospital Association (AHA) calculated that the cost for uncompensated care was \$26.9 billion for all community hospitals in 2004. Many measures that are being instituted to address ED overcrowding simply expand the EDs’ capacities to deal with higher volumes of patients but do little to curtail the inappropriate use of EDs.

Possible Solutions

The national IOM has outlined several key recommendations to improve EDs based on its recent studies. They include the following: (a) create coordinated, regionalized, and accountable prehospital trauma and emergency care systems; (b) create a lead agency (based at the Department of Health and Human Services [HHS]); (c) end ED boarding and diversion; (d) increase funding for emergency care; (e) enhance emergency care research; (f) promote EMS workforce standards; and (g) enhance pediatric presence throughout emergency care.

To improve ED efficiency and enhance patient flow in order to reduce overcrowding problems, it is recommended that hospitals adopt operations management techniques. Notably, the Centers for Medicare and Medicaid Services (CMS) and the Joint Commission need to institute standards that support moving patients to inpatient beds more quickly and discouraging boarding.

In response to the recent national IOM reports, an Academic Emergency Medicine Panel highlighted areas warranting attention at academic medical centers. These include (a) strengthening the education environment in academic EDs, (b) recognizing the importance of emergency medicine residency training and emergency medicine subspecialty development, (c) using educational loan forgiveness to encourage rural emergency medicine practice, and (d) addressing ED crowding and its adverse effects on quality of care and patient safety.

HOSPITALISTS

Hospitalists are physicians whose primary professional focus is the general medical care of hospitalized patients and who provide continuity of hospital care from admission to discharge, often seeing patients in the emergency room and organizing post-acute care. The term *hospitalists* was first coined in 1996. The recent American hospitalist movement continues to grow at a rapid pace.

Background

Hospital-based physicians in Europe and a small number of integrated health delivery systems in the United States, such as Kaiser Permanente, preceded the more general introduction of hospitals to manage inpatient care across the nation. Traditionally, primary-care physicians supervise

inpatient care. Recently, however, some primary-care physicians have begun to delegate the responsibility to a hospitalist, thus converging to European practice, where the general practitioner in the community refers the patient to a consultant for inpatient care.

Hospitalists were first introduced in the mid-1990s, and by 2005, survey data from the American Hospital Association (AHA) reported 16,000 hospitals in the nation. The association's survey indicates that 40% of short-term community hospitals have hospitalists on the staff. The Society of Hospital Medicine (SHM), the professional society for hospitals in the United States, estimates that in 2007 there were 20,000 hospitals in the nation. Most hospitalists are trained internists, family practitioners, and pediatricians.

The AHA survey also showed that larger hospitals were more likely to use hospitalists than smaller hospitals. General hospitals were more likely than specialty hospitals, and hospitals with at least 20 residents and those affiliated with a medical school were more than twice as likely as hospitals with less than 20 residents and those not affiliated with a medical school. Federal government and private nonprofit hospitals were more likely than local government and private for-profit hospitals to use hospitalists. Hospitalists tended to work in hospitals that also made available advanced diagnostic and therapeutic medical devices. Hospitals in urban and wealthier counties were more likely to use hospitalists. Hospitalist use was more prevalent in counties with higher managed-care penetration and greater competition among health maintenance organizations (HMOs). A higher average physician age, an older patient population, and a greater share of primary-care physicians in the county where the hospital was located were all associated with lower adoption rates.

Duties of Hospitalists

The emergence of hospital medicine as a new medical specialty adds a new dimension to the ongoing specialization process in healthcare along the geographic and institutional dimension, namely the site of care provision. Whereas existing medical specialties are largely defined by disease, organ system, patient age, or patient gender, hospitalists are

defined by the setting where they provide care—the hospital. In this sense, hospitalists are akin to intensivists, whose focus of specialization is the intensive-care unit of hospitals. Hospitalists, typically trained as generalists, can be contrasted with the growing number of ever more narrowly defined specialists working within the hospital whose services can no longer be coordinated *ad hoc*.

Although hospitalists enhance coordination of care within the hospital, some believe that they do so at the cost of potentially worsening coordination between the referring physician's office and the hospital. For this reason, hospitalists can be viewed as offering different advantages to physician groups and to hospitals that are comparing the likely benefits and costs of employing hospitalists directly.

Hospitals' Motives to Use Hospitalists

In response to the growing regulatory scrutiny and advances in medicine, coupled with the increasing pressures of prospective payment adjustments and the exhaustion of cost savings through conventional utilization management, many hospitals have been turning to hospitalists to cope with these operational challenges.

As they work exclusively in the hospital, hospitalists specialize in coordinating the care of hospitalized patients and thus are often efficient in managing throughput. By closely monitoring patients and managing the flow of information, hospitalists minimize the unproductive intervals between successive treatment stages, reduce the incidence of hospital-borne pathologies, help in the formulation of and compliance with clinical practice guidelines, and prevent unnecessary use of diagnostic tests and therapeutic procedures, thereby limiting utilization of hospital resources and minimizing the length of stay without compromising patient safety or treatment quality. Hospitalists aid in streamlining the administrative processes that govern hospital-based patient care and mediate between specialist physicians and staff. Given their constant presence in the hospital, their familiarity with the hospital's resources, and their greater social distance from the patient compared with the patient's primary-care physician, hospitalists are well positioned to manage

the utilization of expensive technologies and procedures. In this sense, hospitalists represent a new generation of utilization management.

In addition, hospitalists are often tasked with managing unassigned patients, who are frequently admitted through the hospital's emergency department and whose care is not assigned to a specific physician prior to admission. In academic medical centers, hospitalists are also charged with teaching duties.

Primary-Care Physicians' Motives to Use Hospitalists

The infrequency and the higher severity of the typical hospitalization have lowered the attractiveness of hospital work for office-based physicians. By delegating the hospital-based portion of care of their patients to hospitalists, office-based primary-care physicians can spend more time on office visits, need not invest in the knowledge and skills specific to hospital-based medical care, and can save commuting time between the office and hospitals. As the frequency of patient referrals by office-based primary-care physicians to hospitals has decreased, and as the sophistication of hospital-based care has increased, more and more primary-care physicians are finding it beneficial to use hospitalists.

Primary-care physicians who serve older patient populations may be worried about the potential discontinuity of care that the introduction of hospitalists creates at the point of the patient's transfer from the referring physician to the hospital. This handoff may lead to a loss of patient-specific information, such as comorbidities, medical histories, and treatment preferences, whose importance typically increases with patient age. This discontinuity presents a major challenge to the hospitalist model.

The similar per-episode reimbursement rate for hospital-based and office-based care for primary-care physicians seems to play a role in reducing the reluctance of some physicians to delegate the hospital-based portion of care to hospitalists. More in-depth specialization along the healthcare continuum is also hampered by the prohibition and prosecution of kickbacks and fee-splitting practices.

Employment Models

With regard to the employment model for hospitalists, in 2003, hospitals using hospitalists employed by a hospital or university constituted the largest group, followed by hospitals whose hospitalists were employed by a hospitalist-only group and those whose hospitalists were employed by a physician group. If hospitalists were uniformly engaged in a specific set of tasks, economic theory would predict, all other things being equal, that the healthcare system would converge to a single, cost-minimizing employment model. In this light, the diversity of employment models is puzzling to health services researchers and suggests that variation in the local characteristics of the market for physician services may play a large role. The choice of employment model affects the extent to which the efficiency gains promised by proponents of hospitalist use are realized and shared by the parties involved.

Apart from teaching duties for hospitalists who are employed by teaching hospitals, they are engaged in the same tasks across all employment models. By employing hospitalists directly, hospitals can potentially reward hospitalists for the cost savings, outcome improvements, and patient satisfaction ratings that they may achieve and thereby align the hospitalists' objectives with those of the hospital. This alignment may be particularly important when the hospital chooses to manage costly medical technologies, whose use can be monitored and controlled by hospitalists.

Insofar as hospitalists are charged with managing unassigned patients, who are disproportionately uninsured and therefore do not constitute a source of separate reimbursement for hospitalists, direct employment by the hospital may provide both parties with a convenient solution to the management of unassigned patients.

Some primary-care physicians may prefer to contract with independent provider groups and physician groups if they give them better control over the hospitalists' priorities in treating the referring group members' hospitalized patients. Compared with direct employment by the hospital, this arrangement may mitigate the possible loss of knowledge about the patient's medical history and treatment preferences, which might be particularly serious for older patients.

In addition to primary-care groups and hospitals, hospitalists may choose to organize themselves as freestanding practice groups. Hospitalist-only groups are free to serve multiple primary-care physician groups, as well as multiple hospitals, and therefore may be in a position to diversify across different patient groups that are associated with individual primary-care physician groups and hospitals.

Which employment model prevails in the long term will depend on the number of physicians prepared to work as hospitalists relative to the demand for them. If demand outpaces the supply, hospitalists will likely choose to organize in the form that allows them to capture most of the gains and addresses their personal needs best.

Fraud and abuse laws, as well as ethical considerations and increasing scrutiny, make it difficult to share any potential gains from using hospitalists, unless the party employs them directly. By developing vertically integrated working structures, in which physicians are salaried by the hospital, the incentives of physicians and hospitals are more closely aligned. As bona fide employment relationships are one salient exception to the anti-kickback statute, vertical integration allows hospitals to control costs by supervising physicians through utilization management techniques, clinical practice guidelines, and other care protocols.

Future Implications

The use of hospitalists has emerged partly in response to regulatory pressure, such as the switch to a prospective payment system and the passage of the federal Balanced Budget Act of 1997. In particular, the widely adopted practice of payment per Diagnosis Related Group (DRG) has encouraged hospitals to find new ways to cut the length of stay without jeopardizing quality of care. While the role of hospitalists in reducing average length of stay seems well established, it remains debatable whether this effect was a by-product of or the principal reason for their emerging prominence. It is also not clear whether hospitals will be able to continue to appropriate the efficiency gains from lower hospitalization stays in the long run. The new type of practical knowledge and evidence-based medicine that hospitalists have been helping to develop and propagate will eventually lead to a

new yardstick for payers, who will likely internalize the new standards and lower their effective payments accordingly. As a result, more pressure may be put on hospitalists to come up with even better ways to decrease length of stay further. Another driver of the hospitalist movement is the pay-for-performance model of reimbursement. A growing number of hospitalist programs have quality-based incentives, often matching the pay-for-performance targets of the hospital.

The future course of the diffusion of the hospitalist model is unclear. If the principal barrier to further diffusion of the hospitalist model is a lack of information among nonadopting hospitals, a continued process of learning will encourage more hospitals to adopt and thereby help contain cost further. While initially raising hospital profits, physician wages, or insurance profits, rate-setting entitlement programs may eventually reduce hospital reimbursement rates, which should then be passed on to consumers in the form of lower insurance premiums and taxes. On the other hand, if the principal barrier to further diffusion lies in the small size of benefits compared with the cost of adoption, additional diffusion will be minimal and the efficiency gains may have been already exhausted.

HOSPITALS

Hospitals are the centerpiece of U.S. healthcare. Hospitals are multipurpose healthcare institutions. They provide a place for physicians and other clinicians to treat patients, for special diagnostic and treatment services, and for emergency care services. They are important resources in times of crises, for aggregating healthcare assets to benefit the community, and major sources of employment and other economic benefits. Hospitals also often serve as focal points for the coalescing of people's efforts to address the healthcare needs of communities.

Definitions

Hospitals are increasingly defined by the various organizations that license, regulate, and accredit them. As such, the technical definition of a hospital may vary widely across nations, states, and programs.

The World Health Organization (WHO), for example, broadly defines a hospital as an organization that is permanently staffed by at least one physician, can offer inpatient accommodations, and can provide active medical and nursing care.

The American Hospital Association (AHA) more narrowly defines a hospital as an organization that

(a) has at least six inpatient beds that are continuously available for care; (b) is constructed to ensure patient safety; (c) has an identifiable governing authority responsible for running it, a chief executive who reports to the authority, a medical staff with licensed physicians, and at least one registered nurse supervisor and continuous nursing services; (d) admits patients only by a member of the organization's medical staff; (e) maintains medical records; and (f) provides pharmacy services and patient food services, including special diets.

The National Center for Health Statistics (NCHS) defines a hospital, for the purpose of its surveys, as an organization with an average length of inpatient stay of less than 30 days (short stay) whose specialty is general (medical or surgical) services or that provides general medical care for children. NCHS excludes federal hospitals, hospital units of institutions, and hospitals with fewer than six beds staffed for patient use.

Classifications

Hospitals are classified in many ways, such as by their ownership, the services they provide, whether they are community hospitals, and whether they are members of a multihospital healthcare system.

In terms of ownership, hospitals are classified as being nongovernment not-for-profit institutions (i.e., church operated, or other), investor-owned (for profit) institutions, or government-owned institutions (i.e., federal, state, or local).

In terms of the services they provide, hospitals are classified as being general institutions (providing a wide array of patient services, diagnostic and therapeutic, for a variety of medical conditions), special institutions (providing services for patients with specific medical conditions), rehabilitation and chronic-disease institutions (providing services to handicapped or disabled individuals requiring restorative treatment), or psychiatric institutions (providing services for patients with psychiatric illnesses).

A very important distinction is whether an institution is a community hospital or not. The AHA defines community hospitals as all nonfederal, short-term (having an average length of inpatient stay of less than 30 days), general and other special hospitals (e.g., children's hospitals, obstetrics and

gynecology, rehabilitation hospitals) whose facilities and services are available to the public.

Hospitals can also be classified by whether they are members of a multihospital healthcare system (two or more hospitals owned, leased, sponsored, or contract managed by a central organization) or a single stand-alone institution.

Hospitals in the United States

In 2006, there were a total of 5,747 hospitals registered with the AHA in the United States. Of the total, the majority, 4,927, were community hospitals (85.7%). Most of the nation's community hospitals were nongovernment not-for-profit institutions (2,919 hospitals, or 59.2%), followed by state and local government institutions (1,119 hospitals, or 22.7%) and investor-owned institutions (889 hospitals, or 18.0%). Most community hospitals, 2,926 (59.4%), were located in urban areas, while 2,001 (40.6%) were in rural areas. And most community hospitals (2,755 or 55.9%) were members of a multihospital healthcare system.

In terms of noncommunity hospitals, there were 221 federal hospitals (e.g., Veterans Affairs, Public Health Service, and Department of Justice hospitals), 451 nonfederal psychiatric hospitals, 129 nonfederal long-term care hospitals, and 19 hospital units of institutions (e.g., prison hospitals and college infirmaries).

There were a total of 947,412 staffed hospital beds in the nation, with community hospitals accounting for 802,658 beds (84.7%). There were a total of 37,188,775 admissions to all hospitals, with 35,377,659 admissions to community hospitals (95.1%). The total expenses for all hospitals were \$607,355,354,000, with community hospitals accounting for \$551,835,328,000 (90.8%).

Licensure, Regulation, and Accreditation

Hospitals must meet the myriad standards created by various government regulatory bodies. Such standards include, among others, (a) state and local licensure requirements; (b) conditions of participation for federally funded payment programs (i.e., Medicare, Medicaid, and TRICARE, the Military Health System); (c) rules governing research, the use of controlled drugs, radiation safety, and patient

rights; (d) patient privacy guidelines; (e) state and federal tax-exempt requirements (for not-for-profit hospitals); and (f) federal and state rules regarding assured access to emergency medical care.

The most direct independent force in molding the structure of contemporary hospitals has been the Joint Commission. The Joint Commission sets standards through which almost all nongovernmental hospitals and many other healthcare organizations are measured to attain accreditation approval. This accreditation is not only a means of asserting a quality status to the public at large but also serves as the surrogate approval mechanism for many other regulatory agencies and other state and federal certification. Approval may also be the key to being accepted by payers such as Medicare, Medicaid, and Blue Cross. While the accreditation process is voluntary, and hospitals are required to pay for participation, the link to certification, licensure, and payment makes it all but mandatory. Its impact on the structure of hospital medical staff is, as a result, unavoidable.

History

Specially organized places where individuals sought relief from illness or injury, places to receive care in the process of dying, and places to go for birthing have existed in many forms for thousands of years. The ancient Greeks, Egyptians, and Romans established temples where rites were performed to cure the sick.

Perhaps the oldest highly organized institution specifically dedicated to the care of the sick was established in Mihintale, Sri Lanka, sometime around the 4th century BCE. Archeological evidence appears to show that the well-constructed hospital had a waiting room, a dispensary, examining rooms, residential rooms for patients, and a bath where patients would be immersed in medicinal herbal water or oil.

In Europe, hospitals were typically created by various religious orders. Hospitals were also established as hospices along the major pilgrimage routes. The name *hospital* comes from the Latin *hospes*, referring to either a visitor or the host who receives the visitor. From *hospes* came the Latin *hospitalia*, an apartment for strangers or guests, and the Medieval Latin *hospitale* and the Old

French *hospital*. In England, in the 15th century, the name shifted to mean a home for the elderly or infirm or a home for the down-and-out. *Hospital* only took on its modern meaning as an institution where the sick or injured are given medical or surgical care in the 16th century. Other terms related to hospital include *hospice*, *hospitality*, *hospitable*, *host*, *hostel*, and *hotel*.

In the New World, the Spanish conquistador Hernando Cortez built the first hospital in 1524 in Mexico City. The Hospital of the Immaculate Conception (which in 1663 became the Hospital of Jesus of Nazareth) is today the oldest continuously operating hospital in America. Throughout the Spanish settlement of America, various Catholic orders established a number of hospitals.

As other Europeans settled in what would become the United States, they also established hospitals. As the population of the new country expanded, more hospitals were created. Specifically, hospitals were established for a number of reasons. Religious orders created hospitals in response to local needs. Some communities created hospitals to expand their almshouses and prisons in order to house the insane, the poor, and others who did not have a home in which to receive care, whereas other communities created hospitals to contain patients who were contagious or who were in some other way undesirable. Physicians also created hospitals to have a place to support patient care. Some communities built hospitals as a place to support training of physicians and other professionals to meet their healthcare needs and/or as a place to support research and the development of new medical technology. In addition, individuals and corporations created hospitals as profit-making ventures to fill specific market niches.

Technology and the Modern Hospital

Today's modern hospital emerged in the latter half of the 19th century. Although a number of factors were responsible for its emergence, arguably, the two most important factors were the development of anesthesia and the germ theory of disease and antiseptic techniques.

While American surgeons had much of the knowledge needed to conduct major surgical procedures by the 19th century, because the

surgeons lacked anesthesia, they had to operate quickly, patients suffered great pain and torture, and postoperative infection rates were high and often deadly. It was not until the mid-19th century with the introduction of anesthesia, such as nitrous oxide, ether, and chloroform, making possible the systematic application of surgery, that the growth of hospital services began. As a result, surgeons became the professional leadership in the formalization of hospital organizations well into the 20th century.

In the mid-19th century, individuals such as Oliver Wendell Holmes, Ignatz Semmelweis, Louis Pasteur, Joseph Lister, Robert Koch, and others advanced the germ theory of disease and demonstrated effective measures that could reduce the rate of disease, methods of immunization, and ways to prevent the raging infectious disease death rates in hospitals. With the reduction of diseases such as puerperal fever, a deadly disease of women giving birth, the public no longer viewed the hospital as a place to die; instead, it was a place to be cured. New antiseptic techniques developed by Lister lowered the infection rates from surgery. Previously, almost all wounds became infected, and mortality rates from surgery were as high as 90%.

Today, technologic innovations and medical advances continue to take place in hospitals. For example, recent surgical innovations include minimally invasive surgery, various endoscopic procedures, and the use of surgical robots that allow delicate microprocedures to be performed. In addition, advances in physiology and the monitoring technology of anesthesia have extended surgical procedures to older and sicker patients. Interventional instruments such as the laparoscope and balloon catheters continue to radically change hospital care, while advances in the development of radiation therapy have expanded the treatment options for many diseases. New imaging instruments such as ultrasonography equipment, thermal imaging equipment, high-speed computerized tomography (CT) scanners, magnetic resonance imaging (MRI) equipment, and positron emission tomography (PET) scanners are opening a new world of early and noninvasive diagnostic techniques.

The Hospital Medical Staff

As hospitals evolved through the 19th century, the role of physicians remained as that of independent caregivers and entrepreneurs. Their relationship with the hospitals of their time was as individuals and, for the most part, was neither organizational nor economic. The concept of mutual benefit had mostly to do with the perceived need for a place to keep those patients who could not be treated at home. The physicians performed surgery and attended to their patients, but there was little demonstration of an organized role in the governance or oversight of medical care as a whole.

However, it was in this period that the functional and economic basis for cooperation among physicians grew. Acceptance by a group of colleagues, willingness by those colleagues to refer patients to the member for service, and willingness to see a colleague's patients when he or she was not available were all valuable resources for a physician. As these benefits became more important, the notion of limiting who could join the medical staff of the hospital and share its benefits became more important. Being selective about who may join the hospital medical staff has been a powerful tool for improving and maintaining healthcare quality, but it also has been responsive to economic incentives.

The role of gatekeeper has sometimes been an appropriate one for the hospital medical staff, and sometimes it has been abused. In addition to helping staff focus on maintaining quality, it has also been closely related to economic factors and the success of the staff physicians.

Today's hospital/hospital medical staff partnership is constructed in an environment of regulation more intense than at any other time. But these recommendations and requirements have emerged slowly, over a period of many years, as the concepts of clinical science, technology, and ethical responsibility have grown more complex.

Hospital medical staffs originally began as social organizations that facilitated an orderly referral of patients from one member to another, controlled the growth of the medical staff, and helped nurture the addition of new members deemed desirable. The mutuality of operating and economic interest among staff members and the hospital in which they operated was the powerful

glue that held them together, and the choices made in that mutuality would benefit the patient, whose best interest was served by the increasing availability of medical services.

This was convenient and economically productive at a time when the majority of care was on a fee-for-service basis. The economic basis for this exclusivity was also the basis for attacks on it by excluded physicians.

While the courts in the 1970s and 1980s forced hospital medical staff to become less exclusive and opened staff privileges to any qualified physician, the legitimate need to control access to staff had to be recognized and a new way had to be found to serve that need. There was, in part, as a response, a significant increase in externally imposed regulation on the hospital. This created many more complex responsibilities for the medical staff and its elected officers. Organizing and monitoring to ensure the quality of care became a substantial task. Later, there emerged complex reimbursement methodologies that required even more staff involvement in oversight, regulation, and assurance of fairness to the patient.

Hospital Management

Over the course of the past century, as hospitals increased in size and complexity, and the financing of care moved from self-pay to a third-party reimbursement system, healthcare administration as a profession evolved to meet these new challenges. Early hospital administrators were called superintendents, and they typically had little formal educational training for their jobs—many were nurses who had taken on administrative responsibilities. For example, more than half of the superintendents who were members of the AHA in 1916 were graduate nurses. Other hospital superintendents were physicians, laypersons, and Catholic nuns.

The first degree-granting program in hospital administration was established at Marquette University in Wisconsin. In 1927, two students, both women, received their degrees, but in 1928, the program, with no other graduates, failed.

In 1934, Michael M. Davis, a pioneer researcher in the economics, quality, and organization of medical care, developed the first graduate program in hospital administration at the University of Chicago. Davis recognized that most hospital

superintendents of the time lacked proper training in business. The new program was placed in the university's business school. Davis developed the curriculum, which included 1 year of academic course work in accounting, statistics, and management and a hospital residency. With the success of the program, other universities established hospital administration programs based on Davis's model.

Before the founding of the first graduate program in hospital administration, a group of practicing hospital superintendents came together in 1933 and formed the American College of Hospital Administrators (now the American College of Healthcare Executives [ACHE]), the first professional association for hospital administrators. And while both clinically trained and lay administrators could join the college, the emphasis was clearly on the lay administrator. Among the 106 charter fellows of the college, only 32 were physicians. Over the years, the college has grown; and today it is an international professional society of more than 30,000 healthcare administrators who lead hospitals, healthcare systems, and other healthcare organizations.

While hospitals have continued to evolve, the field of healthcare administration continues to sustain three primary objectives. First, healthcare administrators are responsible for the business and financial aspects of hospitals, clinics, and other health services organizations, and they are focused on increasing efficiency and financial stability. Their roles include human resources management, financial management, cost accounting, data collection and analysis, strategic planning, marketing, and the various maintenance functions of the organization. Second, healthcare administrators are responsible for providing the most basic social service: the care of dependent people at the most vulnerable points in their lives. Third, healthcare administrators are responsible for maintaining the moral and social order of their organizations, serving as advocates for patients, arbitrators in situations where there are competing values, and intermediaries for the various professional groups that practice within the organization.

The challenges faced by the healthcare administrators of hospitals are many. Shortages of nurses and other healthcare workers, concerns for the safety and quality of healthcare services, rising costs, the growing number of uninsured Americans, an aging population, and the rapidly changing

medical technology and practice make managing hospitals a complex and challenging task.

I

IATROGENIC DISEASE

Iatrogenic disease commonly refers to a physician-induced disease and more generally to a disease state caused by the commission of acts by the physician rather than the omission of needed treatment. The word *iatrogenic* comes from the root *iatro*, the Greek word for physician, or more generally a healer, and the word *genic*, meaning to come from or be created by. Thus, iatrogenic disease literally means a disease state that is brought forth by those who intend to heal. More broadly, however, the term *iatrogenic disease* has been referred to any adverse event that is associated with a healthcare provider, including a nurse or medical technician, or treatment. Iatrogenic disease poses itself as a risk to patients, and it can be the result of several factors including negligence, medical error, and/or the adverse effect of treatments. It is estimated that iatrogenic disease is the third leading cause of death in the United States.

Overview

Iatrogenic disease has been cited as a widespread national problem. In 2000, the national Institute of Medicine (IOM) released a report titled *To Err Is Human: Building a Safer Health System*. This landmark report estimated that between 44,000 and 98,000 deaths occur each year in the nation's hospitals from medical errors. An earlier report about medical errors in New York hospitals spurred the Joint Commission to create a sentinel

event-reporting system. After the IOM report, the Joint Commission created a set of national patient safety goals that were incorporated into the accreditation process to reduce medical errors.

The most obvious example of iatrogenic disease is medical errors. Common medical errors include performing an operation on the wrong body part or dispensing the wrong medicine due to negligence; however, this is only a small part of iatrogenic disease. The greatest amount of iatrogenic disease is caused by the unintended side effects or adverse effects caused by drug interactions. These adverse effects may range from mild disease states, such as impaired sleep or indigestion, to severe consequences, such as heart failure, stroke, and death. Sometimes, the adverse effects are known and accepted by the patient because the positive effects of the treatment outweigh the adverse effects. In these cases, while the resulting disease state is in fact iatrogenic, the term is often not applied because iatrogenic disease is generally used pejoratively.

Iatrogenic disease may also result in hospitalized patients acquiring nosocomial infections. For example, hospital staff may unintentionally transmit microbes during the routine patient encounter because of improperly sterilized medical equipment and through the use of unclean or ungloved hands.

Another example of iatrogenic disease derives from interventions that are done or not done as a result of financial incentives. For example, when a healthcare provider decides to use a certain medication because of its association with a

pharmaceutical company, any disease state that results from choosing the particular medicine over a more effective alternative is considered to be an iatrogenic disease. Thus, the referral for an intervention for the purpose of profit rather than for the best interest of the patient also results in iatrogenic disease. Many studies of physician behavior have documented that financial incentives change practice patterns.

Physicians also change their behavior in response to potential litigation, which can be brought on by medical negligence, an action punishable in the U.S. judicial system. This practice, often referred to as defensive medicine, may have positive outcomes because the behavior of the provider changes to try to avoid negligence. However, this behavior may also lead to unnecessary tests, procedures, and treatments, which ultimately result in iatrogenic disease.

A more complicated example of iatrogenic disease is the use of unproven diagnostic and therapeutic modalities. Many practice patterns in modern medicine are not definitively proven to be beneficial. The recently debunked routine practice of prescribing estrogen replacement therapy at menopause for women is a case in point. In this instance, a substantial amount of basic science data, as well as data from observational studies in women, strongly suggested that postmenopausal estrogen protected against heart attacks. However, the results from a randomized controlled trial (RCT), considered the gold standard of evidence-based medicine, showed that hormone replacement therapy actually caused myocardial infarctions. As a result, many women were having iatrogenic heart attacks for decades because of poor-quality data. Similarly, the currently accepted protocol for prostate cancer screening and treatment in men has been studied, and the findings suggest that these processes may lead to iatrogenic disease. To prevent this type of large-scale iatrogenic disease, modern medicine needs the right kind of evidence to guide its actions.

Iatrogenic disease is not limited to conventional medical practices, however. Alternative-medicine practitioners can also cause iatrogenic disease. For example, ephedrine, an active ingredient in many alternative weight loss products, was withdrawn from the market because it was shown to cause strokes.

Future Implications

Iatrogenic disease is a consequence of modern medicine; however, much of this burden can be reduced through a number of changes. For instance, medical errors are being tackled through error reduction strategies—a technique that has been successfully used in the aeronautics industry. Furthermore, the National Institutes of Health (NIH) funds large RCTs on many important treatment modalities, including alternative medicine. Additionally, many organizations have implemented incentives to improve healthcare quality, which are now being considered by Medicare. With new safety-oriented procedures, financial incentives geared toward patient safety and quality, tort reform, and emerging scientific evidence, iatrogenic disease can be overcome.

INDIAN HEALTH SERVICE (IHS)

The Indian Health Service (IHS), an agency of the U.S. Department of Health and Human Services (HHS), is the principal healthcare provider to American Indians and Alaska Natives (AI/AN) and acts as their health advocate. The mission of the IHS is to provide quality healthcare services to the 562 federally recognized tribes of American Indians and Alaska Natives. Its goal is to ensure comprehensive, culturally acceptable personal and public health services and to ensure that these services are available and accessible to those who are eligible. Since its inception, the IHS has been working with various tribes, urban Indian programs, and other Indian organizations to achieve these goals.

Background

The federal government has the responsibility of meeting the health needs of American Indians and Alaska Natives, as promulgated by the Snyder Act of 1921; the Indian Health Care Improvement Act (IHCIA), as amended; and the Indian Self Determination and Education Assistance Act (ISDEAA). The Snyder Act and the IHCIA have provided the authority for the federal government programs to deliver health services, while the ISDEAA promotes the tribal administration of federal Indian programs, including healthcare.

Established on July 1, 1955, the IHS works in partnership with American Indians and Alaska Natives to honor its goal of providing optimal care and to promote the physical, mental, emotional, and spiritual health of American Indians and Alaska Natives, along with protecting their sovereign rights. The IHS serves approximately

1.9 million of an estimated 3.3 million American Indian and Alaska Native population.

More than half of the IHS's budget is handled directly by the tribes. In turn, the IHS helps the tribes develop their health programs and coordinate their health planning using federal, state, and local resources. However, many of the tribes lack the necessary resources to manage their own programs. There is also a growing interest among managed-care organizations to contract with the tribes for clinical services. Some American Indian and Alaska Native leaders worry that these trends may undermine the federal government's responsibility to the tribes.

Health Disparities

While the overall health status of American Indians and Alaska Natives has improved in the past few decades, important disparities still exist between the American Indian and Alaska Native population and the general population in terms of mortality, disease rates, costs, and access to healthcare.

The five leading causes of American Indian deaths in 2004 were heart disease, cancer, accidents (unintentional injuries), diabetes mellitus, and stroke (cerebrovascular diseases). In contrast, the five leading causes of deaths for the entire population of the nation were heart disease, cancer, stroke, chronic lower respiratory diseases, and accidents.

Life expectancy for American Indians and Alaska Natives is lower than for all other races in the nation. The median age of American Indians and Alaska Natives is 28.0 due to high-mortality rates in early life. For example, the infant death rate is 10 per 1,000 live births compared with 7 per 1,000 for the entire U.S. population (2001–2003 rates).

Compared with the nation's population, American Indians and Alaska Natives more frequently die from tuberculosis (750% higher), alcoholism (550%), diabetes (190%), accidents (150%), homicides (100%), and suicides (70%). They also tend to suffer from higher rates of infectious diseases, likely the result of waste disposal and sanitation problems. American Indians and Alaska Natives have the third highest rate of HIV/AIDS diagnoses in the nation, and they are more likely to seek and receive treatment in the later stages of illness, thus resulting in shorter life spans.

American Indians and Alaska Natives have the highest rate of Type II diabetes in the world. The IHS healthcare expense per American Indian/Alaska Native is \$2,158 compared with \$5,921 for the U.S. population. The American Diabetes Association estimates that the average cost of diabetes care is more than \$13,000 per diabetic patient per year, largely due to the cost of pharmaceuticals. In the past, the emphasis of the IHS had been on the clinical care of diabetes and the prevention of complications rather than on the prevention of the disease itself, but that is changing.

Needed services are often rationed due to lack of funding. Funds are not distributed proportionally, and additional funds are not available should more money be needed for health services. The tribes may offer funds but often not enough to cover the shortfalls. Many facilities have negotiated discounts for contract care. Most hospitals have been willing to discount, but many physicians are not always as willing.

Availability of services depends on accessibility to IHS-funded facilities. However, not all IHS facilities offer the same services. And there is often a long waiting time between the call for an appointment and the actual service.

Some services cannot be provided on-site because of the growing complexity of medical care, which is beyond the scope of current IHS clinics and health centers. Sometimes, patients are forced to use contract care or to travel great distances to a discounted hospital or an IHS facility.

This presents a challenge to the private sector, having to deal with the social, cultural, and other characteristics that divide this population from other populations. American Indians and Alaska Natives are a very diverse group, and they cannot be all grouped together because of differences in language skills and customs.

Organization

The IHS is a complex organization, with myriad programs operating under varying circumstances across geographic areas.

Its main headquarters is located in Rockland, Maryland. It also has 12 area offices covering 35 states, most states being in the western portion of the country. Services are administered through these offices and 163 IHS- and tribally operated

service units. The basic organizational element of the healthcare program is the service unit usually serving the local community, and it is often hospital based.

The IHS has its own roster of physicians, nurses, aides, pharmacists, and dentists and is predominantly staffed by American Indians and Alaska Natives. The IHS operates 33 hospitals, 52 health centers, and 38 health stations. Tribal hospitals number 15, with 220 health centers and 116 health stations. There are 34 urban programs in existence, including community health and comprehensive primary healthcare services.

Future Implications

The costs of the IHS are increasing as a result of the overall increasing costs of healthcare and because of increases in the size of the American Indian and Alaska Native population. The eligible population was estimated to increase by 1.6% in 2007, or an additional 30,000 people, which means more healthcare demands for services now and in the future.

However, for FY2009, the IHS will receive federal funding of \$3.3 billion, a \$21.3 million cut. Given the rising costs and insufficient funding, along with a growing trend toward managed care, the IHS faces a challenging future in fulfilling its mission.

INFECTIOUS DISEASES

Microorganisms are everywhere. They are found throughout the environment and by the billions on the skin and in the gastrointestinal and respiratory tracts. Most are quiescent, colonizing the host without producing disease or prevented from doing so by the body's normal defenses. Intact skin and mucosal surfaces, as well as specialized elements of the immune system, serve to limit the host-microbe interaction. However, when circumstances change and this delicate balance is disrupted, such as when a burn destroys intact skin, antibiotic therapy alters normal microbial flora, or surgery disturbs the normal anatomic barriers, microorganisms gain access to the host and create an opportunity for an infection to occur. An infectious disease then is a clinically evident disease affecting the host due to a microorganism or one of its products.

Microbial Factors

The variety of microorganisms capable of infecting humans is broad and includes bacteria, viruses, fungi, protozoa, helminthes, arthropods, and, rarely, proteinaceous substances called prions. Organisms that invade or damage tissue in a

healthy host are termed *primary pathogens*. Their virulence or capacity to cause disease depends on the number of organisms transmitted and their ability to enter tissues, evade the host's defenses and multiply, or produce extracellular products such as toxins. Organisms that invade and cause disease in a host with altered resistance are termed *opportunistic pathogens*. These organisms are often part of the host's normal flora, residing within the gastrointestinal or respiratory tracts, or may be acquired from the host's environment. They take advantage of the host's altered defenses, due to, for instance, genetic defects, immunosuppressive therapy, cancer chemotherapy, or changes in the antimicrobial flora due to exposure to an antimicrobial drug.

Transmission

An exogenous disease, such as malaria, is caused by a microorganism whose natural environmental reservoir is outside the body. Other infections, such as appendicitis, are caused by a constituent of the indigenous microbial flora and designated as endogenous diseases. Organisms may be transmitted to the host by several different mechanisms including direct or indirect contact, which includes hand contact or a sneeze; contaminated food or water; contact with a contaminated inanimate object; or the bite of an insect vector. Entry thus may be by inhalation, ingestion, injection, or direct implantation.

Once transmitted, the organism colonizes the host's tissue at the site or portal of entry before undergoing a period of multiplication, leading to subsequent invasion of tissue and/or production of disease-causing toxins. An infectious disease becomes clinically evident when the microbe invades locally and/or disseminates throughout the body and produces tissue injury or organ dysfunction. Injury may be a direct effect of the organism or its toxins. In some cases, it may be due to the host's own inflammatory or immune response. Some organisms grow only at a specific body site, while others disseminate widely. The host and/or microbe determine the factors accounting for this tissue tropism. Some microbes are obligate intracellular parasites and must invade cells for their survival; malaria spreads in this way. They often have surface molecules that facilitate entry into

their target cells. Other microbes use the host's own scavenger cells but resist the normal killing mechanisms to survive, proliferate, and cause an infectious disease, such as tuberculosis.

Host Immunity

Fortunately, most infections in the normal host are self-limited due to a series of immune mechanisms that have evolved over time. Innate immunity is not influenced by repeated infections, while adaptive immunity follows repeated exposure to an organism or its products. Innate mechanisms constitute the first line of defense. Mechanical barriers, such as skin and mucosal membranes, and normal secretions, such as tears, saliva, and urine, make entry into the body difficult. The indigenous microbial flora discourages pathogenic colonization by competing for binding sites and nutrients or producing inhibitory chemicals called *bacteriocins*. Invasion of the host produces a series of acute-phase responses manifested by mediator molecules such as interleukin-1 and the complement system. These reactions initiate the host's response to limit the spread of the pathogen.

Adaptive or specific immunity has two major coordinated components. The B-lymphocyte system produces specific immunoglobulins, or antibodies against the pathogen. The T-lymphocyte system activates the killer cells to attack intracellular microbes or produce cytokines, chemicals that stimulate other scavenger cells or macrophages, which then may limit the infection.

History

Microbes have populated the earth longer than man has existed, and infections have undoubtedly played a role in his survival. Plagues are noted in the Old Testament and occurred as man began forming aggregate groups large enough to sustain epidemics of new or evolving pathogens that could be transmitted from person to person. The origin of many infectious agents remains a mystery, but man became the established reservoir for many of these microbes. Infected animals and contaminated food and water were additional sources of other organisms. As there was little previous exposure to these microbes, the level of immunity was low, and mortality rates for infections such as

smallpox, rubella, and measles were high. As exposure continued, levels of immunity in the population rose, and resistance increased, leading to lower prevalence, reduced mortality, and more predictable patterns of occurrence.

The Greek physician, Hippocrates, the father of Western medicine, was one of the first to describe diseases such as malaria, tuberculosis, mumps, diphtheria, and probably influenza in enough detail to make them recognizable today. Epidemics of measles and smallpox occurred in ancient Greece and Rome. The Black Plague, which hit Europe in the Middle Ages, killed an estimated 25 million people, or 25% to 50% of the European population at the time.

The European settlement of the Americas in the 15th and 16th centuries introduced smallpox, measles, and typhus into New World populations with no immunity to these diseases. From 1511 to 1560, the population of Mexico declined from about 20 million to 3 million and then to 1.6 million by the turn of the 17th century. The colonization of the New World by Europeans was accomplished more by the pathogens they brought than by their traditional weapons.

Epidemics continue to unfold across the world due to both old pathogens and new ones. The Spanish flu pandemic of 1918 to 1919 killed 25 to 50 million people worldwide. Two other less virulent influenza pandemics occurred in the 20th century, and new strains of the influenza virus are continually emerging. According to many experts, another pandemic is inevitable.

The ability to control many of these pathogens has made great strides in the past several centuries. Edward Jenner developed the first vaccine for smallpox in 1786, which eventually led to its control. It became the first and only infectious disease to ever be managed and eliminated worldwide. The work of Robert Koch and Louis Pasteur and the introduction of the germ theory of disease made the control of infectious diseases possible. Isolation and identification of microbial agents led to descriptions of the epidemiology and natural history of many infectious diseases. By the end of the 19th century, water purification treatment, vector control, and rodent reduction programs were beginning to make strides in the control of many pathogenic microbes. The 20th century saw major public health strides in vaccine development

and usage for the control of polio, measles, mumps, diphtheria, and tetanus. These achievements have truly been one of the public health success stories throughout the developed world, and public health measures to control infectious diseases are having similar success, where implemented, in developing countries. Furthermore, such measures are extremely cost-effective. For example, every \$1 spent on a vaccine against measles, mumps, and rubella (MMR) saves \$21, while every \$1 spent on a vaccine against diphtheria, pertussis, and tetanus (DPT) saves \$29. However, these diseases have not disappeared. If effective vaccination campaigns are not continued until these microorganisms are eradicated everywhere, their reemergence is likely.

The serendipitous discovery of penicillin by Alexander Fleming in 1929 heralded a new age of the treatment of infectious diseases. For the first time, effective therapy for bacterial infections was possible. The post-World War II era brought the discovery and/or synthesis of many new antibiotics, leading to treatment of common infections of the lung, skin, and urinary tract and ever-increasing control of life-threatening bacterial infections such as tuberculosis and typhoid fever. Antimicrobials to treat various viruses, fungi, and parasites have also been developed. With the success of the new antibiotics, some physicians even predicted the end of infectious diseases—an optimistic view that was soon proven false. Unfortunately, microorganisms replicate rapidly, and within a few years of the development of antibiotics, resistance began to emerge. The last three decades of the 20th century brought a resurgence of resistant sexually transmitted diseases; increasing antibiotic resistance in common bacteria; as well as the identification of new infections such as legionnaire's disease, toxic shock syndrome, lyme disease, and acquired immunodeficiency syndrome (AIDS).

In 1992, the national Institute of Medicine (IOM) issued a report, *Emerging Infections: Microbial Threats to Health in the United States*, which emphasized the global nature of emerging pathogens. The landmark report outlines modern demographic, environmental, and behavioral changes leading to diseases of infectious origin whose incidence in humans has increased or threatens to increase in the near future.

Strategies for preventing these infections demanded both national and international

responses. The Centers for Disease Control and Prevention (CDC), in partnership with federal, state, and local agencies, foreign governments, the World Health Organization (WHO), and many groups in private industry, formulated plans to address these emerging infectious disease threats. In the United States, some success has been achieved with the reduction of childhood bacterial meningitis, group B streptococcal infections in infants, and bloodborne diseases such as hepatitis B and human immunodeficiency virus (HIV). Still, worldwide epidemics of tuberculosis, malaria, and AIDS continue. Tuberculosis infects up to one third of the world's population and causes 2 million deaths per year; drug-resistant malaria kills 1 million children in sub-Saharan Africa each year and has crept into new habitats; and AIDS has infected more than 40 million people to date and continues to spread throughout the developed and the developing world. Despite a century of scientific progress, infectious diseases still cause tremendous human suffering, deplete scarce resources, impede social and economic development, and contribute to global instability. Much more work needs to be done before the control of these major pathogens becomes a reality.

Infectious Diseases and Healthcare Today

Healthcare today is delivered in many venues, including physicians' offices, immediate-care clinics, specialty centers, long-term care facilities, emergency departments, and hospitals. The sickest and most vulnerable patients are hospitalized, undergoing the most procedures and interventions and receiving the most medications. They are at risk for a variety of healthcare-associated infections. The national Institute of Medicine's (IOM) report *To Err Is Human: Building a Safer Health System* estimated that hospital-related adverse events in the nation, including hospital-associated infections (HAIs), cause an estimated 44,000 to 98,000 deaths annually at a cost of \$30 billion. HAIs may affect as many as 5 to 15 per 100 hospitalized patients, with associated complications in 25% to 50% of patients in intensive care.

Attempts to prevent hospital infections began with Ignaz Semmelweis's introduction of hand washing with chlorinated lime solution to prevent maternal mortality at the Maternity Clinic in

Vienna in 1847. These efforts were continued with Florence Nightingale's *Notes on Hospitals* in 1863, in which she reported mortality rates for the main hospitals in the United Kingdom and noted the relationship between the lack of sanitary conditions and postoperative complications. In the United States and elsewhere, surveillance and the systematic collection, analysis, and interpretation of data form the basis of infection control essential for the evaluation and subsequent intervention to control infection risk in hospitals and other health-care settings. The CDC in the 1970s began the Study of the Efficacy of Nosocomial Infection Control (SENIC) Project to evaluate the effects of surveillance and reporting on hospital infection rates, and it found that 35% to 50% of all hospital infections were associated with just a few patient care practices: (a) the use and care of intravenous and urinary catheters, (b) surgical procedures, (c) mechanical support of lung function, (d) hand hygiene, and (e) the use of isolation precautions. During the past four decades, it has become clear that hospital-associated infections are good indicators of the quality of patient care. Interhospital comparisons, however, have been difficult due to differences in the severity of illness in patients and lack of standardization of methods of measurement. To reduce infections associated with these interventions, standardized guidelines and prevention programs have been introduced in most hospitals, and they have proven to be cost-effective. Prevention of the transfer of organisms from one patient to another via the hands of healthcare personnel is one of the most important interventions to control HAIs. Hand hygiene, including hand washing and/or the use of alcohol-based hand antiseptics, remains a major compliance problem that is being addressed aggressively in most healthcare settings. Guidelines have been revised, and campaigns including education, compliance monitoring, and feedback are becoming the norm.

Antimicrobial Resistance

The control of healthcare-associated infections has become complicated with the rise of microorganisms resistant to many commonly used antibiotics. The promise that bacterial infections would disappear or be easily controlled with antibiotics has disappeared. New multidrug-resistant organisms

(MDROs) are replacing older more susceptible ones. Today, this is one of the major problems confronting the control of infections, particularly in vulnerable populations in hospitals and long-term care facilities. The pharmaceutical cost of the development and approval of new antibiotics to successfully combat these new threats continues to escalate, and the incentives for a return on investment are diminishing. In the past decade, far fewer new antibiotics have been developed than needed, with only four developed between 2003 and 2007. Of these, only one was a novel drug. Hospitals are currently having to deal with an increasing number of patients with infections due to resistant staphylococci, *Escherichia coli*, and *Candida* species. Most of the hospital-acquired infections in intensive-care units are due to these and similarly resistant organisms. Unsuspected resistance can lead to treatment with an inappropriate antimicrobial, one in which the microorganism is not susceptible. Treatment courses are longer, hospitalization is prolonged, and mortality rates are higher in those infections due to resistant organisms. Controlling these infections in the hospital depends on early detection, hand hygiene, implementation of isolation precautions, and appropriate use of available antibiotics, all of which increase hospital costs in days of decreasing reimbursement. Other healthcare settings, especially long-term care facilities and hospital emergency departments, are facing similar problems.

Effective therapy depends not only on the susceptibility of the organism to the antimicrobial but also on host factors, the virulence of the organism, and the pharmacology of the drugs. Ideally, the choice of an appropriate antimicrobial should strive for maximal efficacy, with minimal toxicity, at the lowest cost, and with the smallest risk of inducing further resistance. To maintain the efficacy of the antimicrobials in use today, several strategies have been instituted or are needed. These approaches include the following: (a) campaigns to educate physicians and the general public to avoid using antimicrobials for common infections such as viral upper-respiratory infections in children or acute bronchitis in otherwise healthy adults; (b) new government regulations limiting the use of antimicrobials in animal feed, which drives the development of resistance in

human pathogens; (c) optimal development and use of vaccines to prevent common diseases such as ear infections and pneumonia in children; and (d) appropriate funding for public health programs to monitor and control emerging and reemerging pathogens.

Unless Americans become better stewards of current antimicrobials and encourage research and development of new ones, the ability to treat even common infections will diminish. Infectious diseases may return as the most common cause of death in the nation.

The impact of the national IOM's *To Err Is Human: Building a Safer Health System*, which included healthcare-associated infections, in terms of morbidity, mortality, and costs sparked organizations such as the Institute for Healthcare Improvement (IHI) to develop several new programs, guidelines, and standards for patient care and safety within healthcare systems. The Five Million Lives Campaign, started in 2007, targets, among other goals, reduction from harm caused by surgical-site infections and infections caused by the multidrug-resistant *Staphylococcus aureus*. Furthermore, several state legislatures are contemplating new laws for screening of patients on entry into the hospital to limit the spread of multidrug-resistant organisms in an effort to address quality-of-care issues. Whether these costly programs will have a lasting impact in today's healthcare milieu remains an open question.

Future Implications

The past several decades have witnessed the emergence of new infectious diseases and the resurgence of infectious diseases once considered vanquished. Today, many microorganisms are resistant to antibiotics, and treatment of infectious diseases is becoming more complex and expensive. New antibiotics and antiviral agents need to be developed, as well as new molecular techniques to better detect and trace the spread of microorganisms rapidly and globally.

INFLATION IN HEALTHCARE

Inflation in healthcare is the continued increase in the price of healthcare goods and services. Inflation in healthcare is reported in several ways. First, the rate of growth in per capita healthcare spending is often compared with the rate of growth in the per capita gross domestic product (GDP) to measure whether healthcare spending is growing faster or slower than the overall economy. Second, national health expenditures as a percentage of GDP are used to determine whether healthcare spending as a proportion of overall spending is growing over time. National health expenditures as a percentage of GDP have steadily increased in the United States from 7.0% in 1970 to 16% in 2007.

Another important measure of inflation in healthcare in the nation is the consumer price index (CPI). The CPI is an overall measure of average retail price changes over time. Medical care is included as two components of the CPI, measuring medical-care services, including professional medical services, hospital and related services, and health insurance, and medical-care commodities, including prescription drugs and nonprescription drugs and medical supplies. Since the CPI measures inflation for goods and services purchased at the retail level, it is limited to out-of-pocket spending for medical care by consumers and excludes, for example, payments for health insurance coverage by employers and the government.

Factors Driving Inflation

Inflation in healthcare can be caused by factors that are related to either the demand or the supply of a healthcare good or service.

Demand-Side Factors

Demand-side factors associated with escalating healthcare spending include changes in the demographic composition of the population, changes in health insurance coverage, changes in the health status of the population, and general economic conditions (e.g., growth in personal incomes, proportion of the population living in poverty).

Demographics can influence healthcare inflation through changes in age, gender, ethnicity/race,

and geographic region of residence. Older people have a higher prevalence of chronic health conditions and use more healthcare resources than younger people. As the nation's population ages, per capita healthcare spending also increases.

Changes in health insurance coverage influence healthcare inflation by changing the consumer demand for healthcare. Increases in health insurance coverage, through more comprehensive coverage or reductions in consumer cost sharing, reduce prices to the individual consumer and increase demand for healthcare. When managed-care organizations increase provider choice by broadening networks and reducing referral restrictions, per-enrollee spending may also increase. Conversely, shifting more costs to the individual consumer through higher copayments or deductibles, for example, decreases the demand for healthcare.

Although considered as a small component, the health status of the population is another driver of healthcare inflation. Behavioral factors such as obesity, smoking, and a general sedentary lifestyle increase healthcare spending. As a population becomes less healthy, per capita healthcare spending also increases.

Finally, growth in personal income may also drive demand for healthcare. Healthcare is a normal good, meaning that as a consumer's income increases, he or she demands more healthcare services.

Supply-Side Factors

Supply-side factors related to escalating healthcare spending include provider supply, changes in provider operating costs, changes in provider payment mechanisms, and advancements in technology.

Changes in the overall provider supply and a mix of the types of providers is one supply-side driver of inflation. Specialists have been shown to use more expensive technology and resources, while midlevel providers, such as nurse practitioners and physician assistants, may be lower-cost alternatives.

Provider operating costs, including wages, medical malpractice premiums, and other operating expenses, can influence inflation. Continued increases in medical malpractice premiums increase operating costs and also encourage increases in defensive medicine, liability-induced changes in

healthcare goods and services provided to an individual patient as a way of reducing the likelihood of incurring a lawsuit. Malpractice litigation accounts for some of the differences in healthcare inflation between nations that are more versus less litigious. Furthermore, shortages in specific labor markets, such as the nurse labor market, also increase inflation by driving up provider operating costs.

Provider payment mechanisms may also influence inflation. Fee-for-service payment mechanisms encourage overutilization, while capitation-based payment mechanisms encourage more cost-effective utilization.

Technological innovations and improvements, such as new equipment, new medical and surgical procedures, and new pharmaceutical drugs, are another driver of healthcare inflation. New technologies may create demand for care that did not previously exist, may increase demand for treatments that are less invasive or have an improved prognosis over older treatments, and may be more expensive per treatment.

Solutions to Mitigate Inflation

Both supply-side and demand-side interventions have been used to mitigate the continued increases in healthcare prices. In the United States, price controls have been implemented for both hospitals and physicians in an effort to reduce price increases. Medicare uses a prospective payment system (PPS) based on Diagnosis Related Groups (DRGs) to control hospital costs and uses the National Physician Fee Schedule to reimburse physicians for professional services. Many private payers also use variations of Medicare's PPS and physician fee schedule. Managed care has been used as a mechanism to reduce healthcare spending primarily through supply-side incentives such as capitation; primary-care gatekeeper physicians; prospective, concurrent, and retrospective utilization review; second-opinion examinations; and prior authorization requirements.

Future Implications

Strong supply-side incentives to mitigate healthcare spending increases, such as those provided by health maintenance organizations (HMOs), have

waned in recent years. In response to a backlash by providers and consumers to the stringent controls used by many managed-care organizations, incentives to control healthcare spending have shifted to the individual consumer. High-deductible health plans coupled with health saving accounts have been touted by both the federal government and employers as a mechanism to reduce rates of healthcare spending growth by shifting more costs to the individual consumer. It seems likely that such plans will greatly increase in the future.

INFORMED CONSENT

Informed consent is the process by which a provider and patient discuss the merits of a proposed therapeutic intervention, and it serves as a significant component of the provider-patient relationship. Informed consent is neither a signature on a consent form nor a tool to avoid a lawsuit, but rather, it is a communication process. The informed-consent process typically includes a discussion between the provider and the patient to help guide the patient's decision to undergo or forgo a specific treatment or intervention. The informed-consent process is an ethically and legally required discussion that is tailored to the particular needs of the patient and to the specific medical circumstances. Informed consent occurs prior to and separate from documentation of any form. During the informed-consent process, patients also have the opportunity to ask questions so that they have a better understanding of the proposed course of treatment and therefore are able to make an informed decision based on all the risks, benefits, and alternatives. The informed-consent process is a distinct, identifiable, and essential factor of patient care in procedurally based specialties such as surgery. In specialties that are not procedurally based, such as internal medicine, the informed-consent process happens naturally during the provider-patient discussion; it is, however, no less essential to building a trusting relationship.

Informed consent should not be coerced, manipulated, threatened, or induced by fraud. The person with the requisite knowledge and experience to perform the therapeutic intervention and explain the critical elements is required to disclose to the patient the diagnosis, the proposed therapy and the rationale for recommending it, the associated risks and anticipated benefits, the available alternatives, and the consequences of refusing treatment. A competent patient retains the right to refuse appropriate treatment. A strong treatment recommendation by a provider is not, however, considered coercion as long as the recommendation is made to the decision maker.

There are four exceptions to the informed-consent disclosure: (1) in emergent situations when life and/or limb are immediately at risk, (2) if the patient is unconscious or incompetent and no

legally authorized patient representative is available, (3) if the patient declines the right to know the information, and (4) if the provider determines that disclosing the information to the patient would actually cause greater harm. The fourth exception, often called therapeutic knowledge, is discouraged in most healthcare institutions, but it is applied on a regular basis under the guise of paternalistic medicine. This entry highlights the experiences and challenges of the informed-consent process in the United States, the United Kingdom, Canada, and Australia.

Overview

Informed consent is based on the contemporary perception of autonomy, or self-determination, which arose from 17th-century political and legal philosophy. The concept of autonomy in the Australian, Canadian, British, and American medical fields, however, did not surface until major social changes took place in the mid 20th century. The American, Australian, Canadian, and British medical societies finally officially recognized patient autonomy in the 1980s. Despite the British medical community's acknowledgment of a patient's right to autonomy, the British legal system remains disproportionately paternalistic compared with that of the United States, Australia, and Canada.

Recent technological advancements have made information more readily available and accessible. As a result, the widespread dissemination of medical information, written in nontechnical language to be easily understood by those who are not medically trained, has led to a change in patients' overall attitudes toward providers. It has also influenced patients' willingness to accept providers' diagnostic and therapeutic decisions and patients' requests for specific medicinal or procedural interventions. Nonetheless, providers still must provide patients with accurate information and facts to help them make appropriate healthcare decisions; without the expertise of medical professionals, individuals may base decisions on marketing and promotion campaigns. Medicine itself has significantly changed because of these scientific advancements. The general use of anesthesia, for example, makes it impossible to obtain a patient's consent to change a surgical plan at the

exact time a surgeon is legally required to obtain it. Providers are able to diagnose seriously ill patients before the patients themselves know it or feel sick, and the number of therapeutic options to select from has increased exponentially. Thus, proper informed consent in this rapidly changing environment is paramount.

Legal Dimensions of Informed Consent

The advancement of the idea of self-determination forms the legal foundation for informed consent. The legal causes of action related to informed consent are battery and negligence. For example, if a provider touches a patient without that patient's explicit consent, then the provider is considered to have committed an act of battery even if the provider believed that the action was in the best interest of the patient. If, however, the provider touched the patient in the exact way in which the patient had consented but failed to provide the patient with pertinent information that the patient considers necessary to decide whether to consent, then the provider is considered to have committed an act of negligence.

The United Kingdom and the United States have long recognized the legal and ethical obligation for informed consent. Comparatively, in Canada and Australia, informed consent is a relatively new concept. Battery was the leading cause of action in the United States and United Kingdom until 1957, when jurists began to hold that negligence was the appropriate cause of action for an alleged breach of a physician's duty to care, specifically the duty to disclose information to patients. However, Canada and Australia base the causes of action on the premise of negligence.

Two legal standards exist for disclosure of information to patients: the professional standard and the reasonable-person standard. The professional standard states that a provider must disclose information that is usually made available by the medical profession. British courts have exclusively used the professional standard. On the other hand, the reasonable-person standard states that a provider must disclose information as to what a reasonable person in the patient's position would want to know in order to decide whether to undergo or forgo a therapeutic procedure or intervention. The reasonable-person standard is

used solely by the Australian judiciary. Canada uses the professional standard with regard to diagnosis only and the reasonable-person standard for disclosure of material information. The United States also uses both the professional standard and the reasonable-person standard. Judicial preference in the United States, however, is clearly for the reasonable-person standard. Successful lobbying by the medical profession resulted in 25 state legislatures enacting professional-standard statutes.

Defenders of the professional standard, independent of country, argue that the standard is consistent with a provider's obligation to provide care in the patient's best interest by providing him or her with the latitude to decide what information to share. The provider, because of his or her medical knowledge and training, is more qualified to make medical decisions for the patient and to determine what information will only serve to confuse or scare the patient. Proponents of the reasonable-person standard, however, argue that this other standard reconciles the tension between a provider's duty to disclose information and a patient's right to make an informed decision with regard to his or her healthcare. The patient cannot make an informed decision without the provider at least providing a modicum of material information. Patients look to providers for guidance, advice, and information that they feel is necessary to decide whether to trust the provider enough to voluntarily agree to consent to the therapeutic intervention. Many have argued that the professional standard is no longer viable and that the reasonable-person standard better serves patients' needs.

Australia and Canada have based their standards for disclosure and causes of action on the legal precedence set in the United States and the United Kingdom. Although there is some indication that Australian, Canadian, and U.S. legal decisions are influencing the beliefs of the British judiciary, currently the English system remains steadfastly wedded to the professional standard for disclosure.

Impact of Healthcare Delivery and Cost

From a delivery-of-care and healthcare systems perspective, engaging in the informed-consent

process requires financial resources and organizational oversight. In the United Kingdom, Australia, and Canada, the healthcare system bears the cost of the provider's time devoted to informing patients. In the United States, the ethical and legal obligation to engage in the informed-consent process approximates to an unfunded mandate as both patients and providers bear the cost. The major healthcare insurance plans do not allow providers to bill for informed-consent discussions, leaving providers to incorporate the discussion into other billable procedures. This practice often causes the discussion to be rushed and/or incomplete. It also means that a provider may delegate the obligation to obtain informed consent to an individual who does not possess the same amount of knowledge of and experience with the therapeutic intervention, resulting in the patient receiving inadequate or incorrect information.

As with financial resources, the United Kingdom, Australia, and Canada have a centralized process for making decisions regarding informed consent. Administrators and providers collaborate to decide on the minimum amount of information that must be disclosed to the patient. In the United States, however, the process is decentralized. It is left to the individual organization or provider to discern which standard for disclosure to follow in order to provide the legally required minimum amount of information to patients.

Impact on Public Health

Informed consent not only affects the individual patient, but it also has profound effects on public health. Through informed consent, providers can engage patients in discussions to prevent and manage chronic diseases and help patients understand the consequences that these diseases have on their health and lifestyles. Providers can also protect the spread or reemergence of infectious disease by reminding patients of the cost of complacency about vaccination. They can also help patients avoid resistance to medications, as well as prevent early mortality, by taking joint responsibility for patient compliance. Finally, providers can rebuild and strengthen the social contract that the medical profession has with the community and with the individual patient.

Future Implications

As greater emphasis is placed on patient autonomy, providers must find a method of reconciling the ethos of paternalism with the patient's right to self-determination. The medical community, not jurisprudence, must take responsibility for developing an informed-consent doctrine that acknowledges and respects patient autonomy while simultaneously supporting the authority of the provider in diagnosis and treatment. This goal can be accomplished through shared decision making and acknowledging the limits of scientific knowledge.

Understanding the degree and accuracy of information communicated during the informed-consent discussion and enhancing the process will benefit both public health and patient care. By viewing informed consent as a therapeutic component of patient care, the provider shows respect for the patient, engages the patient as an active participant in healthcare decisions, improves the patient's understanding of the risks associated with certain behaviors, and increases compliance with suggested medical therapies. This partnership enables the provider to address the patient's concerns at the appropriate time and to build a foundation of trust. The trend toward an increased deference for patient autonomy is growing in the United States, Canada, Australia, and even the United Kingdom.

INNER-CITY HEALTHCARE

Almost half of the world's population resides in an urban area, where some of the most pressing social problems include poverty and pollution. The rapid urbanization of regions has resulted in the need to address a variety of social issues, ranging from poverty, sanitation, and healthcare to education, housing, and family planning.

The inner city is generally characterized as an area of a city where there are a disproportionate number of unemployed or low-pay individuals, single parents, and sick or disabled persons living in poor housing conditions. Inner-city healthcare is a multifaceted issue that relates to the health disparities that exist within the poorer and more densely populated areas of a city. Individuals who reside within the inner city often experience inequalities in health due to lower socioeconomic status, job loss, and various health problems. The health issues of the inner city involve a complex and myriad set of interactions between socioeconomic, behavioral, and environmental factors that relate to race and ethnicity. Some of the most prevalent public health threats in the inner city include homelessness, substance abuse, mental illness, HIV/AIDS and tuberculosis transmission, violence, and pollution. The public policies of an

area can also exacerbate the health conditions of the inner city by not providing adequate housing, social welfare, and access to healthcare. It has been posited that the health problems that evolve in the inner city may also spread to other urban, suburban, and even rural areas. As a result of these consequences, a multifaceted approach is needed to improve the overall health status of inner-city residents.

Overview

The issue of poverty is at the crux of the poor state of health of the inner city. The link between socioeconomic status and health has been previously demonstrated. Poverty is related to poor health, by the barriers created in accessing preventive healthcare, proper nutrition, and housing, as well as to higher mortality rates. Poverty has also been associated with higher rates of violence, child abuse, and familial and community deterioration. There is also some emerging evidence to suggest that the disparity in the distribution of income within states has adverse effects on health, and therefore the distribution of income may be a predictor of the health status of a society.

The phenomenon of an urban health penalty has been used by the American College of Physicians (ACP) to describe the situation when healthier and more affluent residents leave a city and the residents who remain encounter serious health problems that interact with the physical and economic decline of a city. Generally speaking, disproportionate numbers of racial and ethnic minorities inhabit these inner-city areas, which are characterized by economic decay and a multitude of health problems. The issues related to urban health are the consequence of a complex set of interactions between behavioral, socioeconomic, and environmental factors.

Inner cities are challenged by the issues of cost, quality, and access to healthcare, much like the larger U.S. healthcare system. These issues, however, are magnified in inner-city areas because of scarce resources and stresses on the system. Because of this, inequalities and injustices in the health of inner-city residents are readily apparent. The health problems of the inner city include a range of chronic and acute illnesses, such as substance abuse, violence, teenage pregnancies, HIV/AIDS,

sexually transmitted diseases (STDs), mental illness, infant mortality, asthma, tuberculosis, and diabetes. The determinants associated with these health problems are poverty, poor nutrition, lack of adequate housing, violence, and the dearth of social services. The lack of access to appropriate healthcare facilities also exacerbates the problems in these areas. Studies have found that there are differences in preventable hospital admissions between high- and low-income areas throughout the United States. Furthermore, even individuals with universal access to healthcare from Medicare still experience differences in health outcomes. A study by Marian Gornick and colleagues comparing Whites and Blacks found that Blacks and lower-income individuals received fewer preventive services, such as immunizations and screenings, and experienced higher mortality rates. Another study by C. McCord and H. P. Freeman found that the mortality rate in Harlem, New York, is higher than that of the developing country of Bangladesh, which is characterized as having one of the lowest incomes in the world. Additionally, this study found that the survival rate of males beyond the age of 40 is lower in Harlem than in Bangladesh. The reasons cited as the cause of the higher mortality rate in Harlem include cardiovascular disease, diabetes, influenza, homicide, and drug dependency.

Even in egalitarian countries such as Canada, where it is assumed that disparities are nonexistent because of universal access to healthcare, inequalities in health outcomes still remain. A study by David Alter and colleagues found that residents in Ontario from the wealthiest neighborhoods received 23% more coronary angiograms and had 45% shorter waiting time to receive an angiogram than those from the poorest neighborhoods. The authors also found an inverse relationship between mortality 1 year after myocardial infarction and income.

Violence

Violence has been cited as a major cause of morbidity and mortality among young adults and adolescents. Studies have shown that youths in the inner city are often exposed to violence. Violence in these communities can lead to the destruction of social relationships and cause social disarray.

Individuals who engage in violent acts are more likely to be of a lower socioeconomic status and have been physically abused. Violence can have an adverse effect on the mental health of young individuals residing in the inner city and may result in suicidal ideation, posttraumatic stress disorder, and depression.

Mental Illness

Mental illness is one of the major health problems confronting the inner city. One study by P. Koegel and colleagues estimated that 28% of homeless individuals in Los Angeles's Skid Row were chronically mentally ill. Compared with a household sample, the rates of major mental illnesses in this cohort were disproportionately high for every mental disorder examined. Additionally, the rates of substance abuse and schizophrenia were higher among those who were repeatedly homeless or were homeless for longer periods of time.

Asthma

Residents who are poor and reside in certain urban areas and are predominantly racial/ethnic minorities are at greatest risk of developing asthma. The association between living in certain urban neighborhoods and a disproportionate risk of developing asthma has only recently been recognized. Studies have highlighted the geographic variation in asthma deaths in the United States and found that children and young adults who reside in urban areas have significantly higher death rates. On closer examination, it has been found that the death rates from asthma in urban areas are concentrated within the inner-city areas, where poverty is also high. Blacks are reported to have higher rates of asthma at all ages than Whites. A strong correlation is indicated between socioeconomic status and prevalence of asthma. Studies have shown that socioeconomic status is a major factor in the disproportionate burden of inner-city asthma. The living environment, which is highly correlated with socioeconomic status, plays a large role in asthma prevalence. Exposure to pollutants in the living environment may result in the onset of asthma. Family structure and dysfunction may also have a role in asthma morbidity and management.

HIV/AIDS

HIV is another public health concern in the inner city. A variety of risk factors and the lack of healthcare facilities contribute to the high prevalence of HIV in these areas. The use of alcohol and cocaine, particularly crack, has been linked to the spread of STDs and HIV in the inner city. Crack use is thought to contribute to the heterosexual transmission of HIV. Injection drug users are also at risk for HIV transmission by sharing contaminated needles. Men who have sex with men and commercial sex workers also present themselves as potential risk factors for HIV transmission. Given these numerous risk factors, HIV prevalence remains high in the inner city.

Nutrition

The lack of access to fresh food and produce intertwined with the issue of poverty in the inner city results in the poor nutritional status of inner-city residents. Research on an elderly inner-city population found that these residents are at high nutritional risk and lacked resources to pay for food, had poor food intake, and were unable to prepare food. Furthermore, childhood obesity is becoming a major problem among inner-city children. The lack of physical activity and lack of nutritious foods have been cited as the cause of this condition.

Research in the Inner City

Participation by community members is essential to build lasting public health interventions in the inner city. In 1995, the U.S. Centers for Disease Control and Prevention (CDC) established three urban research centers (URCs) to improve the health and quality of life of urban residents in New York, Detroit, and Seattle. The aim of this project was to develop collaborative partnerships among researchers, academics, private and public partners, and community members to create sustainable and effective interventions through community-based participatory research. Through its preliminary work, the URCs established research priorities, acquired core funding, and raised their ability to conduct community-based research. Some of the initial challenges experienced by the URCs included gaining the trust of the community, balancing power, acquiring resources, and

developing effective interventions. The problems common to all the URCs included institutional racism, time constraints, and distribution of resources. Despite these challenges, the work of the URCs resulted in collaborative partnerships, public health programs, and institutional capacity to carry out community-based participatory research in urban areas.

Short-Term Solutions

Addressing the widespread health problems of the inner city poses many formidable challenges and requires a multifaceted and broadly sweeping approach, from primary prevention to specialized and acute care. Changing urban policy to address the root cause of poverty is necessary to mitigate the health problems faced by these communities. As a first step, the link between socioeconomic factors and health status must be recognized to improve the health of inner-city residents. Furthermore, the healthcare delivery system in these areas must be improved by addressing the issues of coverage, providers, and public health. Adequate healthcare coverage must be made available for inner-city residents to access the healthcare system. The Medicaid safety net is an important part of securing access to healthcare for the low-income and vulnerable populations.

Primary-care providers are also an essential component in delivering healthcare to inner-city residents. One of the biggest shortcomings of the healthcare system is the limited number of primary-care providers who practice and deliver care to the urban poor and the decline of office-based primary care in these underserved areas.

The inner city is also plagued by some of the most pressing public health problems, including tobacco use, substance abuse of alcohol and drugs, teenage pregnancies, and violence. The most effective solutions to addressing these problems go well beyond the biomedical model, and it must include the public health approach of primary prevention and education. The environmental context of the inner city, including housing, unemployment, pollution, and violence, must also be properly addressed. These initiatives require collaboration among the government, healthcare providers, communities, and individuals.

The reform and changes to the Medicaid program in the late 1990s have also made it more difficult for the neediest citizens, particularly those who live in the inner cities, to receive needed healthcare. Medicaid managed care and the restriction of providers who can participate in the program have proved to be a challenge. Furthermore, the welfare reform bill, Temporary Assistance for Needy Families (TANF), has made it more cumbersome for needy individuals to receive welfare assistance and food stamps. Nutrition programs are a vital component of the safety net for the urban poor, especially children.

Future Implications

The United States has the most advanced medical technologies available, yet the health of its inner-city residents remains poor. Healthcare reform has been tremendously difficult to achieve, and programs targeting the underserved, including the urban poor, have been minimal. As the federal government continues to reduce funding, the states will have greater responsibility for caring for their most marginalized citizens living in the inner city. It is likely that initiatives targeting the health of inner-city residents will continue to be advocated in the years to come.

INSTITUTE FOR HEALTHCARE IMPROVEMENT (IHI)

The Institute for Healthcare Improvement (IHI) is an independent, nonprofit organization helping to lead the improvement of healthcare throughout the world. Founded in 1991 and based in Cambridge, Massachusetts, the IHI works to accelerate improvements by building the will for change, cultivating promising concepts for

improving patient care, and helping healthcare systems put those ideas into action. Employing a staff of approximately 100 individuals and maintaining partnerships with hundreds of faculty members, the IHI offers comprehensive programs that aim to improve the lives of patients, the health of communities, and the joy of the healthcare workforce.

Background

Healthcare is a highly complex system, vastly underperforming its potential. The gap between what healthcare achieves today and what it could achieve at the same or lower cost is so large that the National Academy of Sciences, Institute of Medicine (IOM), declares it a “chasm.” Crossing this chasm will require massive change. There are examples of excellence—organizations that have overcome obstacles and redesigned patient care. The challenge is to make these examples the rule, not the exception, so that all patients reliably receive the best care possible.

The IHI was formed to help healthcare cross the quality chasm—to shepherd a growing movement of healthcare leaders trying to find alternatives to the status quo.

Organizational Goals

Improving healthcare is the IHI’s fundamental mission and daily work. The institute has adapted its goals from the IOM’s six improvement aims for the healthcare system: care that is (1) safe, (2) effective, (3) patient centered, (4) timely, (5) efficient, and (6) equitable. The IHI calls this the No Needless List, which includes the following: no needless deaths, no needless pain or suffering, no helplessness in those served or serving, no unwanted waiting, no waste, and no one left out.

The IHI seeks to accelerate the measurable and continued progress of healthcare systems toward these bold objectives, leading to breakthrough improvements that are truly meaningful in the lives of patients. The institute accomplishes this by building the will for change, cultivating innovative improvement ideas, and helping healthcare systems put those ideas into action.

Learning System

The IHI’s programs and activities connect people from across the world in an ever-evolving learning system, based on a philosophy of “all teach, all learn.” This system enables committed individuals and organizations to collaborate on improving healthcare—because it is far easier to improve together than it is to do it alone. The system includes four components: (1) innovation, (2) strategic relationships, (3) learning opportunities, and (4) knowledge of the world.

Innovation

At the center of the institute’s work is the creation and testing of new ideas—novel concepts for improving patient care. The IHI collaborates with a handful of cutting-edge organizations, on a project basis, to test new solutions on old problems through research and development that drive the organization’s work.

Strategic Relationships

Once a promising change concept has been successfully developed in one setting, it needs to be fully vetted and piloted in other settings. The IHI maintains a variety of closely aligned strategic relationships, with dozens of organizations, that test and deploy these changes. The most common types of relationships are strategic partnerships, the International Management Package for Administration of Clinical Trials (IMPACT), and learning and innovation communities.

Strategic partnerships are high-level relationships focused on transforming entire systems of care by concentrating on strategic objectives and system-level improvement. In addition to working closely with several major healthcare systems in the United States, the IHI is also involved in strategic-level efforts with providers in the United Kingdom, Sweden, Malawi, and South Africa.

IMPACT is the IHI’s membership network for change, where healthcare organizations come together to achieve dramatic improvement results in clinical outcomes, patient and provider satisfaction, and financial performance. More than 200 quality-minded organizations participate in change initiatives that combine a leadership agenda with a focus on frontline improvement and measurement.

Learning and innovation communities are collaborative change laboratories focused on frontline improvement. Participating organizations work with each other and with IHI faculty to rapidly test and implement meaningful, sustainable change within a specific topic area. Learning and innovation communities are the “next-generation” evolution of the Breakthrough Series, the IHI’s traditional methodology for collaborative improvement.

Learning Opportunities

The IHI offers a wide variety of opportunities for healthcare professionals to learn from expert faculty and experienced colleagues across the world. Some of its learning opportunities include the following: conferences and seminars, Web-based programs, and professional development programs.

The IHI’s annual National Forum is widely viewed as the premier meeting place for people committed to the mission of healthcare improvement. The institute also presents an annual conference on clinical office practice improvement and offers seminars on various quality-related topics.

The institute’s Web programs create opportunities for organizations and individuals to learn and implement best-practice ideas through a series of Web seminars. A variety of online presentations and teaching modules are also available on the IHI’s Web site.

The IHI’s professional development programs are designed for leaders who seek to gain a particular set of skills that are required for an organization to succeed in its improvement agenda. Programs include training for board members, patient safety officers, improvement advisors, operations managers, as well as others involved in critical roles.

Knowledge for the World

The final step in the IHI learning system is the broad dissemination of best-practice improvement knowledge. This is done primarily through various campaigns, IHI.org, professional education, and the institute’s fellowship programs.

In line with many other patient safety programs, the “100,000 Lives Campaign” was a national initiative to drive widespread adoption of six important patient safety practices in U.S. hospitals

between December 2004 and June 2006. Approximately 3,100 hospitals in the nation joined in that effort. Building on this momentum, the institute initiated the “5 Million Lives Campaign,” which aimed to help even more hospitals prevent 5 million incidents of medical harm. The campaign ran between December 2006 and December 2008.

The institute’s online resource, www.IHI.org, contains a wealth of improvement information and tools—available free of charge to anyone, anywhere, whose aim is to improve healthcare.

Through the institute’s Health Professions Education Collaborative (HPEC), academic leaders from dozens of schools of medicine, nursing, pharmacy, and health administration work together to integrate quality improvement into their curricula, so that tomorrow’s health professionals are better prepared to drive this agenda forward.

Last, the IHI’s fellowship programs help equip healthcare leaders with the drive, skills, and experience to spread improvements in the United States and globally. The fellowship programs are sponsored by the George W. Merck family, the Health Foundation, and the Commonwealth Fund. Fellows spend 1 year at IHI, creating a custom-designed education plan and participating in a variety of strategic initiatives.

INSTITUTE OF MEDICINE (IOM)

The 21st century has brought with it a number of complex health problems, including childhood obesity, the threat of pandemic influenza, limited healthcare access and quality, and questions regarding vaccine and drug safety. When developing policies and strategies for coping with these challenges, the nation often turns to the Institute of Medicine (IOM) of the National Academies for advice. Since 1970, when it was created as part of the congressionally chartered National Academy of Sciences, the IOM has functioned as a unique, independent source of unbiased, evidence-based, and authoritative information on matters involving medicine and public health. Through its work, the IOM serves as an advisor to the nation in its endeavor to improve health.

Background

In 1863, President Abraham Lincoln signed the congressional charter that created the National Academy of Sciences, a nongovernmental institution with two aims: to honor top scientists through membership and to investigate, examine, experiment, and report on any subject of science or technology whenever called on to do so by any department of the government.

Since its inception, the Academy has grown to include four distinguished organizations: the National Academy of Sciences, the National Research Council, the National Academy of Engineering, and the IOM. Now known collectively as the National Academies, these four organizations perform unparalleled public service by bringing together experts in all areas of scientific and technological endeavor. These organizations draw on leading national and international experts, both elected members and others, who serve as volunteers without compensation.

The Institute's Work

The IOM provides health-related policy advice in several different forms: written reports reflecting the consensus reached by an expert study committee, symposia and convocations engaging large audiences in the discussion of national issues, summaries and proceedings from conferences and workshops, or "white papers" on policy issues of special interest. Key activities include consensus studies, convening activities, and fellowships.

Consensus Studies

The majority of the institute's work centers on rigorously reviewed consensus studies. Consensus studies are conducted by committees whose members serve without compensation. Each committee's report is subject to rigorous peer review, and all are made public. Consensus studies are managed by one of eight oversight boards of the institute. Depending on the statement of task for the project, studies may be narrow in scope, designed to answer very specific and technical questions, or they may be broad-based examinations that span myriad academic disciplines, industries, and even international borders.

Federal agencies are the primary financial sponsors of consensus studies. However, additional studies are funded by state agencies, foundations, other private sponsors, and the institute itself. The institute provides independent advice; the external sponsors have no control over the conduct of a study once the statement of task and budget are finalized. Study committees gather information from many sources in public meetings, but they carry out their deliberations in private to avoid political, special interest or sponsor influence.

Through this careful study process, the IOM produces approximately 40 reports each year. Many of the reports influence policy decisions; some are instrumental in enabling new research programs; others provide program reviews. The institute may also conduct dissemination workshops to discuss the conclusions and recommendations made by certain committees. Recent institute studies include examinations of the U.S. Food and Drug Administration's role in monitoring and improving drug safety, the recent progress made by obesity prevention initiatives, and ways to reduce

the incidence and cost of medication errors in the nation.

Convening Activities

In addition to its consensus studies, the institute strives to stimulate candid, evidence-based dialogue about key issues through workshops, roundtables, and forums. These convening activities allow government, industry, academic, and other representatives to meet and confer privately on subject areas of mutual interest. These meetings may inform the members about critical issues or provide an opportunity to plan formal institute committee studies. Examples of forums and roundtables include the National Cancer Policy Forum, the Forum on Neuroscience and Nervous System Disorders, the Roundtable on Health Literacy, and the Roundtable on Environmental Health Sciences, Research, and Medicine.

Fellowships

The IOM also advances the field of health services research by hosting three fellowship programs. The Robert Wood Johnson Health Policy Fellowship Program provides an opportunity for outstanding midcareer health professionals to gain an understanding of the health policy process, contribute to the formulation of new policies and programs, and develop in their careers as leaders in academic health centers and in health policy.

The institute's Anniversary Fellows Program provides early-career biological, social, and clinical scientists the opportunity to actively participate in the institute's work. During this 2-year fellowship, the fellows continue their work at their main academic posts while being assigned to a board of the institute. Fellows also participate actively in the work of an appropriate expert study committee or roundtable, including contributing to its reports or other products.

The Distinguished Nurse Scholar Program aims to assist nurses in playing a more prominent role in health policy at the national level. While in the program, each scholar is asked to produce a policy-oriented paper or become actively involved in the institute's work, relevant to his or her area of expertise.

The Institute's Members

The IOM's members are elected on the basis of their professional achievements. By becoming members, these experts commit to serving the institute, without compensation, through a number of different avenues, including (a) serving on a study committee, board, roundtable, or forum; (b) participating in a workshop or expert-level meeting; (c) taking part in an interest group; (d) serving on the institute's council; or (e) reviewing or coordinating reports.

The bylaws of the institute specify that no more than 65 new members and 5 foreign associates shall be elected annually. The announcement of newly elected members occurs at the institute's annual meeting in October. The number of regular members plus foreign associates and emeritus members is currently about 1,500.

An unusual diversity of talent among institute members is ensured by the charter stipulation that at least one quarter of its members be selected from outside the health professions, from fields such as the natural, social, and behavioral sciences, as well as law, administration, engineering, and the humanities.

The IOM is governed by the institute's council, which consists of the council president and 20 members elected to 3-year terms. The council provides policy guidance in addition to approving the annual program plan and fiscal-year budget. All proposals for new and revised projects are reviewed and approved by the 5-member executive committee of the council.

The Study Process

The consensus reports of the institute are viewed as being valuable and credible because of the institution's reputation for providing independent, objective, and evidence-based advice, with high standards of scientific and technical quality. Checks and balances are applied at every step in the process to protect the integrity of the reports and to maintain public confidence in them. The study process consists of four major stages: (1) defining the study; (2) committee selection and approval; (3) committee meetings, information gathering, deliberations, and drafting of the report; and (4) report review.

Stage 1: Defining the Study

Before the committee selection process begins, the institute's staff and members of their boards work with sponsors to determine the specific set of questions to be addressed by the study in a formal "statement of task," as well as the duration and cost of the study. The statement of task defines the scope of the study, and it serves as the basis for determining the expertise and the balance of perspectives needed on the committee. The statement of task, work plan, and budget must be approved by the executive committee of the institute's council and by the governing board of the National Research Council.

Stage 2: Committee Selection and Approval

Selection of appropriate committee members is essential for the success of a study. All committee members serve as individual experts, not as representatives of organizations or interest groups. Each member is expected to contribute to the project on the basis of his or her own expertise and good judgment. A committee is not finally approved until a thorough balance and conflict-of-interest discussion is held at the first meeting and any issues raised in that discussion or by the public are investigated and addressed.

Careful steps are taken to convene committees that meet the following criteria: an appropriate range of expertise for the task, a balance of perspectives, screening for conflicts of interest, and other considerations. The committee must include experts with the specific expertise and experience needed to address the study's statement of task. One of the strengths of the institute is its tradition of bringing together recognized experts from diverse disciplines and backgrounds, who might not otherwise have been able to collaborate. These diverse groups are encouraged to conceive new ways of thinking about a problem.

Merely having the right expertise is not sufficient for success. It is also essential to evaluate the overall composition of the committee in terms of different experiences and perspectives. The goal is to ensure that the relevant points of view are, in the institute's judgment, reasonably balanced, so that the committee can carry out its charge objectively and credibly.

All provisional committee members are screened in writing and in a confidential group discussion about possible conflicts of interest. For this purpose, a conflict of interest means any financial or other interest that conflicts with the service of the individual, because it could significantly impair his or her objectivity or could create an unfair competitive advantage for any person or organization. The term *conflict of interest* means something more than just individual bias. There must be an interest, often financial, that could be directly affected by the work of the committee. Except for those rare situations in which the institute determines that a conflict of interest is unavoidable and promptly and publicly discloses it, no individual can be appointed to serve on a committee of the institute used in the development of reports if the individual has a conflict of interest that is relevant to the functions to be performed.

Membership in the IOM and previous involvement in National Academies studies are taken into account in committee selection. The inclusion of women, minorities, and young professionals is an additional consideration.

Stage 3: Information Gathering and Drafting of the Report

Study committees, typically, gather information through meetings that are open to the public and announced in advance through the institute's Web site, submission of information by outside parties, reviews of the scientific literature, and investigations of the committee members and staff. In all cases, efforts are made to solicit input from individuals who have been directly involved in or who have special knowledge of the problem under consideration.

In accordance with federal law and with few exceptions, information-gathering meetings of the committee are open to the public, and any written materials provided to the committee by individuals who are not officials, agents, or employees of the institute are maintained in a public access file that is available for examination.

The committee deliberates in meetings, closed to the public, to develop draft findings and recommendations free from outside influences. The public is provided with brief summaries of these meetings that include the list of committee members

present. All analyses and drafts of the report remain confidential.

Stage 4: Report Review

As a final check on the quality and objectivity of the study, all IOM reports—whether products of studies, summaries of workshop proceedings, or other documents—must undergo a rigorous, independent external review by experts, whose comments are provided anonymously to the committee members. The institute recruits independent experts with a range of views and perspectives to review and comment on the draft report prepared by the committee.

The review process is structured to ensure that each report addresses its approved study charge and does not go beyond it, that the findings are supported by the scientific evidence and arguments presented, that the exposition and organization are effective, and that the report is impartial and objective.

Each committee must respond to, but does not need to agree with, reviewer comments in a detailed “response to review.” If the reviewer comments are not agreed with and incorporated, the committee must explain clearly its reasons for disagreeing. The response to review is examined by independent report review monitors responsible for ensuring that the report review criteria have been satisfied. After the report has cleared review and all the committee members have signed off on the final report, it is transmitted to the sponsor of the study and is released to the public. The National Academies retains the copyright to all its products. Sponsors are not given an opportunity to suggest changes in reports. The names and affiliations of the report reviewers are made public when the report is released.

INTENSIVE-CARE UNITS

Intensive-care units (ICUs) are specialized units within hospitals that are designed to provide care for critically ill or injured patients. ICUs, typically, have specialized medical equipment and staff to provide continuous care to patients 24 hours a day, 7 days a week. The units also generally have the ability to monitor patients’ cardiovascular, respiratory, and renal functions as well as neurological status. The establishment of ICUs has made care for the sickest patients possible through the use of these advanced medical technologies. Some hospitals maintain multiple ICUs, each designed to handle specific conditions or age groups. For example, neonatal intensive-care units (NICUs) care for infants, pediatric intensive-care units (PICUs) care for children, and cardiac-care units (CCUs) care for heart attack patients. A burn unit in a hospital is also considered an ICU, or a critical-care unit. Patients who may benefit from intensive care include heart attack and stroke patients, victims of multiple trauma or disasters, individuals who require mechanical ventilation, and complicated-surgery patients.

The design of the ICU allows medical staff to monitor their patients closely. Many ICUs are designed so that physicians and nurses can see the patients at all times, either with a direct line of sight or through the use of video monitors. The floor plans dictate adequate traffic flow and use of workspace.

The specialized work that occurs in ICUs saves many lives each year. Healthcare professionals in the ICU possess advanced medical skills that allow them to care for critically ill and injured patients. In addition to providing specialized medical care, ICU staff must be prepared to communicate effectively with family members and support end-of-life decisions.

Overview

The concept behind ICUs has a long history. Florence Nightingale (1820–1910), while serving as a nurse during the Crimean War, separated out the severely injured soldiers from those with minor injury or illness; this practice of triaging allowed the nurses to monitor the seriously wounded patients more closely. During the polio epidemic in the 1940s and 1950s, patients required continuous surveillance and assistance. As a result, many specialized units were established at hospitals to provide these patients with the appropriate care they needed. William Mosenthal, a surgeon at Mary Hitchcock Memorial Hospital in Lebanon, New Hampshire, is credited with establishing the first ICU in the United States (in 1955) that coordinated nursing care and the use of medical equipment in one place for critically ill patients. Today, ICUs are the standard of care for patients with life-threatening diseases and injuries.

Medical Team

The ICU medical team is composed of clinicians from a variety of disciplines, including physicians, nurses, respiratory therapists, pharmacists, and other allied health professionals. These staff members work together to provide advanced medical care to patients. The medical team receives advanced training and possesses specialized skills to care for critically ill patients.

Intensive-care specialists, called intensivists, are board certified in a specialized area, such as surgery or internal medicine, and they have received

additional training and certification in critical care. While open ICUs allow for any attending physician with admitting privileges at the hospital to serve as the physician of record and to direct the patient's care, closed ICUs require that an intensivist serve as the physician of record.

ICU nurses, known as critical-care nurses, also play an important role in patient services and the delivery of care. Often, two nurses staff a single patient in the ICU. This ratio enables the nurses to keep a close watch on patients, and often, they serve as the primary contact with the patient's family. Experienced ICU nurses are able to recognize changes in patient conditions and respond quickly by alerting the attending physician.

Medical Equipment

Typical medical equipment found in ICUs includes monitors, tubes, and ventilators. Monitors are designed to measure a patient's vital functions, such as heart rate, blood pressure, oxygen saturation, and respiration. Intravenous lines (IVs) provide medicine, fluids, and nutrition through a patient's veins; urinary catheters remove urine from the patient's bladder; and nasogastric (NG) tubes, which can be inserted into the patient's nostrils and through the back of the throat into the esophagus and stomach, provide nutrition. Respirators, or ventilators, assist a patient's breathing with the insertion of a tube through the mouth or nose and into the patient's windpipe.

Patients and Medical Conditions

Patients are usually admitted to the ICU from other units within the hospital, such as the emergency department or surgical areas. For example, once trauma patients are stabilized in the emergency department, they are sent to the ICU for advanced care. Surgical patients may be sent to the ICU for care and recovery if an advanced or critical surgery has been performed or if the patient experiences complications following the operation. Critical illnesses such as heart attacks, poisoning, and pneumonia are other examples of conditions that may lead to admission to an ICU.

Many ICU patients require special assistance with bodily functions as a result of severe respiratory disease. Conditions such as chronic obstructive

pulmonary disease (COPD) or pneumonia weaken the lungs, and patients admitted with these conditions often require assistance with breathing.

Once admitted to the ICU, the risk of developing other problems increases for the patient. Infections may develop as the patient's immune system may be in a weakened state due to an existing illness. Common infections in ICU patients include blood infections due to IVs and urinary tract infections (UTIs) due to urinary catheters. Antibiotics and/or the removal of the tubes may be necessary to treat these infections.

Many patients require sedation so that they do not try to remove the tubes or other equipment. Heavy sedation slows a patient's natural physiologic breathing mechanism and may lead to the use of intubation and ventilators, and may slow the patient's recovery.

ICU patients are also at risk of organ failure. Patients may be admitted with problems in one area of their body, but if recovery is slow, other organs and bodily functions may be affected.

Life Support and End-of-Life Issues

Decisions about life support and end-of-life issues are not uncommon for ICU patients and their families, as patients present with life-threatening illnesses. Medical teams and families often face decisions about when to turn off life support. End-of-life issues may arise after a long-term effort to prolong the patient's life indicates no hope for recovery, or they can emerge quickly following the rapid deterioration of the patient's health. Physicians may face ethical decisions about ending a patient's suffering or abiding by the family's wishes.

ICU staff work within the scope of both curative care and palliative care. Curative care refers to the effort to do everything possible to assist the patient's recovery. Palliative care refers to the effort to make the patient as comfortable as possible and allow death to occur naturally.

INTERMEDIATE-CARE FACILITIES (ICFs)

Intermediate-care facilities (ICFs) are a type of care facility for individuals such as the elderly, not acutely ill, mentally ill, or disabled, who are not able to live independently but do not require constant care. Thus, ICFs provide services to patients with health conditions that do not necessarily require hospitalization or skilled nursing care but present a need for subacute care. Intermediate care is generally provided to patients who are medically stable but are not stable enough to be treated in other healthcare settings such as in a long-term care facility, at home, or on an outpatient basis. ICFs are generally a location for patient recuperation or

rehabilitation following an acute episode or a place for the chronically ill to receive care to avoid inappropriate hospitalizations.

The term *intermediate care* implies that the care is provided on a transitional basis, as if moving from one level of care to another. Therefore, intermediate care may refer to the services provided to the patient during the transition stage between hospitalization and home and from needing acute medical attention to being functionally independent. Patients of ICFs generally receive 24-hour care from a multidisciplinary team of health professionals. Some ICFs may resemble nursing homes, providing services in a residential setting, while others may also care for the elderly. ICFs may offer medical, social, and support services to patients; however, the focus of these facilities is on rehabilitating individuals so that they are able to regain the functions of independent daily living and return to a home setting.

Although there are ICFs that treat people with various health conditions, including the acutely and chronically ill, this entry focuses on ICFs for people with mental illness and developmental delays. ICFs for the Mentally Retarded (ICF/MR) in the United States are certified by the Centers for Medicare and Medicaid Services (CMS) and state Medicaid programs. The care provided at these facilities is an optional benefit for Medicaid clients who qualify. The program was originally established in 1971 as a result of federal legislation.

Overview

When a patient is referred to an ICF/MR facility, the ICF/MR team diagnoses the conditions, manages treatment, and offers rehabilitative services for mentally retarded and developmentally disabled individuals. The ICF/MR services are provided in a safe environment and aim to assist individuals in reaching their full potential. Most of the ICF/MR facilities are designed as group homes, serving anywhere from 4 to 15 individuals at a time. Originally, these facilities served larger numbers of clients, with residential populations of up to 200 or more. Smaller-sized facilities, however, allow for more individualized attention and increased quality of care. The majority of ICF/MR facilities are privately operated as state governments have closed many publicly operated ICF/MR facilities over the

past few decades. These facilities serve residents with severe mental retardation or developmental disabilities, in contrast to clients accessing other types of residential programs.

ICF/MR facilities must meet specific guidelines to receive Medicaid reimbursement and maintain their certification. Facilities must be licensed according to state and local law, and they must maintain specific staff-to-resident ratios, depending on the severity of client conditions. Those ICF/MR institutions serving residents with severe physical disabilities or clients who exhibit combative or psychotic behavior must have a staff-to-client ratio of 1 to 3.2. When working with clients who have moderate retardation, the staff-to-client ratio should be 1 to 4. Guidelines require that the staff-to-client ratio must be 1 to 6.4 for facilities that serve clients with mild retardation.

ICF/MR facilities maintain a safe and therapeutic environment that allows some client independence, depending on the client's level of functionality. They offer clients protection against verbal, psychological, and physical abuse. Facilities also provide healthcare and rehabilitation services. Adult day care programs, which provide outside services, are allowed at facilities as long as the programs meet Medicaid requirements and the particular needs of the client.

The Medicaid guidelines for ICF/MR advocate respect and dignity for clients. Facilities are required to provide staff training that addresses behavior, appropriate interventions, and positive reinforcement in delivery of care. Staff must be able to safely address unacceptable client behavior.

Professionals from several disciplines serve clients residing in these group settings. This diverse staff is responsible for assessing and evaluating clients and developing interventions that best serve their needs.

Medicaid requires that ICF/MR facilities coordinate Active Treatment Services for clients, which provide skills-based training for residents who demonstrate increased abilities in areas such as communication, household tasks, and other basic skills. Daily supervision is required for individuals receiving Active Treatment Services. This type of treatment is provided on a formal and informal basis through the client's settings and services. Active treatment may also be used with the aging population to address issues such as physical

fitness and coordination. It is the defining component for ICF/MR certification.

ICF/MR staff must develop individual program plans for each client. In addition to completing assessments and evaluations, staff may work with other team members and partner agencies to best meet the needs of the client. Identification of the clients' specific diagnoses, developmental strengths, developmental and behavioral management needs, and skill deficits contributes to the scope of an individual program plan.

ICF/MR care facilities must also address benchmarks related to clients' physical development and health, nutritional status, motor skills and development, emotional development, speech and language skills, and hearing. These facilities also must address problem-solving and social skills with clients. Other activities include job skills training and independent living.

Medicaid requires that facilities maintain written policies, procedures, and guidelines that deal with client and staff interaction and the management of inappropriate client behavior. Staff interactions with clients should be positive and should contribute to the client's personal growth. Staff communication should also allow for decision-making skill development with the clients. Additionally, the staff must know how to safely deal with clients that act out, teaching residents acceptable and unacceptable behavior. Written policies must detail all methods of intervention for inappropriate behaviors, starting with the least intrusive approach. Examples of interventions include time-out rooms, physical restraints, and medication.

ICF/MR facilities also provide nursing services, dental care, and pharmacy services. All services are documented for quality assurance purposes. Medicaid sends surveyors to certified facilities in order to ensure compliance with specified standards and maintain quality of care.

Future Implications

ICFs will likely continue to remain an important part of the healthcare delivery system for individuals with health conditions that require subacute care. ICFs for the mentally retarded, in particular, provide ongoing care in a residential setting that promotes the health and personal development of its clients. A multidisciplinary approach is offered

to clients to meet their needs through an individualized approach.

INTERNATIONAL CLASSIFICATION FOR PATIENT SAFETY (ICPS)

Established by the World Health Organization (WHO), the International Classification for Patient Safety (ICPS) strives to improve the quality and safety of healthcare. The ICPS aims to define, harmonize, and group patient safety concepts into an internationally agreed-on classification system

that strives for maximum comparability on a global level. By its design, the ICPS is constantly changing to incorporate new language and updated classification schemes. Currently, the ICPS is only available for field-testing purposes, which is being conducted by the Joint Commission. This entry describes the development and theoretical concepts underlying the ICPS system.

Background

In 2002, the WHO's World Health Assembly adopted Resolution WHA55.18, which called for strengthened efforts to address patient safety and quality of care. Recognizing that all WHO member states faced similar challenges, the WHO established the World Alliance for Patient Safety (World Alliance) in 2004. One of the World Alliance's key goals was to develop a standardized language for patient safety in order to provide member states with a common terminology, based on universally understood meanings, to enable them to share and learn from each other's experiences. In 2005, the World Alliance brought together 13 international experts with academic and practical experience in patient safety, research methodology, classification theory, human factors engineering, health informatics, medicine, and consumer advocacy and law, and this drafting group was charged with developing the ICPS.

At its inception, the most vital purpose for developing the ICPS was to enable the evaluation of patient safety from a systems approach and enhance learning not only from patient safety incidents that caused harm to patients but also from those incidents that did not result in harm. These types of incidents are known as adverse events and near misses, respectively. Developing strategies that reduce the risk of harm depends on identifying the factors that contribute to the occurrence of patient safety incidents and the factors that prevent a near miss from becoming an adverse event. To accomplish this, information is collected through disparate systems, including reporting systems, root cause analyses, medical record reviews, consumer or patient reporting, coroner's reports, and medical law cases. These data are then translated into a standardized classification to permit systematic collection, aggregation, examination, education, and ultimately reduction of risk.

Members of the drafting group reviewed the literature and identified the existing patient safety classifications to determine whether an existing system could serve as a starting point for the development of the ICPS. These classifications, however, were developed to address specific aspects of patient safety, such as medication use; they were not designed for the overall domain of patient safety. Because they evolved using different methodologies with dissimilar definitions for concepts, the drafting group determined that these existing methods were not independently fit for global use. Instead, the group decided to construct a new classification based on sound classificatory theory and the experiences of others, including the WHO's International Classification of Diseases; the Joint Commission's Patient Safety Event Taxonomy, endorsed by the National Quality Forum (NQF); and the National Patient Safety Foundation's National Reporting and Learning System of the United Kingdom's National Health Service. The Australian Patient Safety Foundation's Advanced Information Management System and the Eindhoven/PRISMA-Medical Classification Model, developed by Eindhoven University of Technology and Leiden University Medical Center in the Netherlands, were also considered.

Structure and Theoretical Framework

The ICPS was designed to be a flexible descriptive tool that could become a basic foundational element for global learning. Therefore, its construction had to be firmly grounded in classificatory theory and its underlying infrastructure stable and reliable. The classification concepts, or bearers of meaning identified by labels or terms, are arranged into classes or groups based on their similarities to express semantic and attribute-type relationships. The concepts and the relationships between and among them are easily identifiable and separated without difficulty for analysis. New concepts can be incorporated as knowledge in the field of patient safety increases, which allows it to be applicable across disciplines, boundaries, and time. Furthermore, the classification must remain culturally and linguistically sensitive. With this type of infrastructure, the classification can mature, respond to change, maintain predictive capability, and enable learning. To construct a

classification such as this, the ICPS's structure needed a proactive, logical, and relational conceptual framework to serve as its foundation.

In March 2006, the drafting group identified 10 concepts that would serve as the fundamental classes for the ICPS: (1) incident type, (2) patient outcomes, (3) contributing factors/hazards, (4) patient characteristics, (5) incident characteristics, (6) organizational outcomes, (7) detection, (8) mitigating factors, (9) ameliorating actions, and (10) actions to reduce risk. The drafting group then devised a theoretical model of the interrelationships between the classes, based on the theories underlying James Reason's "Swiss cheese model," to understand how the classes influence each other and to determine how the classes should be arranged within the conceptual framework to achieve the project's stated outcome of developing a stable ICPS.

According to Reason, there are two types of approaches to evaluating the occurrence of a patient safety incident. One is the person approach, where the incident is the result of an individual person making a mistake. The other is a systems approach, where the incident is the result of a failure within the system. Reason argues that because individuals are fallible, the system must contain multilayered processes, referred to as defenses or barriers, to protect against the occurrence of patient safety incidents. Their purpose is to avert or reduce the risk of harm by either being built into the system from the start or arising on an ad hoc basis. Using Swiss cheese as a metaphor, the presence of a hole in any one defensive layer does not necessarily mean that a patient safety incident will occur; however, when the holes in several defensive layers align as a result of a combination of active failures and latent conditions, a contributing factor/hazard can move, uninhibited, to become a patient safety incident. Reason postulates that latent conditions can be detected and mitigated before an incident occurs through proactive risk assessment or other error recovery methods. Being able to proactively identify risks and design system approaches to counteract these risks illustrates a system's ability to be resilient.

Applying Reason's theory to the ICPS, once the active failure and latent condition have collided, the system should have the ability to detect the problem and to institute mitigating factors that have the potential to stop the progression toward

a system failure; however, latent and active contributing factors/hazards continuously interact. The drafting group referred to this period as an opportunity to protect against system failure. Once the failure has occurred, and although both latent and active contributing factors/hazards remain, there is still an opportunity for detection and mitigation. If the system defenses or an individual is unable to recover from the error, the patient safety incident occurs. It is at this point that the opportunity to protect against harm exists. A patient safety incident results in a patient outcome and an organizational outcome and possesses patient characteristics and incident characteristics (who was involved and what occurred). The patient outcome can be either an adverse event or a near miss. Both patient outcomes and organizational outcomes require actions to ameliorate circumstances and compensate for any harm after a patient safety incident. Actions taken to reduce risk serve to lessen, manage, or control the harm or probability of harm associated with the patient safety incident. These actions, including proactive and reactive risk assessment, address the issue that allowed the contributing factor/hazard to progress into a patient safety incident. They relate directly to contributing factors/hazards, detection, mitigating factors, and ameliorating actions and can be implemented anytime, not only after a patient safety incident has transpired. Thus, the process is a continuous learning loop.

To illustrate this theoretical model, consider the following example: a 55-year-old man presented to a busy, understaffed hospital emergency department with a fever. Although a resident took a brief medical history, during which the patient indicated an allergy to penicillin, the allergy to medication was not documented in the patient's chart. This negligence is considered a failure of protection. Continuing with this example, the attending emergency physician reviewed the chart, ordered amoxicillin, and administered it for treatment. The patient then experienced a mild allergic reaction to the medication. This adverse drug event is considered a patient safety incident. Because the patient experienced only a mild reaction, observation was ordered to monitor for any further complication. After an investigation of the patient safety incident, through a root cause analysis or other investigatory process, hospital

policy, staffing, and education requirements were reviewed in an effort to reduce risk.

The depiction of the ICPS’s conceptual framework must represent this theoretical flow of ideas in a logical and operational manner if it is to easily map, with relatively low resource expenditure, to existing reporting systems, in addition to being a tool to organize patient safety data and information in a structured classification. Consequently,

the conceptual framework is depicted in a manner that maintains its stability, flexibility, ability to incorporate new concepts, and predictive capacity while simultaneously enabling the creation of translational tables to map data fields contained in the existing reporting systems to those contained in the ICPS. Such a structured approach is a prerequisite for integrating disparate data and information into a common learning platform. Therefore, the

drafting group purposefully arranged the classes to visually depict the learning cycle resulting from a patient safety incident (see Figure 1). Solid lines indicate the semantic relationships between classes, and dotted lines indicate the flow of information.

An incident type is a descriptive term for a category of incidents of a common nature grouped because of shared features. A patient outcome is the impact on a patient that is either wholly or partially attributable to the incident. Together, these classes group patient safety incidents into recognizable, clinically meaningful categories.

Contributing factors/hazards are circumstances, actions, or influences that are thought to have played a part in the origin or development of an incident or in increasing the risk of an incident. Patient characteristics are the selected attributes of a patient, whereas incident characteristics are the selected attributes of an incident, and organizational outcomes are the impact on an organization that are wholly or partially attributable to an incident. Data and information pertaining to system resilience, risk reduction, protection against failure, and protection against harm are captured in the following classes: (a) detection—defined as an action or circumstance that results in the discovery of an incident; (b) mitigating factors—actions or circumstances that prevent or moderate the progression of an incident toward harming a patient; (c) ameliorating actions—actions taken or circumstances altered to make better or compensate any harm after an incident; and (d) actions to reduce risk—those actions taken to reduce, manage, or control the harm, or probability of harm, associated with an incident in order to help reduce risk. Contributing factors/hazards leading to patient safety incidents are influenced by and inform actions to reduce risk, as do concepts contained in the classes detection and mitigating factors. Patient outcomes and organizational outcomes both inform actions to reduce risk. Ameliorating actions also influence and inform actions to reduce risk.

Future Implications

The pragmatic utility of the ICPS is its ability to translate data and information collected in disparate reporting systems into a coded language so that analysis of a single concept or a combination of concepts is possible to identify trends, predict potential problem

areas, and learn from experience. The ability to organize patient safety information through an internationally accepted classification system with a solid conceptual framework is essential if patient safety incident data and information are to be used and disseminated effectively. A standardized patient safety terminology allows for semantic interoperability, making it possible to draw comparisons across sources, disciplines, organizations, borders, cultures, and time. This, in turn, enables surveillance and evaluation to identify actual and potential threats to patient safety. Policymakers can use this evidence-based research to revise existing or to introduce new system-wide solutions, assess the effectiveness of the interventions, and communicate the lessons learned globally.

INTERNATIONAL CLASSIFICATION OF DISEASES (ICD)

The International Classification of Diseases (ICD) is the official coding system used by all the world's nations for recording the causes of morbidity and mortality. The ICD is periodically revised, published, and disseminated by the World Health Organization (WHO). Specifically, the WHO, working with 10 Collaboration Centers, produces the ICD. The purpose of the ICD is to permit valid and reliable comparisons of morbidity and mortality data across time and nations. The ICD plays an important role in reducing the complexities of thousands of diagnoses of diseases and medical procedures to a smaller, more manageable set of standardized diagnostic and procedural codes. It is widely used by public health departments, health-care organizations, and health services researchers to analyze the general health of population groups; monitor the incidence and prevalence of diseases; and compare other health problems in relation to the access, cost, and quality of healthcare.

History

The origins of the ICD can be traced back to the 1850s, when William Farr (1807–1883), the founder of medical statistics, and others developed standardized classifications of diseases for comparative and statistical purposes. Farr, for example, classified diseases into five broad groups: (1) epidemic diseases, (2) constitutional (general) diseases, (3) local diseases arranged according to anatomical site, (4) developmental diseases, and (5) diseases that are the direct result of violence. Although Farr's structure has been modified over the years, it still forms the basis of the ICD.

Over the past 100 years, the ICD has been revised 10 times approximately each decade to incorporate changes in medicine. The 1st edition of the ICD, known as the International List of Causes of Death, was adopted by the International Statistical Institute in 1893. Until the 5th revision of the ICD, the Government of France convened the international conferences that developed the various revisions. After World War II, however, the newly created World Health Organization took over the responsibility for the ICD. In 1948, the WHO

issued the 6th revision (ICD-6), and it has developed and published all succeeding revisions. In 1955, it published the 7th revision (ICD-7). This revision was changed in the United States in 1959 to include various clinical modifications. In 1965, the WHO published the 8th revision (ICD-8), which also was modified in the United States in 1968. The WHO published the 9th revision (ICD-9) in 1977, and it also was modified, this time by the National Center for Health Statistics (NCHS), to include more morbidity data and medical procedure codes. This extension resulted in the ICD-9-CM, with the CM standing for clinical modification. The United States currently requires all the nation's hospitals to use ICD-9-CM diagnosis codes for Medicare and Medicaid claims. In 1994, the WHO released the 10th revision of the ICD (ICD-10). This revision has been adopted for reporting mortality by the NCHS and the state and local public health departments; however ICD-9-CM is still used by hospitals and other healthcare organizations for recording morbidity and for billing purposes.

Key Differences Between ICD-9-CM and ICD-10

The ICD-9-CM contains 17 chapters and two supplementary classifications. The E-Codes classify the external causes of injury and poisoning, and the V-Codes organize factors influencing health status and contact with health services. These two chapters now form part of the main classification in the 10th revision (ICD-10). Although the overall content is similar and the format and conventions of the classification remain unchanged, the ICD-10 is different from its predecessor in many ways.

The main axis for cataloging injury has changed in the injury and poisoning chapter of ICD-10. In ICD-10, injuries are catalogued first by type: All dislocations are grouped together, as are all open wounds. In ICD-10, however, the axis of organization focuses instead on the anatomical site of injury. Thus, all injuries to the foot, for example, are catalogued together, as are all injuries to the head.

The ICD-10 is published as a three-volume set compared with ICD-9-CM's two volumes. The ICD-10 has alphanumeric categories rather than numeric categories to allow sufficient space for future additions and changes without disrupting

the codes and to provide a larger coding frame. Some chapters have been rearranged. For example, certain disorders of the immune system are included with diseases of the blood and blood-forming organs, whereas in the ICD-9-CM, they are included with endocrine, nutritional, and metabolic diseases. Two new chapters have been created for diseases of the eye and adnexa and diseases of the ear and mastoid process. Some codes have been expanded, including those for diabetes, alcohol/substance abuse, and postoperative complications. The ICD-10 has a total of 21 chapters and almost twice as many categories as the ICD-9-CM.

Future Implications

Researchers at the WHO and other organizations are working on the 11th revision of the International Classification of Diseases (ICD-11). The first draft of ICD-11 is expected to be completed by 2010. The final version will likely be published around 2014 and implemented by various nations starting in 2015. It seems likely that the United States will modify ICD-11 to better suit its unique healthcare system and needs.

INTERNATIONAL HEALTH ECONOMICS ASSOCIATION (iHEA)

The International Health Economics Association (iHEA) is an individual, not-for-profit membership association consisting of more than 2,500 members from 72 countries. The iHEA focuses on the collegueship and advancement of individual health economics scholars, students, and researchers. Specifically, the goals of the iHEA are to increase communication among health economists across the globe, foster a higher standard of debate in the application of economics to health and to healthcare systems, and assist young health economists conduct high-quality research at the start of their careers.

Background

Although as early as the 1920s economists began getting together to review each other's work in the area of health and to trade ideas on the subject, there was no formal field of health economics for many decades. One of the first organizations in the field was the Health Economics Study Group (HESG), which was established in the early 1970s in the United Kingdom. Two prominent health economists, Joseph P. Newhouse in the United States and Anthony J. Culyer in the United Kingdom, began the *Journal of Health Economics* in 1981. Thus, by the 1980s, the new field of health economics was clearly established.

Over the years, various regional and national health economics associations were started, many of those in Europe and Anglophone countries following the HESG model. In the United States, a health economics committee was created as part of the medical-care section with the American Public Health Association (APHA), and a sectional affiliate was established in the American Economic Association (AEA), but neither of these entities grew into membership organizations. There were

discussions among health economists about the need for creating an international membership society to encourage communication among health economists, and in 1994, the iHEA was established. Its founding directors included Thomas E. Getzen, Charles Hall, Alan Maynard, Michael A. Morrissey, Joseph P. Newhouse, and Mark V. Pauly. Getzen was the executive director and served as the association's first president, followed by Newhouse, Maynard, and then Pauly.

The association has grown over the years. However, eventually it was recognized that for it to be truly international in scope and not just representative of developed industrial countries, the iHEA would have to seek external funding for members of developing countries. It also recognized that the lack of an active American health economics organization was distorting the membership, and in 2003, the board voted to create the American Society of Health Economists (ASHE) as a subcommittee of the iHEA to provide a more appropriate venue for North American conferences and communications. The ASHE will continue to be a subentity within the iHEA until 2010, and then it will become an independent organization.

Funding and Organizational Structure

The iHEA is largely self-funded through individual dues and fees, which helps it to maintain independence from the specific interests of industry, government agencies, or medical organizations.

Its organizational structure consists of the following: (a) an executive director; (b) a president, who is elected by the membership; (c) a secretary/treasurer; (d) a board of directors; (e) program chairs, for the biennial meeting; and (f) the association's operational staff, which consists of three individuals. Members of the board of directors serve 4-year overlapping terms.

Main Activities

The association's main activities include (a) presenting the annual Kenneth J. Arrow Award in Health Economics for the best published paper in health economics; (b) distributing health-economics-related journals to its members at a discounted price; (c) distributing health-economics-related information

to its members, including a weekly online newsletter; (d) maintaining a world directory of health economists; and (e) conducting a large biennial international conference on health economics.

To be eligible for the association's annual Kenneth J. Arrow Award in Health Economics, a paper must have been published in a peer-reviewed journal in English in the year of the award. Members submit nominations and a copy of the paper to a reviewing committee, who pick the winning paper.

The association provides members with discounts on six journals: (1) *Health Economics*, (2) *Journal of Health Economics*, (3) *European Journal of Health Economics*, (4) *Economics and Human Biology*, (5) *International Journal of Healthcare Finance and Economics*, and (6) *Journal of Mental Health Policy and Economics*.

The world directory of health economists maintained by the association includes information on about 2,300 individuals. It includes the name of the individual and his or her e-mail address, organization/department, and telephone number.

The association's biennial conference is a major international event, and the number of attendees has steadily grown over time. The first conference, called the "iHEA Congress," was held in Vancouver, British Columbia, Canada, in 1996. Subsequent conferences were held in Rotterdam, Holland, in 1999; York, England, in 2001; San Francisco, California, in 2003; Barcelona, Spain, in 2005; and Copenhagen, Denmark, in 2007. The association's 2009 World Congress will be held in Beijing, China.

INTERNATIONAL HEALTH SYSTEMS

Over the past several years, there has been a growing interest in comparing the healthcare systems of various nations. This interest is primarily a result of searches by governments and citizens alike for new solutions to offset increasing healthcare costs. A key element in comparing various national healthcare systems is how they pay for care. Nations generally pay for healthcare through individual out-of-pocket payments, individual private health insurance, employment-based private health insurance, or government financing. In most nations of the world, healthcare is delivered and/or financed by the public sector. In others, such as the United States, most people both pay for and receive their care through the private sector. The United States is unique among nations because it views healthcare not as a public good but rather as a private good that is available to those who can afford to pay for it.

To put the U.S. healthcare system in an international context, two countries—Germany and Canada—are compared. These two countries exemplify healthcare systems different from the private model in the United States. That is, Germany and Canada both provide financial access to healthcare through government-run or government-mandated programs.

German Healthcare System

Germany was the first nation to enact compulsory health insurance legislation in 1883. The law required employers and employees to make payments to voluntary "sickness funds," which would pay for the covered employees' medical care. Initially, only industrial wage earners with incomes less than \$500 per year were included. However, the eligible population was extended in later years.

Today, about 90% of Germans receive their health insurance through the mandatory sickness funds. There are about 500 of these funds, and the majority of individuals remain in one of the funds throughout their life. About 40% of people belong to funds organized by geographic area. About 27% (primarily families of white-collar workers) belong to "substitute" funds, 12% belong to the sickness funds of their companies, and another 12% belong to craft-based funds. About 8% of Germans (mainly those with higher incomes) choose private insurance, and another 2% receive medical services as members of the armed forces. Less than 0.2% of the population has no coverage.

The sickness funds are quasi-public/quasi-private not-for-profit ventures that collect money from members and members' employers. Unlike managed-care organizations in the United States, the funds are not allowed to exclude people due to illness or to raise contribution rates according to age or medical conditions. The funds are required to cover a broad range of benefits, including hospital and physician services; prescription drugs; and dental, preventive, and maternity care. Copayments for care are modest, and on retirement or loss of a job, people and their families retain membership of their sickness fund.

German medicine maintains a strict separation of ambulatory-care physicians and hospital-based physicians. Most ambulatory-care physicians are prohibited from treating patients in hospitals, and most hospital-based physicians do not have private offices for treating outpatients. Traditionally, patients could go directly to an ambulatory-care specialist. However, in recent years, referrals from the patients' primary-care physician to ambulatory-care specialists have become the norm. The German system of dispersed medical-care organization is similar to that in the United States, with little

coordination between ambulatory-care physicians and hospitals.

Controlling healthcare costs has been a problem in Germany in recent years but not to the extent it is in the United States. Negotiations on fees, rates, and prices for care are conducted annually at state, regional, and local levels between the sickness funds, physicians' associations, and hospitals. Today, healthcare costs in Germany are about 10% of its gross domestic product (GDP).

To control costs, Germany has accentuated competition into its insurance system by allowing individuals greater flexibility in choosing a sickness fund. The expectation is that individuals will seek out lower-cost funds and that this consumer choice model will motivate all funds to become more price competitive. However, Germans have shown much allegiance to their sickness funds, and switching behavior has been limited. Overall, the German values of social solidarity and fairness have dampened aggressive price competition and shopping for health plans.

Canadian Healthcare System

In 1947, Saskatchewan was the first Canadian province to initiate a publicly financed universal hospital insurance. Other provinces followed, leading to the Canadian Hospital Insurance Act in 1957 and its full implementation in 1961. Saskatchewan again took the lead in 1961 by enacting a medical insurance plan for physician services. All Canadian provinces covered physician services by 1971, giving Canada a province-based, tax-financed, public, single-payer healthcare system.

Canada, unlike Germany and the United States, has severed the link between employment and health insurance. Wealthy or poor, employed or jobless, retired or under age 18, every Canadian receives the same health insurance, financed in the same manner. Furthermore, the benefits provided by the Canadian provinces are broad, including unlimited hospital, physician, and ancillary services. Provincial plans also pay for outpatient drugs, although most provinces limit eligibility for this benefit to elderly and low-income patients. The Canadian healthcare is unique in its prohibition of private health insurance for coverage of services included in the provincial health plans.

Fifty-five percent of Canadian physicians are general practitioners or family physicians compared with 35% of similar physicians in the United States. As in other national healthcare systems, general practitioners in Canada act as gatekeepers to the medical system. As a rule, Canadians see their general practitioners, who they are free to choose, for routine medical problems and visit specialists through referral by their general practitioner. Also, because of the close scientific interchange between Canada and the United States, the practice of medicine is very similar in both countries.

Studies of the United States and Canada have compared how receipt of a variety of services, ranging from cardiac surgery to mental healthcare, may vary according to income in the two nations. In the United States, the poor receive less care than the wealthy populations, while in Canada, the opposite is the case. The poor, who generally have worse health outcomes, use healthcare services more in Canada.

In 1970, Canada and the United States spent about the same proportion of their GDP on healthcare (a little more than 7% each). However, since that time, Canada has done a better job of containing healthcare costs. In 1998, Canada spent 9.5% of its GDP on healthcare compared with 13.6% in the United States. Notably, the differences in cost between the United States and Canada are not the result of Canadians receiving fewer services overall. For example, elderly Canadians receive 17% more physician services than the elderly in the United States.

Canadians, on average, spend more days in the hospital and see physicians more often than people in the United States. However, Canada has lower costs than the United States because administrative costs are lower, hospital costs per day are lower, and physician fees and prescription drug prices are lower.

Comparing the Performance of Healthcare Systems

Healthcare systems are often compared on the three criteria of cost, access, and quality of care. Germany and Canada, as well as all other advanced nations, have controlled healthcare costs more successfully than has the United States in the past 20 years, though all nations continue

to face challenges in containing their spending. The United States spends more on its healthcare system than any other nation, about 15% of its GDP. In contrast, healthcare spending as a percentage of GDP in other advanced nations averages about 9%.

Some have speculated that the higher costs of healthcare in the United States are due to greater use of services by its citizens. However, recent studies show that the use of services in the United States is lower than in many other nations, including Germany and Canada. It is now acknowledged that the main factors leading to higher costs of healthcare in the United States include high administrative, pharmaceutical, and medical technology costs; defensive medicine practices; and the high incomes of healthcare providers. For example, it has been estimated that administrative costs represent from 18% to 33% of all healthcare costs in the United States. This compares with about 3% in Canada. A major cause of the high administrative and pharmaceutical costs is the fragmented nature of the U.S. healthcare system. Patients move in and out of insurance coverage from year to year, and this puts tremendous strain on the system in terms of administrative practices such as billing and preventive care. Also, the leverage that insurance companies have in the United States to negotiate lower prices for pharmaceuticals is much less in comparison with governments negotiating leverage in other developed nations. Finally, physicians in the United States get paid on average about twice as much as their counterparts in other developed nations.

The United States has not fared well on the access criterion, being the only developed nation lacking some form of universal healthcare coverage for its citizens. The result has been that about 17%, or 48 million, of Americans are uninsured and many more millions have poor insurance coverage. All other major industrial nations provide universal healthcare coverage, and most of them have comprehensive benefit packages with no cost sharing by patients. Although people in the United States can obtain treatment in a hospital emergency department, many studies have shown that people without health insurance often postpone treatment until a minor illness becomes worse, harming their own health and incurring greater costs.

Barriers in the United States include the costs facing low-income people without health insurance

coverage or with limited insurance coverage. In addition, even Americans with above-average incomes find it more difficult than their counterparts in other nations to get care on nights or weekends without going to a hospital emergency department, and many report having to wait 6 days or more for an appointment to see their own physician.

The Commonwealth Fund has conducted a number of studies comparing the U.S. healthcare system with other national systems, using surveys of patients and physicians and other data. In 2007, it ranked the United States last or next to last compared with five other nations—Australia, Canada, Germany, New Zealand, and the United Kingdom—on most measures of performance, including quality of care and access to it. The Commonwealth Fund study ranked the United States first in providing the “right care” for a given condition, as defined by standard clinical guidelines, and gave it especially high marks for preventive care, such as pap smears and mammograms to detect early-stage breast cancers and blood tests and cholesterol checks for hypertensive patients. But the United States scored poorly in coordinating the care of chronically ill patients, in protecting the safety of patients, and in meeting their needs and preferences, which drove the nation’s overall quality of care rating down to last place. American physicians and hospitals experienced more surgical and medical mistakes than their counterparts in other industrialized nations. Furthermore, the United States had the best survival rate for breast cancer, second best for cervical cancer and childhood leukemia, worst for kidney transplants, and next to the worst for liver transplants and colorectal cancer.

In another study comparing eight countries, the United States ranked last in years of potential life lost to circulatory diseases, respiratory diseases, and diabetes and had the second highest death rate from bronchitis, asthma, and emphysema. Although several factors can affect these results, it seems likely that the quality of care delivered was a significant contributor.

Other criteria that Americans are starting to consider in comparing their health systems with those of other nations include fairness, patient satisfaction, use of information technology, and public health. Each is discussed below.

Fairness

The United States ranks last on almost all measures of equity because it has the greatest disparity in the quality of care given to richer and poorer citizens. This is largely due to the fact that health care is not seen as a public good in the United States but a private good that is only available to those who can afford it. As a result, Americans with below-average incomes are much less likely than their counterparts in other industrialized nations to go to a physician when sick, to fill prescriptions, or to get needed tests and follow-up care.

Patient Satisfaction

Many Americans hold negative views of their healthcare system. In Commonwealth Fund surveys of five countries, American attitudes stand out as the most negative, with a third of the adults surveyed calling for rebuilding the entire healthcare system, compared with only 13% who felt that way in Britain and 14% in Canada. These results may be due to Americans paying higher out-of-pocket costs than citizens of other nations. They are also less likely to have a long-term physician, less able to see a physician on the same day they are sick, and less likely to get their questions answered or receive clear instructions from a physician.

Use of Information Technology

Despite the wide use of computers, software, and the Internet, much of the U.S. healthcare system is still operating with handwritten paper records. American primary-care physicians lag years behind physicians in other advanced nations in adopting electronic medical records or prescribing medications electronically. This situation makes it difficult to coordinate care, identify medical errors, and adhere to standard clinical guidelines.

Public Health

In 2000, the World Health Organization (WHO) ranked the healthcare systems of 191 nations. France and Italy were ranked at the top, while the United States was ranked 37th. The United States had a high infant mortality rate and ranked last of 23 advanced nations. The United States also

ranked near the bottom in healthy life expectancy at age 60 and 15th among 19 nations in deaths from a wide range of illnesses that would not have been fatal if treated with timely and effective care. In terms of prevention, the United States did a better job than other industrialized nations in reducing smoking, but it ranked number one in obesity.

Future Implications

Taken as a whole, the mounting national comparative evidence has caused many healthcare experts, purchasers, health planners, providers, and consumers to seriously question the value of the care that is being provided in the United States. For example, in 2001, the national Institute of Medicine (IOM) identified a chasm between the healthcare the nation had and the care it could have. It reported that the nation's current healthcare system cannot do the job, that trying harder will not work, and that future health reform efforts must reduce the huge number of uninsured, who are the major reason for the poor standing of the United States in health globally. It also identified needed improvements in the coordination of care, the use of computerized records, communications between physicians and patients, and many other factors that impair the quality of care.

The United States spends the greatest amount of money on healthcare among all the nations and because of that, many believe it should be able to provide universal access to care and at the same time provide the highest quality of care in the world. However, there are many entities, including physician organizations, insurance companies, medical device manufacturers, and pharmaceutical companies, with tremendous financial resources and political power, that may attempt to block national healthcare reform efforts. Yet there are other market pressures, such as the decline of employer-based health insurance coverage and a growing willingness by Americans to shop for healthcare in other nations, which may increase focus on healthcare reform in the coming years.

J

JOINT COMMISSION

The Joint Commission, formerly known as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), is the largest and oldest accrediting healthcare organization in the United States. It accredits and evaluates approximately 15,000 healthcare organizations and programs in the nation, including general, psychiatric, children's, and rehabilitation hospitals; critical-access hospitals; medical equipment services; hospice services and other home care organizations; nursing homes and other long-term care facilities; behavioral healthcare organizations and addiction service; rehabilitation centers and group practices; office-based surgeries and other ambulatory care providers; and independent or free-standing laboratories.

Founded in 1951, the Joint Commission is an independent, private, nonprofit organization located in Oakbrook Terrace, Illinois, with a satellite office based in Washington, D.C. The Joint Commission's mission is to improve the quality and safety of care received by the public through healthcare accreditation and through services that support performance improvement in healthcare organizations. The Joint Commission carries out its mission by accrediting healthcare organizations and by providing healthcare performance improvement services. It maintains performance-based standards and evaluates healthcare organizations' compliance with these standards in maintaining safety and quality care. Once a

healthcare organization is accredited or certified, it must reapply for accreditation every 3 years or for recertification every 2 years.

The Joint Commission also awards a certification, known as the Disease-Specific Care Certification, to health plans, disease management service companies, hospitals, and other care delivery settings that provide disease management and chronic-care services.

The Joint Commission was formerly led by its longtime president Dennis S. O'Leary and is currently under the leadership of Mark R. Chassin. The Joint Commission is overseen by a Board of Commissioners, which is composed of healthcare professionals, including nurses, physicians, medical directors, and providers, as well as consumers, administrators, employers, a labor representative, health plan leaders, quality experts, ethicists, a health insurance administrator, and educators. The corporate members of the Joint Commission include the American College of Physicians (ACP), the American College of Surgeons (ACS), the American Dental Association (ADA), the American Hospital Association (AHA), and the American Medical Association (AMA). The Joint Commission employs more than 1,000 individuals in its surveyor workforce.

Since the Joint Commission was formed, voluntary accreditation and quality assurance systems have been adopted across the globe, by countries such as Canada, Australia, and various European nations.

While the Joint Commission is not able to cite or fine an organization for not meeting its standards,

its accreditation program does carry significant weight. Under the federal Medicare law, Joint Commission–accredited hospitals are “deemed” to have met the requirements for participation in the Medicare program. Similarly, most states have incorporated Joint Commission accreditation standards into their hospital licensure standards. The failure of an organization to meet the Joint Commission’s standards can result in the loss of accreditation as well as millions of dollars in Medicare and Medicaid funding.

Some of the benefits of Joint Commission accreditation include an outside evaluation of an organization’s quality and safety of care. Joint Commission accreditation also provides knowledge to the public of whether an organization meets or exceeds its standards.

Recent criticisms of the Joint Commission have included the perceived rigor of its hospital survey process in assessing quality care, as the vast majority of hospitals that seek accreditation receive it. A potential conflict of interest cited by critics is the Joint Commission’s subsidiary (Joint Commission Resources) that provides consultation to hospitals on how to gain accreditation and improve their performance. The Joint Commission assuages these concerns by noting that there are policies in place (“firewall”) that create a barrier between its subsidiary and the accreditation division, preventing the sharing of information. Additionally, the composition of the Joint Commission’s Board of Commissioners, made up of members from the AHA, AMA, and the ACP, to name a few, raised some questions about the Joint Commission’s ability to objectively accredit organizations that it oversees.

The Joint Commission has also received a backlash from its constituent members, including the AHA and the AMA. Some of these grievances include the range of variability in the accreditation survey process, the value of Joint Commission services, and the role of the Joint Commission as a peer review organization. AMA members have also felt that the Joint Commission’s requirements had become too burdensome and costly relative to the benefits yielded by its accreditation and that the Joint Commission was unresponsive to physician complaints. State hospital associations have also explored comparable alternatives to the Joint Commission accreditation.

Early History

In 1910, Ernest A. Codman, a Boston surgeon, developed the *end-result system* of hospital standardization. Under this system, hospitals would track every patient to determine if his or her treatment was effective and, if not, to find out how to prevent this from happening again in the future. At the urging of Franklin H. Martin, the ACS was founded in 1913, and the end-result system became a stated objective of this nascent organization. In 1917, the ACS formally established the Hospital Standardization Program, and 2 years later it adopted five official standards, known collectively as the Minimum Standards for Hospitals. The adoption of these Minimum Standards formed the foundation for the accreditation process.

The first on-site hospital inspections took place in 1918, and at the time, only 89 out of 692 hospitals met this standard. The dismal state of hospitals demonstrated the urgent need for a national hospital accreditation program. As the ACS Hospital Accreditation Program’s success grew, more hospitals sought its approval, and by 1950, over half of the hospitals in the United States were accredited.

The ever-increasing complexity of medical care and the growth of nonsurgical specialties after World War II required that hospital standards be reviewed, revised, and updated to reflect these changes. The Hospital Standardization Program would therefore need the support of the entire medical community, and as a result, the ACS sought the participation of other national professional organizations to improve the voluntary accreditation program.

In 1951, the ACS joined with the ACP, the AHA, the AMA, and the Canadian Medical Association to form the independent, nonprofit organization the Joint Commission on Accreditation of Hospitals (JCAH). The primary purpose of JCAH was to provide voluntary accreditation. The following year, JCAH took over the Hospital Standardization Program from the ACS, and in 1953, the *Standards for Hospital Accreditation* was published. The Canadian Medical Association later withdrew from the JCAH in 1959 and created its own accrediting body in Canada.

The JCAH perpetuated the traditions of the ACS by providing voluntary accreditation with

standards agreed on by health professionals as providing quality care, and the accreditation survey would still represent a combination of evaluation, education, and consultation. All information obtained through the survey process would be held in confidence between the JCAH and its member organizations.

The Joint Commission continued to expand its program, now called the Hospital Accreditation Program, and hired and trained surveyors to focus on medical staff and patient care issues.

Evolving Role

With the passage of the Medicare Act in 1965 (PL 89-97), the role of the JCAH shifted, and it became more closely affiliated with the federal government. This law provided that hospitals accredited by JCAH would be deemed in compliance with most of the Medicare Conditions of Participation for Hospitals and, thus, would be deemed eligible to participate in the Medicare and Medicaid programs. The Social Security Act (PL 92-603), later amended in 1972, required that the Secretary of the U.S. Department of Health and Human Services (DHHS) validate JCAH findings and include an evaluation of its accreditation process in the department's annual report to the U.S. Congress. Today, 39 states and the District of Columbia have incorporated the Joint Commission's hospital accreditation into their licensure programs. Although hospitals may be accredited, they must also remain in compliance with state hospital licensing statutes and regulations.

The combination of voluntary, private-sector accreditation and government regulation has served to facilitate the quality assurance process by allowing state governments to focus their enforcement efforts and limited resources on "problem" facilities.

Again in 1966, the JCAH standards had undergone significant revisions to reflect optimal achievable levels of quality rather than the minimum levels of quality. The reason for this major decision was that most hospitals had achieved or maintained the minimal standards and were no longer being challenged. Additionally, with the government's growing involvement in regulating hospitals through state licensure and the federal Medicare program, JCAH would have to define the optimal achievable level of care if it were to remain at the

forefront of hospital standard setting. The optimal achievable standard would be later defined as the best that could be achieved, making the healthcare provided as effective as possible. This impetus resulted in the publication of the *1970 Accreditation Manual for Hospitals*.

Beginning in the late 1960s and early 1970s, the JCAH greatly began to expand its role in accrediting new programs with the growth of other healthcare organizations. Because of JCAH's experience with accrediting hospitals and its widespread acceptance among the medical community, it was fitting for it to branch out into these new endeavors. The JCAH started accrediting organizations that served the developmentally disabled through the Accreditation Council for Services for the Mentally Retarded and Other Developmentally Disabled Persons; psychiatric facilities, substance abuse programs, and community mental health programs through the Accreditation Council for Psychiatric Facilities; long-term care facilities through the Accreditation Council for Long Term Care; and ambulatory healthcare facilities through the Accreditation Council for Ambulatory Health Care. In 1978, the JCAH and the American College of Pathologists created a collaborative agreement for the evaluation of laboratories in hospitals, and in 1983, it began to accredit hospice care organizations as well.

During this period of growth, the Joint Commission established a Professional and Technical Advisory Committee. The Committee's role was to advise the Joint Commission on developing standards and survey procedures. Through its Board of Commissioners, the Joint Commission is able to have close ties with health professionals and maintain its survey process and standards to reflect current knowledge and practices.

With its expanded scope of endeavors in healthcare, the JCAH formally changed its name to the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) in 1987.

Quality Assurance and Patient Safety

With the development of the minimum standards by the ACS, for the first time hospitals were evaluated for the quality of care they provided. When the Joint Commission took over hospital accreditation, it continued to develop standards that

reviewed and evaluated hospital quality. For the most part, however, these evaluations were informal and often subjective. During this time, research into more objective and valid criteria and systematic review procedures for measuring quality were being developed. This later formed the foundation for the Joint Commission's retrospective, outcome-oriented auditing practices that commenced in the 1970s.

Standards were developed that evaluated the quality and appropriateness of care, including safety management, utilization review, and infection control. The Joint Commission also requested that hospitals review the credentials in granting clinical privileges to its medical staff.

While the Joint Commission focused on these quality assurance efforts, hospital audits became more of a routine exercise to meet the Joint Commission's standard requirements rather than focusing on quality care, and therefore this failed to meet its intended objective. In 1979, the Joint Commission addressed this problem by developing a new systematic quality assurance process that focused on hospital-wide assessment activities, including the monitoring and evaluation of all aspects of patient care and problem identification.

Starting in the early 1990s, the Accreditation Manual for Hospitals began to be reorganized around standards that emphasized performance improvement concepts and later shifted to standards that examined an organization's actual performance rather than its capability to perform. Also during this time, the Joint Commission began to conduct random, unannounced surveys of 5% of its accredited organizations.

A sweeping revision to the accreditation process took place with the 1994 Agenda for Change. The Agenda for Change had as its centerpiece integrating performance measurement into the accreditation process to carry out the Joint Commission's mission of continuously improving patient safety and quality of care. During the planning process of the Agenda for Change, the Joint Commission was involved in the development, testing, and implementation of standardized performance measures. As far back as 1986, the Joint Commission established a set of performance measures that were to be collected from and transmitted to all accredited hospitals, known as the

Indicator Measurement System. Although this project never came to fruition, it served as the predecessor and impetus for the new ORYX initiative. With the growing scope of knowledge, the Joint Commission revised its original performance measures and pursued a collaborative approach in the ORYX initiative.

In 1997, the ORYX initiative for the first time used performance and outcome measures in the accreditation process that was applied to hospitals, long-term care organizations, and healthcare networks. ORYX was later expanded to include behavioral healthcare and home care organizations.

ORYX is a tool used by healthcare organizations to evaluate their ongoing healthcare performance and to inform them of their continuous quality improvement efforts. Initial policies called for accredited healthcare organizations to select two of the approved measures. This information was to be collected on monthly data points and transmitted on a quarterly basis to an approved performance measurement system. In July 2002, the first ORYX measures on accredited hospitals were collected. Today, hospitals are required to select three core measure sets in order to satisfy accreditation requirements. To reduce the burden of reporting requirements for hospitals, the Joint Commission worked with the Centers for Medicare and Medicaid Services (CMS) and other entities to standardize these core measures.

Quality Check was established the same year as ORYX, and it serves as a directory of accredited organizations and performance reports available for public use on the Joint Commission Web site. In 2004, the debut version of *Quality Report* became available to the general public, allowing easy access to organization-specific data displayed against comparative state and national data.

Aligned with its mission to improve the quality of care, the Joint Commission established the Sentinel Events Policy in 1996 to review an organization's response to sentinel events during full accreditation surveys and unannounced random surveys. The Joint Commission defines a sentinel event as an unexpected occurrence that involves death or serious physical or psychological injury to a patient. This policy was later revised to promote self-reporting of medical errors and to identify the causes of these events. The Sentinel Events Policy was later further modified so that organizations

could request an on-site review instead of reporting the cause of the sentinel event due to litigation concerns.

In 2002, the Joint Commission established the National Patient Safety Goals to promote specific improvements in patient safety. These goals represent problematic areas in healthcare. To address these concerns, evidence and expert-based solutions to these problems have been prescribed. Some of the future goals of the Joint Commission include improved medication safety, communication by caregivers, and accuracy of patient identification; risk reduction in healthcare-associated infections, surgical fires, patient falls, and the occurrence of influenza and pneumococcal disease in older adults who are institutionalized; prevention of healthcare-associated pressure ulcers; organizational identification of safety risks in the patient population; involvement of patients in their own care; and implementation of relevant National Patient Safety Goals.

Present and Future Directions

Launched in 2004, “Shared Vision-New Pathways” ushered in fundamental revisions to the accreditation process. The focus of this new accreditation process is on organizational systems involved in patient care and healthcare quality. The Joint Commission’s new focus will be on the processes of patient care and the specific issues of a particular healthcare organization. This is in response to some healthcare organizations’ past practices of “ramp-up” efforts to meet Joint Commission requirements immediately preceding an on-site survey.

The term *Shared Vision* is the vision that the Joint Commission and healthcare organizations share on the quality of patient care. The “New Pathways” are approaches to the accreditation process to achieve this shared vision. Some of the modifications under the New Pathways approach include the consolidation of standards to reduce the amount of paperwork and documentation necessary and to focus on patient safety and quality care, the transition from performance reports to quality reports, the periodic performance review (PPR), which will make accreditation more of a continuous and ongoing process, a patient “tracer” methodology, and a customized focus of the on-site survey as directed by the priority focus process.

Another major part of this change is the Joint Commission’s unannounced surveys. The unannounced survey of hospitals will occur every 18 to 39 months after an organization’s first unannounced visit. The Joint Commission will also soon require periodic performance reviews of healthcare organizations that involve conducting a self-assessment in between survey visits.

The Joint Commission continues to evolve and revise its standards to reflect changes in technology and advances in medical knowledge and best practices. Its accreditation has come to be regarded as a symbol of quality indicating that a healthcare organization meets certain performance standards. A healthcare organization must participate in an on-site accreditation survey at least every 3 years to earn and maintain the Gold Seal of Approval. The Joint Commission continues to be at the forefront in developing new standards and initiatives to improve patient safety and healthcare quality.

K

KAISER FAMILY FOUNDATION

The Henry J. Kaiser Family Foundation is a non-profit, private-operating foundation dedicated to providing information and analysis on healthcare issues and policy. It is an important source of facts and analysis for policymakers, the media, the healthcare community, and the general public.

The foundation was established in 1948 by Henry J. Kaiser and his wife, Bess, to meet the unmet healthcare needs of the citizens of the United States. Its founder, Henry J. Kaiser, was a legendary American industrialist who completed massive construction projects such as the Hoover Dam and built Liberty ships during World War II and automobiles after the war. In healthcare, he pioneered the idea for the Kaiser Permanente HMO, which became the model for health maintenance organizations (HMOs) nationwide.

Headquartered in Menlo Park, California, with an additional office in Washington, D.C., the Kaiser Family Foundation funds its own research and communication programs, sometimes in partnership with other research organizations or major media companies. Working with an annual budget of over \$40 million, the foundation operates independently. This independence allows it to provide information on a nonpartisan basis.

Although most of the Kaiser Family Foundation's work concentrates on healthcare issues in the United States, in recent years, it has expanded its scope to include global health issues. The foundation provides up-to-date information,

research-based evidence, and recommendations on various health topics, and it advocates for vulnerable populations. Much of its work relates to medically underserved populations such as low-income families, minorities, women, and people living in developing countries.

Health Policy Programs

The Kaiser Family Foundation has six programs addressing U.S. healthcare policy: (1) Kaiser Commission on Medicaid and the Uninsured, (2) Health Care Marketplace Project, (3) HIV Policy Program, (4) Medicare Policy Project, (5) Race/Ethnicity and Health Care Program, and (6) Women's Health Policy Program.

Begun in 1991, the Kaiser Commission on Medicaid and the Uninsured is the largest operating program of the foundation. The commission focuses on healthcare policy and research regarding low-income families. It examines how Medicaid and the State Children's Health Insurance Program (SCHIP) work and the corresponding issues facing uninsured individuals and families.

The Healthcare Marketplace Project examines the trends and determinants of the nation's healthcare economy. The project provides resources for employer health programs, including information about health insurance, the pharmaceutical industry, and healthcare costs.

The foundation's HIV Policy Program addresses the costs of treatment, the effectiveness of prevention methods, and the political atmosphere surrounding the disease. The program conducts

research and shares the most recent information about HIV/AIDS, including changes in public opinions, policies, and laws.

The Medicare Policy Project provides resources, statistics, and analysis concerning that federal healthcare program. As the American public ages, a growing number of individuals are using Medicare. The project offers comparisons of various Medicare plans and descriptions of benefits, including the new prescription drugs component. The resources provided by the project assist people in understanding and navigating this complicated benefits program.

The Race/Ethnicity and Health Care Program addresses health disparities and the difference in health status among people of color. The program conducts research on issues related to access to care, especially quality healthcare, and recognizes that public policy is an influential factor in reducing health disparities.

The Women's Health Policy Program focuses on the complex issues relating to women's health. It focuses on reproductive health issues, maternal and child health, and the health needs of uninsured women.

Media and Public Education Programs

The Kaiser Family Foundation has five media and public education programs: (1) Entertainment Media Partnership, (2) Media Fellowship and Internship Programs, (3) Program for the Study of Entertainment Media and Health, (4) Public Opinion and Media Research Program, and (5) Kaiser Family Foundation Web sites.

Through its Entertainment Media Partnerships, the foundation conducts several public health information campaigns. Current campaigns provide messages to young people about HIV/AIDS and other sexually transmitted diseases. Media partners involved in these campaigns include MTV, Viacom, BET, Univision, and Fox. In addition, the foundation coordinates a public health information campaign in South Africa.

The foundation's Media Fellowships and Internships Programs offer fellowships and internships to journalists interested in health policy news. These programs help inform and develop journalists' understanding of health policy topics. The foundation also offers several resources and tools for journalists' professional development.

The foundation's Program for the Study of Entertainment Media and Health studies the media's impact on young people. Its work includes an examination of food advertising to children, sex and violence on television, and how youth in the 21st century use media devices. The analysis of this research is used to develop policy and plan community health education programs. In addition to studying the media, the foundation often partners with news media organizations on issues related to health policy. The foundation currently maintains partnerships with *USA TODAY*, *The Washington Post*, the *San Jose Mercury News*, and XM satellite radio.

Through its Public Opinion and Media Research Program, the foundation regularly conducts public opinion polls that survey people's experiences with the nation's healthcare system and determines their views on specific health topics. Results from the polls are made available through the foundation's publications and on their Web sites.

The Kaiser Family Foundation Websites program attempts to keep people informed through its many Web sites. For example, the Kaiser Network is a source of information for health news. The network collects health news stories from around the world and offers daily summaries to consumers through e-mail subscriptions and Web sites. These daily reports cover topics including health policy, HIV/AIDS, women's health policy, and health disparities. On the Kaiser Network Web site, viewers will find headlines featuring top health stories and links to entire articles. The Web site also provides comprehensive information on a particular health issue in its "Issue Spotlight" section. Viewers may also search archives containing 65 years of health opinion polls. The Kaiser Network also provides an archive of HealthCasts. Webcast technology allows the foundation to broadcast events online and archive the products so that consumers may access the resources at a later date. Meetings, conferences, workshops, and other professional development events related to health care and health policy are examples of the types of HealthCasts available through the Kaiser Network.

The foundation's State Health Facts Web site provides health statistics and information for each of the 50 states in the nation. Data provided on this site are collected from a variety of public and private sources. Information about more than 500

health topics is available on this Web site. Viewers may research health data by individual state or make comparisons among states with the resources available on this site. Examples of categories featured on the State Health Facts site include state demographics, economy, health status of the population, health coverage and the uninsured, Medicaid and SCHIP, health costs and budgets, Medicare, managed care and health insurance, minority health, women's health, and HIV/AIDS.

KaiserEDU.org is a foundation initiative that coordinates several resources and tools for students, faculty, and others. Information and data about the health topics addressed by the foundation are provided. University faculty have the opportunity to share course outlines using the Syllabus Library function on the Web site. The foundation makes available the Table of Contents of several major health journals and provides several research tools. Three online tutorials are available that provide information about collecting and analyzing data. The foundation has created a health video library through KaiserEDU.org. This online library contains links to original producers of health videos and documentaries. The foundation does not loan videos; however, it directs viewers to the production source so that they may obtain it on their own. The health video library serves as a clearinghouse as to what type of information is available.

KANE, ROBERT L.

Robert L. Kane is a highly regarded expert in the field of aging and long-term care. Kane holds an endowed chair in long-term care and aging and is a professor at the University of Minnesota School of Public Health in the Department of Health Policy and Management. He also directs the Center on Aging and the Minnesota Geriatric Education Center and codirects the Clinical Outcomes Research Center at the University of Minnesota. In addition, he directs an evidence-based practice center funded by the Agency for Healthcare Research and Quality (AHRQ).

Kane has received numerous awards and honors throughout his long career, including the President's Award from the American Society on Aging, the Polisher Award from the Gerontological Society America, and the Enrico Greppi Prize from the Italian Society of Gerontology and Geriatrics. He has conducted numerous studies on the outcome of care and the organization of care, with an emphasis on the care of the elderly and those needing long-term care. Kane has served on the World Health Organization's (WHO's) Expert Committee on Aging. He has authored or edited more than 30 books and 350 journal articles and book chapters on the topics of health services research, geriatrics, and long-term care.

Kane earned his bachelor's degree from Columbia College in 1961 and his medical degree

from Harvard Medical School in 1965. He did his medical internship, followed by a residency in community medicine, at the University of Kentucky Medical Center.

He began his career in 1968 as an acting coordinator in the Senior Clerkship Program at the University of Kentucky in the Department of Community Medicine. He then went on to serve in the U.S. Public Health Service (PHS) as a service unit coordinator and as special assistant to the Regional Health Director. In 1970, Kane was appointed as an assistant professor and later as an associate professor in the Department of Family and Community Medicine at the University of Utah School of Medicine. After leaving the University of Utah in 1977, he went to the RAND Corporation as a senior researcher and later joined the faculty of the University of California at Los Angeles (UCLA). Following this, Kane served as dean of the University of Minnesota School of Public Health from 1985 to 1990 and then in his current position as a professor.

Kane's current research addresses the outcomes of acute and long-term care with a focus on the effects of hospital and posthospital care while examining methods to better deliver chronic care. He has published a book, *It Shouldn't Be This Way*, with his sister, Joan West, about the personal difficulties encountered in obtaining long-term care for their mother. Kane also formed a national advocacy group, Professionals with Personal Experience in Chronic Care (PPECC), to put long-term care and chronic disease on the political agenda by drawing on the experiences of health-care professionals in the field.

KATZ, SIDNEY

Sidney Katz is a Distinguished Scholar at the Benjamin Rose Institute in Cleveland, Ohio, and Professor Emeritus of Geriatric Medicine and Codirector of the Stroud Center on Scientific Studies of Quality of Life at Columbia University in New York City. His background is in medicine, epidemiology, and health services research, with a focus on rehabilitation, the natural course of aging and chronic disease, long-term care, and quality of life.

Katz has made a number of significant contributions to geriatrics and health services research. He was one of the leading champions of the development of the field of geriatric care. In addition, he was one of the earliest proponents of the idea that the goal of treatment for persons with chronic illness was improving their quality of life. In his research, Katz moved away from focusing only on disease diagnoses to examining the interaction and impact of multiple chronic diseases. Furthermore, he argued that functional status was a more useful measure of total disease burden and an important indicator of service quality and quality of life. Moreover, Katz led the team that developed the first indices of activities of daily living (ADLs) to measure changes in physical function. His work emphasized the centrality of physical function in the field of geriatrics and health services research and yielded a relatively precise, standardized measure of physical functioning. The Katz Index of ADLs clarified the hierarchal

nature of functional limitations and became pivotal in the development of measures of outcome quality in rehabilitative and long-term care.

Born in Cleveland, Ohio, Katz earned a bachelor's degree in general sciences (1944) and a medical degree from Case Western Reserve University (1948). He attended the Walter Reed Army Medical Service graduate school and received a master's degree (1984) in medical sciences from Brown University. Over the course of his long and distinguished career, Katz has been a U.S. Navy corpsman in World War II, a professor in the School of Medicine at Case Western Reserve University, an army physician in Korea, a department chair in the College of Medicine at Michigan State University, and associate dean of Medicine at Brown University. In 1986, he founded Brown's Center for Gerontology and Health Care Research, which for more than 20 years has carried out his vision of emphasizing multidisciplinary research in training clinicians, behavioral scientists, and statisticians in health services research with an emphasis on geriatrics, gerontology, and chronic disease management.

Katz has been a champion for improving the range and quality of long-term care services available to older persons in their homes, communities, and long-term care facilities, and he has been an advisor to national and world leaders. As a member of the national Institute of Medicine (IOM), he has served on many committees aimed at improving healthcare quality, but his most distinguished service came as chair of the IOM Committee on Nursing Home Regulation. This Committee's recommendations were largely adopted by the U.S. Congress in the nursing-home reforms contained in the Omnibus Budget Reconciliation Act of 1987 (OBRA-87). OBRA-87 was the most fundamental reform of federal nursing-home standards since the passage of the Medicare and Medicaid programs and specified a new model of nursing-home care that included uniform resident assessment, increased attention to residents' rights and quality of life, a revised process for inspecting nursing homes, and a range of enforcement remedies. The IOM committee's recommendations, as incorporated in OBRA-87, were resident centered and outcome focused, shifting regulators from attention to paper compliance with regulations to a focus on the real care and quality of life experienced by nursing-home residents. Furthermore, the

philosophy of OBRA-87, with its focus on resident-centered care, provided considerable support for the current move emphasizing culture change in nursing homes.

Katz has been recognized for his service and research in a number of ways, including receiving the Bronze Star for his service in a Mobile Army Surgical Hospital in the Korean War. He is listed in *Who's Who in Health Care* and has received a number of awards and honors, including the Lifetime of Caring Award from the American Geriatrics Society's Foundation for Health and Aging. Brown University established an honorary lectureship in his name, Columbia University awarded him its Medal of Excellence in Scholarship and an Award for Excellence in Health Policy Research in Geriatrics and Gerontology, and the Benjamin Rose Institute established the Katz Policy Institute in his honor. He also has been recognized by the Gerontological Society of America, receiving the Maxwell Pollack Award for Productive Aging for research that directly improved policy or practice and the Donald P. Kent Award for exemplifying the highest standards of professional leadership in gerontology through teaching and service.

KELLOGG FOUNDATION

The W. K. Kellogg Foundation located in Battle Creek, Michigan, has been funding community-based approaches to health and well-being since its inception in 1930. Established by Will Keith Kellogg (1860–1951), the founder of a global ready-to-eat cereal company and one of the world's largest philanthropists, it was originally named the W. K. Kellogg Child Welfare Foundation and focused its attention on the health needs of children living in Michigan's rural communities by providing hearing tests, eye exams, immunizations, and school lunches under the aegis of its Michigan Community Health Project (MCHP). Since that time, the foundation has provided seed funding and ongoing support for education, service, and research in public health, including food security and health professions education, as well as agriculture and community development. In keeping with Kellogg's intention to use a portion of his fortune to help people help themselves, its priorities have consistently leaned toward empowerment strategies and sustainable development. In recent years, it has diversified its funding, directing more money toward projects in the developing world, particularly Southern Africa (10% of total giving in 2006) and Latin America (8% of total giving in 2006).

The Kellogg Foundation's mission is to help people help themselves through the practical application of knowledge and resources to improve their quality of life and that of future generations. In 2007, the foundation refined its mission to focus more closely on vulnerable children. Its operations are rooted in several core values, including fidelity to the spirit and intent of its founder, a belief that individuals have an inherent capacity to effect change in their lives, organizations, and communities and that innovativeness in thoughts and action leads to enduring and positive change in both formal and informal systems. The foundation operates under the guiding principles of partnership, empowerment, and community development. Throughout its history, this orientation has influenced its role in public health and health services research.

Background

By its 25th anniversary in 1955, the Kellogg Foundation's assets stood at \$124 million. From an annual payout of \$26,000 in 1930, it was now able to give \$4.4 million. In 1980, its 50th anniversary year, the foundation made grants of more than \$52 million. In 2005, its 75th anniversary year, its assets had grown to \$6 billion, and its annual grant making totaled \$243 million. As of August 2007, the foundation's assets were over \$8.4 billion.

A review of the Kellogg Foundation's first decade sheds light on its operations over history. Most activities during the 1930s were directed toward filling the gaps in service resulting from the financial hardships and community dislocations caused by the Great Depression. Even during these early years, the foundation showed its commitment to innovative solutions to public health problems, most notably by hiring Margarite Wales as nursing director. Wales had experience in the landmark Henry Street Settlement House, widely regarded as having given birth to the discipline of public health nursing while improving neighborhood conditions and the personal health of residents of New York City's Lower East Side. The foundation's commitment to nursing continues to this day.

By the middle of its first decade, the foundation had established its first graduate medical education program, awarding fellowships to U.S. and Canadian physicians. Its commitment to health professions education was further demonstrated later in the decade, when, in 1939, it made a grant to the University of Michigan to establish the Institute of Graduate and Post-Graduate Dentistry, designed to provide continuing education for dentists in the community. In the early 1940s, the Kellogg Foundation, with the Rockefeller Foundation, helped build the University of Michigan School of Public Health; this is the first instance of another foundation tradition: using its resources to leverage even greater resources.

In addition to funding health profession education, in 1938, the Kellogg Foundation began funding Michigan State University to develop and host short agricultural education courses for young people from Michigan's farm communities. The foundation funds similar programs to this day.

Activities in the spirit of helping people help themselves can be traced back to the foundation's early history. From 1931 to 1948, the foundation supported the Michigan Community Health Project in seven Michigan counties. This comprehensive community development project consolidated rural schools, built hospitals and health departments, and encouraged volunteers to deliver essential services. In 1938, the foundation conducted a poll of the counties that were participating in the project to determine if residents found it beneficial and would be willing to be taxed in order to continue it. The answer was a resounding "yes," which reflected the popularity of the services and the level of community commitment and willingness to support it.

Enduring Themes

These themes—serving underserved communities, pursuing community-based approaches, employing empowerment strategies, enhancing community-based learning opportunities for health professionals, financing research on agriculture, and funding innovative approaches to recognized public health problems—guide the foundation to this day.

Serving Underserved Communities

Over the past 15 years, the Kellogg Foundation has addressed a number of issues that affect U.S. communities experiencing impaired access to healthcare, disinvestment in public health infrastructure, and educational disadvantage. In 1998, responding to the increasing number of Americans lacking health insurance, the foundation launched its Community Voices Initiative: Health Care for the Underserved to sustain safety net providers through partnerships with community health and human service providers. Community Voices is national in scope and is managed by the National Center for Primary Care (NCPC) at the Morehouse School of Medicine. In addition to providing funding for at-risk safety net providers, the foundation continues to provide direct service in communities of dire need. As an example, the School-Based Health Care Policy Program, a 5-year effort begun in 2004, was designed to provide school-based health throughout the United States using a consumer-centered model of quality care.

Pursuing Community-Based Approaches

Many examples of health-related community-oriented approaches have already been discussed. The foundation's community-oriented strategy touches other program areas as well. For example, in 1997, the Kellogg Foundation launched its Mid-South Delta Initiative connecting 55 counties in Arkansas, Louisiana, and Mississippi in community-based efforts to strengthen regional economic opportunities. This multifaceted program of technical assistance, business loan guarantees, and home ownership programs positioned the foundation to make substantial contributions to Hurricane Katrina relief. Katrina-related giving played a major role in foundation programs for several years.

Employing Empowerment Strategies

The Mid-South Delta Initiative is one of many Kellogg Foundation-funded projects that employed a local empowerment strategy. The foundation funded the Pathways to Collaboration project, organized by the Center for the Advancement of Collaborative Strategies in Health at the New York Academy of Medicine, and provided multi-year funding for seven partnerships around the nation to address local issues through community-driven collaboration.

Enhancing Community-Based Learning Opportunities for Health Professionals

Investment in health professions education has been a core activity of the foundation. Innovations include funding National Medical Fellowships, Inc. to develop a pool of qualified students to enter health professions education for careers in community-based health services by building partnerships with communities. During the 1990s, three multiyear health initiatives—Community Partnerships for Health Professions Education, Graduate Nursing and Medical Education, and Community-Based Public Health—were launched. These three programs shared a strategic interest in helping to make systems more responsive to the needs of people in the community. At the same time, the foundation invested in a series of other projects, known as Community Partnerships, to redirect health professions education toward community-based primary care. Taken together, these projects

provided millions of dollars to health professions schools and their community partners, training many public health professionals and primary-care professionals (nurses and physicians) to practice in community-based settings and actively engaging their communities in setting priorities toward achieving healthier communities and individuals. During the same period, the foundation invested in many of the U.S. Historically Black Colleges and Universities, allowing them to reshape their curricula in an effort to increase the number of minority applicants to graduate education.

Financing Research on Agriculture

The Kellogg Foundation invests in primary research on foodstuffs and agricultural practices. Launched in 2000, its Food and Society Initiative is designed to ensure access to a food supply that is safe and nutritious and grown in a manner that protects the environment while adding economic and social value to rural and urban communities. In keeping with its orientation toward investment in the future, it is also funding Iowa State University to revise Iowa's education programs in order to prepare food system professionals to meet the emerging needs of the agriculture sector of the economy. The foundation also supports various environmental projects, including groundwater protection and remediation. In the 1990s, the Integrated Farming Systems Initiative funded 18 projects to build demonstrations of viable agricultural systems that also ensure protection of the environment. Projects include the central Ohio Darby Creek Watershed, a successful collaboration between local farmers, environmentalists, and the Nature Conservancy.

Funding Innovative Approaches to Recognized Public Health Problems

In 1996, the Kellogg Foundation launched the Turning Point Initiative to improve public health nationwide through the development of community-based public-private partnerships. This ambitious project, undertaken in collaboration with the Robert Wood Johnson Foundation, set out to change the basic framework and infrastructure of public health through a collaborative process that engaged a wide-range of partners, including the

Centers for Disease Control and Prevention (CDC), the national Institute of Medicine (IOM), the American Public Health Association (APHA), the National Conference of State Legislatures, the National Association of Local Boards of Health, and the National Association of County and City Health Officials (NACCHO). Turning Point addressed a myriad of issues and responded to the changing priorities after the September 11, 2001, terrorist attacks, creating collaborative structures for preparedness, including bioterrorism. During 1996–2002, the foundation funded 41 local public health departments in 14 states to engage in strategic planning and policy development using an inclusive, collaborative approach. Most significantly, a model public health act was published in 2003 and has been used as a template for public health law reform efforts in a number of states.

International Programming

In 1937, two Montreal physicians were awarded Kellogg fellowships, beginning the foundation's work outside the United States. Upon his retirement in 1938, Kellogg spent a significant amount of time in Mexico, thus beginning the foundation's interest in Latin America. In 1941, nine physicians from Chile came to Battle Creek, a visit that resulted in a health professions fellowship program that brought over 200 Latin American health professionals to the United States between 1941 and 1945. The foundation has maintained a programmatic focus in Latin America since that time. Starting in 1985, the foundation funded the Integrated Health Program at Federal University of Ceara in Fortaleza, Brazil. This program created a network of hospitals and clinics linked to the university to improve care in communities and broaden the training of health professionals. Today, the foundation maintains an office in Latin America and funds health professions education, public health initiatives, and community development projects in many Latin American countries.

In 1985, the Kellogg Foundation began to fund programs in Africa. Since that time, it has funded direct service, educational scholarships, health professions training, and community partnerships. After the fall of apartheid in South Africa, the foundation decided to refocus its African

priorities. Using the community participatory approach it has espoused throughout its history, the foundation conducted a thorough program review, meeting with hundreds of community members, professionals, and policymakers across southern Africa. Ten demonstration sites were developed in rural areas with a programmatic focus on civic engagement, economic opportunity, skills and leadership development, and health and well-being. Today, funding for health professions education continues, and a regional office, staffed by Africans, currently operates in South Africa.

Funding Priorities

Information regarding the foundation's current funding priorities is available on the foundation's Web site. Funding is available through specific requests for proposals as well as unsolicited responses to general funding guidelines; most often, the foundation prefers a short preproposal when responding to general guidelines. It will consider a wide range of activities that support its stated mission and goals. Requests can include funding for research, operational expenses for established programs, capital requests, loans, equipment, conferences, media projects, endowments, and development campaigns when these requests are part of a broader program and/or funding effort. Program-planning grants and study proposals may also be considered when tied to specific projects in line with the foundation's priorities. In keeping with its philosophy of helping people help themselves, provisions to ensure project sustainability after funding ends are critical for a successful proposal.

Impact on Health Services Research

The Kellogg Foundation's commitment to health and well-being has been consistent throughout its history. This has included funding for direct service, health professions education, and policy initiatives. Traditionally, it has supported research not as an end in itself but as a vital part of accomplishing these other goals; the same can be said regarding specific medical conditions such as tuberculosis or HIV. Many of their priorities,

including strengthening access to healthcare, promoting policy development that supports healthy communities and individuals, and promoting social change at the systems level, require extensive research and evaluation components. In recent years, its efforts to encourage community-oriented health professions education have produced research findings of importance to the discipline of health services research. The Turning Point Initiative has directed funding toward policy development, bioterrorism, and preparedness research at local, county, and state levels. There is every reason to expect the W. K. Kellogg Foundation to continue to play an important role in these areas.

KIMBALL, JUSTIN FORD

Justin Ford Kimball (1872–1956) was an educator and healthcare insurance pioneer and innovator, credited with founding the first health insurance plan in the nation, which would ultimately become Blue Cross and Blue Shield. Kimball was born on a farm near Huntsville, Texas, in 1872. In 1890, he earned an undergraduate degree from Mount Lebanon College in Louisiana, and in 1899, he received a master's degree from Baylor University. Kimball undertook postgraduate work at the University of Chicago and attended law school at the University of Michigan. He subsequently worked as a teacher, principal, and superintendent in schools in Louisiana and Texas. Beginning in 1902, he practiced law but returned to educational leadership in 1905.

Kimball proved to be an exceptional administrator, and in 1914, he became Superintendent of Public Schools in Dallas, Texas. He held that position until 1924, when ill health forced him to resign. After his resignation, Kimball remained active as a lecturer and speaker, eventually joining the faculty of Southern Methodist University in 1925 as a professor of education. In 1929, he became vice president of Baylor University, in charge of the Colleges of Medicine and Dentistry, School of Nursing, and the University Hospital in Dallas to provide oversight of the university's medical education and "to shore up the shaky finances" of Baylor University Hospital.

Kimball found that a large share of Baylor University Hospital's unpaid bills were from Dallas schoolteachers. In 1929, almost concurrently with the great stock market crash that sparked the Great Depression, he developed a not-for-profit insurance plan whereby Dallas schoolteachers could prepay, at 50 cents a month, or \$6.00 a year, for 21 days of inpatient care in a semiprivate room at Baylor Hospital. The plan would take effect after a patient's first week in the hospital, with payments being \$5.00 a day. On its first day of subscription, 1,356 teachers signed up for the plan, and by December 1929, 75% of Dallas

teachers were enrolled in the plan. Within 5 years, the "Baylor Plan" provided health insurance coverage for some 408 diverse employee groups, totaling 23,000 members, eventually covering 3 million people within a decade. By 1933, the American Hospital Association (AHA) started regulating and approving similar prepayment plans, and the Blue Cross symbol, a blue Geneva cross known as a universal symbol of healthcare, came into use the following year. During 1944, the Baylor Plan merged into what would become one of the nation's Blue Cross and Blue Shield plans.

In 1939, Kimball, who was 67 year old, retired from Baylor University, but he remained active as a lecturer. He served on the Dallas civil service commission and from 1949 to 1952 was a member of the Texas State Board of Education. He died at his Dallas home in 1956.

After his death, the American Hospital Association (AHA) established the Justin Ford Kimball Innovators Award in his honor. The award recognizes individuals who make innovative contributions in bringing together healthcare delivery and financing.

L

LEAPFROG GROUP

The Leapfrog Group is an initiative that was started by large employers that purchase healthcare. Leapfrog works to create breakthroughs in the safety, quality, and affordability of healthcare. It is supported through its membership base, as well as the Business Roundtable (BRT), the Robert Wood Johnson Foundation (RWJF), and others. The mission of the Leapfrog Group is to facilitate enormous leaps forward in the safety, quality, and affordability of healthcare by supporting informed healthcare decisions of purchasers and consumers and by promoting healthcare that is high in value by realigning incentives and rewards.

Background

In 1998, a consortium of large employers began to discuss how they could collaborate and use their purchasing power to influence the quality and affordability of healthcare. These employers realized that billions of dollars were being spent on healthcare without any evaluation of its quality or its providers. A 2000 national Institute of Medicine (IOM) report, *To Err Is Human: Building a Safer Health System*, estimated that as many as 98,000 hospital patients die each year from preventable medical errors. The report recommended that large employers could use their market leverage to influence the quality and safety of healthcare. The founders of Leapfrog recognized that significant “leaps” forward could be taken to improve patient

safety and quality by rewarding hospitals that implemented substantial changes. In 2000, BRT set aside funding, and the Leapfrog Group was officially created.

The Leapfrog Group has a growing consortium that includes many of the nation’s largest corporations and other large purchasers of healthcare that provide benefits to more than 37 million individuals across the country. Member organizations of Leapfrog agree to make their healthcare-purchasing decisions with the goal of encouraging quality improvement among the providers and consumers involved. Leapfrog estimates that if all hospitals in the nation implemented its first three leaps of recommended safety and quality practices, more than 65,000 lives could be saved, more than 907,000 medical errors could be prevented, and about \$41.5 billion could be saved annually.

Initiatives

The Leapfrog Group is well-known for its Hospital Quality and Safety Survey, which is conducted annually and completed by hospitals on a voluntary basis. The survey measures hospital performance on the use of computer physician order entry, evidence-based hospital referral, intensive care unit staffing by physicians experienced in critical care medicine, and the Leapfrog safe practices score. Leapfrog’s survey goals are based on the following criteria: There is substantial scientific evidence that the safety and quality practices can significantly reduce preventable medical errors; the implementation of these practices is feasible;

consumers can readily benefit from these practices; and health plans, purchasers, and consumers can readily distinguish if these practices are present or absent in selecting their healthcare provider.

In 2008, the survey integrated the first set of hospital efficiency measures using standardized measures from the Joint Commission. The survey also serves as the basis for Leapfrog's Hospital Rewards Program, a pay-for-performance program that assesses the value of patient care by measuring performance along two dimensions—the quality of the care hospitals provide and how efficiently they deliver it.

To fuel the drive toward value-driven health care, Leapfrog developed the Incentive and Reward Compendium, a free database that categorizes and describes financial programs—such as those that reward providers with quality bonuses—and non-financial programs—such as those that reward providers with public recognition. These programs aim to affect hospitals, physicians, health plans, and/or consumers.

Bridges to Excellence and The Leapfrog Group have also formed a partnership to use the strengths of each organization to develop and implement programs that reward healthcare providers. Leapfrog lends its expertise in performance measures and public reporting, while Bridges to Excellence contributes its knowledge of implementing programs that reward healthcare providers for quality improvement.

Purchasing Principles

Leapfrog works to create improvements in the quality of healthcare by building transparency through its voluntary survey, providing incentives and rewards to hospitals that improve the quality of care they provide to patients, and creating consistency and leverage for change by collaborating with other organizations to develop quality and safety initiatives. Leapfrog's member organizations agree to follow four principles when making healthcare-purchasing decisions for their employees: increase awareness and inform enrollees about healthcare safety, quality, and affordability and the importance of comparing among healthcare providers; reward and recognize healthcare providers for making significant advances in the safety, quality, and affordability of healthcare;

hold health plans accountable for implementing the purchasing principles of Leapfrog; and build the support of consultants and brokers to use Leapfrog's principles with their clients.

To promote these purchasing principles, the Leapfrog Hospital Rewards Program, a pay-for-performance program, was launched in 2005 to drive improvements in hospital quality and efficiency for five clinical conditions by rewarding hospitals that demonstrated excellence in sustaining improvements. The five clinical conditions are (1) coronary artery bypass graft, (2) percutaneous coronary intervention, (3) acute myocardial infarction, (4) community-acquired pneumonia, and (5) deliveries/neonatal care. The efficiency measure applies a regional price adjuster to the average reimbursement a hospital receives for a given condition.

Current Issues

Beginning in June 2001, the Leapfrog Group began collecting data on hospitals by surveying urban and suburban hospitals in six geographic regions, which has now grown to 33 regions. The survey of the 33 regions covers more than 1,300 hospitals. These hospitals represent about 58% of all hospital beds in the nation, and they serve over half of the population of the nation. Free access to the ratings of these hospitals can be found at Leapfrog's Web site.

The Leapfrog Group continues to advocate for change by improving the quality and safety of patient care through its member organizations' purchasing power. Leapfrog's efforts have become a driving force in transforming the nation's healthcare system to ensure high-quality care and purchasing based on value.

LEE, PHILIP R.

Philip R. Lee is an academic who has served as a senior federal health policy official in two administrations. He also is a frequent advisor to federal, state, and local health policy makers.

Born in San Francisco, Lee grew up in Palo Alto, California, and is one of five children, all of whom became practicing physicians. Lee earned a medical degree from Stanford University in 1948. He joined the U.S. Navy and served as a medical officer from 1949 to 1951. From 1951 to 1956, Lee was a fellow at the New York University's Medical Center and Goldwater Hospital. He completed a fellowship at Mayo Clinic from 1953 to 1955 and earned a master's degree from University

of Minnesota in 1955. From there, Lee rejoined the faculty at New York University until he returned to Palo Alto in 1956. There, he worked as an internist at the Palo Alto Medical Clinic, which was founded by his father, Russell Lee, in 1930.

As a practicing physician during the 1960s, Lee joined a group called the Chowder and Marching Society, headed by Lester Breslow. The society met monthly and presented papers on various health policy topics. Also during this time, Lee was one of the founders of the Bay Area Committee for Medical Aid for the Aged. Additionally, he became actively involved in the King-Anderson Bill, which later became Medicare Part A. It was during this time that he became interested in governmental policies and practices.

In 1963, Lee left his medical practice and joined the federal government, becoming the director of health services in the Office of Technical Cooperation and Research in the Agency for International Development (AID). While in that position, he assisted in developing the first federal policies on family planning, malaria control, environmental sanitation, medical education, and the Food for Peace program. Additionally, he worked to better coordinate AID with the U.S. Public Health Service.

From 1965 to 1969, Lee served as the first assistant secretary in the U.S. Department of Health, Education and Welfare (now split into the Department of Education and the Department of Health and Human Services) under President Lyndon B. Johnson. In his position, Lee was involved in a wide range of policy issues, including bioethics, biomedical research, environmental health, family planning, and the education of health professionals. One of his main tasks was to implement the Medicare program, which was passed in 1965.

From 1969 to 1972, Lee served as the chancellor of the University of California, San Francisco (UCSF), where he helped increase the enrollment of minority students, particularly in the health professions. In 1972, while he was a professor in the School of Medicine, he founded the Institute for Health Policy Studies, which was the first of its kind in the nation. Lee served as the director of the institute until 1993, when he retired from UCSF to accept the appointment of Assistant Secretary for Health in the Department of Health and Human

Services under President Bill Clinton from 1993 to 1997. Additionally, Lee served in several other capacities. He was the first president of the San Francisco Health Commission. He served on the Board of Trustees of the Carnegie Corporation and the Mayo Foundation. And he headed the federal Physician Payment Review Commission (PPRC) from 1986 to 1993.

Lee has been honored for his many accomplishments. He received the David Rogers Award from the Association of American Medical Colleges (AAMC) in 1998, the National Academy of Sciences, Institute of Medicine's Gustav O. Lienhard Award in 2000, the American Public Health Association's Sedgwick Medal in 2000, the Henrik Blum Award from the California Public Health Association in 2001, and the National Hero Award in 2002. In 2007, the health policy institute he founded at the University of California, San Francisco, was renamed the Philip R. Lee Institute for Health Policy Studies in his honor.

Lee is the author or coauthor of more than 150 articles and four books. One of his books, *The Nation's Health*, is in its seventh edition. Although he is retired, Lee is currently working on policy issues such as diversity in medical education, financing national health insurance, and evidence- and population-based healthcare.

LEWIN GROUP

The Lewin Group is a nationally recognized healthcare and human services management consulting firm. The Lewin Group provides policy-focused empirical research, hands-on technical assistance, and evaluation services to federal, state, and local governments, foundations, associations, hospitals and health systems, insurers and health plans, and medical technology companies.

Background

Founded by Lawrence S. Lewin in 1970, the Lewin Group, which is located in Falls Church, Virginia, recently was acquired by Ingenix, Inc., a leading health information technology company. Lewin's strategic and analytical services aim to help clients improve policy and expand knowledge of healthcare through the integration of evidence-based practices; enact, run, and evaluate programs to enhance delivery and financing of healthcare and human services; deal with shifts in healthcare practice, technology, and regulation; optimize performance, quality, coverage, and health outcomes; and create strategies for institutions, communities, governments, and people to make healthcare and human services systems more effective. Lewin's consultants are drawn from industry, government, academia, and the health professions. Many are national authorities whose strategies for health and human services system improvements come from a personal experience with imperatives for change.

Lewin's policy research work includes both long-term studies and quick-turnaround policy analyses. Federal and state clients and others count on the Lewin Group for their in-depth experience and innovative, analytic approaches.

Modeling Health Reform

The Lewin Group has been a leader in the health reform and coverage arena and is one of the few

independent sources of information on the financial impacts of health coverage expansion and national and state health reform initiatives. The Health Benefits Simulation Model (HBSM), developed by The Lewin Group, is a well-vetted, proprietary microsimulation model of the U.S. healthcare system. The model, based on the Medical Expenditures Panel Survey data and surveys of employers and health plans, provides a comprehensive representation of public and private insurance coverage and health spending. These data enable The Lewin Group to simulate the effect of a wide range of health reform initiatives on major stakeholder groups, including employers, state and federal governments, families, and providers. The model has been used by Republicans and Democrats to analyze a broad range of health reform proposals at both the state and the federal level, including The Lewin Group's independent analysis of the Clinton health reform proposal of 1993, comparative analysis of the proposed health plans of President George W. Bush and Senator John F. Kerry (D-MA) during the 2004 presidential campaign, President Bush's health insurance proposal of 2007, and the Healthy Americans Act introduced by Senator Ron Wyden (D-OR). The Lewin Group has developed comparisons of alternative coverage expansions for organizations such as the Robert Wood Johnson Foundation (RWJF) and the Commonwealth Fund. Lewin also has modeled a wide range of health reform models for individual states, including tax credits, the single-payer model, and individual mandate proposals.

Cost-of-Illness Studies

The Lewin Group's cost-of-illness studies provide information on both the direct medical costs associated with a disease and the indirect costs, such as lost productivity and premature deaths. These costs are estimated from the perspective of society, healthcare payers, and consumers.

Lewin recently completed a study on the national cost of diabetes for the American Diabetes Association. The study estimated the national economic burden of diabetes at \$174 billion in 2007, approximately \$116 billion in additional healthcare expenditures attributed to diabetes and \$58 billion in lost productivity from absenteeism,

reduced productivity, permanent disability, and premature mortality.

In addition, Lewin continues to estimate the economic cost of drug abuse in the United States for the Office of National Drug Control Policy. Lewin has also studied the economic burden of alcohol abuse for the National Institutes of Health (NIH) and is updating these estimates for the Centers for Disease Control and Prevention (CDC) 2008 report. Other studies being conducted include the prevalence and cost of 17 digestive conditions for the American Gastroenterological Association; the cost of obesity, alcohol abuse, and tobacco use for the U.S. Department of Defense/TRICARE Management Activity; the cost of skin disease for the Society for Investigative Dermatology; and the cost of Chronic Fatigue Syndrome for the CDC.

Long-Term Care

Lewin's Center on Long Term Care brings together experts from across the organization to promote systems change for individuals who have long-term care needs due to chronic conditions or disability. The Lewin Group's staff provides policy development support and technical assistance for the U.S. Administration on Aging's (AoA) efforts to reform the nation's long-term care system so that older adults and individuals with disabilities can live independent lives in their communities. The organization also assists states and local communities to understand the implications of the aging baby boom population and its impact on the range of government services, from transportation to housing and healthcare.

Lewin also recently conducted a study documenting the significant number of older adults, particularly among the "oldest old" (persons 85 and older), who have elected to stay in their homes and in residential alternatives rather than move to nursing homes. The findings speculate on the impact this shift will have on the future demand for long-term care. Through the Centers for Medicare and Medicaid Services (CMS)-sponsored National Direct Service Workforce Resource Center, Lewin additionally supported efforts to improve the recruitment and retention of direct-service workers, who help people with disabilities and older adults to live independently.

Healthcare Workforce: Supply and Demand

An adequate supply of healthcare workers is integral to achieving the nation's goal of ensuring access to quality and affordable healthcare. The Lewin Group is helping healthcare stakeholders understand the implications of demographic trends; changes in the healthcare operating environment; and policies and programs on efforts to train, recruit, and retain health workers. Lewin uses a quantitative approach to help decision makers in the public and private sectors deal effectively with health worker supply and demand and related issues, such as workforce management and program design. The Lewin Group has also worked with the Health Resources and Services Administration (HRSA), states, professional associations, health systems, insurers, and others to develop models that project supply and demand for physicians, nurses, and other health workers.

LICENSING

Healthcare professionals are licensed by the government to protect the healthcare consumer and to ensure a minimum standard of quality of care. Most healthcare professionals cannot practice unless they are licensed. The licensing of healthcare professionals in the United States is carried out at the state government level, and it limits who can and who cannot provide care. The federal government, however, also plays a role in the regulation of healthcare providers by coordinating state licensure programs through a centralized database known as the National Practitioner Data Bank (NPDB), which contains disciplinary actions of providers, and by imposing requirements on providers who receive federal reimbursement (e.g., Medicare, Medicaid).

Background

The government sanction of medical practice dates back thousands of years in India and China. In the Western world, King Henry VIII of England in 1518 established a charter to grant licenses to qualified physicians. In the United States, the American Medical Association (AMA) played a pivotal role in the 19th century supporting state enactment of licensure laws for physicians. Between 1874 and 1915, licensing requirements for medical practice were passed in all states in the nation. Often, as one state passed licensing requirements, poor-quality physicians would move to another unregulated state to practice. However, eventually, as all states required licensing, many poorly trained and unqualified physicians left the profession,

which ultimately resulted in better quality of care and increased status of the profession.

The push by the AMA for state licensure served as a model for the licensing of other healthcare professionals. By the 1920s, most states enacted licensing programs for dentists, pharmacists, nurses, and other healthcare providers. Most allied health professionals, including dental hygienists, physical therapists, and emergency medical technicians, were required to receive licensing by 1960. The health professions have generally advocated for state licensure in addition to standardized education and training.

Role of State Licensing Boards

State licensing boards serve as gatekeepers to control the entry of clinical practice. The role of the state boards is to confirm a provider's training and education and to administer a prerequisite examination before allowing providers to engage in clinical practice. The state boards issue licenses to providers who pass the examinations, renew licenses, and enforce the basic standards of the profession. Members of state boards generally consist of individuals in the profession and sometimes include consumer representatives. The state boards may function independently or as part of a state's department of health. State licensing boards operate under statutes and regulations and have oversight by the state legislature. The boards also maintain procedural rules.

The licensing of providers usually entails two components. First, they must have graduated from a school that has been certified in the state desired to practice in as well as pass a state-administered examination. Second, they must also provide the state board with basic information about themselves. The education requirement has allowed for state oversight of education curricula.

The renewal of a license is generally based on not having any disciplinary action against a provider since the period of the individual's last review and fulfilling a certain number of continuing-education units. If a provider, however, has had a disciplinary action against it, it must be given due process that entails a fair proceeding to contest the charges before the state board revokes or suspends its license. The provider must be properly informed of the charges and be given a fair hearing. An

appeal board may determine if proper procedures were followed if a discipline is sanctioned, and the provider may appeal to the courts. Although disciplinary actions are made public, they are usually not widely publicized.

Issues of Licensing

The state licensure of healthcare providers raises several issues. Since licensure is carried out at the state level, there are wide variations in professional standards as well as in the enforcement of those standards. The coordination by states and the federal government on the NPDB is also precarious. Providers with disciplinary action against them may be able to evade enforcement officials and seek licensure to practice in another state.

The use of professional peers on state licensing boards is also an area of contention. Although professional peers have the credentials necessary to evaluate other providers in their profession, serious questions have been raised about the objectivity of such a review process and whether this is really a form of professional self-regulation. There are concerns that professional peer board members may be more interested in maintaining the reputation of their profession or may impose barriers to the entry of new providers to control competition. Furthermore, consumer advocates argue that the low level of enforcement by state licensing boards is indicative of the boards serving the interests of the profession over those of the public.

Future Implications

Licensing continues to play an important role as the cornerstone of ensuring quality in healthcare. However, there remain some concerns over whether licensing is best carried out at the state or federal level and whether the professions are able to adequately regulate themselves. Also, there are questions over whether patients are better protected by government oversight or through economic market forces. For the time being, state licensing remains the foundation for regulating the clinical practice of most healthcare professionals.

LIFE EXPECTANCY

Life expectancy is the average number of years that an individual of a given age is expected to live. Life expectancy may be determined by race, gender, or other characteristics using age-specific death rates or life tables for the population with that characteristic. Life expectancy at birth is often cited, but it can be given for any age group.

For example, in 2005, the life expectancy at birth for the total U. S. population was 77.8 years; for those 65 years of age, it was 83.7 years; and for those 75 years of age, it was 87.0 years.

Health services researchers use life expectancy as a broad indicator of the overall health of a given population. They often compare the life expectancy and health expenditures of nations with various health delivery systems. Although the United States has a higher life expectancy than the global average, it is only slightly higher than the average for developed nations. The United States ranks 48th highest in life expectancy, surpassed by nations such as Japan, Sweden, Switzerland, Australia, and Canada.

History

The English statistician John Graunt constructed the first life table, a statistical table that uses age-specific death rates to determine a group's average life expectancy. Graunt, who is considered the founder of the science of demography and vital statistics, was interested in studying the effects of epidemics on populations. He analyzed the *Bills of Mortality*, which recorded the weekly count of births and deaths in London parishes. In 1662, he published the results of his findings in *Natural and Political Observations Made Upon the Bills of Mortality*.

Edward Wigglesworth constructed the first life table in America in 1793. Wigglesworth used mortality data reported in 1789 from Massachusetts, Maine, and New Hampshire. He estimated the average life expectancy at birth was about 35 years.

Actuaries have been constructing and using life tables for decades to determine the premium rates for life insurance policies based on the average life expectancy of enrollees. Actuaries at the Social Security Administration (SSA) also use life tables to monitor Social Security enrollees. And the National Center for Health Statistics (NCHS) uses life tables to monitor mortality trends in the nation's population.

Recently, the concept of life expectancy has been modified to focus on healthy life expectancy, sometimes called health-adjusted life expectancy (HALE), which extends life expectancy measures by accounting for the health states of populations. In 2000, the World Health Organization (WHO)

reported for the first time healthy life expectancy for its 191 member countries.

Reasons for Increased Life Expectancy

During the 20th century, life expectancy in the United States rose dramatically. In 1900, the average life expectancy at birth for the nation's total population was 47.3 years; by 1999, it had increased to 76.7 years. This increase in lifespan is attributable to many advances in the nation's public health. In 1999, the Centers for Disease Control and Prevention (CDC) identified a number of factors that contributed to the dramatic increase in life expectancy, including vaccinations, control of infectious diseases, safer and healthier foods, healthier mothers and babies, safer workplaces, motor vehicle safety, decline in deaths from coronary heart disease and stroke, and recognition of tobacco use as a major health hazard.

Public health vaccination campaigns in the nation have eliminated many deadly diseases. Because of vaccinations, once common deadly diseases, such as diphtheria, tetanus, poliomyelitis, measles, mumps, and rubella, have been virtually eliminated. And smallpox has been totally eradicated.

Public health efforts led to the establishment of local and state health departments across the nation. These health departments initiated environmental and sanitation programs, such as clean drinking water, sewage disposal, garbage disposal, mosquito control, and educational programs, which decreased exposure to infectious diseases.

Safer and healthier foods were developed. Better food processing has resulted in fewer deaths because of microbial contamination. In addition, foods have become more nutritious; many are fortified to eliminate major nutritional deficiency diseases such as rickets, goiter, and pellagra.

Mother and infant deaths have been greatly reduced by better hygiene and nutrition programs. In addition, there was greater access to healthcare, family planning programs, antibiotics, and technological advances in maternal and neonatal medicine.

Work-related deaths, injuries, and health problems have greatly declined as a result of more safety measures and greater regulation. Once common diseases such as coal workers' pneumoconiosis

(black lung) and silicosis have come under better control.

Engineering improvements in both vehicles and highways and changes in personal behavior, such as the use of safety belts, child safety seats, or motorcycle helmets, and decreased drinking and driving, has resulted in a large reduction in motor vehicle-related deaths.

The discovery of the major underlying risk factors of heart disease and stroke—smoking, diet, exercise, and blood pressure control—has resulted in smoking cessation and blood pressure control programs. There was also improved access to early detection and better medical treatment.

Since the 1964 Surgeon General's report on the health risks of smoking, smoking among adults has decreased, and millions of smoking-related deaths have been prevented. Public health anti-smoking campaigns have resulted in greater public awareness of the major health-related problems caused by smoking.

Future Implications

While the average life expectancy in the United States has risen to nearly 78 years, it seems unlikely that it will continue to increase at a fast pace in the future. Much of the past increase in life expectancy was due to decreases in infant mortality and infectious diseases, and other factors. In the future, any increase in life expectancy will likely be small incremental gains of perhaps a month or two per year. Some future years may even see a slight decrease in life expectancy due to factors such as increased diabetes and obesity.

LOMAS, JONATHAN

Jonathan Lomas was a faculty member in the department of clinical epidemiology and biostatistics at McMaster University in Hamilton, Ontario, Canada, from 1982 to 1997; Professor of Health Policy Analysis from 1992 to 1997; and inaugural Chief Executive Officer of the Canadian Health Services Research Foundation (CHSRF) from 1997 to 2007. Although Lomas’s undergraduate training was in experimental psychology at Oxford University, his landmark contributions have been as a scholar in the field of health policy analysis and as an innovator in improving the relevance and use of health services research in health system decision making.

Lomas’s scholarly contributions touched on all three “levels of health policy” (as he called them)—clinical policy, administrative/organizational policy, and public policy, but it was his research in the domain of clinical policy that first brought him widespread attention. His most widely cited scholarly article, “Do Practice Guidelines Guide Practice? The Effect of a Consensus Statement on the Practice of Physicians,” was published in the prestigious

New England Journal of Medicine in 1989. His research on administrative and public policy addressed highly topical policy issues such as the regionalization of health services delivery in Canada. His writing about innovative models for priority setting in health services research (“On Being a Good Listener . . .” *Milbank Quarterly*, 2003) and about conducting research in close partnership with health systems decision makers (“Using ‘Linkage and Exchange’ to Move Research Into Policy at a Canadian Foundation,” *Health Affairs*, 2000) has been highly influential among research-funding organizations.

Under Lomas’s leadership, the CHSRF designed its research programs (i.e., the Capacity for Applied and Developmental Research and Evaluation [CADRE] program) to build a critical mass of applied health services and nursing researchers in Canada and to create a supportive environment for these researchers to engage with decision makers. It also designed training and support programs for decision makers, such as the Executive Training for Research Application (EXTRA) program, and a widely emulated 1:3:25 rule for organizing research reports. Its program designs and “linkage and exchange” philosophy have served as a point of reference for many large and small organizations seeking to improve the use of research in decision making in Canada and internationally.

Lomas is also known for cofounding McMaster University’s Centre for Health Economics and Policy Analysis, his scholarly work with the Population Health Programme of the Canadian Institute for Advanced Research (1988–2004), and his service contributions in Canada (Federal, Provincial, Territorial Advisory Committee to Deputy Ministers on Health Services, 1994–1996; Ontario Premier’s Council on Health, Well-Being and Social Justice, 1991–1994; Interim Governing Council and Institute Advisory Board of the Canadian Institute of Health Research, 1999–2004) and the United States (member of the board of directors of the Association for Health Services Research and its successor AcademyHealth, 1999–2005).

He also made an impact through consultancies for the World Health Organization (WHO) and other international agencies in Australia, Indonesia, Myanmar, the Philippines, South Korea, Sri Lanka,

and Thailand. He was a visiting scholar at the University of Gadjah Mada in Indonesia (1990), the University of Sydney and the Department of Health of the New South Wales Government in Australia (1996–1997), the Dutch national research and development agency ZonMw (2004), and the Ministry of Health in New Zealand (2007). In recognition of his scholarly and professional impact, the University of Montreal awarded him an honorary doctorate degree in 2005, and he was elected a fellow of the Royal Society of Canada and the Canadian Academy of Health Sciences in 2006.

LONG-TERM CARE

Long-term care (LTC) includes a wide variety of health and support services that are provided to the frail, the elderly, and individuals with chronic disease conditions and disabilities. LTC is largely personal, custodial, and unskilled care provided to those who cannot care for themselves for extended periods of time. The majority of those receiving LTC are the frail elderly who suffer from multiple chronic diseases. In the United States, about 60% of all individuals 65 years of age or older require at least some type of LTC services during their lifetime, and over 40% need care in a nursing home for some period of time. In 2006, there were 37.3 million people in the nation 65 years of age or older, or about one in every eight Americans. By 2030, the number is expected to grow to 71.5 million people, or about one in every five Americans. Although the family is the primary source of LTC, the increasing size of the nation's older population coupled with decreasing family size and high divorce rates will invariably increase the demand for paid LTC services.

The need for LTC services for people suffering from chronic disabilities is often estimated using the criteria of Activity of Daily Living (ADL) or the Limitations of the Instrumental Activities of Daily Living (IADL). The ADL criteria include bathing, dressing, getting in or out of bed, getting around inside, toileting, and eating; and the IADL criteria are light housework, laundry, meal preparation, grocery shopping, getting around outside, managing money, taking medications, and telephoning. According to the National Institute on Aging, in 2006, about 20% of all Medicare enrollees, including 5% who were institutionalized, had limitations in one or more ADLs. However, only about half of those individuals were estimated to be receiving personal care. The majority of those (65%) who received personal care obtained it from unpaid caregivers (i.e., spouse, adult children, other family members, and friends), about 26% received personal care from both unpaid and paid caregivers, and the remaining 8% received personal care from only paid caregivers.

Projected Demand for Paid Care

The demand for paid LTC services is expected to increase sharply in the future because of the growth in the nation's older population. A simulation study conducted by the Urban Institute in 2007 estimates that between 2000 and 2040 the number of older adults with chronic disabilities in the nation will more than double, increasing from about 10 million to about 21 million individuals. Although the study projected an overall declining rate of old-age disability during the period, the total number of individuals with disabilities will more than double simply because of the enormous size of the older population by 2040. This trend is troubling because at the same time that it will be occurring, family size is likely to decline, and there will be rising divorce rates and an increase in female employment rates. As a result, the demand for paid LTC services is projected to increase sharply in the future. The study estimates that the number of old people receiving paid home care will increase from 2.2 million to 5.2 million and the number of older nursing home residents will increase from 1.2 million to 2.7 million individuals.

Financing Long-Term Care

Meeting the projected need for LTC will be a daunting task for both the private and the public sectors, considering that LTC services for older adults already represent a substantial share of the nation's total healthcare spending. In 2005, nursing home and home health care accounted for slightly over 10% of national personal health expenditures, or about \$169 billion. This amount does not include care provided by family or friends on an unpaid basis (often called "informal care"). It only includes the costs of care from paid providers.

The largest share, 48%, of the nation's LTC costs are paid for by Medicaid, a jointly funded state and federal program; state and local governments pay for 19%; and the private sector (through out-of-pocket and insurance premiums) pays 31% of the total LTC costs. However, the federal government pays for LTC through its portion of the Medicaid program and also through the Medicare program. These two sources pay for 50% of the nation's LTC costs, making the federal government the single largest payer for LTC.

Medicare Coverage

Since the implementation of Medicare's hospital prospective payment system in 1983, which encouraged the nation's hospitals to shorten patient length of stays and discharge patients as quickly as possible, nursing homes have seen an increasing number of individuals requiring post-acute rehabilitation. Specifically, Medicare Part A will pay for their care at a skilled-nursing facility (SNF) only if the care occurs within 30 days of a hospitalization of 3 or more days and is certified as medically necessary. Covered services are similar to those for inpatient hospital stays but also include rehabilitation services and medical equipment. However, Medicare does not cover nursing facility care if the individual does not require skilled nursing or skilled rehabilitation services. Although the number of SNF days provided by Medicare is limited to 100 days per benefit period, the average length of stay in an SNF is usually less than 2 weeks. Under Medicare, no copayment is required for up to 20 days; a copayment is required for Days 21 to 100; and after 100 days, the individual pays the total cost.

While SNF care may be viewed as an extension of hospital inpatient care rather than true LTC, home health care has increasingly been transformed into a source of long-term personal assistance for Medicare beneficiaries, especially those with severe functional limitations and cognitive impairment. Both Medicare Part A and B cover part-time or intermittent skilled nursing care and home health aide services, and some therapies that are ordered by a physician and provided by a Medicare-certified home health agency. Specifically, Part A covers the first 100 visits following a 3-day hospital stay or an SNF stay, and Part B covers any visits thereafter. Home health care under Part A and B has no copayment and no deductible.

Medicare Part A covers hospice care for individuals with a terminal illness, generally individuals who are not expected to live more than 6 months. Although Medicare does not consider hospice care to be an LTC service, an increasing number of hospice patients are living well beyond 6 months, and hospices are becoming more like an LTC setting for those with terminal illnesses who are bed-stricken. Hospice services include

drugs for symptom control and pain relief, medical and support services from a Medicare-approved hospice provider, and other services not otherwise covered by Medicare (e.g., grief counseling). Hospice care is usually provided in a patient's home (which may include a nursing home if that is where the patient lives) or a hospice care facility. However, Medicare does cover some short-term hospital and inpatient respite care provided to a hospice patient to allow the usual caregiver to rest.

Medicaid Coverage

Although the number of short stays has increased, the majority of nursing home residents require long-term custodial care. Most nursing home care is paid for by Medicaid and by the resident's own resources. According to the National Center for Health Statistics 2004 National Nursing Home Survey, Medicaid paid for at least some of their care for 65% of all nursing home residents, private/other sources paid for 22%, and Medicare paid for 13%.

During the past decade, a growing number of older individuals have opted to reside in community residential facilities, such as assisted living facilities, board and care, and continuing-care retirement communities, instead of being placed into nursing homes. Currently, an estimated 1 million individuals live in residential facilities, largely financed from their own resources. The public sector has taken note of this trend. States, which have been concerned about the increasing number of Medicaid residents in nursing homes, have started using Medicaid to fund those living at home and in the community through Home and Community-Based Service (HCBS) waiver programs. The primary purpose of such programs is to keep those at risk of being institutionalized in nursing homes at home or in the community. The program provides family members with supplementary services including adult day care services to help them continue to provide care. Some states are also trying to relocate nursing home residents back in the community. As a result of these and other changes, the percentage of total Medicaid spending on nursing homes was reduced to 44% in 2006, and the percentage of spending for home health and personal care increased to 41%.

Dual Eligible Beneficiaries

Some Medicare enrollees also are Medicaid recipients, and they are called *dual eligibles*. For those who are dual eligibles, Medicare covers its set of medical services, while Medicaid pays for the individual's Medicare premiums and cost sharing, and—for those below certain income and asset thresholds—LTC services. The dual eligibles tend to be older, sicker, poorer, and they use more expensive medical services. The dual eligibles have an important impact on LTC spending. Since Medicare covers SNF care, some dual-eligible patients are discharged from hospitals to SNF for LTC services. After Medicare stops paying for their care, the dual eligibles rely on Medicaid to pay for their LTC services. In some cases, noninstitutional options may have been more appropriate, which may have provided better outcomes for the individual and lower costs for both Medicare and Medicaid. Efforts are now being made to better coordinate and integrate LTC services between Medicare and Medicaid.

Private Coverage

Medicare and Medicaid are not ideal providers of LTC. For the most part, Medicare was designed to provide acute care not LTC, and the Medicaid program was designed to provide medical care to the deserving poor in certain limited categories, particularly women and children. Specifically, Medicare only pays for medically necessary SNF or home health care. While Medicare pays for about 18% of LTC, it only pays under specific circumstances. If the type of care needed does not meet Medicare's rules, it does not pay. In terms of Medicaid, individuals with assets and financial resources often do not qualify for Medicaid unless they use up their resources by paying for care and become poor. Furthermore, states apply strict preadmission screening to deter people from being institutionalized in nursing homes.

Because of the many problems associated with Medicare and Medicaid, most people who need LTC end up paying for some or all of their care using their own assets and financial resources. However, LTC is very expensive. For example, based on national averages for 2006, a semiprivate room in a nursing home costs \$171 per day, a pri-

vate room in a nursing home costs \$194 per day, a stay in an assisted living facility (one-bedroom unit) costs \$2,691 per month, the use of a home health aide service costs \$25 per hour, the use of a homemaker service costs \$17 per hour, and a stay in an adult day healthcare center costs \$56 per day.

To pay the costs of LTC, some people purchase LTC insurance. Currently, about 10% of the nation's population purchase LTC insurance. The average annual premium costs for a policy purchased in 2005, across all age groups of buyers and all types of insurance policies, was just over \$1,900. This represents a comprehensive policy (covering both nursing facilities and at-home care) that provides an average of 5.5 years worth of benefits, with a daily benefit payment of \$143. Most policies purchased also included some form of automatic inflation protection.

Other insurance also pays for some limited LTC services. Most Medicare enrollees purchase a Medicare supplemental insurance plan, or Medigap insurance, which is sold by private health insurance companies to cover some of the "gaps" in expenses that are not covered by Medicare. In addition to covering some of the costs of Medicare's copayments and deductibles, some Medigap policies also provide additional benefits such as at-home recovery care.

A reverse mortgage may also be an option for some individuals who need LTC and expect to live in their current home for several years. A reverse mortgage is a special type of home equity loan, where home owners 62 years of age or older receive a loan against their home that does not have to be paid back as long as they live in their home. The home owner receives a lump-sum payment, a monthly payment, or a line of credit against the value of the home without selling it.

Public Policy: Acts Related to Long-Term Care

A number of federal acts are directly related to LTC. Some of the major acts include the Deficit Reduction Act of 2005, the Older Americans Act of 2001, the Millennium Health Care and Benefits Act of 1999, and the Balanced Budget Act of 1997. Each act is discussed below.

Deficit Reduction Act of 2005

The Deficit Reduction Act of 2005 refined the eligibility requirement for state Medicaid recipients by tightening standards for citizenship and immigration documentation and by changing the rules concerning LTC eligibility. Specifically, the period for determining community spouse income and assets was lengthened from 36 to 60 months, individuals whose homes exceeded \$500,000 in value were disqualified, and the states were required to impose partial months of ineligibility. The act also contained a provision allowing for the expansion of a National LTC Partnership program to all states. The goal of the program is to encourage individuals to purchase private LTC insurance. In the program, individuals who exhaust their LTC insurance benefits can retain a greater amount of their assets and still qualify for state Medicaid, without having to "spend down." Specifically, purchasers would be allowed to keep a dollar of assets for every dollar they receive in benefits from the program. The ability to retain additional assets, yet still use Medicaid as a "safety net" if private coverage does not suffice, is an incentive for more individuals to purchase at least a moderate amount of private coverage.

Older Americans Act of 2001

The Older Americans Act of 2001 is one of the most significant laws affecting LTC. It changed the bias toward institutionalizing LTC. In passing the act, the U.S. Congress recognized the family's role in providing LTC. The act has the goal of retaining the family as caregivers of the elderly who desire to be cared for in the home. It provides funding, through state and local Aging Network agencies, to help families and older individuals remain independent within their communities. While there are no specific financial eligibility criteria for Older Americans Act services, they are generally targeted at low-income, frail seniors over age 60 and minority elders and seniors living in rural areas.

Millennium Health Care and Benefits Act of 1999

The Millennium Health Care and Benefits Act of 1999 expanded the Veterans Health Administration's (VHA) programs to increase access to nursing home care and other extended care services to

veterans who do not have service-related disabilities but who are unable to pay the costs of necessary care. For those who qualify, the benefits can provide financial assistance for some LTC costs. Copayments may apply depending on the veteran's income level. The VHA also has a Housebound and Aid and Attendance Allowance Program that provides cash grants to eligible disabled veterans and surviving spouses in lieu of formally provided homemaker, personal-care, and other services needed for assistance in activities of daily living and other help at home.

Balanced Budget Act of 1997

Several provisions of the Balanced Budget Act of 1997 addressed the explosive growth of Medicare's home health care expenses in the early 1990s. Home health care, which in 1989 accounted for only 2.5% of all Medicare Part A expenditures, exceeded 15% of the total in 1996. To stem the growth, the act moved home health care to a prospective payment system, and it discouraged hospital ownership of home healthcare agencies. The act dramatically reduced Medicare's home health care expenditures and utilization; expenditures in the following 2 years after the act's passage declined by 52%, the percentage of Medicare beneficiaries receiving home health care services for the first time declined by about 20%, and the use among those who availed of these services declined by 39%.

Future Implications

The projected future growth in the nation's older population will seriously challenge both the private and the public sectors. With declining family size and high divorce rates, the need for paid LTC services will greatly increase in the future. Many future retirees will likely not have the necessary financial resources to afford the LTC they need. The future strain on the Medicare and Medicaid programs will be enormous. To address these issues, policymakers must develop new innovative ways of financing and providing LTC, which politicians will support and the general public will accept.

LONG-TERM CARE COSTS IN THE UNITED STATES

Long-term care (LTC) is often viewed as a service involving only the elderly. In reality, individuals of

all ages, including children, nonelderly adults, as well as older persons, use LTC services. Approximately 37% of LTC recipients are under 65 years of age. Individuals in these three age groups can be further subdivided into classes, including those individuals facing physical challenges, persons with persistent and severe mental illness, children with developmental disabilities, adults with intellectual disabilities, persons with some type of dementia, and individuals with some combination of these challenges.

In 2005, expenditures in the United States for LTC services such as nursing home care, assisted living, and home health totaled over \$200 billion. Roughly 72% of those expenditures came from the public coffers, largely the Medicaid or Medicare programs, with payments from private insurance (7.2%), other private spending (2.7%), and out-of-pocket expenditures by individuals accounting for most of the rest of spending on formal LTC services.

Indeed, LTC is an area of healthcare where consumers or their families pay a relatively substantial proportion of the costs of formal care. Historically, for the health services used by the elderly, only expenditures for prescription medications have been more heavily funded by out-of-pocket expenditures. In 2005, out-of-pocket expenditures for LTC financed 18% (\$37 billion) of the costs of all LTC services.

Costs are quite high for those paying for LTC from personal funds, especially when one considers the average income of those frail and vulnerable individuals in need of it. In 2006, the estimated average annual cost of a private room in a nursing home was just over \$70,000. For those who could afford it, a private room in an assisted living facility might cost more than \$30,000 a year for room, board, oversight, and basic services, such as medication assistance, with the potential for substantial additional costs for special services, such as more extensive personal care, medications, and therapies. With an hourly cost of an estimated \$25 per hour for a home health aide, an individual receiving only 4 hours of personal care assistance per day would spend more than \$36,000 a year for such help.

While much attention is focused on public expenditures for care, it is important to emphasize that no matter which group of LTC recipients we

discuss, informal caregivers provide the vast majority of care. Family and friends provide an estimated 80% of all LTC. Informal caregivers typically provide many hours of care each week, and the average duration of caregiving is over 4 years—and usually longer for caregivers of persons with Alzheimer's disease. Nearly half of these caregivers place their own economic status and retirement at risk by reducing or losing employment and income to provide care. The value of unpaid care is difficult to determine, but in 2006, the AARP Policy Institute estimated that the value of unpaid LTC was \$354 billion annually, which substantially exceeded the total expenditures on formal services.

Long-Term Care and the Elderly

The variety of individuals receiving LTC and the variety of settings in which it can be provided make it difficult to succinctly summarize all aspects of its costs. The remainder of this entry focuses on LTC costs for the frail elderly, who constitute more than 60% of those needing LTC services. Special attention is given to the projected LTC costs associated with aging among the baby boomer generation.

High mortality rates and lower life expectancy during the 19th and early 20th centuries kept the issue of LTC off the policy agenda. Life expectancy at birth in 1900 in the United States was only 47 years, and children with profound disabilities and individuals with developmental disabilities had an even more limited life expectancy. The few persons who survived into old age in America were cared for either by their families at home or in the local "poor farms" or "almshouses" supported by local or county governments or charitable organizations. Many of those with persistent and severe mental illness also faced institutional care or relegation to poor farms. But, by 2004, life expectancy at birth was almost 78 years, life expectancy for someone aged 65 years had increased to 84, and life expectancy for someone at 75 years of age had increased to nearly 87.

In the mid 20th century came the passage of the Medicare and Medicaid programs. That legislation placed LTC costs firmly on the policy agendas of the states and the federal government. The Medicaid program, which is jointly funded by the states and the federal government, pays for the vast majority

of LTC costs. In 2005, Medicaid paid just over \$100 billion for nursing home and home care services, almost 49% of the total costs of these services, compared with just over \$42 billion (20%) paid by Medicare for these same types of services.

A major concern of some policymakers has been the transfer of assets by the elderly to younger family members to qualify for Medicaid LTC services. However, the U.S. Government Accountability Office (GAO) analysis of the 2002 Health and Retirement Study data indicated that those elderly most likely to need LTC services had a median annual income of less than \$14,000 and median nonhousing assets of less than \$4,000. Recapture of transferred assets in such a population is not likely to have a significant impact on Medicaid expenditures for LTC.

One of the current policy debates surrounding LTC costs is *rebalancing*. Since the implementation of Medicaid, public funding for LTC has almost exclusively supported the provision of LTC in institutional settings (nursing homes). At the same time, almost all consumers would prefer to receive LTC in a community setting, and public funding agencies want to reduce expenditures for the most expensive type of LTC, nursing homes. Rebalancing is typically thought of as requiring an increase in the proportion of funding going to community-based care while reducing the proportion of funds going to nursing home care. Another alternative, of course, is simply expanding expenditures for LTC and targeting these additional funds for use in other forms of residential LTC and for home- and community-based services.

Rebalancing is currently far from complete. In 2005, almost two thirds of LTC expenditures went to support nursing home care for individuals with severe physical and cognitive impairment. Despite this, the inadequacy of nursing home reimbursement is apparent. The majority of nursing homes are understaffed and thus at risk of being unable to meet the needs of their residents.

Another policy option that many hoped would help reduce the public costs of LTC was LTC insurance. However, LTC insurance has not seen the growth in the number of policyholders needed before it can serve as a substitute for a significant proportion of Medicaid payments to nursing homes. The elderly find it difficult to afford LTC insurance, and younger individuals have shown

little interest in paying premiums now for benefits that they may need in 30 to 40 years.

Dealing With the Baby Boomers

No discussion of LTC costs in this country can be complete without a discussion of what many see as the looming explosion in LTC needs and expenditures as the baby boomer generation ages. Baby boomers include those individuals born between 1946 and 1964. Based on estimates from the Urban Institute's simulations, the number of older adults with disabilities will increase from 10 million to 21 million from 2000 to 2040. The number of elderly receiving paid home care will increase from 2.2 million to 5.3 million, while the number of nursing home residents will grow from 1.2 to 2.7 million. All this will occur at the same time that the number of middle-aged or younger individuals who might serve as informal or formal caregivers will fall because of long-term reductions in the nation's birth rate.

As the more than 70 million baby boomers age, some estimates indicate that Medicaid costs will grow from 3% of the U.S. gross domestic product (GDP) in 2000 to approximately 11% of GDP by 2080. Some researchers argue relatively persuasively that reduced disability in the elderly population could dramatically reduce these projected expenditure levels.

These population dynamics and cost projections have raised serious concern among many analysts and policymakers. The federal government's response to these concerns, at this point, has largely been an attempt to increase individual responsibility by encouraging the purchase of LTC insurance and increased personal savings for LTC costs. The Centers for Medicare and Medicaid Services (CMS) informational campaign for Medicare recipients, titled "Own Your Own Future," is only one example of this approach.

As the baby boomers age, the nation will be faced with a series of difficult decisions. How much of the cost of LTC is the responsibility of society, and how much is the responsibility of the individual? What reallocations of social and personal resources will be necessary to meet the challenges presented by the projected explosion in the number of frail elders who will need LTC? What is an equitable distribution of total LTC spending?

How can we balance spending for the elderly's LTC needs with other pressing social priorities?

However, we might do well to remember that at each stage of its life course the baby boomer generation has presented unprecedented challenges to our society. First, this generation needed expanded public school services; then they needed expanded higher education; and then they needed jobs. At each point, our society successfully reallocated or generated the resources to meet those needs. One can only wonder how this looming challenge will differ from those earlier trials.

LUFT, HAROLD S.

Harold S. Luft is a leading health services researcher. He is perhaps best known for his work on how health maintenance organizations (HMOs) achieve cost savings compared with fee-for-service medicine and his discovery of the volume-quality relationship in healthcare—the inverse relationship between the volume of hospital procedures performed and in-hospital patient mortality for certain surgeries and medical conditions.

Luft is the former Caldwell B. Esselstyn Professor of Health Policy and Health Economics and director of the Institute for Health Policy Studies at the University of California, San Francisco (UCSF). In 2008, he became the director of the Palo Alto Medical Foundation Research Institute.

Born in 1947 in Newark, New Jersey, Luft received his bachelor's degree, master's degree, and doctorate from Harvard University, where he specialized in health sector economics and public finance. Prior to joining UCSF in 1978, he was an assistant professor in the Health Services Research Program at Stanford University.

Luft has undertaken research in a variety of areas, including the applications of cost-benefit analysis, the relationship between hospital volumes and patient outcomes, the regionalization of hospital services, HMOs, risk assessment and risk adjustment, quality and outcomes of care, and

healthcare reform in various states and communities. He also has studied the role of large databases and informatics tools to improve healthcare.

Throughout his long career, Luft has authored or coauthored five books and almost 200 scientific journal articles. His most recent book, *Total Cure: Rebuilding the American Healthcare System*, proposes a fundamental restructuring of the nation's financing and delivery of healthcare. He also has served on many editorial boards, including the journal *Inquiry*, and was the coeditor-in-chief of *Health Services Research* from 1997 to 2006.

Luft has received many awards and recognitions for his outstanding contributions to the field. He was awarded the Investigator Award in Health Policy Research from the Robert Wood Johnson Foundation (RWJF) in 2004; the Distinguished Investigator Award from the Association of Health Services Research in 1999; and the William B. Graham Prize for Health Services Research, sponsored by the Association of University Programs in Health Administration (AUPHA) and the Baxter Allegiance Foundation, in 1998. He also was a fellow of the Center for Advanced Study in Behavioral Sciences, the National Science Foundation, and the Carnegie Foundation and a Graduate Prize Fellow at Harvard University.

Luft is a member of the National Academy of Sciences, Institute of Medicine (IOM). He was a member of and chaired the National Advisory Council of the Agency for Health Care Policy and Research (now the Agency for Healthcare Research and Quality). He is a research associate at the National Bureau of Economic Research (NBER). In addition, Luft has served on the board of AcademyHealth. And he also has been a consultant to a number of federal agencies, including the Health Care Financing Administration (HCFA) (now the Centers for Medicare and Medicaid Services [CMS]), the National Institute of Mental Health (NIMH), the U.S. Commission on Civil Rights, and the U.S. General Accounting Office (GAO) (now the U.S. General Accountability Office).

Luft has also been pivotally involved in multidisciplinary postdoctoral training for more than 35 years. He served as the codirector or associate director for three training programs sponsored jointly by UCSF and the University of California, Berkeley.

M

MALPRACTICE

Malpractice is defined as professional negligence that results in injury or harm to an individual. Although the term *malpractice* can be applied to other professions, the most common reference is in the area of medicine or healthcare. The Joint Commission defines malpractice as “improper or unethical conduct or unreasonable lack of skill by a holder of a professional or official position.” Malpractice arises from the branch of law called tort law or civil law, where a remedy can be provided for the action. This is different from criminal law or penal law, where causes of action lead to prosecution. When malpractice occurs in healthcare delivery, it is referred to as *medical malpractice*, although it can involve any healthcare provider or facility.

This entry focuses first on the elements necessary to establish a claim of medical malpractice. Then, it discusses the incidence of malpractice. Last, this entry addresses the limitations that may occur as a result of medical malpractice claims.

Elements of Malpractice

To make a claim that medical malpractice has occurred, a claimant must establish four elements: (1) duty, (2) breach of duty, (3) causation, and (4) damages. All four of these elements must exist and must be proven for a medical malpractice claim to be satisfied. Unlike criminal actions, where the standard is “beyond a reasonable

doubt,” in civil actions such as malpractice, the standard of proof is “the preponderance of evidence, which means more likely than not,” or 51 on a scale of 100.

Duty

The *duty of care* is a legal obligation that requires that an individual adhere to a reasonable standard of care when performing acts that could cause harm to another. Although the law does not necessarily define the duty of care, its meaning may develop through common law or local customs. For example, physicians generally are said to have a duty of care by virtue of the physician–patient relationship. This relationship may be established when a patient first makes an appointment to receive care and treatment, or it may be established when a physician is consulted to render emergency care and treatment. Hospital or other healthcare facility personnel are said to have a duty of care because they are either employees or contractors for an agent that agrees to deliver services to a patient. Pharmacists also have a duty of care when they can reasonably foresee that their actions or inactions could reasonably cause harm to clients. Although all healthcare employees generally are expected to honor the duty of care for patients under their care, there have been cases where employees have successfully argued that they did not have a duty of care because provision of care would have violated their own ethical principles.

In healthcare, the duty a professional owes to an individual under his or her care is based on

standards of care. Standards of care address the reasonableness of care and hold a professional accountable to deliver care as would a reasonable person with similar training and skills in similar circumstances. This is known as the *reasonable-person standard*.

Standards of care may be defined in a number of ways. For an individual holding a license to practice a profession, the standard may be defined through the elements articulated in a scope of professional practice. This is generally one of the ways by which standards of care can be established for physicians, dentists, nurses, physical and occupational therapists, and other similarly credentialed individuals. Standards of care also may be established by state laws, by accrediting and professional associations, and through organizational policies and procedures that govern how care is to be rendered.

Depending on the locale, standards of care may follow national standards or be based on local customs and practices. If a national standard is applied, this means that the reasonable-person standard would be based on what similarly trained individuals with similar skills would do under the same conditions anywhere in the United States. On the other hand, if a local standard is applied, the standard would reflect what similarly trained individuals would be expected to do in communities that have the characteristics of the community where the care was rendered. Since most health-care professionals are expected to be educated to deliver care anywhere, it is more common to find a national standard of care applied.

In determining the applicable standard of care for specific actions of a professional, there is an expectation that if a professional carries out a task *requiring* special knowledge and skill, she or he will be evaluated as if she or he *possessed* the requisite knowledge and skill to perform the task. For example, if a resident physician performs a procedure such as insertion of a chest tube and causes the patient harm, that resident will be judged by the standards that govern the insertion of a chest tube by a fully trained physician in the appropriate medical specialty. If those reasonable-person standards are not met, the resident will be deemed to have deviated from acceptable standards of practice.

The issue of “reasonable person” often emerges when more than one group of professionals

possess the knowledge and training to carry out a specific role. This can occur, for example, when advanced-practice nurses, physician’s assistants, or other similarly credentialed individuals perform functions that had previously been only in the scope of physician practice. In these cases, the other professionals will be held to the same standard as that expected of the physician.

Breach of Duty

A *breach of duty* occurs when the care rendered is unreasonable or fails to meet the reasonable-person standard of care previously described. In medical malpractice, an expert witness is generally called upon to help establish the applicable standard of care and then to testify as to whether the healthcare professional met or breached the standard established.

There are three common legal terms that relate to the manner in which a professional might fail to meet the applicable standard: (1) nonfeasance, (2) misfeasance, and (3) malfeasance. *Nonfeasance* refers to the failure to do something that was expected. For example, if the applicable standard of care for a particular hospital indicates that a medical patient’s vital signs are to be taken every 4 hours, failure to take them at that interval as a minimum would constitute nonfeasance. Similarly, if a patient had laboratory tests ordered and the laboratory, although able, failed to collect the necessary specimens, that would also be considered nonfeasance. Nonfeasance is also referred to as an *error of omission*. Failure to act or nonfeasance, in itself, however, does not constitute malpractice.

Misfeasance occurs when there are errors due to mistakes or carelessness. Medical errors such as wrong-site surgery, administration of medication or treatments to the wrong patient, failure to adequately respond to information about changes in a patient’s medical condition, or prescribing medications that may be contraindicated based on a patient’s other medications or medical history are examples of mistakes or carelessness. These types of errors are also referred to as *errors of commission*. In its report *To Err Is Human: Building a Safer Health System*, the national Institute of Medicine (IOM) identifies the types of errors that commonly occur in healthcare and establishes strategies to improve communication between healthcare workers as an approach to

reducing these errors. In addition, the Joint Commission has identified strategies to improve institutional responses to *sentinel events*, those instances of misfeasance that lead to death or serious injury. Although most of the breaches of standards of care that lead to claims of malpractice come from errors and mistakes that are deemed misfeasance, not all misfeasance will lead to sustainable claims of malpractice.

Malfeasance is intentional wrongdoing. It occurs when an individual or group does something that is legally or morally wrong. An example of intentional wrongdoing in healthcare might be filling a patient's prescription for an expensive medication with a placebo yet charging the patient or the health insurance company for the medication that was ordered. At a time when the cost and quality of healthcare are under intense scrutiny, it has been argued that health insurance company actions denying access to needed costly services for subscribers is also a form of malfeasance. Although malfeasance can result in allegations of malpractice, the intentional wrongdoing often makes this a criminal offense.

Causation

The third element that is necessary to establish a claim of malpractice is that the breach of duty or failure to meet the prescribed standard of care must be the direct cause of injury to the patient. This is often the most difficult element to prove in a lawsuit that arises out of an act of negligence. To satisfy this element, the plaintiff or injured party must prove that but for the actions of the healthcare provider, the injury sustained would not have occurred. Causation is attributed based on the concept of probability. To satisfy this element, an expert witness must be able to state to a degree of reasonable probability (51%) that the injury was caused by the breach of standard of care.

Major discrepancies can exist between the plaintiff's and the healthcare professional defendant's positions about causation even if there is agreement that the professional did not meet the applicable standard of care. For example, a nurse providing care to a mother in labor may have incorrectly read the fetal monitor strips. Although the nurse did not recognize some of the changes on the strip, this error may not be deemed to have

caused an injury when the infant was born with a congenital malformation. However, an expert witness for the plaintiff might allege that the failure to correctly read the fetal monitor strips led to a delay in the delivery of the infant, which further compromised the infant's condition at birth.

Sometimes there are areas of disagreement about causation depending on the types of healthcare providers involved and the applicable scopes of practice. For example, if a nurse saw that a patient was not responding to a particular treatment or medication and communicated that to the physician and the physician delayed getting to the hospital to care for the patient, it may not be possible to attribute responsibility to the nurse for the delay. However, if the nurse saw that the patient was not responding to treatment and communicated it only in the medical record, without making the physician aware of the problem, then he or she could be judged with a reasonable degree of medical probability to have caused the injury that occurred to the patient as the result of delayed medical care.

Damages

The final element that must be satisfied in a case alleging malpractice is that damages have occurred. To recover damages, a plaintiff must establish that he or she suffered physical, financial, or emotional injury as the result of the healthcare professional's deviation from the acceptable standard of care. If a plaintiff is able to establish that all the elements of malpractice have been satisfied and a judge or jury agrees with this determination, a monetary settlement is imposed to compensate for the injuries sustained.

There are three types of damages that may be awarded to a plaintiff: (1) economic, (2) noneconomic, and (3) punitive. Economic damages are the result of actual costs or financial losses sustained by the plaintiff or his or her family because of the negligence. These may include the cost of additional or subsequent care associated with any residual impairment, lost wages of the individual or of a family member who has had to provide care to the injured individual, and estimations of future care costs.

Noneconomic damages are those damages that the law assumes to accumulate from the

consequences of the negligent act. The plaintiff can be compensated for emotional stress, interference with his or her enjoyment of life, and what has been called pain and suffering. Although some jurisdictions have made efforts to limit awards for noneconomic damages, they still constitute a significant amount of the damage recovery for a plaintiff.

Punitive damages are what are called punishing damages: Punitive damages are awarded to punish a wrongdoing that is outrageous in character. One of the legal terms used when a request is made for punitive damages is that the act represented a *reckless disregard* for the safety and well-being of the injured party or that the care rendered was incompetent. Two examples of acts that could lead to the award of punitive damages are providing health care when impaired by drugs or alcohol or failure to provide care for a patient despite repeated requests to be physically present. Hospitals can also be charged with punitive damages when they continue to grant privileges to a staff member who has acted in the manner described above. In addition, hospitals have been charged punitive damages for holding themselves out to the community as offering a particular type of service but not delivering it in a way that meets the appropriate standard of care. For example, if a hospital says that it does open-heart surgery but does not have trained and available support staff, an award of punitive damages could result from the injury or death of a surgical patient because of the inappropriate staffing. Although punitive damages are often requested in malpractice cases, they are infrequently awarded. However, when they are awarded, they can be significantly higher than the total of the economic and noneconomic damages awarded. In some jurisdictions, health malpractice insurance companies are prohibited from covering the cost to a defendant related to the award of punitive damages.

Incidence of Malpractice

Although the actual number of claims for malpractice is unknown, there are data that suggest that patient injuries occur too frequently. In 1999, a national IOM report estimated that as many as 98,000 individuals die in the nation's hospitals each year as a result of medical errors. This number

was similar to that reported in earlier studies. A 1984 Harvard research study found that 1% of a representative sample of all patients hospitalized in New York State experienced injuries and one quarter of that number died. If the New York findings were extrapolated nationwide, the numbers would represent more than 234,000 patient injuries and 80,000 deaths per year from negligence. A 2006 follow-up of the 1999 national IOM study found that 1.5 million people were harmed due to medication errors alone. More than half of these errors occurred in long-term care facilities with the remainder divided between outpatient facilities treating Medicare recipients and hospitals.

Despite the number of injuries and deaths reported, fewer than 1% of physicians nationwide have had claims made against them for malpractice. Although this number is rising, the scope of the involvement of physicians and other professionals remains small. About one half of all cases brought to trial in 2002 in the 75 largest counties in the United States involved cases against surgeons, and one third were against nonsurgeon physicians. In the same report, 90% of plaintiffs alleged death or permanent disability.

Although there are significant errors that can and do occur in the delivery of healthcare, the rate of success in winning a malpractice claim in court is low. Although almost 52% of other civil torts are settled in favor of the plaintiffs, in medical malpractice cases that number drops to 27%.

Resulting Limitations

A major concern with medical malpractice is that the increasing numbers of claims, the costs associated with defending them, and the sizes of the awards when the claims are successful have led to limitations in access to healthcare. The loss of access is not related to the inability of patients to pay for care but rather to decisions by professionals to leave practice completely, leave specialty practice, or limit the types of medical conditions that they are willing to treat. In the past several years, for example, many obstetrician-gynecologists are limiting their practices to gynecology only, and neurosurgeons and other subspecialists are limiting the sizes of their practices or are refusing to perform complex surgical procedures. In many cases, these decisions are made due to the

high cost of malpractice insurance coverage. In other cases, the decisions are made due to the high cost of emotional investments in refuting claims that the professionals believe are unjustified.

Rising medical malpractice insurance premiums coupled with the growing number of uninsured or underinsured individuals nationally may be a prescription for disaster. Many individuals who lack adequate health insurance coverage have limited access to care and do not appropriately manage their chronic medical conditions, nor do they receive preventive care. When they do seek needed care, often their disease conditions are more advanced and complex, hence healthcare providers are at increased risk of making errors. It is these errors that lead to future claims of malpractice and a cycle that many believe is out of control.

MANAGED CARE

Managed care is a complex system that involves the active coordination of and arrangement for the provision of health services and the coverage of health benefits. The term *managed care* was coined in the 1980s to name the array of emerging health insurance products that were evolving in response to skyrocketing healthcare costs. To differentiate these new products from traditional insurance, commercial insurers adopted the generic term *managed care* to describe health benefit products that attempted to control the cost of care by restricting the choice of providers or the use of medical services. Today, it encompasses a broad spectrum of organizational structures and benefit plans such as (a) health maintenance organizations (HMOs), (b) preferred provider

organizations (PPOs), (c) point of service plans (POS), (d) individual practice associations (IPAs), (e) exclusive provider organizations (EPOs), and (f) consumer-directed healthcare (CDH).

The exact nature of managed care is constantly evolving in response to the changing demands of consumers, employers, and regulators. There are three key components of managed care: (1) the network or contractual relationship with healthcare providers, (2) the oversight or coordination of medical care, and (3) the structure of the covered healthcare benefits and copayments. Early managed-care plans were nothing more than networks of providers who agreed to accept lower reimbursements to be included in a plan's network of preferred providers: hence, preferred provider organizations or PPOs. There were benefits or financial penalties if the insured did or did not use a preferred provider. Later on, managed-care organizations added medical-management initiatives such as preauthorization of services and mandatory second opinions. In response to rising political pressures, medical management has evolved away from prior authorization to focus more on care coordination and disease management. Recently, financial incentives and disincentives have taken the forefront in efforts to influence healthcare costs, taking the form of CDH. CDH uses an array of benefit designs with higher copayments, higher deductibles, or both to empower consumers to more effectively manage their healthcare.

Contracting and Networks

Provider contracting was the easiest and therefore the first component of managed care to be implemented. Insurers began requiring providers who wanted to be included in their network of preferred providers to agree to negotiated discounts off their standard rates. Prior to the advent of PPOs, most hospital services were being reimbursed at 100% of the billed charges. These fees were loosely based on cost plus some percentage above the estimated cost. This methodology actually encouraged higher charges and contributed to the rapid escalation of healthcare costs.

Physicians and other healthcare providers had been reimbursed at billed charges or community-average rate, known as *usual, customary, and reasonable* (UCR). Early PPOs simply negotiated a

lower reimbursement, usually taking an additional 10% or 20% off the billed or UCR fees.

Whereas the discounting of fees yielded some initial cost relief, it did not change the inherent dynamics; each insurer developed different contracting strategies to try to affect hospital costs. Most hospitals preferred a variant of fee-for-service. Thus, the most common arrangement was a greater discount off the billed charges. Under some contracts, facilities would agree to a flat, daily rate (per diem). Initially, these rates were all-inclusive for all levels of care. Eventually, per diem contracts became more sophisticated, and the rates were negotiated based on the complexity of the service provided, with higher rates for more complex services such as intensive care units, maternity, pediatrics, and so on. As technology and costs advanced, per diem contracts began to include carve-outs for high-cost devices (e.g., implantable pacemakers) and medications.

Another method of facility reimbursement—developed and implemented by Medicare in the mid-1980s—was based on Diagnostic Related Groupings (DRGs). Facilities received a fixed reimbursement for all anticipated services based on the expected average cost of care for a patient with a specific discharge diagnosis. DRG payments fundamentally changed the dynamics of hospital reimbursement. Once hospitals were no longer reimbursed on a cost-plus basis, they began to address the different factors that influenced the cost of care in their facilities. Hospitals instituted utilization reviews of patient stays to identify and address the excessive length of hospitalizations. Hospitals also implemented pharmacy and therapeutic committees to identify opportunities to lower medication and medical-device costs. These efforts led to shorter lengths of hospitalization; increased use of lower-cost, generic, and therapeutically equivalent medications; and greater standardization of implantable medical devices and appliances.

A few hospital systems were so confident in their ability to manage costs that they began taking the risk of *global capitation* for the inpatient and outpatient care they provided. Some hospitals established their own health plans; others negotiated full-risk contracts with insurers. Although few of these contracts and health plans remain, the collective efforts of hospitals to manage their cost

of care have resulted in shorter lengths of hospitalization and a more efficient use of resources.

Although relatively rare, organ-transplant services were an early focus of managed-care organizations due to their high cost, wide variation in cost, and variation in the outcomes for similar transplant services across the country. Often, the higher-cost facilities were achieving less favorable outcomes with lower survival rates. In an effort to achieve better outcomes for lower costs, insurers began limiting coverage for transplants to preferred facilities. These preferred facilities were often referred to as *centers of excellence*. Eventually, preferential contracting for centers of excellence expanded to include other complex medical procedures as well as some high-volume or high-cost cardiac procedures.

To encourage patients to seek care at these preferred centers of excellence, insurers would usually cover patients' additional travel and housing expenses. In addition, health coverage plans were often designed to waive or limit patient cost sharing if services were obtained at the insurers' preferred centers. Initially, each insurer developed his or her own list of centers of excellence based on individual criteria. However, as the process spread, specialty medical societies and academic medical centers became involved in developing criteria and tracking outcomes. This led to increased accountability and more transparency.

Medical Management and Care Coordination

A 1986 RAND Corporation Report suggested that one third of medical procedures were unnecessary. This perception of overuse became an early focus of managed care. Initial efforts to influence the care provided included (a) mandatory second opinions for elective surgery, (b) prior authorization for elective procedures and diagnostic tests such as CT scans, and (c) limiting the networks of medical specialists. Prior authorization programs were implemented to reduce the use of high-cost, frequently ordered procedures and to ensure that patients were referred to in-network preferred facilities and providers.

In addition to prior authorization of elective hospitalizations, hospitalizations were reviewed against external criteria and benchmarks. The

clinical criteria for determining the medical need for ongoing hospitalization that were developed by InterQual, Inc. were the most commonly used criteria by hospitals and were adopted by the Medicare program in 1999. InterQual's criteria did not set an expected length of stay for a hospitalization; rather, they assessed whether a patient needed to remain at a particular level of care (e.g., intensive care or hospitalization) based on the treatment and services the patient was receiving.

Health plans tended to use the inpatient care guidelines developed by Milliman and Robertson, Inc. (now Milliman, Inc.) in the late 1980s. The Milliman care guidelines assigned an expected length of stay for each hospitalization based on an optimal outcome. The guidelines were evidence based and reviewed by expert panels of physicians. The Milliman care guidelines specified the expected progression of hospitalized care for specific medical and surgical procedures. Before the Milliman guidelines were introduced into a market, the actual length of hospital stays was usually significantly longer than the optimal length specified by the guidelines. Initially, extended hospitalization due to a delay in care would result in denial or carving out of hospital days—that is, nonpayment of hospital charges for the excess days; within 6 to 12 months, hospitalization lengths of stay shortened, approaching the guideline targets. Initially, denial of payment for hospital days accounted for a small portion of the resultant savings (5–10%). Most of the savings came from shorter hospitalizations due to the changes in practice patterns brought on by the clinical guidelines.

Once physicians and hospitals modified their practice patterns to conform to the guidelines, the denial of payment was minimal (2–3%), and there was marginal subsequent decrease in hospitalization lengths of stay. This lack of ongoing improvement often called into question the need for continuing inpatient utilization management programs. This tension intensified in the late 1990s when public and political perceptions of managed care soured. As a result, many insurers scaled back their inpatient utilization management programs.

Outpatient utilization management programs, although effective, did not result in such clear-cut savings. The major impact was not through denial

of services, which averaged 2% to 4%, but rather was due to a reduction in the number of services requested by providers due to their perception of oversight, the *sentinel effect*. In the inpatient setting, the sentinel effect was demonstrated by the shorter length of hospitalization. In the outpatient setting, it was more difficult to measure the impact: As the sentinel effect resulted in a reduction in the services requested, it was measurement of a nonevent. The impact of the sentinel effect was believed to be 2 to 3 times greater than the effect of the actual denials. However, as most insurers did not have detailed authorization statistics to measure the impact of changes in the utilization management programs, their effectiveness was often underestimated.

Even with the streamlining and automation of these programs, they often cost 1% to 1.5% of premiums. Ignoring the sentinel effect savings of 4% to 9% and accounting only for the savings from denials, the net savings from these utilization management programs was in the 1% to 3% range, which was often thought to be too little to justify the administrative costs and the negative marketing impacts. In response to a public and political backlash against managed care in the late 1990s, many insurers reduced or eliminated their utilization management programs, choosing instead to influence use through increased financial cost sharing and deductibles. By eliminating their utilization management programs, insurers also took themselves out of the unenviable role of trying to control healthcare costs by managing the demand for services. Instead, insurers attempted to influence healthcare costs through higher copayments, greater cost sharing, and higher deductibles.

By increasing consumers' out-of-pocket costs for healthcare services, insurers and employers hoped to slow the rise in healthcare costs by discouraging unnecessary care. However, there is concern that higher deductibles and cost sharing may have a negative impact on health outcomes by discouraging early intervention and preventive care. For commercial and Medicare populations, there is greater emphasis on managing use through financial disincentives and cost sharing than through robust utilization management programs, one notable exception being in the area of managed Medicaid.

Disease and Care Management

In the 1970s and 1980s, some academic medical centers, large medical groups, and staff- or group-model HMOs had multidisciplinary specialty clinics that focused on a single condition or disease (diabetes, cystic fibrosis, anticoagulation, etc.). These programs were predominantly disease focused and institution based and were developed to streamline the operational aspects of a clinic visit.

Health plans and insurers developed *disease management* programs in the early 1990s to lower hospitalizations and emergency room visits for high-use patients with specific diseases, hence the name *disease management*. Individuals were identified for enrollment in disease management programs by retrospective claims reviews or by provider referrals.

Nurse case managers, pharmacists, and physicians would review hospital medical claims and pharmacy records to identify opportunities for intervention to prevent repeat hospitalizations. A key focus of these programs was educating patients and their families so that they could better understand and manage their illness. These programs would emphasize the (a) importance of following treatment recommendations, (b) early recognition of exacerbations and complications, and (c) methods for preventive intervention.

Numerous studies documented the lack of standardization of care and the slow adoption of national treatment guidelines by physicians. Disease management programs were one method used by managed care to disseminate and encourage the use of evidence-based guidelines. By adopting and promoting national guidelines to patients and physicians, disease management programs attempted to improve health outcomes through greater compliance with the recommended treatment guidelines. Managed-care organizations could identify individuals who met the criteria for inclusion in a disease management program from medical claims data, hospital admissions records, emergency department visits, and pharmacy claims. Once the individuals were identified, nurse case managers and pharmacists would review their medical histories and claims data to assess if their care was in compliance with the guideline recommendations. If changes in treatment protocols were needed, a nurse, pharmacist or physician would contact the

individual's treating physician to obtain additional information and review the recommended guidelines. If necessary, a nurse case manager or a physician could also contact the physician to discuss additional intervention, such as a consultation with a specialist or more frequent physician visits. Initially, disease management programs for asthma and congestive heart failure were very successful in encouraging adoption of the guidelines, improving outcomes, and reducing costs.

Disease management programs continued to evolve, increasing the number of diseases covered, the scope of the interventions, and the comprehensiveness of the interventions. Disease management programs became more proactive in identifying candidates for their programs by using sophisticated predictive-modeling software in their analysis of medical claims, pharmacy, and laboratory data. Predictive modeling allowed disease management programs to identify individuals who were at greater risk for complications from their illness and to initiate interventions to prevent costly treatments for complications and hospitalizations.

During the past decade, traditional disease management programs have expanded beyond a single-disease focus to encompass the individual's overall healthcare needs. As a result, the term *disease management* has transitioned to *care management* to signify these changes. The options for intervention have also greatly expanded. Current care management programs provide a wide array of education options, from quarterly newsletters to comprehensive Web-based educational offerings. Interventions may be as simple as prescription refill reminders or may include ongoing home-based monitoring of symptoms and an expanding array of biometric information such as blood pressure, weight, and blood oxygen saturation. By identifying early changes in their conditions, individuals, nurse case managers, and physicians can intervene early and prevent or minimize exacerbations of the conditions.

Whereas the scope of care management programs has expanded, the emphasis has remained on improving health outcomes through greater standardization of care in compliance with evidence-based medical guidelines. A RAND Corporation study, in 2003, estimated that patients with chronic illness received only 55% of the care recommended by the established national guidelines. Another

study, conducted by the Dartmouth Atlas Project, suggests that 30% of U.S. healthcare costs could be saved by increased standardization of care, emphasizing preventive care, and focusing on managing chronic disease.

Medicaid Managed Care

One area in which managed care has continued to grow is Medicaid. Since the early 1990s, state Medicaid programs have turned increasingly to managed care to improve access to care and to contain costs. Many states have enrolled sizable portions of their Medicaid beneficiary populations in some form of managed care. As Medicaid programs provide health coverage to individuals and families with low incomes, the copayments and beneficiary out-of-pocket expenses are minimal. Unlike commercial programs in which managed-care organizations have attempted to substitute financial cost sharing to control costs, Medicaid managed care has continued to emphasize utilization management and disease management programs to achieve savings. Although the nature and composition of these utilization management programs vary greatly by state and by company, the majority of their cost savings result from reduced inpatient use and pharmacy expenses.

Future Implications

Over the past 30 years, managed care has undergone a dramatic evolution. The term *managed care* now represents such a broad array of products, services, and interventions that it nearly defies explicit definition. Managed care can broadly be described as any strategy of organizing healthcare delivery to influence cost. Another way to define managed care is to describe what it is not—unmanaged care: unrestricted healthcare coverage that allows the beneficiary to see any healthcare provider for any service at any time without any financial consequences.

As healthcare costs continued to rise, the government, payers, and individuals sought solutions and alternatives. Managed care offered consumers expanded coverage and lower out-of-pocket expenses with some restrictions on access and limitations on use. It offered employers price moderation and insulated consumers from the true

financial costs of their healthcare. Managed care's expansion of coverage for preventive services, well-child examinations, prenatal care, immunizations, pharmacy services, and disease care management programs went from being new and innovative programs to basic requirements of health insurance coverage.

In part as a result of managed care's success in expanding covered benefits, controlling healthcare costs, and financially insulating consumers from the cost of their care, there was a backlash against any constraints or restrictions on individuals' healthcare desires: In the face of managed care's successes, people questioned whether such restrictions were necessary or appropriate. Managed care became the scapegoat for rising healthcare costs and Americans' reluctant recognition that societal resources for healthcare were not unlimited.

In response to political and marketplace pressures, managed care developed new strategies and products that imposed fewer restrictions and gave consumers greater control along with greater financial responsibility for their health care. These consumer-directed products substituted the individual's willingness to pay for managed care's medical-necessity criteria. For a price, this approach removed managed-care programs from the process of making decisions about whom individuals could see or what care was medically necessary and allowed unimpeded access to care. Individuals with sufficient financial means can access all the care that they desire; conversely, a greater number of Americans are deciding what healthcare they get based on what they can afford.

Although CDH has been a politically successful strategy, rising healthcare costs continue to erode health insurance coverage. The proportion of employers offering health insurance coverage has declined to 60% in 2006 from 69% in 2000. Employers that continue to offer health coverage are requiring employees to pay a higher portion of health insurance costs through higher premium contributions, increased copayments, and larger deductibles. All these changes are leading to a rising number of uninsured individuals as people are unable or unwilling to pay these higher out-of-pocket costs. With the demand for healthcare services in the United States continuing to grow faster than our ability to pay for them, it is clear that the future will require trade-offs: Will healthcare

coverage be affordable and accessible or will there be restrictions and limitations? Are individuals entitled to all the healthcare services they want? Should everyone be guaranteed the healthcare they need? Regardless of the payment mechanism—single payer, nationalized health system, or the current model—some form of managed care will likely remain.

MARKET FAILURE

A market failure exists in the healthcare market when the allocation of goods or services is not efficient—an *allocative inefficiency*. Efficiency is measured by the concept of *Pareto efficiency*, a situation where goods or services have been allocated among members of society in such a way that they cannot be reallocated so as to improve the welfare of at least one member without reducing the welfare of others. A *perfectly competitive market* is a hypothetical ideal market in which there are (a) a large number of buyers and sellers in the market, (b) free entry into and exit out of the market, (c) homogeneity of the goods or services, and (d) perfect knowledge. A perfectly competitive market is an efficient market and the yardstick against which economists and others measure whether a *market failure* exists. A market failure is problematic because it results in a market transaction that is socially inefficient—that is, where the market price does not equal the marginal cost and where potential welfare gains to trade exist but are not achieved. In this entry, the common types of market failure in healthcare are explained, and then potential solutions to these failures are discussed.

Types of Market Failure

The healthcare market exhibits a number of properties that deviate from a socially efficient market. The most significant characteristics of the healthcare market that result in a market failure include (a) the presence of *market power*, (b) information

problem of *uncertainty*, (c) *asymmetric* information, and (d) the existence of positive and negative *externalities*.

Market Power

Market power exists when an individual firm has the ability to influence the market price of a good or service with the result that the price exceeds the marginal cost of the good or service. Market power violates the assumption that a sufficiently large number of sellers exists to guarantee that each individual seller is a *price taker* in a perfectly competitive market. Market power includes situations ranging from imperfect competition, in which multiple sellers compete against each other and each has some influence over the price, to a monopolistic market, in which there is only one seller and this seller has control over the entire market. The presence of market power leads to market failure because of *deadweight loss*—that is, a loss to society due to a market price that is greater than and a market quantity that is less than the market price and quantity in an efficient market.

A classic example of a monopoly in the healthcare market is the market for a drug that is covered by a patent. With a patented drug, only one manufacturer has the legal right to produce the drug until the patent expires, creating a monopoly market until the patent's expiration. As a monopolist, the manufacturer will charge a price that exceeds the efficient price (i.e., the price that would exist in a perfectly competitive market) and sell a quantity of the drug that is less than the efficient quantity.

More commonly, firms may have *monopoly power*, a situation in which there are multiple sellers of a good or service but one seller can increase its price and still maintain at least some of its market share. Both physicians and hospitals exercise varying degrees of monopoly power. A physician could increase his or her fee for an office visit, for example, and still keep some patients. Whereas some patients may decide to go to a different physician after the fee increase, other patients will remain at the physician's practice. This ability to increase fees without losing all the firm's business is market power. Again, because an efficient market means that sellers are price takers, this is a clear violation of a perfectly competitive assumption.

Uncertainty

Uncertainty about an individual's future demand for medical care is an information problem that leads to a market failure in the healthcare market. The unpredictability of illness creates uncertainty regarding when healthcare will be needed, what services will be required, and how much the care will cost. Uncertainty creates a market failure because consumers (i.e., patients) do not know the type or quantity of services that they will need and producers (i.e., providers) do not know the type or quantity of services that they will need to provide.

Uncertainty abounds in healthcare. The occurrence of illness is largely unpredictable. Once an individual becomes ill, the diagnosis is not always known with certainty. Clinical symptoms such as fever, cough, abdominal pain, and shortness of breath are symptomatic of many illnesses. The optimal treatment also may not be certain. Many illnesses can be treated in multiple ways, and the outcomes are not perfectly tied to these treatments. Individuals would like to insure against all these types of uncertainty; however, a market does not exist for all of them.

Asymmetric Information

A second information problem in the healthcare market is asymmetric information. Asymmetric information is a situation where one party in a relationship has more information or more accurate information than another party. This inequality of information violates the perfectly competitive assumption that all parties involved in a transaction have perfect information. Asymmetric information leads to a market failure if demand and supply are interdependent rather than independent.

In healthcare, a market failure stems from asymmetric information in situations where consumers do not have the expertise to independently determine their own demand for healthcare services or monitor the quality of the services provided. Consumers may lack sufficient knowledge to diagnose their illness, evaluate the different courses of treatment, and select the optimal treatment. Hence, the provider influences the consumer's demand thereby creating interdependence between demand and supply.

In addition, consumers have less information about the quality of their healthcare providers

than the providers have about their own quality. For primary care and other frequently purchased services (e.g., care for chronic conditions), consumers have the opportunity to learn about the quality of the provider over time, through experience or trial and error. For services that individuals make use of infrequently or only need once (e.g., a kidney transplant), asymmetric information is a more important issue. The consumer cannot learn about the quality of a provider through experience and, therefore, is unable to monitor the quality of the care delivered.

Because of specialized medical training, a provider usually has more information than the patient about his or her diagnosis and the necessary treatment. The provider acts as an agent of the patient, thereby diagnosing the patient's illness, recommending a treatment, and often, providing the recommended treatment. Through this principal-agent relationship, the patient delegates some decision-making power to the provider, thereby allowing the provider to influence his or her demand. Even if a provider shares with the patient all available information about his or her illness, treatment options, and expected outcomes, it may still be difficult or even impossible for the individual consumer to make the optimal decision without the provider's recommendation, given the complexity and quantity of medical information that must be assimilated for complicated health problems.

Externalities

An externality exists when the decision of a consumer or producer incurs costs or benefits for other consumers or producers. An externality is negative when an individual's or a firm's decision creates a cost for others; it is positive when an individual's or a firm's decision creates a benefit for others. An externality results in a market failure because the market price fails to take into account the social costs and benefits that are realized by individuals or firms other than the consumer or producer.

Externalities in healthcare may affect production or consumption. An example of a *positive consumption externality* is obtaining a flu vaccination. By obtaining a flu shot, an individual directly benefits by protecting himself or herself from contracting the flu. And other members of

society benefit from the individual who obtained the flu shot, as well, because it reduces their risk of contracting the flu. An individual's decision on whether to obtain a flu shot is based on his or her marginal cost compared with his or her marginal benefit from receiving the vaccination. The individual does not consider the downstream consequences of his or her decision (i.e., whether the risk to others of contracting the flu is reduced by him or her receiving a flu shot). When individuals bear the full cost of a decision in the presence of a positive consumption externality, too few goods or services will be purchased in the market—that is, too few people will purchase a flu shot—even though other members of society also benefit from the decision. A classic example of a *negative consumption externality* is smoking: An individual's decision to smoke in a public place has a negative impact on others through secondhand smoke.

On the production side, research is a common *positive production externality*. An individual or firm producing scientific research affects the welfare of others in society by creating knowledge that could benefit the broader community. When the full costs of research are wholly borne by the individual scientist or institution, however, too little research will be undertaken. An example of a *negative production externality* is a hospital that incinerates used surgical supplies containing PVC, which turns into the toxic chemical dioxin when burned. The firm passes a social cost onto other individuals by increasing their risk of cancer, but this cost is not borne by the firm itself.

Solutions

The government may intervene in situations where the market cannot achieve an efficient allocation on its own. The government has several mechanisms by which to intervene and improve the market. However, government involvement is not necessarily the optimal action; many believe that it should only step in if the marginal benefits from the intervention exceed the marginal costs of the intervention, after factoring in spillover effects on other markets and individuals. In addition, as technology and other innovations evolve over time, new markets may develop to facilitate more efficient allocations.

Health Insurance

Health insurance is a mechanism that mitigates market failure associated with uncertainty. Health insurance protects an individual against financial losses associated with healthcare costs due to an illness or injury that cannot be predicted either in terms of occurrence or magnitude. For groups in which private coverage is not accessible, the government may function as the insurance provider. Public insurance programs, such as Medicare and Medicaid, ensure that the highest-risk individuals who do not have access to employer-provided health insurance offerings can obtain insurance coverage. At the same time, health insurance also introduces additional market problems, including *moral hazard* and *adverse selection*.

Taxes

To solve the problems of externalities—where the marginal private benefits do not equal the marginal social benefits or where the marginal private costs do not equal the marginal social costs—taxes and subsidies (i.e., negative taxes) can be used. Taxes are used when the marginal private costs are less than the marginal social costs, and subsidies are used when the marginal private benefits are less than the marginal social benefits.

Taxes alter the economic incentives of the buyer and seller: Taxes make it more costly to produce the externality, causing the quantity of the externality to decrease. The tax should equal the additional cost levied on the parties harmed by the externality, and the funds raised should be used to compensate those individuals. Although taxes force the creator of the externality to internalize the costs of their actions, taxes are not a perfect solution for several reasons. First, they allow the externality to continue; hence, individuals will still be harmed by the externality but will theoretically be compensated for their loss. Second, it is difficult to assess the actual cost of the externality that is imposed on others, so the tax is only an approximation of the real cost. Third, taxes generate monitoring costs to ensure that the parties creating the externality pay the tax.

Regulation

Direct government involvement is another solution to many market failures. With no regulation, pharmaceutical companies might invest less in research and development—and ultimately develop fewer new drugs that society would benefit from—because other companies could act as free riders and replicate the inventor's products without incurring the research and development costs required to bring a new product to market. Patent protections, therefore, encourage pharmaceutical companies to invest more in research and development by providing a protected period of time when the developing company will be the sole provider of its drug.

Regulation also more clearly defines and enforces property rights when they are ambiguous in the market. By assigning property rights, regulations determine whether one party has the right to produce an externality or another party has the right to not consume the externality. Smoking bans in public places—restaurants or bars, for example—implicitly assign the right to clean air to the non-smoker and remove the right to smoke in these places, thereby prohibiting smokers from passing along secondhand smoke to others. As with taxes, it is important to assess the marginal costs and benefits of regulations. Smoking bans decrease the likelihood of illnesses such as lung cancer but may impose a cost on other parties (e.g., restaurants and bars) if the net effect is fewer patrons, smaller tabs per patron, or both.

Antitrust policies prevent the existence of monopolies, the most extreme type of market power. If a monopoly or oligopoly is beneficial to a market because of economies of scale, however, the government may allow its formation but may regulate prices.

Licensing of health professionals and healthcare organizations is a regulatory strategy to mitigate a market failure related to the lack of information on the quality of providers. Licensing and certification ensures a minimum quality level but restricts the quantity of providers and limits competition from other types of providers through restrictions on the scope of practice.

The Availability of Information

New technology and other innovations can improve the availability of information. New diagnostic

technologies can improve the certainty of a diagnosis, and the Internet has created a venue for consumers to freely access information on healthcare providers. For example, the Centers for Medicare and Medicaid Services (CMS) now publish information on the Internet on hospital processes of care, outcomes of care, and patient satisfaction to allow consumers to compare the quality of care provided across the nation's hospitals.

New technological advances such as those made through the widespread adoption of the Internet will continue to improve the availability of information, which may be the most consequential change. Yet, distilling the vast amount of medical information available on the Internet, selecting the most valid and credible information, then assimilating it to a level that is useful to the individual consumer is no small feat. An Internet search through Google on diabetes treatment or diabetes care, for example, turned up 2.5 million results.

Although the Internet has armed consumers with more information to help diagnose their illnesses, determine alternative courses of treatment, judge the potential health outcomes, and judge provider quality, healthcare providers nevertheless remain the experts in delivering healthcare. Comparative information on healthcare quality—about which providers give the best care and have the best risk- and severity-adjusted outcomes—remains limited. Although several Web sites provide comparative information on some hospital-based healthcare outcomes, most quality comparisons continue to rely on either intermediate outcomes or proxies of quality—such as the occurrence of malpractice judgments, patient satisfaction data, and process outcomes—rather than health and healthcare outcomes. Further work is needed to determine how to accurately measure and compare health and healthcare outcomes across the continuum of providers (e.g., hospitals, physicians, nursing homes) and report the findings in a manner that is both easily accessible and comprehensible to consumers.

Two external forces may also increase information transparency. First, a shift to high-deductible health insurance plans increases the need for consumer-targeted information in the public domain on both quality and prices so that consumers can assess both the quality and out-of-pocket costs of alternative treatments. Second, medical travel—travel for

medical care outside one's home country—may also increase the availability and comparability of information on quality and prices for some services. Non-U.S. healthcare providers catering to international patients, including U.S. patients, now publish on the Internet inclusive prices for the common surgical procedures provided at their facilities. (In the United States, although prices have been relatively transparent for a small set of elective procedures traditionally not covered by health insurance [e.g., Botox and LASIK surgery], it has generally been very difficult if not impossible to obtain, in advance, the price that an uninsured individual will pay out of pocket for a surgical procedure or hospitalization.) These two forces may ultimately drive providers to disseminate information on prices and quality and, ultimately, compel the government to facilitate the collection and dissemination of comparative information.

MARMOR, THEODORE R.

Theodore (Ted) R. Marmor is Professor Emeritus of Public Policy and Political Science at Yale University, where he taught from 1979 to 2007. Currently he is an adjunct professor of public policy at the John F. Kennedy School of Government at Harvard University. His specialization is the contemporary welfare state in North America and Europe, with particular expertise on healthcare policy. His research on healthcare has yielded a national and international reputation as the most recognized academician in healthcare policy and politics. Marmor's first book, *The Politics of Medicare* (1970), is a classic in the field. The second edition of *The Politics of Medicare* (2000) traces developments in healthcare policy since the enactment of Medicare in 1965. In the decades since Medicare was enacted, Marmor has been a prominent analyst of health policy and advocate of universal healthcare.

Born in New York City on February 24, 1939, he received his bachelor's degree from Harvard University in 1960; attended Wadham College, Oxford from 1961 to 1962; and then returned to Harvard, earning his doctoral degree in 1966. Marmor began his academic career as an assistant

professor of political science and was promoted to associate professor at the University of Wisconsin during 1967 to 1970, then joined the faculty at the University of Minnesota (1970–1973) and later the University of Chicago (1973–1979) before going to Yale University in 1979.

In 1966, Marmor was special assistant to Wilbur Cohen, the Secretary of Health, Education, and Welfare; he served as associate dean at the School of Public Affairs during his tenure at the University of Minnesota; and at Yale University, he chaired the board of its Center for Health Services. He was a member of President Carter's Commission on the National Agenda for the 1980s and a senior policy advisor to Democratic presidential candidate Walter Mondale during the 1984 election campaign. Marmor has testified before congressional committees about healthcare reform, social security, and welfare policy in addition to acting as an expert witness in health-related judicial proceedings, including the constitutionality of the Canada Health Act, disputes over Medicare, and U.S. asbestos litigation.

Marmor serves on the editorial boards of the *Journal of Comparative Policy Analysis: Research and Practice*; the *Journal of Health Services Research and Policy*; the *International Journal of Health Planning and Management*; and the *Journal of Health Politics, Policy, and Law*. He was a centennial visiting professor at the London School of Economics (2000–2003) and has been a fellow or visiting fellow with the Australian National University, the Canadian Institute for Advanced Research, All Souls College at Oxford University, and the Netherlands Institute for Advanced Study. During 1993 to 2003, he was director of the Robert Wood Johnson Foundation Post-doctoral Program (Medical Care and Social Sciences).

Marmor has authored or coauthored 13 books, nearly 200 scholarly articles and book chapters, and more than 100 op-ed pieces in magazines and newspapers here and abroad. His scholarship has appeared in many prestigious journals, including the *American Political Science Review*, the *Michigan Law Review*, the *American Journal of Obstetrics and Gynecology*, the *New England Journal of Medicine*, the *Journal of Health Politics, Policy, and Law*, and the *Canadian Medical Association Journal*.

MATHEMATICA POLICY RESEARCH (MPR)

Mathematica Policy Research, Inc. (MPR), established in 1968 as a division of Mathematica, Inc., is a policy research organization that specializes in data collection and evaluation and policy analysis. The company provides research expertise, survey design and implementation techniques, information technology, and policy assessments to a wide variety of clients, including government agencies, universities, and foundations. For the past 40 years, MPR has helped to inform, shape, and enrich public policy.

Organizational Structure

MPR was incorporated under its current name in 1975, and it became an employee-owned entity in 1986. Headquartered in Princeton, New Jersey, the organization also has offices in Washington, D.C.; Cambridge, Massachusetts; and Ann Arbor, Michigan. The organization has partnered with the Robert Wood Johnson Foundation (RWJF) to establish the Center for Studying Health System Change (HSC), which is a wholly owned subsidiary of Mathematica, Inc. The HSC and MPR

share administrative resources and collaborate on key studies and research projects.

Two major divisions of MPR are the surveys and information services division and the research division. The surveys and information services division gives clients the tools, technology, and customized surveys that help them gather appropriate and meaningful facts and figures. The research division builds on these efforts, providing findings and scientific evidence that policymakers can use in their decision making.

In the surveys and information services division, staff members help clients (a) identify the best data collection methods, (b) design custom survey instruments for small and large samples, (c) recognize the special needs of data collection in diverse populations, (d) conduct statistical analysis and modeling, and (e) use advanced technology for surveying and data management. MPR takes into account factors that may cause bias and skew survey results such as language barriers and subject disabilities. The organization also employs Internet technology and Web-based techniques to enhance its surveys.

The research division conducts research for the public and private sectors, strengthening an evidence-based approach to shaping policy agendas. The division is responsible for (a) developing experiments and demonstrations; (b) quantitatively evaluating programs by looking at economic and statistical analyses of their effects, benefits and costs, quality, and value of output; and (c) qualitatively evaluating implementation and operations, using process and case study analyses. Researchers also predict the effects of proposed changes through the use of microsimulation and provide ongoing support to bolster research infrastructure. Through the expertise of systems analysts, social psychologists, economists, sociologists, demographers, and education specialists, the division is focused on conducting policy analyses to better understand the implications of policy choices in key research areas. The organization strives to communicate and disseminate its findings to policymakers and the general public.

Main Research Areas

MPR has conducted studies on programs and policy in the following areas: education, labor, welfare, nutrition, disability, early childhood, and

healthcare. The organization focuses on these areas because they remain central to local, state, and federal policy.

Education

MPR provides research and evaluation of education efforts ranging from early-childhood schooling, to kindergarten through 12th grade, and beyond. It examines elementary reading and mathematics curricula, teacher quality, interventions for at-risk youth, after-school initiatives, college access and preparation, charter schools, school choice programs, education technology, school and student performance competencies, and career-focused education. The organization is also committed to improving education research overall by strengthening research methods and reviews. The organization administers the What Works Clearinghouse, a tool established by the U.S. Department of Education's Institute of Education Services that collects, reviews, and reports on studies of education programs, practices, and products. It is also involved with the evaluations of the Teach for America, No Child Left Behind, Head Start, and Upward Bound programs.

Labor

By examining the factors that affect the workforce, MPR helps to inform career training and placement interventions as well as employment policies. The organization focuses on research aimed at expanding opportunities for at-risk youth, disadvantaged adults, young people living in poverty, experienced workers who have lost their jobs, people who are involved in criminal activity and the criminal justice system, and others who face barriers to entering the workforce.

Welfare

MPR is involved in many projects that evaluate welfare reform efforts at the state and national levels. For example, it has examined initiatives—designed to help Technical Assistance for Needy Families (TANF) recipients—that look at interventions aimed at strengthening families, father involvement and support, healthy relationships, and abstinence education for teens. The organization

evaluates welfare-to-work initiatives, efforts to increase job opportunities, long-term dependency on multiple public aid programs, and cost projections for federal and state programs. These research efforts help educate policymakers and program administrators seeking to improve the systems.

Nutrition

The organization's researchers study nutrition issues such as access to food, public food and nutrition assistance programs, emergency food assistance networks, and growing trends in obesity. For more than 30 years, the organization has extensively examined the Food Stamp Program and the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), helping policymakers assess reform efforts and continue to make revisions. In addition, its researchers have studied school nutrition programs, including school lunch and breakfast programs, as well as initiatives to improve children's diets and eating habits. With its findings, MPR informs ongoing efforts to improve the dietary status of all Americans.

Disability

For people living with disabilities and chronic diseases, advances in medicine and technology lead to more opportunities and increased independence; such changes may have important public policy implications at the state and national levels. The organization conducts research on programs such as Social Security and Medicaid, and it also gathers data on children with disabilities and their families. In addition, the organization looks at job programs for disabled adults. Mathematica's Center for Studying Disability Policy (CSDP) works with disability organizations and advocacy groups to enhance policy changes; it focuses on assessing service delivery, financing, resources, and disincentives. These efforts help leaders develop public policy to meet the changing needs of this special population.

Early Childhood

MPR studies and evaluates interventions aimed at improving the well-being of young children. These programs include (a) Head Start, (b) the Family and Child Experiences Survey (FACES),

(c) affordable day-care programs, (d) preschool curricula, and (e) initiatives serving low-income families.

Healthcare

In addition to its work relating to chronic disease and disability, MPR conducts a wide range of studies on health and the healthcare system. Researchers analyze costs, financing, insurance mechanisms, and coverage. MPR has also explored the effectiveness and quality of public- and private-sector services and the delivery of care. Specific projects include assessing the success of Medicaid, the State Children's Health Insurance Program (SCHIP), and private coverage options at increasing access to care for low-income families. The organization's work is also concerned with public health initiatives such as chronic-disease management programs and infectious-disease control measures. It evaluates programs that are designed to address mental health parity and health systems quality, and it also examines the role of advanced technology in improving health outcomes. Last, it provides leadership and policy advocates with the tools to promote sound and informed policy agendas.

Future Implications

MPR continues to provide policymakers and the general public with key information. Over the past few years, it has worked increasingly with international clients and begun addressing issues at a global level. Moving forward, the organization will ensure quality data collection, evaluation, and analysis for the United States and beyond.

MAYNARD, ALAN

Alan Maynard is a well-known, highly respected health economist in the United Kingdom. Maynard has been instrumental in initiating policies for the UK National Health Service (NHS). Specifically, he proposed the establishment of the General Practitioner Fund Holding, from which physicians are given budgets to fund their activities as well as secondary care for their patients. He also proposed that the NHS only pay for pharmaceutical drugs that their manufacturers could demonstrate to be cost-effective and efficient. This proposal ultimately led to the formation of the National Institute of Clinical Excellence (NICE).

Maynard is a professor of health economics and the director of the York Health Policy Group in the Department of Health Sciences at the University of York. He is also an adjunct professor at the University of Technology in Sydney, Australia.

Maynard was educated at the University of Newcastle-upon-Tyne, earning first-class honors in economics in 1967. He received a bachelor's degree from the University of York in 1968. He did his postgraduate work at the University of York; while there, he was introduced to the field of public expenditure, which ignited his interest in healthcare. He taught economics as an assistant lecturer and then lecturer at the University of Exeter from 1968 to 1971. From there, he returned to the University of York as a lecturer in economics. In 1977, he became senior lecturer at York,

where he founded the Graduate Program in Health Economics, serving as its director until 1983. In 1983, he became a professor of economics and the founding director of the Centre for Health Economics at York. From 1995 to 1996, he served as the secretary and chief executive of the Nuffield Provincial Hospitals Trust, a foundation that funds research in health policy. In 1996, he returned to the University of York as a professor of health economics and the director of the York Health Policy Group.

Maynard was made an honorary member of the Faculty of Public Health Medicine of the Royal Colleges of Physicians in 1993. He was elected president of the International Health Economic Association (iHEA) in 1999. He was named a fellow at the Academy of Medical Sciences for the United Kingdom in 2000. In 2002, he was named adjunct professor at the Centre for Health Economics in Research and Evaluation at the University of Technology in Sydney, Australia. He has been awarded honorary doctorate degrees from the Universities of Aberdeen (2003) and Northumbria (2006).

He is the founding editor of *Health Economics* and has written more than 250 scholarly articles and 10 books. He also is a member of the editorial boards of the *British Journal of Obstetrics and Gynaecology*, *Pharmacoeconomics*, *Health Manpower Management*, and the *Drug and Alcohol Review*.

In addition to Maynard's academic experience, he has served the NHS as a member of the York Health Authority (1983–1991), nonexecutive director of the York National Health Service Hospital (1991–1997), and has been the chair of the hospital since 1997.

Maynard has provided consultant services for the UK Department for International Development, the World Health Organization (WHO), and the World Bank on healthcare issues in Cyprus, Greece, Thailand, Brazil, Mexico, China, Botswana, South Africa, Bolivia, Chile, Lithuania, Latvia, Hungary, Russia, Malawi, Serbia, Kyrgyzstan, and Ukraine.

Currently, Maynard is working on improving the performance of health technology assessment and workforce productivity. In the next 10 years, he hopes to see proper routine measurement and management of patient-reported outcome measures.

MCNERNEY, WALTER J.

In his 45-year career, Walter J. McNerney (1925–2005) had a profound impact on the nation's healthcare system. McNerney played a pivotal role in the creation of the federal Medicare program, he was a leading educator in hospital administration, and he was the president of the national Blue Cross and Blue Shield Association.

Born in 1925 in New Haven, Connecticut, McNerney earned a bachelor's degree in industrial administration from Yale University in 1947. After graduation, he taught advanced mathematics at the Hopkins School, a private college-preparatory school in New Haven. He left New Haven to attend the University of Minnesota, where he earned a master's degree in hospital administration in 1950. Over the next several years, he held various administrative

positions in hospitals in Providence, Rhode Island, and Pittsburgh, Pennsylvania.

McNerney joined the faculty of the University of Michigan in 1955, where he founded and headed the university's hospital administration program in the School of Business. While at the university, he developed the program's curriculum, taught hundreds of students, and conducted one of the largest, most comprehensive research projects ever undertaken in healthcare. The landmark project detailed the availability, use, quality, finance, and politics of healthcare across the state of Michigan. The results of the project were published in *Hospital and Medical Economics*, a massive two-volume set.

In 1961, McNerney left the University of Michigan to become the president of the national Blue Cross Association. As president, he oversaw the merger with the Blue Shield Association and the subsequent creation of the national Blue Cross and Blue Shield Association. McNerney was instrumental in getting the independent Blue Cross and Blue Shield plans to offer health maintenance organizations (HMOs) and managed-care plans, because he thought that the implementation of managed care was inevitable.

In 1963, he founded the journal *Inquiry*. Today, *Inquiry* is one of the top three peer-reviewed scholarly publications in the field of health services research.

McNerney was a leading advisor to President Lyndon B. Johnson. In partnership with the administration's Wilbur J. Cohen, he developed the blueprint for the Medicare program that, together with Medicaid, was signed into law in 1965. Under President Richard M. Nixon, McNerney also served as chairman of the task force on Medicaid. The panel's final report called for an overhaul of the federal-state apportionment of costs and responsibilities, issues that remain contentious to this day.

After retiring from the Blue Cross and Blue Shield Association in 1981, McNerney went back to academe, becoming the Herman Smith Professor of Health Policy at the Kellogg School of Business at Northwestern University. While teaching at the university, he continued to consult with numerous organizations. He retired in 1998 after suffering a stroke. In 2005, McNerney died at his Winnetka, Illinois home, at the age of 80.

During his long and illustrious career at the University of Michigan, the Blue Cross and Blue Shield Association, and Northwestern University, McNerney mentored hundreds of students as well as junior and senior managers. He served on numerous government and private-sector committees and advisory bodies. He frequently testified before various congressional committees. He worked tirelessly with community organizations and charitable foundations. He wrote 3 books and more than 75 articles on various aspects of health-care. His areas of expertise included healthcare insurance, management, financing, education, leadership, philanthropy, strategy, and policy. Because of his large number of areas of expertise and wide general knowledge, many considered McNerney a 20th-century Renaissance man.

MEASUREMENT IN HEALTH SERVICES RESEARCH

Measurement in health services research often involves assessing a person's well-being through self-report instruments. Whereas the presence of disease and its effects on mortality can be directly ascertained through clinical observation, the assessment of well-being requires the development of self-report instruments. The measurement of well-being and other internal states (e.g., depression) involves an individual's responses to items that represent various manifestations (e.g., symptoms, attitudes, and beliefs) that collectively reflect the main features of the constructs. The use of measurement in health services research has grown since the 1960s due to policy initiatives such as President Lyndon B. Johnson's "War on Poverty" that necessitated self-report measures to guide program planning and monitor program effectiveness. With support from the National Center for Health Services Research (NCHSR), development and use of multi-item scales has increased dramatically across the spectrum of health services. As a result of contributions from many different disciplines, an array of measures of health status and health outcomes have been developed to evaluate whether healthcare is achieving its mission of reducing disease, disability, and pain and improving health-related quality of life.

Overview

For health service measures to achieve their intended purpose, they must be developed on the basis of a sound theoretical framework and a thorough understanding of the constructs being measured, and rigorous procedures must be used during instrument validation. Sophisticated statistical procedures for data analysis cannot compensate for measures that lack sufficient reliability, validity, and sensitivity. For the responses to individual items or questions to translate into

meaningful measures, consideration should be given not only to the underlying theory and the empirical evidence but also to the measurement model being used. Presently, the most common approach in health services research for obtaining meaningful scores on measurement instruments is the *classical test theory* (CTT) approach in which raw item scores are mathematically manipulated, usually by summing across the item scores to obtain a total score. Similarly, the prevalent *instrument validation strategies* are derived from the CTT procedures for instrument development. However, there are alternative measurement models, including the Rasch model and item response theory (IRT), that provide viable alternatives to CTT and are starting to gain acceptance in health services research.

Classical Test Theory

For more than 80 years, CTT has been the basis for the development and evaluation of health services instruments. Under this framework, no distributional assumptions about scores are made. Like modern test theories, CTT does make the assumption that the trait being measured is unidimensional. Perhaps due to its simplicity and relatively weak assumptions, CTT continues to be the prevalent measurement model in health services research. Whereas CTT has played an important role in measuring the diverse panoply of health conditions, the major limitations associated with it have been well-documented in the psychometric literature: (a) sample dependence, (b) test dependence, (c) all items are not created equal, (d) scores are nonlinear and noninterval, and (e) lack of efficiency.

Sample Dependence

Under CTT, item parameters (e.g., item difficulty and other item statistics) are sample dependent. This means that items may have greater difficulty estimates or reflect high severity when they are administered to respondents at the low end of the score continuum but have smaller difficulty estimates or reflect less severity with respondents at the high end of the score continuum. That item statistics depend on the sample with which they are estimated means that these statistics have limited value, except when the sample is similar to

the ultimate patient population for which future instruments will be constructed. Unfortunately, such similarity is rare because instrument validation studies most often rely on samples of convenience, and over time, a population's level of the construct being measured may change.

Test Dependence

The test score, which is often used as a descriptor of a respondent on a given construct, is test dependent. If the level of "difficulty" of the items in the test instrument is changed, as might be done in the context of computer-adaptive tests, then the test scores are no longer on the same mathematical metric. Therefore, they are not a useful variable for comparing respondents to each other or to performance standards.

All Items Are Not Created Equal

The creation of raw scores by summing item responses assumes that the items are equivalent with respect to their position on the construct. In general, this is not a valid assumption.

Scores Are Nonlinear and Noninterval

Ideally, measures derived from health services instruments should be linearly related to the construct being measured. Furthermore, the magnitude of change represented by a single unit on the measurement continuum should remain constant across the measurement spectrum. Regardless of a score's range or whether it is converted to a standard metric, raw scores do not possess the property of linear interval measurement. Noninterval measurement can have serious implications regarding the sensitivity of CTT-based instruments. Research comparing CTT-based scores to Rasch-based measures indicates that the raw scores tend to overestimate trait levels at the low end of the measurement spectrum and underestimate trait levels at the high end.

Lack of Efficiency

In the 1980s, with healthcare practitioners and researchers demanding more measures, the need arose for greater efficiency without a loss of reliability and validity. The CTT model is less than

ideal for efficiency because it achieves greater test reliability by increasing the number of items.

Rasch and IRT Measurement Models

Although the early work in IRT took place at the same time as that of the Rasch model, the Danish mathematician and statistician Georg Rasch (1901–1980) was the first to formalize his measurement model. Common to the Rasch and other IRT models is the idea that underlying a respondent's performance on a set of items, questions, performance tasks, or even rating scales is a set of human characteristics known as *latent traits*. These traits, broadly or narrowly defined, are not directly observable. Instead, they must be inferred from an individual's responses to the items or questions comprising the measurement instrument. The IRT measurement model provides an estimate of a given trait by specifying a probabilistic relationship between the items and their characteristics and the estimated trial level. In the Rasch model, this probabilistic relationship is stated most simply for dichotomous items.

There are three features of the Rasch model that are of particular note. First, the use of a probabilistic model allows instrument developers to compare the actual and expected response patterns for a set of items, thereby providing a mechanism for assessing the *model fit*. If the responses are generally consistent with the *model expectations*, the measure is judged to fit the Rasch model and, therefore, has the desired properties of conjoint additivity and sample-free and test-free measurement. Second, the direct comparison between *person measures* and item parameters is possible because both are measured on the same scale: the logit or “log odds ratio” scale. The ability to distinguish person measures and item parameters has important implications with respect to the assessment of change and the evaluation of an instrument's generalizability across cultures. Third, the use of logarithms permits the “bent ruler” of raw scores to have linear and equal-interval properties. Logarithms are useful in transforming curvilinear functions into linear relationships. In the 19th century, the German experimental psychologist Gustav Fechner (1801–1887) was the first to realize that the relationship between stimuli and responses when measuring human characteristics is not linear

but rather logarithmic. This suggests that the logarithmic scale both has desirable measurement properties and is well suited for measuring many human characteristics.

Multiparameter IRT Models

Other IRT models include additional item parameters. Whereas the Rasch model makes the assumption that discrimination is equal for all items, multiparameter models typically estimate an *item discrimination parameter*. In educational testing, a *guessing parameter* also may be included. Whereas its *difficulty* refers to the location of the item on the measurement continuum, its *discrimination* refers to the steepness or the slope of the item's characteristic curve (ICC). Items with steep ICCs indicate that a unit change in a person's measure corresponds to a large change in the probability of endorsing the item. Conversely, low discrimination indicates that a unit change on the measure corresponds to a relatively small change in the probability of item endorsement. The guessing parameter is quantified as the probability of item endorsement at the lower asymptote of the ICC.

Research has demonstrated that the Rasch model has properties, associated with additive conjoint measurement, that are required by parametric statistics and advantageous for accurate assessment of change over time. If the data fit the model reasonably well, the Rasch model—compared with CTT and other IRT models—makes the clearest justification that interval- and even ratio-level measurement is obtainable with the survey instruments.

Application of Rasch Measurement

Although Rasch and IRT have their roots in educational testing, these measurement models have been adapted for use in health services research. Some of the earliest health-related applications of Rasch and IRT were in the field of rehabilitation. The initial efforts generally involved the use of the Rasch model. This may be due, in part, to the fact that the Rasch model has lower sample size requirements, compared with multiparameter models, to obtain stable item parameters and accurate person measures. This makes it more suitable for the measurement of highly select

populations such as persons with specific types of physical impairments.

Rehabilitation emphasizes monitoring and assessing a person's abilities with respect to physical functioning and the performance of the activities of daily living (ADL). Rehabilitation researchers quickly recognized the limitations in raw scores and the potential of Rasch measurement to produce precise, equal-interval measures. The use of the Rasch model to provide unambiguous measures of the change resulting from rehabilitation made it an attractive alternative to the estimation of change using raw scores, which has long been known to have serious problems. The application of modern measurement models quickly spread to other areas of health research, including health services research.

Measurement of Change

In health services research, the analysis of change is a difficult issue, which may be complicated or confounded by the properties of the measurement instruments. Because of its linear, interval-scaling properties, Rasch measurement enables the assessment and adjustment of measures over time—when the meanings of items may have changed due to differing interpretations of the items and differing use of the rating scale from time one to time two. For the research purpose of interpreting the outcomes, the development of linear, interval, clinical measures makes it possible to move past the reliance on statistical significance, with numbers that are difficult to interpret clinically, to the assessments of outcomes that have clear clinical criteria. Having clinical milestones on the ruler enables the use of much simpler and more easily interpretable numbers that tell the practitioner and researcher (a) how many patients got better in each group, (b) how many patients are borderline and require careful watching, and (c) how many patients are still severe and require a stronger or a different intervention.

Assessing the Cross-Cultural Stability of Item Parameters

To assess individual change, it is important to establish the stability of item parameters over time. It is also critical to determine if measures are

equivalent between culturally defined groups. Measurement equivalence is necessary to make accurate quantitative comparisons across culturally or linguistically defined groups. During the past decade, numerous journal articles have been published concerning the cross-cultural and linguistic equivalence of health and health outcome measures using modern measurement methods. The ability of the Rasch and other IRT measurement models to separate person measures and item parameters and the use of differential item functioning (DIF) analysis have undoubtedly contributed to the growth of this area. Compared with test developers in the fields of education and psychology, health outcome researchers have been slow to acknowledge the presence of DIF in their instruments. However, the incorporation of Rasch and IRT methods in health services research in recent years has led investigators to examine DIF on several measures across a variety of culturally and linguistically defined groups. DIF by country or language has been identified on measures of functional status, disease activity, pain, substance abuse, and health-related quality of life. The presence of DIF does not necessarily indicate that the item(s) producing DIF are biased. DIF may reveal the presence of real group differences. For instance, males and females frequently differ in their presentation of depressive symptoms; likewise, adolescents and adults may differ in their patterns of substance use and symptoms of substance dependence and abuse.

Whereas the Rasch and IRT models provide a mechanism for detecting and adjusting for DIF, it is also important to generate theories and hypotheses that explain the causes of DIF. Rather than simply purging items that fail to fit the measurement model or controlling for DIF through the use of anchoring and equating procedures, understanding the causes of these problems can add greatly to the researchers' ability to write better items. It is also important to note that although DIF is extremely useful in detecting *item bias*, *measures* may be biased or nonequivalent in other ways. For instance, a construct can be defined differently across different cultures (*construct bias*), and there may also be differences in the sample characteristics and administration procedures (*method bias*). Thus, whereas DIF represents an important tool in establishing cross-cultural equivalence, it must be

integrated into a larger process of establishing cross-cultural validity.

Computerized Adaptive Testing

Healthcare providers are under increasing pressure from consumers as well as public and private funders to demonstrate that they can provide evidence-based interventions that achieve reliable outcomes. To make matters more complicated, public and private funders have been demanding more detailed assessment (e.g., to diagnostic criteria or a standard for a given area) or other evidence of the standardization of care. Of course, they are also concerned about how the scores translate into diagnosis, placement, and treatment-planning recommendations, particularly for specialty and costly services. Although these efforts hold promise, they also have associated costs: Longer assessments may lead to patient fatigue or agitation; the staff time to learn, administer, interpret, and report on the standardized assessment consumes resources and is costly for the treatment agencies.

Computerized adaptive testing (CAT), coupled with modern psychometric methods and *item banking*, represents a promising solution to the measurement problems encountered with the traditional fixed-form instruments. The combined use of CAT, Rasch, and IRT measurement models plus item banking provides comprehensive and precise measurement with a limited burden to respondents.

CAT algorithms are designed to select and administer a subset of items in a process likened to a binary search. The selected items are tailored to the person's level on the measured construct, and the unnecessary items are eliminated from the assessment process with a minimal loss of measurement precision. This results in a reduced respondent burden and enhanced content specificity. Conversely, item banking increases the content coverage and minimizes the presence of measurement floor and ceiling effects. In addition, CAT is more practical and reliable over a wide range of score levels. Evidence of the efficacy of CAT has revealed several practical advantages, including (a) substantial reductions (50–90%) in the respondent burden, (b) the virtual elimination of ceiling and floor effects, and (c) gains in precision. Though CAT offers significant benefits, the development of

a working CAT requires considerable time and resources, particularly with respect to item bank development and maintenance. A well-developed CAT, however, if it gains widespread acceptance in the field, has the potential to replace the plethora of instruments that now exist for the measurement of health constructs. A CAT item bank can contain enough items to exhaustively represent the construct of interest and produce scores on a single standardized ruler.

Future Implications

The tools for achieving high-quality, valid, and precise measurement in health services research are now readily available. The use of Rasch models is increasing, and they can be applied to a wide range of new applications. These measurement models will likely continue to be adopted toward the ultimate goal of improving each individual's health and well-being.

MECHANIC, DAVID

David Mechanic is the René Dubos Professor of Behavioral Sciences and the director of the Institute for Health, Health Care Policy, and Aging Research (IHHCPAR) at Rutgers University. He is a pre-eminent medical sociologist whose research and writing deal with the social aspects of health and healthcare.

Mechanic earned his bachelor's degree from the City College of New York (1956) and his master's (1957) and doctorate (1959) degrees in sociology from Stanford University. In 1960, he joined the faculty of the University of Wisconsin–Madison where he was the chair of the Department of Sociology (1973–1979) and the director of the Center for Medical Sociology and Health Services Research (1972–1979). In 1979, he moved to Rutgers University where he was dean of the Faculty of Arts and Sciences (1980–1984) and, in 1985, became the founding director of IHHCPAR, which he continues to direct. Mechanic also serves as the director of the Robert Wood Johnson Foundation's Investigator Awards in Health Policy Research Program.

Mechanic has been an extraordinary and pioneering leader in the social and behavioral sciences of health, health services, and health and mental health policy over the past 40 years. His work has been innovative in a number of research areas. Mechanic developed the field of illness behavior—that is, the study of how people

perceive, evaluate, and selectively act in response to symptoms. His conceptualization of the appraisal and meaning processes that accompany illness as affected by socialization and situational cues has influenced generations of work on the use of health services.

One of Mechanic's distinctive qualities has been his vision in identifying trends and defining new research areas and perspectives in healthcare policy. In his classic study on the social adaptation to stress, he developed an alternative theory to the then pervasive psychodynamic perspective. His model, showing how adaptation was influenced largely by active instrumental initiatives structured by social context and communication patterns, became the dominant research paradigm in the study of stress, coping, and social support.

Mechanic was one of the first researchers to recognize the possibilities yet also the worrisome issues related to managed care. His early articles on the rationing of healthcare established a framework for examining alternative allocation mechanisms. His work on the dynamics of physician payment in capitation and fee-for-service practices in the United Kingdom and the United States anticipated future studies of payment mechanisms. Other major contributions are noteworthy for examining risk selection, population health, policy challenges in addressing racial disparities, and trust relationships between clients and physicians.

Mechanic's recent work explores why reaching consensus and implementing significant reform in the American healthcare system is so problematic. He reasons that until the political will and concerted efforts for change favor the healthcare needs of the population and not the benefit to individuals and organizations who profit from healthcare, reform will remain elusive.

Mechanic has received many notable awards, including the Health Services Research Prize from the Association of University Programs in Health Administration (AUPHA) and the Baxter Allegiance Foundation; the Distinguished Investigator Award from the Association for Health Services Research; the Rema Lapouse Award and the first Carl Taube Award from the American Public Health Association (APHA); and the Distinguished Career Award for the Practice of Sociology, the

Distinguished Medical Sociologist Award, and the Lifetime Achievement Award in Mental Health from the American Sociological Association (ASA). He received the Benjamin Rush Award (with Lecture) from the American Psychiatric Association (APA) and gave the Inaugural Lecture of the Award in the Behavioral and Social Sciences honoring Matilda White Riley at the National Institutes of Health (NIH). Mechanic was elected to the National Academy of Sciences (NAS), and he was also the first sociologist elected to the national Institute of Medicine (IOM).

MEDICAID

Medicaid is a federal and state entitlement program that provides medical benefits to low-income and low-resource individuals and families who meet federal and state eligibility requirements. The Medicaid program is the largest source of medical funding for poor people in the United States. Medicaid is overseen by the Centers for Medicare and Medicaid Services (CMS) in the U.S. Department of Health and Human Services (HHS), but the program is primarily administered at the state level. The federal government provides financial assistance to states, with a greater share of financial support going to states with lower average per capita incomes. Although states vary widely in their program requirements and the services offered, there are certain groups and services that must be covered, including care for children, pregnant women, and disabled individuals. The State Children's Health Insurance Program (SCHIP) and the Program for All-Inclusive Care for the Elderly (PACE) are two special programs within Medicaid designed to cover uninsured children and to provide home- and community-based care to the elderly, respectively.

Background

Medicaid was initially planned as an addition to programs that provided cash assistance to vulnerable groups such as the elderly, disabled, and children and families. Medicaid was signed into law in 1965, as Title XIX of the Social Security Act. It was designed to be a joint program between the states and the federal government to provide medical assistance to qualified needy individuals. This program is primarily coordinated by state agencies with additional funding provided by the federal government.

Medicaid has grown significantly in recent years due to (a) increased use of services; (b) expanded coverage to larger and growing populations; (c) increased costs associated with medical care, drugs, and technology; and (d) an increased need for acute and long-term care. In 2006, total federal and state Medicaid costs reached \$303.8 billion, and the program covered close to 59 million people or 20% of the population in fiscal year (FY)

2005. Medicaid costs are expected to rise significantly in the coming years: Estimates place Medicaid costs in FY2009 at \$445 billion.

Who Medicaid Covers

To receive Medicaid, individuals or families must fit in a certain designated group. Although there is wide variation among the states, there are certain groups they must cover to receive federal funds. States must provide coverage to those already receiving federal income assistance, such as families eligible for coverage through Aid to Families With Dependent Children (AFDC). Although AFDC was replaced in the 1996 welfare reform bill with Temporary Aid for Needy Families (TANF), Medicaid generally covers anyone who would have been eligible under the AFDC guidelines of 1996. States must also cover individuals falling into one of the other seven *categorically needy* eligibility groups. Many of the designations for coverage require incomes at or below the federal poverty level; for reference, for 2007, 100% of the federal poverty level for a family of four was \$20,650 per year or \$1720.83 per month. (There are different poverty levels for families in Hawai'i, Alaska, and Washington, D.C.) However, having a low income is not sufficient to receive coverage through Medicaid: One must also fit in one of the designated eligibility groups. Furthermore, low-income persons with a certain amount of other assets usually would not be eligible for Medicaid until they "spend down" or deplete their assets to fit in a *medically needy* category (see below).

The categorically needy include (a) families eligible for AFDC (as of 1996), (b) pregnant women and children under 6 years old with a family income at or below 133% of the federal poverty level, (c) children aged 6 to 19 with a family income up to 100% of the federal poverty level, (d) caretakers of children under age 18 (or age 19 if the child is still in school), (e) Social Security Income recipients, (f) individuals receiving adoption or foster care assistance through Title IV of the Social Security Act, (g) people living in medical institutions meeting certain Social Security income requirements, and (h) certain Medicare beneficiaries.

In addition to the categorically needy groups, 34 states and the District of Columbia offer coverage to those fitting in designated medically needy groups. This category allows states to offer coverage to individuals who otherwise would not be covered under Medicaid. The conditions for the medically needy groups can be more restrictive than those for the categorically needy, but people are able to spend down to reach their state's medically needy level. If a state does choose to have a medically needy category, there are certain groups that the federal government requires the state to cover: (a) pregnant women for 60 days post-delivery, (b) children under 18, (c) certain newborns for the 1st year of life, and (d) some blind people. Additional groups that states may choose to cover include (a) children under 21 who are full-time students, (b) caretaker relatives, (c) people over age 65, (d) blind people, (e) disabled people, and (f) others who would be eligible if they were not already enrolled in a health maintenance organization (HMO).

There is a third group of people that receive benefits from Medicaid, and they fall in another category known as "special groups." For example, Medicaid will pay the Medicare premiums, deductible, and coinsurance fees for Medicare recipients who have incomes less than 135% of the federal poverty level. Medicaid will also pay Medicare Part A premiums for Qualified Working Disabled Individuals, who are disabled people who lose Medicare because they are working. These individuals must meet certain income requirements as well and have an income less than 200% of the federal poverty level. The Ticket to Work and Work Incentives Acts of 1999 allow states to expand their Medicaid eligibility to working disabled people. Disabled individuals between the ages of 18 and 65 can be offered Medicaid coverage, even if they exceed Social Security income guidelines, if they are able to and choose to work. If an individual's disabling condition improves, he or she may still be eligible for coverage but may have to share part of the cost of medical care. Certain states offer coverage for special medical conditions as well, but this varies widely by state. For example, 10 states and the District of Columbia offer Medicaid coverage to uninsured tuberculosis patients (for tuberculosis treatment only), and all 50 states offer Medicaid coverage for a specific

period of time for women with breast or cervical cancer. All 50 states provide long-term care services for Medicaid-eligible people who qualify for individual care.

Under the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, also known as the *welfare reform bill*, legal resident aliens who entered the United States after 1996 are ineligible for Medicaid coverage for the first 5 years they are in the country. However, states have the ability to modify this requirement if they choose to cover legal resident aliens earlier. All states must provide and cover emergency services for legal aliens.

Program of All-Inclusive Care for the Elderly

PACE was designed to provide an alternative to institutional care for those over 55 years of age requiring skilled nursing care. Working in PACE teams, caseworkers manage and coordinate all the necessary care and services for these individuals, usually provided through adult day-care centers, home health care, and outpatient hospital care. The program helps individuals maintain a more independent lifestyle and still receive the care they need. The providers are paid exclusively through PACE, and they are not able to implement any limits or costs to the patients.

State Children's Health Insurance Plan

Title XXI of the Social Security Act enacted SCHIP and allows states to incorporate SCHIP as part of Medicaid or as an independent program. SCHIP provides additional federal funds for states to cover uninsured children through Medicaid. SCHIP reaches a group of children that would not have otherwise been eligible for Medicaid coverage by covering those up to age 19 whose parents' income is too high for Medicaid but too low to afford private insurance. SCHIP usually covers families with an income at or below 200% of the federal poverty level. All state SCHIP programs must include free immunizations and well-baby visits; other services may have a copay. The immigration status of the parents usually does not matter in regard to medical coverage for their children: As long as the child is a U.S. citizen, he or she will be covered by Medicaid.

Approximately 25% of all the children in the United States, and 50% of all the low-income children, receive their health coverage through Medicaid or SCHIP. Since SCHIP was authorized in 1997, the rate of uninsured children has dropped from 23% in 1997 to 14% in 2005. Children who are covered report similar access to primary and preventive care as children covered by private insurance (but lower access to dental care). Since SCHIP began, improved health outcomes for covered children have been reported, such as fewer emergency room visits for asthma and improved school performance.

What Medicaid Covers

There are certain services that states must provide coverage for, as mandated by the federal government. For people who fall in the categorically needy groups, states must provide coverage for (a) inpatient and outpatient hospital visits; (b) laboratory tests and X rays; (c) pediatric and family nurse practitioners; (d) nursing facility services for individuals over age 21; (e) regular screening up to age 21 as part of Early and Periodic Screening, Diagnosis, and Treatment (EPSDT); (f) family planning care and supplies; (g) rural health clinic care; (h) physician services; (i) dental services; (j) home health services for individuals eligible for nursing care, including home health aides and medical supplies; (k) nurse midwife services; (l) prenatal care; and (m) postpartum care for 60 days. For states with medically needy categories, the following services must be covered: (a) prenatal care and delivery, (b) postpartum care for certain groups under age 18, and (c) home health services for certain groups.

States have the option of providing additional services that are listed under Medicaid law and may also provide some services to certain groups of medically needy individuals. For some of these optional services, states are eligible for federal funding. Examples of additional services for which states can receive federal support are (a) diagnostic services, (b) clinic services, (c) care centers for mentally retarded individuals, (d) prescription drugs and prosthetic devices, (e) optometrist services and eyeglasses, (f) nursing services for individuals under age 21, (g) transportation services to and from medical care, (h) rehabilitation services and physical

therapy, and (i) home- and community-based care for individuals with chronic conditions.

How Medicaid Works

Medicaid is overseen by the CMS in the HHS. The federal government provides some guidelines for who will be covered and how, but the requirements and programs vary widely by state, and states take the primary role in administering their statewide Medicaid programs. Medicaid is funded through federal and state funds, and the federal government pays different shares for different states. The share from the federal government is determined by the Federal Medical Assistance Percentage (FMAP), which uses a formula comparing the state's average per capita income with the national average per capita income. This federal-funding share is inversely associated with the state's per capita income. Thus, in a state with a lower per capita income, the federal government will pay a larger share of Medicaid, and in states with higher per capita incomes, the federal government will pay a smaller share. The government share, or FMAP, must be between 50% and 83% of Medicaid costs. In 2008, the federal minimum FMAP was 50% with the highest share, paid to Mississippi, at 76.29%. The FMAP for Washington, D.C. was recently raised permanently from 50% to 70%. For children covered under SCHIP, the federal government pays a higher share, averaging about 70% for all states. The federal government reimburses 100% for care through the Indian Health Service (IHS), a branch of the HHS. It also provides extra financial support to the 12 states that provide the highest rates of emergency care to undocumented immigrants.

There has been recent growth in the use of managed care in Medicaid as an alternative method of both payment and delivery of services. States can apply for waivers from the government in designing and implementing Medicaid managed-care programs. Two sections of the Social Security Act describe waivers available to states in this area: (1) Section 1915(b) allows states to design "innovative healthcare delivery or reimbursement systems" and (2) Section 1115 allows states to carry out demonstration projects to test programs designed to cover uninsured individuals without significantly raising costs. In 2006,

approximately 65% of Medicaid recipients were enrolled in managed-care programs, up from only 14% in 1993.

The state is responsible for paying the providers who offer services to Medicaid recipients and accept Medicaid payments. Providers are usually paid through fee-for-service methods or prepayment programs such as the managed-care programs mentioned above. It is also the responsibility of states to ensure that there are enough providers in certain geographic areas who accept Medicaid. For hospitals that treat a disproportionate number of Medicaid recipients and other low-income or uninsured people, the state must make additional payments through a system known as the Disproportionate Share Hospital Adjustment. Some Medicaid beneficiaries may pay a small copayment for services, but there are certain groups that the federal government excludes from having to pay any share of medical costs. These special groups include (a) pregnant women, (b) children under the age of 18, (c) hospital or nursing home patients who would otherwise pay for their own care, and (d) anyone receiving emergency care or family planning services.

States have the power to determine the amount and duration of services they will cover, such as the number of days in the hospital or the number of doctor visits. However, federal law stipulates that these limits be fair and not discriminate on any basis. For example, states cannot limit coverage for medically necessary services for children, such as those considered part of EPSDT.

Like the waivers for managed-care programs and the inclusion of extra groups, states can also apply for waivers to cover additional services such as community- or home-based services for individuals who would otherwise require institutionalization. However, to receive a waiver the state must offer evidence that the plan or service addition is cost-effective.

In administering the state Medicaid program, each state is responsible for (a) setting the rates of payment; (b) establishing eligibility guidelines; (c) determining the types and durations of eligible services; (d) informing recipients about participating providers; and (e) ensuring that recipients receive timely, quality, and appropriate medical care. In addition, the state legislature is able to change state Medicaid policies.

The Cost of Medicaid

Total Medicaid costs for 2006, including both the federal and state expenditures, reached approximately \$303.8 billion. Of this figure, 57.8% was for acute care, 36.6% for long-term care, and 5.6% for disproportionate-share hospital payments.

Considering the approximately 59 million Medicaid recipients, the overall average cost per person is about \$4,662, but the costs vary considerably among certain groups. For example, children constitute about 50% of all Medicaid recipients and are covered at an average cost of about \$1,617 per child. Adults make up about 26% of Medicaid recipients at an average cost of \$2,102 per person. Care for elderly and disabled Medicaid recipients costs the most by far: the elderly make up 10.3% of Medicaid recipients and cost an average of \$11,839 per person; disabled individuals covered by Medicaid (14.1% of all recipients) cost an average of \$13,524 per person.

In the coming years, long-term care will continue to be a large and growing expense for Medicaid. In 2006, Medicaid paid \$48.6 billion for nursing facilities, accounting for 41% of the total costs in these areas. The program paid an additional \$45.4 billion for home health and personal care.

Dual Eligibility

Under certain circumstances, individuals can be dually eligible for both Medicare and Medicaid. Medicare beneficiaries whose incomes and resources are low enough to qualify in one of Medicaid's eligible categories can receive Medicaid assistance in addition to their Medicare coverage. In these cases, Medicaid supplements Medicare coverage, and additional services not covered by Medicare may be covered (e.g., nursing home care beyond Medicare's 100-day limit). The two main groups of Medicare recipients who are eligible for assistance from Medicaid with Medicare premiums and copayments are known as (1) Qualified Medicare Beneficiaries (QMBs) and (2) Specified Low-Income Medicare Beneficiaries (SLMBs). QMBs are Medicare recipients with incomes less than 100% of the federal poverty level; for these individuals, Medicaid pays their Medicare Part A and Part B premiums, coinsurance, and deductibles. For SLMBs, an income less than 120% of the federal poverty level is sufficient to meet the

eligibility requirement, and Medicaid will pay their Part A and Part B premiums. A third group—working disabled people who have incomes less than 200% of the federal poverty level and who have lost Medicare because they have returned to work—are known as Qualified Disabled and Working Individuals; they are eligible to buy Medicare Parts A and B, and Medicaid will pay their Medicare Part A premiums. A final group of qualified individuals—those who have Medicare and are between 120% and 175% of the federal poverty level—are also eligible to receive Medicaid assistance in paying their Part B premiums. With Medicare Part D recently enacted, Medicaid will no longer provide prescription drug benefits for dually eligible Medicare recipients. It must be noted that in all these cases of dually eligible people, Medicare will always pay first because Medicaid is the payer of last resort. Nationwide, about 6.5 million Medicare recipients receive supplemental assistance from Medicaid.

Future Implications

In the future, managed care will likely become a more popular method as states seek to provide and pay for care for Medicaid recipients and, at the same time, control costs. Medicaid costs will continue to rise as the population ages, long-term care use becomes more frequent, eligible populations grow, and the cost of medical care increases.

MEDICAL ERRORS

Until the 2000 report by the national Institute of Medicine (IOM) *To Err Is Human: Building a Safer Health System*, medical errors were a relatively low priority in the U.S. healthcare system. Medical errors were regarded as uncommon. Physicians and other healthcare providers generally attributed them to “a few bad apples” and the occasional slip. However, data pointing to the pervasiveness of the problem were already available, leading the IOM to estimate that between 44,000 and 98,000 Americans die each year as a result of medical errors.

Since that report, medical errors and patient safety have become a major focus of health services research and policy making, providing a key role for the former in shaping the latter, as both government and nongovernmental organizations

develop regulations and guidelines for reducing errors to improve patient safety and the quality of care. There has also been a major shift from blaming the individuals who make errors to recognizing that the individuals function within systems and that those systems critically influence individual performance.

Definitions and Concepts

Key definitions and concepts—many adapted from systems-based research on error prevention in other industries—underlie the current efforts to understand and prevent medical errors. An error is defined by the IOM as either the failure of a planned action to be completed as intended or the use of a wrong plan to achieve an aim. The former is referred to as an *error of execution* and the latter as an *error of planning*. This formulation is based on the work of James Reason and others who extensively studied accidents in aviation and other industries.

Errors of execution are due either to *slips* or *lapses*. A slip is an observable error of execution, such as when a surgeon inadvertently cuts the wrong tissue. A lapse is unobservable, as when an internist forgets to order antibiotics for a patient with pneumonia after intending to do so. In both cases the physician knew what the right thing was to do and intended to do it. In contrast, errors of planning are mistakes in that the actions proceeded as planned but the plan was wrong.

Errors may be classified as *biomedical* or *contextual*, the former occurring because of inattention to processes occurring within the boundary of the skin and the latter from inattention to processes expressed outside that boundary—that is, processes that form the context of a patient’s illness. Failing to prescribe a medication that effectively treats a serious condition is a biomedical error. Prescribing a medication that a patient cannot afford when a less costly effective medication is available is a contextual error. In both instances, the patient does not obtain the necessary therapy: in the first, from a failure to attend correctly to the patient’s disease and, in the second, from inattention to the context surrounding the disease.

Fortunately, not all errors result in an *adverse event*, the term for an injury that is caused by medical mismanagement. Neglecting to wash one’s

hands prior to examining a postsurgical wound is an error, for instance, but in most cases this does not result in a wound infection because of the patients' inherent capacity to fight off infection. Conversely, adverse events may occur despite flawless care: A patient's surgical wound may become infected despite excellent sterile technique. Harm that is specifically attributable to error is termed a *preventable adverse event*.

Occasionally, preventable adverse events are due to *negligence*—when the care provided falls below the standard expected of a reasonable and knowledgeable practitioner under the circumstances, as established in a court of law. Most preventable adverse events, however, are considered to be the end result of conditions in the organization that preceded the actual incident.

James Reason distinguished *active* from *latent* errors. Latent errors may include the faulty design of instruments or technologies, poorly installed or functioning equipment, or a dysfunctional work environment where communication or work conditions are not suitable to meet the demands of the job. They may be difficult to detect, but they form the backdrop for the observed, or active, error. The point where an active error occurs is also referred to as the *sharp end* of the system, as in the slip of a surgeon's knife, whereas the latent preconditions for the error are referred to as the *blunt end*, as in the faulty lighting or poor staffing that diminishes an operator's technical performance at the time of the preventable adverse event.

The structured process for identifying contributing factors such as latent errors leading up to an incident is often described as *root cause analysis*, or *systems analysis*. A critical incident may be a near miss or close call, in which an error or series of errors did not produce an injury only because of chance. It may also be a *severe adverse event*, sometimes termed a *sentinel event*, in which severe injury or death to a patient occurred. Reason has described what he calls the "Swiss cheese" model: the view that "holes" may be identified in every layer of an organization's systems of operation. In organizations that lack a culture of safety, where teams may not work well together, or equipment is poorly functional, the holes may be sufficiently large and numerous that it is not uncommon for them to "line up," leading to error chains that result in a high incidence of preventable adverse events.

The Scope of the Problem

Safety is defined as freedom from accidental injury. Because of the high prevalence of preventable adverse events that injure patients, healthcare is unfortunately not as safe as it could be. Early awareness of the magnitude of the problem emerged in 1991 from the Harvard Medical Practice Study of approximately 30,000 randomly examined discharges from 51 hospitals in New York State in 1984. That study found that 3.7% of the hospitalizations were prolonged or resulted in disability because of an adverse event. More than half (58%) of these adverse events were deemed preventable, and 27.6% met the legal criteria for negligence. Nearly one fifth (19%) of the adverse events were medication related, 14% were due to wound infections, and technical complications accounted for 13%. Overall, 13.6% of adverse events were fatal.

Similar findings emerged from a subsequent corroborative study published in 2000 and are based on an analysis of 15,000 hospital discharge records from Colorado and Utah in 1992. The investigators selected a representative rather than a random sample of hospitals, and the records were reviewed by only one rather than two physicians but with greater standardization of the review process. Adverse events were found to be slightly less common at 2.9%; however, the proportions deemed preventable and negligent were nearly the same as those found in New York at 53% and 29.2%, respectively.

The most significant difference between the two studies was the incidence of adverse events that were fatal: The rate of 6.6% in Colorado and Utah was about half the number in New York. Variations in study design, margin of error, and actual differences in error rates in the two studies could all contribute to the discrepant findings. Extrapolating from these numbers to the more than 33 million hospital admissions in the nation in 1997, and excluding unpreventable adverse events from the analysis, produced the widely quoted estimate that medical errors may cause 44,000 to 98,000 preventable deaths per year.

Smaller studies and the recognition that several categories of errors are missed using exclusively hospital-based discharge data has led many to believe that the estimates of preventable adverse

events and fatal incidents, as serious as they are, nevertheless *underrepresent* the true magnitude of the problem. In an analysis of more than 1,000 intensive-care units (ICUs) and surgical patients admitted to a teaching hospital, preventable adverse events were identified in 45.8% of the cases, with 17.7% leading to disability or death. The chance of an adverse event increased by about 6% per day of hospitalization.

Furthermore, because most methods for identifying errors and their adverse effects are limited to assessments of the medical record, they miss contextual errors, which are rarely documented. For instance, the failure to take into account a patient's lack of transportation to a Coumadin clinic when prescribing the blood thinner for atrial fibrillation may lead to a preventable bleed, but the medical record will show only that the patient did not adhere to an apparently correct plan of care. Identifying such errors requires case analysis, direct observation, or standardized patients to simulate the conditions under which they might occur.

Preventable Adverse Drug Events

Medication errors are the most studied medical errors because of the extensive charting associated with medication administration and the ever-increasing volume of medications administered each year. Medication errors may occur during (a) prescribing, (b) dispensing, (c) administering, (d) monitoring, and (e) the systems management control process. The latter includes failures to identify drug interactions or to coordinate the administration of medications with other aspects of care (e.g., holding anticoagulation medication before a surgical procedure). When a medication causes an injury it is called an *adverse drug event* (ADE). When such an event is due to medication error it is termed a *preventable adverse drug event*.

At least 1.5 million preventable adverse drug events occur each year in the United States as a result of medication errors. Of these, about 22% occur in hospitals, 31% in outpatient Medicare patients, and 47% in long-term care nursing homes. These data exclude (a) all outpatients under 65 years of age who are not enrolled in the Medicare program, (b) errors patients made taking their own medications, and (c) errors of omission when healthcare providers neglected to prescribe

medications with established benefit (e.g., beta blockers for postmyocardial infarction).

A compendium of data on medication errors and preventable adverse drug events is contained in the 2007 national IOM publication *Preventing Medication Errors*. Prescribing and administration errors are the most common. In hospitals, between 0.1 and 0.3 medication orders are incorrect per patient per day. Medications are incorrectly administered 11% of the time, not counting "wrong time" errors. On average, one administration error, such as the wrong dosage or the wrong rate of administration, occurs per patient per day.

Not all healthcare facilities have the same error rate. In studying 36 facilities, medication administration error rates ranged from 0% to 26%. Error rates have been linked to incomplete or illegible prescriptions and, at the blunt end of the system, to hiring practices that lead to high patient-to-nurse ratios with high nurse workloads.

The morbidity and costs of preventable adverse drug events are high. A 1997 study conservatively estimated that 400,000 inpatient adverse drug events occur in the United States per year at a cost of \$5,857 per incident. Adjusting for the rise in healthcare costs and inflation, the additional hospital costs incurred per inpatient preventable adverse drug event in 2008 was \$12,403 with avoidable healthcare expenses totaling \$5 billion. Based on a 2000 study of the ambulatory costs of Medicare patients (again making similar adjustments), just in this subset of the nation's population, outpatient preventable adverse drug event costs in 2008 are \$3,406 per incident and \$1.5 billion nationally. Note that none of these estimates take into account lost earnings, losses related to not being able to carry out the activities of daily living (ADL) such as self-care, and the effects of pain and suffering. The calculations also do not include the costs related to preventable adverse drug events when patients do not take their medications correctly or due to overuse and underuse errors by healthcare providers when prescribing.

Disclosures of Errors

Physicians have long feared disclosing medical errors to patients because of concerns that they are more likely to be sued. Employers and insurers shared similar concerns and did not encourage

disclosure. However, recent evidence clearly shows that physicians who exhibit transparency and say they are sorry for the medical error are, in fact, substantially less likely to be sued. Furthermore, the legal penalties for deception—for withholding information or misleading patients—have become a further incentive for truth telling.

Several ethical tenets commonly applied to the physician–patient relationship also mandate full disclosure of adverse events. First, adverse events often have consequences that require medical intervention. Patients can only participate in decision making regarding subsequent care if they are fully informed of the circumstances necessitating further intervention. In this respect, disclosure is an essential component of autonomy and informed consent.

Second, truth telling is considered essential to respect for persons. When patients entrust themselves to physicians, they expect full transparency, even with regard to near misses. In studies where patients have been given hypothetical scenarios involving even minor incidents related to their care, 98% say that they would want to know what happened. Furthermore, they have indicated that they would be more likely to sue their physicians if they later discovered that information had been withheld or covered up. Hence deception— independent of the actual physical harm that occurred—is regarded by patients, almost universally, as a harm in itself.

Third, full disclosure is essential to justice and fairness. Although they may, in fact, be less likely to sue, patients have the right to seek compensation for injuries when they occur, if they so choose.

Error Reporting

In addition to the legal and ethical imperatives for candor with patients about errors related to their care, disclosure of all such incidents internally and to regulatory bodies through formalized reporting systems is critical to accountability and quality improvement. There are a number of obstacles, however, to effective error reporting systems. Physicians may fear negative repercussions, including malpractice litigation, disciplinary action, or loss of hospital privileges. They may be hesitant to personally acknowledge errors in a profession that emphasizes perfectionism. They may be skeptical

that their reports, which are often time-consuming to file, will be used to improve care. At the institutional level, organizations also face concerns about how they are regarded and practical issues about how best to use the data. A major challenge, then, is creating reporting systems that (a) are easy to access, (b) provide certain legal protections to reporters and institutions, and (c) use the data to improve the processes of care.

Reporting systems for medical errors and adverse events can be mandatory or voluntary. Also, reporting can come directly from the provider, or reports may be submitted by the organization. Finally, reporting can be to an external monitor, such as a state or federal entity, or remain internal to the organization with periodic external audits. Each has its advantages and disadvantages. For instance, direct reporting by practitioners to a national database provides frontline information and bypasses the employer, which may be reassuring to a reporter who is reluctant to notify management each time an error occurs. On the other hand, internal tracking of errors enables organizations to identify system problems and make the necessary changes.

Since the mid-1980s, a growing number of individual states have had adverse event reporting systems of various kinds. The number of reports filed has ranged from fewer than 20 in a year in some cases to tens of thousands in others, indicating the severity of the problem of underreporting. States have also varied greatly in the information made available to the public. Patient confidentiality is always maintained, but whether the names of physicians, hospitals, and health systems or the numbers of adverse events per site are released and whether the data are freely accessible on the Internet all vary. Synthesis and analysis of data, particularly across states, has been almost uniformly poor.

At the federal level, the U.S. Food and Drug Administration (FDA) is an example of a national reporting program for adverse events linked to medications and other medical products. All malfunctions, serious injuries, and deaths must be reported by either the facility or the manufacturer, depending on the circumstances. However, these problems are generally not due to provider or systems errors at the organizational level. The focus is on identifying product defects or risks associated with products through postmarketing surveillance.

To address the unmet need for a comprehensive reporting system that is easily accessible, provides legal protections, and has analytic and response capabilities, the U.S. Congress passed the Patient Safety and Quality Improvement Act of 2005, which established Patient Safety Organizations (PSOs) to collect and process confidential information reported by healthcare providers. The law gives full confidentiality protection to reporters and limits the use of the information in legal proceedings. Both public and private entities—for-profit or not-for-profit (excluding insurance organizations)—may apply to become PSOs if they are capable of meeting the complex requirements to qualify. The act also created a network of patient safety databases (NPSDs) for centralizing data to establish national as well as regional statistics related to errors, adverse events, and the effect of safety improvement initiatives.

Internationally, concerns about medical errors, adverse events, and the strategies for reporting them have developed in parallel. Australia, Canada, and the United Kingdom have all initiated reporting systems. The World Health Organization (WHO) has created the World Alliance for Patient Safety, following a resolution in 2002. Its charge includes a broad range of safety initiatives, such as data collection on adverse events related to healthcare delivery in developing countries, as well as guidelines for adverse event reporting.

Despite these efforts, physicians indicate that medical-error-reporting systems are still inadequate. A survey of U.S. physicians found that they were more likely to discuss errors with their colleagues than make a formal report. Only a third of physicians felt that reporting systems at their organizations were adequate. Few had confidence in the process. Nevertheless, 83% indicated that they had, at some point, filed a formal report of an error. Major areas where physicians wanted to see improvement were in assurances that (a) reports remain confidential and nondiscoverable, (b) the data will guide system improvements, (c) there will be no penalties or other negative repercussions, and (d) the process will take less than 2 minutes to complete.

Although physicians have concerns about the reporting process, interest in the problem of errors and how to prevent them is high. Most physicians

now believe that reporting errors is necessary to improve patient safety, and most feel that they are not getting adequate information about how to prevent them. Increasingly, physicians are embracing a culture of safety.

Progress in Reducing Errors

There has been a major shift in attitudes toward medical errors and the need to protect patients from preventable harm. In the peer-reviewed medical literature, articles addressing issues of patient safety more than tripled during the 5 years following the 2000 IOM report, compared with the previous 5 years. The number of federally funded patient safety research awards increased nearly 30-fold. Starting in 2001, the U.S. Congress has appropriated \$50 million annually to fund many of these studies.

What has been the impact of such investments? Evidence that healthcare has become substantially safer is not yet strong. There have been discrete studies showing improvements in certain areas. For instance, hospitals with tight infection control procedures have documented a reduction in hospital-acquired infections, and fatalities related to the accidental injection of concentrated potassium chloride have been prevented by removing the product from nursing unit shelves. There may be many other such examples of a positive effect. Underdeveloped error tracking systems have confounded efforts to assess progress.

A number of organizations, along with the government, have committed to the patient safety movement, setting specific goals and strategies for preventing medical errors. The Agency for Healthcare Research and Quality's (AHRQ's) Center for Quality Improvement and Safety leads the federal government's efforts to (a) set standards and measures called *patient safety indicators*; (b) educate healthcare providers, administrators, and the general public; and (c) guide the research agenda. The Joint Commission has played a key role in enforcing change by requiring hospitals to follow specific error prevention strategies, such as (a) improved patient identification, (b) surgical-site verification, and (c) standards for communicating information. Private-public partnerships—such as the Institute for Health Improvement's (IHI's) 100,000 lives campaign, which enlisted thousands

of hospitals to adopt proven methods of reducing avoidable deaths—have been cosponsored by the federal AHRQ, the Centers for Disease Control and Prevention (CDC), and the Centers for Medicare and Medicaid Services (CMS), exemplifying a broad-based commitment to make health-care safe. Building on that momentum, the IHI and its partners embarked on a “5 million lives” campaign to protect patients over a period of 2 years from 5 million incidents of medical harm. The movement to eliminate medical errors is still young but maturing rapidly.

MEDICAL GROUP PRACTICE

Medical group practice, a form of medical practice that dates back to the 1800s, can be defined in a number of ways. The Medical Group Management Association (MGMA), an organization representing group practice executives, administrators, and managers, and the American Medical Association (AMA), the nation’s largest physician association, consider medical group practices to have the following elements: (a) a formal or legal arrangement; (b) three or more physicians; and (c) shared business and clinical operations, facilities, staff, and equipment.

Recent federal health legislation regarding physician self-referral, known as the Stark legislation (named for U.S. Congressman Fortney “Pete” Stark), has defined medical group practice in a slightly different manner. First, the federal legal definition is broader in scope, including groups with two or more physicians. At the same time, this definition applies more stringent criteria that stipulate that (a) all physicians in the group must provide a full range of patient care services appropriate to their specialties and be responsible for the bulk of the care provided through the group; (b) group income and expenses must be distributed according to an established plan; and (c) decision making in the group must be centralized with respect to functions such as governance, budgets, billing, and use.

Regardless of how they are defined, the ways medical group practices look and act vary considerably. Medical group practices may be composed of physicians with the same specialty or physicians with different specialties. And they can include

other types of medical professionals such as dentists and podiatrists. These groups may be embedded within larger health systems. They may work out of a single location or many locations. Medical group practices may or may not be physician owned. These practices can range in size from a few physicians to thousands of primary-care and specialty-care providers. One of the best-known medical group practices in the nation is the Mayo Clinic, which is based in Rochester, Minnesota, and employs more than 3,300 physicians, scientists, and researchers at multiple sites across the country.

Importance

Medical group practices are important to the study of health services research because they represent an increasingly common vehicle for the delivery of medical care. They also, theoretically, hold much potential for improving the quality and efficiency of the delivery of medical services.

The number of medical group practices and the number of physicians practicing in them has grown over time. The AMA reported that there were just over 4,000 medical group practices in 1965 but nearly 20,000 in 1996, representing approximately 11% and 32% of all physicians in the nation. More recently, the Agency for Healthcare Research and Quality (AHRQ) supported a collaborative study between the MGMA and the University of Minnesota School of Public Health that sought to establish a nationally representative database of medical group practices. This effort resulted in the estimate that the number of medical group practices had grown to nearly 37,000 in 2003 and that the physicians in them represented almost 67% of all office-based physicians in the nation. Based on these findings, medical group practices deliver a large proportion of the medical care in the nation.

One reason for the establishment and continuation of medical group practices is that increased medical specialization and technical complexity require the integration of multiple physicians into a single practice to provide appropriate and necessary patient care services. Medical group practices are also an attractive employment option for many physicians because they may provide certain advantages over solo practice. For example,

medical group practices often provide malpractice coverage, the sharing of on-call duties, and the intellectual challenge and stimulation of working with colleagues from a variety of disciplines and specialties.

Medical group practices are thought to contribute to the efficient and high-quality delivery of medical care in a number of ways. Some medical group practices provide a wide and complex range of services on-site. Medical group practices may contain costs through centralized purchasing, uniform coding and billing, and the sharing of auxiliary medical and administrative staff. These practice groups may be able to enhance access to care through extended office hours. A medical group practice's organizational culture—including factors such as the extent to which the group's physicians share information, are innovative and collegial, and subscribe to a group identity—is also thought to affect healthcare costs and quality.

Future Implications

Medical group practices are an increasingly important feature in the healthcare delivery system in the United States. As a result, it is increasingly important and necessary when conducting health services research to consider their impact on the quality, effectiveness, and efficiency of the delivery of medical care. However, given the large number of medical group practices and the wide variation in the ways they are organized, the influences of this type of practice may be difficult to disentangle from other causal factors in an already complex system of healthcare delivery. These factors can include (a) a physician's training, (b) the medical group's payment structure, (c) its organizational culture, (d) the influences of partners and colleagues, (e) the rules and standards established by the health maintenance organizations (HMOs) and health insurance companies with which the group is contracted, (f) patient expectations, and (g) community standards. As knowledge of medical group practices and their operations continues to grow, health services researchers will be able to make vital improvements in the delivery of healthcare.

MEDICALIZATION

Medicalization is a process through which human problems come to be defined as medical problems. In brief, society considers certain behaviors to be deviant. But "deviance" is not inherent in the behavior; instead, it is the result of social judgments that shift over time in response to the ideas expounded by the social institution prevailing at the time. For example, deviant behavior was seen as sinful when religion was the predominant social institution and in a position to define the nature of human problems. As confidence in empirical explanations began to take hold, the view that

deviance is a matter of *sinfulness* gave way to the view that deviant behavior is a violation of social norms and laws, that is, *badness*. Medicalization signifies the most recent shift, transforming the definition of deviance again, this time from *badness* to *sickness*.

The Power to Define Sickness

The concept of medicalization was introduced during the second half of the 20th century when Americans were registering rising distrust in and disillusionment with the values being expounded by the leaders of most social institutions. Hence, the times were conducive to rejecting a socially defined view of deviance in favor of a medical-based perspective. Critics argued, and many observers agreed, that the prerogative to determine what is and what is not a medical problem gives physicians tremendous power. The question of whether this is more socially beneficial or detrimental remains unsettled.

Talcott Parsons (1902–1979), an American, Harvard University sociologist, is credited with initiating discussion of the vital social role played by physicians in differentiating between true sickness and malingering. He based this proposition on the premise that social stability and continuity require that all members of society fulfill their respective social roles. Because the "sick" role offers the benefit of excusing a person from normal responsibilities, it is important to ensure that people do not take inappropriate advantage. By identifying what constitutes real illness, physicians are in a position to grant patients a temporary exemption from their normal role responsibilities. By labeling symptoms as true illness, physicians are granting the patient a period of "legitimated deviance." Physicians then go on to restore the sick person to full health so that he or she can carry out the normal role expectations. Because physicians are willing to accept this weighty burden, Parsons maintained that they should be generously rewarded.

Parsons's model of the sick role depicted recovery from acute illness as the only acceptable resolution to a period of legitimated deviance. Detractors pointed out that this portrayal meant that those who did not or could not get well were doomed to being permanently labeled as deviants.

A number of observers have made the point that having the power to determine whether the symptoms patients present with are, in fact, indicative of a disease gives physicians undue power to act as moral arbiters. From time to time, the discovery of a newly identified disease reinvigorates the charge that physicians have too much power and that patients' complaints are too often dismissed as illegitimate. The discovery of Lyme disease provides a vivid illustration. According to media reports, it was only through the efforts of one courageous woman that the disease was finally identified. Because her symptoms were so common (i.e., headaches, body rashes, and flu-like conditions), she was diagnosed with various conditions from poison ivy to hysteria by the many physicians she visited. The media reported that the physicians denied the existence of this particular patient's disease because it did not fit a recognized diagnostic label. Not only was she repeatedly told that she was a hypochondriac, she was denied the benefits of the sick role as well as treatment.

The story, which received much media attention at the time, had the effect of bringing numerous patients to physicians' offices with similarly vague symptoms insisting that they, too, had Lyme disease. When physicians did not find evidence of the disease, many of these patients became convinced that callous physicians were unwilling to treat them, fueling the view that medicine's power was certainly excessive and probably socially dysfunctional.

The question whether physicians should have the final say in determining whether a particular set of symptoms is indicative of the existence of disease—the essence of medicalization—continues to be contentious, particularly as groups of people who share some experience that they believe has caused them to experience a particular set of symptoms insist that physicians identify those symptoms as a disease or syndrome. Understanding the ramifications associated with the sick role helps explain the persistent efforts on the part of many of those afflicted with various human problems to portray them as illnesses.

Physicians and the Promotion of Medicalization

Whether physicians are actively engaged in promoting and sustaining medicalization is another

point of debate. A number of commentators have taken the position that the medical profession has, in some instances, purposefully engaged in expanding its scope of control. Michel Foucault, for example, noted that early practitioners of psychiatry were particularly zealous in their efforts to define the limits of acceptable social behavior. Thomas Szasz stated that psychiatrists were finding evidence of mental illness in people who were simply rejecting the roles that society imposed on them. He maintained that psychiatrists were guilty of trying to convince such people that their behavior indicated that they were "sick," and they required medication to help them fit in the role or roles, often undesirable ones, that society had prescribed.

Similarly, the idea that women who resisted the limited range of social positions and roles dictated by society from the post-World War II period through the rebellious 1960s were likely to be the objects of such labels and treatment is, at least in some circles, now a matter of conventional wisdom. Feminists argue that the medical profession continues today to impose its definition of the feminine ideal: They say that plastic surgeons are defining our standards of beauty, both facial and in body shape, and that other physicians are ready to prescribe a wide range of pharmaceuticals—including weight-loss medications, mood-altering drugs, sleep aids, energy boosters, and so on—more to women than to men. The fact that some women demand such treatments they attribute to a distorted set of social values which are promoted by a wide range of self-interested parties who benefit from the medicalization of such common conditions as aging-related changes.

Physicians' motivations for actively promoting medicalization, to the extent that they may have been doing so, have not yet been examined closely. Whether physicians are motivated by the promise of increased income, as the representatives of managed-care organizations have argued; or by greater social prestige and authority, as some social scientists maintain; or are truly interested in improving the lot of people who are not only plagued by pain and suffering but stigmatized as well, which is the position taken by spokespeople for the medical profession, has not been the subject of much debate or investigation.

Eliot Freidson is one of the few social scientists whose observations addressed the issue directly. He argued that physicians are not so much motivated by the possibility of increased income as by the opportunity to gain professional recognition and possibly have their names attached to the discovery of a new disease or syndrome. He proceeded from the observation that medicine had been very successful in its efforts to define the scope of and monopolize medical work through medical licensure. That, he pointed out, effectively prevents other health practitioners from ministering to patients' complaints using treatments other than those approved by the medical profession. Freidson coined the term *professional dominance*. He argued that physicians behave in a dominant fashion in their interactions with anyone over whom they can impose their authority, from patients to other healthcare workers. Feminists embraced Freidson's observations on the role physicians assigned to nurses—who are overwhelmingly female—as handmaidens to physicians.

It is worth noting that critics of medicine's power were most vocal during the same years that society was registering especially high regard for the medical profession: during the post-World War II years until the end of the 1970s. Throughout this period, prestige surveys consistently accorded medicine the top rank compared with other occupations. Surveys documenting the level of trust society was willing to accord particular social institutions consistently found that medicine inspired more trust than other social institutions. The decline in trust in the profession of medicine coincided with the rise of managed care during the 1980s. The spokespeople for managed-care organizations presented themselves as interested in protecting patients from physicians who, they said, were more interested in their own pocketbooks than their patients' welfare. Thereby, in a few short years, the corporate sector succeeded at what social critics had been striving to accomplish for several decades.

The charge that physicians engage in medicalization lost much of its condemnatory power in this atmosphere, given that a wide range of other failings were also being attributed to the profession. Yet patients have generally said, and continue to say, that their own physicians are wonderful but that they are the exception.

Medicalization and the Role of Other Interested Parties

The criticism aimed at the medical profession that it promotes the medicalization of routine human problems has not had an ameliorating effect because the list of additional agents interested in promoting medicalization continues to expand. Many members of the public afflicted with certain conditions have been active in their efforts to aid, abet, and pressure medicine to define those conditions as sickness. One practical reason why patients would want to do this is that having a condition defined as an illness results in medical insurance coverage. Another reason is that there are certain conditions that members of the public want very much to see labeled as sickness to avoid the stigma attached to the alternative: Sickness indicates that the cause of the problem is biological and not the result of weakness of character—that is, it is sickness not badness.

Attention deficit disorder, hyperactivity, and hyperkinesis are illustrative of this phenomenon. Some parents and teachers initially identified socially disruptive behaviors as problematic and requested medications that will reduce the incidence of such behavior. Physicians must, of course, agree to diagnose the condition as an illness and prescribe medications designed to control the behavior. The thrust of the criticism is that the diagnosis is being too liberally applied. An important question that does not generally arise is whether diagnosing and medicating the child as having a “minimal brain dysfunction”—that is, a sickness—is more or less damaging than determining that the child is a social deviant who willfully misbehaves and deserves to be punished—that is, that the child is bad.

Further evidence that the medicalization of children's behavior is not waning is apparent in the discovery of new syndromes: “school refusal behavior,” for example, (i.e., skipping school), which has recently been identified by some psychiatrists as a sign of an anxiety disorder requiring medical treatment.

Posttraumatic stress disorder (PTSD) is another example of a more or less successful effort to have particular behaviors recognized as illness rather than badness. The designation allows those having difficulty readjusting to civil society after wartime

service in the military to receive the benefits that go along with the sick role—from the psychological and emotional benefits that come with the extension of sympathy, to the greater understanding and tolerance of absence from work due to a range of physical and psychological problems.

There are also instances of a less successful transition from badness to sickness as reflected, for example, in the social attitude toward alcoholism. Many individuals who have this problem have been unwavering in their efforts to have society accept the view that alcoholism is a disease. The Yale School of Alcoholism Studies (which emerged in the 1930s), now the Rutgers Center of Alcohol Studies (as of 1962)—neither of which has operated under the auspices of medical practitioners—have provided the main impetus for dissemination of this definition. Physicians, generally, have been less eager to define alcoholism as a disease; in part, no doubt, because alcoholism does not lend itself to a traditional medical approach to either prevention or cure. Medical treatment of the health problems brought on by alcoholism, though, is uncontested.

The role played by the public health community must be included in the discussion of medicalization because of its stance on the value of punishment versus therapeutic intervention in controlling certain behaviors. Members of the public health community not only oppose the use of legal sanctions to reduce the prevalence of deviant behavior, they also oppose treating people who engage in destructive and risky behavior on an individual basis. They hold that control of such behavior would be better addressed through population-based solutions. Public health practitioners have argued that the morbidity and mortality associated with violence, intravenous drug abuse, and other forms of substance abuse should be viewed in much the same way as other man-made diseases—smoking-related illnesses, for instance—and treated accordingly. They point out that intervention at the level of treating the individual who is suffering the consequences of engaging in risky behaviors comes too late. They maintain that more benign approaches, particularly public education, would be far more effective.

There are also instances of medicalization being *imposed* on the medical profession, as illustrated by the legal mandate governing how physicians deal with child abuse. Physicians are required to

report suspected cases of child abuse when they examine children brought to their offices or, more likely, the emergency room. Medical treatment of the child is not at issue. However, some physicians resist reporting this form of deviance arguing that the children are likely to suffer further abuse when the abuser is threatened with legal sanctions and the removal of the child from the home.

Demedicalization

There is one well-known case of demedicalization—homosexuality. The first edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM)* published by the American Psychiatric Association (APA) in 1952, listed homosexuality as a “Sociopathic Personality Disorder.” It continued to be listed as a form of “sexual deviation” over the next two decades even as the challenge from homosexual activists, both within and outside the APA, gained momentum. In 1973, the APA Board of Trustees voted to adopt a new definition. As of that time, only those homosexuals who are disturbed by their condition are to be considered candidates for treatment. Many in the gay community welcomed the change. Others pointed out that there was no counterpart for the designation of “Homosexual-Conflict Disorder” for heterosexuals, as in “Heterosexual-Conflict Disorder.” Society has become more accepting of homosexuality and homosexual unions since the early 1970s. Whether the APA’s decision contributed to the shift in social attitudes is not clear.

New Forces Promoting Medicalization

Although the term *medicalization* is now less likely to be invoked, the process appears to be proceeding at an accelerating rate along two related paths. One is the treatment of conditions that research indicates will lead to illness in the future and that can be identified using objective indicators of physical status. The second revolves around the possibility of enhancing the performance of persons who are healthy.

Turning to the first path, medicine has been more aggressive in recent years in lowering the cutoff that separates what is a normal reading from what requires attention for a range of physical indicators such as hypertension, cholesterol level, and diabetes. Physicians often strongly recommend lifestyle

changes, primarily more exercise and changes in diet. Although this may be a form of medicalization, it is not one that provides the benefits long associated with the sick role. In fact, it requires a certain amount of sacrifice in giving up familiar patterns of behavior that are not considered deviant. Whether society comes to define self-indulgent eating habits and avoidance of exercise as deviant and requiring some form of intervention (e.g., increased regulation or taxation) besides physicians' admonitions remains to be seen. The shift in social attitudes toward drinking and driving provides a good example of society's power to redefine what is acceptable versus unacceptable behavior, without physicians taking the leading role.

Whether the health problems that result when patients will not or cannot make the behavioral changes that are intended to lower readings on their blood pressure, low density lipids, and blood sugar should be defined as syndromes is a matter of debate in the medical community. Obesity is a case in point. From the medical profession's perspective, defining what is and what is not a disease revolves around questions of ethics and a consensus regarding best practices, not issues of social deviance. To illustrate, the American Academy of Family Practice (AAFP) declared, in 2004, that obesity is a disease; the American Medical Association (AMA), however, maintains that it is clearly a major health problem but not a disease. Those who favor defining obesity as a disease say that this will cause it to be taken more seriously. Those who are opposed say that doing so will have the effect of diminishing personal and social responsibility.

Ethics and best practices are also at issue in how medicine should treat such touchy problems as gender allocation surgery at birth, gender-based selection of fetuses, treating women who have lost interest in sex with testosterone creams, and so on. There is no denying the fact that members of the public are demanding a wide range of interventions and that there are growing numbers of willing providers. To illustrate, according to the American Society for Aesthetic Plastic Surgery (ASAPS), 11.5 million cosmetic procedures were performed in the United States in 2005. This is a 444% increase from 1997 to 2005. There were 3.29 million Botox injections, making it the most popular procedure. By some estimates, this procedure has become a \$15 billion business.

Now that patients are increasingly directly involved in requesting treatment for what they perceive to be unwelcome and avoidable physical problems, direct-to-consumer advertising by pharmaceutical companies is a new force in convincing the public that their problems are actually syndromes that can be successfully treated with prescription drugs. Some physicians say that they feel pressured to prescribe medications when there is no evidence that a person is afflicted with the illness featured in the ads. Even when patients do experience some of the symptoms being described in the ads, physicians often maintain that waiting to see whether the symptoms diminish is preferable to reaching at once for pharmaceuticals.

The second newly evolving medicalization path revolves around the "heal or enhance" debate, which has been limited to revelations about athletes, until recently, but is increasingly affecting the general public. Some physicians take the position that anything that helps patients is within the legitimate scope of medical practice. Others argue that *restoring* function should not be confused with *enhancing* function. The worry is that it is becoming more and more difficult to draw the line between ethical and unethical practices. Is it ethical to prescribe stimulants that can help enhance grades? Is it ethical to prescribe Alzheimer's medications to enhance memory? Is "cosmetic neurology"—described by its main promoter as the modulation of "motor, cognitive, and affective systems"—an acceptable medical practice? The demand for such enhancements is clearly growing where competitive pressure is greatest—that is, in professional athletics and advanced educational training.

It is difficult to imagine what might replace the medicalization process that shifts badness to sickness, especially as it is increasingly accompanied by the promise of an unrestrained potential to redefine a wide range of human problems as medical problems, which people might then rid themselves of simply by taking a pill.

MEDICAL SOCIOLOGY

Medical sociology is a large, substantive area within the general field of sociology. Using a sociological perspective, theories, and research methods, medical sociology is concerned with the social causes and consequences of health and disease. Some of the major areas that medical sociology studies include (a) the social aspects of health and disease, particularly health and illness behavior and the role of the sick; (b) the social behavior of healthcare professionals and their patients, particularly physician–patient interaction; (c) the social functions of healthcare organizations

and institutions, particularly hospitals and health-care networks; (d) the social patterns of health services; and (e) the international comparisons of healthcare delivery systems, particularly comparing the healthcare system of the United States with that of Canada and the United Kingdom.

History

Although a number of medical sociology articles appeared in the late 19th and early 20th centuries, the field is generally regarded as beginning in 1951 with the publication of Talcott Parsons's book *The Social System*. In his book, Parsons (1902–1979), the influential American, Harvard University sociologist, presented a functionalist theory of the "sick" role. He argued that patients who (a) do not intentionally cause their own illness, (b) seek help from a physician, and (c) strive to get well are entitled to relief from their normal role responsibilities—a period of legitimated deviance. Those who do not follow these rules are engaging in deviant behavior and must be socially sanctioned. Otherwise, Parsons argued, society risks social instability. As for physicians, Parsons said that they bear heavy responsibility for insuring that patients do not take advantage of the sick role. Accordingly, they deserve a high level of social reward in the form of status and income.

Although Parsons's theory of the sick role has become a basic concept in medical sociology, other sociologists have strongly criticized it. They point out that the theory (a) fails to address the wide variations in the way people view sickness and define sick-role behavior; (b) does not take into consideration various types of diseases, such as chronic diseases and mental illness; (c) is based on a traditional, one-to-one interaction between a patient and a physician, which frequently does not occur; and (d) is based on a middle-class pattern of behavior that fails to consider the sick role of lower socioeconomic classes.

In the 1970s, medical sociology changed dramatically. Many medical sociologists suddenly reversed their position and embraced a *critical theoretical perspective*. They argued that physicians act in a *dominant* fashion in their interactions with patients and other healthcare workers. This assessment captured society's growing skepticism

regarding physicians' social position, but it did not have much practical impact on physicians.

That changed during the 1980s with the emergence of managed care. Managed-care spokespeople announced that they would not only eliminate the inefficiencies associated with nonprofit-organizational management but also protect patients from physicians who were primarily motivated by profit. The medical-sociological critique was no longer daring. A backlash against managed care did not come until the mid-1990s, and by that time social confidence in medicine, if not in one's own physician, had been badly damaged.

System Goals

In retrospect, the medical-sociological contribution to understanding healthcare delivery was most clearly identified with the discipline of sociology during the 1950s and 1960s when the work was primarily theoretical. It is clear that medical-sociological observations reflected concern about the quality of healthcare. The fact that medicine was delivered in private offices with little professional oversight meant that social control over quality was a basic social concern. During the 1970s, medical sociologists did the underlying work on access or the availability of healthcare. This body of work constitutes a major methodological contribution. By the 1980s, cost containment rose to the forefront pushing medical-sociological work aside in preference to medical economics.

Availability of Data and Interdisciplinary Research

The introduction of computers during the 1980s had a radical effect on medical sociology and other disciplines involved in health services research. Internet technology permitted the government to collect and report statistics in a timely manner and make them publicly available. This, combined with the fact that healthcare had become a central social concern, meant that an increasing number of institutions, as opposed to individuals, were interested in analyzing health statistics for the purpose of influencing policy. Organizations began employing researchers, who were expected to work as members of interdisciplinary teams and produce clearly written position papers free from

exclusive disciplinary jargon. Many medical sociologists now define themselves as health services researchers or population health researchers.

Current Status and Future Direction

Today, medical sociology is a mature, objective, and independent field of study and work. There are a large number of professional medical sociologists conducting research and teaching in many countries, including the United States, Canada, Australia, Germany, Japan, and the United Kingdom. Medical sociology is the third largest section in the American Sociology Association, and it is the largest section in the British and German sociological associations. Most college and university sociology departments in the United States offer introductory courses in medical sociology, and several universities have well-established doctoral degree programs in medical sociology. Through the decades, medical-sociology concepts and research methodologies grounded in mainstream sociology have become integrated into the larger health research enterprise. The reverse is also true: Medical sociology continues to expand but is doing so in recognition of advances outside the discipline.

MEDICAL TRAVEL

Medical travel refers to persons traveling outside their home region in pursuit of healthcare that is more accessible, of higher quality, or of lower cost. It is a narrower term than *medical tourism* (also *health tourism*), which refers to consumers seeking health services of all kinds outside their home region—including spa treatments and other wellness services—as well as the industries that cater to these consumers. The *medical tourism industry* includes care providers and also related services such as intermediaries, concierges, travel specialists, and providers of room and board for medical travelers. Medical travel is distinct from *travel medicine*, which refers to preventive medical care provided to consumers in preparation for their planned travel (e.g., vaccinations for diseases occurring in the destination area).

Reasons for Medical Travel

There are many reasons why patients travel for medical care; most can be categorized into three main areas: (1) access, (2) cost, and (3) quality. Patients travel for access reasons if they are seeking care that they cannot receive in their own community. Access may be subcategorized according to (a) patients who are seeking care that is not provided in their home region versus (b) patients who may be able to receive comparable care at home but not in a timely fashion, and so they are seeking more expeditious care elsewhere. Seeking care unavailable in one's own community is probably the oldest form of medical travel; stories of epic journeys to find a mystical healer or rare elixir are relatively common and date back many centuries. A more modern example can be found in the patients from the United States who have

traveled to India to receive hip-resurfacing treatments, because the treatment was viewed as superior to hip replacement surgery but the procedure was not yet approved in the United States. The other subcategory—more expeditious access—includes patients who live in countries with nationalized healthcare systems who may face months-long wait times for treatment at home and who can receive immediate care in other countries with the same or very similar procedures. (Seeking more expeditious care can be viewed as an unfair or selfish practice by others from the same community, who sometimes refer to the practice as *line jumping*.)

Patients also travel for care in pursuit of lower costs. Elective procedures—that is, those not covered by insurance plans (e.g., cosmetic surgery)—can involve significant out-of-pocket expenses, and so these procedures are an important driver of cost-based medical travel. The financial motivations for comparison shopping can be even more substantial for uninsured and underinsured patients who have the financial resources to pursue care outside their communities' safety nets. Such patients, particularly those in need of major medical procedures, have substantial financial incentive to seek out the most cost-efficient care they can find, given their comfort level with travel as well as the perceived competency and safety of the procedures and care providers. Hospitals in developing countries, which have much lower operating costs, can provide some procedures for 20% or less of the amount that providers in the United States would charge. This can save uninsured patients tens or even hundreds of thousands of dollars, enough to make medical travel options enticing for a substantial proportion of patients needing high-end care. Given the size of this cost differential, some insurers have also begun providing plans—for U.S. employers with workers in states bordering Mexico—that require medical travel for nonurgent care.

The final category, quality, may similarly be broken down into several subcategories. One such segment comprises wealthy individuals from developing countries where there are few or no modern healthcare systems. In addition to traveling to other countries for major procedures, such patients may also travel to receive a better standard of routine care. A second important segment is patients pursuing cutting-edge healthcare—in

particular, high-tech procedures that may only be available from a finite number of providers in the world and are perceived to be superior to the more readily available treatment options. Inbound medical travel to major academic medical centers in the United States typically falls in this latter category.

Because medical travelers often pay up front and in cash, most health systems regard these patients as a particularly desirable clientele. Some developing countries, in particular, have come to view medical travelers as an important foundation for other types of economic development. Patients who come to a country for care may tend to stay longer in that country than other kinds of tourists do and, as a result, spend additional money in the local economy. Like tourists of other types, once medical travelers have visited a country for the first time, they are also more likely to return. For these reasons, the governments of some countries have established organized efforts to attract these patients to their private healthcare systems.

Accreditation

Although access, cost, and quality all pose measurement challenges, the quality of healthcare is a particularly complex and difficult construct on which to compare care providers internationally. Different countries, and sometimes different regions within a country, often have very different approaches to quality assurance and credentialing, making meaningful comparisons across providers very difficult. Providers who want to attract an international patient base need to demonstrate quality via universally acceptable means, which has led to substantial interest in pursuing internationally recognizable accreditations. The most widely used hospital accreditation provider is Joint Commission International, an international program offered by the Joint Commission, based in the United States. Other providers, such as the International Organization for Standardization, also offer accreditation programs primarily for institutional, international, health services providers. Surgeons and other physicians can achieve similar accreditation status by maintaining board certification in countries in which their international patients either reside or feel confident.

Future Implications

The forecasts of future growth in medical travel vary considerably but, in general, predict that it will continue to expand at a pace exceeding the broader growth in medical services worldwide. As healthcare costs continue to escalate, as pressures for greater transparency in quality and cost facilitate performance comparisons, and as experiences with medical travel become more familiar, the range of and the opting for costly, nonurgent medical services on a global scale will grow. Further advances in technologies that support telemediated services will also facilitate the remote provision of precare and aftercare, which may also foster the expansion of medical travel options in the coming years.

MEDICARE

Medicare is a health insurance program for (a) people aged 65 or older, (b) people under age 65 with certain disabilities, and (c) people at any age with end-stage renal disease (ESRD). It is the nation's largest health insurance program, covering nearly 44 million Americans. The Medicare program is administered by the Centers for Medicare and Medicaid Services (CMS), and beneficiaries may apply for Medicare benefits 3 months before they reach 65 years of age. Almost 9 million individuals, or approximately 20% of Medicare beneficiaries, receive their care through the Medicare Advantage program, and more than 90% of beneficiaries receive prescription drug coverage of some type. Medicare spending is a large component of the federal budget and national health spending: In 2006, Medicare benefit payments totaled \$374 billion and accounted for 12% of the federal budget. The spending on Medicare benefits is about 20% of the nation's total healthcare expenditures.

History

President Lyndon B. Johnson signed the Medicare program into law in 1965 as Title XVIII of the Social Security Act. The Medicare program was originally designed to provide health insurance to the aged.

Prior to its enactment, there were several key moments in history that led up to the Medicare legislation. In 1935, the first federal government health insurance bill was introduced in the U.S. Congress. Later, in 1945, President Harry S. Truman became the first sitting president to officially endorse the idea of national health insurance. In 1961, President John F. Kennedy recommended to the U.S. Congress a health insurance program for the elderly under Social Security, and in 1965 President Lyndon B. Johnson signed Medicare into law.

Throughout the history of Medicare, there have been several major reforms to the program. When first implemented in 1966, Medicare primarily covered persons over the age of 65. In 1973, Medicare eligibility was extended to people with disabilities and those with ESRD. In 1976, health maintenance organizations (HMOs) began to be offered as a Medicare option. In 1983, the Medicare program began reimbursing hospitals based on a prospective payment system. In 1997, the Medicare+Choice program was enacted and is known today as Medicare Part C or the Medicare Advantage plans. In 2003, President George W. Bush signed the Medicare Modernization Act (MMA) into law, establishing a voluntary, outpatient prescription drug benefit program—known as Medicare Part D—that became available to Medicare beneficiaries in 2006. Under this law, Medicare Advantage was also established, allowing private insurance companies to offer choices in coverage to Medicare beneficiaries.

Medicare's Parts

Medicare consists of four parts: A, B, C, and D. The original Medicare plan included Medicare Part A (hospital) and Part B (medical). Medicare Part C is also called the Medicare Advantage plans (HMOs and preferred provider organizations [PPOs]). Medicare Part D is for prescription drug coverage. Medicare Parts B, C, and D are optional. Most individuals either have Parts A and

B, Part D and a Medigap (Medicare Supplemental Insurance) policy, or Part C (which combines Parts A and B) and Part D.

Eligible individuals do not have to be retired to get Medicare. Unlike Social Security, working people can still receive full Medicare benefits at age 65. People who are already receiving Social Security benefits are automatically enrolled in Medicare without an additional application.

Medicare Part A

Most people do not pay for Medicare Part A because they contributed to the Medicare Trust Fund for 40 quarters. Medicare Part A is largely financed through hospital insurance taxes; it provides basic protection against the costs of inpatient hospital and other institutional-provider care. Officially, this program is called the Hospital Insurance Benefits for the Aged and Disabled, although it includes much more than just hospital benefits. Medicare Part A not only helps pay for inpatient hospital stays, but it also covers skilled nursing care, home health care, and hospice care. Unofficially, this program is sometimes called basic Medicare or hospital insurance because the authorization for the program is Part A of Title XVIII of the Social Security Act.

Whereas most people do not pay a premium for Medicare Part A, they are responsible for a deductible for inpatient hospital stays. The deductible is the amount a person with Medicare must pay for healthcare before Medicare begins to pay. There was a deductible of \$1,024 in 2008 for hospital stays of up to 60 days, and additional costs for longer stays. The costs are different for other Medicare Part A services. Skilled-nursing facility coinsurance, for example, is \$128 per day for days 21 through 100 for each benefit period.

Medicare Part B

Medicare Part B is a voluntary program that covers the costs of physician and other healthcare practitioner services, items, and supplies not covered under the basic program. It is financed through monthly premiums from enrollees and contributions from the federal government.

This program is more formally known as the Supplementary Medical Insurance Benefits for the

Aged and Disabled, but it is often also called supplementary Medicare or the medical insurance program. Medicare Part B is medical insurance that helps cover physicians' services and outpatient care such as preventive services, including screening tests and vaccinations, diagnostic tests, some therapies, and durable medical equipment, such as wheelchairs and walkers.

In addition to the monthly premium for Medicare Part B, there is also a deductible; in 2008, this was \$135. This means that in 2008, a person with Medicare was responsible for the first \$135 of his or her Medicare approved Part B medical services before Medicare Part B started paying for care. The deductible amount can change each year. People with the original Medicare plan also are responsible for some copayments or coinsurance for Medicare Part B services. The amount depends on the service but is 20% in most cases.

Medicare Part C

A third Medicare program, Medicare Part C, expands managed-care options for beneficiaries who are entitled to Part A and are enrolled in Part B. Medicare Part C was created under the Balanced Budget Act of 1997 and is also called Medicare Advantage. This program was formerly known as Medicare+Choice. Since January 1, 1999, beneficiaries have had the option of choosing to receive their health benefits through the traditional Medicare fee-for-service program or to select a managed-care plan certified under Medicare Advantage. The payments Medicare makes to a Medicare Advantage plan replace the amount that Medicare would otherwise have paid under Parts A and B.

There are several types of Medicare Advantage plans. A Medicare Advantage organization (MAO) is a public or privately owned entity organized and licensed by a state as a risk-bearing entity (with the exception of provider-sponsored organizations receiving waivers) and is certified by the CMS as meeting the Medicare Advantage contract requirements. A Medicare Advantage plan has health benefits coverage—offered by an MAO under a policy or contract—that includes a specific set of health benefits offered at a uniform premium and uniform level of cost sharing to all Medicare beneficiaries residing in the service area (or segment of

the service area) of the plan. A Medicare Advantage plan may also provide a prescription drug benefit. In 2008, 9.7 million beneficiaries were enrolled in Medicare Advantage plans with the majority (70%) in HMO plans.

Medicare Part D

Most recently, the Medicare program was expanded by the MMA of 2003 to include a prescription drug benefit under a new Medicare Part D of the Social Security Act. Beneficiaries entitled to Part A and enrolled in Part B, enrollees in Medicare Advantage and private fee-for-service plans, and enrollees in Medicare Savings Account Plans are all eligible for the prescription drug benefit. The prescription drug benefit became available to eligible individuals on January 1, 2006.

Premiums and Enrollment

Most people do not have to pay a monthly charge (premium) for Medicare Part A because they or their spouse paid Medicare or Federal Insurance Contributions Act (FICA) taxes while they were working. This is the tax withheld from a person's salary, or that an individual pays from their self-employment income, that funds the Social Security and Medicare programs. When people pay these taxes on their earnings, it is called Medicare-covered employment. If a person and his or her spouse did not pay Medicare taxes while they were working or did not work long enough (usually 10 years or 40 quarters in most cases) to qualify for premium-free Part A, he or she may still be able to get Medicare Part A by paying a monthly premium. In 2008, the Part A premium was \$233 for people having 30 to 39 quarters of Medicare-covered employment, or \$423 for those who are not otherwise eligible for premium-free hospital insurance and have fewer than 30 quarters of Medicare-covered employment.

Qualifying beneficiaries can choose whether or not to enroll in Medicare Part B medical insurance. Those who enroll are responsible for a monthly premium for Medicare Part B, which was \$96.40 in 2008. Starting January 1, 2007, some people with higher annual incomes—more than \$80,000 if filing an individual federal income tax return or more than \$160,000 if married, filing jointly—pay

a higher Medicare Part B premium. These amounts change each year. The majority of beneficiaries pay only the standard Medicare Part B premium.

People can sign up for Medicare Part B at any time during a 7-month period that begins 3 months before the month they become eligible for Medicare. This is called the initial enrollment period (IEP). People who do not take Medicare Part B when they are first eligible may have to wait to sign up during a general enrollment period (GEP). This period runs from January 1 through March 31 of each year, with coverage effective July 1 of that year. Most people who do not take Medicare Part B when they are first eligible will also have to pay a premium penalty of 10% for each full 12-month period they could have had Medicare Part B but did not sign up for it, except in certain situations. In most cases, individuals will have to pay this penalty for as long as they have Medicare Part B.

Most people covered by a group health plan based on current employment (their own or their spouse's) can delay enrolling in Medicare Part B without a penalty. These individuals get a special enrollment period. They can enroll in Medicare Part B at anytime while they are still covered by their employer or union group health plan based on current employment, or during the 8 months following the month the employment ends or the group health plan coverage ends, whichever is first. Most people who sign up for Medicare Part B during a special enrollment period do not pay higher premiums.

People who choose Medicare Part B usually have the premium automatically taken out of their monthly Social Security or Railroad Retirement payment. Federal government retirees may be able to have the premium deducted from their retirement check.

People can choose to get Medicare healthcare coverage in several ways. Which Medicare plan people choose may affect their costs, benefits, and convenience, and their physician, hospital, and pharmacy choices. Nonetheless, no matter how people choose to get their Medicare healthcare, they are still enrolled in the Medicare program.

The original Medicare plan is available nationwide; it is also known as "fee-for-service." People in the original Medicare plan may go to any physician, specialist, hospital, or other healthcare provider who accepts Medicare. However, there are

other plans besides the original Medicare plan that people can choose to get their Medicare health coverage.

Medigap Insurance

A Medigap policy is a health insurance policy sold by private insurance companies to fill the “gaps” in coverage under the original Medicare plan, including the deductibles, coinsurance, and copayments mentioned above. Some Medigap policies also provide benefits that Medicare does not include such as emergency healthcare when traveling outside the United States. The insurance companies that sell these policies must follow federal and state laws that protect people with Medicare. The Medigap policy must be clearly identified as Medicare Supplement Insurance.

A Medigap policy only works with the original Medicare plan. If an individual joins a Medicare Advantage plan or other Medicare plan, then the Medigap policy cannot pay any deductibles, copayments, or other cost sharing under the Medicare plan. In all states except Massachusetts, Minnesota, and Wisconsin, a Medigap policy must be one of 12 standardized plans (A–L) so that people can compare them easily. Each plan has a different set of benefits. The benefits in any Medigap plan A to L are the same for any insurance company. It is important for individuals to compare Medigap policies because the costs vary.

In most Medicare Advantage plans, members usually get all their Medicare-covered healthcare through that plan. The plan may offer extra benefits such as Medicare prescription drug coverage as well as coverage for vision, hearing, dental, or health and wellness programs. If a plan offers a network of healthcare providers and hospitals, people may very often have to use only that panel of providers. However, it is important to note that people who join a Medicare Advantage plan are still in the Medicare program and still receive all their regular Part A and Part B services. Additionally, beneficiaries in a Medicare Advantage plan still have Medicare rights and protections.

Medicare Prescription Drug Benefits

All people with Medicare now have the option to join a plan that covers prescription drugs. Anyone

who has Medicare Part A, or Part B, or both Part A and Part B is eligible to join a Medicare drug plan and must enroll in a plan to get Medicare prescription drug coverage. However, people who live outside the United States or who are incarcerated may not enroll and are not eligible for coverage. The CMS contract with private companies offering Medicare prescription drug plans to negotiate discounted prices on behalf of their enrollees. People may also receive Medicare drug coverage through a Medicare Advantage plan or other Medicare plan, if they are enrolled in one. Some employers and unions may provide Medicare prescription drug coverage through employer/union group plans to their retirees. The drug benefit is offered through stand-alone prescription drug plans (PDPs) and Medicare Advantage prescription drug (MA-PD) plans, such as HMOs that cover all Medicare benefits, including drugs.

Generally, there are two types of enrollment periods when people can sign up for Medicare prescription drug coverage: (1) the IEP is for 7 months starting 3 months before the month they become entitled to Medicare; (2) the annual coordinated election period is from November 15 to December 31 each year. During this period, a person who is not enrolled in a Medicare drug plan can choose to enroll.

People who do not enroll when they are first eligible may have to pay a penalty to enroll later. Most people who wait until after the end of their IEP to join a Medicare drug plan will have their premiums go up 1% of the national base premium for every month they waited to enroll. These individuals will usually have to pay this penalty as long as they have Medicare prescription drug coverage.

The costs of prescription drug benefits vary depending on the plan. Plans must provide a standard level of coverage, but they may offer more coverage or additional drugs, usually at a higher monthly premium. In most cases, for coverage in 2008, people paid a monthly premium that varied for different plans, a deductible, and a copayment or coinsurance. Once a Medicare beneficiary spent \$4,050 out of pocket for covered drug costs during 2008, they paid 5% of their drug costs for the rest of the calendar year. This is called *catastrophic coverage*, and it could take effect even sooner in some plans. All these amounts can change each year.

Medicare Part D plans vary in benefit design, covered drugs, and utilization management tools, such as prior authorization, quantity limits, and step therapy. The CMS established minimum requirements for Medicare Part D plan formularies to help ensure that plans do not offer formularies that discriminate against or discourage the enrollment of certain types of beneficiaries. Enrollment in Medicare drug plans is voluntary, with the exception of dual-eligible (people in both Medicare and Medicaid) and certain low-income beneficiaries who are automatically enrolled in a prescription drug plan if they do not choose a plan on their own.

Many people with limited income and resources will get extra help paying for prescription drugs. The extra help is available to people with Medicare who have an income below 150% of the federal poverty level and limited resources. Resources also are counted for the person and a spouse, if living together. The resource limits in 2007 were \$11,710 for an individual and \$23,410 for a married couple.

Future Implications

The Medicare program continues to fulfill the vision of President Johnson's Great Society by furnishing healthcare services for the elderly as well as for persons with disabilities and ESRD. The program serves tens of millions of Americans each year by providing essential healthcare coverage. However, there is growing concern over Medicare's rising costs and questions about the ability of the program to sustain itself over time. The public policy debate concerning the direction and solvency of the nation's Medicare program will be an increasingly important topic of discussion in the future.

MEDICARE PART D PRESCRIPTION DRUG BENEFIT

On December 8, 2003, President George W. Bush signed into law the Medicare Prescription Drug, Improvement, and Modernization Act of 2003, or MMA. This legislation was the most significant expansion of the nation's Medicare program since its inception in 1965. The MMA provides seniors and individuals with disabilities with voluntary prescription drug coverage, referred to as Medicare

Part D. The new coverage began on January 1, 2006. Until the MMA, Medicare did not provide coverage for outpatient prescription drugs.

The Medicare prescription drug benefit is voluntary insurance that covers both brand name and generic prescription drugs at participating pharmacies. All Medicare beneficiaries are eligible for this coverage, regardless of income level and financial resources, health status, or current prescription expenses. Individuals enrolled in Medicare Part A (hospital insurance), Medicare Part B (medical insurance), or both Part A and Part B are eligible for Medicare Part D. To obtain prescription drug coverage, a Medicare beneficiary must enroll in a Medicare prescription drug plan.

The Centers for Medicare and Medicaid Services (CMS), the U.S. federal agency that administers the Medicare program, contract with private companies offering Medicare prescription drug plans and negotiate discounted prices on behalf of Medicare beneficiaries. Individuals may also receive Medicare drug coverage through Medicare Advantage plans or another Medicare plan, if they are enrolled in one. Some employers and unions may also provide Medicare prescription drug coverage to their retirees through employer/union group plans.

Enrollment

Generally, there are three periods of time when individuals can sign up for Medicare prescription drug coverage. The IEP is 7 months long, starting 3 months before the month of becoming entitled to Medicare. Second, there is an annual coordinated election period from November 15 through December 31 each year. During the annual coordinated election period, individuals who are not enrolled in a Medicare drug plan may enroll, and individuals who are already in a Medicare drug plan may drop or switch plans. The change will be effective from January 1 of the following year. Third, there are special situations that entitle individuals to a special enrollment period, such as an involuntary loss of *creditable prescription drug coverage* or a change of permanent residence out of the plan's service area.

In most cases, if an individual does not join a plan during the IEP, his or her premium will increase 1% of the national base premium for every full month he or she waits to enroll.

(The national base premium was \$27.35, for 2007). The individual will have to pay this penalty, in addition to the premium, for as long as he or she has Medicare prescription drug coverage. Moreover, one may have to wait until the next annual coordinated election period, November 15 to December 31, to enroll. The enrollment will be effective from January 1 of the following year. However, if a person has other drug coverage that is at least as good as the Medicare prescription drug coverage, called *creditable prescription drug coverage*, the penalty will not apply.

Coverage and Costs

Medicare drug plans are not all the same. Plans vary based on costs, which drugs are covered, and which pharmacies are in the network. Like other insurance, if an individual joins a Medicare drug plan, in most cases he or she will pay monthly premiums, which vary by plan, and a yearly deductible. They will also pay a part of the costs of the prescriptions, including a copayment or coinsurance. Costs will vary depending on the specific Medicare drug plan. Some plans offer more coverage and additional drugs for a higher monthly premium.

There may be a point during the year when a Medicare beneficiary will be paying 100% coinsurance, called the *coverage gap*. However, there are some Medicare drug plans that do not have a coverage gap or that pay for some drugs during the gap. Once the total out-of-pocket costs paid by a beneficiary reach a set amount (\$3,850, in 2007), the plan will pay all but 5% or a small copayment for the rest of the year. This is called *catastrophic coverage*. All plans must offer this catastrophic coverage. The CMS sets the standard premium, deductible, and copayment amounts every year. These are minimum requirements for drug plans offering basic coverage.

As already noted, all individuals with Medicare can get prescription drug coverage. This is true regardless of their income level and financial resources, health status, or how much they pay for prescriptions. Moreover, many individuals with limited income and resources will get extra help paying for their prescription drugs. Individuals with the lowest incomes will pay no premiums or deductibles and only have a small or no copayments. And individuals with slightly higher incomes

will have a reduced deductible and pay a little more out-of-pocket (15%) coinsurance.

Covered Drugs and Participating Pharmacies

Medicare Part D–covered drugs are defined as (a) drugs available only by prescription, used and sold in the United States, and used for a medically accepted indication; (b) biological products; (c) insulin; and (d) vaccines. The definition also includes medical supplies associated with the injection of insulin (i.e., syringes, needles, alcohol swabs, and gauze). Certain drugs or classes of drugs, or their medical uses, are excluded by law from Medicare Part D coverage.

Not all Medicare Part D–covered drugs are included by each drug plan. Each plan has a *formulary* or list of covered drugs. Plans' formularies must include a range of drugs to ensure that individuals with different medical conditions can get the treatment they need. A plan's formulary may not include every drug that a beneficiary takes. However, in most cases, a similar drug that is safe and effective will be available.

Medicare requires plans to have convenient pharmacies for individuals to choose from. Each company offering a Medicare drug plan will have a directory of pharmacies that work with the plan. Generally, a beneficiary must use one of the pharmacies listed in this directory for the plan to cover their prescriptions. However, some plans will allow individuals to use a pharmacy that is not in the plan's network for a higher cost. Plans cannot require the use of mail-order pharmacies, but they may offer them as an option, many times at a reduced cost to the beneficiary.

Future Implications

The CMS estimate that 39 million individuals—more than 90% of all Medicare beneficiaries—have prescription drug coverage. Of these individuals, approximately 24 million have coverage through the Medicare Part D program. As the population ages and more individuals join the Medicare program, Medicare Part D prescription drug coverage will become an increasingly important part of the nation's healthcare delivery system.

MEDICARE PAYMENT ADVISORY COMMISSION (MEDPAC)

The Medicare Payment Advisory Commission (MedPAC) is a small, independent, federal agency that advises the U.S. Congress on issues affecting the Medicare program. Established by the Balanced Budget Act of 1997, the commission monitors the Medicare program, reviews its policies, conducts studies, and makes recommendations to Congress. MedPAC combines the functions of two prior government agencies: the Prospective Payment Assessment Commission (ProPAC) and the Physician Payment Review Commission (PPRC).

Commissioners and Staff Members

MedPAC is composed of 17 commissioners and approximately 35 professional staff members. The commissioners, who are appointed by the U.S. Comptroller General and the head of the U.S. General Accountability Office (GAO), serve 3-year terms (subject to renewal) on a part-time basis. Appointments are staggered to maintain continuity: Every year approximately five or six commissioners end their appointments and new commissioners are appointed. The commissioners come from various geographic regions, and they bring a wide array of experience and expertise. Currently, the commissioners include actuaries, lawyers, physicians, and policymakers.

The commission's professional staff members include an executive director as well as various policy analysts, research assistants, administrative staff, and consultants. Its staff members prepare analyses of proposed regulations, write issue briefs, and contribute to the preparation of congressional testimony. Furthermore, they provide technical support to the staffs of congressional committees through memos and briefings.

Purpose

The commission's statutory mandate is quite broad. In addition to advising the U.S. Congress on payments to private health plans participating in the Medicare program and to providers in Medicare's traditional fee-for-service program, the commission also analyzes access to care, quality of care, and other issues affecting Medicare.

Public Meetings

The commission holds seven formal public meetings per year in Washington, D.C. At these meetings, the commission's professional staff members present their research and research regarding policy issues for the commissioners to discuss, and the commission's reports and specific recommendations to the U.S. Congress are approved. Time for public comment is always provided. Each meeting's agenda and briefs, as well as the transcripts from the meetings, are posted on the commission's Web site.

Commissioners and professional staff members also seek input on Medicare issues through informal meetings with individuals interested in the program,

including staff members from various congressional committees and the Centers for Medicare and Medicaid Services (CMS), healthcare researchers, medical providers, various beneficiary advocates, and professional associations.

Publications

MedPAC publishes a variety of documents, including reports, data books, congressional testimony, contractor reports, comment letters, Medicare basics, and payment basics. Its specific recommendations to the U.S. Congress and supporting analyses are published in two annual reports, which are issued in March and June of each year. These have included consideration of Medicare payment policy and promoting greater efficiency in Medicare. At the request of Congress, the commission also publishes reports on a variety of other Medicare-related subjects.

The commission publishes a yearly data book that provides statistical information on a variety of Medicare topics (e.g., national healthcare and Medicare spending, Medicare beneficiary demographics, and dual-eligible beneficiaries). It is frequently called on to testify before Congress and to submit reports on various Medicare issues. MedPAC publishes various reports that have been produced under contract for them by outside authors. The commission often submits formal comments on proposed regulations issued by the Secretary of the Department of Health and Human Services (HHS) and on various Medicare-related reports to Congress. It also publishes Medicare Basics for the public (e.g., Medicare benefit design, Medicare Advantage benchmarks, and payment compared with the average Medicare fee-for-service spending) and Medicare Payment Basics (e.g., ambulatory surgical centers payment system and clinical laboratory services payment system), both of which provide brief overviews of various Medicare topics.

All its publications are available on the commission's Web site.

Future Implications

MedPAC is in a unique position to influence policy making for the nation's Medicare program. In the past few years, the commission's recommendations have had substantial impact, and the U.S.

Congress feels obligated to weigh its recommendations carefully. The commission's reports and testimony make important contributions to federal legislation. In the future, with the growing number of elderly people and the rising costs of Medicare, the commission's recommendations will continue to be highly valued.

MENTAL HEALTH

More than 50 years ago, the World Health Organization (WHO) defined mental health as a

complete state of mental and physical well-being, and not simply the absence of disease. This definition emphasizes the positive features of mental well-being. Good mental health is associated with positive family, community, and school or work involvement, as well as with a supportive group of friends.

In contrast, mental illness usually is associated with the absence of one or more of these positive involvements. Mental illness can be characterized by problems in one's thinking, emotions, behaviors, or any combination of these three. The American Psychiatric Association (APA) has developed a classification system for mental disorders based on these characteristics, published as the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*.

The most common mental disorders among adults in the United States are depression and anxiety, each of which affects about 10% of the population. Much less common are bipolar disorder—a combination of depression and mania, which affects about 4% of adults—and schizophrenia, which affects about 1% of the adult population. Both can lead to disabilities, and both bipolar disorder and schizophrenia are known to have a genetic basis, at least in some population groups.

About 25% of adults have a mental disorder within a 1-year period, and about 50% will have a mental disorder in their lifetime. About 6% of adults become seriously disabled as a result of mental illness. Less is known about the rates of specific mental illnesses in children and adolescents. However, about 20% of youths suffer from one or more disorders, and 9% to 13% of them are seriously disabled. Soon, national data will be available on the rates of specific disorders in this population.

Historical Overview

Because mental illness has not been well understood in the past, the history of mental illness and care is characterized by misunderstanding and exclusion. These can lead to stigmatization, by which a person or a family is blamed for the mental illness and deliberately excluded from social groups, community activities, and work. Only recently has mental illness been truly recognized as a treatable illness from which one can recover.

In the American colonial period, people who had mental illness were called “the insane” and were cared for by their families or in local almshouses. Around the time of the American Revolution, a system of state mental hospitals was constructed. The first of these facilities, Eastern State Hospital, was built near Williamsburg, Virginia, shortly before the Revolution. Usually, these facilities were located in rural areas because it was thought that persons with mental illness would benefit from good air and the quiet atmosphere of a rural setting.

After World War I, it became clear that a large number of potential recruits had been excluded from military service because of mental illness. It also became clear that battle fatigue, suffered by soldiers who had experienced combat, was a form of mental illness. As a result, in the early 1930s, the Veterans Administration created a system of general hospitals that also provided psychiatric care. In the early 1940s, a system of general hospitals in local communities was created, many of which offered psychiatric care, and in the 1950s, a large number of private psychiatric hospitals were founded, principally in urban areas.

In 1949, President Harry S. Truman signed legislation creating the National Institute of Mental Health (NIMH). In 1954, the drug chlorpromazine (sold under the trade names of Largactil and Thorazine) was approved in the United States for psychiatric treatment. It was hailed as a wonder drug to treat severe mental illness. With the advent of drug therapy, the nation’s state mental hospitals began to empty, a process later called *deinstitutionalization*. However, many of the former inpatients of the mental hospitals became homeless, were placed in nursing homes, or were even incarcerated in jails or prisons.

In 1963, President John F. Kennedy signed federal legislation creating a national system of community mental health centers, which would be available throughout the nation. It was estimated that 1,500 of these facilities would be required to serve the entire American population. More than 800 facilities were built before President Ronald Reagan ended federal funding for the program in 1981.

From 1980 to the end of the 20th century, the mental healthcare field strove to provide effective care in local communities for public clients who

had mental illnesses that led to serious disabilities. Although effective programs were developed for both adults and youths, these programs were not broadly implemented. In 1992, President George H. W. Bush signed federal legislation creating the Substance Abuse and Mental Health Services Administration (SAMHSA) with the mission of improving both mental health and substance use care throughout the nation.

With the dawning of the 21st century, a new awareness has developed that effective care is available, that one can recover from mental illness, and that one who has had a mental illness can lead a happy and productive life in the community. This new approach has been heralded by representatives of the mental healthcare community and broadly embraced by many Americans.

Many successes in mental health have been achieved, in large measure due to the development and growth of an effective mental health consumer movement in parallel with the rapid growth of the family movement. Many American communities have access to (a) an affiliate of Mental Health America, representing consumers; (b) an affiliate of the National Alliance for Mental Illness, representing both families and consumers; and (c) the Federation of Families for Children’s Mental Health, representing both families and children.

Recent Reports

Several recent reports will likely have a major effect on the future of mental healthcare in the United States.

More than 200 years after the first U.S. Surgeon General took office in 1798, the first-ever *Mental Health: A Report of the Surgeon General* was issued in 1999. This report examined the scientific foundation for current mental illness care practices and identified opportunities for care improvement. Significantly, the scientific foundations of mental health clinical and services research was found to be quite robust. The report identified the integration of mental health with general healthcare as the step forward needed most in the near term, with the goal that the two systems become one and treat both mind and body at the same time.

In 2002, slightly more than 25 years after President Jimmy Carter convened the first President’s Commission on Mental Health,

President George W. Bush convened the President's New Freedom Commission on Mental Health. The new commission met for a year and then issued a report titled *Achieving the Promise: Transforming Mental Health Care in America* in 2003. The report identified six major goals for the improvement of mental healthcare in America: (1) Americans understand that mental health is essential to overall health; (2) mental healthcare is consumer and family driven; (3) disparities in mental health services are eliminated; (4) early mental health screening, assessment, and referral to services are common practice; (5) excellent mental healthcare is delivered and research is accelerated; and (6) technology is used to access mental healthcare and information.

In 2005, the prestigious national Institute of Medicine (IOM) issued a study titled *Improving the Quality of Health Care for Mental and Substance Use Conditions*. This landmark study provided a plan for achieving the goals outlined by the President's New Freedom Commission on Mental Health. A new set of "care rules" was identified to improve care quality. These rules promoted (a) better provider-consumer information exchange, (b) more stable care relationships, and (c) a more central role for consumer input regarding care. Care quality was determined to relate to six factors: (1) safety, (2) efficiency, (3) effectiveness, (4) equitability, (5) timeliness, and (6) person-centeredness. (For the latter, IOM identified the consumer's input as the "true north" of the healthcare system.) Finally, four key strategies were recommended to bring about necessary system changes: (1) financing reform, (2) training of providers, (3) implementation of care that has a sound scientific basis, and (4) better use of information technology and performance measures. As with each of the earlier reports, it was strongly recommended that the integration of mental health and general healthcare be a high priority.

Who Receives Care?

At least half of those who experience a mental disorder each year do not receive any care at all. Among the 10% to 12% of the American population who do receive mental healthcare, about half (5–6%) actually see a mental health specialist. These specialists include psychiatrists,

psychologists, social workers, psychiatric nurses, marriage or family therapists, and clinical mental health counselors. Typically, these providers see clients either in the practitioner's office or in an outpatient clinic or community mental health center.

The remaining 5% to 6% of the American population who receive care for mental illness are seen only by a general, medical physician. This pattern is particularly pronounced for children, who likely are seen only by their pediatricians, and for elderly persons, who likely are seen only by their personal physicians. Most primary-care physicians are not adequately trained to recognize and treat the full spectrum of mental illnesses.

About one fourth of those who experience a mental disorder each year suffer from a serious mental illness such as schizophrenia and suffer the greatest consequences in their loss of community participation. Many of these people are homeless and jobless because of their illnesses. Frequently, they receive their only mental healthcare through a state mental health agency, sometimes in a state mental hospital or local, outpatient, mental health clinic.

Each year, many other Americans have a range of mental health problems with symptoms that are not severe enough to qualify as mental illnesses. Only a very small percentage of this group seeks or receives care. Often, when care is sought, the first point of contact is a company employee assistance program, many of which offer both mental health and substance use care services, or a school or college health service.

If so many youths and adults have mental illnesses, why do so few receive care? In a word, stigma, which can lead to the rejection of care for fear that other family members, neighbors, fellow employees, and friends will find out. Many people interpret seeking care as a sign of weakness and fear that it will have negative effects in the future, such as diminished job prospects or the loss of friends. Stigma can also manifest through negative managerial, boardroom, and legislative decisions about funding for mental healthcare. It is well-known, for example, that insurance benefits for mental illnesses provide less annual and lifetime coverage than for physical disorders. This differential has spawned major efforts by national mental health leaders to seek parity for mental health benefits in both

private and public insurance plans. In its most extreme forms, stigma manifests as discrimination against people with mental illness.

Some progress has been made in addressing the stigma of mental illness. Depression, anxiety, and even schizophrenia show up on some television shows as part of a character's story line. Well-known national figures have disclosed their own illnesses: Tipper Gore, the wife of the former vice president Al Gore, and Mike Wallace, a longtime anchor on the popular investigative television newsmagazine show *60 Minutes*, both have discussed their bouts with depression. And the popular author Danielle Steel has written a gripping account of the bipolar disorder suffered by her eldest son. National organizations have also mobilized to combat stigma. As a result, the stigma associated with mental illness has diminished, but it has not yet been extinguished.

Recent Improvements in Care

In the past quarter century, there have been changes in the way Americans view mental health and the way mental illness is treated. Many of these changes are positive steps, though others have introduced new societal problems. The main changes are discussed briefly below.

Care Has Moved From Institutions to the Community

There are about 250,000 fewer psychiatric beds today compared with 25 years ago. Community-based care has expanded dramatically. Yet many persons have been left behind. Witness the dramatic growth in mental illness among the homeless as well as among the less affluent segments of American society.

Care Is Better Integrated Into Overall Support Systems

It is now widely understood that those with the most severe mental illnesses require care systems that span mental health, overall health, rehabilitation, and social support services in the community. At the heart of such systems are case managers who work to achieve better community integration for their clients. Yet many of these systems lack

essential components, particularly in the most rural areas and the poorest urban areas.

Care Includes a Broad Range of Modern, Psychotropic Medications

Medications are now available for virtually all the major mental illnesses. Yet many people do not receive modern medications because they lack the financial resources to pay for them. Even when more effective, modern formulations are available, older medications—some developed as long ago as 50 years—are used because they cost less. Some newer medications have also given rise to concerns about secondary effects, particularly metabolic changes that can lead to diabetes and heart disease.

Care Has Become More Consumer and Family Centered

A quarter century ago, mental healthcare providers made virtually all the decisions about the nature of mental healthcare and its duration. Now, consumers and family members help define the objectives and the content of care. Yet a chasm frequently exists—between the provider and consumer perspectives and between the consumer and family perspectives—that can diminish the effectiveness of care.

Debate Over Forced Treatment Continues

In the past, this debate focused on inpatient commitment. Now, it focuses on outpatient commitment in community settings. Some community members and professionals favor outpatient commitment or court-determined and directed outpatient care if clients do not follow recommended treatment practices. Many consumers oppose it as an infringement on personal rights. This debate has fostered the development of creative alternatives. For example, *advance directives* are similar to a living will in that a person makes his or her wishes known in advance and appoints a personal representative to reflect these views of patient care in subsequent proceedings. It may be useful to view forced outpatient commitment as a measure of system failure in that it generally occurs only when prior care has not been adequate.

Disparities in Mental Healthcare Have Been Identified

It has been known for decades that racial, ethnic, gender, and age disparities exist in the occurrence of mental illnesses and in mental healthcare services. Yet it is only recently that these disparities have been recognized as national policy concerns. As a result, mental health providers and systems will need to learn to adapt themselves to a broader diversity of clients and develop a heightened level of sensitivity to cultural and biological differences.

Integration of Mental and Physical Healthcare Services Has Begun

Until as recently as a decade ago, mental healthcare and physical healthcare systems operated in separate, parallel worlds. With approximately 5% to 6% of the American population receiving mental healthcare only from general physicians, there is an urgent need to open a dialogue on better ways to integrate the two fields. It is now realized, for example, that financial incentives, training, and new system configurations will be needed. A similar dialogue has started between the mental health and substance use care fields.

Other issues also will need to be addressed. As more effective community care systems are built in the short-term future, they will need to consider (a) the role that the faith-based community can play in prevention and early intervention, (b) the potential role of private-public partnerships, (c) the need for effective linkages with the human service community, and (d) the need for effective outreach to those who are disenfranchised or subjected to discrimination. Moreover, the new community systems must have the capacity to respond to disasters, which can have major effects on mental health and well-being similar to those experienced after the 9/11 terrorist attacks in New York and Washington, D.C.

In the distant future, several other trends can be anticipated to emerge or strengthen. One trend that is likely to affect mental healthcare is the move toward consumer- and family-centered care. Consumers and family members will seek and receive more responsibility for health and healthcare. Already, consumer-operated and peer-supported mental health services have become more common, with individuals and family

members allowed and expected to take on a greater role in the direct management of mental disease.

The use of new technologies will likely become an even more important vehicle for delivering mental healthcare. Currently, telecommunication, computer, and Internet technologies are being linked to offer “care at a distance.” Several thousand Web sites now offer interpersonal psychotherapy, expanding the scope of mental health care services, much as the telephone expanded healthcare providers’ ability to help their patients in the past. Rapid advances also are being made in voice-activated automatic-response systems and in the application of artificial-intelligence systems to real-world problems. As a result, it is now possible to receive care and guidance through a computer program without human intervention. Other automated systems are being developed to monitor—at home, in real time—and report physical symptoms to healthcare providers. As these noninterpersonal technologies become more pervasive, new concerns are likely to arise about how and when human intervention in the mental healthcare process is appropriate or even essential.

Also very promising will be the development of new genetic treatments over the next 5 to 10 years for biologically based mental disorders. To date, virtually no genetic interventions are recommended or implemented in the mental health field. Now that the basic human genome has been mapped, this situation may change radically as genetic interventions are developed for mental disorders that have a genetic basis.

MENTAL HEALTH EPIDEMIOLOGY

Mental health epidemiology is the study of the prevalence and incidence of mental health disorders. This entry defines basic epidemiology concepts and describes the historical development of mental health epidemiology in the United States. In conclusion, it outlines some of the promising new directions mental health epidemiology will likely take in the future.

Only in the past 30 years have public health and health services researchers been able to combine

statistical sampling methods, interviewer scales, and appropriate analytical tools and collect detailed information on specific medical diagnoses that can be generalized to a defined national population. This combination of resources has enabled researchers to measure the magnitude of mental health disorders in the United States's population. In general terms, researchers now estimate that about one quarter of the nation's adult population has a diagnosable mental disorder in any 1-year period of time and that the lifetime expectation is that about 1 in 2 adults will suffer from these disorders. For children and adolescents, the 1-year figure is about 1 in 5. For any other medical disorder (e.g., heart disease, diabetes, hepatitis), these figures would be considered signs of a public health crisis.

Some Basic Concepts of Epidemiology

To understand epidemiology, several key concepts are critical. Two important basic concepts are the *prevalence* and the *incidence* of disease. Prevalence refers to the *total* number of disease cases in a period of time for a defined population. This period of time can be 1 day in length, called *point prevalence*, or 1 year in length, called *period prevalence*. Incidence refers to the number of *new* disease cases occurring during a period of time for a defined population, either *point incidence* or *period incidence*, as differentiated above.

A major goal of epidemiology is to measure both the prevalence and the incidence of a disease. By definition, the ratio of incidence to prevalence will always be 1 or less. The higher this ratio, the greater the turnover in the diseased population. For example, depression has both a high incidence and a high prevalence, which means that there is considerable turnover in the population with this disease and that many persons with this disease recover in a relatively short period of time. In contrast, schizophrenia has a very low prevalence and even lower incidence. This means that there is a very low turnover in this population and that persons with this disease have it for a long period of time.

To measure a disease's period prevalence, measures of the number of disease cases at Time 1 and Time 2 are required. Period prevalence is the sum of these two figures (i.e., point prevalence plus incidence). Remember that the period prevalence is always equal to or greater than the period

incidence. By extension, it should be noted that point prevalence can be viewed as the sum of the disease cases at the beginning of a day plus the number of new incident cases over the course of the day.

Period incidence also requires measurement at two time points. Period incidence means that a person does not have the disease at Time 1 but develops the disease between Time 1 and Time 2. By extension, point incidence means that a person did not have the disease at the beginning of the day but developed the disease over the course of the day.

Frequently, sociodemographic factors such as age, gender, race or ethnicity, and place of residence are examined in relation to a disease. From such analyses, for example, Hollingshead and Redlich were able to determine that the prevalence of mental illness was 8 times as large in the lowest social class as compared with the highest social class.

Early Work in Mental Health Epidemiology

Beginning in 1840, the U.S. superintendent of the census began to collect information, as part of the nation's decennial census of population, on the number of persons living in households who were "insane or idiotic." Similar data were collected on persons residing in state mental hospitals. The sum of these two numbers provides a very primitive, early estimate of the prevalence of mental illness in the United States. This procedure was continued until 1900 with progressive refinement in the diagnostic categories.

After that time, specific questions on mental illness were no longer asked of the household population, but data were collected more frequently on state mental hospitals. Over time, the data collected from state mental hospitals, *treated prevalence*, became the surrogate for total community prevalence—that is, the sum of the community and hospital figures. These hospital data were reported by the U.S. Public Health Service in a publication series called *Patients in Mental Institutions*. As additional types of hospitals—Veterans Administration Medical Centers, general community hospitals, and private psychiatric hospitals—were developed in the 1930s and later, their figures were also added to these data collections.

Beginning of the Modern Era

The beginning of the modern era of mental health epidemiology can be traced to a famous study conducted in Stirling County, New York, in 1952. At that time, Stirling County was rural, with a total population of about 20,000 persons. More than 1,000 male and female adult heads of households were interviewed for the study, and the American Psychiatric Association's new *Diagnostic and Statistical Manual of Mental Disorders (DSM-1)* was used for the first time. Two psychiatrists reviewed the interview ratings. The purpose of the study was to examine the relationship between sociocultural disintegration and specific mental disorders. Lifetime prevalence was estimated at 57% for all *DSM-1* disorders measured, and current prevalence was estimated to be 90% of the lifetime rate.

An equally famous study from this period is the Midtown Manhattan Study conducted in 1954. The study population included 175,000 adults between the ages of 20 and 59 who resided in Midtown Manhattan. Of this number, 1,660 were interviewed. Two psychiatrists reviewed the ratings. The purpose of the study was to examine the relationship between stress indicators and mental impairment. Unlike the Stirling County Study, the Midtown Manhattan Study developed an overall measure of mental disorders and ratings for several symptom groups rather than ratings for specific disorders. Current prevalence was estimated at 81.5% for mild to incapacitated impairment. No lifetime prevalence figure was provided.

Both of these studies contributed significantly to the understanding of how to conduct mental health epidemiological fieldwork. However, both also had considerable limitations. Both were surveys conducted in small geographical areas, and both were focused on the noninstitutionalized population. Persons with mental illness who resided in psychiatric hospitals at the time of the studies were not counted.

It should be noted that the newly formed National Institute of Mental Health (NIMH) was developing *psychiatric case registers* at about the same time the Stirling County and Midtown Manhattan studies were being conducted. A psychiatric case register is a continuous recording of all persons who present for mental health treatment

from a defined geographical area, together with detailed treatment data. A case register is a very valuable tool for understanding the precise patterns of care provided to persons with specific disorders. The most notable of these psychiatric case registers were for the states of Maryland and Hawaii and for Monroe County, New York. The two state case registers were discontinued at the end of the 1960s, and the Monroe County case register was discontinued at the end of the 1980s.

A Landmark National Study

From the time of the Stirling County and Midtown Manhattan studies until the early 1980s, work was underway at NIMH and in the mental health research field to improve the measurement of specific mental disorders using interview techniques. At the same time, the specification of mental disorders was refined with the release of the second and third generation of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-II and DSM-III)*. From these efforts came the Diagnostic Interview Schedule (DIS). The DIS was the first field survey instrument that could be administered solely by a lay interviewer and from which specific mental illness diagnoses could be derived, with further clinical review.

The DIS became the basic survey instrument for the epidemiological catchment area (ECA) project conducted in 1983 under the leadership of NIMH. This survey project was conducted among persons 18 years of age and older in five geographic areas across the nation: (1) New Haven, Connecticut; (2) Baltimore, Maryland; (3) St. Louis, Missouri; (4) Durham, North Carolina; and (5) Los Angeles, California. The purpose of the study was to produce lifetime and annual prevalence estimates for specific mental disorders and to produce estimates of the incidence of these disorders for a 1-year period. The national estimates were produced using the 1980 population figures, even though the data were collected in 1983. Annual period prevalence was estimated to be 28.1% for all disorders, and separate estimates were provided for specific disorders. A very important finding from this study was that only about 15% of the adult population received any mental healthcare, and only 6% received care from a mental health provider such as a psychiatrist or psychologist.

The ECA project was widely acclaimed at the time it was reported to the field, and its results were used broadly for policy, clinical, and financial analysis. To the present time, this study has provided the only annual incidence figures for specific diagnoses that have ever been collected on a national basis. Problems of individual recall were noted in the lifetime prevalence figures; hence, they have received relatively little attention by the field.

Current Generation of Work

Almost a decade after the ECA fieldwork was completed, a new study, the National Comorbidity Survey (NCS) was undertaken between 1990 and 1992 on a national probability sample of more than 8,000 persons, 15 to 54 years of age, from the household population. NIMH supported this new study. This effort was the very first to assess mental illness in a national probability sample. It was also the first effort to use the World Health Organization's Composite International Diagnostic Instrument (CIDI), based on the *DSM-III-R* and administered by lay interviewers. Fourteen different psychiatric disorders were assessed. Annual prevalence figures were similar to those reported from the ECA, with almost 30% of respondents having a mental illness. Lifetime prevalence was reported to be almost 50%. Equally important, more than half of all the persons with a lifetime disorder had a history of three or more comorbid disorders. Of those with a disorder in the past year, less than 20% received any care; for those with a lifetime disorder, the percentage receiving any treatment was less than 40%.

A broad range of mental health issues have been explored by researchers using NCS data, which are publicly available; numerous scientific articles have been published from it. However, NCS did not include a scale for schizophrenia, and it did not collect incidence data.

In 2001 and 2002, the same set of NCS respondents was reinterviewed. NIMH and the Center for Mental Health Services supported this effort. The reinterview study is called NCS-2. This study was conducted to examine the course of mental disorders, as well as the relationship between primary mental disorders and secondary substance use disorders. From this study, the framework of the "window of opportunity" has been developed.

This framework points to opportunities to intervene between the onset of a primary mental disorder and the onset of a secondary substance use disorder to prevent the latter.

At the same time, an NCS-R (Replication) prevalence survey was carried out on a new national probability sample of 10,000 respondents, 18 years of age and older, using a revised CIDI based on *DSM-IV*. More than 32% of the respondents had a disorder in a 1-year period, and more than 57% had a lifetime disorder.

Currently, the results from a parallel study of 10,000 adolescents, called the NCS-A (Adolescents), are being analyzed. Once reported, this study will be the first national effort to collect detailed prevalence information on a national probability sample of adolescents, 12 to 17 years of age.

Some Related National Work

In 2006, funding was provided by the Center for Mental Health Services to add mental health questions to the Behavioral Risk Factor Surveillance System (BRFSS), operated by the U.S. Centers for Disease Control and Prevention (CDC). The BRFSS is composed of 51 parallel, state telephone surveys of samples of adults and is conducted each year. The mental health questions added to the BRFSS were the first eight items from the Physician Health Questionnaire (PHQ-8), which provide a measure of depression. Unlike all earlier mental health epidemiology efforts, the BRFSS is capable of producing direct state estimates in addition to national estimates. In this first effort, 38 states added the mental health questions. Initial results will be available from the Center for Mental Health Services.

In 2007, the BRFSS work was extended by adding the K-6, a measure developed in the NCS to assess whether an adult respondent has serious mental illness. These results will be released in 2008.

Promising New Directions

As indicated above, mental health epidemiology in the United States has steadily progressed from small, local studies using inconsistent nonstandardized measures to sophisticated, national probability samples using internationally recognized and validated research instruments. The field of

mental health epidemiology is also developing the capacity to make accurate, state-level estimates, which will be very useful for state and local health planners, various departments of state government, and state policymakers.

The future will likely hold many changes for the field of epidemiology in general and for mental health epidemiology in particular. Some of the anticipated changes are outlined below.

Electronic Health and Personal Health Records

A process is already underway to implement electronic health records (EHRs) and personal health records (PHRs) in the United States. Comprehensive EHRs will contain detailed continuous information on a person's health status and the healthcare he or she receives. PHRs will translate this information into action steps that consumers will be able to take to improve their health status and the quality of their care, as well as to engage in self-care activities.

The EHRs and PHRs will provide an entirely new source of data for mental health epidemiology. These electronic files will be universal. They will be continuous records. And they will contain detailed information on the full range of a person's comorbidities. The implication is that traditional epidemiological-survey data collections will be replaced by continuous data collection from these electronic files.

To facilitate this outcome, it will be essential to ensure that very high-quality information is entered into these EHRs and PHRs, using the very best instruments available. The VistA EHR developed by the U.S. Department of Veteran Affairs for military veterans has already demonstrated how this might be accomplished. More effort needs to be spent on ensuring comparable data standards in EHRs and PHRs for items and scales measuring mental health epidemiology.

Improved Knowledge Base

Two types of scientific advances hold considerable promise for the future of mental health epidemiology. First, with the decoding of the human genome and the development of large-scale population samples of DNA, it will be possible to determine genomic patterns for persons with particular

disorders. Some mental disorders, such as schizophrenia and depression, are already known to have genetic components, at least in specific population subgroups. As this knowledge is developed, it will need to be incorporated into mental health epidemiology.

Second, major efforts are currently underway to develop what is called *personal medicine*. Stated simply, this is an effort to match care uniquely to a particular individual. Hence, rather than a general drug formulary for a psychotropic medication, the formula would be prepared specifically for each individual. Clearly, how each patient responds to a medication could be used to develop an entirely new classification system for mental disorders: Instead of relying on a series of questions to identify a particular disorder, drug responsiveness could be used for this purpose.

Enlightened Consumers

As the mental health consumer movement continues to evolve in the United States, consumers will be able (a) to better recognize the signs and symptoms of mental illness, (b) to understand and evaluate the quality of care they receive, and (c) to engage in self-help activities. This is all part of a major transformation effort to promote true recovery and independence. As this evolution progresses, consumers and the providers who serve them may become less willing to participate in national or state mental health epidemiology survey efforts. They will also want to know and understand how the results from such research can be applied directly to their own care and recovery. Hence, future research efforts will need to include new components that address these concerns and interests.

Stigma and Privacy

The mental health field has two preeminent concerns that need to be addressed on an ongoing basis. The first is stigma based on the ideas that (a) people feign mental illness and are really laggards, (b) mental health treatment doesn't work, and (c) mental health treatment is too expensive. Although these contentions are not true, they color any debate about mental health issues from the U.S. Congress to a local community group. A 1-year

prevalence of 25% may not be taken seriously as a public health crisis because of stigma and because of unfounded beliefs about persons with mental illness and the care they receive.

Major national efforts are underway to combat stigma against persons with mental illness. These efforts take the form of educational campaigns, discussions with family members and consumers, and engaging people in mental health initiatives. With an annual prevalence of 25% and a lifetime prevalence of 50%, virtually every family in the nation has one or more members who experience mental illness.

The second and related issue is privacy or confidentiality. Because of work and social discrimination, persons with mental illness are very reluctant to share information about their illness or care. These wishes for privacy need to be respected, and strong standards of confidentiality need to be enforced. And healthcare providers, insurers, employers, and other institutions all need to be held to a very high and strict standard in this area.

Those engaged in mental health epidemiology need to recognize these issues and address them head-on. To address stigma, they need to consider mental illness in the general context of all illnesses. Past research on comorbidity is a very positive movement in this direction. With regard to confidentiality, researchers need to ensure that epidemiological data are not released inappropriately, particularly as the nation moves into the era of EHRs and PHRs.

META-ANALYSIS

Meta-analysis, a tool developed to summarize the findings from randomized clinical trials (RCTs), can be used by many scientific fields, including health services research, to statistically combine data from many individual studies. A meta-analysis adds up the results for each participant in the experimental group and in the control group of all the relevant studies and presents an easily understood summary; it also provides a visual depiction of the outcome, a *forest diagram*, in which the

results of each study are shown, making it obvious if all the studies agree or not. For example, if some studies find that an intervention or experimental group is worse than the control group, and other studies find it better, the disagreement can be seen at a glance.

The term *meta-analysis* was coined by the American statistician Gene V. Glass while he was a faculty member at the University of Colorado at Boulder in 1976. However, the practice actually originated before 1976 as many meta-analyses were published earlier. The use of meta-analysis in clinical medicine was systematically developed in the United Kingdom by the Cochrane Collaboration, an international group of thousands of volunteers founded in 1993 and named after the British epidemiologist Archibald “Archie” L. Cochrane (1909–1988). The Cochrane Collaboration is an international, not-for-profit organization that produces and maintains systematic reviews of health-care interventions, doing their meta-analysis in a standard way. These meta-analyses are published electronically in the Cochrane Database of Systematic Reviews, which are published many times a year and can be easily updated.

Meta-analysis consists of (a) a systematic search of the literature, identifying studies by predefined criteria; (b) extracting numerical results from each study for the experimental and control subjects, on various outcomes and their difference; plus (c) the calculation of parameters reflecting their statistical confidence (e.g., standard deviation and sample size).

The Meta-Analytic Method

To conduct a meta-analysis, a researcher conducts a literature search to find all the studies that meet certain predefined qualitative and quantitative inclusion or exclusion criteria. This is often computer based, with each search term and database used listed. As computer searches often miss important articles and reports, hand searches are also necessary, including searching the bibliography in each journal article to identify other applicable studies. If possible, the translations of the relevant foreign-language articles should be acquired.

It is vital that all studies in the meta-analysis meet reasonable criteria; otherwise there is the potential for bias. Meta-analysis is no better than the studies that go into it. If there is bias in even a

few studies, it will translate into bias in the meta-analytic summary. Sometimes, one will see a meta-analysis with rather exacting criteria for the selection of studies. This may defeat the purpose of a meta-analysis because having very exhaustive inclusion criteria excludes studies that do not fit with the researcher's preconceptions. For this reason, the Cochrane Collaboration always includes a list of excluded studies. The criteria for study inclusion should be simple and straightforward and capture all the well-controlled studies in a field. One can then examine some of the minor methodological differences across studies by *sensitivity analysis* and *meta-regression* to see if they do make a difference.

It is not appropriate to statistically evaluate a participant's measure twice, as if it were for different subjects. Each participant should be counted only once. To demonstrate this *double publication redundancy*, investigators may initially report on the first 20 subjects and, in another article, report on a total of 60 subjects that include the original 20 subjects. Clearly, the same participants counted twice or more will amplify any finding. In addition, bias is introduced when undue weight is given to the findings of groups reporting their data in multiple publications as opposed to those reporting their findings in only one source.

Some researchers perform multiple statistical analyses and stress the most favorable outcome. For meta-analysis, predefined systematic numerical information should be extracted from each study.

The Statistics of Meta-Analysis

Effect Size

The *effect size* is the magnitude of the difference between the intervention or experimental groups and the control groups, regardless of the sample size. This is different from the *statistical significance*, which is defined as the probability that such a finding may happen by chance, leading to the rejection of the null hypothesis. Statistical significance is dependent, in part, on the sample size, so studies with a large number of subjects may yield a highly significant result. The effect size of a *continuous variable* is frequently expressed as the mean, or average, of the experimental group minus

the mean of the control group divided by their pooled standard deviation.

Many outcomes are inherently qualitative, for example, living versus dead or having a disease versus not having a disease. For qualitative or *discontinuous* data, the effect size for an intervention-control comparison is primarily expressed as the difference between the percentages with and without an event in the experimental group and the control group using indices such as *odds ratios*, *risk ratios*, or *risk differences* to provide a measure of the differences. Inherently qualitative outcomes should be dealt with as such. Here, researchers would generally prefer using a continuous variable, but sometimes it is useful to supplement with a dichotomous variable. Dichotomizing data should be done using predefined criteria. An advantage of dichotomous data is that information from each individual subject can often be extracted (i.e., the results stem from real participants) from the observations of individual subjects rather than conducted on summary statistical parameters. This approach is inherently meaningful to researchers, whereas a change of abstract continuous units may not be.

The statistical methods for analyzing qualitative data are essentially a *stratified* or *fold contingency table*. Epidemiologists have been using these statistical methods for many years.

Studies often present a vast amount of data obtained through the use of various rating scales, measurement instruments, and statistical techniques, which makes it difficult to compare the results as they are expressed in a wide variety of units. In meta-analytic statistics, the control group mean or average is subtracted from the intervention or experimental group mean and then divided by the pooled group standard deviation, a process that is similar to the notion of *percentage change scores*. As a result, the data are expressed in uniform units. This allows researchers to focus their attention on the hypothesis they are examining rather than be distracted by the many different units among studies.

Statistical Methods

Most meta-analysis uses standard statistical techniques for continuous data and the Mantel-Haenszel model, or some variant thereof, for discontinuous data. Because continuous data possess

more power than discrete data, continuous data are preferred, when available, to derive the effect size. The sample size, mean, and standard deviations can be easily extracted from RCTs as well as many other types of published studies. Unfortunately, many reports provide the sample size and means for the assorted groups but do not report the standard deviations (or standard error of the mean) that are needed for effect size calculations. Standard deviation or its equivalent should always be reported. Sometimes, standard deviations can be computed from the results of the statistical test presented. Part of meta-analysis is the calculation of variance in standard units. Meta-analyses can be done with fixed (assuming each study to have a fixed effect size) or random models (not assuming this). Generally, random models put more emphasis on the smaller studies.

Consistent Results

One of the major objectives of meta-analysis is to demonstrate, when studies are combined, that the findings are consistently homogenous. When consistent findings are present, some studies will be clearly statistically significant whereas others may have strong nonsignificant trends in the same direction, which summates the essential agreement, because the results are similar.

Sensitivity Analysis and Meta-Regression

The pattern and consistency of results across all studies is vital. For example, if there are several small-sample, positive RCTs and many large-sample, negative trials, it is likely that the smaller studies were deviations or wishful thinking. If the results between individual studies are highly dissonant, it is erroneous to conclude that the overall effect is statistically significant. Rather, the prudent conclusion is that some studies show intervention effects and others do not, which requires the researcher to explain this discrepancy. It is preferable to appraise studies by a priori criteria for methodological precision and then examine if there is a similar effect size in the more rather than less rigorous studies.

There are many arbitrary assumptions that can go into a meta-analysis, involving how to classify studies and the exact criteria for inclusion. It is

important to perform a *sensitivity analysis* by analyzing the same data set with different assumptions, often with 5 to 10 alternate examinations. The blinding and randomization or other methodologies protect against bias. Sensitivity analysis is recalculation of the meta-analysis under different assumptions. Frequently researchers will drop a certain type of study to determine if the other studies produce the same results as the total, thereby demonstrating that the overall results are not an artifact of a given type of study. A sensitivity analysis can be done by using a different choice in deciding which studies to include, or a different outcome measure. However, the problem with dropping studies is the loss of statistical power.

A *metaregression* differs in that it includes all the studies but examines whether there is a systematic difference between one or another *moderator variable*. The moderator variables could be continuous or dichotomous (i.e., the meta-analytic equivalent of analysis of variance or analysis of covariance). The moderator variables are not randomly assigned nor are they usually blinded. Many biases could affect moderator variables. The same cautions that apply when imputing cause from statistical correlation analysis apply to a meta-regression as it is an exploratory technique.

The Graphic Inspection of Results

The quintessence of meta-analysis is the inspection of the data. Thus, this method generates a visual or numeric illustration of each study in the context of all the others. A review of the actual data gives the analytical reader a feel for the data. When the results from several studies are converted into similar units, a simple inspection of a graph or table quickly displays which trials have dissimilar outcomes from the majority. Such disparate outcomes can also be examined by a variety of statistical parameters. For example, a researcher can calculate a statistical *index of homogeneity*, whereby he or she can remove the most discrepant study from the analysis, recalculate, and in so doing reveal that all but one study in the data set are homogenous. If two studies are discrepant, then the researcher can remove both from the study and again recalculate the parameters of statistical homogeneity, and so on. When there are a number of blinded studies, the interpretation of

efficacy is usually straightforward, particularly when the results are not statistically significant. A few biased studies mixed in with valid studies might produce a significant difference. In interpreting the results of the meta-analysis, it is important to examine the effect size and its significance, as well as the consistency of the results. The confidence interval or standard deviation and sample size provide a bridge to inspect uncertainty in the same units.

Meta-Analysis Versus Narrative Reviews

Narrative reviews of scientific findings are often based on clinical wisdom and can be highly subjective: The author of a narrative review may accept the results of studies without any critical assessment. The author may summarize several highly publicized references in support of a certain position, even reporting redundant data, but the reader may discover that many of the quoted studies are inadequately controlled. The author selectively chooses what studies to mention and selects what aspects to mention or omit, as well as giving his or her opinion as to what the bottom line is. Additionally, limited evidence from controlled studies failing to find a big difference is often interpreted as finding the opposite result. But an area that is not studied does not imply the opposite of the hypothesis, only insufficient studies. Ideally, the researcher should carefully consider each individual study before coming to any conclusions. However, when there are many controlled studies, the individual researcher often cannot remember all the results. Thus, a meta-analysis can often provide a more meaningful summary than a narrative review.

The File Drawer Problem

One of the most important drawbacks in meta-analysis is the “file drawer” problem. Researchers have found that positive findings are much more likely to be published than negative findings. And positive findings are more likely to be printed in more prestigious journals. Estimates can be made according to assumptions about such a pattern. An example of such estimates is the *funnel plot*, which is often included in a meta-analysis. However, such plots are no better than the assumptions

underlying them. To minimize this bias, researchers recommend including all reasonable-quality studies as well as search reports of symposia, meeting presentations, relevant Web sites, exhibits, and other available unpublished data; they also recommend contacting investigators and funding sources for data and, if necessary, obtaining data using the Freedom of Information Act.

One safeguard is to calculate the number of participants whose negative results (hypothetically hidden in a file drawer) would convert a positive meta-analysis to a negative one (the fail-safe number). It seems likely that the file drawer issue is also a problem for narrative reviews as they generally do not seek to consider all relevant studies.

Omnibus Methods

Meta-analysis does not simply count the number of studies that display a significant difference, average their means not weighted by sample size, or add up the *p values*. These methods, which are referred to as omnibus or vote-counting methods, have many methodological problems. The results obtained by adding *p values* can be excessively influenced by a few disparate studies, as shown by various researchers using simulation models.

Implications

A large literature on meta-analysis has developed over the years, documenting the extensive experience and the methodological and statistical issues associated with it. The most important aspect of a meta-analysis, no matter how technically excellent, is no better than the soundness of the judgment that goes into the selection of the studies and their interpretation so that they make sense mechanistically.

Although meta-analysis has been traditionally used to summarize RCTs and genetic studies, it can also be used to summarize various health services research studies, case-controlled studies, observational studies, or even uncontrolled studies that use a common methodology. Knowledge of the data provides some empirical benchmarks to help distinguish empirical findings from the results of dogma, wishful thinking, or political pressures.

MIDWEST BUSINESS GROUP ON HEALTH

The Chicago-based Midwest Business Group on Health (MBGH) is a leading regional healthcare coalition of major private and public employers. The MBGH works with its member employers to help them control and lower their healthcare costs and obtain more value for their healthcare benefit dollars. As an organization, the coalition offers its members a wide variety of health benefit, educational seminars; networking opportunities; initiatives and demonstration projects; and group purchasing programs. The MBGH is also a member of the National Business Coalition on Health (NBCH).

Background

Established in January 1980 by a small group of large, Midwest employers, the nonprofit MGBH has grown to include more than 80 major employers responsible for more than 2 million covered lives in 11 states. These employers collectively spend more than \$2.5 billion annually on their employees' healthcare benefits. Over the years, the coalition's mission has also broadened and expanded. Initially, it was mainly concerned with ways to lower and control the costs of healthcare; today, it also addresses the quality, safety, and value of healthcare.

Membership

The MBGH is primarily funded through employer membership dues. Membership is for a 12-month period with dues based on the employer's number of U.S. workers. Public and nonprofit employers receive a 50% discount off their membership dues. Specifically, the coalition has four membership categories: (1) business members, which are for-profit organizations (e.g., Bank of America, Caterpillar, and Ford Motor Company); (2) provider members, which are community-based healthcare provider organizations such as hospital systems (e.g., Advocate Health Care, Alexian Brothers Hospital Network, and Carle Clinic Association); (3) nonprofit and government members, which include academic, research, and government organizations (e.g., the Federal Reserve Bank of Chicago, the state of Illinois, and the University of Chicago); and (4) associate members, which include providers of healthcare and medical products or consulting and management services (e.g., Abbott Laboratories, Deloitte, and Johnson and Johnson Health Services).

Organizational Structure

The MBGH is governed by a board of directors, which consists of the president, chief executive officer, and secretary of the coalition and 18 board members. The board members are elected from the various member employers. A professional staff of six individuals—the president, vice president, director of projects and communications, director of operations,

membership and administration coordinator, and projects coordinator—manages the coalition.

Products and Services

The MBGH provides three types of services to its member employers: (1) learning network programs, (2) health benefit purchasing groups, and (3) health benefits and quality initiatives. These services help member employers connect and learn from each other as well as obtain various products and services.

The coalition's learning network programs include the following: (a) monthly learning network meetings; (b) an annual conference; (c) employer, health, roundtable discussions; (d) health system user groups; (e) benchmark survey services; and (f) monthly, Medicare, employer forum telephone calls. The employer, health, roundtable discussions address pharmacy benefits, consumer-directed health plans (CDHPs) and consumerism, union benefits, and wellness and health management issues.

To help its member employers obtain competitive rates, superior services, performance evaluations, and performance guarantees, the MBGH has established an affiliate, the Midwest Health Purchasers Foundation (MHPF), which provides various health benefit purchasing groups. The foundation helps coalition member employers (a) enroll their workers in several Chicago health maintenance organizations (HMOs), (b) obtain pharmacy services (e.g., retail, mail, and specialty drugs), (c) obtain health promotion and risk management services, (d) obtain disease management services (e.g., acute-care counseling, and high-cost case management), (e) obtain audit services to examine the performance of third-party administrators (TPAs) and health plans, (f) manage Medicare Part D services, and (g) implement and manage incentive programs and products.

The MBGH undertakes a large number of health benefit and quality initiatives. Specifically, the coalition develops and supports various initiatives that test healthcare measurement tools and improve community health. Some of its recent initiatives include (a) an employee self-report tool that analyzes the impact of chronic disease on productivity; (b) measuring the costs of overuse, underuse, and misuse of healthcare and the role of purchasers in addressing these problems;

(c) determining what information consumers want to know about their physicians; and (d) studies of employer adoption of value-based benefit strategies and the correlation of benefit incentives to changes in employee behavior.

In 2003, the MBGH's initiative on the cost of overuse, underuse, and misuse of healthcare gained national attention with its estimate that about 30% of all direct healthcare outlays are the result of poor quality of care. In 2007, the MBGH, working with two pharmacist associations, initiated Taking Control of Your Health, a diabetes management demonstration project. The project uses specially trained pharmacists to conduct individual meetings with employees to help educate, motivate, and empower them to better manage their diabetes. In 2008, the coalition received a grant from the National Business Group on Health (NBGH) to expand the program.

MILBANK MEMORIAL FUND

For most of its history, the Milbank Memorial Fund has collaborated with decision makers in the public and private sectors to use the best available evidence and experience in making policy for healthcare and population health. Its founders, Elizabeth Milbank Anderson—who provided the endowment in increments between 1905 and 1921—and Albert G. Milbank—who led the board from 1905 until his death in 1949—dedicated the fund to devising effective policy to improve the well-being of people, especially those with low incomes.

History

The fund's history can be divided into five segments: (1) 1905 to 1920, (2) 1921 to 1936, (3) 1937 to 1961, (4) 1961 to 1989, and (5) 1990 to the present. From 1905 until Elizabeth Milbank Anderson's death in 1920, the Memorial Fund Association, as it was then called, worked with officials of government and charitable agencies that served the poor in New York City. Notable projects included constructing public baths on models devised by health officials in Europe; increasing children's access to health and related services; and demonstrating the feasibility of a "home hospital," residences, and health services for families, one or more members of which had tuberculosis.

Between 1921 and 1936, the fund and its allies in government and medicine addressed major issues in improving access to appropriate healthcare and related services. Its first chief executive, John A. Kingsbury, a veteran manager in city government and charitable organizations, organized multiyear demonstrations of new methods of integrating services provided by the government and charities in New York City, Syracuse, and rural Cattaraugus County, New York. The fund appointed a technical board of prominent health experts to advise and evaluate these projects. This board produced a periodic bulletin evaluating the work of the demonstrations and commissioned a book about each of them. The bulletin, published continuously since 1923, is now the *Milbank Quarterly*.

The fund addressed controversial issues of health policy between 1926 and 1935. In 1926, for example, it helped organize the consortium of foundations to finance a Committee on the Costs of Medical Care (CCMC). Research reports by the committee's staff are landmarks in the history of health services research. In 1932, however, most of the physician members of the CCMC refused to sign its final report because it recommended the prepayment of healthcare and the reorganization of physicians into large group practices dominated by specialists.

Kingsbury and his staff at the fund advocated including these recommendations, as well as funding to expand access to health services, in the Social Security Act of 1935. The fund seconded two employees to the staff of the cabinet-level committee that drafted what became the Social Security Act. This advocacy increased antagonism toward the fund among critics of the CCMC report in organized medicine. Several medical societies recommended that physicians advise mothers to boycott Borden's condensed milk—an ingredient in infant formula—because stock in that company accounted for a substantial percentage of the fund's assets. In 1935, the board of the fund fired Kingsbury but reaffirmed its commitment to increased access to health services.

During the next quarter century, the fund maintained this commitment but through projects and publications that avoided controversy. Its chief executive from 1937 to 1961, Frank Boudreau, was a public health physician who had joined the new social medicine movement as an official of the League of Nations. He led the fund in conducting and commissioning policy-related research on nutrition, fertility and birth control, and mental health. The fund convened annual conferences addressed and attended by researchers and policy-makers. In the 1950s, fund staff helped inform policy on substituting community for institutional care of the mentally ill and facilitated the establishment of the Population Council.

The fund chose not to prioritize activities related to policy between 1961 and 1989. Alexander Robertson, chief executive from 1961 to 1967, managed a fellowship program in social medicine for young academic physicians from North and South America. His successor from 1967 to 1977, Leroy Burney, accorded priority to the reform of

higher education for public health. The next chief executive, Robert H. Ebert—1978 to 1984 and 1988 to 1989—organized a fellowship program in clinical epidemiology; several of its alumni became leaders in the field subsequently called evidence-based health research and practice. Sidney Lee, 1984 to 1988, mounted projects to improve the health of migrant and seasonal workers and their families.

In the 1960s, the *Milbank Quarterly* became, and has remained, a highly regarded, international journal of research on health services and policy and on population health. The fund was designated an operating foundation under 1967 amendments to the Internal Revenue Code on the basis of the *Quarterly* and miscellaneous reports.

Since 1990, however, the fund has used its regulatory status as an operating foundation to collaborate with many decision makers in the public and private sectors to bring the best available evidence to bear on policy and practice. A new chairman, Samuel L. (Tony) Milbank (1990 to present), and two presidents, Daniel M. Fox (1990–2007) and Carmen Hooker (2007 to present), led this restoration of what had been the fund's mission during its first half century.

Future Implications

The fund currently prioritizes responsiveness to its constituents, who are mainly decision makers but also include researchers who are able to inform policy in the United States and other countries. The fund's largest program since the early 1990s has been its partnership with the Reforming States Group (RSG). The RSG is a voluntary association of senior officials of the legislative and executive branches of government from each of the states, from most Canadian provinces, and recently, from Australia, England, and Scotland. Its members assist one another to acquire and assess evidence and experience that could improve policy for healthcare and population health.

In addition to its work with the RSG, the fund and its constituents have recently addressed issues that include (a) public health law reform, (b) the adequacy of the income available to retirees over the next generation, (c) the importance of global health issues for American foreign and security policy, and (d) improving long-term and palliative

care. The fund continues to publish the *Milbank Quarterly* and occasional reports and copublishes a book series with the University of California Press.

MINIMUM DATA SET (MDS) FOR NURSING HOME RESIDENT ASSESSMENT

The provision of appropriate care in nursing facilities requires comprehensive knowledge of residents' strengths, weaknesses, and problems. As one feature of the Omnibus Budget Reconciliation Act of 1987 (OBRA 87), the U.S. Congress sought to ensure the availability of such information by mandating a national resident assessment system, including a uniform set of items and definitions for assessing all residents in

nursing facilities in the United States. The need for uniform resident assessment in long-term care had been long recognized. A 1986 study by the national Institute of Medicine (IOM) focused on how to improve nursing home regulation and identified uniform resident assessment as a cornerstone of any effort to improve quality. Indeed, this recommendation, along with a host of others in the Institute's report, formed the basis for many of the nursing home reform provisions in OBRA 87, requiring each certified nursing facility to conduct a comprehensive, accurate, standardized, reproducible assessment of each resident's functional capacities.

In 1988, the Health Care Financing Administration (HCFA) (now the Centers for Medicare and Medicaid Services [CMS]) contracted with the Research Triangle Institute, the Hebrew Rehabilitation Center for the Aged, Brown University, and the University of Michigan to develop and evaluate a uniform resident assessment system. The resident assessment instrument that emerged was designed as a minimum data set (MDS) of items, definitions, and response categories aimed at providing a comprehensive assessment. In addition, the resident assessment protocols (RAPs), which are part of the resident assessment instrument (RAI), provide guidelines for more in-depth assessment of 18 conditions that affect the functional well-being of nursing home residents (e.g., falls, urinary incontinence, cognition difficulties, and use of restraints).

Development of the Instrument

In developing the RAI, more than 60 prior assessment instruments that had been developed for screening, admission, and research purposes were reviewed for comprehensiveness and to identify common domains, items, definitions, responses, and scoring patterns. These were used to develop multiple instrument drafts, all of which underwent extensive review by literally hundreds of experts representing all the professions that work with nursing home residents. The resulting instrument contains more than 300 data elements, many of which measure the traditional domains of functioning, personal-care activities, and the amount of "hands-on" and supervision time associated with each

personal-care area, as well as basic demographic factors. Other domains covered in the MDS include (a) decision making; (b) behavioral problems; (c) symptoms, diagnoses, and conditions; (d) social interaction and regulations; (e) skin care needs; and (f) services received. Newest of all were data elements about the residents' life-long behavioral styles and preferences, as well as documentation of the existence and type of an advance directive.

Field Testing

As with all research instruments, extensive field testing and reliability testing were undertaken. Numerous sets of independent reliability trials were undertaken during the development processes. The results of these reliability studies clearly demonstrated that when MDS data are gathered in a research context, it is possible to obtain reliability levels that make the data useful for research purposes. The MDS items met traditional standards of good reliability in key areas of functional status such as cognition, activities of daily living (ADL) performance, continence, and disease diagnoses.

Development of reliable data on the functional status of nursing home residents is a task that largely defies traditional approaches to measurement. Nursing home residents are a special population and present special measurement challenges. Most nursing home residents have some level of cognitive impairment and exhibit behavior changes. The abilities and status of many nursing home residents with physical or cognitive impairments vary throughout the day and over time. Still others have communication difficulties that impede traditional research interview interactions. These characteristics seriously limit the effectiveness of simple "point in time" estimates of a resident's status, no matter how well standardized, and argue against relying on a single informant, which is the usual approach with research instruments. For these reasons, the assessment approach incorporated in the MDS relies on the input of multiple individuals who interact with the resident throughout the course of the day or night.

As part of an evaluation of the national implementation of the MDS, the quality-of-health status and the resident assessment information in the

residents' charts before and after the implementation of the MDS was addressed. Research nurses extracted data from a sample of more than 2,000 nursing home residents in more than 250 randomly selected facilities in 1990 and again in 1993. The analyses revealed that, in 1990, accurate information was available in 68% of the items in the patients' records, whereas in 1993, that average had climbed to 84%. Although accuracy levels from records sampled from participating nursing homes varied considerably in the 10 states studied, in all cases there was an improvement in data accuracy associated with the introduction of the MDS.

The most recent reliability study of the MDS compared the assessments performed by *facility* nurses—on between 25 and 30 residents from more than 250 facilities located in 10 states—with those undertaken by *research* nurses uniformly trained by a team of researchers. Of the more than 100 items evaluated, almost all revealed high levels of reliability, although there was substantial inter-facility variation that suggests that some facilities departed from the standard approach. These findings are consistent with studies finding substantial disagreement between selected MDS items in residents' charts and research data collected about the same residents.

Clinical Scales

The utility of the MDS for clinical and research applications has been further enhanced by the development of concise and clinically meaningful scales summarizing the functioning of individual residents. For example, the Cognitive Performance Scale, which replicates the mini-mental-status exam at an accuracy of nearly 90%, has been developed from items in the MDS. Similarly, an ADL scale that captures the hierarchy of ADL performance has been formulated and a new measure of “social engagement” developed, which is one of the first efforts to quantify a qualitative aspect of the personal and social interactions of an individual in a nursing home. Other summary measures of items in the MDS include measures of mood, behavioral disruption, medical instability, and more refined aspects of cognitive and executive functioning, including qualitative features of dementia.

Computerized Data

To facilitate ongoing quality monitoring and case-mix reimbursement for both Medicare and state Medicaid programs, the Centers for Medicare and Medicaid Services (CMS) mandated the computerization of all MDS data in 1998. Since then, all MDS assessments are computerized and transmitted to a national repository maintained by CMS. These data are used (a) by state regulators charged with inspecting nursing homes to ensure compliance with the Medicare and Medicaid conditions of participation, (b) by Medicare and some state Medicaid programs to differentially pay facilities as a function of the acuity of their residents, and (c) to create quality measures that are publicly reported on national Web sites to assist individuals and their families in selecting a nursing home. Furthermore, nursing facility management—as a stimulus to guide and initiate internal quality improvement efforts—increasingly uses MDS data on residents' acuity, pattern of services use, and quality.

Use for Policy, Regulatory, and Quality Improvement

The MDS is being extensively used for policy, regulatory, and quality improvement purposes. The new measure of resident case-mix, which is being used to reimburse facilities differentially (Resource Utilization Groups—III), is based on the MDS. State regulators inspecting nursing homes also use the MDS in residents' charts to determine whether the residents assessed as potentially having selected care needs are getting the relevant services. Finally, drawing on the concepts of statistical quality improvement, quality indicators are being developed as benchmarks against which nursing homes can compare their quality of performance.

The impact of the nationally mandated MDS for U.S. nursing home resident assessment has been profound. The MDS has also been adopted in other nations. As of 2008, the MDS has been translated into 20 languages (e.g., French, Spanish, Italian, Swedish, German, Chinese, Japanese, and Korean). Canada and Iceland have adopted a version of the MDS as the basis for reforming their own nursing home programs and to institute

case-mix reimbursement and quality management programs. Finland, Germany, Italy, and Switzerland have instituted experiments in large geographic areas. An international organization, the InterRAI, has been formed with the express purpose of sharing experiences in implementing the MDS as (a) a clinical-care-planning tool, (b) an administrative information system for management decisions, and (c) a basis for policy analysis of a nation's health-care system.

Future Changes

The original, national Institute of Medicine (IOM) recommendations suggested that the MDS not be static. In keeping with that suggestion, CMS commissioned an early redesign of the initial instrument, and this was implemented in 1996. Nearly a decade later, CMS has announced that it will be introducing a major redesign of the MDS (Version 3.0) in 2009. This new instrument has the benefit of many years of additional research on the utility of various measures of quality, functional performance, and clinical-care needs. It also has benefited from considerable additional research focused on capturing the "voice" of the residents' experiences and quality of life. Changes from the earlier versions include a focus on directly interviewing the residents and an emphasis on their quality of life in addition to their quality of care. This means that facility staff will first attempt to directly ask residents questions about their experience in the home, with all the associated problems of response acquiescence, residents' unwillingness to complain, and cognitive impairment difficulties. Whereas earlier versions of the MDS appeared to underestimate the prevalence of psychosocial problems, it is likely that new difficulties will arise with the revised version. Nonetheless, in keeping with the spirit of the original recommendation, resident assessment instruments must be dynamic, reflecting the changing context of nursing home care and the case-mix of the patients served.

In many ways, the introduction of the MDS has catapulted the nursing home industry into the information age. It is possible, given the implementation of the MDS, that the goals of the IOM recommendations may be reached and that ongoing comprehensive assessment may actually have a

positive impact on the quality of care for nursing home residents.

MORAL HAZARD

Moral hazard arises in implicit and contractual relationships in which one party behaves differently because of the relationship, and these actions improve one party's utility but have a negative consequence for the other party. In healthcare, moral hazard is most commonly associated with insurance, where the purchase of health insurance induces an increase in the likelihood of a loss covered by the insurance policy, the size of the loss, or both the likelihood and size of the loss.

Asymmetric Information

Moral hazard arises because of asymmetric information between the two parties. When one party, the *agent*, has more information than another party, the *principal*, in a relationship, the agent can take actions that are not observable to the principal and that benefit the agent but are costly to the principal. If the information and actions were perfectly observable to both parties, the agent would be unlikely to take these actions. For example, an individual without auto insurance may take many precautions to prevent his or her car from being stolen: He or she may only park the car in security-monitored parking lots, install a security system, and make certain that no valuables are left in plain sight in the car. If this individual purchases an auto insurance policy that fully insures against theft, the individual may not take any of these precautions—he or she may park in high crime areas, not use a car security system, and leave valuables in plain sight in the car—because the individual knows that the insurance company will reimburse him or her if the car is stolen. As the insurance company cannot monitor how the individual safeguards the car against theft, these actions benefit the individual; it takes less time and effort not to use these safeguards, but by not taking these actions, he or she increases the chance that the car will be broken into or stolen. In economic terms, this increases both the likelihood of a loss occurring and the size of the loss, if a loss occurs.

Although both moral hazard and *adverse selection* arise because of asymmetric information between parties, moral hazard is a “hidden action”

taken by the agent, which is not observable by the principal. Adverse selection, on the other hand, is known as a “hidden type” or “hidden information” problem where the principal cannot observe the characteristics of the agent before entering into an implicit or explicit contract, and the agent makes decisions about the relationship that benefit him or her but are costly to the principal.

Health Insurance

Moral hazard in health insurance can occur in two basic ways. *Ex ante* moral hazard occurs when an insured individual takes less preventive care than he or she would take if the individual did not have insurance, and these preventive-care efforts would reduce the likelihood or size of a loss covered by the insurance policy. The second type of moral hazard occurs *ex post*, when an individual demands more healthcare services when covered by an insurance policy than he or she would demand if the individual paid the full cost of healthcare. The evidence that *ex post* moral hazard exists in health insurance is quite strong. Although there has been less evidence in support of *ex ante* moral hazard, it is gaining attention in the health insurance market.

Ex ante moral hazard includes the actions taken by an insured individual prior to contracting an illness or disease that increase the probability of contracting the illness or increase the cost of medical care covered by health insurance once the illness is contracted. Examples of *ex ante* moral hazard include a lack of preventive care, for example, an unhealthy diet, sedentary lifestyle, and other health behaviors that increase the likelihood of obesity and chronic health conditions such as heart disease and diabetes. Through healthy-lifestyle behaviors such as a healthy diet and physical exercise, an individual can reduce the risk of these chronic conditions. The theory of *ex ante* moral hazard suggests that individuals who have insurance will invest in fewer healthy-lifestyle behaviors than those without health insurance because they do not bear the full cost of their unhealthy-lifestyle behaviors when covered by insurance.

Ex post moral hazard takes place after a loss occurs—in healthcare, this means after an individual becomes ill. Without health insurance coverage, an individual will purchase healthcare

services up to the point where the marginal cost of these services is equal to the marginal private benefit obtained from these services. Health insurance coverage reduces the marginal cost of these services that is paid by the consumer. Therefore, with health insurance coverage, the consumer still purchases services up to the point where his or her private marginal cost of these services equals his or her marginal private benefit. However, in that the consumer's marginal private cost is reduced, the quantity of services consumed is higher. As the generosity of a health insurance policy increases, ex post moral hazard also increases, because the consumer bears a smaller proportion of the cost of care. In the most extreme case where an insurance policy fully covers the cost of medical care and the consumer has no out-of-pocket costs, the consumer uses medical care up to the point where he or she obtains almost no marginal benefit from these services, even though the full cost of care is still paid by the insurer.

Solutions

Health insurers use a combination of mechanisms targeted at the demand for care (i.e., mechanisms that are targeted at consumers or enrollees) and the supply of care (i.e., mechanisms targeted at healthcare providers) to mitigate ex post moral hazard. Demand-side mechanisms shift some of the risk originally borne by the insurer to the enrollee through deductibles and coinsurance. Shifting risk to the enrollee increases the marginal cost of care consumed by the enrollee. Although increasing enrollee cost sharing mitigates moral hazard, the trade-off is a reduction in risk spreading, which is an inherent purpose of health insurance.

Supply-side mechanisms are strategies that target providers, including financial incentives such as reimbursement strategies and nonfinancial incentives such as the use of gatekeeper primary care physicians, second opinions, prior authorization, and review of usage. The use of capitated per-member-per-month compensation rather than per-unit fee-for-service reimbursement is one solution that has been used to reduce moral hazard. Fee-for-service reimbursement aligns the financial incentives of the healthcare providers with the enrollees, incentivizing the delivery of more

services or more expensive services than necessary. A shift to capitation removes the financial incentive to provide more than necessary care. Instead, the provider is incentivized to provide efficient services to treat an illness, aligning the provider's incentives with the health insurer rather than the enrollee, thereby reducing the extent of ex post moral hazard.

Solutions to mitigate ex ante moral hazard need to incentivize enrollees to obtain preventive care by reducing the financial and nonfinancial costs of taking preventive actions or by increasing the marginal costs of failing to take preventive actions. Health insurers may fully cover the costs of immunizations, for example, to encourage enrollees to obtain them.

Future Implications

The U.S. federal government and private health insurers alike have been promoting *consumer-directed health plans* (CDHPs)—high-deductible health plans with health savings accounts—as a mechanism to control increasing healthcare costs. CDHPs directly target ex post moral hazard. These plans shift a greater proportion of the risk to the consumer and, by increasing the consumer's cost, require him or her to share the burden. CDHPs give the consumer an incentive to search for and obtain the most efficient healthcare services. For CDHPs to be successful, however, both prices and information on the quality of care must be transparent and publicly available so that consumers can compare across both treatments and healthcare providers to identify the most efficient method and provider of care. Although the nation's healthcare industry is improving the dissemination of information on the quality of healthcare through Web sites such as Hospital Compare, information is not yet easily available to all consumers. For example, not all consumers have access to or know how to use the Internet. Furthermore, solutions to mitigate moral hazard must be balanced with trade-offs that increase the risk borne by the individual consumer. The nation's healthcare industry is still searching for the optimal combination of risk spreading and moral hazard.

MORBIDITY

The term *morbidity* comes from the Latin word *morbidus*, meaning a condition of being unhealthy or having a disease or an illness. Today, morbidity refers to an illness, disease, or disability. It also includes the burden caused by a health condition or the state of poor health. Morbidity is often measured using the incidence or prevalence rates of a disease in a population. Public health and health services researchers study the incidence rates of diseases to determine trends. For example, the incidence rate will show whether a specific disease is increasing or decreasing in a population. In contrast, the prevalence rate will show the overall burden of a disease, which may be used to

determine the resources needed and consumed for treatment.

Overview

Morbidity or illness greatly affects an individual's as well as a population's quality of life. When trying to define or measure the factors that cause some individuals to be unhealthy, it is important to also understand the concept of health. The determinants of health have been acknowledged by the World Health Organization (WHO) to include (a) the social and economic environment, (b) the physical environment, and (c) the person's individual characteristics and behaviors. As the leading causes of illness and death have shifted from infectious diseases to chronic diseases, there has been much work to better understand the social determinants of health and the causes of morbidity. Some commonly used indicators of a population's health include the presence of child abuse, poverty, youth suicide, alcohol-related traffic fatalities, teenage drug use, depression; social networks and social capital.

Measures of Morbidity

Since the mid-1800s, conditions affecting health status began to be measured in a routine and systematized manner in the United States. As a result, incidence and prevalence rates have been used to measure the presence and rate of illnesses or conditions that interfere with a population's well-being. The *incidence rate* is also known as the cumulative incidence or the number of new cases of a disease or condition, and the *prevalence rate* refers to the number of existing cases of a disease or condition in a population.

The incidence rate can be calculated and used whenever a condition (physical or mental health related) has a defined diagnosis. Incidence rates can also provide a measure of the risk of acquiring a particular condition. An example of the incidence rate of diabetes in a city of 141,000 residents with 535 new cases of diabetes in 2008 would require the following calculation: $535/141,000 = 0.00379$ or 3.8 per 1,000 population. Given that the incidence rate of diabetes was 0.4%, if an individual was a member of that population he or she had a 0.4% chance of getting diabetes. It should be

cautioned that extrapolating population data to individuals can be misleading because individual risk factors and behaviors vary widely.

The second common measure of morbidity is prevalence. For example, if a researcher was interested in the prevalence of breast cancer among women in a given city with 141,000 residents and there were 5,076 cases of breast cancer during 2008, the prevalence rate would be calculated as follows: $5,076/141,000 = 0.036$ or 36 per 1,000 population. Because prevalence also measures the total number of existing cases of a condition in a population, it can be used to determine the burden of that disease on society. In other words, knowing that 36 residents per 1,000 population, or 5,076 residents currently have breast cancer can give some guidance as to the demand for healthcare services as well as the public health programs that should be provided.

By examining the incidence and prevalence rates, the trends and patterns in the distribution of diseases can be studied. From this information, decisions can be made in terms of resource distribution and planning efforts for prevention and treatment.

In addition to the morbidity associated with specific conditions, it is important to be aware that in many populations, especially the elderly, there will be multiple morbidities (comorbidities) present at the same time. Thus, comorbidities must also be taken into account to understand the full burden of disease.

Measures of Disease Burden

Measures of morbidity, which generally include quality of life or years of life lost due to an increase in morbidity, are difficult to quantify. However, several measures of morbidity have been developed that combine the concepts of the number of years lived with the quality of those years. The two most commonly used measures are the disability-adjusted life year (DALY) and the quality-adjusted life year (QALY).

The DALY was developed by the Global Burden of Disease study by the WHO as a means of estimating the burden of disease in various parts of the world. This study not only looked at life expectancy tables but also factored in the burden of injuries, risk factors, and diseases. DALYs combine the effect

of years of life lost prematurely and the disability of a population. As a result, mortality and morbidity are combined into a single measurement.

QALY is another method of measuring the burden of disease by taking into account not only the quantity of years lived but also the quality of life. Each year of perfect health is rated as 1.0 and death is rated as 0. QALYs are often used in cost-utility analyses to measure the effectiveness of specific medical interventions. Regarding the use of QALYs, there have been several debates as to whether some years should actually be rated with negative numbers, because some conditions might be viewed as worse than death. Furthermore, it is difficult to define what is “perfect health.”

The Compression of Morbidity

Due to the increasing recognition of the growing burden of disease, there is now a greater emphasis on the *compression of morbidity*, that is, reducing the number of years that individuals are affected by chronic diseases. The goal of the compression of morbidity is to keep populations disease free for as long as possible. The objective of the compression of morbidity is to decrease the number of years that an individual suffers from disease at the same time maximizing his or her life span. It has been suggested that aging-related morbidity can be reduced through healthier lifestyles.

The Global Burden of Disease

In one of the most comprehensive research projects ever undertaken to look at the global burden of disease, the WHO identified the most important risk factors that are the causes of disability, disease, and death in the world today. Globally, the top 10 risks are (1) being underweight; (2) having unsafe sex; (3) having high blood pressure; (4) using tobacco; (5) consuming alcohol; (6) having unsafe water, sanitation, and hygiene; (7) having iron deficiency; (8) having indoor smoke from solid fuels; (9) having high cholesterol; and (10) being obese.

In developing countries, such as those in sub-Saharan Africa, being underweight is the major cause of disease burden; this condition also affects hundreds of millions of the poorest people throughout the world. On the other hand, in developed

countries the leading risks of disease are tobacco use, alcohol consumption, high blood pressure, high cholesterol, and obesity. A disturbing finding from this report was the conclusion that the world is living more dangerously than ever before. In regard to health, this is because the poor have few choices in their lives, and those not limited by poverty who do have choices make the wrong choices concerning their health behaviors and activities.

Future Implications

Measuring and understanding the determinants of morbidity are key to ensuring the health and vitality of a population. As the leading causes of morbidity and mortality in developed countries shift from infectious to chronic diseases, appropriate health planning must be undertaken. Additionally, in developing countries, the urgent need to stem the rise in infectious diseases is paramount to decrease the burden of morbidity and improve the quality of life.

MORTALITY

Mortality is simply defined as death, and it is the end result of life. A *mortality rate* is the proportion of deaths in a given place over a specified period of time. The numerator includes the number of persons who died in a given geographic area over a period of time, and the denominator is the total population in the same geographic area. The mortality rate is generally reported as a proportion of deaths per 1,000, 10,000, or 100,000 individuals. In health services research, mortality rates are often used as general indicators of the health and well-being of groups and populations.

Overview

Mortality rates are based on death data that come from *vital statistics registries*. Vital statistics include all the prominent life events: births, marriages, divorces, and deaths. The registration of all these life events is required in the United States, and state health departments compile vital statistics summaries on deaths. The primary source of death information in the United States is the standardized death certificate, which is kept by individual state health departments and is completed by physicians or coroners at the local level. The major components of the death certificate include personal identifiers, demographic information, and the manner and cause of death.

Mortality Rates and Ratios

There are many types of mortality rates and ratios, for example, the *crude mortality rate*,

age-standardized mortality rate, disease-specific mortality rate, and infant mortality rate. Each type of mortality rate and ratio has its specific uses and limitations. The following are the most common types of mortality rates.

The Crude Mortality Rate

A crude mortality rate represents a rough estimate of mortality and is seldom used because it does not take into account the variations in a group's or population's age composition. The crude mortality rate is calculated by taking the total number of deaths during a 1-year period divided by the total population midyear for a specified geographic area. The rate is usually presented as deaths per 100,000 individuals. Crude mortality rates can sometimes be misleading. For example, a developed country may have a higher crude mortality rate than a developing country because of the increased number of elderly who may die in a given year. Therefore, mortality rates generally should be standardized to reflect this difference in population characteristics.

The Age-Standardized Mortality Rate

An age-standardized mortality rate is determined by taking the number of deaths in a specific age cohort occurring during 1 year divided by the midyear population of the specific age cohort. The derived rate is usually presented in terms of deaths per 1,000 or 100,000 individuals. Age-specific rates are refinements on the crude mortality rates. Note that, in putting a limitation on age, the same restriction must be applied to both the numerator and denominator, so that every individual in the denominator group will be at risk for entering the numerator group.

The Disease-Specific Mortality Rate

The disease-specific mortality rate is specified for a certain disease, such as tuberculosis or HIV/AIDS. The numerator in this rate is the number of deaths from a specific cause or disease and the denominator is the total population at midyear. Again, these rates are usually expressed in terms of annual mortality figures from a specific cause per 1,000 or 100,000 individuals.

The Case Fatality Rate

The case fatality rate is a measure of how severe a disease is and is usually reported as a percentage. The case fatality rate is calculated by taking the number of deaths from a specific cause after the onset of the disease (i.e., after diagnosis) during a specified period of time divided by the number of cases of the disease, multiplied by 100. This "rate" illustrates the percentage of individuals who die from a specified disease within a certain time after diagnosis.

The Proportional Mortality Ratio (PMR)

The PMR is a measure of the proportion of deaths from a specific disease compared with all deaths. The PMR is calculated by taking the total number of deaths from a certain disease over a specified period of time divided by the total number of deaths from all causes in the identical period of time. The PMR does not measure the risk of dying from a specific disease: The proportions change as a result of increases or decreases in the mortality rates of other diseases.

The Maternal Mortality Rate

The maternal mortality rate is calculated by dividing the number of deaths from childbearing causes during 1 year over the total number of live births during the identical year. This proportion is usually reported as deaths per 100,000. The maternal mortality rate measures the number of mothers who die giving birth.

The Infant Mortality Rate

The infant mortality rate is an overall measure of infant deaths. The numerator for this death rate is the number of children under the age of 1 who die over a 1-year period, and the denominator is the total number of live births during the same year. The result is typically multiplied by 1,000 to calculate a rate of infant deaths.

The Perinatal Mortality Rate

The perinatal mortality rate measures the number of infant deaths occurring around the period of

birth. The perinatal mortality rate is calculated by taking the number of fetal deaths and the number of infants under 1 week of age who die during a period of a year divided by the total number of live births plus the total number of fetal deaths in the same year. This rate is typically expressed as deaths per 1,000.

The Neonatal Mortality Rate

The neonatal mortality rate is calculated by dividing the total number of children under 28 days old who die during a particular year by the number of live births during the same year. This rate is usually multiplied by a factor of 1,000.

The Fetal Mortality Rate

The fetal mortality rate is calculated by dividing the number of fetal (unborn infant) deaths during a particular year by the total number of live births plus fetal deaths during the identical year. This rate is usually multiplied by a factor of 1,000.

The Standardized Mortality Ratio (SMR)

The SMR is used to examine the differences in death rates between what is observed and what is expected. It is calculated by dividing the number of individuals who die per year by the number of individuals expected to die during the same year multiplied by 100. An SMR of less than 100 indicates that the observed deaths are less than what is expected, a value of 100 shows that the number of expected deaths is equal to the number of observed deaths, and an SMR of more than 100 demonstrates that observed deaths are greater than what is expected.

The Years of Potential Life Lost (YPLL)

The YPLL is a mortality index that has been used increasingly in recent years. It indicates the number of "years lost" as a result of an early death. It is calculated by first subtracting an individual's age at death from a standard age of life expectancy (generally, 65 years old). The smaller the subtrahend, the larger is the number of years of potential life lost. This calculation yields the YPLL for one individual. To calculate YPLL for the

entire population, the YPLLs for all individuals are added together for a specific cause of death. YPLLs can be used to compare the causes of premature deaths.

Sources of Mortality Data

There are several sources of mortality data that are available to health services researchers. Information from death certificates is aggregated in comprehensive mortality databases and is reported by various federal agencies. Data may also be collected by agencies at the time of death for the purposes of issuing survivor benefits. Researchers may need this information on mortality and the cause of death to calculate a variety of mortality rates, to assess survival rates for a disease of interest, or to verify deaths in a multisite clinical trial.

The Morbidity and Mortality Weekly Report (MMWR)

The MMWR is published weekly by the U.S. Centers for Disease Control and Prevention (CDC). This publication originated from the National Quarantine Act, passed by the U.S. Congress in 1878, requiring American Consuls to file reports on conditions abroad and on vessels bound for U.S. ports. From these reports, the surgeon general of the U.S. Public Health Service (PHS) prepared weekly abstracts for transmission to PHS officers, collectors of customs, and state and local health authorities. The format, content, and sponsoring government agencies have changed over the years until, in 1961, the CDC published its first issue of MMWR. The MMWR is the only regular weekly periodical published in the United States that documents morbidity from all 50 states and 5 territories and mortality from 121 cities that represent one third of the nation's population.

The National Death Index (NDI)

The NDI was created in 1981 by the National Center for Health Statistics (NCHS) in response to a growing need for a national source of mortality data. The NDI is compiled from death certificate data received from all 50 state health departments. It is particularly useful to verify large numbers of

deaths. The NDI is considered to be the gold standard of death databases; however, it is available only to researchers in medical and health sciences research for statistical purposes. There is a cost associated with the NDI data and suitable projects must be approved by NCHS, which necessitates additional time as the review and approval of projects may take several months.

The Death Master File (DMF)

The DMF is compiled and maintained by the U.S. Social Security Administration (SSA) and is only one of several mortality databases available to the public: For small studies, where the verification of only a few deaths is necessary, Web searches may be quickly and easily completed at no cost. SSA data depend on an individual having a Social Security number, and the death must have been reported to the SSA. The DMF contains only basic information on each decedent. However, once the verification of death has been confirmed, researchers can then procure the death certificates from the appropriate state agencies. The cause of death information also can be acquired from the SSA.

The Beneficiary Identification and Records Locator Subsystem (BIRLS)

The BIRLS is a death database maintained by the U.S. Department of Veterans Affairs (VA). This database was created in the 1970s as an update to a manual system designed to collect information for veterans' benefit programs. The majority of BIRLS records are of veterans whose survivors applied for death benefits. The inclusion of a veteran's death record depends on the submission of a copy of the individual's death certificate to the VA. This database has two major limitations: First, it only contains data on U.S. veterans, and second, it is only available to VA researchers.

The World Health Organization (WHO) Mortality Statistics

The WHO statistics include mortality information from WHO member states around the globe. WHO collects and distributes data on (a) mortality,

(b) estimates on causes of deaths and the global burden of disease, and (c) statistics on life expectancy. Mortality rates can be compared and contrasted across nations as much of the WHO data collected are universally standardized. For example, the cause of death information is reported for all countries using International Classification of Diseases (ICD) codes.

Future Implications

Mortality data play an important role in health services research studies because it provides a general indication of a population's health as well as the trends and patterns in the leading causes of death. As the demographics of populations shift, mortality data will continue to be used to examine the demand and need for specific healthcare services. Mortality rates are also used as one measure of the quality of care provided by healthcare institutions and systems.

MORTALITY, MAJOR CAUSES IN THE UNITED STATES

For decades, heart disease, cancer, and stroke have been the top three leading causes of death in the United States. Deaths from heart disease, cancer, and stroke together account for almost 60% of all deaths in the nation. The prevalence of these three major diseases has important implications for the delivery, organization, and exploitation of healthcare services. It also guides public health policy and programmatic efforts at the national, state, and local levels. Mortality trends, risk factors, and the prevention of each disease are discussed below.

Heart Disease

Heart disease is the leading cause of mortality in the United States with about 700,000 deaths occurring annually, accounting for approximately 29% of all deaths in the nation. Heart disease, also known as cardiovascular disease, encompasses a number of abnormal conditions, including coronary heart disease (CHD) and hypertension (high blood pressure), that affect the heart and its blood vessels. CHD is the most common type; it leads to hardening and narrowing of the arteries, making it harder for blood to reach the heart. It can lead to angina (chest pain or discomfort), myocardial infarction (heart attack), congestive heart failure, or arrhythmia (abnormal heart beat).

Mortality Trends

Mortality rates for CHD rose in the United States during the period from 1949 to 1967 and have been declining since, particularly for acute myocardial infarction and chronic ischemic heart

disease (CIHD). Death rates decreased steadily from 1968 to 1981, but the decrease has begun to slow. An increasing number of people survive their first heart attack.

The mortality declines have been attributed to prevention efforts as well as to improvements in medical care. There have been substantial decreases in the prevalence of some of the major cardiovascular risk factors such as smoking, elevated total cholesterol, and high blood pressure. Advances in medicine have led to a revolution in the treatments for established heart disease, with major breakthroughs in evidence-based medical and surgical techniques, including the use of coronary artery bypass grafting, coronary angioplasty, and stents. Despite overall declining trends, heart disease mortality is still a disparate burden on minority populations.

Risk Factors

Extensive research has identified both the major and contributing risk factors associated with an increased risk of developing CHD, but their exact significance and prevalence have not been precisely determined. Some of these risk factors are modifiable, whereas others are not. The risk of developing CHD is directly proportional to a person's number of risk factors as well as to the level of each risk factor.

Major nonmodifiable CHD risk factors include age, male gender, and heredity, including race. The children of parents with heart disease are more likely to develop the disease. African Americans, who tend to have more severe high blood pressure than Whites, have a higher risk of heart disease. The risk of heart disease is also higher among Mexican Americans, American Indians, native Hawaiians, and some Asian Americans than among Whites. Major modifiable risk factors include smoking, high blood cholesterol, high blood pressure, physical inactivity, obesity and being overweight, and having diabetes mellitus. Additional factors contributing to CHD risk include stress and excessive alcohol intake.

Prevention

Taking steps to prevent and control the known risk factors can reduce the occurrence of CHD.

Additionally, knowing the signs and symptoms of a heart attack, calling for emergency medical services, and immediately going to a hospital are crucial to positive outcomes. People who have had a heart attack can also work to reduce their risk of future attacks.

Despite our greater understanding of the risk factors of CHD, the prevalence of both obesity and diabetes in the U.S. population has increased over the past 25 years, with approximately 34% of adults aged 20 and over being obese. The rising prevalence of obesity and diabetes may reverse the decline in CHD-related deaths. Aggressive public health programs to control these risk factors are urgently needed.

Cancer

Cancer is the second leading cause of mortality in the United States with about 500,000 deaths occurring annually, accounting for approximately 23% of all deaths. Cancers, also called *malignant neoplasms*, include a large group of diseases in which abnormal cells divide without control and can invade healthy body tissues. Cancer cells can spread to other parts of the body through the blood and lymph systems. There are more than 100 different types of cancer. Lung cancer is the most common cause of cancer-related deaths in the United States for both men and women, resulting in approximately 157,000 deaths each year. Among men, prostate cancer mortality is second, followed by colon and rectum cancer. In women, lung cancer, breast cancer, and colon and rectum cancer are the leading types of fatal cancers. Among women, breast cancer is the most common cancer and the second most common cause of cancer death, with approximately 40,000 deaths per year.

Mortality Trends

Whereas the rates for other major chronic diseases have decreased substantially since 1950, cancer-related death rates showed a steady increase until the 1990s. The death rate from all cancers combined has decreased by 1.6% per year since 1993 for men and 0.8% per year since 1992 for women. The first decline in the number of cancer

deaths occurred in 2003, when there were 369 fewer cancer-related deaths than in 2002. From 2003 to 2004, the number of recorded cancer deaths decreased by 1,160 in men and by 1,854 in women. Compared with the peak rates in 1990 for men and 1991 for women, the cancer death rate in 2003 was 16.3% lower for men and 8.5% lower for women.

Among men, most of the increase in cancer death rates prior to 1990 was attributable to lung cancer. Since 1990, the age-adjusted lung cancer death rate in men has been decreasing. Death rates from prostate and colorectal cancers have also decreased. Among women, lung cancer is currently the most common cause of cancer death, with the death rate more than twice what it was 25 years ago. Breast cancer death rates were constant from 1930 to 1990 but have since decreased by about 24%. The death rates for stomach and uterine cancers have decreased steadily since 1930; colorectal cancer death rates have been decreasing for more than 50 years.

Overall, *cancer incidence rates* are higher in men than in women. Among men, African Americans have the highest incidence followed by Whites, Hispanics, Asian Americans/Pacific Islanders, and American Indians/Alaskan Natives. Racial differences in cancer incidence among women are less pronounced; White women have the highest incidence rates followed by African Americans, Hispanics, American Indians/Alaskan Natives, and Asian Americans/Pacific Islanders.

Overall, *cancer death rates* are higher for men than for women in every racial and ethnic group. African American men and women have the highest rates of cancer mortality. Death rates for myeloma and cancers of the prostate, larynx, stomach, oral cavity, esophagus, liver, small intestine, colon and rectum, lung and bronchus, and pancreas are all higher in African American men than in White men. Death rates for African American women are also higher than for White women for myeloma and cancers of the stomach, cervix, esophagus, larynx, uterus, small intestine, pancreas, colon and rectum, liver, breast, urinary bladder, gallbladder, and oral cavity. Although cancer death rates are higher in African American men and women than for their White counterparts, the cancer death rate is declining faster for African Americans than for Whites.

Risk Factors

A number of cancer risk factors have been identified, including increasing age, family history of cancer, environmental factors, and lifestyle factors. As with heart disease, some of the risk factors are modifiable and others are not. Perhaps the most recognized and preventable cancer risk factor is tobacco use. Research clearly indicates that tobacco use is a major cause of cancer-related deaths. It has been estimated that cigarette smoking accounts for 85% of all lung cancers in smokers. Another risk factor is postmenopausal obesity, which is associated with breast cancer due to the conversion of adipose tissue to estrogen. A lack of vitamins B and D may also be a risk factor for breast, prostate, and colon cancers.

Prevention

To lower the risk of developing cancer, the American Cancer Society recommends (a) avoiding tobacco products, (b) consuming a diet rich in fruits and vegetables and low in saturated fats, and (c) exercising moderately and maintaining a healthy weight. Specifically, the society recommends eating five or more serving of fruits and vegetables a day, which may protect against cancers of the mouth and pharynx, esophagus, lung, stomach, and colon and rectum. It recommends that adults engage in at least moderate physical activity for 30 minutes or more on 5 or more days a week.

Stroke

Stroke is the third leading cause of mortality in the United States; about 160,000 stroke deaths occur annually, accounting for approximately 7% of all deaths. Stroke, sometimes referred to by the older term *cerebrovascular accident* (CVA), occurs due to interrupted blood flow to an area of the brain. This may be caused by an arterial blockage or rupture. Hence, stroke is classified into two major types: ischemic (blockage) or hemorrhagic (rupture). *Ischemic stroke* can occur due to thrombosis, embolism, or systemic hypoperfusion. *Hemorrhagic stroke* can result from intracerebral hemorrhage or subarachnoid hemorrhage. Approximately 80% of strokes are due to ischemic cerebral infarction and 20% to brain hemorrhage. A transient

ischemic attack (TIA) is defined clinically by the temporary nature of the associated neurological symptoms, which last less than 24 hours by the classic definition. Recognition of a TIA is crucial because it is an important predictor of future ischemic events.

Regardless of the cause, an interrupted blood supply to the brain results in cell damage and neurological injury. Consequently, functions controlled by the affected area of the brain, such as speech, movement, and memory, may be lost. The outcome depends on the location and extent of the brain area damaged. A small stroke may result in only minor problems such as weakness of an arm or leg. Larger strokes may result in paralysis on one side of the body or loss of the ability to speak. Some people suffer transient loss of function and recover completely from strokes. More than two thirds of survivors, however, experience some type of residual disability as well as emotional problems.

Strokes can occur at any age. However, the risk of having a stroke more than doubles for each decade a person lives beyond the age of 55. Nearly 75% of all strokes occur in people over the age of 65. Stroke death rates are higher for African Americans than for Whites, even at younger ages.

Mortality Trends

Overall, stroke mortality declined steadily from 1950 through the mid-1970s, then increased. During 1979 to 1989, stroke mortality declined one third more rapidly than the other 10 leading causes of death. Recent data, however, suggest that there is a slowing of the decline in stroke mortality rates. For the period 1968 to 2005, the decrease in stroke mortality rates appears to be due to improving survival rates rather than from a decline in the incidence of stroke.

The constant morbidity rates combined with constant rates of high blood pressure highlight the need for improved prevention to reduce the number of strokes. For several decades, the southeastern United States has had the highest stroke mortality rate in the nation and has been described as the "stroke belt." It is not clear what factor or factors contribute to the higher incidence and mortality from stroke in this region.

Risk Factors

Some of the risk factors for stroke are non-modifiable, such as age, gender, and race. The risk of stroke increases with age. Males are more susceptible overall to having a stroke, but women aged 35 to 44 are also susceptible—possibly due to pregnancy and oral contraceptive use—as are women over age 85. One's family history, environment, and lifestyle also influence the risk of having a stroke.

Modifiable risk factors for stroke include high blood pressure, smoking, diabetes, asymptomatic carotid stenosis, atrial fibrillation, and hyperlipidemia. Blood pressure, especially systolic blood pressure, increases with age. Isolated high systolic blood pressure (more than 160 mmHg) is an important risk factor for stroke in the elderly. Smoking causes reduced blood vessel distensibility leading to increased arterial wall stiffness. Smoking is also associated with increased fibrinogen levels, increased platelet aggregation, decreased high-density lipoprotein (HDL) cholesterol levels, and increased hematocrit. Diabetes is a risk factor for atherogenesis and leads to obesity, high blood pressure, and hypercholesterolemia. Hyperlipidemia also contributes to atherogenesis and, hence, stroke. In older persons, congestive heart failure is an important risk factor for stroke. Other factors that may be risk factors for stroke include obesity, physical inactivity, poor nutrition, alcohol abuse, drug abuse, sickle-cell anemia, hormone replacement therapy, and oral contraceptive use.

Prevention

To prevent the occurrence of stroke, regular adult screening for high blood pressure at least every 2 years is recommended for appropriate management, evaluation, and treatment. Appropriate control of high blood pressure for patients with Type 1 or 2 diabetes significantly reduces their incidence of stroke, whereas blood glucose control has been proven to be less effective. The long-term use of anticoagulants such as aspirin and warfarin, especially for individuals with atrial fibrillation, has been shown to decrease stroke mortality. Patients with coronary disease and hyperlipidemia should be managed with statins to lower the risk of stroke. Last, patients who smoke should be encouraged to stop.

Intersecting Risk and Prevention Pathways

Although heart disease, cancer, and stroke are separate diseases, they have many overlapping risk factors and prevention pathways. Obesity, physical inactivity, and tobacco use as well as high blood cholesterol, high blood pressure, and diabetes are risk factors for heart disease, some cancers, and stroke. For example, cigarette smokers are more likely to develop heart disease than are non-smokers, smokers have a much higher incidence of lung cancer than nonsmokers, and smoking approximately doubles a person's risk for stroke.

Responding to public health campaigns, millions of Americans have changed their eating habits, reducing saturated fat in their diets and lowering their serum cholesterol levels. Fewer adults are smoking cigarettes. More people with hypertension are being treated to control their high blood pressure. And millions of people exercise during their leisure time. These changes in lifestyle have significantly contributed to the decline in heart disease, cancer, and stroke deaths. At the same time, however, a large number of people continue to be physically inactive and are overeating, gaining weight, and becoming obese. In addition, these three diseases may all occur at any age from childhood to adulthood. And many adolescents and teenagers are engaging in unhealthy behaviors such as smoking.

Further reducing major risk factors such as high blood pressure, high blood cholesterol, tobacco use, diabetes, physical inactivity, and poor nutrition could eliminate much of the incidence of heart disease and stroke as well as some cancers. Determining effective prevention measures and therapy is increasingly important for both understanding past disease trends and planning future preventive and therapeutic strategies.

MULTIHOSPITAL HEALTHCARE SYSTEMS

Multihospital healthcare systems are defined as two or more hospitals owned, leased, sponsored, or contract managed by a central organization. They are also sometimes referred to as *hospital chains*. In 2006, the American Hospital Association (AHA) reported a total of 369 multihospital healthcare systems in the United States. These systems contained 2,755 hospitals, nearly 56% of all

U.S. hospitals. The vast majority of the systems, 299, or 81%, were not for profit. Of the remaining systems, 65 were investor-owned (for-profit) and 5 were government-owned organizations.

Horizontally and Vertically Integrated Systems

Multihospital healthcare systems are often differentiated as being either horizontally integrated or vertically integrated systems. The term *horizontally integrated system* refers to groups of similar organizations providing similar services (e.g., two or more community hospitals). The primary goal of developing a horizontally integrated system is generally to capture the market for a particular service within a specific geographic location. These types of multihospital systems tend to be in close geographic proximity to one another. *Vertically integrated systems* attempt to link different levels of healthcare services (e.g., primary care, acute care, and postacute care) together to move toward providing full service delivery. Such multihospital systems may include the ownership of managed-care organizations, for example, that can serve as feeders to the inpatient facilities. This type of multihospital system can be dispersed across a wide geographic area (e.g., in different states). Most multihospital healthcare systems in the United States are vertically integrated.

Reasons for System Integration

There are a number of reasons cited regarding the benefits—to an autonomous, freestanding hospital—of joining a multihospital healthcare system. One of the primary goals of integrating into multihospital systems is to achieve economies of scale and scope in delivering healthcare. In theory, when hospitals integrate into a system, they can take advantage of significant cost savings in organizational operation. These economies can be achieved in a variety of ways. First, multihospital systems may be able to reduce costs by receiving volume discounts on the purchase of services and supplies. Second, equipment and service costs can be reduced by eliminating overlap and duplication. Third, administration costs can be reduced by centralizing functions such as marketing, legal, human resource management, and planning.

A second perceived benefit of systems integration is the spreading of financial risk. In theory, members of multihospital systems are better able to absorb the financial impact of a turbulent healthcare environment than are freestanding hospitals.

Third, multihospital systems help hospitals provide better-coordinated patient care. In a vertically integrated system, for example, it may be possible to provide a full array of patient care services without having to refer the patient to an outside provider. Such a system can provide the continuum of care from primary care through inpatient care to postacute or long-term care.

A fourth factor cited as being a benefit of integration is increased administrative efficiency. By centralizing many administrative functions, it is possible to standardize many processes, including planning, marketing, human resource management, and quality improvement strategies.

Finally, all the benefits listed above can be enhanced through the development of an integrated, systemwide information system. The ability to have current, accurate information on all phases of the system's operation enhances its ability to both respond and be proactive to enhance success.

The empirical evidence on whether such benefits have actually been achieved is not clear. Although some multihospital systems report reductions in operational costs, in general, such claims of gains seem exaggerated. The most recent data available indicate, for example, that the average total cost per occupied hospital bed is higher in multihospital systems than in autonomous freestanding hospitals. Vertically integrated systems owning managed-care organizations do seem to have lower costs than systems without such ownership. This may indicate that a useful gatekeeper function is being performed by the systems' health maintenance organizations (HMOs).

The Veterans Administration

One of the largest vertically integrated multihospital systems in the nation is operated by the Veterans Administration (VA). Its mission is to provide a full array of healthcare services to U.S. military veterans. The veterans healthcare system is headed by the undersecretary of health and is

funded by federal tax dollars. The fiscal year 2008 budget for the Veterans Health Administration (VHA), which runs hospitals and other health facilities, was in excess of \$36 billion, which represents more than 40% of the VA's total annual budget. The VHA operates 153 medical centers and 724 community-based outpatient centers across the nation and employs more than a quarter of a million people.

The operation of the VA as a system is one example of successful integration. According to Phillip Longman, VA hospitals have moved from being some of the worst healthcare providers in the nation to some of the very best. The benefits derived from running the VA with systemwide standards of care, safety, and quality improvement have been substantial and have occurred in a relatively short time frame.

Future Implications

The general trend in the percentages of hospitals integrated into multihospital healthcare systems—over the 5 most recent years for which AHA data are available—indicates an increase. The percentage of hospitals in systems has risen from less than 46% to nearly 55% between 2001 and 2005.

Although the evidence is mixed on whether multihospital healthcare systems deliver the potential benefits noted earlier, it is apparent that they offer some advantages. As the healthcare environment continues to remain turbulent, autonomous freestanding hospitals will feel pressure to band together with other institutions to ensure their survival.

N

NATIONAL ALLIANCE FOR THE MENTALLY ILL (NAMI)

Founded in 1979 by family members of seriously compromised mental health consumers in Wisconsin, the National Alliance for the Mentally Ill (NAMI) is one of the nation's largest grassroots health organizations. With a national office in Arlington, Virginia, and state-based organizations in all 50 states, NAMI is well connected to communities across the country. NAMI organizations and their supporters strive not only to improve the quality of life of those who suffer from mental illness but also to eliminate mental illness all together. Although NAMI started out with the purpose of supporting consumers of mental healthcare, it now also supports family members of those who have mental illness. NAMI supporters include a variety of community leaders, educators, healthcare providers, researchers, advocates, and families. The organization is open to all who are interested in membership.

Education and Training

Education and training opportunities through NAMI are targeted to four major audiences: consumers, families and caregivers, the general public, and providers. Consumer education includes multimedia presentations, a NAMI support group, and the Peer-to-Peer program, which offers individualized information.

Education for families is delivered through the Family-to-Family program, which provides education for family members of those with mental illness and a multimedia presentation, *Hearts and Minds*, which aims to decrease heart disease among mental health consumers.

Trained consumers prepare and present programs for the general public to community groups through an educational speakers' bureau that demonstrates recovery and provides accurate education about mental illness. The general efforts include the multimedia presentation *In Our Own Voice*. Parents and Teachers as Allies is a program specific to educators that is provided by teachers who are trained mental health consumers and family members.

Education for providers includes the NAMI Provider Education course, taught by consumers, consumers' family members, and mental health professionals, which offers 10 weeks of training for mental health providers.

Advocacy Functions

NAMI's initial purpose was to protect the most disabled mentally ill individuals who could not advocate for themselves. Rather than focus solely on the patient, NAMI encourages a partnership between healthcare teams, consumers, and their families. Today, NAMI is advised by the Consumer Council and provides numerous avenues for consumer support.

The NAMI on Campus initiative provides student-led support to fellow students who either have mental illness or are affected by it in another

way. Services include education for students, faculty, and college administrations; advocacy for students with mental illnesses; and promotion of early detection and treatment. Efforts to counter the effects of stigma against mental illness are of equal importance.

NAMI's Multicultural Action Center (MAC) was created in response to reports by the Surgeon General and the national Institute of Medicine (IOM) regarding the extreme toll that lack of quality treatment for mental health has taken on our country. The center seeks to secure culturally sensitive access to mental health services for all persons and their families, especially people of color, who are disproportionately represented among consumers who receive low-quality mental health services or none at all. Current priorities regarding policy changes for the center include health disparities; culturally competent services, including proper language fit between providers and consumers; research, particularly in the area of genetics, children and adolescents with mental illness, and depression; and the overrepresentation of mental illness in correctional systems. In connection with the group's Support Technical Assistance Resource (STAR) Center, MAC produces a newsletter called *Recovery for All*.

NAMI also conducts educational courses for consumers and families, including the Peer-to-Peer course for consumers, the NAMI-CARE (Consumers Advocating Recovery Through Empowerment) Mutual Support Program, and the *Hearts and Minds* multimedia program. It offers resources such as the NAMI Information Help Line and online communities for discussion of common interests. The Child and Adolescent Action Center provides discussion groups for teen consumers as well as for parents and caregivers of children and adolescents.

Internet Resources

Other services provided over the Internet include the following: legal support and guidance for consumers; resources for providers; mental health news and pertinent research updates; legislative alerts and updates; and FaithNet, a Web site representing the partnership between the faith community and NAMI.

Initiatives

Many public awareness initiatives are spearheaded by NAMI. Mental Illness Awareness Week, held during the 1st week of October, is intended to raise public awareness about the myths of mental illness and the benefits of treatment. NAMI Campaign for the Mind of America is a political initiative designed to create relationships at the local, state, and federal levels of government. These relationships are meant to promote policies that advance mental health through economic and scientific systems.

NAMI Action Centers focus on the specific needs of unique groups such as children and adolescents, multicultural populations, and clients of the criminal justice system. These action centers work to develop and promote education, advocacy, and research among these particular groups.

Policy Research

Mental healthcare policy is a priority for NAMI and is highlighted through specific areas of interest, including integration of consumers and family members in development of mental health services in all settings, equitable access to the most current and complete mental healthcare interventions, and insurance coverage for mental health services. The research activities and awareness initiatives supported by NAMI focus on positive policy change.

Publications

NAMI produces several publications for its members, including the quarterly *The Advocate*. It also provides many specialty publications that address the multifaceted needs of its members. The NAMI Child and Adolescent Action Center publishes *NAMI Beginnings*. And *Recovery for All* is published in connection with the STAR Center and MAC.

Events

NAMI hosts a series of annual *NAMI Walks* held at multiple sites with the purpose of raising funds and awareness of treatment needs of mental health consumers; in 2007, more than 69 walks were

held throughout the country. Another large fundraiser is the annual Washington, D.C., black tie affair, *Unmasking Mental Illness Science and Research Gala*, which helps to raise money for research efforts focused on identifying the etiology and treatment of mental illness.

Future Implications

NAMI remains committed to improving the lives of individuals suffering from mental illness as well as their families and communities. Through outreach, support, education, and research efforts, NAMI can help increase understanding of mental health and promote policy changes that affect this area.

NATIONAL ASSOCIATION OF HEALTH DATA ORGANIZATIONS (NAHDO)

The National Association of Health Data Organizations (NAHDO) is a national, nonprofit membership and educational association established to promote the uniformity and public availability of health data to inform healthcare cost, quality, and access decisions. Based in Salt Lake City, Utah, the association brings together the public and private sectors of the health information industry to improve and facilitate the collection and use of healthcare data for diverse audiences and applications.

Background

The Washington Business Group on Health (WBGH)—now the National Business Group on Health (NBGH)—and the Intergovernmental Health Policy Project (IHPP) at George Washington University established NAHDO in the spring of 1986. Representatives from state health data organizations in Arizona, Colorado, Iowa, Maryland, New Hampshire, New Jersey, and Tennessee met with WBGH and IHPP in Washington, D.C., to launch NAHDO. Shortly thereafter, the new association became a private, not-for-profit, national, educational membership organization.

In 1989, NAHDO's board of directors broadened the membership qualifications to include organizations and individuals from both the private for-profit and the not-for-profit sectors. Today, the association's membership includes state health data organizations, federal agencies, peer review organizations, software and hardware vendors, consulting groups, universities, representatives from state and regional hospital associations, managed-care organizations, health services research organizations, and the media.

NAHDO is governed by a board of directors representing states, healthcare organizations, corporations, and payers. The organization is funded through membership dues, meeting revenues, and grants. NAHDO's staff, the board of directors, and its members work as a community of professionals

to overcome the political and technical challenges to healthcare transparency and performance reporting. Some segments of the healthcare industry still resist independent, objective public reporting on quality and cost. The association works with its members and other allies to improve the underlying data sources and promote consumers' use of the data.

Functions

NAHDO monitors the data collection and release policies of state and private health data organizations. Members and reporting data agencies and their national and local stakeholders use this information for planning purposes. The association also uses this information to advocate sustainable funding for statewide health data systems and to advise states about best practices in data collection and dissemination. The group provides technical assistance and guidance to states to establish statewide health data hospital inpatient and emergency department reporting systems, facility-based ambulatory-surgery reporting systems, health maintenance organizations, and health plan performance measurement systems, and recently, the group began to facilitate the establishment of all-payer, all-claims reporting systems for commercial and public health plans. The association also provides technical assistance to health data agencies to produce data products and comparative reports, including consumer quality reports and Web sites.

Partnerships

NAHDO is a leader in promoting and implementing national standards that support public health and quality reporting purposes. NAHDO's National Standards Consultant is a voting member of the National Uniform Billing Committee (NUBC), which maintains hospital content standards under the Health Insurance Portability and Accountability Act of 1996 (HIPAA), and a voting member of the American National Standards Institute X12N and Health Level 7 (HL7), both data standards maintenance organizations. NAHDO actively worked to add standard data fields to the core uniform billing standard (Uniform Bill 04), such as a "present-on-admission indicator" for each

diagnosis and a standard race and ethnicity standard for electronic hospital transactions. The association and its standards consultant have produced the *Health Data Reporting Guide* for the national X12N standards for inpatient hospital encounters to be used by state agencies.

NAHDO represents state health data system interests in national forums, including the National Quality Forum (NQF), to promote measures that are relevant for state and public health agencies and provides testimony and comment to federal agencies and national entities, including the National Committee on Vital and Health Statistics. The association is a leader in the implementation of Web-based data query systems, and it provides technical assistance to states implementing Web-based reporting and promotes data dissemination policies that support interactive, dynamic Web-based data release. It also works with its members, state data system stewards, to make healthcare data available for public health programs and surveillance.

Activities and Meetings

NAHDO has convened annual meetings of its members for more than 20 years, and it conducts special regional and topical workshops as well as online conferences called webinars. These meetings and webinars facilitate state-to-state information sharing and transfer of knowledge. The association's technical expertise also includes discussion forums, Listservs, and newsletters. Like most membership-based associations, NAHDO's success is directly linked to its members' involvement, expertise, and commitment to its mission.

NATIONAL ASSOCIATION OF STATE MEDICAID DIRECTORS (NASMD)

The National Association of State Medicaid Directors (NASMD) is a professional and bipartisan nonprofit organization composed of officials from Medicaid programs in the 50 states, the District of Columbia, and the U.S. territories. It is one of the nine affiliate organizations under the American Public Human Services Association (APHSA). Its focus is on improving the health and well-being of adults, children, and families by advocating for effective public human service policies. The NASMD, whose members include state directors and their senior staff, has operated as a focal point for communication between state programs and the federal government since 1979. It also works to provide an information network for the states on pertinent Medicaid policy and program issues. Its efforts help inform and influence legislative policy, federal and state regulations, health information technology, and Medicaid reform. The key issues addressed by the NASMD include the following: citizenship requirements, coordination of benefits, long-term care, and prescription drug coverage.

Organizational Structure

The structure of the NASMD includes a 12-member Executive Committee. In addition to a chair, vice chair, cochair, and immediate past chair, representatives from four geographic regions and the U.S. territories serve on this committee. Two members from each region—the Midwest, West, Northeast, and South—sit on the committee; whereas the U.S. territories have a single member. This group oversees administrative matters for the association, represents the NASMD in meetings with the Centers for Medicare and Medicaid Services (CMS), offers testimony before the U.S. Congress when appropriate, and provides overall policy guidance for the association.

Technical Advisory Groups

The association also has several Technical Advisory Groups (TAGs). These work groups are a joint effort of state programs and the CMS. They get together to discuss issues that may arise from Medicaid programs and operations. TAGs do not set policy; rather, they serve as a sounding board to develop strategies surrounding technical or operational concerns. If the TAG determines that the issue being dealt with might have significant policy implications, group members will defer to the Executive Committee or the full NASMD for consideration. TAG members communicate strategies and solutions to the states in their region, helping provide the necessary information and resources.

The NASMD currently has 10 TAGs, which cover issues such as welfare reform, long-term care, managed care, and prescription medications. The Eligibility Policy TAG helps state programs and the CMS to interpret and implement welfare reform laws as they affect eligibility for recipients; the Chronic Care TAG, formerly known as the Long-Term Care TAG, handles home- and community-based services, quality and cost-effectiveness of these services, and delivery-of-care methods; and the Fraud and Abuse Control TAG serves as a forum for all control activities, including effective methods of identifying fraud and excess and implementing legislation to strengthen control measures. The Managed Care TAG looks at the cost setting, quality assurance, and state and federal issues that may come to light in the development and implementation of managed-care programs.

Similarly, the Quality TAG offers ongoing information to state programs on the quality of services provided by managed-care programs. The Pharmacy TAG assists state programs with issues concerning prescription drugs, alternative medications, drug utilization, cost containment of medication coverage, and drug dispute authorizations; and the Systems TAG helps CMS and state programs to review the quality of their systems and data collection. The Payment Error Rate Measurement (PERM) TAG was initiated in 2007 to help address issues associated with this new program; the Medicaid and Mental Health TAG helps state programs to address mental health benefits and to identify challenges that arise in this area; and finally, the Coordination of Benefits/Third Party Liability TAG helps to develop better coordination and collection of third-party payments.

Centers

The NASMD also houses the Center for Workers with Disabilities, which helps states administer Medicaid Infrastructure grants. Specifically, the center assists states in developing Medicaid-Buy-In programs for employees with disabilities, and it provides technical guidance and support to states to increase the number of disabled individuals in the workforce. Like the NASMD, the Center for Workers with Disabilities serves as an information exchange between state programs, offering resources for program development, policy analysis, and technical assistance. It benefits from the resources of NASMD, especially when partnering with federal agencies, other state organizations, and policymakers.

The Medicaid and Mental Health Center is also affiliated with the National Association of State Medicaid Directors. This center collaborates with the Substance Abuse and Mental Health Services Administration (SAMHSA), the National Institute of Mental Health (NIMH), and the National Association of State Mental Health Program Directors (NASMHPD) to explore the relationship between Medicaid benefits and mental health needs. The center also collects information and resources on a broad array of services, including state regulation of residential facilities, mental health parity legislation, depression care, service utilization, reimbursement and cost-effectiveness,

and drug therapy effectiveness. While the center focuses on mental health services, it handles the dissemination of information and resources in the same way as NASMD and the Center for Workers with Disabilities.

Future Implications

The NASMD and the APhSA continue to support the changing needs of Medicaid administrators and professionals. State regulations and federal legislation remain dynamic, shifting to reflect new approaches to human services and public health policy. In response to policy reform and new laws, the NASMD created new TAGs and focused on specific key regulation issues. In this sense, the association will play an ongoing and vital role in helping state Medicaid programs and administrators, as well as federal agencies, politicians, and the general public, to provide needed support and resources.

NATIONAL BUSINESS GROUP ON HEALTH (NBGH)

The National Business Group on Health (NBGH) is a nonprofit healthcare coalition that represents large employers' views on national health policy issues and provides practical solutions to its members' healthcare concerns. Based in Washington, D.C., the NBGH's members include mainly large companies, which provide coverage to more than 50 million workers, retirees, and their families throughout the United States. Under the leadership of its president, the NBGH strives to attain transparency, increase the use of technology assessment to ensure access to beneficial new technologies, eliminate ineffective technologies, and make evidence-based practices the standard of healthcare.

Background

The NBGH (formerly known as the Washington Business Group on Health) was founded in 1974 to serve as a leading voice for large employers dedicated to finding innovative and progressive solutions to the nation's most important healthcare issues.

Mission

The main objective of the NBGH is to provide business solutions, be the national voice of large employers, link large employers with Washington, drive national policy on healthcare and productivity issues, and encourage hands-on membership involvement.

Membership

Over 290 companies are members of NBGH. Many of the members are Fortune 500 companies. Current members include such companies as American Express, the Boeing Company, Cisco Systems, DuPont Company, Ford Motor Company, IBM Corporation, Marriott International, Inc., NIKE, Inc., Time Warner, Wal-Mart Stores, Inc., and Xerox Corporation. Membership dues fund

most of the coalition's activities; however, it does receive funds from the federal government, private foundations, and other health-related sources.

Governance, Staffing, and Organizational Structure

The NBGH is governed by a board of directors, which consists of approximately 20 individuals from member companies and the president of the coalition. NBGH's staff consists of approximately 33 individuals, including a president, five vice presidents, and 27 managers, analysts, and other employees. Staff members work in eight areas: (1) finance and administration; (2) membership and member services; (3) public policy; (4) Institute on the Costs and Health Effects of Obesity; (5) Institute on Health Care Costs and Solutions; (6) Global Health Benefits Institute; (7) the Center for Prevention and Health Services; and (8) the Institute on Health, Productivity and Human Capital.

Activities, Services, and Products

The NBGH provides many activities, services, and products for its members. The coalition holds a number of meetings throughout the year, including leadership meetings, employers' summits, and an annual national conference. It holds weekly webinars and monthly conference calls. The NBGH also conducts a number of surveys of its members and provides the results of its surveys to members so that they can benchmark their performance in various areas.

Many of the NBGH's activities center in a number of institutes, committees, and councils. Its institutes and committees include the following: Global Health Benefits Institute; Institute on Health Care Costs and Solutions; Institute on the Costs and Health Effects of Obesity; National Leadership Committee of Consumer Directed Health Care; and National Committee of Evidence-Based Benefit Design. The coalition's councils include the following: Public Policy Advisory Group; Council on Employee Health and Productivity; and Pharmaceutical Council.

The NBGH is engaged in a number of public policy initiatives. It provides its membership with timely information and analysis on health policy issues that have a direct impact on employers. The coalition also encourages its members to be actively

involved in the political process by writing to members of the U.S. Congress and signing petitions. Additionally, the NNBGH works to assist legislators and policymakers to understand how certain issues affect employer-sponsored healthcare.

The NNBGH publishes newsletters, policy briefs, and reports. Many of these publications are available on the coalition's Web site. However, some publications are only available to member companies.

The NNBGH presents several annual awards to its members and others, including the Award for Excellence and Innovation in Value Purchasing, the Best Employers for Healthy Lifestyles Award, and the Behavioral Health Award, to recognize individuals, employers, and programs.

Future Implications

The NNBGH's membership continues to grow, as large businesses are confronted with increasing challenges in tackling complex healthcare issues. With its membership's pivotal involvement, the NNBGH works to improve the health of tens of millions of individuals across the nation. The NNBGH remains a leading voice in advocating for change in healthcare, and it will likely continue to play a key role in shaping the future of the nation's healthcare system.

NATIONAL CENTER FOR ASSISTED LIVING (NCAL)

The National Center for Assisted Living (NCAL) is the assisted living voice of the American Health Care Association (AHCA), the nation's largest association representing long-term care. The diversification of long-term care has brought rapid growth to the assisted living profession, and the center is an important resource for professionals in the field. Specifically, the Center serves the needs of the assisted living community through advocacy activities, education, networking, professional development, and quality initiatives.

Background

Located in Washington, D.C., the NCAL is an individual membership association. Through its national federation of state affiliates, the Center supports lobbying efforts at the state level. While the Center primarily focuses on federal issues, it also provides the support that state affiliates need to affect policy decisions regarding assisted living issues.

The Center's state affiliates actively represent assisted living providers' interests in state regulatory

issues. In recent years, assisted living has received increasing attention at the federal level: the U.S. Congress, the Department of Labor, the General Accountability Office (GAO), and the Department of Health and Human Services have each examined various aspects of assisted living operations.

The NCAL and the AHCA have worked together to offer strong federal representation and have the largest long-term care federal relations in Washington, D.C. Both organizations are recognized as important sources of information and opinion by policymakers and regulators. Whether serving on a federal agency task force or testifying before the U.S. Congress, the Center ensures that its members' voices are heard.

Activities

The NCAL represents the assisted living community through various communications and by working directly with the media. The general public's perception of assisted living affects all the staff members of assisted living organizations and the environment in which providers operate. Whether delivered through news releases, direct media mailings, media interviews, or responses to media queries, the Center's research findings and position statements find their way into newspapers, magazines, and newsletters reaching the public and other critical audiences.

The Center publishes books, reports, and newsletters. One of its most widely read publications is *A Consumer's Guide to Assisted Living and Residential Care*, which is designed to help consumers select an assisted living facility that meets their needs. The book provides a description of services and includes a checklist and cost calculator.

The Center periodically publishes guidance resources for providers. For example, in 2007 it published *The Power of Ethical Marketing*, complimentary copies of which it distributed to all interested parties on request.

The Center publishes a number of monthly newsletters. Its *Assisted Living Focus* covers the latest business news, trends, regulatory activity, and legislative developments concerning long-term care and assisted living. This newsletter also provides examples of some of the best practices in assisted living residences across the nation. The *AHCA/NCAL Gazette* is a daily publication

designed to keep state association leaders informed of state and national news that affects long-term care professionals so that they can incorporate current national trends into their decision making at the state level. *AHCA Notes* is a monthly newsletter that updates the Center's members on long-term care trends as well as state and national regulatory and legislative activity. Additionally, the Center has an e-newsletter, *NCALconnections*, which is targeted at the association's leadership, state affiliates, and associate business members.

The Center also created and sponsors the National Assisted Living Week. Held each September, this annual event is designed to raise awareness of the assisted living profession and to encourage community support. Each year, the Center develops an original *National Assisted Living Week Planning Guide* as well as a product catalog for its members. Both are designed to promote high-quality services in assisted living residences nationwide.

The NCAL is committed to high-quality assisted living services and provides a number of tools and educational products designed for the assisted living professional. The Center actively supports Quality First, a covenant for healthy, affordable, and ethical long-term care, and adherence to its principles and goals. The Center also maintains a professional staff of experts who are available to answer member questions and who conduct original studies, surveys, and other timely research on assisted living.

Together, the NCAL and AHCA host an annual convention and offer a number of educational seminars that are designed to keep assisted living professionals apprised of the latest trends, innovations, theories, and legal developments that affect their operations. State affiliate associations also provide regional educational programs. The NCAL and the AHCA also collaborate to maintain the Mark A. Jerstad Information Resource Center, which contains a wide collection of materials about assisted living that can be accessed by members.

The NCAL's Web site is widely used. Its features include consumer and long-term care information, weekly electronic updates of issues and trends, regulatory issues, previews of and order forms for publications, other assisted living products, and "members only" information.

NATIONAL CENTER FOR HEALTH STATISTICS (NCHS)

Located in Hyattsville, Maryland, the National Center for Health Statistics (NCHS) is the primary health statistics agency of the federal government. NCHS is part of the Centers for Disease Control and Prevention (CDC). Through cooperation with states and other partners, the CDC provides health surveillance to monitor and prevent outbreaks of disease, implement strategies to prevent disease, and maintain national health statistics.

The primary mission of NCHS is to compile statistical information to guide public health and health policymakers. Mandated by the U.S. Congress, NCHS addresses the entire spectrum of human health from birth through death. It investigates overall health status, lifestyles, and exposure

to unhealthy influences affecting designated populations. Data are also gathered on the onset and diagnosis of illness and disability. For health policymakers, NCHS investigates the use and financing of healthcare and rehabilitative services. In addition to data collection and analysis, NCHS disseminates its data to interested health partners, conducts studies in statistical and survey research methodology, and provides technical assistance in access to or use of existing health-related data. It also has cooperative working programs with public and private agencies and organizations at the state, national, and international levels.

History

The first NCHS surveys on the nation's health were mandated through the federal National Health Survey Act (PL 84-652) enacted on July 3, 1956. The purpose of these surveys was to provide continuing study of the nation's health. These surveys also provided a means for the study of methods and techniques for obtaining statistical health information and disseminating the findings to those who could benefit from them.

In 1960, NCHS became an established organization within the U.S. Public Health Service (PHS) through the merging of the National Health Survey and the National Office of Vital Statistics. The PHS became responsible for vital statistics in 1946 as a result of the transfer of that responsibility from the U.S. Bureau of the Census.

NCHS was established in law and its mandate codified under Section 306 of the Public Health Services Act through the Health Services Research and Evaluation and Health Statistics Act of 1974 (PL 93-353). This act required NCHS to perform a variety of functions related to health in the United States. NCHS was called on to collect a wide range of statistical information on illness and disability nationwide. Data from birth, death, marriage, and divorce records were to be obtained annually. NCHS also had the role of supporting research, demonstrations, and evaluations regarding survey methods. Technical assistance was to be provided to state and local jurisdictions. Finally, this act established the National Committee on Vital and Health Statistics, which provided an expert advisory committee to the Secretary of the Department of Health and Human Services (HHS).

Authority was established in 1970 and then formally instituted through PL 95-623 in 1978 to create the Cooperative Health Statistics System. The purpose of this program was to coordinate as well as provide support and evaluation of the state and federal health statistics systems.

In 1989, with the establishment of the Agency for Health Care Policy and Research by PL 101-239 for the study of healthcare effectiveness and outcomes, the legislative authority of the National Center for Health Services Research (NCHSR) was eliminated. This law produced a number of amendments to NCHS's authority.

As the interest in obtaining more detailed data on racial and ethnic populations grew, the federal Disadvantaged Minority Health Improvement Act of 1990 (PL 101-527) mandated NCHS to obtain vital statistics, conduct national surveys, and establish a grants program for learning more about minority populations.

Data Sources and Surveys

NCHS employs a variety of methodologies and collaborations with public and private health partners to obtain accurate information regarding the health of the population, influences on health, and health outcomes. Data systems and surveys are employed, with some conducted annually and others periodically. Systems based on populations collect information through personal interviews with individuals, physicians, and facility administrators in healthcare organizations. They also obtain information through examinations, such as physical and dental examinations, laboratory tests, and nutritional assessments. Systems based on records look at hospital records, state vital registration and state death certificates for information. Many of NCHS's surveys are conducted via telephone interviews, including the National Immunization Survey (NIS), the National Asthma Survey (NAS), the National Survey of Children's Health (NSCH), and the Joint Canada/United States Survey of Health (JCUSH).

Population-based surveys include the National Health Interview Survey (NHIS), the National Health and Nutrition Examination Survey (NHANES), and the National Survey of Family Growth (NSFG). Record-based surveys include the

National Health Care Survey (NHCS) and the National Vital Statistics System. Many key surveys and data sources are detailed below.

National Health and Nutrition Examination Survey (NHANES)

The NHANES is a very comprehensive assessment that aims to get a picture of the health and nutritional status of the general population. Data are obtained on a nationally representative sample of approximately 5,000 people of all ages each year. Much focus has been placed on obtaining data on African Americans, Mexican Americans, adolescents, pregnant women, and people over age 60. While some of the data are obtained through home-based personal interviews, much of the information is collected through the use of specially designed Mobile Examination Centers that allow for quality control. These mobile centers travel to 15 sites in the nation each year, conducting physical medical examinations, standardized dental examinations, physiological measurements, and laboratory tests on blood and urine. The data collected include the prevalence of specific conditions or chronic diseases, blood pressure, serum cholesterol, body measurements, nutritional status and deficiencies, and exposure to environmental toxins.

NHANES also studies a number of diseases, medical conditions, and health indicators that affect the nation's population. These conditions include allergies, anemia, diabetes, eye disease, hearing loss, kidney disease, nutrition, obesity, oral health, osteoporosis, physical activity and fitness, vision, cardiovascular disease, cognitive functioning, environmental exposure, infectious diseases, reproductive history, sexually transmitted diseases, supplements, and medications. These data are considered the most authoritative source for standardized clinical, physical, and psychological information on the nation's population. Findings from the survey are used by a joint U.S. Department of Health and Human Services and U.S. Department of Agriculture program that monitors the diet and nutritional status of Americans to create food policies and dietary guidelines. Results are published in Series 11 of the *Vital and Health Statistics* series and *Advance Data from Vital and Health Statistics*.

National Health Care Survey (NHCS)

The NHCS is a record-based survey designed to collect data that can be used to analyze patient outcomes, the relationship between health and use of health services, and the use of healthcare services at the local level. The NHCS constitutes a family of surveys each of which relates to a specific setting. Currently, there are four surveys that study aspects of ambulatory- and hospital-care settings: the National Ambulatory Medical Care Survey (NAMCS), which samples visits to nonfederally employed physician's offices that primarily provide service in direct patient care; the National Hospital Ambulatory Medical Care Survey (NHAMCS), which is conducted in a national sample of hospital emergency and outpatient departments in the 50 states and the District of Columbia; the National Hospital Discharge Survey (NHDS), which obtains a representative sample of information on inpatients discharged from short-term hospital stays in general and children's general hospitals; and the National Survey of Ambulatory Surgery (NSAS), which provides the only national sample of information regarding ambulatory-surgery visits.

Two other surveys included in this family of surveys are the National Home and Hospice Care Survey (NHHCS) and the National Nursing Home Survey (NNHS), which address long-term care settings. The NHHCS collects information about licensed or certified agencies providing home and hospice care as well as their current patients and discharges. The NNHS provides a national sample of data about licensed or certified nursing homes, their residents, and their staff.

National Health Interview Survey (NHIS)

The NHIS is a major data collection project of NCHS. Beginning with the National Health Survey Act of 1956, continuing surveys and studies were established to gather current, accurate statistical information on illness and disability in the United States. These studies and surveys were specifically concerned with measuring the incidence, prevalence, and distribution and effects of disease, and the medical services rendered to treat them. The first survey from this act was initiated in 1957 and is now called the National Health Interview

Survey. In 1960, NCHS began conducting the survey following the merging of the National Health Survey and the National Vital Statistics Division.

The NHIS is a population-based survey providing principal information on the status of health, illness, and disability of civilian, noninstitutionalized populations in the nation. The survey is conducted annually through interviews of approximately 50,000 households. Questions are based on current health topics, which may vary from year to year. For example, in 1986, topics focused on health insurance, vitamin use, dental care, and longest job worked. In 1990, the focus was on health promotion and disease prevention, assistive devices, podiatric services, and hearing impairments. Since 1987, questions on knowledge and attitudes about HIV/AIDS have been included each year. Data from the survey provide information on the incidence and prevalence of disease and the relationship between health and demographic and socioeconomic characteristics. Results of the survey are published in Series 10 of *Vital and Health Statistics* series and *Advance Data From Vital and Health Statistics*.

National Immunization Survey (NIS)

The NIS, sponsored by the National Immunization Program (NIP) and conducted jointly by NIP and NCHS, began in 1994. This survey monitors childhood immunization coverage levels among children in the nation. Estimates of vaccination coverage are generated for each of 78 Immunization Action Plans (IAP) which include the 50 states, the District of Columbia, and 27 large metropolitan areas; NIS also provides estimates at the national level. Newly licensed vaccinations recommended for use are included as well. The survey uses a random digital dialing telephone method, searching for households with children aged 19 to 35 months currently living in the nation. Parents or guardians are interviewed to provide names and dates of vaccines charted on the child's "shot card" that is kept in the home. Demographic and socioeconomic information is also collected. At the end of the interview, the interviewers ask permission to follow up by mail with the child's vaccination providers, which may include pediatricians, family physicians, and other health providers, for verification. Quarterly estimates of

vaccination coverage are calculated, and data are used to evaluate progress toward national goals, such as the Healthy People 2010 initiative. The CDC also uses this data to identify states with the highest and lowest rates of immunization.

Longitudinal Studies of Aging (LSOAs)

The LSOAs is a collaborative effort between NCHS and the National Institute on Aging (NIA). Two cohorts of persons aged 70 years or older are studied for changes in health, functional status, living arrangements, and the use of health services as they move through the older ages of life. Four surveys are included in this project: the 1984 Supplement on Aging (SOA); the 1984–1990 Longitudinal Study of Aging (LSOA); the Second Supplement on Aging (SOA II); and the 1994–2000 Second Longitudinal Study of Aging (LSOA II). A recent addition is the 1994–2002 LSOA II Linked Mortality File, which includes all the participants of the LSOA II aged 70 and older. It provides follow-up mortality data, including fact, date, and cause of death, from the LSOA II participation from 1994–2000 through December 31, 2002.

National Survey of Family Growth (NSFG)

The NSFG, a population-based survey conducted through household interviews of women of childbearing age, monitors change in childbearing practices and measures reproductive health. More specifically, these data address family-planning practices and attitudes, factors influencing fertility, fecundity impairments, sexual activity, family formation, and aspects of maternal and child health. Cycles I and II of this survey began in 1973 and 1976, with interviews conducted with approximately 10,000 never-married women aged 15 to 44 years. The population sample was expanded with Cycles III and IV in 1982–1983 and 1988, respectively, to include a representation of all women aged 15 to 44 years regardless of marital status. At this time, new topics were also introduced to include beginning of sexual activity, first use of contraceptives, first use of family planning services, knowledge and experience of sexually transmitted diseases, and adoption. During Cycle IV in 1990, respondents were reinterviewed by telephone. Results are published in Series 23 of the

Vital and Health Statistics series and *Advance Data From Vital and Health Statistics*.

National Vital Statistics System (NVSS)

The NVSS is a collaborative intergovernmental effort to obtain official vital statistics on the registration of births, deaths, marriages, and divorces at the state and local levels within the 50 states, two cities (Washington, D.C., and New York City), and five territories (Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana Islands). These data provide public health officials with important information for monitoring progress in achieving health goals. These data can tell public health officials, for example, the number and location of teen births in a given year, the risk factors for problematic pregnancies, the rate of infant mortality, the leading causes of death, and the life expectancy of a population. One very significant component of the NVSS is the National Death Index (NDI). In collaboration with state offices, NCHS is able to index death records that may be used for epidemiological studies or verifications of death for individuals being studied. Additional components of the NVSS include Linked Birth and Infant Death Data Set, the National Survey of Family Growth, the Matched Multiple Birth Data Set, the National Maternal and Infant Health Survey, and the National Mortality Follow-back Survey. Data from the NVSS are published in electronic form through the *Vital Statistics of the United States*, the *National Vital Statistics Reports*, and additional reports. In addition, electronic micro-data files containing individual vital records are accessible for public use.

Health Topics

NCHS also produces data covering a wide range of specific health topics. Summary data sheets are made available on its Web site for important current health concerns. The site provides portraits of health status for specific critical age groups, such as infants and toddlers, children, adolescents, and older adults. Information on health conditions such as cancer, injuries, obesity, and teenage pregnancy is available. Individual summary data sheets also address current health-related issues, including

patient safety, health insurance and access to care, and racial and ethnic health disparities.

Utilization of Data

Numerous audiences make use of NCHS data. The U.S. Congress and health policymakers use the data to track initiatives, prioritize prevention and research programs, and evaluate outcomes. Epidemiologists, biomedical researchers, and health services researchers look for trends in diseases, uncover the relationship between risk factors and diseases, and monitor the use of health services. Pharmaceutical and food manufacturers, research firms, consulting firms, and trade associations make use of the data for their businesses. Public health professionals employ this information to determine preventable illnesses and evaluate intervention programs. Physicians use the data to evaluate health and risk factors in their patients, such as cholesterol, weight, blood pressure, and growth chart records for children. Media and advocacy groups rely on the data to help raise awareness of major health issues such as cancer, diabetes, heart disease, Alzheimer's disease, and health disparities.

International Activities

The NCHS works collaboratively with other countries and other agencies of the PHS to conduct comparative international research. Experts from the United States and other countries are brought together to focus on specific health issues of mutual interest. Some examples of global research include the examination of perinatal and infant mortality, health and healthcare of the elderly, and international comparability of health data.

Research and Survey Methodology

The NCHS also maintains an active program in statistical research and survey methods. The National Laboratory for Collaborative Research in Cognition and Survey Measurement, a major initiative started in 1985, applies cognitive methods in questionnaire survey research design. The NCHS develops and tests its data collection instruments in collaboration with other internal programs and through research contracts with

academic scientists. Another area of interest for NCHS is determining analytical methods for their registration systems and sample surveys. Research is also conducted on the development of automated and graphical technology. Survey design research, where a program is developed to evaluate, redesign, and link many of the surveys so as to improve efficiency and analytical capability, remains an important area of focus.

Publications and Data Access

The NCHS uses multiple means to disseminate vital and health statistics and the results of its research to as broad a range of people as possible. In addition to publications, public use data files, and unpublished tabulations, efforts are made to reach various specialized groups of data users, health professionals, and the general public through journal articles, presentations, speeches, conferences, workshops, and consultations. Information services available through the NCHS also provide reference and referral services, maintain mailing lists for distribution of new publications, coordinate requests for presentations and exhibits, and issue a catalog of publications and electronic products.

Its Web site makes data on current important health concerns available. Published reports also are available both in print and online. Major publication series include *Health, United States, Vital and Health Statistics*, *Advance Data From Vital and Health Statistics*, *Vital Statistics of the United States*, and *Monthly Vital Statistics Report*. In addition, data files for public use are made available to researchers for analysis. Pretabulated tables of state-level data are prepared on specific interest health issues such as births and deaths. State and national data on a range of health topics are available through interactive data warehouses, examples of which include *Health Data for All Ages* and *Trends in Health and Aging*. At the Research Data Center, detailed data are available through secure access.

Future Implications

The NCHS plays a vital role in the collection, interpretation, and dissemination of important health data. Through its many surveys and studies, as well as its collaborative efforts with state,

regional, community, and academic entities, the NCHS captures broad and in-depth information on individuals, health professionals, and health-care institutions. Further advances in technology will make this data, recommendations, and research findings even more accessible.

NATIONAL CITIZENS' COALITION FOR NURSING HOME REFORM (NCCNHR)

The National Citizens' Coalition for Nursing Home Reform (NCCNHR) is a nonprofit membership

organization that advocates for the rights, safety, and dignity of America's long-term care residents. Located in Washington, D.C., NCCNHR is a coalition of approximately 200 citizen advocacy organizations with members from 42 states in the United States as well as long-term care ombudsman from most states. These organizations and NCCNHR's approximately 1,000 individual members work to improve the quality of long-term care, largely focusing on nursing home care and assisted living but recently expanding to include home and community-based care.

Both its mission and structure make NCCNHR a unique organization. Most citizen advocacy groups in healthcare tend to focus on one disease or on conditions affecting a single organ system (e.g., American Cancer Society), or they focus on a specific group of citizens (e.g., AARP), attempting to address the entire spectrum of their health needs. In contrast, NCCNHR advocates for individuals receiving one type of healthcare—residential long-term care.

This national-level coalition of diverse citizen action groups had its beginning in 1975. Its founder, Elma L. Holder, was then working with the National Gray Panthers' Long-Term Care Action Project. She organized a conference in Washington, D.C., that included members of a dozen citizen advocacy groups who came together to speak with the nursing home industry concerning the need for fundamental change in their operations. At the conference, attendees discovered that they shared a variety of common interests. These interests and goals led them to form NCCNHR. Holder became NCCNHR's first executive director, a position she held for two decades, during which she transformed the organization from a small startup advocacy group to its current status as the primary voice of nursing home residents in national public policy.

Throughout its years of operation, NCCNHR has engaged in a wide variety of activities to improve nursing home care. It has trained members of the national service program Volunteers in Service to America (VISTA), operated a National Long-Term Care Ombudsman Resource Center, maintained an information clearinghouse on residential long-term care, issued reports on a range of topics, published books to inform consumers and policymakers, and educated members of the

U.S. Congress and officials in executive branch agencies who play major roles in long-term care public policy. It also provides important technical assistance and support to its member organizations that work for change at the state and local levels.

One of NCCNHR's greatest achievements was its involvement in the development, passage, and implementation of the Nursing Home Reform Act, part of the federal Omnibus Budget Reconciliation Act of 1987 (OBRA-87). NCCNHR was the motivating core of a coalition of consumer groups, unions, and provider associations that generated bipartisan support for the OBRA-87 reforms. OBRA-87 contained the seeds of a new model of nursing home care that included uniform resident assessment, increased attention to resident rights and quality of life, and a revised set of quality standards and enforcement remedies. OBRA-87 was a fundamental change in federal regulation, shifting the focus of regulators from paper compliance with regulations to the actual care and quality of life experienced by residents. Furthermore, with its focus on resident-centered care, it laid the foundation for the current movement for culture change in nursing homes.

As important as its role in the development and passage of federal legislation was, NCCNHR also deserves considerable credit for its dogged determination to ensure that all elements of OBRA-87 were implemented in their original form. While the nation's nursing home industry did not use all of its considerable political power to oppose OBRA-87's passage, the industry did commit itself to delaying the implementation of the enforcement remedies and attempting to have these measures watered down as they were translated into rules and regulatory procedures. During this period of conflict in the mid-1990s, NCCNHR was the unifying force that brought together citizen advocates, medical and gerontological professionals, and policymakers to fight against efforts to repeal segments of OBRA-87 or to render it toothless in its implementation.

In recent years, NCCNHR has expanded its emphasis from concerns about standards and enforcement to include more engagement with the nursing home industry and regulatory agencies in their quality improvement efforts. In part, this change reflects the nursing home industry's relative success in riding the wave of "healthcare excellence," which is so popular in current public

policy circles. This approach to thinking about quality moves policymakers away from a purely punitive or regulatory approach. Instead, it places much more emphasis on collaborative quality improvement efforts involving government, consumers, and providers. As part of this effort, NCCNHR has embraced the culture change movement in nursing homes, voicing its support for such resident-centered approaches to care as the Pioneers, the Eden Alternative, the Wellspring Initiative, and the Green House Movement.

In terms of its organizational structure, NCCNHR is governed by a 20-person board, which includes a number of nursing home residents. Board members are elected by NCCNHR's member groups and meet quarterly to deal with policies, financing, and strategic planning. The Executive Director, approximately seven paid staff members, a few consultants, and volunteers conduct its Washington, D.C., operations. As with many groups advocating for vulnerable populations, maintaining adequate funding is NCCNHR's major organizational challenge. It has an annual budget of approximately \$1.2 million. Over 40% of NCCNHR's current revenues come from a grant supporting its operation of the National Long Term Care Ombudsman Resource Center. Other grants and donations provide the remainder of NCCNHR's revenues.

Recently, NCCNHR changed its name. It is now the NCCNHR: the National Consumer Voice for Quality Long-Term Care. This new name reflects its broadened mission. Since its inception in 1975 it has, with scarce resources, successfully advocated for millions of frail and vulnerable Americans receiving nursing home care. Its current advocacy efforts include such public policy issues as nursing home staffing standards, poor working conditions in nursing homes, residents' rights and empowerment, the development of family councils for residents' families, reducing physical and chemical restraint use, the high costs of poor quality care, and the adequacy of quality assurance in assisted living and other forms of residential care.

NATIONAL COALITION ON HEALTH CARE (NCHC)

The National Coalition on Health Care (NCHC) is one of the nation's largest and most broadly representative alliances working to improve healthcare in America. The nonprofit and nonpartisan NCHC was founded in 1990 and comprises more than 70 organizations, employing or representing about 150 million Americans. The coalition works to bring large and small employers as well as consumer, labor, and religious groups, primary-care providers, and health and pension funds together. The core principles of NCHC include the following: bringing healthcare coverage to all, managing healthcare costs, improving healthcare quality and patient safety, increasing administrative simplification, and ensuring more equitable financing. The coalition's slogan states that the nation is capable of achieving better and affordable healthcare for everyone.

Overview

The NCHC is headquartered in Washington, D.C. The honorary cochairs of the organization include former presidents George H. W. Bush and Jimmy Carter. The present cochairs include the former governor of Iowa, Robert D. Ray and the former member of the U.S. Congress from Florida, Paul G. Rogers. In addition, 14 members serve on the Board of Directors; these individuals are prominent in the fields of politics, academia, and health and community services and in the business sector. The NCHC also has a staff comprising the president, executive director, senior vice president for policy and strategy, senior vice president for operations, and administrative staff. Additionally, the various members of the coalition include large and small businesses; labor, consumer, religious, and primary-care provider groups; distinguished leaders from academia, business, and government; and distinguished politicians.

Purpose and Principles

The NCHC seeks to focus public attention on the current problems and inequities in America's healthcare system. It strives to provide people with factual information, helping them to form educated opinions and bring about necessary change. In addition, the NCHC's health advocacy efforts are centered on three main issues: (1) the state of the quality of healthcare in the nation, (2) the rising costs of healthcare, and (3) the growing number of uninsured and underinsured Americans. These issues have been addressed by the coalition's national social marketing and education strategy campaign, which is focused on establishing a national policy that will ensure access to quality, appropriate, and affordable healthcare.

To accomplish the goals of improving the quality of care, lowering costs, and providing health insurance coverage to all Americans, the NCHC has identified five guiding principles that it feels are necessary for effective policy reform.

Healthcare Coverage for All

The NCHC advocates for mandatory health coverage for all. This goal can be accomplished in many ways, including efforts that involve the use

of employer and individual mandates, Medicaid and State Children's Health Insurance Program (SCHIP) expansion, individual subsidies, and a number of related ideas as part of a multifaceted approach.

Cost Management

The NCHC supports the creation of an independent board, chartered and overseen by the U.S. Congress, that would be responsible for establishing and administering measures for calibrating rates and limitations to keep costs and insurance premiums in alignment with defined annual targets.

Improvement of Healthcare Quality and Safety

The NCHC recommends the establishment of a federal board to lead the development and coordination of a national effort to improve healthcare quality and set common treatment standards. In addition, the proposed board would oversee protocols for patient records, prescription ordering, billing standards, and privacy standards.

Equitable Financing

The NCHC's members suggest that health plans should be funded from a wide variety of sources, including general revenues, earmarked taxes and fees, employer contributions, individual contributions, and co-payments. The NCHC also advocates the use of sliding scale assistance for lower-income citizens.

Simplified Administration

The NCHC endorses the establishment and utilization of a core standard healthcare benefits package to create a consistent set of ground rules for patients, payers, and providers. The creation of a national information technology structure for healthcare should ultimately lead to decreased costs and medical errors.

Strategies

The NCHC uses different approaches to target and reach healthcare interest groups, community

activists, the media, and the general public. The coalition began its work by identifying concerns and gaps in the public's knowledge. As a result, it has published a series of reports designed to furnish basic information about the changes and challenges in the nation's healthcare system.

One of NCHC's recent reports, *Prevention's Potential for Slowing the Growth of Medical Spending* (2007), deals with the preventive aspects of healthcare interventions. Using immunizations as an example, the report highlights the future cost savings of early prevention efforts. Previous reports released by the coalition have focused on cost, quality, and access to healthcare.

In addition to publishing reports, the NCHC furthers its advocacy campaign through involvement in public forums, congressional hearings, conferences, social events, and media appearances. Much of the coalition's work is available and accessible online at its Web site.

As a nonpartisan alliance, the NCHC briefs policymakers and shares its reports with politicians and bureaucrats in the administration. Local representatives that are coalition members also reach out to other organizations and opinion leaders at the state level. In the past, the coalition has also conducted a national advertising campaign in popular media outlets, including *The New York Times*, *The Washington Post*, *USA TODAY*, and *Roll Call*. Coalition members also place advertisements in their own internal publications and in the local media.

Fact Sheets

The NCHC has developed fact sheets on many issues, which are broadly classified into five categories: health insurance coverage, cost, quality, world healthcare data, and economic sheets. Several of the coalition's available economic fact sheets point out the impact of rapidly escalating healthcare costs and insurance premiums on workers and their families, business operations, small businesses, pension programs and beneficiaries, the federal budget, state governments, and local communities. Healthcare researchers, healthcare activists, and the general public can use these compiled resources. For example, the fact sheet on World Healthcare Data provides information on Canada, France, Germany, the United Kingdom,

and Japan. These data offer a global view of different healthcare systems, their funding resources, and the costs associated with them.

Future Implications

The NCHC is a broad-based organization that advocates for a multitude of changes to the nation's healthcare system. It is important to note, however, that the coalition's members also include large national insurance companies and pharmaceutical corporations. While these members might represent a conflict of interest, the coalition continues its media campaigns and furthers its commitment to improving the quality of healthcare, decreasing healthcare costs, and increasing access to health insurance coverage.

NATIONAL COMMISSION FOR QUALITY LONG-TERM CARE (NCQLTC)

The National Commission for Quality Long-Term Care (NCQLTC) is a nonpartisan and independent body charged with the responsibility for improving long-term care in the United States. The commission, which has been cochaired by former U.S. Senator Bob Kerrey and former Speaker of the House of Representatives Newt Gingrich, comprises appointed commissioners who reflect a diversity of backgrounds ranging from academic, government, quality improvement, and long-term care settings. The commission was created as an outgrowth of a long-term care industry-driven quality initiative titled "Quality First: A Covenant for Healthy, Affordable, and Ethical Long-Term Care," and it is overseen by The New School.

In 2004, three leading long-term care organizations called for an independent commission to evaluate the quality of long-term care in the nation, identify the factors that influence quality improvement, and recommend strategies to sustain quality improvement nationally. The commission was convened in October 2004 and was originally housed at the National Quality Forum. The three founding organizations—the Alliance for Quality Nursing Home Care (AQNHC), the American Association of Homes and Services for the Aging (AAHSA), and the American Health Care Association (AHCA)—provide funding for the commission's work. The commission functions independently, led by its executive director Doug Pace, and is currently located at The New School.

Background

The growing concern over the quality of long-term care prompted the three major long-term care organizations listed above to pledge to a 5-year voluntary initiative entitled "Quality First: A Covenant for Healthy, Affordable, and Ethical Long-Term Care" on July 16, 2002. This initiative was aimed at attaining excellence in the quality of care and services for older persons as well as increasing the public trust in the delivery of care

and services. The reasoning behind this initiative was that, if quality could be reliably measured and the results made publicly available, providers would be motivated to improve their quality, and the public would be able to distinguish between good and poor performers.

At about the same time, the U.S. Department of Health and Human Services (HHS) launched its Nursing Home Quality Initiative (NHQI) and the Home Health Quality Initiative (HHQI). With the growing number of initiatives focused on long-term care, there was a need for an independent body to evaluate long-term care quality, identify the factors that influence improvements in quality of care, and make recommendations about national efforts that could result in sustained quality improvement.

Long-Term Care Reform

The nation's long-term care system is currently straining to meet the demands of a growing older population whose magnitude was never anticipated. Some of the challenges that the system is confronted with include individuals who face a loss of independence because of disability and who may also be confronted with a loss of home, income, and/or assets. Individuals may also face a loss of their family and choice among long-term care options. Often families have little of the information or training needed to support those with disabilities; direct care workers are generally paid low salaries and receive little respect from the medical community and general public. Provider organizations may be pressured to deliver high-quality care but face constraints with low reimbursements. In addition, regulatory agencies are unable to enforce regulations that should serve to protect individuals receiving long-term care due to staffing shortages; and policymakers are grappling with pressures to improve long-term care while balancing the budget.

Given the challenges of the nation's long-term care system, the commission is committed to finding solutions to the most pressing questions that affect the aging population. These questions include the following: How can long-term care be financed consistently with policies that ensure that all Americans have choices? How can long-term care workers be retained? What are the best approaches for improving and ensuring quality? Where can

Americans obtain credible information to compare their options for long-term care?

Although the nation's long-term care system faces significant challenges, there is much promise of finding feasible solutions. The commission has laid out a road map for long-term care reform with six key areas: culture transformation, empowering individuals and families, workforce, technology, regulation, and finance.

The commission believes that the culture of long-term care can be transformed through organizational innovations that improve an individual's quality of life and quality of care. Some promising initiatives that can facilitate this cultural transformation include resident-centered care and the provision of palliative and hospice care. Additionally, individuals and families can be empowered through a broader array of high-quality, affordable, and accessible long-term care services that are available in homes and communities. Family caregivers must also be given the tools, information, and support that will allow them to continue their role in caring for those with disabilities. The long-term care workforce must be supported to improve their working conditions and wages and be provided with greater opportunities for advancement. Technology should be used more effectively to promote higher quality of care and greater consumer independence. Furthermore, long-term care regulations must be accurate, timely, and consistently implemented to improve quality. Last, the commission believes that there should be a long-term care financing system that is fair and equitable and that every American should have access to the services they need to live independently for as long as possible.

Future Implications

The long-term care system is faced with daunting challenges in the way of meeting the needs of a growing elderly population. On December 3, 2007, the commission issued its final report that called for a national discussion about how the nation can create a new and better long-term care system. The report features recommendations in the areas of workforce, quality, and technology. In addition, it also discusses important steps that must be taken in identifying crucial features of a long-term care financing system.

NATIONAL COMMITTEE FOR QUALITY ASSURANCE (NCQA)

The National Committee for Quality Assurance (NCQA) is a major driving force in improving the quality of the nation's healthcare system. NCQA establishes standards of quality and service that health plans should provide to their members. Known for its Healthcare Effectiveness Data and Information Set (HEDIS) measures, NCQA provides voluntary accreditation of physicians, medical groups, and health plans. It strives to transform the quality of healthcare through measurement, transparency, and accountability.

Background

Located in Washington, D.C., the National Committee for Quality Assurance (NCQA) was founded in 1990 as a private, nonprofit organization. At the time, there were few nationwide efforts to systematically measure and improve quality. Since then, NCQA has been working vigorously with employers, providers, health plans, patients, and policymakers to build a consensus on healthcare quality. These efforts have focused on how to best measure and improve quality.

NCQA maintains a diverse set of programs to accomplish its mission of improving quality in healthcare. Specifically, it offers five accreditation programs, four certification programs, and four physician recognition programs that apply to health plans, medical groups, and individual physicians, all of which are voluntary. NCQA relies on the system of measure, analyze, improve, and repeat to address healthcare quality.

Quality Assessment

NCQA employs a variety of approaches to assess healthcare quality, including on- and off-site surveys, audits, satisfaction surveys, and performance measures. It uses these methods in its accreditation, certification, recognition, and performance programs that evaluate organizations, medical groups, and physicians. Through these programs, NCQA obtains relevant information on healthcare quality that is made available to consumers, employers, health plans, and physicians. The information gathered from these programs can be used by consumers and employers to make informed purchasing decisions regarding their healthcare as well as drive quality improvement efforts.

NCQA's seal is highly recognized as a symbol of quality. The organizations and individuals who participate in NCQA's programs earn the privilege of using the Committee's seal. Organizations that seek NCQA accreditation must pass a rigorous and comprehensive review and complete an annual performance survey. Health plans must meet more than 60 standards and report on performance in more than 40 areas to be accredited with additional criteria that continue to be added each year. Although the standards and requirements per assessment program vary, the participating organizations and individuals must be able to demonstrate

that quality practice, clinical, and satisfaction thresholds are met. In 2008, NCQA started evaluating preferred provider organizations (PPOs) on the same standards, measures, and patient experience ratings that it uses to evaluate health maintenance organizations (HMOs) and point of service (POS) plans, to allow consumers and purchasers to reliably compare across different health plans.

Many of the nation's leading employers, federal and state government, and individual consumers rely on NCQA's accreditation to select among various health plans. Furthermore, in more than 30 states, health plans that are NCQA accredited are exempted from most or all of the requirements of annual state audits.

NCQA also offers a variety of educational programs and publications for providers and organizations to help meet quality goals. These programs include educational seminars, online continuing education programs, corporate training, and special events.

Performance Measurement

NCQA has played a significant role in refining performance measures. Performance measures allow for the direct comparison of health plans. In the mid-1990s, NCQA developed objective measures that resulted in a standardized measurement tool known as the Healthcare Effectiveness Data and Information Set (HEDIS), which is widely used by the industry. It has also developed other measures for various healthcare organizations.

HEDIS is a tool used by over 90% of the nation's health insurance plans to measure areas of patient care and service. This comprehensive tool surveys a broad area of healthcare that includes 71 measures over 8 domains of care. HEDIS measures cover the effectiveness of care; health plan stability; cost of care; access of care; use of services; informed choice; health plan information; and satisfaction of care. Some areas of HEDIS measurement include breast cancer screenings, beta-blocker treatment after a heart attack, antidepressant medication management, and comprehensive diabetes care.

The availability of HEDIS allows for an objective, standardized measurement and reporting that permits side-by-side comparison on the performance of health plans and comparison of performance to benchmarks. HEDIS also enables

health plans to target their areas of improvement. To stay current, the HEDIS measurement set is updated annually. Employers and patients use HEDIS data and accreditation information to make their purchasing decisions. Health maintenance organizations (HMOs) submit HEDIS data to participate in the Medicare Advantage program.

The early efforts of HEDIS included a narrow set of preventive process measures. Since then, HEDIS has grown to include a broad array of measures that include the underuse, overuse, value, processes, and outcomes of care. In 2008, HEDIS included measures that assess how many children under 2 years of age and enrolled in a Medicaid managed-care program have been tested for lead exposure. Another new measure examined if patients with aggravated chronic obstructive pulmonary disease (COPD) received prescriptions for bronchodilators and systemic corticosteroids at discharge from a hospital or emergency department.

As the HEDIS measures continue to evolve, NCQA ensures that the measures contain the features of relevance, soundness, and feasibility. NCQA also makes certain that the measures are valid, address focal areas, and are not onerous to implement.

NCQA has published *The State of Health Care Quality* since 1997, which gives an overall assessment of the U.S. healthcare system. This report is released just prior to the open-enrollment season when individuals choose their health plan for the following year. Over the past 5 years, the report has shown that health plans have made significant improvements across a broad range of quality measures.

Physician Recognition

NCQA's physician recognition programs help patients identify providers who consistently deliver evidence-based care. Employers have also begun to realize the value of the physician recognition program.

In collaboration with the American Diabetes Association and the American Heart Association/American Stroke Association, NCQA has developed two physician recognition programs. These programs recognize physicians who deliver excellent care to patients with diabetes or cardiac-related

illnesses. Physicians who participate in the recognition programs have also rapidly improved the care they deliver. Those who participated in the Diabetes Physician Recognition Program increased their rates of nephropathy screening, lipid screening, and blood pressure control by 50% to 100% within 5 years.

Another program, the Physician Practice Connection, recognizes physicians who have implemented practice systems, such as electronic medical records, that help them consistently deliver high-quality care. A new program will identify physicians who provide efficient and effective evidence-based care for patients with back pain.

Public Reporting

An educated consumer serves as a powerful driving force for improving healthcare. Thus, NCQA works to facilitate informed consumer choices by making available, free of charge, most of the information it collects on health plans, medical groups, and physicians to the media and individuals via the Internet. To reach as wide an audience as possible, NCQA also maintains a partnership with *U.S. News & World Report* to produce its annual list of “America’s Best Health Plans.”

NCQA also has a number of tools available to help consumers make informed decisions. The interactive Health Plan Report Card contains a searchable database that allows consumers to choose an appropriate health plan. The report card, which is based on the review of hundreds of health plans, includes a comprehensive evaluation of member satisfaction, clinical quality, and key systems and processes as well as accreditation information and performance ratings. NCQA also makes available an online directory of physicians in its recognition programs and a quality dividend calculator that can estimate the increased productivity and decrease in sick days that are the result of selecting a high-quality health plan. Quality Compass is another tool developed for consumers. This tool contains comprehensive health plan performance data, trend data, and health plan-specific HEDIS rates, in addition to regional and national averages. With Quality Compass, users can track quality improvement, analyze annual plan performance, develop custom reports, and conduct market analyses.

Public Policy

NCQA also maintains an active public policy department. The department works with legislators and policymakers to educate them on how to support healthcare policies that benefit the public. In addition, the NCQA works collaboratively with other organizations to advance policies that improve the efficiency and quality of the healthcare system.

Future Implications

The National Committee for Quality Assurance (NCQA) continues to stimulate significant improvements in healthcare quality through its quality assessment, performance measurement, and physician recognition programs. It is furthering its work by developing a broader set of performance measures and expanding the boundaries of quality. NCQA remains a leader for facilitating change in the nation’s healthcare system by providing employers and consumers with the necessary tools and information to make informed choices.

NATIONAL GUIDELINE CLEARINGHOUSE (NGC)

The National Guideline Clearinghouse (NGC) is a federally funded Web site devoted to maintaining a current database of clinical practice guidelines for physicians, other health professionals, and healthcare providers. Specifically, the mission of the NGC is to provide objective, detailed information on clinical practice guidelines and to further their dissemination, implementation, and use. The clearinghouse accomplishes its mission through a number of different components. It provides a searchable database of current clinical practice guidelines, each with an abstract and full-text version (or link to purchase). It offers guideline comparisons—either in the form of automatically generated side-by-side comparisons or novel documents written by the clearinghouse—comparing differences and similarities between guidelines on the same topic. Guidelines and guideline comparisons can be downloaded to personal digital assistants (PDAs) for easy, mobile viewing. The Web site contains an annotated bibliography section that offers a database of clinical-practice-guideline-related resources from peer-reviewed journals and other sources. Finally, it provides a Listserv for discussion of clinical-practice-guideline-related issues and questions.

Background

The initial construction of the NGC began in 1997. To gain input and support for the proposed clearinghouse, individuals in the U.S. Department of Health and Human Services (HHS) met with representatives from the American Medical Association (AMA), the American Association of Health Plans (AAHP), and the U.S. Agency for Health Care Policy and Research (now the Agency for Healthcare Research and Quality, or AHRQ). In December, 1998, the clearinghouse was launched, and it was officially unveiled in January, 1999.

When launched, the clearinghouse included approximately 200 clinical practice guidelines and other related material. By 2000, the number of guidelines had more than tripled to nearly 700. Similarly, the number of visitors to the Web site increased substantially. By the end of the 1st year of its operation, there were more than 17 million hits and 1 million sessions (a "hit" is looking at one page, while a "session" involves multiple concurrent hits).

Usage has continued to increase to approximately 38,000 visits a week. The average user visits about 10 pages and stays for around 6 minutes. Also, the clearinghouse is continuing to grow in size every week—it currently has over 4,000 guidelines available on the Web site.

Clinical Practice Guidelines

Clinical practice guidelines are commonly defined by the national Institute of Medicine (IOM) as "systematically developed statements to assist practitioner and patient decisions about appropriate healthcare for specific clinical circumstances." The number of clinical practice guidelines has greatly increased during the past two decades. This has primarily been due to research studies that showed that physician's practices and treatments vary greatly and to the increase in managed care. The belief is that using clinical practice guidelines can lead to more standardized practice and thus increased quality and cost-effectiveness.

Health Partners, a health insurance company based in Minnesota, found that among its physicians, more than 80 different treatments were being used for bladder infections. To address this

type of substantial variation in treatments, clinical practice guidelines have been developed—in theory care can now be standardized to effective treatment plans. However, the situation is not that simple—in the NGC, there are 13 different guidelines relating to urinary tract infections (including bladder). Physicians must sift through these guidelines to see which one is applicable to their particular patients—since some guidelines may be age or gender specific or may be related to a specific subtype of the condition (chronic urinary tract infection, for example).

A different study looked at the cost-effectiveness of clinical practice guidelines. It found that, among coronary-care intensive-care unit patients, discharging patients according to the established guideline decreased the amount of time spent in the hospital without changing mortality rates or health status at follow-up. This saved an average of \$1,000 per patient.

Development of Guidelines

Historically, one of the major problems with clinical practice guidelines has been the lack of a consistent set of rules used in their development and implementation. To address this problem, the NGC has implemented a number of requirements for inclusion into its database.

Guidelines submitted for inclusion must be current (within the past 5 years). They must include systematically developed statements that help physicians and others make decisions for their patients. They must be developed under the auspices of medical specialty associations; by relevant professional societies, public or private organizations, government agencies at the federal, state, or local level; or by healthcare organizations or plans. Finally, they must be available in English for free or for a fee. Among guidelines submitted to the clearinghouse for inclusion, only about 10% are rejected for not meeting the inclusion criteria.

Additional recommendations for guideline development have been discussed in various journal articles. The articles suggest making a formal cost analysis a part of guidelines, defining evidence and how it was selected, making data available for review, and the use of randomized controlled trials as part of the evidence.

Users of Guidelines

Information on who uses clinical practice guidelines varies based on a number of factors. Among family practitioners, about 60% were at least somewhat familiar with three relevant guidelines; 14% reported not being familiar with any of the three presented guidelines. The use of the guidelines varied based on the guideline, ranging from 44% to 64%. Additionally, staff-model health maintenance organization (HMO) physicians were very likely (100%) to use guidelines, especially as compared with those in private practice (23%).

As for those who use the NGC, it is difficult to know exactly, but most likely nurses and physicians are its greatest users. The majority of hits come during normal business hours, suggesting that healthcare providers may be using it at work or during their practice. It is also believed that younger physicians are using the clearinghouse more than older physicians, because younger physicians are more likely to be trained in information systems and feel more comfortable using the Internet in general.

Issues and Problems

While clinical practice guidelines seem like a good idea in theory, there are often issues and problems in their implementation. These problems include keeping the guidelines up to date with current knowledge, methodological problems with their development, the usefulness of the guidelines to patients with multiple comorbidities, and the problem of physician resistance to using the guidelines in their practices.

Keeping Guidelines Current

With constantly changing research and technology, clinical practice guidelines are also changing. This means that a physician or other healthcare provider may access a guideline, use its recommendations, and later find out that it is already out of date or inaccurate. In addition, depending on the nature of the guidelines, different review criteria might be required. For example, the treatment for ingrown toenails is less dynamic than cancer therapies; therefore, clinical practice guidelines relating to cancer treatment should be reviewed more

frequently than those relating to more established treatments.

One review of 279 clinical practice guidelines found that a large majority (89%) of them failed to include a statement about when they should be reviewed or when they should expire. This becomes problematic because, as previously discussed, without a set date of review; these guidelines might continue to be reviewed long after they have been made current.

Additionally, the time at which a study is published can be a year or more after the data was initially taken. A guideline is partially based on studies, so it may take another year or two before a guideline is published. By the time the guideline is found in the NGC, it may be based on data that are 3 to 4 years old. Thus, when reviewing guidelines (especially ones without a set expiration date), physicians and other healthcare providers should note the dates of the supporting studies and any other dates provided in the guideline.

The NGC works to minimize this problem by requiring all guidelines to have been made current within the past 5 years. It automatically eliminates those that are older from its database, unless there is evidence that it has been or will soon be updated.

Guideline Methodology

Another problem is the consistency in methodology of the guideline development. In a study of 279 clinical practice guidelines, not one of the guidelines met all the criteria set forth by the authors. Most frequently, the guidelines lacked methodological standards such as not disclosing information about how data was obtained, extracted, selected for inclusion, and graded.

One additional problem is implicit value judgments used in the guidelines. Frequently, the authors of guidelines have to make a decision about what the patient is most likely to want. While these decisions may seem relatively obvious, not all patients may share the same values as the researchers. For example, one article cited an example of this problem with the use of aspirin instead of ticlopidine in the treatment of patients with transient ischemic attack (or mini stroke). Aspirin is cheap and available over the counter; however, ticlopidine produces a 15% lower risk of another attack. This lower risk, however, comes at a price—including

monetary, temporal (needing refills and trips to the pharmacy), and bodily (it requires periodic white blood cell counts). The assumption that the authors point out is frequently held by researchers is that the patient would rather take the cheaper over-the-counter aspirin than the more expensive, more effective ticlopidine. While this may be true for most patients, it may not be true in every case. Therefore, clinical practice guidelines should make explicit any implicit value judgments made in the development of the guidelines.

Comorbidities

Guidelines are often written with one medical condition in mind. However, many patients have comorbid conditions or multiple diseases. For example, 48% of Medicare beneficiaries have three or more chronic disease conditions. One study examined this problem explicitly by looking at relevant clinical practice guidelines for a hypothetical 78-year-old woman with five comorbid conditions: osteoporosis, osteoarthritis, Type 2 diabetes, hypertension, and chronic obstructive pulmonary disease (COPD). It found that strictly following all the guidelines would produce drug-disease and drug-drug and drug-food interactions. In addition, the patient would be taking 12 medications (19 doses) per day at five different times. The estimated cost of the drugs would be about \$400 per month.

Strictly following clinical practice guidelines that only focus on one disease can be difficult. It is important to be aware of the limitations of the guidelines in treating patients with comorbidities. In addition, it may be beneficial for future guidelines to address and prioritize comorbidities.

Physician Resistance

Not all physicians are interested in using clinical practice guidelines or the NGC. Some physicians are reluctant because they feel that using guidelines is “cookbook medicine,” which takes away their medical skills. Others are reluctant to use them in everyday practice because they feel comfortable with medical conditions they see on a regular basis; however, they might consult relevant guidelines for preparing presentations, treating complex cases, or in other special situations.

Specialists are most likely to consult clinical practice guidelines in their respective journals. So the NGC may not be as popular as it might, because physicians are already accessing guidelines from different sources. If they hold their own journal in the utmost regard, then they may have no interest in or need for searching for other guidelines from other sources.

Future Implications

Clinical practice guidelines can be beneficial if regularly used and properly developed. With the advent of new technology, it has become possible to centralize information—in this case, in the form of the NGC. The clearinghouse has grown dramatically over the past several years, and it will undoubtedly continue to grow. Additionally, as it grows, so will the number of people who will use it. Currently, there are thousands of visits per week, and this number will grow as knowledge of this database grows.

Clinical practice guidelines were originally developed to standardize practices to more evidence-based interventions and in an attempt to lower costs. It has been shown that these guidelines can accomplish both of these goals given the right conditions. For large change to be realized, guidelines must be appropriately developed (including cost analysis and statements of implicit judgment) and more widely used in practice.

Ultimately, the NGC is a valuable resource for physicians and other healthcare providers. It continues to provide a central access point for current clinical practice guidelines.

NATIONAL HEALTHCARE DISPARITIES REPORT (NHDR)

The *National Healthcare Disparities Report* (NHDR) is a comprehensive overview of the racial, ethnic, and socioeconomic disparities in the access to and quality of healthcare in the nation's general population; among priority populations including women, children, the elderly, racial and ethnic minority groups, low-income groups, and residents of rural areas; and for individuals with special healthcare needs, including the disabled, people in need of long-term care, and people requiring end-of-life care. The federal Healthcare Research and Quality Act of 1999 directed the Agency for Healthcare Research and Quality (AHRQ) to develop an annual NHDR to provide a summary of the state of healthcare disparities in the United States. The first NHDR was released in 2003. The 2004 report built on the first report by providing an updated national overview of disparities and added another critical goal: tracking the nation's progress toward eliminating healthcare disparities.

The 2005 report focused mainly on tracking progress toward eliminating disparities, while the 2006 and 2007 reports focused on healthcare access and quality improvements for different populations across the nation.

Overview

The NHDR is a vital step in the effort to improve healthcare in the United States. By tracking racial, ethnic, and socioeconomic disparities in healthcare access and quality over time, this can increase the general awareness about disparities and inspire action to reduce and/or eliminate them. The NHDR also offers data and analyses that can help researchers, policymakers, clinicians, administrators, and community leaders to monitor the trends, determine areas of greatest need, identify best practices for addressing those needs, and develop new and improved interventions to eliminate healthcare disparities. Additionally, communities and providers can use the NHDR methods and measures to determine the most serious disparities, create targeted interventions, and track progress against national standards.

Key Findings of the Reports

The 2003 Report

The 2003 NHDR presented seven key findings: (1) inequality in quality persists, (2) disparities come at a personal and societal price, (3) differential access to healthcare may lead to disparities in quality, (4) opportunities to provide preventive care are frequently missed, (5) knowledge of why disparities exist is limited, (6) improvement is possible, and (7) data limitations hinder targeted improvement efforts.

Specifically, the report confirmed that there were significant inequalities in healthcare quality in the nation along racial, ethnic, and socioeconomic lines. For example, the report showed that compared with Whites, minorities were more likely to be diagnosed with late-stage breast and colorectal cancer and patients of lower socioeconomic status were less likely to receive recommended diabetic services and were more likely to be hospitalized for diabetes and its complications.

Healthcare disparities were also found to be costly for individuals and for society as a whole. Disparities in quality of care can lead to missed diagnoses and poorly managed care, resulting in avoidable and expensive complications. For individuals, disparities in healthcare can cause disability, lost productivity, and morbidity. For society, treating conditions that have worsened as the result of poor care and/or poor management results in considerable financial costs, notably for taxpayers, who fund public healthcare programs.

Barriers to access to healthcare can also lead to adverse health outcomes. For example, individuals without health insurance coverage or a usual source of care are generally less likely to obtain preventive healthcare services and are more likely to delay seeking needed care. As a result, these individuals are more likely to seek medical care with their illness at later and less treatable stages.

Disparities among population groups were also found to exist in the use of evidence-based preventive services. For example, many racial and ethnic minorities and individuals of lower socioeconomic status were less likely to receive screening and treatment for cardiac risk factors and recommended immunizations.

Findings from the report suggested that targeted efforts could reduce healthcare disparities. For example, community-based cervical cancer screening and outreach programs may be the reason why Black women have higher screening rates for cervical cancer and no evidence of later-stage cervical cancer presentation despite the fact that in general Blacks and the poor are more likely to seek care with later-stage cancers and to have higher death rates.

The 2004 Report

The 2004 NHDR presented three key findings: (1) disparities are pervasive; (2) improvement is possible; and (3) gaps in information exist, particularly for specific medical conditions and populations.

Specifically, the report found that disparities were pervasive in the nation's healthcare system. Disparities affected healthcare across all dimensions of access and quality; across many medical conditions, levels and types of care, and healthcare settings; and within many subpopulations.

The report found that in both 2000 and 2001, Asians, when compared with Whites, received poorer quality of care for approximately 10% of the quality measures and had poorer access to care for approximately one third of the access measures. Also, Blacks, when compared with Whites, received poorer quality of care for approximately two thirds of the quality measures and had poorer access to care for approximately 40% of the access measures.

Several gaps identified in the 2003 NHDR were filled in the 2004 report. These included increased information on hospital care received by American Indians and Alaska Natives; healthcare delivered in community health centers; children with special healthcare needs; and a broader analysis that allowed for the separation of disparities related to race, ethnicity, and socioeconomic status.

The 2005 Report

The 2005 NHDR presented four key findings: (1) disparities still exist, (2) some disparities are diminishing, (3) opportunities for improvement still remain, (4) and information about disparities is improving.

Specifically, the report found that disparities still existed in nearly all aspects of healthcare. Minorities and the poor continued to receive lower-quality healthcare than comparison groups and also had worse access to care. The report found that for racial minorities, more disparities in quality of care were improving than were worsening. The persistence of disparities indicated that opportunities for improvement remained.

The 2006 Report

The 2006 NHDR presented four key findings: (1) disparities still remain; (2) some disparities are decreasing, while others continue to increase; (3) there remain opportunities to reduce disparities; and (4) information on disparities is getting better, but there are still gaps.

Specifically, the report found that minorities and the poor continued to receive poor-quality care and had poor access to care. The report also highlighted that for the poor, most disparities were getting worse. These gaps indicated that ample opportunity existed to continue to improve these

deficient areas and also indicated the need for better data and measures.

The 2007 Report

The 2007 NHDR presented three key findings: (1) disparities in healthcare quality and access are not decreasing, although progress continues to be made; (2) the largest gaps in quality and access are not being reduced; and (3) lack of health insurance coverage continues to be a major barrier to reducing disparities.

Specifically, the report found that although overall progress continues to be made to improve healthcare quality, some of the largest gaps in quality persist. For example, the proportion of Blacks who receive hemodialysis has improved since 2001, and their current rate of treatment is not statistically different from Whites. However, despite the improvement, gaps in health still remain. Blacks were found to have a 10 times higher rate of new AIDS cases than Whites. The report also highlighted that the growing number of uninsured individuals significantly contributes to the problem of poor healthcare quality.

Future Implications

Moving forward, the improvement in available data and the recording of trends in access and the quality of healthcare will enable future NHDRs to identify and lead to decreases in inequities in health. By tracking outcomes and looking at the most vulnerable populations, these reports will continue to serve as important tools in eliminating health disparities.

NATIONAL HEALTHCARE QUALITY REPORT (NHQR)

The National Healthcare Quality Report (NHQR) is a comprehensive source of information on trends in the quality of healthcare provided to the American people. It is published annually by the U.S. Agency for Healthcare Research and Quality (AHRQ). A key objective of the report is to inform the U.S. Congress and national healthcare policy-makers on quality of care issues as well as to monitor the impact of federal and state changes in healthcare. The report is relevant to health services researchers because they investigate the link between healthcare quality, access, and costs, as well as how the translation of evidence into clinical practice and organizational actions affects outcomes of care.

Background

The idea behind reporting the quality of healthcare to the general public originated towards the end of the 20th century at a time when national discourse on health reform and strategies to improve performance in quality and safety of care had gained momentum. A strategic imperative of

reform called for accountability and transparency as important catalysts to fostering system changes. During the 1990s, a Clinton Presidential Advisory Commission on Consumer Protection and Quality in the Health Care Industry issued a report in 1998 calling for a national commitment from the public and private sectors to improve healthcare quality and reporting. By the end of the decade, the U.S. Congress enacted the Healthcare Research and Quality Act of 1999 directing the AHRQ to publish annual reports that addressed the quality information gap. Around the same period, the National Academy of Sciences, Institute of Medicine (IOM), released two seminal reports on healthcare quality (*To Err Is Human* and *Crossing the Quality Chasm*) that would shape the overall framework of the NHQR.

Framework

The NHQR is anchored on a framework that sets forth the concept of healthcare quality resulting from the dynamic interplay between the organizational delivery system domains and consumer domains of care. The organizational domains correspond to the traits of quality that exemplify effectiveness (giving care based on current scientific knowledge, avoiding overuse or underuse), safety (avoiding harm), timeliness (giving care when needed), and patient-centeredness (giving care that respects patient preferences and values). The consumer domains correspond to the traits of quality that result from obtaining care, which include staying healthy, getting better, managing chronic illness or disability, and coping with end-of-life issues. Thus, quality is indicated by a matrix of the four dimensions of organizational quality and four dimensions of consumer care to exemplify the interdependence between healthcare structures and how outcomes of consumer care influence system performance.

Content Focus

The U.S. Congress stipulates that the NHQR provide information on the relationship between quality, outcomes, access, utilization, and changes over time on frequently occurring clinical conditions, including the impact of federal and state policy changes. In this capacity, the NHQR differs from

other national comparative quality reports because it provides a broad perspective on quality, by assessing progress and defining actions to improve performance across a wide range of provider settings, clinical conditions, and populations. Although the report was commissioned to inform Congress, it also seeks to enhance awareness among policy leaders, purchasers, providers, health professionals, researchers, and the lay public using a chart-book format that highlights key findings and themes to facilitate and encourage the use of data among this audience. Findings of quality outcomes are presented in chapters organized by the four domains of organizational quality, plus appendixes with data tables and measurement specifications for researchers and analysts. The report underscores four basic themes that point to what areas of quality are improving, where variability remains, where progress is strong, and where opportunities for improvement remain, using examples across states and regions by clinical conditions and patient characteristics. It also highlights progress on measures used in national quality initiatives such as Medicare's Quality Improvement Organizations (QIOs) and disease management programs. The NHQR is also published with a companion report, the National Healthcare Disparities Report (NHDR), which emphasizes trends in the quality of healthcare for racial and ethnic minority groups and other vulnerable populations.

Quality Measures

The NHRQ draws on a broad set of quality measures selected based on their importance (e.g., health effects on morbidity and mortality, financial impact), scientific soundness, and feasibility for collection. Quality measures are constructed using various public- and private-sector data sources collected from national and federal data systems, sample data from healthcare facilities and individual providers, population survey data, surveillance and vital statistics data, and health plan data from the Health Employer Data Information System (HEDIS). Each year, the report analyzes 200 to 300 measures, balanced across dimensions of organizational and consumer care, to present information on quality for frequently occurring medical conditions across different populations seeking care and treatment in

acute-, ambulatory-, preventive-, nursing-, home health, and managed-care settings.

Future Direction

While the NHQR is the broadest analysis of longitudinal data on national trends in the quality of healthcare, it remains a work in progress. The analysis of measures has gradually expanded since it was first published in 2003. A major challenge to maintaining its viability as a trustworthy source of information on trends in quality of care hinges on advancements in the field of quality measurement itself. National initiatives to expand measurement across the entire spectrum of medical conditions, populations, and provider settings are likely to remain public policy imperatives for reducing variation in the quality of healthcare for all Americans.

NATIONAL HEALTH INSURANCE

National health insurance provides healthcare coverage for all of a country's population against the costs associated with illness and required healthcare. The term also refers to government-financed, guaranteed, and/or mandated health insurance for all citizens. The system, as a rule, is publicly funded from general tax revenues and does not include direct charges to patients such as deductibles or copayments. The various types of national health insurance systems may differ in terms of how they are structured and financed. Some form of national health insurance currently exists in Australia, in Canada, in China, in virtually all of Europe, in New Zealand, and in much of Africa and Asia.

Overview

National health insurance systems begin with the basic assumption that healthcare is an entitlement and a right of citizens and even, in many cases, of residents. It aims to insure all citizens for a comprehensive range of medical and hospital services, generally covering inpatient and outpatient services, physician services, prescription drugs, and many forms of rehabilitation. A national health insurance system places virtually all responsibility for both regulation and financing of healthcare with government. The government sets standards for a core set of benefits that must be included in the healthcare or medical programs, and it provides funding for these services. In a national health insurance system, some private insurance, which is relatively expensive, may be available to individuals who wish to use it as a supplement or, in some cases, as a substitute for the national program. As a supplement, this private insurance may cover those services that are not included in the basic health insurance scheme, such as prescription

drugs, dental and vision services, and certain forms of institutional care. Overall, public sources cover the vast majority of healthcare that may be needed by an individual. In Canada, for example, the national health insurance system represents about 70% of total healthcare spending.

The major features of a national health insurance system include the following: It is universal, covering all citizens; it is comprehensive, covering all conventional medical care including inpatient and outpatient services; it is accessible, with no restrictions on services that are covered or extra charges to patients; it is portable within a country; and it is publicly administered and under the control of government or a nonprofit agency or organization.

In many national health insurance systems, private practitioners provide healthcare services and are paid on a fee-for-service basis. A fee schedule for all services is set each year through negotiations between the government, insurers, and providers. Annual fee increases are determined by the previous year's rate plus an allowance for inflation and increases due to advances in technology and innovation. There are similar negotiated fee schedules for diagnostic tests and referrals to specialists. Most physicians are self-employed in either solo or small-group practices, as are other practitioners such as dentists and pharmacists. In some national health insurance systems, physicians receive an annual salary as employees of the government.

For inpatient services, hospitals are not-for-profit and are overseen by boards of trustees or by a government regulatory agency. They receive an annual global budget, and these funds are expected to cover all care for all the patients in a given year. Institutional care outside the hospital is provided by facilities such as nursing homes and rehabilitation centers, which are reimbursed on a per diem basis.

In a national health insurance system, all citizens have the same public insurance coverage for physician and hospital care, which covers all medically necessary services. Patients have free choice of any provider in the system (which is virtually all physicians). While other industrialized countries, including the United States, rely on patient cost-sharing arrangements such as deductibles and copayments, most national health insurance systems have elected not to use these methods for cost

containment. As a result, there are not direct costs to seeking care for those covered by a national health insurance system. Under this type of system, primary care is the foundation of healthcare, and patients are encouraged, though not required, to visit their primary-care physician rather than seeking a specialist directly. Eighty-five percent of Canadians, for example, have a primary-care physician whom they see on a regular basis. Specialists receive a larger fee for their services when a primary-care physician refers their patients to them. This practice encourages providers to direct patients to use their generalist appropriately.

In a healthcare system organized around national health insurance, every individual who is covered is issued an insurance or medical card. Consumers present this card when they visit the physician or the hospital; the provider, in turn, submits charges to the government or agency administering the system for reimbursement. For the basic set of medical services covered by public insurance, no further paperwork is required by either the patient or the physician. For care received in a hospital, the hospital is responsible for managing the resources allocated for each case to keep within its annual global budget. Additional paperwork may be required for supplemental services that are insured privately.

This basic public insurance for physician and hospital services includes only limited coverage for a variety of supplemental health benefits, and the majority of these supplemental services are paid for through private insurance or out-of-pocket payment by patients. Those services that are not fully covered by the public insurance scheme include prescription drugs, dental care, vision care, medical equipment and appliances, independent living arrangements for the disabled and the services of allied health professionals. While some public coverage for these services is available in limited cases, the rates of coverage vary on a case-by-case basis. In some countries, for example, the coverage and rates vary by geographic region or area. Because of this, supplemental health benefits are often funded through private health insurance or through additional allocations by regional or local governments. In many cases, these costs for additional or supplemental services have been rising, as they are not subject to the same price bargaining structures as physicians' fees and hospital costs.

National Health Insurance in Context

National health insurance can best be understood by examining the different methods for financing and organizing healthcare systems. There are three basic sets of institutional relationships in different healthcare systems: reimbursement, contractual, and integrated. The reimbursement system, which is usually combined with fee-for-service payments, is common in countries with a mix of public and private insurers and providers, including Canada, Germany, Japan, and the United States. The contract system is found in social insurance systems, as in the Netherlands, which has predominantly private, nonprofit providers. It involves an agreement between providers and third-party payers to impose limits on the total amount and distribution of spending. Contract agreements typically include global prospective budgets for hospitals and rules for reimbursement, including per diem or capitation payments. Integrated systems combine into one agency the funding for as well as the provision of health services. Health professionals are usually salaried employees, and agency budgets serve to control spending. Public integrated health systems are found in the United Kingdom and the Scandinavian countries.

In general, countries combine these relationships in the healthcare system through social insurance or public health services. Social insurance countries finance healthcare from general taxation or from compulsory payroll and employer contributions. Employment-based taxes often provide the financing for nonprofit "sickness funds" that then reimburse providers for services. There are two broad types of integrated public systems: those that are nationally integrated, such as the United Kingdom's National Health Service (NHS); and those that are organized at the local level through the counties, as in Scandinavia.

Similarities and Differences With the U.S. System

The United States does not have a comprehensive healthcare system that provides a core set of services to all citizens. Instead, some form of national health insurance is provided to the elderly through the nation's Medicare program, to low-income and

disabled persons through the state-administered Medicaid program, to veterans through the Veterans Health Administration (VHA), and to low-income children through the State Children's Health Insurance Program (SCHIP). These American programs are remarkably similar to national health insurance programs in countries such as Australia, Canada, England, and New Zealand, in terms of their organization and financing. Some of the administrative or organizational relationships, such as the federal/state partnerships, are similar to those in Canada.

In Canada, as in the United States, most physicians operate in private practice. Unlike the U.S. model, however, all Canadian physicians are part of the same insurance program. The benefit of this model for the Canadian system is two-fold: a single fee schedule can be negotiated for all providers in each province; and the risks and benefits of participation are spread among all physicians.

Some, though not all, of the cost-control mechanisms used in many national health insurance systems are also common in U.S. public and private insurance programs. The most notable exception to this is the fact that the Canadian system does not use point-of-care patient cost-sharing mechanisms such as deductibles and copayments, as do most U.S. private insurers and, increasingly, Medicaid and Medicare plans. The global budgeting scheme used for payment to hospitals in Canada is different from the U.S. Medicare's Diagnosis Related Groups (DRGs) mechanism used to control the costs of an episode of hospital care. The global budget arrangement in Canada is perhaps somewhat more labor-intensive for the hospital because it requires overall planning for all patient encounters in a year rather than the immediate resource management for each individual episode of care required by DRGs.

U.S. managed-care organizations typically pay providers through a capitation arrangement, where payments are made on a per-patient basis. Rather than capitation, however, physicians in many national health insurance systems are paid on a fee-for-service basis for each patient encounter; these fees are negotiated in advance, however, and are much lower than in the United States, even under capitation schemes.

The most striking difference is the breadth of coverage offered by most national health insurance

systems. Between 90% and 95% of citizens in these systems are insured by public health insurance, and in most cases the government will pay for care provided to patients regardless of whether they have an insurance card. As a result, physicians do not incur financial risk by caring for uninsured patients, as is the case in the United States.

Administrative Costs and Cost Controls

Estimates of administrative costs in national health insurance systems range from less than 1% to rates similar to those of U.S. private insurers, which is roughly 20%. These studies attempt to take into account additional sources of overhead not included in the lower estimates, such as the hidden costs of tax-based financing and patient-time costs. Notwithstanding such attempts to uncover real but hidden costs of national health insurance systems, administrative costs of these healthcare systems are significantly lower than those in the United States.

Two components at play in these systems appear to be key to achieving administrative efficiency. First, a macromanagement approach to cost control sets and enforces overall budgetary limits on hospitals and clinics. Being a single-payer system saves time and cost for both the coverage party, either the government or a not-for-profit agency, and the provider, by having a single billing system. Second, by setting global budgets, rather than itemizing charges and then billing for each encounter with each individual patient, the system reduces the amount of time and personnel needed for administration.

Waiting Lists

Waiting lists, or queues, are a concern for consumers in national health insurance systems and for American policymakers looking at these systems. Waiting times for certain procedures are longer in many of the national health insurance countries than they are in the United States. This issue is a source of anxiety for Canadian patients, for example, as well as a difficult planning concern for its policymakers. In response, the Canadian province of Ontario operates a waiting list management program, which uses guidelines that include indicators of severity and urgency to place patients in

appropriate rank order. Studies suggest that those with more severe or urgent conditions do experience shorter waiting times.

It is difficult to get accurate data on the average waiting times for nonemergency procedures in Canada because there are separate waiting lists for each category of procedure, and there have been no organized efforts to collect data on waiting times until recently. These recent efforts include a survey of people in Canada and four other countries that shows that the average waiting time for elective surgery was more than 1 month, with 27% of people surveyed indicating that they had waited more than 4 months.

Some analyses also suggest that mortality rates for people waiting for coronary artery bypass graft are actually lower than expected mortality rates for cardiac patients generally, which indicates that the waiting list management system has been successful at identifying and rapidly treating those patients whose cardiac disease requires immediate attention.

Studies have found waiting times to be longer in Canada than in the United States for a variety of elective surgeries. For example, in a study of knee replacement comparing a large sample of American Medicare patients to Canadian patients, researchers found that the average waiting time was twice as long in Canada. The waiting period for the initial orthopedic consultation was 4 weeks, as compared with 2 weeks in the United States; the waiting period for the knee replacement surgery was 8 weeks, as compared with 3 weeks in the United States. The study found no differences in overall satisfaction with the surgery between the two groups.

The type of rationing embodied by waiting lists also applies to other types of high-technology healthcare services, such as the use of magnetic resonance imaging (MRI) machines. National health insurance systems usually set limits on the number of MRI machines that will be available, and it plans where they will be available geographically. In 2004 there were 4 times more MRI machines per million in the United States than in Canada (19.5 vs. 4.6). In this case, too, there does appear to be a rational process based on medical need and urgency that determines the patient's placement in the queue and ultimate receipt of services.

Waiting lists for elective procedures are often considered a source of cost control in Canada because they can reduce use and therefore spending, but they do not appear to be a large source of the overall spending differential with the United States. The procedures for which the waiting lists in Canada are the longest account for a very small proportion, approximately 3%, of overall spending in both the United States and Canada.

Costs and Benefits

Overall, it is very difficult to assess the costs and benefits of a national health insurance system as compared with a system that is a mix of public and private insurance or with one dominated by private health insurance. Some of the benefits of national health insurance include universal or near-universal coverage, predictable overall costs for the healthcare system, affordability for consumers, equity across user groups, efficiency in the allocation and use of resources, and provision of comprehensive care in inpatient and outpatient settings. The costs of this system include rationing of care, waiting lists, relatively high taxes for citizens, and restrictions on the types of care that will be covered. These costs and benefits will be assessed and balanced in different ways depending on the objectives government, consumers, and providers want to achieve.

From another perspective, it is almost impossible politically in most national health insurance systems to cut benefits, even with the cost pressures facing most systems. It would violate the principles of universality and solidarity that are associated with these systems. On the other hand, the national insurance model makes it possible to eliminate, or nearly eliminate, the administrative costs that are associated with multiple payers. The national health insurance model has considerable leverage in bargaining with providers.

As a result of affordable access to healthcare services for all citizens, Canadians enjoy very good health relative to people in other industrialized nations, including the United States. In a study comparing 13 of the world's major industrial countries using a total of 16 health indicators, Canada ranked 3rd on average, while the United States ranked 12th. The 13 countries included Australia, Belgium, Canada, Denmark, Finland, France,

Germany, Japan, the Netherlands, Spain, Sweden, the United Kingdom, and the United States. In other words, national health insurance systems appear to produce very positive health outcomes.

What many Americans find appealing about national health insurance systems such as those found in Australia, Canada, and the United Kingdom is that they eliminate insecurity about the availability of health insurance and the potential for financial ruin caused by illness. The systems also contain costs, with a smaller proportion of total economic activity devoted to healthcare, as compared with the current system in the United States.

Lessons to Be Learned

What can we learn from a national healthcare system, such as the Canadian system, whose fundamental philosophical and organizational principles are so different from our own? Perhaps more than one might at first glance think. As already noted, the United States already has various healthcare insurance programs that are universal in nature; these programs focus on specific groups of people and not the population as a whole, though.

The United States should evaluate what can be learned from national health insurance systems and the policy challenges they face in the context of a crisis of expectations. Americans want access to high-quality healthcare that offers choice among providers at relatively low costs without any type of rationing in the form of queues or waiting times. In other words, they want high-quality healthcare on demand and they want to be empowered to make their own selection of providers and treatments based on the best medical information available. Existing national health insurance systems provide some good examples and some promise that such expectations can be met under a national system. These systems, as a whole, have managed to insure all citizens for a comprehensive range of medical and hospital services, while also containing medical costs. However, there are fundamental philosophical barriers to adopting such a system in the United States, and this is where the crisis of expectations becomes most apparent. Canada, for example, has been successful in creating a relatively low-cost, easy-access healthcare system that includes a great deal of choice and only moderate

waiting times. But it has done so through governmental power and control. American consumers also want their healthcare system to be relatively free of government regulation. To this extent, national health insurance may be beyond the scope of possible reform options.

However, if Americans see that they could actually spend less on healthcare, this attitude may begin to change. For example, the United States now spends approximately the same percentage of its gross domestic product (GDP) on public health insurance programs as other industrialized countries, about 7%. The United States uses that percentage to cover a small portion of people, while the other countries are able to cover all their citizens with the same amount. The U.S. spends another 7%, or \$800 billion, for private insurance, and the number of uninsured American has grown to 47.5 million.

Other dimensions of quality and patients' experiences help assess how desirable national health insurance may or may not be in the United States. Waiting times for U.S. patients with insurance are less than those for most Canadians who do not have life-threatening conditions. The longest waits and greatest anxiety are experienced by American patients who do not have health insurance coverage, although one solution to this well-documented disparity would be a system that afforded more complete coverage to all Americans.

Universal health insurance means providing insurance to all, not necessarily requiring that everyone share the same system. What is essential in this type of system is that health insurance provide coverage to all people in comparable terms. Since 1985, tension between consumers, providers, and third-party payers, including government, has been growing over which goals or objectives to maximize. The tensions are reflected in the vexing task of balancing cost containment, quality assurance, and freedom of choice for consumers and providers. Systems of national health insurance offer some important lessons for the United States on each of these critical dimensions.

NATIONAL HEALTH POLICY FORUM (NHPF)

The National Health Policy Forum (NHPF), created in 1971, is a think tank that provides current research and information to senior staff in the U.S. Congress and executive agencies in an objective format and that offers an opportunity to discuss complex health issues in a private setting. It was founded based on a recognized need to provide accurate, unbiased information to senior

congressional staff and administrators of executive agencies in Washington, D.C.

Health policy issues often contain many layers and require complex decisions for policymakers. The NHPF offers a nonpartisan exchange of information, thus providing policymakers with an opportunity to sort through the complex layers to make accurate and informed decisions. The forum itself does not take positions on specific health issues, but rather, provides objective information based on research and data to policymakers. It works to promote understanding of complex health issues and foster decision making. The NHPF is affiliated with George Washington University.

Organizational Structure

The NHPF consists of a staff of 19 people who produce resources for policymakers and the general public. The forum's employees have strong backgrounds in federal government, which provides an understanding of not only the governmental process, but also the exact types of issues and decisions faced by policymakers.

The forum's director is responsible for overseeing the activities of the staff. The director serves as a resource not only to the staff, but to policymakers and funding bodies as well. The director is responsible for the direction of the educational activities provided to federal policymakers. The forum's deputy director coordinates grant writing and reporting activities, daily operations, and programming.

In addition, the NHPF has a publications director, who serves as editor for all publications produced by the forum and guides production of print materials, visuals, and the forum's Web site. Research associates are assigned to conduct research and analysis of specific health issues. The health issues addressed by research associates range from healthcare provider issues, aging services, and long-term care to health-care safety net and public health issues. Research associates conduct research, analyze the results, and write reports about their assigned health issues.

Activities and Services

The NHPF produces several types of resources including issue briefs, background papers, and short briefs about programs and practices called "the Basics." Materials categorized under this sec-

tion aim to provide a basic introduction to a health topic. Issue briefs are short reports analyzing a variety of health-related topics and issues, whereas background papers provide a more in-depth examination of a major health issue, looking at the history, theory, and the various positions of a topic.

The NHPF also conducts meetings and workshops on a regular basis for researchers, policymakers, leaders in the healthcare industry, and consumers. Participants attend these events on an invitation-only basis. Forum meetings provide an opportunity for leaders and decision makers in health policy to come together to discuss health issues in an off-the-record setting. A specific health topic is designated for each forum session. An expert speaker or panel presents current information relevant to the designated topic. In addition to regularly scheduled forum sessions, senior congressional staff may request briefings on specific health issues. These briefings offer more in-depth analysis and discussion of a topic. The forum makes materials and handouts from these sessions available on its Web site.

The forum's Web site provides users with access to the same health policy information that is provided to policymakers. Information and materials including issue briefs, background papers, site visit reports, and meeting archives are grouped by content area. The Web site includes information about aging and long-term care, behavioral health, children's health, coverage and access, federalism, Medicaid, Medicare, pharmaceuticals, private markets, public health and preparedness, quality, research and technology, and welfare.

The NHPF also provides access to papers produced by the Health Insurance Reform Project (HIRP) on its Web site. The HIRP, another non-profit, nonpartisan organization working as an independent voice in the health policy arena, strives to improve the health insurance and healthcare industries by monitoring trends and policy. While it is also affiliated with George Washington University, HIRP is separate from the forum.

The forum also coordinates site visits for federal policymakers. Site visits are held throughout the country to showcase innovative programs and to demonstrate how local health communities deal with specific issues. Recent site visits addressed topics relating to senior citizen health and housing, rural health systems, health records, access to care, and quality of care.

Funding

The NHPF is supported by grants and financial contributions from several foundations and corporations. While 98% of its funding comes from a number of private foundations such as the W. K. Kellogg Foundation and the Robert Wood Johnson Foundation, approximately 2% of its revenue comes from corporate contributions from health insurance companies, pharmaceutical companies, and other private corporations.

NATIONAL HEALTH SERVICE CORPS (NHSC)

The National Health Service Corps (NHSC) is a federal program that recruits primary healthcare professionals to serve in designated Health Professional Shortage Areas (HPSAs). The Corps enlists primary-care physicians and other healthcare practitioners with scholarships and education loan repayment plans that require work in underserved areas of the nation. In FY2007, the program's budget was \$125 million.

Background

The U.S. Congress created the NHSC in 1970 with the passage of the Emergency Health Personnel Act (PL 91-623) in response to the increasing geographic imbalance in access to primary care. By the end of the 1960s, rural areas suffered shortages of physicians as existing physicians retired and new ones preferred practicing in less remote areas. Innercity urban areas also were experiencing the loss of physicians and other healthcare professionals.

To identify areas of need, the federal government broadly defines and specifically identifies HPSAs. These areas have a shortage of primary-medical-care, dental, or mental health providers and may be geographic (a county or service area), demographic (low-income population), or institutional (comprehensive health center, federally qualified healthcare center, or other public facility). Specific shortage areas are designated by the Secretary of the Department of Health and Human Services (HHS). Currently, there are over 5,000 designated shortage areas in the nation. These shortage areas encompass about 50 million Americans, or 20% of the U.S. population.

Organizational Structure

The NHSC program is managed by the U.S. Department of Health and Human Services, Health Resources and Services Administration's Bureau of Health Professions (BHPr). The program has a national advisory council, which comprises 15 clinicians and healthcare administrators. The council identifies priorities, suggests and analyzes policy changes, and generally advises possible improvements in access to primary care through the program to the Secretary of the HHS and the Administrator of the Health Resources and Services Administration (HRSA).

Scholarship and Loan Programs

Under the NHSC Scholarship Program, student recruits agree to serve 1 year as a salaried professional in an approved underserved area after graduation for each year that they received the full tuition scholarship. After their commitment, scholarship

recipients may enter private practice wherever they wish, but the hope is that they will stay in the underserved area. The scholarships are available to U.S. citizens studying to be allopathic or osteopathic physicians, dentists, nurse practitioners, physician assistants, nurse midwives, and other specific healthcare professionals.

The NHSC Loan Repayment Program, added in 1987, allows healthcare professionals to join the Corps and practice in an underserved area in exchange for repayment of a portion of their educational loans. Both newly graduated as well as seasoned professionals are eligible. The loan repayment program contracts require a minimum 2-year commitment to the placement site, and recipients may be able to extend the assignment to gain further loan repayment. Newly graduated or seasoned professionals are eligible, but must be U.S. citizens and be licensed and/or certified (depending on the profession). Specifically, eligible professionals include allopathic and osteopathic physicians, primary-care certified nurse practitioners, certified nurse-midwives, primary-care physician assistants, general-practice dentists, registered clinical dental hygienists, health service psychologists, licensed clinical social workers, psychiatric nurse specialists, marriage and family therapists, and licensed professional counselors.

Other Programs

The NHSC also recruits professionals to serve on a basis other than to repay obligations of a scholarship or for loan repayment. One such recruiting effort is the Rapid Response Program. Rapid responders, all primary-care professionals, serve as U.S. Public Health Service (USPHS) commissioned officers for 3 years in a medically underserved area and receive training to be part of a mobile team available in case of a large scale or national emergency.

Additionally, the NHSC also runs the Ambassador Program, which is composed of volunteers on college and university campuses or in communities. The Ambassador Program is composed of about 650 members. College Ambassadors help promote careers in primary care and inform, recruit, and support interested students. Community Ambassadors also help recruit clinicians and provide mentorship and support for Corps members.

Program Success

Since its inception, the NHSC has supported over 27,000 health professional recruits in every state, territory, and possession of the United States. In 2007, the program had 4,600 health professionals working in underserved urban and rural areas, with 50% serving in community health centers. They serve 5 million people. As part of its mission, the Corps hopes that its members will continue to practice in underserved communities once they have fulfilled their obligatory service. Records show that many Corps members do not stay at their original placement site, leaving the impression that access in underserved areas is not dramatically improved in the long term. However, further studies reveal that, although these professionals do not necessarily stay in their original placement site, many do go to other underserved areas to practice. Over 75% of those who repay their loans continue to work in underserved areas, while just over 60% of scholarship recipients remain.

NATIONAL INFORMATION CENTER ON HEALTH SERVICES RESEARCH AND HEALTH CARE TECHNOLOGY (NICHSR)

The National Information Center on Health Services Research and Health Care Technology (NICHSR) was established by the federal National Institute of Health Revitalization Act of 1993 (PL 103–43). A unit of the National Library of Medicine (NLM), the NICHSR has the broad mission of improving the collection, storage, analysis, retrieval, and dissemination of information on health services research, clinical practice guidelines, and healthcare technology, including the assessment of such technology. The NICHSR has a professional staff of six, including librarians and a health data standards specialist. It reports to the director of the NLM.

Goals

The overall goals of the NICHSR are as follows: (a) to make the results of health services research, including clinical practice guidelines and technology assessments, readily available to health practitioners, healthcare administrators, health policymakers, payers, and the information professionals who serve these groups; (b) to improve access to data and information needed by the creators of health services research; and (c) to contribute to the information infrastructure needed to foster patient record systems that can produce useful health services research data as a by-product of providing healthcare.

Health services research is a multidisciplinary field; its research domains include individuals, families, organizations, institutions, and communities. As a result, evidence from health services research is spread through a variety of sources, often making it difficult for health professionals, healthcare administrators, and health policymakers

to find the information needed to guide their decision making. It is the role of the NICHSR to meet this need by coordinating the development and management of information resources and services at the NLM in the fields of health services research and public health.

Databases

An important aspect of this role is the selection of health services literature for the NLM's collection, including both published research and grey literature (e.g., material that is not found through conventional channels such as recent technical reports and working papers from research groups or committees). This function is coordinated jointly through the NICHSR, the Literature Selection Technical Review Committee (LSTRC), and the NLM's Technical Services Division. This bibliographic information used to reside in a separate database known as HealthSTAR, but in 2000, it was integrated with other NLM resources. It is now available in the following ways: (a) journal citations are added weekly to the NLM's PubMed; (b) books, book chapters, technical reports, and conference papers are added regularly to the NLM's online catalog, LocatorPlus; and (c) meeting abstracts from AcademyHealth (formerly the Academy for Health Services Research and Health Policy and the Association for Health Services Research) and Health Technology Assessment International (HTAi) (formerly known as the International Society of Technology Assessment in Health Care) are accessible through the NLM Gateway.

In addition to these resources, the NICHSR coordinates the development and maintenance of databases related to health services research. Available databases include the following: (a) HSTAT, a free, Web-based resource of full-text documents that provide health information and support healthcare decision making; (b) HSRProj, a database of citations to research-in-progress funded by federal and state agencies and foundation grants and contracts; and (c) Health Services and Sciences Research Resources (HSRR), a free searchable catalog of research databases, survey instruments, and software relevant to health services research, behavioral and social sciences, and public health. The HSRProj became available in 1995. It builds on a

database developed by the staff of AcademyHealth and the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill. Finally, the NLM's Directory of Information Resources On-line, known as DIRLINE, has a special subfile covering health services research organizations, including those involved in technology assessment and development of clinical practice guidelines.

Recent Activities

In 2005, the NICHSR launched the HSR Information Central, a Web portal designed to centralize access to health services research information. The HSR Information Central was developed with input from the Agency for Healthcare Research and Quality (AHRQ), the National Cancer Institute (NCI), the Health Services Research and Development Service (HSR&D) at the Veterans Administration, and other organizations. A librarian evaluates each link on the HSR Information Central before it is added to the site, and users of the site are encouraged to submit additional Web links via the "Suggest-a-Link" form available at the site.

In addition to its online databases, the NICHSR and other NLM staff develop guides, fact sheets, bibliographies, and other products targeted to health services researchers. The NICHSR has developed classes and other training materials designed to assist health sciences librarians in providing health services research to their patrons. Core library recommendations have been developed for the areas of health services research methodology, health outcomes, health economics, and health policy. These lists include books, journals, and Web sites and are intended to guide individuals unfamiliar with the subject area. The NICHSR has also created online self-study courses, such as "Finding and Using Health Statistics," "Introduction to Health Care Technology Assessment," and "Health Economics Information Resources."

The NICHSR collaborates with NLM units and with members of the National Network of Libraries of Medicine to exhibit NLM products and services and to present training classes at national meetings of health services research-related organizations. The NICHSR, along with other NLM staff, is an active participant in Partners in Information Access

for the Public Health Workforce. This initiative works to improve information for public health working professionals. Other partners include the Agency for Healthcare Research and Quality (AHRQ), the American Public Health Association (APHA), the Association of Schools of Public Health (ASPH), the Association of State and Territorial Health Officials (ASTHO), the Centers for Disease Control and Prevention (CDC), the Health Resources and Services Administration (HRSA), the Medical Library Association (MLA), the National Association of County and City Health Officials (NACCHO), the National Network of Libraries of Medicine (NN/LM), the Public Health Foundation (PHF), and the Society for Public Health Education (SOPHE). The NICHSR also works closely with the AHRQ and other organizations to improve the dissemination of the results of health services research.

Future Implications

The passage of the federal Health Insurance Portability and Accountability Act of 1996 (HIPAA) created new challenges for health services research, focusing on computer-based patient records, security, and privacy standards. Recent research and development efforts at the NICHSR have focused on the expansion of the Unified Medical Language Systems' Metathesaurus to improve its utility in creating and retrieving computer-based patient records, as well as the funding of extramural research and evaluation involving the creation and use of computer-based patient records.

NATIONAL INSTITUTES OF HEALTH (NIH)

The National Institutes of Health (NIH) is the principal federal agency responsible for overseeing and financially supporting health-related and biomedical research. It funds and oversees research conducted within the United States as well as research conducted internationally. The primary goal of the NIH is to promote health and prevent disease through health-related research that provides significant insights and solutions to these problems. The NIH is regarded as one of the world's leading biomedical research centers and it is the hub of medical research activity in the nation. Researchers at the NIH are at the forefront of finding ways to prevent, treat, and cure diseases as well as find the causes of rare and common diseases. The NIH works to improve the health of people in the United States and save the lives of millions.

The NIH consists of 20 institutes and 7 centers, each with its own specific areas of research and resources of health information. The NIH is 1 of 11 U.S. Public Health Service Agencies of the U.S. Department of Health and Human Services (HHS). The NIH's headquarters and main campus are located in Bethesda, Maryland, with satellite sites across the nation. In 2007, NIH had a staff of more than 18,000 employees and a budget of nearly \$28 billion. Additionally, more than 83% of the NIH's funds were awarded through competitive grants and contracts to over 325,000 researchers located at universities, medical schools, and research institutions throughout the nation and the world.

History

The political and historical context has contributed to the multifaceted organization of the NIH's institutes, centers, and offices and their myriad roles and responsibilities. The NIH began in 1887 with one research scientist, Joseph J. Kinyoun, working in a one-room laboratory within the Marine Hospital Service (MHS). As a physician he was authorized to create the Hygienic Laboratory located at Staten Island, New York. The Hygienic Laboratory was primarily used to conduct bacteriological research focusing on screening for infectious diseases such as cholera among merchant seamen and officers of the U.S. Navy. As a result, research activities were limited to biological investigations, and they did not address other factors affecting the public's health.

During the early 20th century, the general public increasingly believed in the usefulness of science to advance the health of Americans, which provided numerous opportunities to expand the roles and responsibilities of the Hygienic Laboratory. A series of legislative events prompted the transformation of the Hygienic Laboratory into a federal agency responsible for the nation's health.

In 1930, the Hygienic Laboratory was officially renamed the National Institute of Health, and it was authorized to provide research training fellowships through the passage of the Ransdell Act (PL 71-251). The U.S. Congress passed the Public Health Service Act (PL 78-410) in 1944, which gave the U.S. Surgeon General of the Public Health Service (PHS) increasing authority to fund research

studies and designated the newly established National Cancer Institute (NCI) as an Institute of the NIH. Accordingly, the NIH gradually began to enlarge its facilities and research funding mechanisms. The NCI was already authorized by the U.S. Congress in 1937 through the National Cancer Institute Act (PL 75-244) to provide research funds to nonfederal workers and to sponsor research training fellowships outside of the organization. As the other institutes were established, between 1948 and 2000, the thriving NCI grants and research training programs continued to expand. Funding for the NIH grew tremendously during this time period, from \$2.5 million in 1944 to more than \$1 billion in 1966. And NIH funding has continued to expand.

Overview

Over the decades, the significant work of the NIH has resulted in numerous important discoveries and medical treatments that have saved the lives of many, increased the life expectancy of the nation's population, and improved the quality of life of individuals. The NIH has been able to translate research findings into interventions that have benefited the general public, patients, and their families. Furthermore, the outcomes of the NIH's research have resulted in decreased death rates from heart disease, stroke, HIV/AIDS, and sudden infant death syndrome (SIDS); the increased survival rate of childhood cancer patients; and prevention of the spread of infectious diseases through vaccinations.

In addition to conducting cutting-edge research that has transformed medical science, the NIH also provides funding and training opportunities. All its institutes support research, funding, and training opportunities for research scientists in a variety of settings such as hospitals, universities, and laboratories. The NIH centers also provide and coordinate resources that facilitate intensive research training and development of a strong national research infrastructure. Under the guidance of the Office of the Director, the 27 institutes and centers aim to meet the four stated overarching goals of the NIH: (1) to foster fundamental creative discoveries, innovative research strategies, and their applications as a basis to advance the nation's capacity to protect and improve health significantly; (2) to

develop, maintain, and renew scientific human and physical resources that will ensure the nation's capability to prevent disease; (3) to expand the knowledge base in medical and associated sciences in order to enhance the nation's economic well-being and ensure a continued high return on the public investment in research; and (4) to exemplify and promote the highest level of scientific integrity, public accountability, and social responsibility in the conduct of science. The establishment of these institutes reflects the direction of present scientific discoveries and societal needs. Specifically, the NIH concentrates its research agenda and educational efforts on input from expert researchers and clinicians, patient advocacy and grassroots organizations, and representatives from the U.S. Congress.

With federal funds, the NIH supports intramural and extramural research studies in which both types of studies undergo a careful process of scientific review before investigation, and they follow strict guidelines throughout the research process. Intramural research activities are conducted in NIH laboratories and at the NIH Clinical Center at its main campus in Bethesda. Seven major NIH Inter-Institute Scientific Interest Groups are organized by the NIH Office of Intramural Research and offer training opportunities and expert guidance for junior researchers. The NIH Office of Extramural Research (OER) develops and implements NIH grants, policies, and guidelines primarily for university investigators. The NIH awards funds to external organizations to help accomplish its program goals through research grants, cooperative agreements, and contracts.

In FY2006, approximately 50,000 research grants were awarded through the OER. Grant applications and cooperative agreements are subject to a system of two separate peer reviews. One is a scientific assessment, and the second is an evaluation of the first assessment as well as resource funding allocations.

Contracts are reviewed under a separate process including a request for proposals (RFP) based on the needs of the specific institute. RFPs are reviewed by peer reviewers and NIH staff reviewers. The offers that are deemed the most beneficial to the public are awarded contracts. The peer review system constructs a foundation of decision making based on scientific integrity and responsibility regarding the federal stewardship of funds.

Institutes

The NIH comprises 20 different institutes that work to accomplish its overarching goals. Each institute is briefly discussed below.

National Cancer Institute

The National Cancer Institute (NCI) was established in 1937 to conduct and support research concerning the cause, diagnosis, prevention, and treatment of cancer and to regularly provide federal cancer statistics. Of all the institutes at the NIH, the NCI has the largest budget, at nearly \$4.7 billion. The NCI publishes a large number of articles, books, and other material on various types of cancer, treatment options, clinical trials, coping with cancer, testing for cancer, nutrition, and cancer risk factors.

National Eye Institute

The National Eye Institute (NEI) was established in 1968 to conduct and support vision research to prevent and treat visual impairment and blindness. The NEI conducts public educational programs through its National Eye Health Education Program. The NEI publications include information about eye diseases and disorders and eye care resources.

National Heart, Lung, and Blood Institute

The National Heart, Lung, and Blood Institute (NHLBI), established in 1948, fosters and furthers research on cardiovascular diseases as well as sleep disorders. The NHLBI publications include health assessment and educational resources for patients, clinicians, and researchers.

National Human Genome Research Institute

The National Human Genome Research Institute (NHGRI) was established in 1989 to represent the work of the NIH on the International Human Genome Project (IHGP). After the successful completion of the IHGP in 2003, the NHGRI continues to conduct and support human genome research. The NHGRI educational resources include a Human Genome Project CD and genetics and genomics education resources for the public.

National Institute on Aging

The National Institute on Aging (NIA), created in 1974, is focused on better understanding the aging process through scientific research. Currently, the NIA funds external research studies on the biology of aging, behavioral research, neuroscience, and geriatrics and gerontology. The NIA's publications include information related to healthy aging, medications, safety, Alzheimer's disease, health conditions related to aging, and care giving.

National Institute on Alcohol Abuse and Alcoholism

The National Institute on Alcohol Abuse and Alcoholism (NIAAA) was established in 1970 to conduct and support research on the causal factors, diagnosis, prevention, and treatment of alcohol-related conditions. The NIAAA's publications include the journal *Alcohol Research and Health*, professional education materials for researchers and clinicians, and pamphlets and brochures on alcohol-related topics for the public.

National Institute of Allergy and Infectious Diseases

National Institute of Allergy and Infectious Diseases (NIAID), which focuses on research on infectious, immunologic, and allergic diseases, was established in 1948. The NIAID strategic plan for the 21st century includes further investigation of allergic diseases and asthma, autoimmune diseases (e.g., Type 1 diabetes, rheumatoid arthritis, and multiple sclerosis), HIV/AIDS, tuberculosis, malaria, influenza, hepatitis, and bioterrorism.

National Institute of Arthritis and Musculoskeletal and Skin Diseases

The National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), created in 1986, examines and supports research on the causal factors, diagnosis, prevention, and treatment of arthritis and musculoskeletal and skin diseases. The NIAMS' Information Clearinghouse provides health information for professionals and the general public.

National Institute of Biomedical Imaging and Bioengineering

The National Institute of Biomedical Imaging and Bioengineering (NIBIB) is the most recently established institute. Since 2000, it has worked to foster the study of biomedical technology and engineering. Currently, the NIBIB supports external research studies on biomaterials, biomedical informatics, biomedical and medical imaging, nanotechnology, nuclear medicine, tissue engineering, and ultrasound.

National Institute of Child Health and Human Development

The National Institute of Child Health and Human Development (NICHD) was established in 1962 to conduct and support the study of infants, children, and their families and human development across the lifespan. The NICHD currently supports external research studies on developmental biology and perinatal medicine, reproductive health, child development, and pediatric and maternal HIV/AIDS. It also sponsors health campaigns to target problems such as autism, obesity, and sudden infant death syndrome (SIDS).

National Institute on Deafness and Other Communication Disorders

Since its inception in 1988, the National Institute on Deafness and Other Communication Disorders (NIDCD) has focused on the study of communication disorders. Currently, the NIDCD is conducting research studies on human communication and genetics, sensory and signal transduction mechanisms, and physiological and developmental studies of the inner ear.

National Institute of Dental and Craniofacial Research

The National Institute of Dental and Craniofacial Research (NIDCR) was established in 1948 to conduct and support research on the causal factors, diagnosis, prevention, and treatment of craniofacial-oral-dental diseases and disorders. The NIDCR is currently conducting research studies on genomics and proteomics, as well as the repair and

regeneration of tissues related to craniofacial-oral-dental diseases and disorders.

National Institute of Diabetes and Digestive and Kidney Diseases

The National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), established in 1948, supports and conducts research on the study of diabetes as well as endocrine, metabolic, digestive, kidney, urologic, and hematologic diseases. The NIDDK clearinghouse provides publications for patients and researchers on diabetes and digestive, kidney, and urologic diseases.

National Institute on Drug Abuse

Established in 1973, the National Institute on Drug Abuse (NIDA) works to advance research on the causal factors, diagnosis, prevention, and treatment of drug abuse and addiction. The NIDA provides a vast array of prevention and treatment resources to healthcare providers, researchers, parents, and teachers, as well as to students and young adults. Currently, the NIDA supports external research studies on treatment for drug disorders, drug abuse aspects of HIV/AIDS, genetics and genomics of drug addiction, and prescription drug abuse.

National Institute of Environmental Health Sciences

The National Institute of Environmental Health Sciences (NIEHS) was created in 1969 to conduct and support the study of environmental factors and causes related to health and illness. The NIEHS 2006–2011 Strategic Plan includes goals to increase the understanding of environmental influences related to human biology and to expand clinical research programs on environmental exposures.

National Institute of General Medical Sciences

The National Institute of General Medical Sciences (NIGMS), active since 1962, focuses on the study of biomedical sciences for understanding the pathways of disease diagnosis, prevention, and treatment. The NIGMS funds studies on bioinformatics and computational biology; cell biology and biophysics; structural genomics and proteomics

technology; genetics and developmental biology; and pharmacology, physiology, and biological chemistry.

National Institute of Mental Health

The National Institute of Mental Health (NIMH) is charged with advancing research on the causal factors, diagnosis, prevention, and treatment of mental illness. It was established in 1949. Currently, the NIMH funds external research studies on basic neuroscience and behavioral science, adult and pediatric mental disorders, biobehavioral processes related to HIV/AIDS transmission and infection, and mental health interventions.

National Institute of Neurological Disorders and Stroke

The National Institute of Neurological Disorders and Stroke (NINDS), created in 1950, conducts and fosters research on the causal factors, diagnosis, prevention, and treatment of neurological disease and stroke. The NINDS areas of neuroscience research include, but are not limited to, the structure and functioning of the nervous system through examining neural circuits, neural environment, neurodegeneration, and neurogenetics.

National Institute of Nursing Research

Since 1986, the National Institute of Nursing Research (NINR) has focused its efforts on nursing research among individuals, families, communities, and populations. Currently, the NINR areas of research emphasis include improving health promotion and quality of life, eliminating health disparities, and advancing end-of-life research.

National Library of Medicine

The National Library of Medicine (NLM), established in 1956, strives to advance the study of biomedical informatics and communications. The NLM is located at the NIH headquarters in Bethesda, Maryland, and serves as the world's largest medical library. The NLM's online databases, such as PubMed/Medline, include biomedical publications from thousands of journals; MedlinePlus serves as a resource for health information for professionals and the general public.

Centers

In addition to its 20 institutes, the NIH houses 7 research centers. Each center is briefly discussed below.

Center for Information Technology

The Center for Information Technology (CIT) has been working to develop computer systems, provide computer facilities, and conduct computational research since its creation in 1964. The CIT supports NIH's institutes with information technology, computing, and telecommunications services. For example, the CIT's Division of Computational Bioscience applies technologies to biomedical applications such as biomedical informatics and medical imaging.

Center for Scientific Review

The Center for Scientific Review (CSR), which was established in 1946, recruits and organizes expert peer reviewers into study sections to evaluate the research grant applications sent to the NIH. These external experts are recruited nationally and represent the areas of expertise needed to effectively decide on funding of the most promising research activities.

John E. Fogarty International Center

The John E. Fogarty International Center (FIC) was established in 1968 to promote and support research on global health. Currently, the FIC funds research studies in the developing world on brain disorders, maternal and child health, and infectious diseases, such as HIV/AIDS and tuberculosis. It also supports international research partnerships.

National Center for Complementary and Alternative Medicine

In 1999, the NIH created the National Center for Complementary and Alternative Medicine (NCCAM) to focus on complementary and alternative medical (CAM) practices and training efforts. Currently, the NCCAM areas of research emphasis include mind-body medicine practices, pharmaceutical and pharmacokinetic properties of

CAM products, energy medicine, traditional/indigenous practices, and ethical and social issues related to the use of CAM.

National Center on Minority Health and Health Disparities

The National Center on Minority Health and Health Disparities (NCMHD), established in 1993, conducts and supports research to improve minority health and eliminate health disparities. Currently, the NCMHD provides loan repayment funds for researchers working in minority health and health disparities research, as well as for those who are developing external research training programs and centers.

National Center for Research Resources

The National Center for Research Resources (NCRR), created in 1962, provides researchers with biomedical resources as well as technological support to develop successful clinical research environments. Currently, the NCRR focuses on providing support in biomedical technology, clinical research, comparative medicine, and research infrastructure.

NIH Clinical Center

Originally established as a research hospital facility in 1953, the NIH Clinical Center (CC) supports clinical research conducted by all the NIH institutes and centers. Admission to the CC is selective and based on NIH study objectives. The CC also provides numerous training opportunities to researchers through lectures and computer-based training as well as fellowship programs.

Future Implications

For more than a century, the NIH has been responsible for improving the nation's health through biomedical and behavioral research. The NIH continues its important work of discovering new knowledge to improve the nation's health through its ambitious research agenda. Additionally, through its institutes and centers, the NIH strives to provide resources and expertise in the broad spectrum of clinical medicine and public health. The NIH furthers its goals by sponsoring research,

fellowships, training, and infrastructure development. Through the translation of biomedical research discoveries into means of disease prevention and improvements in clinical outcomes, reduction in the individual and societal burden of disease is being achieved.

NATIONAL MEDICAL ASSOCIATION (NMA)

The National Medical Association (NMA) promotes the collective interests of physicians and patients of African descent and other minority and underserved populations in the United States. The association carries out this mission by serving as the collective voice of Black physicians. It is a leading force for parity in medicine, the elimination of health disparities, and the promotion of optimal health.

History

The National Medical Association was founded in the fall of 1895 at the Cotton States and International Exposition in Atlanta, Georgia, after a group of Black physicians were denied admission into the American Medical Association (AMA). In a climate of segregation, the National Medical Association was founded to provide an organization for Black physicians and health professionals. Robert F. Boyd of Nashville, Tennessee, served as the association's first president.

The main priority for the first National Medical Association's agenda was how to improve the health of the nation's Black population, which exceeded 10 million in 1912, and increase the number of Black physicians to adequately serve the health of that population. The association's members worked on these priorities by opening hospitals with an emphasis on physician training and by studying the major diseases contracted by Blacks, such as tuberculosis, hookworm, and pellagra.

In 1909, the first issue of the *Journal of the National Medical Association* was published. Charles V. Roman served as the journal's first editor. From its beginning, the journal focused on scholarly research and findings regarding the treatment, management, and prevention of illness and disease.

In the 1940s, the National Medical Association continued its efforts to eliminate discrimination in the nation's hospitals and medical schools. In 1951, the association was responsible for several segregated medical schools located in the South and nearby states beginning to admit Black students. Within a 10-year period, the number of Black students attending these medical schools

doubled. By the 1960s, 14 of the 26 southern medical schools admitted Black students.

In 1957, the first Imhotep National Conference on Hospital Integration was held. This annual meeting was sponsored by the National Medical Association, the National Association for the Advancement of Colored People (NAACP), the National Urban League, and the Medico-Chirurgical Society of the District of Columbia (an affiliate of the National Medical Association). This conference was successfully used as a platform to disseminate strategies to foster the elimination of segregation in healthcare.

During the turbulent 1960s, the National Medical Association was a viable force in the nation's civil rights movement. The association advocated for civil rights by coordinating sit-ins, marches, and picket lines and by lobbying to pass a federal civil rights act. It supported Martin Luther King Jr.'s efforts to register voters in Selma, Alabama, which ultimately led to the passage of the Civil Rights Act of 1965. The passage of this act was instrumental in giving Blacks hope of improving their health status by outlawing discrimination in government-funded health programs. In particular, the act assured them access to healthcare through Medicare and Medicaid programs, and the professional staffs and patient populations at hospitals were desegregated.

Activities

Currently, the National Medical Association represents more than 30,000 Black physicians and their patients. The association continues to publish the *Journal of the National Medical Association* monthly, the quarterly *Healthy Living* newsletter, targeted to physicians and patients, and the e-newsletter *NMA News*. It also publishes the *Convention Daily News*, which is available at the association's Annual Convention and Scientific Assembly, where about 1,000 scientific sessions are held.

The association offers many continuing medical education (CME) courses at its national assembly as well as at regional, state, and local society meetings offered in its 33 state and 98 local affiliated medical societies. All its courses are accredited by the Accreditation Council for Continuing Medical Education.

The National Medical Association sponsors a wide range of externally funded programs. These include the Smoking Cessation Program, the National Diabetes Education Program (cosponsored with the U.S. Department of Health and Human Services' National Diabetes Education Program [NDEP]), the Clinical Trials Project Impact program to increase minority physicians and consumer awareness and participation in clinical trials, and the Black Bag Mentoring program to facilitate African American residents' and students' access to practicing physicians.

In 2004, the association formed The W. Montague Cobb/National Medical Association Health Institute. The focus of the institute is to identify, develop, and implement solutions that will reduce racial and ethnic health disparities and improve the health of all Americans. The institute has four centers: (1) the Multicultural Health Center; (2) the Research, Surveillance and Professional Education Center; (3) the Community/Public Media Information Center; (4) and the Mobilization and Advocacy Center.

The association holds an annual National Colloquium on African American Health to foster its advocacy mission by offering programs to train healthcare leaders to address and eliminate health disparities of Blacks, other minorities, the poor, and the medically underserved.

The National Medical Association's advocacy efforts are continued through its International Affairs Committee, which serves as a resource to assist and enhance association members' participation in medical missions around the world. In addition, association members' spouses formed the Auxiliary to the National Medical Association. The auxiliary's current efforts consist of developing and promoting a National Auxiliary Program on Health, Education, and Legislation.

The association also supports the Student National Medical Association (SNMA). Started in 1964 by medical students from Howard University College of Medicine and Meharry Medical College, the Student Medical Association currently has over 5,000 members, including medical students, pre-medical students, residents, and physicians. Its primary focus is the needs and concerns of medical students of color, although its efforts include encouraging elementary, high school, and college students to consider and prepare for medical and scientific careers. The National Medical Association

also provides a Career Center to assist in the employment and recruitment of minorities into medical professions.

NATIONAL PATIENT SAFETY GOALS (NPSG)

The Joint Commission's National Patient Safety Goals (NPSG) address problematic areas in healthcare by using evidence- and expert-based solutions. The NPSG are composed of implementation expectations and requirements for Joint Commission-accredited organizations. Where possible, the goals focus on systemwide improvements. The goals are program specific and apply variously to ambulatory care, office-based surgery, behavioral healthcare, critical-access hospitals, disease-specific care, home care, hospitals, laboratories, long-term care, integrated delivery systems, managed-care organizations, and preferred provider organizations (PPOs). All Joint Commission-accredited healthcare organizations are expected to implement the goals or approved alternatives to the services the organization provides in order to obtain or maintain their accreditation. The first goals were approved in 2002 and have been updated annually since then.

Development of the Goals

Formed in February 2002, the Sentinel Event Advisory Group (SEAG), a panel of patient safety experts including nurses, physicians, pharmacists, risk managers, and other professionals, oversees the development and improvement of the NPSG and implementation requirements. Each year, the SEAG works with the Joint Commission staff to identify potential new goals and requirements through a systematic review of the relevant literature and information from available patient safety incident databases, such as the Joint Commission's Sentinel Event Database and the U.S. Pharmacopeia's Medmarx Database. Once potential goals are identified, input is sought from practitioners, provider organizations, purchasers, consumers, and patient advocacy groups. The SEAG then determines the highest-priority goals and requirements and makes its recommendations to the Joint Commission. To maintain the focus of accredited organizations on the most salient patient safety issues, the SEAG may recommend the retirement of selected goals or requirements. Retired goals or

requirements will usually continue as accreditation requirements under the relevant accreditation standards. The gaps in goal numbering indicate that a goal has been retired.

Specifically, the 2008 NPSG goals for hospitals were as follows:

Goal 1: Improve the accuracy of patient identification.

Goal 2: Improve the effectiveness of communication among caregivers.

Goal 3: Improve the safety of using medications.

Goal 7: Reduce the risk of healthcare-associated infections.

Goal 8: Accurately and completely reconcile medications across the continuum of care.

Goal 9: Reduce the risk of patient harm resulting from falls.

Goal 10: Reduce the risk of influenza and pneumococcal disease in institutionalized older adults.

Goal 11: Reduce the risk of surgical fires.

Goal 12: Implement the applicable NPSG and associated requirements by components and practitioner sites.

Goal 13: Encourage patients' active involvement in their own care as a patient safety strategy.

Goal 14: Prevent healthcare-associated pressure ulcers (decubitus ulcers).

Goal 15: Identify safety risks inherent in its patient population.

Goal 16: Improve recognition and response to changes in a patient's condition.

Last, the organization fulfills the expectations set forth in the Universal Protocol for preventing wrong-site, wrong-procedure, and wrong-person surgery, and associated implementation guidelines.

Challenges in Meeting the Goals

Depending on the goal, healthcare organizations may face various system, resource, personnel, behavioral, and/or cultural barriers to goal implementation. Some goals have been consistently criticized for the added burden they place on an

already overstretched system. For example, Goal 8, the "medication reconciliation" goal, calls for healthcare organizations to obtain an accurate list of medications from patients and to define a process to ensure that information is accurately communicated from provider to provider. The intent of the goal is to prevent patient safety incidents involving adverse drug events by ensuring that healthcare providers have accurate patient medication information so that the provider can effectively care for the patient. However, inordinate attention has been paid to documentation or "obtaining the list," and therefore, the intent of the goal is sometimes lost. Organizations that have successfully implemented medication reconciliation programs are those that have integrated the practice of medication reconciliation into existing processes and then worked to refine those processes to eliminate duplication and redundancy. Organizations that struggle with implementing medication reconciliation are those that tend to add these processes on to existing systems without considering the potential implications of doing so.

Future Implications

The NPSG focus attention on problematic areas in healthcare. Successful implementation of the goals is challenging for healthcare organizations, given the complexity of organizational systems, resources, personnel, and cultures. There are no one-size-fits-all solutions, and there is only emerging research that supports the effectiveness of some of the goals. Because the goals are intended to prevent patient harm and improve safety, the Joint Commission will continue in these efforts despite the difficulties in implementation.

NATIONAL PRACTITIONER DATA BANK (NPDB)

Administered by the Health Resources and Services Administration (HRSA), the National Practitioner Data Bank (NPDB) is a federal information clearinghouse responsible for receiving, storing, and disseminating information about medical malpractice payments and adverse actions taken against healthcare practitioners. Established under the Health Care Quality Improvement Act of 1986, the NPDB began collecting data on September 1, 1990. The purpose of the data bank is to improve medical-care quality and safety by restricting the ability of incompetent physicians, dentists, and other practitioners to move from state to state without the disclosure of previous medical malpractice payments and adverse actions. The NPDB is intended to be an alert system that facilitates a comprehensive review of a healthcare practitioner’s professional credentials.

Types of Reports

The NPDB receives six types of reports: (1) medical malpractice payments made on behalf of a practitioner, (2) licensure actions taken by state

medical and dental boards, (3) professional review actions taken by hospitals and other healthcare entities exercising significant peer review activities, (4) professional society membership actions, (5) actions taken by the U.S. Drug Enforcement Administration (DEA), and (6) Medicare and Medicaid exclusions. Medical-malpractice payments are the most common type of report received by the NPDB. Since its inception, the NPDB has received about 320,000 medical malpractice reports, which represent about 75% of all reports. State licensure actions are the next most common type of report, at 14%, followed by Medicare and Medicaid exclusion at 8.0% and clinical privileging actions at about 4%. Professional society membership and DEA actions make up less than 0.5% of all reports in the data bank.

Types of Providers Covered

While the NPDB covers a wide variety of medical practitioners, physicians are those most often reported to the data bank. Physicians make up approximately 70% of all practitioners reported to the data bank. Dentists make up the next largest group, at 13%, followed by nurses and nursing-related practitioners, who account for 9%, and chiropractors, who represent about 3% of those practitioners reported.

Types of Entities Reporting

Just as there are a variety of types of reports in the NPDB, there are also a variety of entities providing those reports. Any entity that makes a medical malpractice payment on behalf of a practitioner for full or partial settlement of a claim or judgment must submit a report to the NPDB. In general, medical malpractice reports are made by insurers or carriers; however, these reports may also be filed by other types of organizations that make such payments. Self-insured hospitals, physician groups, and managed-care organizations can also file reports. State medical and dental boards are required to report state licensure disciplinary actions related to professional competence or conduct. Other professional boards are not required to report to the data bank. Any hospital or other healthcare entity that takes a professional review action that restricts or suspends the clinical

privileges of a physician or dentist for more than 30 days must report that action to the NPDB. Physicians and dentists may voluntarily surrender or restrict their clinical privileges while being investigated for possible professional incompetence or improper professional conduct in return for suspension of the investigation. In these cases, the healthcare entity must also file a report. This situation is considered a reportable clinical privileging action. Clinical privilege actions for other practitioners may also be reported, but these reports are not required. Professional societies are required to report membership actions taken for reasons related to professional competence. The DEA provides up-to-date information on revocations and voluntary surrenders of its registration numbers. Finally, Medicare and Medicaid exclusions are publicly available through the *Federal Register* and do not require a specific reporting entity.

Federal agencies are not subject to the provisions of the Health Care Quality Improvement Act of 1986. The Secretary of the U.S. Department of Health and Human Services (HHS) signed separate memoranda of understanding with various federal departments to ensure their participation in the NPDB program. The Secretary signed memoranda of understanding with the U.S. Department of Defense (DOD) in 1987, the DEA in 1988, and the U.S. Department of Veterans Affairs (VA) in 1990. Other memoranda of understanding include ones with the U.S. Public Health Service (PHS), signed in 1989 and 1990, and with the U.S. Coast Guard and the U.S. Department of Justice, Bureau of Prisons, signed in 1994. Under those memoranda of understanding, 257 medical malpractice cases were reported to the NPDB through 2005.

Access to Information

The only entities that are required to access information from the NPDB are hospitals. According to the authorizing legislation, all hospitals are required to query the data bank when a physician initially applies for employment or membership on their medical staff, and at least every 2 years thereafter. Other entities that exercise significant peer review, such as managed-care organizations and physician groups, may also query the data bank.

Healthcare practitioners may self-query the data bank about themselves at any time. A practitioner may dispute the accuracy of a report in the data bank or the fact that the report should have been filed. If the dispute between the practitioner and the report is not resolved, the practitioner may ultimately request a review of the report by the Secretary of the HHS.

Research and Impact

A great deal of research on the NPDB has focused on using the longitudinal, national data set to provide information on trends in medical malpractice claims. For example, one study compared 2001–2004 median anesthesia malpractice payments with those for a similar period a decade earlier and documented a 28% decrease in the number of anesthesia-related payments per 100,000 population but a substantial increase in the median payment amount from \$69,330 to \$205,222.

While studies focusing on medical malpractice payments are most common, a few studies of trends in adverse actions have also been published. These studies tend to focus on the lack of reporting in this area. For example, one research study documented that between 1991 and 1995 only 34% of hospitals reported one or more clinical privileging actions against a physician. In addition, the annual rate of reporting to the data bank for these types of actions actually fell over the period, from 12% in 1991 to 10% in 1995. Subsequent studies by the Office of the Inspector General (OIG) of the HHS found that 60% of hospitals and 84% of health maintenance organizations (HMOs) had not reported a single adverse action to the data bank in almost 10 years of data collection.

A number of studies have focused on the quality and usefulness of the data housed in the data bank. The studies determined that, in general, querying entities found the reports in the data bank useful because they confirmed information received from other sources, although they did not often change the credentialing decision of the entity. However, the studies also found a low level of completeness of data in the data bank.

Another important area of research has been the potential impact of the NPDB on medical malpractice claim settlements and adverse actions. A number of researchers and policymakers have

hypothesized that in the face of the reporting requirements of the NPDB, individuals and organizations may take steps to avoid settlements or reportable adverse actions. This assumption is because a report to a federal data bank is considered onerous, notwithstanding that hospitals require physicians to submit the same information and the NPDB essentially serves as a check on physician honesty. Because of this perceived burden, some have suggested that 29-day clinical privilege suspensions, which are not reportable, are one major explanation for the limited reporting of adverse clinical privileging actions.

In the arena of medical malpractice payments, the practice of corporate shielding has become an issue of major concern to policymakers. Because medical malpractice payments on behalf of institutions are not reportable to the NPDB, some have suggested that attorneys may be working out arrangements to name institutions, such as hospitals and corporate physician groups, rather than individual physicians, in final settlements in order to avoid reportable physician payments. This practice may be responsible for the unexpectedly lower number of medical malpractice reports to the NPDB. However, a study of physician medical malpractice claim settlements before and after implementation of the NPDB found that physicians and insurers were significantly less likely to settle claims since the introduction of the NPDB, especially those less than \$50,000.

Future Implications

Given the current view that quality and safety in healthcare are the responsibility of the healthcare system rather than any single individual, the approach of the NPDB may be antiquated because it focuses on incompetent practitioners. However, at this point in time, a number of factors suggest that the NPDB plays an important ongoing role in quality assurance. While hospitals are required to query the NPDB when credentialing physicians, many hospitals routinely use the data bank, asking questions that are not required, as part of their credentialing process. It is also important to note that the ideal healthcare system is not yet attainable. Fragmentation and poor communication are and will remain a reality for many years to come, and information clearinghouses that facilitate the

flow of information in the presence of those deficiencies will continue to play an important role in safeguarding the interests of both patients and providers.

NATIONAL QUALITY FORUM (NQF)

The National Quality Forum (NQF) is charged with planning, developing, establishing, and coordinating voluntary consensus standards for healthcare quality, measurement, and reporting through a formal, structured consensus development process. Located in Washington, D.C., the NQF is a private, nonprofit organization with open membership that represents a unique consortium of over 350 public and private healthcare-related organizations including federal agencies, healthcare providers, consumers/patients, purchasers, industry, and other stakeholders. In this capacity

the NQF has significant influence over healthcare policy decisions made at the federal level.

Background

In 1996, President Clinton created the U.S. Advisory Commission on Consumer Protection and Quality in the Health Care Industry. The commission was given the broad charge of investigating the changes occurring in the nation's healthcare system and recommending measures to promote and ensure healthcare quality and value and protect consumers and workers in the healthcare system. In 1998, the commission's final report recommended the creation of a public-private forum for healthcare quality measurement and reporting to focus incentives for quality improvement on national priorities while ensuring the public availability of information needed to support the marketplace and oversight efforts. By May 1999, the Quality Forum Planning Committee had put in place the structure needed to establish the National Forum for Health Care Quality Measurement and Reporting, now known as the NQF, as a voluntary consensus standard-setting body. The NQF, empowered by the federal National Technology Transfer and Advancement Act of 1995 and the Office of Management and Budget (OMB) Circular A-119, sets standards for the U.S. Department of Health and Human Services (HHS), the Centers for Medicare and Medicaid Services (CMS), and the Agency for Healthcare Research and Quality (AHRQ).

Organizational Structure

The NQF is governed by a board of directors composed of individuals from its diverse membership. The NQF members are organized into various member councils including the following: consumer council; health plan council; health professional council; provider organization council; public/community health agency council; purchase council; quality measurement, research, and improvement council; and supplier/industry council. These councils contribute expertise to the development of standards and vote on the endorsement of national consensus standards.

Functions

The NQF's primary activities fall into three categories: (1) consensus development process; (2) national healthcare priority setting and other convening functions; and (3) leadership, education, and award activities. Each of the categories is discussed below.

Consensus Development Process

The consensus development process is the formal process the NQF uses to develop and endorse voluntary national consensus standards. Projects that undergo the consensus development process may be suggested by the NQF's members, member councils, staff, and board of directors or by external entities. These projects must be consistent with NQF priorities.

Specifically, the consensus development process consists of five steps: (1) consensus standard development; (2) widespread review; (3) member voting; (4) consensus standards approval committee action and the board of directors' endorsement; (5) and evaluation. At the initiation of the consensus development process, a steering committee is formed to oversee, advise, and ensure that input is obtained from relevant parties. Steering committees reflect the diversity of the NQF membership and may also include technical advisors as needed. The measure developer (or steward) assumes responsibility for submission of candidate standards and updates to endorsed standards and provides input as requested to the deliberations of the steering committee. An NQF project officer guides this process and acts as the liaison between the committee and the NQF.

The consensus standard development procedure results in draft recommendations that are based on those of the steering committee. They are reviewed, edited, and approved by the steering committee. And the steering committee must reach a consensus before the draft recommendations can proceed for further review, with all dissenting views documented. Explicit description of the scientific base for the draft recommendations is required. Widespread review begins with NQF member and public prevailing review of the draft recommendations. Members, member councils, and the public have the opportunity to comment

prior to initiation of voting. Based on the comments of members and the general public, the NQF staff may revise the draft recommendations and circulate such revisions to the steering committee for additional review prior to preparing the recommendations for voting. All comments are made available to members when voting on the draft recommendations. All members are given the opportunity to vote on the draft recommendations. Members may approve the recommendations, propose modifications and/or conditions, or vote not to approve the recommendations. All results are then forwarded to the consensus standard approval committee for consideration. That committee may approve the standard or recommend a second round of voting. The board of directors will affirm or overturn the actions of the consensus standard approval committee. Recommendations endorsed by the board of directors are designated as NQF-endorsed consensus standards. Members and the public have the opportunity to appeal an endorsement, and an appeal will be given due process review by the appropriate committees. The board of directors will then act on the appeal by responding with a rationale for maintaining or repealing the endorsement. Since its inception, the NQF has endorsed over 200 consensus standards, ranging from adult diabetes to safe practices for better healthcare.

National Healthcare Priority Setting and Other Convening Functions

The NQF is involved in numerous priority-setting activities designed to improve the quality of healthcare in the nation. One example, establishing safe healthcare practices, includes efforts in therapeutic drug management, cancer care, substance abuse, and healthcare-associated infections. The NQF is also involved in setting priorities for public reporting improvement, payment strategies, information technology, and healthcare system performance. These efforts include examination of patient safety incidence classification, pay-for-performance, electronic medical records, and healthcare equity, effectiveness, and efficiency. To obtain key stakeholder and member input as well as to inform the public, the NQF convenes high-level meetings and conferences regularly.

Leadership, Education, and Award Activities

The NQF recognizes individuals and healthcare organizations that have significantly contributed to the improvement of quality and the safety of care. The NQF and *Modern Healthcare* acknowledge the exemplary performances that have effectively used performance measurements to drive change across various settings and times, fostered a transparent and accountable culture aimed at rebuilding the social contract between healthcare and the community, and increased the expected level of a health system's performance in the areas of quality and safety with the National Quality Healthcare Award. In collaboration with the Joint Commission, the NQF presents the John M. Eisenberg Patient Safety and Quality Award annually to individuals and healthcare organizations that have made significant contributions to enhancing patient safety through performing research and providing service reflective of patients' needs and perspectives. Honorees are acknowledged for individual achievement, research, advocacy, and system innovation at the organizational, local, regional, and national levels.

Future Implications

The NQF, recognized as one of the principal organizations for quality and safety improvement in the nation, endorses consensus-driven healthcare standards, and develops national strategies for healthcare improvement. Through these major areas, the NQF will likely continue to influence the nation's future healthcare policy and promote system improvement and consumer/patient understanding.

NAYLOR, C. DAVID

C. David Naylor is the president of the University of Toronto. He is an internationally recognized leader in the fields of health services research, evidence-based medicine, and health policy.

Naylor received a medical degree from the University of Toronto in 1978 with scholarships in medicine, surgery, and pediatrics. As a Rhodes Scholar at Oxford University in the Faculty of Social and Administrative Studies, he earned a doctoral degree in 1983. Subsequently, he trained in general internal medicine at the University of Western Ontario and then for a year in Toronto as a Medical Research Council of Canada (MRC) fellow in clinical epidemiology.

Prior to becoming the president of the University of Toronto, Naylor was the dean of medicine and Vice Provost of Relations With Health Care Institutions at the University of Toronto. Previously, he was a senior scientist of the Medical Research Council of Canada (MRC). Naylor also developed and led a research program in clinical epidemiology

at the Sunnybrook Health Science Centre in Toronto and was responsible for developing the Institute for Clinical Evaluative Sciences, where he was the inaugural chief executive officer. In addition, he was one of the founding architects of Ontario's Cardiac Care Network.

Naylor has authored or coauthored over 300 publications in diverse fields such as social history, public policy, epidemiology, biostatistics, and health economics, as well as clinical and health services research in most fields of medicine. He has been the driving force behind developing a capacity for multidisciplinary health research in Canada and was on the national task force that established the framework for the Canadian Institutes of Health Research (CIHR). In 2003, Naylor chaired the National Advisory Committee on SARS and Public Health. This Committee's report led to the creation of the Public Health Agency of Canada, to increased commitments to public health at the national level, and to the appointment of Canada's first chief public health officer.

In addition to publishing frequently cited papers, Naylor has served on several editorial boards, including the *Journal of the American Medical Association*, the *British Medical Journal*, and the *Canadian Medical Association Journal*.

Naylor's service has been recognized through major national and international awards for research and leadership in medicine, including the John Dinham Cottrell medal by the Royal Australasian College of Physicians, the Malcolm Brown award by the Royal College of Physicians and Surgeons, the Michael Smith award by the Medical Research Council, and the Research Achievement award by the Canadian Cardiovascular Society. Most recently, he was appointed a fellow of the Royal Society of Canada.

NEWHOUSE, JOSEPH P.

Joseph P. Newhouse is a preeminent health economist. He has published extensively in the fields of health economics, health policy, and health services research. He also has trained many health economists.

Born in 1942 in Waterloo, Iowa, Newhouse earned a bachelor's degree and doctoral degree in economics from Harvard University. In 1963–1964, he was a Fulbright Scholar at the Johann Wolfgang von Goethe University at Frankfurt am Main in the Federal Republic of Germany.

Since the early 1970s, Newhouse has been a leading researcher, public servant, and scholar in health economics and health policy. He conceived and carried out significant, and in some cases unique, research projects; his research spans such

diverse areas as health insurance incentives, health-care payment systems, healthcare costs, health technology, risk adjustment, medical malpractice, and the impact of poor health habits. While at the RAND Corporation (1968–1988), he markedly expanded its health research and health policy expertise. Most notable was the RAND Health Insurance Experiment (HIE), one of the largest social science experiments in U.S. history. In leading the HIE, Newhouse oversaw an unprecedented research effort for more than 15 years. HIE papers, reports, and the definitive HIE summary *Free for All?* form the canonical basis for understanding healthcare demand and the response to insurance incentives, healthcare quality, and health outcomes in America.

Newhouse left the RAND Corporation and became a faculty member at Harvard University in 1988. As of 2007, he holds the ranks of John D. MacArthur Professor of Health Policy and Management (jointly in the Faculty of Arts and Sciences, Harvard Medical School, Harvard School of Public Health, and Kennedy School of Government); Director, Division of Health Policy Research and Education; and Director, Interfaculty Initiative on Health Policy. He created a doctoral program in health policy that exemplifies productive, collegial collaboration across the major schools at Harvard and that has trained more than 100 doctoral graduates now serving on university faculties, in public health agencies, and major health foundations.

Since 1966, Newhouse has authored or coauthored 350 publications (books, reports, and peer-reviewed journal articles). In 1981, Newhouse founded the *Journal of Health Economics*, an important economics journal. He continues to lead the editorial board, having edited more than 1,000 papers in the intervening years.

Newhouse has an extensive public service record. He has served as chair of the Prospective Payment Assessment Commission (ProPAC), commissioner of the Physician Payment Review Commission (PPRC), and vice chair of the Medicare Payment Advisory Commission (MedPAC). In 1977, he was elected to the national Institute of Medicine (IOM) and served two terms on the IOM governing council.

Newhouse has been the recipient of numerous awards, including the first David N. Kershaw

Award honoring persons under 40 years of age for distinguished contributions to public policy analysis and management (1983), the Baxter Health Services Research Prize and the Administrator's Citation from the U.S. Health Care Financing Administration (HCFA) (both in 1988), and the Distinguished Investigator Award from the professional association AcademyHealth (1992). He is a past president of the Association for Health Services Research (now AcademyHealth) and the International Health Economics Association, and he was the inaugural president of the American Society of Health Economics. He was elected fellow of the American Academy of Arts and Sciences (1995) and fellow of the American Association for the Advancement of Science (2002).

NIGHTINGALE, FLORENCE

Florence Nightingale (1820–1910) was responsible for professionalizing nursing. She also was a sanitarian, a hospital administrator, and an early biostatistician. Born in Florence, Italy, in 1820, to a wealthy British couple, Nightingale grew up in England. She became well educated for a woman of those times. As a young woman, Nightingale had a calling from God asking her to do His work, though she did not discover His plan until years later. As a result of her interest in then current social issues, she began to visit the homes of the sick in villages near her home. While a woman of means would never become a nurse, on a tour in Europe, she visited a Prussian hospital and school

for deaconesses in 1846. She later returned to train as a nurse, subsequently becoming, in 1853, the unpaid superintendent of a London establishment for sick gentlewomen.

The Crimean War broke out in 1854; reports criticizing the British medical facilities for the wounded resulted in her appointment to officially introduce female nurses into the military hospitals in Turkey. Although the physicians did not initially welcome her and her nurses, the women's skills were quickly appreciated. Nightingale's actions improved both the sanitary and emotional status of the wounded soldiers. Under her administration, the mortality rate of patients in the hospital decreased significantly. Her rule that she should be the only nurse in the wards at night earned her the title of the "Lady With the Lamp." Nightingale performed statistical analyses of disease and mortality. She ultimately became the general superintendent of the Female Nursing Establishment of the Military Hospitals of the Army.

Nightingale returned from the Crimean War in August 1856, soon participating in the creation of the Royal Commission on the Health of the Army. She contributed information in the form of her *Notes on Matters Affecting the Health, Efficiency, and Hospital Administration of the British Army, Founded Chiefly on the Experience of the Late War. Presented by Request to the Secretary of State for War*.

Nightingale was committed to the use of statistics, which she employed to support her ideas on healthcare and public health. She worked with the British statistician William Farr. As a result of her statistical accomplishments, she became the first woman to be elected as a fellow of the Royal Statistical Society, in 1858.

Perhaps Nightingale's greatest achievement is her elevation of the status of nursing: It became a respectable profession for women. In 1860, she established a nursing school at London's St. Thomas' Hospital. Nurses, trained in her program, worked in staff hospitals throughout Britain and abroad, establishing nursing training schools using her model.

Nightingale was an advocate of the pavilion style of hospitals: completely detached pavilions, separating medical pathologies, to prevent the spread of diseases. Her *Notes on Nursing* was first published in 1860; its latest printing was in 1992.

She campaigned to improve health standards, writing extensively on the subject. Queen Victoria awarded her the Royal Red Cross in 1883. Nightingale became the first woman to receive the Order of Merit in 1907. She died at the age of 90 in 1910.

NONPROFIT HEALTHCARE ORGANIZATIONS

A nonprofit healthcare organization is legally structured as a not-for-profit corporation and is prohibited from distributing profits to its owners, members, or other individuals with oversight for the organization. Nonprofits have a charitable mission related to the provision of healthcare

services, teaching, research, and/or community service, and they are legally required to work towards the mission. These organizations are owned by their “community,” which may be a religiously affiliated or unaffiliated community or other nongovernmental association. Nonprofit hospitals are the dominant type of hospital ownership in the United States. Other types of healthcare organizations may also be organized as nonprofits, including long-term care facilities and health plans. Only a small percentage of the nation’s nursing homes are nonprofit, with the majority being proprietary or for-profit organizations.

Characteristics

Several characteristics conceptually differentiate nonprofit from other types of ownership, particularly for-profit healthcare organizations, including the primary stakeholders of these entities, the benefits of tax-exempt status, their sources of capital, and the provision of community benefits.

Ownership

A nonprofit healthcare organization is owned by its community, meaning that it is owned by a community or other nongovernmental association, such as a church or fraternal organization, and is governed by a voluntary, self-perpetuating board. Nonprofits may or may not be religiously affiliated. This is distinct from a for-profit healthcare organization, which is owned by its shareholders and governed by an elected board, and from a public hospital, which is owned by the federal, state, or local government and, in the case of federal and state-owned hospitals, principally serves selected populations (e.g., military) or, as in the case of local, government-owned hospitals, often serves the indigent. While for-profit organizations distribute their profits back to their shareholders, nonprofit organizations are prohibited from distributing profits to those who control the organization, although incentive-based compensation for organization leaders is common. Profits are implicitly reinvested into the organization’s community—through enhanced services, new plant and equipment, or other initiatives that provide a community benefit.

Tax-Exempt Status

As tax-exempt entities, nonprofit healthcare organizations are expected to provide community benefits, commonly achieved through charity care, education and training, research, and/or community service. Tax-exempt status means that the organization is exempt from paying federal, state, and local taxes, including income, sales, and property taxes. In addition to being exempt from taxes, a nonprofit organization may use tax-exempt bond financing, which lowers its cost of capital investments. Nonprofit organizations have the advantage of being exempt from paying income taxes on interest income generated from tax-exempt bonds. Nonprofits may accept charitable donations, and donors may deduct these charitable contributions. From the federal perspective, a healthcare organization qualifies under Section 501(c)(3) of the Internal Revenue Service (IRS) tax code in the United States. Nonprofit organizations must also meet state requirements for nonprofit entities to receive a state income tax exemption as well as local requirements for local sales and property tax exemptions. These requirements vary by state and are often more stringent than federal requirements.

Sources of Capital

Nonprofit healthcare organizations rely on several primary sources for capital. These include charitable contributions, which are tax deductible by the donor, debt, retained earnings, and government grants. Having a tax-exempt status provides nonprofits with the opportunity to use tax-exempt debt as one mechanism to finance capital investments. For-profit organizations use retained earnings and debt to fund capital investments, but they also use equity capital from investors and return-on-equity payments from third-party payers.

Community Benefit

Although the provision of community benefit is the linchpin of qualifying as a nonprofit healthcare organization, there is no unambiguous definition of what community benefit entails, how it should be measured, or what qualifies as a sufficient amount in terms of measuring whether a nonprofit

organization meets its community benefit obligations. Community benefit is generally considered to include services that are unprofitable but provide an important contribution to the community. Uncompensated care, Medicaid-covered services, and certain unprofitable service lines are considered to be community benefit. Uncompensated care is composed of charity care and bad debt. Charity care includes services that are provided but for which the provider does not expect a payment. Generally, the decision about whether services qualify as charity care is made prospectively or as early in the delivery of care as possible when a prospective decision is not feasible. The provider does not bill the patient or insurer, nor does the provider pursue collection of payment from an external source. Hospitals often use a sliding scale based on income to determine whether an individual is eligible for charity care and, if so, the amount of the discount. In addition, hospitals may use an asset test to determine eligibility. Bad debt, on the other hand, is care for which payment is expected to be collected by either the patient or the insurer but is ultimately not paid. Hospitals make an effort to collect these payments using internal and/or external collections processes. Some argue against the inclusion of bad debt as uncompensated care, because organizations make an active attempt to collect payment from the patient and/or insurer and, after a sufficient amount of time, elect to write off the uncollectible amount.

Medicaid-covered services are classified as a community benefit, because reimbursement from state Medicaid programs is often below the cost of providing the care. In addition, certain unprofitable services lines, such as the emergency department, high-level trauma, and labor and delivery, are considered as community benefits. Most nonprofit hospitals also provide additional community outreach programs, such as community health screenings, health education programs, immunizations, and community health assessments of unmet needs. Research that generates findings available to the community may also be included as a community benefit.

The valuation of community benefit is highly variable across organizations. No consistent guidelines exist for how to quantify or report the dollar value of these benefits. While nonprofit organizations may report a dollar amount of community

benefit, cross-institution comparisons would be questionable—reports of community benefit may, for example, value charity care based on the charges for care provided to these patients, even though charges reflect neither the organization's costs nor expected payments. Organizations may or may not include bad debt and losses from services provided to Medicare and Medicaid patients.

Comparison of For-Profit and Nonprofit Organizations

The fundamental structure of nonprofits suggests that these organizations should behave in a manner that differs from for-profit entities. The charitable mission—to provide a community benefit—of a nonprofit differs from that of a for-profit, whose implicit or explicit mission is to increase the wealth of its shareholders. The difference in missions suggests that nonprofit organizations should provide more services to the community in which they reside. In addition, because of the shareholder-driven mission, for-profits conceptually have a greater incentive to provide more and more profitable services than their nonprofit counterparts, which may mean providing fewer unprofitable services and serving fewer indigent patients.

From a practical perspective, whether for-profit and nonprofit healthcare organizations are intrinsically different has long been debated. Some argue that the economic incentives inherent in the distribution of profits to shareholders are vastly different from the incentives for organizations that do not answer to shareholders. Others maintain that the ultimate motivation of both types of organizations is similar—both strive to maximize earnings over expenses (i.e., accounting profits) and must meet the needs of the patient to remain profitable and, therefore, should be expected to behave similarly. In addition, the lines between nonprofits and for-profits have blurred, due to relationships between the two.

Importance of Profit

Regardless of the type of organization, both for-profits and nonprofits must earn a profit or surplus in the long run to remain financially viable. To achieve this goal, both types of organizations must respond to their community's needs and

provide high-quality care. While for-profits return a portion of their profits to shareholders, they must also make investments in their organizations to remain competitive. Likewise, nonprofits could not achieve their missions without earning profits for future investments to remain competitive.

Hybridization of Ownership Type

While some organizations are purely nonprofit or for profit, others may have elements of both within the same corporation. Examples include a nonprofit organization owning a for-profit subsidiary; a nonprofit organization contracting with a for-profit organization to provide specific services, as when a community hospital contracts with a for-profit anesthesiology group to provide anesthesiology coverage in the surgical suite; and joint ventures between nonprofit and for-profit organizations.

Efficiency

While some claim that for-profits provide less efficient care, in terms of either providing more services and more expensive care than needed or charging prices that are disproportionately higher than costs compared with nonprofits, others argue that for-profits are more efficient because of their underlying mission to generate a profit for shareholders. Systematic evidence comparing the quality of care among nonprofit and for-profit hospitals does not exist, however, to support these claims.

Quality of Care

It has been argued that for-profits provide lower quality of care than their non-profit counterparts. However, there is little consistent evidence to support this claim. While some studies have found higher quality of care in nonprofit hospitals, other studies have found no difference or higher quality in for-profits.

Uncompensated Care

Research has been mixed on whether nonprofit organizations provide more uncompensated care than their for-profit counterparts. Some studies have found that provision of uncompensated care is greater among nonprofits, while other studies

have found no significant difference. Studies of nonprofit to for-profit hospital conversions have suggested that those converting to for-profit entities do not change their level of uncompensated care provided to the community.

The Future of Nonprofit Healthcare

In recent years, nonprofit hospitals have been under increased scrutiny to explicitly quantify their benefit to the community. Two findings have led federal and state governments to investigate whether nonprofits are meeting their community benefit obligations. First, evidence has suggested that nonprofit and for-profit hospitals provide similar levels of uncompensated care, calling into question the marginal contributions that nonprofits make to the community, which are required to qualify for tax-exempt status, and whether their marginal contribution is equivalent to the tax benefits they receive from possessing tax-exempt status. Second, because insurers negotiate payment rates with hospitals that are lower than those charged by the hospitals, uninsured individuals have often been obligated to pay more for care than otherwise similar individuals with insurance. Coupled with this issue, there have been complaints about aggressive debt collection practices by nonprofit hospitals that contradict the organizations' charitable mission. Nonprofit hospitals' billing and collection processes have been questioned in light of these organizations' tax-exempt status.

States have implemented a variety of requirements for nonprofit hospitals, in particular to ensure that they are meeting their community benefit obligations. State-mandated methods of demonstrating community benefit include the requirement of a written charity care policy that is accessible to patients; mandating a minimum threshold for the value of community benefit as a percentage of net patient revenue or operating revenue; mandating that community benefit is at least equivalent to the value of the tax-exempt benefits received by the hospital; and routine documentation of the hospital's community benefit contributions. As hospital competition continues, nonprofit and for-profit hospitals will increasingly become less differentiated. The need for nonprofit hospitals to be price, quality, and outcomes competitive with for-profit hospitals will also continue. These

organizations will need to justify their benefits to the community while at the same time providing care that is both of high quality and efficient.

NURSE PRACTITIONERS (NPs)

Nurse practitioners (NPs) are nonphysician clinicians who are nurses with graduate degrees in advanced-practice nursing. The primary function of nurse practitioners is to promote wellness through patient health education. Their role has expanded to include the following: taking patients' comprehensive health histories, performing physical examinations, ordering laboratory tests and procedures, and formulating and managing care regimens for acutely and chronically ill patients. Nurse practitioners work in a variety of settings, including physician offices, clinics, hospitals, and nursing home facilities. In 2008, there were about 160,000 nurse practitioners in the United States.

History

The nurse practitioner movement began in the United States in the mid-1960s, with the preparation of pediatric nurse practitioners at the University of Colorado. Initially, the profession was developed in response to a shortage of physicians, especially in rural areas where healthcare access was limited. Over time, other states also began nurse practitioner training programs, and their role in healthcare greatly expanded. Today, nurse practitioners are integral to all kinds of practices, including those located in underserved, rural, and inner-city areas and in private collaborations, independent practices, hospitals, and continuing care and nursing home facilities. Additionally, other countries such as the United Kingdom, Canada, Australia, and New Zealand have embraced nurse practitioners.

Clinical Roles

The most significant clinical role of nurse practitioners relates to their professional efficacy and autonomy in practice. They can diagnose, treat, prescribe medications, order diagnostic testing, and refer patients to other healthcare professionals. Nurse practitioners monitor and adopt evidence-based practice and bring the framework of prevention, early intervention, and patient/family health education into their work. In the United States and other countries, nurse practitioners

have a specific license for practice. In the United States, most such licenses are granted and supervised by a state's board of nursing. This licensing distinguishes nurse practitioners from physicians' assistants, who typically practice under direct supervision of physicians and whose practices are authorized by a state's board of medicine.

While nurse practitioners can and often do work independently, most have collaborating physicians who review cases and provide ongoing consultation. The nursing board in a particular state may or may not require the existence of a relationship with a physician colleague. However, most advanced-practice nurses and physicians alike find the relationship stimulating and informative. The teamwork nature of such collaboration often is visible in primary-care practices or hospital specialty services, where physicians and nurse practitioners work in the same setting. Patient satisfaction and patient outcomes in these collaborative practices are similar to or better than in many traditional, physician-only practices.

Preparation

Nurse practitioners are prepared at the master's level or beyond. The educational programs are designed to make the graduate eligible for certification as a nurse practitioner in a specific area, such as care of families, children, or adults, in psychiatry, or in women's health. Certification is gained by completing the requisite educational program and passing an examination offered by specific certifying bodies. These entities are generally associated with a specific practice, such as midwifery. A significant educational requirement is actual practice under the close supervision of a licensed and certified nurse practitioner, with a minimum of 1 year of practice, or a physician. Four hundred or more hours of such practice are required. Some specialties require additional training, such as working with a minimum number of mothers in childbirth to qualify in midwifery.

Practice Standards

The American Academy of Nurse Practitioners (AANP) defines the standards of practice for nurse practitioners and updates or revises them periodically. The eight standards defining the

framework for nurse practitioners are as follows: (1) the process of care, including assessment of health status, diagnosis, development of a treatment plan, implementation of the plan, and follow-up evaluation of the patient; (2) care priorities, including patient and family education, provision of competent care, facilitation of entry into the healthcare system, and a safe environment; (3) interdisciplinary and collaborative responsibilities as a member of the healthcare team; (4) accurate documentation; (5) patient advocacy; (6) quality assurance and continued competence; (7) adjunct roles, including mentor, educator, researcher, manager, and consultant; and (8) research as a basis for practice. These standards reflect an origin in the general practice of nursing. Nurse practitioners do not replace nurses in practice settings. Rather, nurses and nurse practitioners provide a broadened skill mix from which to serve patients.

Doctorate in Nursing Practice

From the comprehensive nature of these standards, nursing educators realized that the depth and extent of preparation warranted redefining the earned education credential as a practice doctorate similar to that given in other professions, such as pharmacy, medicine, and dentistry.

The American Association of Colleges of Nursing (AACN) approved a policy statement saying that the doctor of nursing practice (DNP) degree be required for entry into nursing practice as an advanced practice nurse by 2015. With this policy statement, the AACN outlined the eight essential elements of doctoral education for advanced practice nurses. These elements include (1) the scientific underpinnings for practice, (2) organizational and systems leadership for quality improvement and systems thinking, (3) clinical scholarship and analytical methods for evidence-based practice, (4) information systems/technology and patient care technology for the improvement and transformation of healthcare, (5) healthcare policy for advocacy in healthcare, (6) interprofessional collaboration for improving patient and population health outcomes, (7) clinical prevention and population health for improving the nation's health, (8) and advanced nursing practice.

Disadvantages of the requirement of the DPN degree may include the increased costs to the students due to longer programs of study. There is a nationwide shortage of faculty in nursing schools. Initially, the costs of educating DNP degree students by doctorate of philosophy (PhD)-prepared faculty may prove challenging, but the growing numbers of DNP graduates will quickly offset this shortage. Finally, the costs to the nation's health-care system may be increased by DNPs who command higher salaries than current nurse practitioners. The additional preparation, however, should bring additional clinical leadership and skills to ensure that the latest scientific findings are readily translated into patient services.

Future Implications

While licensed independently, nurse practitioners only recently gained legal authority to bill separately from physicians. A provision in the federal Balanced Budget Act of 1997 states that nurse practitioners can receive direct Medicare Part B reimbursement, which is 85% of the physician rate. Prior to this legislation, nurse practitioners had to file under a physician's Medicare provider number. Some private insurance companies, however, did not follow the change in Medicare regulations and do not allow nurse practitioners to seek payment under their own provider number. Variations also exist among state Medicaid programs. California, for example, authorized nurse practitioners to bill its Medicaid program, Medi-Cal, directly, and be reimbursed at 100% of the physician reimbursement rate.

Many areas of the nation are expanding the role of nurse practitioners. As of 2006, all 50 states have awarded nurse practitioners prescription authority, with varying limitations. Many states also include controlled substances among the medications nurse practitioners can prescribe.

Because they possess independent licenses, nurse practitioners are viewed as challenges to health-care quality by some groups, most notably the American Medical Association (AMA). The AMA's concern is that nurse practitioners do not have the same preparation as physicians and should, therefore, be closely supervised. State legislatures, where efforts to shape nurse practitioner practices are revisited often, can reflect this tension. An area of

typical concern is the authority of nurse practitioners to prescribe medications. While all states have authorized them to write prescriptions, this authority was approved on a state-by-state basis. Florida also has restrictions on the number and types of nurse practitioner-managed offices that physicians may supervise, and other states may choose to follow this example.

NURSES

Nurses are an integral part of the nation's health-care system, providing treatment and care to ill or

injured patients. There are currently more than 2.9 million nurses in the United States, which includes registered nurses (RNs), licensed practical nurses (LPNs), nurse practitioners (NPs), and others. While the definitions and theories about the field of nursing continue to grow and change, the role of the nurse remains vital for medical care.

History

The modern term *nurse* is derived from the Latin word *nutrire*, meaning to nourish or nurture. Florence Nightingale (1820–1910) is considered the founder of modern nursing. Recent analysis of Nightingale's letters to the Sisters of Mercy, who accompanied her to battlefields in the Crimea, reveal that she was greatly influenced by these religious women, who provided crucial skills in organizing and implementing care for the injured and wounded. On her return to England, Nightingale used this experience and knowledge to become a clear advocate for patient care, specifically the kind done by nurses. In 1859, Nightingale articulated the defining characteristic of nursing knowledge as “putting the constitution in such a state as it will have no disease,” or that it can recover from disease. She provided the profession significant public respect at a time when nurses were viewed as untrained and incompetent. After the Crimean War, around 1856, the public view of nursing evolved from the negative portrayal to that of an angel of mercy, largely due to Nightingale's influence.

The image of nursing continued to form and re-form. Today, nurses are largely viewed as careerists. During the 1920s, nurses were often viewed as women whose priorities were romance, marriage, and motherhood. By the end of World War II, however, nurses were seen as heroines and professionals. This portrayal soon reverted to a “sex object” image, where nurses were seen as women who were satisfying the needs of men and male physicians. The careerist image, however, began to compete with the “sex object” image throughout the mid-1960s and into the 1980s, when it finally became predominant.

Contemporary Definition of Nursing

Virginia Henderson (1897–1996), another pioneer in nursing, was dedicated to the scientific

knowledge that underpins the practice. Her view was bolstered by her singular focus to catalog relevant information from all disciplines. She and her colleagues accomplished this work long before computerized databases or nursing and allied health indexes existed. She defined nursing for practitioners worldwide as assisting individuals, sick or well, in the performance of those activities contributing to health or its recovery (or a peaceful death) that they would perform unaided if they had the necessary strength, will, or knowledge, and to do this in such a way as to help them gain independence as rapidly as possible. Henderson's definition embraces the concept that nurses meet patients wherever they are on a health, illness, and death continuum. It resonated with nurses worldwide, resulting in many translations of her work. Single-handedly, Henderson stimulated the international recognition of the common threads that join all nurses.

Struggle to Advance the Science of Nursing Practice

Continuing Henderson's work, early nursing scholars based their science on social, biological, and medical sciences. Yet they remained challenged to articulate what was specific to the practice of nursing. Beginning in the 1950s, the scholars in nursing began to develop and disseminate various nursing models. In particular, efforts were aimed at theory development so that nursing could develop specific evidence to guide its practice. Interestingly, most of the nursing research conducted into the mid-1980s focused on the individuals who were either nurses or nursing students, not on the nursing actions they performed. This approach changed dramatically after 1986, when the U.S. Congress created the National Center for Nursing Research within the National Institutes of Health (NIH). Nursing research then became part of the largest biomedical science entity in the nation. NIH funds support rigorous scientific efforts to promote the understanding of what happens to patients, without regard for the characteristics of the provider. Financial support of investigations of nursing workforce issues remained in other parts of the U.S. Department of Health and Human Services (HHS), such as the Agency for Healthcare Research and Quality

(AHRQ) and the Health Resources and Services Administration's Bureau of Health Professions (BHPPr).

Nursing Theories

The nursing conceptual models describe the interrelationship of concepts and the application of theory to identify, analyze, interpret, and evaluate client-based interventions and outcomes. Four concepts appear in most nursing theories or models: the person, the environment, the nurse, and health. These theories are generally classified as middle-range or practice theories. This remains a major descriptor of nursing theories today. A thorough review of nursing theories demonstrates the continuing impact of other health disciplines, with reliance on developmental scholars, such as Helen Erikson and Abraham Maslow, and the behavioral and socio-cultural sciences.

Dorothy Johnson's Behavioral System Model, established in 1959, focuses on common human needs, care and comfort, and stress and tension reduction. In 1964, Imogene King's Systems Framework, on the other hand, examined personal, interpersonal, and social systems. Myra Levine sought the need to move nursing away from the medical model and, in 1996, developed her Conservation Model, which focuses on adaptation as a means to preserve the integrity and wholeness of the person. Levine's work often is used in combination with standardized nursing nomenclatures, such as the Nursing Intervention Classification, to capture the practical benefits of this model. The Betty Neuman Systems Model, developed in 1972, also includes the concepts of adaptation, client holism, and stress in the client environment.

Dorthea Orem began developing her theory in the 1950s and formally presented her Self Care Model in 1970. The theory focused on nursing practice to move patients toward independence. That same year, Martha Rogers presented her theory of the Science of Unitary Human Being, which is not built on causality but is congruent with an action worldview. Another product of the 1970s was the Sister Callista Roy Adaptation Model, which concentrates on the adaptation processes of individuals, families, and groups.

Contemporary Nurses and Nursing

The contemporary nurse is a well-educated professional, either male or female. With more than 2.9 million nurses in the United States, RNs are the largest constituent of the nation's healthcare professions. Nursing distinguishes itself with a holistic focus on the patient and families and attention to actual or potential health problems. Nurses meet healthcare needs in virtually all settings, with more than half employed in hospitals, followed by community and public health centers, ambulatory care, nursing homes, and nursing education. Today's nurse uses assessment skills to diagnose a patient's response to illness and potential health conditions or needs and then develops an individualized plan of care. Nurses also collaborate with other healthcare professionals. A rich lexicon of nursing diagnoses and evidence supports professional nursing practice. The professional nurse continuously evaluates and modifies the patient's care plan and adjusts interventions to achieve the best possible outcomes.

Current Nursing Shortage

The United States currently faces a major crisis in nursing—the shortage of nurses presently and the increasing shortage predicted in the next 25 years. This shortage began in the late 1990s and is unlike previous shortages. Historically, classic principles of supply and demand mediated the crisis. Employers made economic and other enticements to make nursing a more desirable profession, and educational institutions increased enrollments to meet the demand. However, multiple factors make the current shortage different from those experienced in the past.

Not only is the nation's general population aging, but the nursing workforce itself is aging as well. Data from the 2004 National Sample Survey of Registered Nurses indicate that the population of nurses is aging quickly. For example, the average age of nurses in the nation is 46.8 years, with approximately 41% over 50 years of age. Only 8% are less than 30 years of age. It is anticipated that there will be more than 1 million RN vacancies by 2010. From 2000 through 2004, the average age of graduating nurses was 32.6 years, in

contrast to 27.8 years in 1984. In sum, the current nursing population is aging, and those who enter the field are older than before. Clearly, there is a pressing need to expand the pipeline of those entering the nursing profession, especially at a younger age. The potential for women to enter the historically male-dominated professions, such as medicine and other fields, has changed nursing demographics and presents a challenge to increasing the number of nurses.

Nursing school leaders indicate that a national faculty shortage is the major reason that more than 32,000 qualified applicants are not enrolled annually. Nursing faculty are on average 55 years of age or older, with 20% anticipating retirement in the next 10 years. Competition for clinical placement sites and space in general science laboratory courses compounds the difficulties faced by academic administrators as they attempt to expand enrollment.

Changes in the nation's healthcare delivery system have shifted most medical care from hospitals to outpatient settings. Those patients who are admitted to hospitals today experience illness intensities comparable with those in intensive-care units less than 50 years ago. Multiple societal factors, such as major changes to how Medicare calculates reimbursements to hospitals, converged to create new strategies for cost containment and control throughout healthcare, especially in hospitals. As nurses are the largest component of most hospitals' personnel expenditures, multiple approaches were undertaken to shift from an expensive, intensive RN workforce to less expensive and less well-educated personnel.

Nurses and other healthcare workers became alarmed at the diminishing quality of care associated with the decreasing numbers of nurses directing patient care. In some states, such as California, nurses successfully lobbied for state laws that specify the ratio of nurses to patients. Other advocates, such as the national Institute of Medicine (IOM), called for systematic and systemic efforts to manage patient care and decrease medical errors. Health services researchers have examined patient outcomes in relation to the preparation of the nursing staff. These studies documented better outcomes when patient care is directed by nurses with a baccalaureate or higher degree. Seminal work supported by the American

Academy of Nursing (AAN) aimed to identify the characteristics of hospitals associated with best practices, and strong patient outcomes were identified. Now, those hospitals can become designated as Magnet Hospitals, through the American Nurses Credentialing Center. The designation is awarded by examining both qualitative and quantitative evidence of meeting 65 standards that define the highest quality of nursing practice and patient care.

Another strategy to overcome the nation's shortage of nurses is to recruit and retain nurses who were educated in other countries. The number of foreign nurses in the United States totaled approximately 90,000 in 2004, and they were most common in California, Florida, New York, Texas, New Jersey, and Illinois. In some countries, such as the Philippines, there is a deliberate effort to prepare individuals to work in their native country as well as in the United States. In general, nurses are lured from poor nations by the promise of higher wages. However, such migration patterns can deplete nations of their own healthcare workforce.

Nursing Education

Early nursing education began as informal conferences and lecture-style training by physicians to nursing students in hospital-based programs. The nation's first formal nursing school was established in 1872 at the New England Hospital for Women and Children in Boston. Using Nightingale's model of nursing preparation, other schools were soon established, including the New York Training School at Bellevue Hospital, the Connecticut Training School for Nurses, and the Boston Training School for Nurses at Massachusetts General Hospital.

Hospital-based nursing training programs used the apprenticeship model in awarding the graduate a diploma. In the middle of the 20th century, there was a shift from the diploma program to college or university preparation, with the introduction of the 2-year associate degree. Many hospital-based nursing programs were shortened from 3 to 2 years to compete, but eventually most closed or merged into academic programs. In 2006, diploma programs made up only 4% of all the basic RN education programs in the nation.

In 1952, the associate degree in nursing was developed at Teacher's College, Columbia University in New York. To alleviate the nursing shortage of that time, this degree was designed to prepare technical nurses in 2 years. Typically, associate-degree nursing programs are offered at community or technical colleges. Graduates may take the RN licensure examination, because they are taught nursing theories and have gained practical and technical experience and skills. In 2005, associate-degree programs made up 58.9% of all U.S. basic nursing education programs. The increased demand for nurses is felt keenly at the community college level, where waiting lists for admission may have more than 1,000 individuals for 60 openings.

As the demand for further professionalism grew, many programs developed to offer a baccalaureate degree in nursing. The University of Minnesota School of Nursing opened in 1909 and is considered the first university-based nursing education program in the nation. The Yale University School of Nursing opened in 1924 and offered the first program contained within an autonomous academic unit. The baccalaureate degree with a major in nursing reflects the richness of the academy's curriculum with liberal arts and science courses designed to prepare individuals as critical thinkers, both in nursing and in life. Today, the degree is earned in 4 years. However, 5-year programs existed through most of the 1960s, as nursing faculty struggled to merge clinical content into educational models of academia. In 2005, there were 573 U.S. colleges and universities offering a baccalaureate degree in nursing.

Within the nursing profession, there has been lengthy debate to define the appropriate education level for entry into practice. The American Nurses Association (ANA) and the National League for Nursing (NLN) both support the baccalaureate degree to enter general practice as an RN. Others, such as the American Association of Colleges of Nursing (AACN), support entry into general practice at the master's level and into advanced practice at the doctoral level.

It is important to note that preparation for LPNs—called licensed vocational nurses (LVNs) in some states—occurs nationwide often in the last year of a high school program or the 1st year of an associate-degree program. There were approximately

710,000 LPNs in the nation in 2005. There is a separate licensing examination for LPNs and LVNs that is overseen by the National Council of State Boards of Nursing (NCSBN). Their scope of practice is regulated by State Boards of Nursing, which typically describe LPN practice as under the direction of the RN with great emphasis on physical care and related medical procedures.

The percentage of nurses who had earned a high school diploma decreased from 63.2% in 1980 to 25.2% in 2004. During that same period, nurses graduating with an associate's degree increased from 18.6% to 42.2%, and nurses entering the profession with a baccalaureate degree or higher increased from 17.4% to 31%. With the findings that better patient outcomes are associated with nurses with a baccalaureate or higher degree directing care, there is concern that the continuing large percentage of diploma and associate-degree nurses entering the field may be a disadvantage to patients.

Licensure

To practice as RNs, all graduates must prove their competency by passing a national examination. The examination is administered by the NCSBN and called the National Council Licensure Examination for Registered Nurses (NCLEX-RN). Successful completion of the examination is necessary for licensure in all states. Individual state laws and regulations govern the practice of nursing in each state. State differences concern topics such as the requirements for continuing education, the delegation of authority to other providers, and the scope of advanced practice. A compact now exists among several states so that participating states automatically recognize and accept the nursing license of individuals from another compact state. Most states, however, accept only the test results and require an application for practice within its boundaries. With nurses increasingly using telecommunications to address patient issues across state lines, the demand for more compact state agreements will likely grow.

Future Implications

Nursing is a dynamic profession that remains focused on patient outcomes, including peaceful

death. Nursing scholars continuously develop the evidence necessary to refine the practice, while healthcare leaders support and recognize the importance of nursing to the totality of healthcare in the United States.

NURSING HOME QUALITY

Life in all its richness occurs in nursing homes. Sickness, love, caring, kindness, anger, abuse, indifference, excitement, boredom, laughter, sex, and death all transpire in nursing homes. Time-study data indicate that the average nursing home resident receives less than 1½ hours of care each day from nursing staff, indicating that treatment is a relatively small proportion of what fills the everyday life of nursing home residents. Thus, although excellent care and treatment are important, quality of care is only one aspect of quality in the nursing home. Because nursing homes are where people live, as well as receive health and rehabilitative care, discussions of nursing home quality become at the most global level deliberations about how to measure and ensure residents' well-being, in the fullest sense of the term.

While nursing homes serve a variety of populations, quality of care for long-stay residents is the focus here. This entry first provides basic information on nursing homes and their occupants. Next, it discusses how quality of care is usually measured in nursing homes. It then discusses the larger issue of quality of life. Last, it discusses the current quality assurance process in nursing homes and the future of nursing home care.

Nursing Homes and Nursing Home Residents

This discussion of nursing home quality necessarily occurs within the context of the current nursing home industry and resident population. On any given day, approximately 16,000 nursing homes in the United States provide care for roughly 1.6 million residents. Most nursing homes are for-profit, investor-owned enterprises operated by multifacility chains. The average size of nursing homes is approximately 100 beds, with an occupancy level below 90%. Over two thirds of longer-stay nursing home residents receive their care under the auspices of state Medicaid programs. Recent data indicate that state Medicaid programs pay on average about \$120 per day (over \$40,000 annually) for care. Private-pay residents now pay an average of about \$190 per day (almost \$70,000 annually). The federal Medicare program pays the bulk of costs for shorter-stay residents.

Almost all nursing homes accept Medicaid and/or Medicare funds. Receipt of these public funds requires that a nursing home be licensed by the state and certified to participate in and receive payment from these programs. Licensure and certification carry with them an elaborate array of requirements about financial reporting and resident care. The most basic of these requirements involve annual cost reports and annual on-site surveys by multimember teams who evaluate the degree to which a nursing home meets state licensure and federal certification standards.

Most admissions to nursing homes (just over 50%) come from hospitals. A large number of individuals, over the course of a year, come into nursing homes and then either die or leave within weeks. These short-stay individuals who return home are largely in the nursing home to recover from some acute disease episode such as the flu or to recover from an acute exacerbation of a chronic disease condition such as diabetes or from physical, speech, or occupational rehabilitation after a fall or stroke. On any given day, these short-stay residents constitute about 10% of a nursing home's population, but they constitute over 60% of all individuals admitted annually to nursing homes. Only about one quarter to one third of those admitted to a nursing home will be in the same nursing home 3 months after admission.

Only about 10% of long-stay nursing home residents are under 65 years of age. The average long-stay nursing home resident is a female over 75 years of age. Generally, she suffers from multiple chronic diseases and has a number of health problems, which are likely to include arthritis, hypertension, heart disease, and diabetes as well as decreased ability to see and hear. Like the majority of the residents surrounding her, she has episodes of urinary incontinence and some level of cognitive impairment. She also needs significant physical assistance with a number of activities of daily living (ADLs).

Quality of Care

Like other health services researchers, investigators conceptualize nursing home quality in terms of Avedis Donabedian's triad of structure, process, and outcome, with most researchers considering outcomes the most telling indicator of

quality of care. In nursing home research, the structural quality measure with the greatest impact on process and outcome quality is nurse staffing. Turnover of direct-care staff, nursing supervisors, and administrators are also structural measures that gather considerable attention as instances where quality of care is put at risk. Some evidence indicates that for-profit ownership also tends to be associated with poorer-quality care, but part of that relationship may be attributed to the generally lower staffing levels and higher staff turnover at for-profit homes. Process quality measures that receive the most attention are the presence of urinary incontinence without a scheduled toileting plan, the use of physical restraints, psychotropic medication use, the prevalence of feeding tubes, or the use of urinary catheters.

Outcome measures of importance for measuring nursing home quality include mortality, declines in functional status or activities of daily living (e.g., ADLs), worsening cognitive status, worsening conditions (e.g., continence), accidents, falls, or hospitalizations for ambulatory-care-sensitive conditions (e.g., diabetes). Unfortunately, little research finds strong links between these outcomes and the various process quality measures noted above. For both short- and long-stay residents recovering from an acute disease episode, significant improvement is a common outcome. However, that is not the case for the average long-stay nursing home resident.

Analyses of nursing home quality are almost invariably observational studies. To enhance their validity, observational studies involving process quality or outcome quality measures usually require some type of case-mix or acuity adjustment. A major difficulty arises in studies of nursing home quality focused on outcomes. In these studies, it is difficult to determine the degree to which any undesirable outcome resulted from poor nursing home performance rather than from the natural processes of declining health beyond the nursing home's control. For example, a resident's decline in ADL function does not mean with certainty that poor care occurred. Instead, unavoidable decline in one of the resident's chronic disease or health conditions (e.g., congestive heart failure) may have adversely affected his or her ADL function. For only a few outcome quality measures is poor quality of care a truly necessary condition (e.g., medication errors).

Those researchers involved in the necessary risk adjustment process in nursing home outcome studies have two options. Either they can include variables in their models that may overadjust, giving some nursing homes undeserved credit for bad-quality care, or they can omit some variables from their models, possibly underadjusting and failing to give some nursing homes credit for good-quality care. For example, when looking at pressure ulcer rates in a nursing home, should one adjust for residents being bedfast? Being bedfast clearly raises the likelihood of a pressure ulcer. But why is a resident bedfast? The resident may be bedfast because of some natural process of declining health, such as increased respiratory distress, or he or she may be bedfast because the nursing home failed to provide an aggressive mobility program that would have kept the resident mobile. Thus, including whether a resident is bedfast in an acuity adjustment model for the presence of pressure ulcers may be overadjusting, but omitting it from the model may mean underadjusting.

Researchers can avoid confounding the impact of individual factors and nursing home performance by looking at changes over time in resident status, using only admission information as baseline data. For almost all residents, provider performance and resident characteristics are orthogonal at admission. However, using this approach, researchers must show that the early months of care that serve as the focus of most such efforts do not differ dramatically from outcomes later in a resident's nursing home stay.

Quality of Life

Quality-of-life issues for nursing homes and their residents can incorporate a long list of dimensions. These include, but are not limited to, helping preserve residents' dignity, respecting their privacy, maintaining positive relationships with staff or other residents, serving high-quality food, enhancing opportunities for resident autonomy, assuring their security, and providing a clean and pleasant physical environment.

Quality-of-life data can be gathered in two ways. Researchers can observe some of these dimensions, such as staff-resident interactions, using standardized tools. Residents can also report on their perceptions concerning all these dimensions.

Each of these approaches, however, is troublesome. Observers cannot assess all aspects of quality of life. More fundamentally, observers (even family members) are not the true recipients of care and may not share residents' perceptions of services or living arrangements. Residents are, of course, the ideal reporters. However, a large proportion of residents suffer from levels of cognitive impairment that make interviewing them difficult or impossible.

The most extensive effort aimed at developing an interviewing strategy for quality of life resulted in 10 dimensions. However, the measurement scales reflecting only a few of these dimensions demonstrated good internal consistency. Additionally, facility characteristics explained very little of the variance in quality of life. Reasonably, residents' characteristics were much stronger predictors of their quality-of-life scores. Such measures, as the developers indicate, are at this point probably best used to identify cognitively intact residents within the nursing home who might be the focus of individualized interventions. While these measures are not yet well-suited for assessing nursing homes' performance in general, they are important steps in the process of moving quality of life into the mainstream of nursing home quality measurement.

Quality Assurance

As the national Institute of Medicine (IOM), Committee on Nursing Home Regulation met over 20 years ago, the committee chair Sidney Katz described quality assurance in nursing homes as a three-legged stool requiring good assessments, good standards, and good enforcement. The IOM report from this committee provided a blueprint for a new approach to ensuring quality in nursing home care. The Nursing Home Reform Act in the Omnibus Budget Reconciliation Act of 1987 (OBRA-87) was a direct descendant of the IOM committee's report. OBRA-87 mandated a comprehensive assessment system titled the Resident Assessment Instrument or Minimum Data Set (MDS), which served as the first leg of Katz's stool. New standards in OBRA-87 that included quality-of-life issues and focused more heavily on outcomes than paper compliance formed the second leg. Then, new enforcement remedies, which included fines, temporary management, and placing a hold

on Medicaid admissions to a nursing home, were added to the traditional remedies of deficiency statements from the annual certification and licensure survey conducted by the states and de-certification of the nursing home, to give the stool a truly solid base. The MDS was implemented in 1989. However, the enforcement standards and remedies were held up for many years by the nursing home industry. When finally implemented, they were watered down, and the expanded range of remedies has not been used vigorously by most states.

Current activities in quality assurance in nursing homes have begun to focus more heavily on quality indicators reporting and public information. The Centers for Medicare and Medicaid Services' (CMS) Nursing Home Compare (NH Compare) Web site allows individuals to obtain detailed information about the past performance of every Medicare- and Medicaid-certified nursing home in the nation. The reports in NH Compare include data on deficiencies cited during the annual (9–15 months apart) survey visits, quality indicators (QIs) from the MDS, and staffing data gathered during the annual survey visits. While MDS data may reflect what is in the medical records, recent research indicates that the staffing data reported to CMS by for-profit and larger nursing homes, when compared with Medicaid cost report data, may overreport staffing levels. A number of state-level reporting systems are somewhat more elaborate than NH Compare. Some state systems provide relative rankings of nursing homes (e.g., one through four stars) and include data on financial performance and expenditure patterns as well as more traditional and staffing data. Initial research findings indicate that such reports may affect nursing home activities, but there is no convincing evidence that such reports affect consumer choices.

In addition, a few researchers are now emphasizing the degree to which nursing home performance affects traditional quality indicators. Early research indicates that a relatively small percentage of the variation in ADL function over time may be attributable to nursing home performance. To the degree that this conclusion is supported by further research into other quality indicators, the quality-reporting movement in the nursing home sector may be at some risk. These reporting systems implicitly assume that nursing home performance explains a meaningful proportion of the variance in

each published indicator. That this assumption is rarely tested is, at this point, a problematic aspect of nursing home performance measurement.

Future Implications

The past few years have been marked by the nursing home industry's emphasis on quality improvement rather than quality assurance, the seeming failure of the current enforcement model, and the lack of serious enforcement activities. At the same time, a group of innovators have begun to offer alternative models of nursing home operations that focus directly on resident-centered care and enhanced quality of life. The Eden Alternative, the Pioneer Network, the Wellspring Initiative, and the Green House Movement are important examples of such alternative models of nursing home operations. All these models focus on more resident-centered care that emphasizes quality-of-life issues and better working conditions for nursing home staff. The Green House Movement takes a lesson from the group home model in community mental health and goes so far as to deconstruct the average 100-bed nursing home into a series of cottages with permanently assigned nurse aides and "circuit-riding" clinical staff.

Where these innovations have successfully been implemented and sustained, they have resulted in changes in the quality of life for residents. However, most nursing homes lack the willingness or ability to implement and sustain such innovations. With an industry dominated by for-profit, owned business entities and with high average turnover rates for senior administrative and clinical staff (ranging from 6 to 18 months), the likelihood of sustained, pervasive change in the nursing home industry seems relatively low. Some nursing homes, often not-for-profits in the least need of transformation, may change and sustain those innovations. Many nursing homes will likely focus on avoiding bad survey results and lawsuits, while maintaining the level of quality that allows them to receive an appropriate return on their investments.

A panel of distinguished experts in long-term care were recently asked what they thought would be the "one thing" that might have the greatest likelihood of enhancing quality in long-term care. The most frequent answer was additional staffing, followed closely by additional funding. But

some of the less frequent answers were interesting as well. One expert said that the real problem lies in the dominance of investor-owned businesses in the nursing home industry. Another expert suggested that the greater involvement of communities in nursing homes would bring considerable benefit.

Some policy analysts, however, consider nursing quality to be something of a vestigial issue. They believe that the current “rebalancing” of long-term care reimbursement to provide more incentives for home care, combined with the growth of the assisted living industry, will sound the death knell for the nursing home industry. However, many doubt that either home care or assisted living can be the panacea that these analysts believe. They argue that home care cannot be effective without adequate staff and considerable family support; and the availability of individuals to provide either paid or informal support, both of which are largely provided by females 40 to 60 years of age, will not be increasing at the rate of increase in the number of impaired elderly 75 years old or older.

Nursing homes most likely will not be vanishing soon from the long-term care tableau. They may change in relatively unforeseen ways as the populations whom they serve change. They may, as they have in the past, go through cycles of popularity with investors on Wall Street. Much about the future of long-term care in the nation is unclear, and much about long-term care may change as policymakers begin to address the aging of society. But nursing homes and the quality of care they provide will likely not disappear from the public policy agenda.

NURSING HOMES

Nursing homes are licensed residential facilities with professional staff that provide continuous nursing care and health-related services for individuals who do not require hospitalization but cannot be cared for at home. These facilities provide 24-hour care for adults 18 years of age or older who are not in the acute phase of illness but who have significant functional deficiencies. Functional deficiencies are generally measured by individuals' ability to perform basic activities of daily living (ADLs), such as the ability to independently dress, eat, bathe, get around, and use the toilet themselves. Individuals may need nursing

home care for a short period of time, such as for rehabilitation or recovery after an injury or illness. Other individuals may require long-term or permanent care for chronic or progressive physical or mental illness or infirmity.

Types

Nursing homes provide different levels of care designed to meet the wide range of needs of individuals. They may specialize in short-term or acute nursing care, intermediate care, or long-term, custodial nursing care. Many of the nation's nursing homes provide more than one level of care.

Skilled-Nursing Facilities

Skilled-nursing facilities (SNFs) provide relatively short-term nursing and rehabilitative care. Skilled care is generally provided to assist patients during recovery following hospitalization for acute medical conditions. These facilities are state-licensed, and registered nurses (RNs), licensed practical nurses (LPNs), and certified nurse aids (CNAs) provide care. The services of other health-care professionals such as therapists, social workers, and dietitians are also available. Hospitals often have arrangements with skilled-nursing facilities to provide follow-up care for patients who no longer need acute hospital services. Skilled-nursing facilities provide skilled care and rehabilitation until the patient is able to return home or requires longer-term placement.

Intermediate-Care Facilities

Intermediate-care facilities provide care for individuals who are recovering from acute medical conditions but do not need continuous care or daily therapeutic services. Intermediate care is provided by skilled professionals such as RNs, LPNs, therapists, and other health professionals under the supervision of a physician.

Custodial-Care Facilities

Custodial-care facilities provide assistance to patients in activities of daily living, such as bathing, dressing, eating, and toileting. Individuals who are recovering from a disabling injury or illness

may temporarily need custodial care. For other individuals who are losing their ability to function independently due to chronic or progressive disease or frailty due to advanced age, custodial care may be a long-term need. For some, ongoing professional nursing and other services may be required along with custodial care. If custodial-care residents become ill or injured, they may spend a period of time in skilled care and then return to custodial care.

Many nursing homes also provide specialized services such as hospice and respite care. Hospice care offers supportive services for terminally ill patients and their families. Nursing homes may also provide respite care for individuals who are being cared for at home to allow a family caregiver relief for short periods of time. Some nursing homes have specially equipped units for persons who are ventilator-dependent, have Alzheimer's disease, or have spinal cord injuries.

Services Provided

Nursing homes provide a wide range of services, including medical-care services; nursing-care services; other professional healthcare services; personal-care services; spiritual, social, and recreational services; and residential-care services.

Medical-Care Services

Regardless of the level of care required, all nursing home residents are under the supervision and care of a physician. Physicians certify the continuing need for nursing home care and are responsible for the resident's overall care plan. Physicians also evaluate and prescribe for the resident's medical conditions and determine the types of restorative and rehabilitative services that are required. All nursing homes must have a medical director who can address medical issues and other concerns with the resident, the resident's family, and the attending physician.

Nursing-Care Services

In the United States, all nursing homes are required to have a licensed practical or vocational nurse (LPN/LVN) on duty 24 hours a day and an RN on duty for at least one shift each day. Nursing

services include the regular assessment of residents' needs, administration of medications and treatments, and coordination of care.

Other Professional Healthcare Services

Nursing homes provide rehabilitative and restorative services such as physical, occupational, respiratory, recreational, and speech therapy. In addition, dental services, dietary consultation, laboratory, X-ray, and pharmaceutical services are available.

Personal-Care Services

Nursing assistants also provide personal-care and supportive services for residents who require help with activities of daily living, such as eating, bathing, walking, and toileting.

Spiritual, Social, and Recreational Services

Nursing homes offer a wide range of services and programs to meet the spiritual and social needs of residents. Clergy and social workers are also available to support family members and friends. Most nursing homes also offer a wide variety of in-house recreational activities and organized trips.

Residential-Care Services

Nursing homes provide general supervision within a safe and secure environment along with basic housing and sustenance.

Eligibility

Each state has its own nursing home eligibility criteria. A prescreening assessment is completed for every individual being considered for nursing home admission. The assessment includes the evaluation of an individual's physical and cognitive limitations, medical conditions, the type and level of assistance required, and skilled-care needs. Although there is some variation across states, the requirements are very similar overall. For skilled-nursing facilities, a state's requirements include a need for at least one skilled service ordered by a physician, such as the administration of medications, special

catheter care, rehabilitation, or nasogastric tube for gastrostomy feedings.

Paying for Nursing Home Care

Many Americans incorrectly assume that the federal Medicare program or standard or supplemental health insurance policies will pay for nursing home care. Consequently, many people do not plan ahead financially or purchase long-term care insurance to provide for their care in the event of infirmity or an extended illness. Nationally the costs of nursing home care often exceed \$50,000 annually, or more than \$4,000 a month.

Medicare

The federal Medicare program is available to those nursing home residents who are eligible for the program, either through age or disability, and who require a skilled level of nursing home care. Generally, Medicare covers services after hospitalization. The number of days that Medicare will pay for skilled-nursing facility care is limited to no more than 100 days per episode of care. During the first 20 days of care, Medicare pays 100% of care. Between 21 and 100 days, Medicare requires a copayment. Many older persons have a Medicare supplement or Medigap insurance policy. This supplemental insurance pays in conjunction with Medicare, but most supplements stop paying when Medicare reimbursement ends. Medigap insurance policies are sold by private insurance companies. To buy a Medigap insurance policy, the individual must already have Medicare Part A and B insurance. Finally, each individual must buy separate Medigap insurance policies, as coverage will not be provided under a spouse or family member's insurance policy. Neither Medicare nor Medigap insurance policies will pay for custodial nursing home care.

Medicaid

If persons have exhausted their Medicare payments for nursing home care, or if they do not require skilled care, they may qualify for Medicaid coverage to pay for their nursing home care. However, Medicaid is only available to persons who have low incomes or limited resources. To

qualify for Medicaid, individuals may have to spend out-of-pocket for care until their income drops to the level required for Medicaid eligibility. States vary in how they consider an individual's assets, such as the spousal home, when determining eligibility for Medicaid. Persons who stay in nursing homes for an extended period, often until death, are typically supported by Medicaid.

Long-Term Care Insurance

A relatively small number of individuals choose to purchase long-term care insurance in the event that they may need long-term care in the future. This insurance must be purchased prior to needing long-term care, and eligibility for this type of insurance is based on health status at the time of purchase. Some financial planners recommend purchasing long-term care insurance when a person is in his or her late 50s or early 60s. Premiums are based on age, health status, and type of plan purchased.

Individuals often consider three things when deciding which long-term care insurance to purchase: the daily benefit, the benefit period, and the elimination or deductible period. The daily benefit is the amount of money that the individual will receive from the insurance company for care on a daily basis. The benefit period is the length of time that benefits will be provided (options generally include 1, 2, or 3 or more years of coverage, or a lifetime plan). And the elimination or deductible period is the number of days the individual is responsible for paying for long-term care before the insurance begins to pay for the care.

Licensing and Certification

State governments are responsible for overseeing the licensing of nursing homes. Each state is contracted by the U.S. Department of Health and Human Services' Centers for Medicare and Medicaid Services (CMS) to monitor its nursing homes. Facilities that want to provide care and be reimbursed by Medicare and Medicaid must adhere to at least minimum state quality requirements. States conduct onsite inspections to determine whether a facility meets quality and performance standards. Inspections are typically yearly, but can occur more frequently, especially if

concerns are voiced or if complaints are made about the care provided. The inspection process includes observations of care processes, staff/resident interactions, and the physical environment. The inspection team also interviews a sample of nursing home residents and family members about the care in the home. Care providers and administrators are interviewed, and clinical records are reviewed based on standardized protocols. The inspection team, which includes an RN, also examines food preparation and storage, fire safety, safe construction standards, and issues related to possible resident abuse. If problems are identified, the CMS can take action against the facility. This can range from imposing a fine, to denying payment, to assigning a temporary manager or installing a state monitor. If the problems are not corrected, the CMS can terminate its agreement with the nursing home. At that point, the nursing home is no longer certified to provide care to Medicare beneficiaries and Medicaid recipients, and these residents will be transferred to other facilities. With the loss of those residents, the nursing home is very likely to close.

Selecting a Nursing Home

Although the individual requiring nursing home care should be involved as much as possible, selecting a nursing home often becomes the responsibility of a family member or friend. Fortunately, there are many resources available to assist in making the decision.

A number of steps in choosing a nursing home have been identified. Generally, the first step in choosing a nursing home is to discuss with a physician the specific types of services that are required and the level of care that is needed. Alternatives to nursing home care should also be discussed at this time. Home care services or adult day care should be considered as a possible alternative, and financial arrangements must also be taken into account.

Once it is determined that nursing home care is required, the next step is to identify local nursing homes that provide the types of services that are needed. There are a number of resources that can provide information. These include state long-term care ombudsman programs, health departments, hospital discharge planners, social workers, geriatric case managers, state or local departments of

aging, the Medicare Web site and informational materials, and Web sites of individual facilities. Friends, neighbors, and clergy may also offer recommendations.

When the list has been narrowed to those local facilities that provide the needed services, family members and future residents will want to evaluate services and amenities. They should talk with administrative personnel at each facility to arrange for a tour. They should plan to visit each facility two or three times at different times of the day and arrange visits to observe meals and recreational activities. Personal observations and interactions with staff will provide the most valuable information about the quality of care provided by the nursing home.

For example, family members and individuals will need to determine if the nursing home is in a quiet, safe area that is accessible, as continued contact with family and friends is a vital aspect of a resident's well-being. They will also need to note if the building is in good repair, has adequate space, and appears clean and safe. Potential residents and families will also want to pay attention to social interactions within the facility and the availability of group activities. Residents should all have the opportunity to take part in activities that provide mental, physical, and social stimulation and decrease the likelihood of isolation. Monthly programs and activities should be posted at each nursing home.

During these initial visits and tours, families and individuals should talk to all levels of staff, including the director and nursing assistants; they should observe the staff interactions with the residents, meal presentation and preparation, and resident interactions in the dining room and other common spaces. Potential residents and family members should talk directly to the other residents, inquiring about their experience in the facility and their daily activities. Finally, they should be aware of any special services the nursing home offers to residents, such as religious services, particular diet preferences, or field trips.

It is also important to evaluate quality when selecting a nursing home. Every nursing home facility is inspected annually by its state health department. The survey results are available at the facility and the public may review the report of the facility's performance using Medicare's "Nursing

Home Compare" Web site. Survey results address all aspects of care provided by the nursing home, from what might be considered minor infractions to major issues of concern. A staff representative can answer questions and provide additional information about the report and about whether identified problems have been corrected.

Often the potential nursing home resident is unable to be involved in every step of the selection process; it is essential, however, to the degree that it is possible, that he or she be involved in the final choice. Many people are reluctant to enter a nursing home, even if it is necessary. Of the options available, the facility chosen must be a place where the individual believes that he or she will be most comfortable.

Ombudsmen

In 1978, the U.S. Congress amended the Older Americans Act to include a requirement that each state develop a long-term care ombudsman program. Provisions of the act require that each state institute a program that defines the function and responsibilities of ombudsmen, addresses complaints, and advocates for improvements in the long-term care system.

The ombudsman program is administered by the federal Administration on Aging, and most state ombudsman programs are housed in their state unit on aging. There are 53 state long-term care ombudsman programs and about 600 regional programs in the nation. Over 8,400 volunteers have been certified to handle complaints. Nationally, the ombudsman program handles over 264,000 complaints annually. An individual 18 years of age or older who has the time and interest may volunteer to become an ombudsman. Although specific requirements vary from state to state, generally ombudsmen may not have a family member who is a resident in a local nursing facility, and they must not be employed by or have ownership in a long-term care facility. Volunteers must provide references, and criminal background checks are required. Once accepted into the program, ombudsman volunteers receive training and are certified.

Long-term care ombudsmen serve as advocates for nursing home residents. The ombudsmen provide a wide range of services for nursing home

residents and their families, from advising in the selection of an appropriate nursing home to resolving complaints made by or for residents. They may also address a wide range of quality of care and quality-of-life concerns that can include unanswered call buttons, roommate problems, staffing issues, food concerns, and unsanitary conditions. They often visit nursing homes to reach out to residents and families, as well as receiving complaints by telephone, mail, and e-mail.

Ombudsmen conduct educational sessions for nursing home staff, family, resident councils, and others. Programs include residents' rights, restraint reduction, abuse and neglect regulations, and how to deal with difficult behaviors. They also provide general information to the public on nursing homes and other long-term care facilities and services, residents' rights, and legislative and policy issues. Nursing homes are required to clearly post information about the ombudsmen program and how residents or other concerned individuals may contact an ombudsman.

Cultural Change Movement

The cultural change movement is a grassroots effort to transform the culture of aging. This effort, led by a group called the Pioneer Network, grew out of a small group of providers and researchers who were interested in changing the culture of nursing home care into places for living and growing rather than decline and death. This group has identified 13 core values for improving the quality of long-term care in persons' homes, assisted living, nursing home, and other facilities. The Pioneer Network also acts as a liaison between long-term care researchers and nursing homes to encourage nursing homes to participate in research and to help researchers and providers to translate findings into practice.

OBESITY

Obesity is a major public health problem in the United States; it has a significant impact on access, cost, and quality of healthcare. The prevalence of obesity has increased over the past 30 years to the point where many refer to it as an obesity epidemic. Today, more than 65% of adults in the nation are either overweight or obese. Additionally, 33.6% of children between 2 and 19 years of age are at risk of being overweight or are overweight. Obesity is currently the second leading cause of preventable deaths in the nation, and it may surpass smoking as the leading cause of preventable death in the future.

The link between lifestyle and obesity starts in the prenatal period. Children are exposed to parental behaviors, which they may model later in life. School lunch programs aim to meet nutritious guidelines but often do so with limited resources. An emphasis on academic standards frequently reduces time for free play and activity in school, either during recess or gym class. Computers, television, and video games are widely available to children, who often prefer these activities to physical activity after school and on weekends. Adults are bombarded with fast-food establishments, convenience foods, and demanding time constraints, which may lead to poor food selection and inactivity. Taken together, the typical American family has significant barriers to making healthy food choices and participating in physical activities.

Assessment of Risk

An important measure of weight and obesity is the body mass index, or BMI. The BMI is used to assess a person's risk of weight-related comorbidities based on his or her relative weight to height. The formula for calculating the BMI is $BMI = \text{weight (kilograms)} / [\text{height (meters)}]^2$. The nonmetric conversion formula is $BMI = \text{weight (pounds)} / [\text{height (inches)}]^2 \times 703$. For example, a person who weighs 175 pounds and is 66 inches tall (or 5 foot 6 inches) has a BMI of 28: $\text{weight (175 pounds)} / [\text{height (66 inches)}]^2 \times 703 = 28$.

A healthy BMI for adults is between 18.5 and 24.9. A BMI less than 18.5 is considered underweight and may be associated with decreased immune function, osteoporosis, decreased muscle strength, and trouble regulating body temperature. At BMIs greater than 25, a person's risk of weight-related illness or comorbidities increases. Between 25.0 and 29.9 adults are classified as overweight, and people with a BMI of 30.0 or higher are considered obese.

In children, the BMI is stratified by age and gender. This is done to control for the changes in body fat that are expected as children grow. It also allows for the differences in body fat between boys and girls. BMI-for-age tables are available from the Centers for Disease Control and Prevention (CDC) and are used to help healthcare practitioners assess adiposity (fatness) in children. A BMI-for-age that is less than the 5th percentile is considered underweight. Healthy weights include

BMI-for-age from the 5th percentile to less than the 85th percentile. A child is at risk of being overweight with a BMI-for-age from the 85th percentile to less than the 95th percentile. A BMI-for-age greater than or equal to the 95th percentile is classified as being overweight. There is no obese classification for children (2–19 years of age).

Adipose tissue (fat) that is deposited around the midsection of the body is more metabolically active than fat that is distributed in the extremities. Abdominal fat that is out of proportion to total body fat is an independent risk factor for obesity-related morbidity and mortality, even in individuals with a normal BMI. Waist circumference is used to assess the risk from abdominal obesity. Relative-risk cutoffs for waist circumference are gender specific, whereas BMI is independent of gender.

Nutrition

At the most basic level, weight gain occurs when calories taken in exceed calories expended. When a person eats more calories than he or she expends (through basal metabolism, thermic effect of food, and physical activity), he or she gains weight. If a person eats fewer calories, he or she loses weight. During the last 30 years, there have been changes in the nutrient composition of meals and portion sizes, which has contributed to the increasing calorie intakes of individuals. A public misperception regarding portion size and serving size further adds to the confusion.

Portion Size

Portion size is the amount of food or beverage that is consumed in a single eating event. Serving size is the standardized unit for measuring food that is used in dietary guidance. For example, a person might eat one bowl of pasta and consider it a serving; however, a serving size for pasta is half a cup. The bowl of pasta is the portion size that was consumed. Consider a typical breakfast from 30 years ago—coffee and a muffin. An 8-ounce cup of coffee with whole milk and sugar has approximately 45 calories. The portion size of a muffin 30 years ago was approximately 1.5 ounces (210 calories). At many restaurants today, a medium coffee (16 ounces) may have upward of 350 calories, while the muffin size has increased to

4 ounces (500 calories). This results in an increase of almost 600 calories for the same meal.

Consumers also equate size to value. When people eat in restaurants or purchase prepackaged foods, they expect a large portion for their money. Small portions are seen as cheap or insufficient, so restaurants respond by offering 12-ounce steaks and family-size bowls of pasta as single entrees. There is also an incentive to buy big at fast-food restaurants. Customers are offered the opportunity to upsize an order at minimal cost. Oversized portions are not limited to food. Beverage portions are also increasing. Soft drinks used to be served in 6- to 8-ounce portions; today consumers can choose between 12-, 20-, and 24-ounce containers. People can easily drink 150 to 180 calories per 12-ounce portion.

Breastfeeding and Infant Formula

The overconsumption of beverages starts in infancy. Formula-fed infants have their intake measured by how many ounces they consume from the bottle at each feeding. Parents often think that babies need to drink the entire bottle, even if the child shows signs that he or she is finished. When this happens, babies do not learn what satiety (fullness) feels like, and they may overeat when they are older. Breastfeeding provides an opportunity for babies to self-regulate caloric intake. Mothers are unable to measure how much milk is consumed from the breast, allowing babies to stop eating when they feel full. Some mothers may gauge consumption by monitoring how long each nursing session lasts; however, babies adjust their suck rate as hunger subsides. Nursing in response to hunger (nutritious nursing) may result in a higher milk intake than comfort nursing. The protective effects of breastfeeding on excessive weight gain in childhood may be dose dependent. The greater the opportunity children have to self-regulate intake, the more they are able to recognize hunger and satiety cues.

Parental Influence

Parental choice once children are weaned from breast milk or formula also affects the risk of excessive weight gain. When juice and juice drinks replace breast milk and formula, children consume

large amounts of calories with little nutritional value. These calorie-dense beverages often take the place of nutritious foods. Children also lose out on the beneficial effects of fiber and phytochemicals that are found in fruits and vegetables. Putting infants and children to sleep with bottles of juice or milk contributes to excessive weight gain and tooth decay. For many children, their only exposure to vegetables is in the form of French fries. Children often mimic their parents and caregivers when deciding what to eat. When children see their parents eating high-fat, sugary foods, they will want to do the same. If healthy foods, including fruits and vegetables, are regularly offered, children will develop an affinity for their taste. Including children in the food-purchasing and -preparation process can also entice them to eat a variety of healthy foods. After age 2, most children can safely switch to low-fat or fat-free dairy products. Parents should avoid adding salt to food, both during the cooking process and at the table. A preference for salty foods is an acquired taste—if children do not eat salty foods when they are young, most will continue to avoid them as adults.

Dietary Guidelines

The Dietary Guidelines for Americans have been published at least every 5 years since 1980. This joint venture by the U.S. Department of Health and Human Services (HHS) and the U.S. Department of Agriculture (USDA) aims to educate Americans on healthy eating habits. There is also an emphasis on how dietary intake can help reduce the risk of several chronic diseases, including obesity. These guidelines, commonly known as the Food Guide Pyramid, received a major revision that was released in 2005. The My Pyramid food guidance system is an interactive, Web-based system that allows users to customize calorie recommendations by age and gender. It also provides recommendations for pregnant and lactating women. This system incorporates physical activity recommendations to further encourage Americans to improve their health through lifestyle modification.

Lifestyle

Technological advances, such as television, computers, and automobiles, as well as the growth of

the nation's fast-food industry, have changed many individuals' lifestyles, contributing to the increase in obesity. Important elements of lifestyle are physical activity, screen time, and eating habits.

Physical Activity

The CDC and the USDA recommend at least 30 minutes of moderate-intensity activity for adults most days of the week to maintain health. To improve health and lose weight, 60 to 90 minutes of moderate-intensity activity are necessary. Children and adolescents should engage in moderate-intensity activities daily for optimal health. One way to measure daily physical activity is with a pedometer. A pedometer is a device that measures how many steps the wearer takes each day. Ten thousand steps per day correspond to approximately 60 minutes of moderate-intensity activity, or the amount recommended for healthy living and weight loss. By adjusting activities of daily living, it is possible to meet the recommended activity levels for most adults without exercising.

Individuals who are successful in maintaining their weight loss long-term have incorporated exercise into their lifestyle. Exercise enhances weight loss efforts by building muscle and bone mass and improving cardiovascular endurance. Exercise also helps control blood sugar levels, reduces blood pressure, and lessens feelings of depression and anxiety. Fifteen minutes of brisk walking or climbing the stairs for 15 to 20 (cumulative) minutes per day expends about 100 calories. The benefits of exercise are cumulative, so people can perform different activities throughout the day (in 10-minute increments) and still improve their well-being.

Screen Time

The American Academy of Pediatrics (AAP) recommends no more than 2 hours of quality screen time for children over the age of 2 each day and no screen time for children under the age of two. Screen time includes television viewing (including movies), computer usage, and playing video games. Data from the 1988 to 1994 National Health and Nutrition Examination Survey found that 26% of children watch more than 4 hours of television per day. These children had greater

BMI than children whose television viewing was limited to less than 2 hours per day, and they were less likely to engage in vigorous physical activity. Children who engage in regular physical activity that incorporates free play and structured activities are more likely to engage in regular physical activity as adults. As opportunities for physical activity decrease during the school day, it is important that parents encourage their children to engage in active behaviors after school and on weekends. Parents can model good behaviors by designating family activity times and making healthy choices for themselves. Praising children when they accomplish new goals will further encourage them to participate in physical activities.

Eating Habits

The increase in the number of fast-food establishments, loss of family meal times, and increase in the availability of convenience foods have all contributed to obesity. Many people do not eat breakfast because of time constraints or because they think it will help them lose weight. However, skipping breakfast contributes to overeating later in the day, both at mealtimes and with snacking. It has been found that children who skip breakfast have lower test scores and more difficulty concentrating in school.

Where people eat is almost as important as what they eat. Eating a majority of meals away from home tends to result in higher caloric intakes than if the majority of meals are eaten (and prepared) at home. The loss of the family mealtime has been identified as a contributory factor in childhood obesity. Family mealtime provides an opportunity for the entire family to step back from their hectic daily schedules and focus on the family unit. It also provides an opportunity for parents to model healthy eating behaviors for their children.

Prevention

There are many national-, state-, and local-level initiatives under way to combat the obesity epidemic. Nationally, Healthy People 2010 is setting the stage for improving the health of all Americans. Among their Leading Health Indicators (a list of

10 high-priority public health issues) are physical activity and overweight and obesity. The Safe Routes to School Program is one example of a Healthy People 2010 initiative to increase physical activity and reduce overweight status in children. This \$612 million program has been implemented in more than 20 states, providing support to local communities that are interested in increasing the number of children who walk or ride their bicycles to school. The Small Step campaign encourages Americans to make small efforts to improve their health and reduce their risk of weight-related medical problems.

Many states are now requiring BMI report cards; students have their BMI assessed annually at school, and the results are sent home to parents. Physicians in West Virginia will be provided with BMI wheels and training to encourage BMI assessments on all patients. And the Florida Department of Health has created the Hispanic Obesity Prevention and Education Program to help address the increasing prevalence of obesity among that ethnic group.

Nationally, Mexican American girls (under age 20) have the highest percentage of overweight; for boys, non-Hispanic Blacks have the highest percentage, followed by Mexican American boys. There is a similar trend in adult females—the age-adjusted prevalence of overweight and obesity is higher in non-Hispanic Black and Mexican American women than in non-Hispanic White women. There is little difference in prevalence among men in these three groups.

Research

Several genes are being studied to gain a better understanding of their role in regulating weight and appetite. These genes include leptin, proopiomelanocortin (POMC, a leptin receptor), prohormone convertase 1, melanocortin receptors 3 and 4, and transcription factor single-minded 1. The insulin gene is also being studied. Neurotransmitters such as serotonin, norepinephrine, and dopamine play a role in weight control and satiety and are the focus of several pharmaceutical products designed to treat obesity. The central cannabinoid (CB1) receptors are thought to play a role in the regulation of food consumption and may have a role in reducing hunger sensations.

Treatment

While many people are able to ameliorate their risk of weight-related illnesses by making healthy lifestyle choices, some are unable to achieve a healthy weight on their own. The 1998 National Institutes of Health's (NIH's) Clinical Guidelines on Managing Overweight and Obesity recommended that the U.S. Food and Drug Administration (FDA) approve weight loss drugs so that they may be used as an adjunct therapy to lifestyle modification in patients with a BMI of 30 or higher with no weight-related comorbidities or in patients with a BMI of 27 or higher with obesity-related comorbidities (or risk factors). Obesity-related comorbidities include diabetes mellitus, sleep apnea and obesity-related hypoventilation, asthma, nonalcoholic fatty liver disease, gallbladder disease, orthopedic problems, hyperinsulinemia, polycystic ovary syndrome, and metabolic syndrome (which may include hypertriglyceridemia, low-HDL cholesterol, hypertension, impaired glucose tolerance, and/or increased waist circumference).

Currently, the only FDA-approved medications for weight loss are sibutramine (Meridia) and orlistat (Xenical). Sibutramine is a norepinephrine, dopamine, and serotonin reuptake inhibitor that works by decreasing appetite. Orlistat is a gastric lipase inhibitor that reduces fat absorption in the intestines. Orlistat recently received FDA approval to be sold over the counter as Alli, although at lower doses than the prescription version.

In addition to pharmaceutical therapy, some obese individuals may benefit from bariatric (weight loss) surgery. There are four surgical procedures commonly performed in the United States for obesity: Roux-en-Y gastric bypass, adjustable gastric banding, sleeve gastrectomy, and biliopancreatic diversion (with or without duodenal switch). The adjustable gastric banding and sleeve gastrectomy work by restricting the amount of food that can be consumed at any given time by decreasing the size of the stomach pouch. The Roux-en-Y gastric bypass and biliopancreatic diversion provide restriction in addition to malabsorption. In both of these procedures, the size of the stomach pouch is reduced (restrictive component), and parts of the intestines are bypassed (malabsorptive

component). Bariatric surgery should be restricted to individuals with a BMI of 40 or higher or a BMI of 35 or more with obesity-related comorbidities. Bariatric surgery programs should include education on lifestyle modification and behavioral therapy. Only the adjustable gastric banding is reversible.

Future Implications

The etiology of obesity is multifactorial and difficult to treat. There is a clear environmental impact on the increasing rates of overweight and obesity. Expansive unhealthy food selections and decreased opportunities for physical activity are significant contributory factors to America's expanding waistline. What is not fully understood is the role of genetics in the obesity epidemic. Animal studies looking at the role of various genes in appetite regulation and weight control are not easily reproduced in humans. Until scientists are able to discern the true role of genes in the obesity epidemic, it is up to families and each individual to make healthy lifestyle decisions to reduce the risk of becoming obese.

O'LEARY, DENNIS S.

Dennis S. O'Leary is the former long-time president of the Joint Commission, the leading health-care accrediting body in the United States. Under his leadership, the Joint Commission's accreditation process successfully changed from being primarily focused on the structural measures of healthcare organizations to process measures and care-related outcomes. He also started cutting edge healthcare standards relating to pain management, patient safety, emergency preparedness, and the use of patient restraints. And he launched a series of public policy initiatives.

A Kansas native, O'Leary earned a bachelor's degree from Harvard University and a medical degree from Cornell University Medical College in New York. After 2 years of internal medicine training at the University of Minnesota Hospital, he completed his residency and a hematology fellowship at Strong Memorial Hospital in Rochester, New York. He is board certified in Internal Medicine and Hematology.

Prior to joining the Joint Commission, O'Leary spent 15 years at the George Washington University Medical Center in Washington, D.C. At the medical center, he was a professor of medicine, and he served as a senior manager in several positions. He was the medical director of the university's hospital for 10 years, the dean for clinical affairs at the university, and the vice president of the university's health plan, an academic health maintenance organization (HMO). In 1981, O'Leary received national attention for his role as the university hospital's spokesman for the care given to President Ronald Reagan after he was shot in a failed assassination attempt. He frequently briefed the national and international news media about the president's medical progress.

O'Leary became president of the Joint Commission in 1986. During his 21 years at the Joint Commission, he greatly expanded its scope and size. Under his leadership, the organization moved beyond its original hospital base to accredit a wide range of extended-care and ambulatory-care service organizations. It initiated an international accreditation program and a consultation services program. And the organization undertook a series of projects with the World Health Organization (WHO). Under O'Leary, the Joint Commission's budget and staff quadrupled in size.

During his career, O'Leary received many awards and honors. He is a member of the National Academy of Sciences, Institute of Medicine (IOM). He also is a master of the American College of Physicians and a fellow of the American College of Physician Executives, the American College of Healthcare Executives, and the American Dental Association. In 2000, *Modern Healthcare* magazine identified him as one of the nation's 25 most influential leaders in healthcare during the past quarter-century. In 2005, he was given the Distinguished Service Award, the highest honor from the American Medical Association (AMA), for his advancement of healthcare quality and patient safety. And in 2006, he received the Ernest Armory Codman Award from the Joint Commission for his leadership role in using performance measures to improve healthcare quality and safety.

After leaving the Joint Commission at the end of 2007, O'Leary was appointed to the board of directors of the Consumers Advancing Patient Safety (CAPS), an organization that promotes patient-centered healthcare.

ORYX PERFORMANCE MEASUREMENT SYSTEM

ORYX is a tool used by healthcare organizations to evaluate their ongoing performance and to inform continuous quality improvement efforts. The ORYX initiative was developed and implemented by the Joint Commission and came into use in 1997. This system for the first time included performance and outcome measures in the accreditation process that was applied to hospitals, long-term care organizations, and healthcare networks. ORYX was later expanded to also include behavioral healthcare and home care organizations.

The concept of ORYX was to be a continuous, data-driven process that evaluates a healthcare organization’s standard of compliance and the outcomes of this process. Joint Commission officials note that ORYX provides purchasers and consumers of care with another level of assurance that Joint Commission–accredited organizations are evaluated on outcomes in addition to the on-site surveys that take place.

Initial policies regarding ORYX called for accredited healthcare organizations to select two of the approved measures, also known as noncore measures, and to report data on at least 20% of the patient population from a list of 60 performance measurement systems that met the Joint

Commission’s criteria. This information was to be collected on monthly data points and transmitted on a quarterly basis in an electronic machine-readable format via the Internet or electronic bulletin board services to an approved Performance Measurement System (PMS). The Joint Commission delayed the reporting of core measures for long-term care, home care, and behavioral-health organizations so that applicable core measures could be identified. This was in response to the lack of national consensus on appropriate performance measures for nonhospital settings of care. ORYX provides healthcare organizations with a greater degree of flexibility in selecting measures, which was identified as a problem in the past under the Indicator Measurement System (IMSystem).

In July 2002, the first ORYX measures on accredited hospitals were collected. Hospitals are required to collect and report on at least three core measures or up to nine measures if not participating in core measurement activities, to satisfy the requirements of accreditation. Nonhospitals must collect six measures to satisfy accreditation requirements. To reduce the burden of reporting requirements for hospitals and other healthcare organizations, the Joint Commission has worked closely with the Centers for Medicare and Medicaid Services (CMS), the National Quality Forum, and other entities to develop and standardize these core measures.

One criticism of the ORYX program is that healthcare organizations may focus their quality improvement efforts on only the reported measures of quality or selected measurements that they perform well on. In addition, critics cite that the measures only represent a small number of medical conditions. The Joint Commission concedes these facts; however, it is acknowledged that healthcare organizations will eventually have to report measures on a greater percentage of their population. Some professionals question how performance data will correlate with hospital accreditation and the ability of the Joint Commission, a private organization supported by the hospital industry, to objectively evaluate hospital performance.

History

The Joint Commission’s history of performance measurement can be traced back to the early days

of Ernest Codman, who established the concept of the data-driven “end-result” system in the 1900s. The Joint Commission’s Agenda for Change had at its centerpiece the goal of incorporating performance measurement into its accreditation process. During the period leading up to this, beginning in 1986, the Joint Commission was in the process of developing, testing, and implementing standardized performance measures and also establishing the infrastructure to transmit and collect these performance measurement data. This initiative was known then as the Indicator Measurement System (IMSystem). The reason for the development of the IMSystem was that until this point compliance with standards was the basic measure of healthcare quality. This new paradigm to look at the actual results and outcome of care called for a more integrated approach to evaluation of healthcare organizations. The use of performance data by the Joint Commission would facilitate the quality improvement efforts of healthcare organizations, ensure accountability, and combine performance with standards compliance in the accreditation process.

The IMSystem was to be a national comparative measurement system comprising indicators of outcome and process measures that would reflect the appropriateness or effectiveness of performance. Outcome indicators were also to be appropriately risk adjusted to account for differences in patient-level factors. The set of performance measures under the IMSystem included perioperative care, obstetrical care, trauma care, oncology care, infection control, and medication use. The goal at the time was that hospitals would collect and start to transmit data on these measures beginning in 1995 but they would retain choice and flexibility in selecting appropriate measures to report on. The IMSystem did not take off due to the quickly changing measurement environment and because many hospitals felt that this project was not practically feasible. Although the IMSystem never reached fruition, it served as the predecessor for the new ORYX initiative. With changing knowledge, the Joint Commission revised its original performance measures and pursued a collaborative approach in the ORYX initiative.

In 1999, the Joint Commission sought input from healthcare professionals about the initial set of hospital core measures. The Attributes of Core

Performance Measures and Associated Evaluation Criteria were used to evaluate candidate measures as potential core measures. After the core measures were developed, the Joint Commission initiated a pilot project to test the feasibility and usefulness of these measures. Out of the 11 state hospital associations that were interested in participating in this project, 5 (Connecticut, Michigan, Missouri, Georgia, and Rhode Island) were randomly selected to participate and identify a single performance measure system and participant hospitals. Through this pilot demonstration, the Joint Commission was able to receive feedback, as well as modify and assess the reliability of the core measures. After this feedback period, the Joint Commission made a series of revisions to the initial core measures prior to the full-scale implementation of this project.

During 1995, a request for PMSs to participate in the ORYX initiative was made. Candidate PMSs were evaluated against specified characteristics known as the Attributes of Conformance. The Attributes of Conformance were created by the Joint Commission to ensure that PMSs had the technical and operational infrastructure necessary to support this performance measurement initiative in the present as well as the future. The attributes of PMSs typically included appropriate performance measures that focused on organization performance, clinical processes and/or outcomes, operational database, processes that ensure data quality, risk adjustment methods, feedback to participating organizations, and usefulness and relevance to the accreditation process. The initial attributes were defined at the minimal level; however, they have been modified several times because of the growing need to maintain data quality.

After candidate PMSs passed this initial evaluation, a “request for indicators” was issued to receive PMS extant measures for review, evaluation, and approval for use in ORYX. Once they were approved, healthcare organizations could select these measures to satisfy the requirements of ORYX. The Joint Commission’s database stores more than 15,000 extant performance measures.

PMSs that satisfied the selection criteria were listed for accredited healthcare organizations to select and contract with in order to meet accreditation requirements. PMSs serve as an intermediary between the Joint Commission and accredited healthcare organizations to receive and aggregate

transmitted data. PMSs ensure data quality, analyze and risk adjust the data, and provide feedback to participating organizations. At present, more than 400 PMSs have been evaluated, and 98 PMSs currently participate in the ORYX initiative.

Once the Joint Commission receives the aggregated data from the PMSs, the data are passed through an automated filter process. The Joint Commission developed a software application to compare incoming data against specific statistical process control decision rules, known as the Auto-Stat process. All the data reported are run through this application, which provides comparative information and helps identify any outliers. Only data that have passed through this filtering process are then included in the Joint Commission's database. The Joint Commission conducts three types of analyses on its data: data quality assessment, intraorganizational analyses, and interorganizational analyses. These data are important in the Joint Commission's Priority Focus Process aligned with its new accreditation process, Shared Visions-New Pathways.

Data quality is assessed through the data filter process, through PMS audits, and during the on-site survey of accredited healthcare organizations. Intraorganizational analyses involve the use of control charts to assess the processes involved in the results being measured. This analysis includes evaluating the data to examine trends and patterns in organizational performance and identifying areas for improvement. The organization-specific data are also used to develop a customized on-site survey agenda and will be factored into the accreditation decision-making process. To evaluate whether an organization is performing within an acceptable range during a given period of time, the Joint Commission conducts a comparative interorganizational analysis. This analysis entails comparing an individual organization with a comparison group's data, which is then summarized in a comparison chart. The comparison chart includes an organization's observed rate, the expected rate, and the expected range or acceptance interval associated with the expected rate.

When the Joint Commission initially began to use performance measurement data, it was focused primarily on the presurvey report during the on-site visit. This presurvey report was tailored specifically for each accredited healthcare organization and

included a control and comparison chart for each measure selected. The control chart examined the organization's performance over time, while the comparison chart compared the organization with other organizations collecting the same measures.

The Joint Commission also commenced to use ORYX data to detect sentinel events at facilities. If the Joint Commission learns of a sentinel event through the quarterly reporting by hospitals, this will be considered to be self-reported by the healthcare organization and would require a root-cause analysis and action plan or an evaluation of the response.

Some limitations of the ORYX initiative are that small rural hospitals do not typically have enough cases of events to draw any meaningful conclusions. Thus, hospitals with an average daily census of fewer than 10 patients and a monthly ambulatory population of fewer than 150 patients are currently exempted from submitting data on the ORYX requirements. Additionally, the issue of multiple comparisons of organizations across time and cross-sectionally may have resource implications.

As new technologies rapidly emerge and advances are made in healthcare, the Joint Commission must continue to find ways to adapt to reflect the growing sophistication of performance measurement. To meet this challenge, the Joint Commission's Performance Measurement Strategic Issues Work Group has developed areas of focus for the next 5 years. These focus areas include refining the receiving of standardized-performance measurement data from participating healthcare organizations, expanding the breadth of measure sets available that healthcare organizations may select, creating applications that will be able to use measurement data in the accreditation process as well as public reporting efforts, coordination of data demands and prioritization of measurement areas to reduce data collection burden and eliminate duplication for healthcare organizations, and continued support for the role of the National Quality Forum as the leader in setting measurement objectives.

Ongoing Activities

At present, the Joint Commission has identified five core performance measure sets for hospitals: (1) myocardial infarction, (2) heart failure,

(3) pneumonia, (4) pregnancy and related conditions, and (5) surgical infection prevention. Additionally, intensive-care unit (ICU), pain management, children's asthma care, and hospital-based psychiatric-service measures are scheduled to be implemented soon.

The process involved in creating these measures includes working with a technical expert panel, testing, and development of technical specifications. All these core measures have been reviewed and approved by the National Quality Forum.

Quality Check[®] was established the same year as the ORYX initiative and serves as a directory of accredited organizations and performance reports available for public use on the Joint Commission's Web site. In 2004, the debut of Quality Report became available to the general public at www.qualitycheck.org, which allowed easy access to organization-specific data that included composite scores for each set of reported measures. This result is displayed against comparative state and national data.

The use of measurement data in the accreditation process has also grown with the evolution of these measures. In addition to being used for continuous quality improvement efforts of healthcare organizations and the Joint Commission's presurvey report, performance measures are also used to focus on the on-site accreditation survey through the Priority Focus Process (PFP). The PFP compiles data from various sources and identifies one or more focus areas for the on-site survey.

Data management efforts of ORYX data have also evolved over time with newer methods. In the beginning of the ORYX initiative, data quality was focused primarily on missing data and outliers. Data integrity became even more important with public reporting and the core measures. As a result, the Joint Commission continues to monitor data quality after each quarter of data submission. Currently, the issues involved in the data management of ORYX include the aggregation of data and the reliability of data collection.

Other Health Quality Initiatives

In 1999, the National Quality Forum was formed to review and approve performance measures. The National Academy of Sciences, Institute of Medicine's report *Crossing the Quality Chasm*

outlined the quality improvement objectives for the nation. With many actors now involved in health-care quality, the Joint Commission became engaged in initiatives such as the Hospital Quality Alliance.

The federal CMS heads a program similar to the Joint Commission's ORYX, known as the Hospital Quality Alliance: Improving Care Through Information. This is a public-private partnership aimed at improving care in the nation's hospitals by measuring and publicly reporting on this care. This program collects information on hospital performance measures for heart attack, congestive heart failure, pneumonia, and surgical infections, and it plans to continue to expand in the future. This initiative grew out of the collaboration between the CMS, American Hospital Association (AHA), Federation of American Hospitals, and Association of American Medical Colleges (AAMC) and is supported by the Agency for Healthcare Research and Quality (AHRQ), National Quality Forum, Joint Commission, American Medical Association (AMA), American Nurses Association (ANA), National Association of Children's Hospitals and Related Institutions, Consumer-Purchaser Disclosure Project, American Federation of Labor and Congress of Industrial Organizations (AFL-CIO), AARP, and U.S. Chamber of Commerce. A *Hospital Compare* report, which provides an easy to use interface on hospital performance, can be found at www.hospitalcompare.hhs.gov.

Future Goals

The Joint Commission envisions that performance measurement will become a seminal part of the information technology infrastructure. Some future objectives of the Joint Commission's performance measurement data include the following: the creation of a national standardized data set, continuous data monitoring and follow-up with healthcare organizations to identify areas for ongoing improvement, refining standards through the use of measure data, including measurement data in the AHRQ's National Health Care Quality and Disparities Reports, the use of measurement data to improve the quality of care through research, the use of measurement data to identify high-reliability healthcare organizations, the use of measurement data to identify evidence-based practices and establish national benchmarks,

establishing processes to support increased use of measurement data by consumers, and the use of measurement data to ascertain healthcare organization reimbursements levels.

The development of new core measures will eventually replace noncore measures in nonhospital areas (long-term care, ambulatory care, home care, and behavioral health). Additionally, the Joint Commission plans to seek patient-level data, which will ensure higher levels of data quality; information regarding development; increased research related to performance measurement and quality improvement efforts; increased support for the Joint Commission's new accreditation process; and ongoing support of efforts to ensure the relevance, usefulness, reliability, and validity of the measures.

With the increasing sophistication of medical care, the Joint Commission will continue to identify measures that are no longer relevant and will find ways to randomly collect data on these "retired" measures. Additionally, the Joint Commission expects to implement patient perception of care as a core measure over the next several years through a standardized hospital patient experience-of-care tool, known as the CAHPS Hospital Survey.

As the Joint Commission continues to work with its national partners in quality improvement and performance measurement efforts, it is guided by the continued expansion and coordination of nationally standardized core measurement capabilities and increasing the use of measurement data for quality improvement efforts, benchmarking, accountability, decision making, accreditation, and research. It is anticipated that the attainment of these goals will lead to the continued improvement in patient safety and quality of healthcare organizations.

OUTCOMES-BASED ACCREDITATION

Outcomes-based accreditation is an objective, data-driven process of externally evaluating providers, healthcare facilities, or health plans through the use of performance measures. Risk-adjusted outcome measures, such as mortality, quality of life, patient functional ability, and patient satisfaction, are used to compare among providers of care and healthcare organizations to make choosing a provider more meaningful to patients since patients are ultimately concerned about their health outcomes.

History

Florence Nightingale was the first to study health outcomes by measuring mortality and infection rates in British military hospitals during the Crimean War. In the early 20th century, a pioneering physician at the Massachusetts General Hospital in Boston, Ernest Codman, proposed an *end-results system* to examine patient outcomes of surgical procedures. At the time, Codman's idea was viewed as radical and against the medical establishment. Building on Codman's idea, Avedis Donabedian developed a framework for quality assessment that included structure, process, and outcomes. Structure refers to the structural characteristics of healthcare organizations, such as the number of certified staff, equipment, and medical technologies; process includes all the processes involved in providing care to the patient; and outcomes are the results of the care rendered by the provider.

Historically, accreditation reviews were primarily based on structural features since they were easy to measure; however, recently there has been a movement to further examine process and outcomes measures that give a more comprehensive view of patient care quality and enable consumers and purchasers to make informed healthcare decisions. By using the framework of Donabedian and Codman's end-result system, organizations such as the National Committee for Quality Assurance (NCQA) and the Joint Commission have started using outcomes to accredit health plans and healthcare facilities.

Accrediting Organizations

The NCQA, a private, nonprofit organization, is dedicated to improving healthcare quality by accrediting and certifying a wide range of healthcare plans through its set of performance measures known as the Health Plan Employer Data and Information Set (HEDIS). The mission of the NCQA is to provide information to purchasers and consumers on the quality of care of managed-care organizations that will allow them to make informed purchasing decisions. Beginning with HEDIS 3.0, the NCQA started to make progress by including the outcomes measures of patient function and satisfaction in its evaluation process. The major barrier to the initial implementation of

outcomes measures in HEDIS was the lack of information technology infrastructure to capture these measurements. NCQA's report *A Road Map for Information Systems: Evolving Systems to Support Performance Measurements* outlined the upgrades needed to meet the demand of outcomes measurement.

The Joint Commission, an independent, private, nonprofit organization, accredits and evaluates approximately 15,000 healthcare organizations and programs in the United States. In 1997, the ORYX Performance Measurement System for the first time integrated performance measures into the Joint Commission's accreditation process. Beginning in July 2002, the first core measures on accredited hospitals were collected.

The purpose of ORYX is to link patient outcomes with accreditation to make the accreditation process more valuable while focusing on patient-centered care. ORYX is used as a supplement to the standards-based survey by continuously monitoring the performance of organizations, facilitating continuous quality improvement, and targeting the on-site survey. To meet accreditation requirements, some healthcare organizations must submit data on a specified minimum number of measures to a performance measurement system or the Joint Commission, and these data are reviewed by the surveyor(s) at the on-site survey. Using data reported from the organization's core measures, the surveyors assess the performance improvement activities of the organization during the on-site survey.

The Joint Commission intends to use ORYX to identify data trends that will enable organizations to improve the quality of care. To reduce the burden of reporting requirements for hospitals, the Joint Commission has worked closely with the Centers for Medicare and Medicaid Services (CMS) to align performance measures.

Issues of Using Outcomes

The contention surrounding the use of patient outcomes in accreditation includes the issues of risk adjustment, the case-mix of patients, and the small number of cases of individual providers. Risk adjustment is a statistical method that tries to control for the differences in patient characteristics or case-mix that may unduly affect outcomes. For example, a provider that treats a greater number

of sicker patients may appear to have worse outcomes than a provider that treats relatively healthier patients. Therefore, risk adjustment statistically adjusts for these underlying differences in the case-mix of patients.

The issue of small numbers is also a problem that arises where providers may not treat a sufficient number of cases to draw statistically valid conclusions regarding a provider's performance. This may limit the comparisons that can be made among providers for a given set of conditions.

Other issues concerning the use of outcomes include the fact that a patient's outcome is shaped by many other factors outside the provider's control, even if appropriate care was given. Conversely, a patient may still have a good outcome despite the poor processes of care delivered by the provider due to the resiliency of the human body. Additionally, it may take many years before a particular health outcome is observed, and therefore, outcomes may need to be tracked longitudinally for an extended period. Furthermore, data on health outcomes can be labor intensive, costly, and difficult to collect.

The field of outcomes measurement is still young, where there are only a few available measures for specific conditions. Measuring outcomes for the purposes of accreditation relies on the collection of valid and reliable data; standardized data elements and definitions; appropriate risk adjustment methods; information technology infrastructure; and the ability to compare outcomes across providers, organizations, and health plans.

Future Implications

Outcomes measures in accreditation will continue to play an important role in evaluating healthcare providers, organizations, and health plans. The development of additional measures of outcomes will be needed to broaden the set of conditions available. With the greater availability of outcomes measures through accrediting bodies, consumers and purchasers will be able to make more informed decisions of where to seek and purchase their care and will continue to pressure healthcare providers, organizations, and health plans to continuously improve the quality of care they deliver.

OUTCOMES MOVEMENT

The outcomes movement is an initiative designed to improve the quality of healthcare by identifying what works (and encouraging its use) and what doesn't (and discouraging the use of those

treatments). It establishes links between health-care practices and procedures with specific outcomes, for the patients as well as the healthcare system. It involves evaluating in a scientific manner the consequences of medical care, diagnostic testing, and other services. This information is then pooled and analyzed and made available to the medical-practice community, healthcare administrators, and third-party payers. The goal is the development of care guidelines that improve patient outcomes and result in effective and efficient healthcare organization and delivery.

In the past, medical-care practices often developed because of anecdotal information and the experience of the individual physician and his or her colleagues. At times, this led to geographic differences in the use of a particular medical intervention. In such cases, the geographical area in which the patient would be treated served as an important predictor of the selected treatment protocol. The outcomes movement is an attempt to develop, as an alternative, a data-driven approach that makes sense across the board. This is done by systematically collecting information about patients and the medical interventions they experience. The outcomes of those interventions for the patient and the healthcare system are then documented and made available to the medical/patient community. These data are analyzed and the results used to develop best practices to improve the quality of care.

History

The value of outcomes measurement was recognized in the early 1900s, when Ernest A. Codman (1869–1940), a New England surgeon, said that treatment results and benefits should be documented. Codman created “end-result cards,” which contained basic patient demographic data, the diagnosis, the treatment, the short-term outcomes, and, when possible, the outcomes after 1 year. He contended that this type of information was necessary to make sound judgments about treatment efficacy. The movement became energized in the 1960s with the work of Avedis Donabedian (1919–2000), a physician and public health academician with a strong interest in healthcare quality. Donabedian’s quality model began with structure (the medical facilities and personnel), continued with process (the treatment),

and led to the outcomes (the effects of the care on patients). Donabedian stated that outcomes are crucial to judging the value of medical care and noted that mortality data alone are not sufficient. Quality-of-life indicators and patient satisfaction, though less easily measured, are also relevant and should be studied as well, in his view. At this point, the outcomes movement focused primarily on the patient rather than the healthcare delivery system as a whole.

The rapid rise in healthcare costs in the 1970s and 1980s has put the outcomes movement into an additional context. The focus now includes the financial issues and the concomitant effects on the medical system, insurance reimbursement, and federal programs. Technological innovations, the cost of new drugs and therapies, and the aging of the nation’s population have thrust the issue of medical-care costs into the forefront. Insurance companies and other third-party payers as well as clinicians and hospital administrators have sought to distinguish between available therapies and those that work and matter. Researchers began to take note of the fact that different geographical areas exhibited wide variation in the use of resources and in the rates of certain medical procedures. After much investigation, however, the researchers did not find any meaningful differences in population characteristics and patient outcomes. This suggested, for example, that some surgical procedures were unnecessary, and limiting them to situations in which they would provide benefit could help contain rising costs. Other research claimed to demonstrate the lack of efficacy of some traditionally used interventions. By the 1990s, assessment and data-driven healthcare became the new mantra, and the outcomes movement came of age.

Current Usage

The outcomes movement provides an important framework for reviewing and refining medical care. Simply put, positive outcomes support the treatment or policy being studied, and negative outcomes suggest modification/elimination of that approach. At its best, outcomes research can provide information about the efficacy of the treatment and care, improve quality, save money, alter public policy in beneficial ways, and guide decision making.

As physicians and patients increasingly are able to obtain aggregated information about the harms and benefits of a medical intervention, they can make appropriately informed decisions. The medical community also uses this information to develop best practices—that is, the identification of treatment guidelines that work most effectively and with maximum benefit to the patients in specific situations. This information likewise is being used to develop and modify public policy as agencies strive to incorporate evidence in their public health initiatives. This includes disease prevention as well as the development of cost-effective and efficient disease-screening recommendations.

The trend toward shared or patient-centered decision making, likewise, has spurred interest in outcomes data. Patients increasingly are doing their own searches to ascertain the benefits and harms of specific treatment alternatives and seeking that kind of data from the medical profession. Outcomes data about survival and function probabilities are intrinsic to these efforts.

Health outcomes data are now multifaceted and include not just mortality data but also quality-of-life measures, such as the ability to function. In addition, outcome data about patient attitudes and satisfaction are becoming increasingly important to clinicians and hospital leadership, in part due to the competitive healthcare environment. Data can come from administrative and clinical databases, disease registries, clinical trial data, and census information, with an emphasis on large and more inclusive databases.

However, some critics of outcomes-based recommendations argue that solely relying on aggregated data doesn't allow for the flexibility that is necessary to adapt to the needs of the individual patient. The desire to eliminate variation can lead to treatment protocols that are too standardized, in this view. Counterarguments state that outcomes data are principally valuable when medical interventions have been carefully and thoroughly studied. Many ambiguities exist in diagnosis and treatment; so individual physician interpretation is and will continue to be crucial in complex cases. Other critics have argued that outcomes research initiatives have design limitations and are primarily cost containment strategies. Public programs such as Medicaid and Medicare require that outcomes data be designed to improve the

quality of care as well as to study and monitor resource utilization.

Economic studies can be done in various ways; they can take into account cost-to-outcome data, which focus on the cost of treating a disease. Cost-effectiveness studies compare the cost of one treatment over another and the benefit of that treatment over the other in terms of a specific outcome. Cost-utility studies weight outcomes according to how they are valued. The structure-process-outcome taxonomy has been found to be useful in studying administrative and economic effects on systems. Administrative outcomes studies focus on structure, process, and personnel. Economic outcomes may include the cost of care, unnecessary or inappropriate care, length of patient stay, patient readmission, return to work, and the ability to provide self-care.

Government financial support has been an integral part of these initiatives, with research funded through organizations such as the Agency for Healthcare Research and Quality (AHRQ). Research supported by the AHRQ and other government organizations has become part of the report card for healthcare purchasers and consumers to judge healthcare quality.

The AHRQ has established evidence-based practice centers, which are designed to analyze information and develop recommendations that are relevant to decision makers. The focus areas now include the U.S. Preventive Service Task Force, which reviews evidence in clinical prevention initiatives and provides technical support; the Technology Assessment Program, which studies the clinical utility of medical interventions to help the Centers for Medicare and Medicaid Services (CMS) make outcomes-based decisions for the Medicare program; the Generalist Program, which reviews a broad spectrum of clinical, behavioral, economic, and health system delivery issues; the Effective Health Care Program, which provides comparisons of effectiveness studies for patients, clinicians, and policymakers to use in making their decisions; and the Scientific Resources Center, which provides scientific and methodological assistance to several of the above programs.

These efforts, and others that will occur in the future, are designed to provide the basis for continuous quality improvement, as medicine strives to improve patient outcomes and to do so

within an efficient and effective healthcare delivery system.

P

PACIFIC BUSINESS GROUP ON HEALTH (PBGH)

The Pacific Business Group on Health (PBGH) is a large California healthcare business coalition. The PBGH includes more than 30 large companies as well as a subcoalition of more than 20 high-tech businesses. In total, these members represent more than 3 million employees, dependents, and retirees, accounting for about \$10 billion in annual healthcare expenditures. To become a member of the PBGH, an employer must have at least 2,000 covered lives in California. Excluded from membership are healthcare consulting groups, insurance companies, health plans, hospitals, medical groups, and any other healthcare industry employers. The coalition is active in healthcare purchasing, quality improvement, and consumer engagement in health decision making.

Overview

The PBGH was founded in 1989 in San Francisco, California, with the mission of seeking to improve the quality and availability of healthcare while moderating costs. The actions taken to realize this mission have evolved from evaluating health plans to assessing other levels of healthcare delivery, such as hospitals, provider groups, and individual providers, as well as engaging the individual consumer in the process of quality assessment and cost moderation.

In the coalition's 1st years, the process of obtaining information from health plans was not in place and was not yet possible. In 1991, the PBGH introduced the Consumer Assessment Health Plan Survey, which began with a survey of the use of prevention guidelines by health plans. The survey revealed large variations. The PBGH used this information to bring together health plans to set guidelines on preventive services and to communicate these guidelines to providers. Observing the lack of data collection and reporting in California, the PBGH formed the California Cooperative Healthcare Reporting Initiative (CCHRI) in 1993. The CCHRI, which is managed by the PBGH, is a collaborative of healthcare purchasers, health plans, and many healthcare providers that produces a yearly report of performance data through a single process. Data collection and reporting has become a collaborative rather than competitive process for this group. In 2001, the CCHRI agreed on standardized diabetes treatment guidelines for the state's health plans and medical groups. The Ambulatory Quality Alliance (AQA) named the CCHRI as one of six organizations in the country to pilot physician-level performance information in 2006.

In 1996, the PBGH launched its consumer information initiative through its HealthScope. The information on the Web site is generally used by members of the PBGH to customize information for their own employees so they can make value-based decisions about their health plan. In later years, HealthScope began to include quality information on hospitals and medical groups.

Moving forward, the PBGH now also plans to assess how best to communicate physician-level choice information.

In 1997, the PBGH won a state bid to privatize a small-group purchasing pool called the Health Insurance Plan of California. The PBGH renamed the pool Pacific Health Advantage and within 4 years enrolled 147,000 members through 11,000 small employers.

The PBGH also helped form the Leapfrog Group in 2000 to communicate hospital performance measures to consumers. During this time period, the PBGH also partnered with the State of California to ask hospitals to voluntarily report performance measures related to coronary artery bypass graft (CABG) surgery. The PBGH followed in the footsteps of New York State and published risk-adjusted outcomes reports available on its HealthScope Web site. Two out of every three hospitals voluntarily participated, and, following the successful publication by the PBGH, legislation was passed in California to make the reporting mandatory starting in 2003.

That same year, the PBGH piloted a program to measure the clinical performance of individual physicians. This effort was furthered by convening a national meeting in 2004 to outline the technical and methodological issues facing the task of assessing individual physician performance. The report, *Advancing Physician Performance Measurement: Using Administrative Data to Assess Physician Quality and Efficiency*, presented significant challenges and a road map for the future. In 2005, the PBGH worked with the California Medical Association and other stakeholders to deliver unprecedented consensus on physician performance measurement. The PBGH is already providing national leadership in developing measurement and reporting systems for individual physicians, and an expanding leadership role figures largely in their plans for the future.

The PBGH's role in purchasing healthcare and controlling costs is directly manifest in The Negotiating Alliance, a mutual benefit corporation. The Negotiating Alliance promotes value-based purchasing through an annual Request for Proposals and a negotiating process on behalf of 400,000 covered lives. The alliance leverages the power of 19 large employers to obtain the best pricing as well as accountability for quality.

Future Implications

The PBGH has written and published many articles, reports, and press releases. The organization has provided testimony to many government commissions and legislatures and has offered its expertise through participation in many forums and meetings. The PBGH, through pilot programs of healthcare measurement and consumer participation, is an active participant in practical health services research. While the PBGH represents many companies with several million covered lives, its influence on healthcare delivery, both statewide and nationally, eclipses this direct service to its members. The PBGH is shaping the healthcare environment of tomorrow by providing leadership on health services measurement and the process of involving consumers in using that information.

PAIN

The word *pain* derives from Sanskrit and Latin roots: *pu*, meaning purification, and *poena*, meaning punishment. Pain can be physical, psychological, or sociocultural. Pain can be manifest in a variety of forms, such as back pain, bone pain, and tooth pain. Pain is a subjective and variable experience and depends on the individual, as individuals may have different thresholds. Pain is a symptom of many medical conditions, and it can have a significant impact on an individual's quality of life and daily functioning. The diagnosis and treatment of pain is based on its classification according to its duration, intensity, type, source, and location. For example, pain can be classified as either acute or chronic. Most bodily pain is able to be resolved with little or no intervention and is generally considered to be acute pain. Chronic pain, also known as persistent or intractable pain, on the other hand, is considered to be an illness and not a symptom.

Pain can be defined in many different ways. One commonly used definition defines pain as an unpleasant experience that can be sensory or emotional in nature, is generally associated with possible or actual damage to bodily tissues, and is expressed through an individual's behavior.

Importance

Pain plays an important role in health services research. Specifically, it directly affects access, cost, quality, and outcomes of healthcare. For example, the occurrence of pain is one of the most common reasons for a physician visit by individuals, resulting in about half of all Americans seeking medical care each year. In addition, pain causes visits by individuals to other ancillary healthcare providers, including physical therapists, occupational therapists, nurses, and psychologists, among others, as well as visits to complementary and alternative medical providers

such as acupuncturists and massage therapists. The annual cost associated with pain exceeds \$5 billion in the United States.

There are several burdens associated with pain, including costs of healthcare, disability, and lost productivity. Pain is one of the leading causes of disability and functional problems. Furthermore, back, neck, and upper extremity pain are cited as the most common reasons for being sick and taking time off from work, resulting in work and productivity losses. An estimate from a national health survey found that about 18% of U.S. workers experienced approximately 149 million days of lost work due to back pain.

Models of Pain

Historical models of pain include Descartes's mind-body model. The Cartesian model of pain held that there is a direct connection between the nerves and the brain and had a dualistic view of mind and body. Pain is the result of an injury that causes a sensation in the person's mind. The model assumed that the greater the injury, the greater the pain that is experienced by the individual. Pain was thought to result in direct tissue damage to the body. This model also held that pain is either physical or psychological in nature.

Modern models of pain integrate the biological, cognitive, emotional, behavioral, and social aspects of this phenomenon. Studies have shown that many factors may have an influence on pain perception and that this is the result of not only physiological aspects but cognitive and behavioral aspects as well. The modern models tend to view pain as a sensory and emotional experience that is not necessarily the result of tissue injury or a nerve signal.

Pain Scales

Pain has been recognized as a vital sign that should be properly monitored and alleviated. Pain management has been acknowledged to result in faster recovery, improved quality of life, and increased productivity of the individual. Healthcare providers seek to diagnose pain according to its onset, duration, character, location, and severity as well as the symptoms associated with it. The diagnosis of pain requires that the healthcare

provider examine a patient's symptoms, condition, and medical history. Pain assessment generally also examines a person's pain threshold in addition to his or her pain tolerance.

A number of pain scales have been developed to assess and evaluate an individual's level of pain, using various methods. For example, the McGill Pain Questionnaire is a tool that is often used to gain a verbal assessment of an individual's pain. The Brief Pain Inventory uses an interview technique to evaluate how pain affects an individual's daily functioning. Scales have also been created to rate an individual's pain, such as the Numeric Rating Scale and the Faces Pain Scale, that assess the intensity of pain as minimal to severe as well as monitoring a person's pain over time to evaluate if the individual responds to treatment. These pain scales also enable medical researchers to compare the results between groups of patients.

PAN AMERICAN HEALTH ORGANIZATION (PAHO)

The Pan American Health Organization (PAHO) is the world's oldest international public health agency, and it is recognized as part of the United Nations system. PAHO has over a century of experience in working to improve the health and living standards of the people in the Americas. PAHO serves as the World Health Organization's (WHO) Regional Office of the Americas as well as the health organization of the Inter-American system. The agency has scientific and technical experts located at its headquarters in Washington, D.C., at its 27 country offices, and at its 9 scientific centers that work on health issues of primary concern to countries in Latin America and the Caribbean. The mission of PAHO is to strengthen local and national health systems and to improve the health of the people of the Americas through various joint collaborative efforts.

History

PAHO was established in 1902 to work with all countries in the Americas to raise the living standards and improve the health of their peoples. PAHO comprises member states that include all 35 countries (Antigua and Barbuda, Argentina, Bahamas, Barbados, Belize, Bolivia, Brazil, Canada, Chile, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, Ecuador, El Salvador, Grenada, Guatemala, Guyana, Haiti, Honduras, Jamaica, Mexico, Nicaragua, Panama, Paraguay, Peru, Saint Lucia, St. Vincent and the Grenadines, St. Kitts and Nevis, Suriname, Trinidad and Tobago, the United States, Uruguay, and Venezuela) in the Americas, with the addition of Puerto Rico as an associate member; participating states (France, the Netherlands, and the United Kingdom and Northern Ireland); and observer states (Spain and Portugal). PAHO's policies are set through its governing bodies. To advance its organizational mission, PAHO maintains collaborative efforts with Ministries of Health, universities, nongovernmental organizations (NGOs), governmental agencies, and others.

PAHO works to promote primary healthcare strategies in communities by increasing access to care and encouraging the efficient use of limited resources. The organization has been involved in assisting countries to combat reemerging infectious diseases such as cholera, tuberculosis, and dengue as well as emerging infectious diseases such as AIDS, through technical assistance, support, and work with NGOs. In addition, PAHO works to prevent the spread of chronic diseases that have begun to afflict populations in the developing countries of the Americas. The work of PAHO is supported by the contributions of its member governments as well as outside funding that aids special programs.

The PAHO focuses its efforts to target the most vulnerable members of society, including women, children, workers, the elderly, refugees, and displaced persons as well as to address equity issues in terms of access to care. The Pan American approach of having countries cooperate and work together toward shared goals has been an essential part of PAHO's history. The agency has been pivotal in initiating multinational collaborative health ventures in Central America, the Caribbean, the Andean Region, and the Southern Cone. The height of political collaboration resulted when the American heads of state accepted the "Health Technology Linking the Americas" initiative at the Summit in Santiago.

The eradication of smallpox from the Americas in 1973, with worldwide eradication 5 years later, has been one of PAHO's great successes. Another major effort, begun in 1985, to eradicate polio, was accomplished in September, 1994, when the Americas were declared to be polio free by the International Commission. PAHO is close to its goal of eliminating measles from the Americas and continues to introduce vaccines that are available against other diseases, including the Haemophilus influenza B vaccine to prevent meningitis and respiratory infections. PAHO continues to assist countries to secure the necessary resources to provide for the immunization and treatment of all vaccine-preventable diseases. The agency is also working to reduce morbidity and mortality from diarrheal diseases, including cholera, through case management and oral rehydration therapy, as well as to ensure the diagnosis and treatment of respiratory infections.

PAHO'S Work

PAHO distributes scientific and technical information that is made available through its publications, Web site, libraries, and documentation centers. It also provides technical assistance in the various areas of public health, in addition to organizing disaster relief coordination and emergency preparedness programs.

PAHO supports initiatives to control malaria, Chagas' disease, urban rabies, leprosy, and other diseases affecting people in the Americas. Additionally, it is collaborating with others to address nutritional deficiencies, including iodine and vitamin A deficiencies, as well as protein-energy malnutrition. The organization has also been working with countries to cope with health problems that have resulted from industrial development, including cardiovascular disease, cancer, and substance abuse. It also conducts projects on behalf of other United Nations agencies, international organizations, government agencies, and foundations.

PAHO works to enhance the health sector capacity in countries to address their priority areas. The agency is involved in training health professionals as well as increasing the capacity of national training institutions. PAHO is also working to further integrate women into society and improve the health status of women.

Priority Areas

An important priority area of PAHO is to reduce infant mortality and prevent an additional 25,000 infant deaths a year through the use of the Integrated Management of Childhood Illness strategy. The agency is also marshalling the necessary resources to train healthcare workers to evaluate the health status of children brought in to a health post or clinic as well as to diagnose, treat, and prevent disease.

Recognizing the health consequences and costs associated with tobacco use, the governing bodies of the Pan American Health Organization have directed it to curtail the use of tobacco. Additionally, with an emphasis on equity, a continued priority area of PAHO includes adequate sanitation, improvement of drinking water supplies, and increased access to healthcare for the poor. Furthermore, advocacy efforts have been directed

to reduce gender inequity and address the unique health problems of women.

PATIENT-CENTERED CARE

Patient-centered care is care that is sensitive and responsive toward the individual needs, preferences, and values of the patient. The national Institute of Medicine (IOM) named patient-centered care as one of the six domains of health-care quality. Additionally, the importance of this

concept is starting to be recognized by the medical community. Studies have shown that patient-centered care results not only in increased patient satisfaction but also in improved patient medical outcomes. Licensing and regulatory bodies, as well as board certification agencies, have begun to include patient-centered criteria in their approval processes for medical professionals. Despite these various efforts, many physicians and other health-care providers are still not currently practicing patient-centered care.

Overview

The following highlights an example of patient-centered care. A patient presents with throbbing pain in his right leg in a hospital emergency department. The nurses and physicians deal with him gently, as they seek his medical history, and discern the source of his problem. This kind of calm, tender treatment of the ill and infirm is at the core of patient-centered care.

Although patient-centered care is starting to be recognized as an important aspect in healthcare, it has been slow to be fully embraced. National surveys conducted by the Commonwealth Fund found that about 1 in 5 adults has difficulty in communicating with his or her physician. And about 1 in 10 adults has been treated disrespectfully during a healthcare visit. There have also been reports of patients who receive conflicting information from their healthcare providers or of the results of medical tests and medical records not being available at the time of the patient's visit.

As a result of these shortcomings, patients are being asked to become active partners in their healthcare. Through a patient-centered health system, there would be increased patient-provider communication and greater availability of educational materials and tools to help patients make more informed decisions. A patient-centered health system would increase access to care and include timely appointments and off-hour services. The increased use of information technology would be essential to achieve this model.

A patient-centered health system would also include greater continuity of care among primary care and specialist physicians, post-hospital-discharge follow-up, and disease management. Making sure that patients have a medical home is

key to developing a patient-centered care model. Furthermore, providing patients with pertinent information on the quality of providers as well as regular feedback would contribute to an improved healthcare system.

According to a study in 2006, physicians say that they favor patient-centered care, but only 22% of physicians actually incorporate these standards into their daily practices. Some practices of patient-centered care, such as same-day appointments, have been integrated; however, other aspects related to care coordination, team-based care, and information systems have yet to be widely implemented. Some other key findings from this study were that physicians in group medical practices of 50 or more are more likely to adopt components of patient-centered care than solo practitioners and that, although 73% of primary-care physicians think that team-based care results in better care decisions, 33% think that the team process makes care cumbersome, and 21% think that it increases the likelihood of medical errors. Only 2% of primary-care physicians are paid for e-mail correspondence with patients. Additionally, 87% of primary-care physicians think that improved teamwork or communication among providers would be effective in improving the quality of patient care.

Patient Feedback

There is reported to be a significant gap between physicians' endorsement of the concept of patient-centered care and their actual adoption of practices to implement it. For example, only 36% of primary-care physicians and 20% of specialists indicated that they receive data based on patient satisfaction surveys, but more than one-quarter indicated that they were actually rewarded based on patient survey data.

Furthermore, physicians report that there is an array of barriers to their adoption of patient-centered care practices, including lack of training, knowledge, and costs. It has been suggested that different incentives might help to facilitate increased adoption of patient-centered practices. If physicians are given the correct tools and practice environment, and also develop a partnership with their patients, then a patient-centered system may be better able to take shape.

Improved Medical Outcomes

Some experts say that patient-centered care needs to be presented differently to physicians. Rather than being an abstract concept, patient-centered care should be shown as something that affects medical outcomes. Demonstrating this will increase the number of physicians who adopt the practice.

For example, health services researchers note that nearly 6% of hospital admissions are caused by patients failing to take prescribed medications (also known as *noncompliance*). The word *compliance* connotes that the patient should do exactly what the physician orders; however, physicians know that an authoritarian approach does not necessarily translate to the best medical outcomes. By being more patient-centered, physicians would treat patients as partners by involving them in planning their healthcare and encouraging them to take responsibility for their health. Experts note that a growing body of research, published during the past three decades, has shown that the nature of the physician-patient conversation has a direct bearing on compliance.

Studies have also shown that patients are more likely to take their medications, abstain from poor nutrition, and show up for appointments on time when allowed to help set their treatment plans. This ultimately promotes patient compliance and leads to better quality of care. Physicians generally underestimate the number of patients who refuse to comply with their regimens. It has been estimated that between 40% and 50% of diabetic patients do not abide by their medication regimens. Similarly, the figure for hypertensive patients is about 40%.

In addition to better medical outcomes, a patient-centered system leads to decreased costs. It has been noted that it is much less expensive to promote compliance than to hospitalize patients because they have not taken their blood pressure pills. One study found that at least half of the patients who were given a prescription did not receive the full benefit because they did not take it, they did not take the right dosage, or they stopped taking it prematurely.

Provider-Patient Communication

Communication with patients is the key to patient-centered care. There are five simple steps that

physicians and other healthcare providers can take to communicate more effectively with patients.

First, the patient must determine whether he or she agrees on what the health problem actually is with the physician. A patient with a headache may believe that it is caused by a sinus infection, which should be treated with an antibiotic. However, the physician may believe that it is a migraine and needs a different medicine. If this difference is not resolved, the patient may not take the product as prescribed.

Second, once the patient and physician agree, attainable treatment goals must be set. If a hypertensive patient has a diastolic blood pressure of 120 mmHg, the physician may not want to try to bring it down below 90 mmHg immediately. Rather, the physician may suggest 110 mmHg as a short-term goal. Once this has been reached, the physician can use that to motivate the patient to reduce it even more.

Third, there is generally more than one option to treat a given condition. Physicians should review a reasonable range of alternative treatment options and discuss the benefits and possible side effects of each one in terms that the patient understands.

Fourth, the patient and physician must decide on a feasible course of treatment. They can choose the medical option that makes the most sense. For example, a patient with hypertension may have just remarried and may not want a low-cost drug that could reduce sexual drive. Therefore, he or she may opt for a high-cost product with no sexual side effects. Dosage frequency requires a similar discussion.

Last, the physician should test the patient's knowledge. He or she should ask patients to repeat what they have been told about their illness and treatment plan. It is also important for patients to demonstrate any techniques they have been taught, such as injecting insulin or using a peak flowmeter. For example, some physicians have diabetic patients practice needle sticks in their office using an orange.

There are also questions at the end of a patient visit that allow physicians to screen for likely non-compliance. An example of this is, "On a scale of 1 to 10, with 10 being the highest, how important do you think it is for you to do the things we've been talking about?" By gathering this type of information, the physician may discover that a

diabetic patient is convinced that his or her disease is fatal and that any treatment would be in vain. An answer like that will inform the physician that there is a need to further discuss the disease and its management.

Additionally, a physician should probe by asking, "On a scale of 1 to 10, how confident are you that you can adhere to this treatment regimen?" A heavy smoker who is absolutely convinced that he or she needs to give up cigarettes may have a confidence level of 1 that this can be accomplished. However, by examining further, there may be signs that additional counseling and support are needed to monitor the patient closely during the withdrawal stages.

PATIENT DUMPING

Patient dumping—the denial of examination and stabilization services for persons with medical emergencies for reasons unrelated to medical need—constitutes a long-standing issue in U.S. health law and policy. It is relatively common to see the concept of patient dumping expressed strictly in relation to financial motive. In fact, financial motive is not a prerequisite to either the concept of dumping or to legal liability. Legal violation can result even without financial motive, for example, if an HIV-positive patient with a medical emergency is turned away because staff physicians refuse to treat him or her. (In such a situation, a hospital may be in violation not only of antidumping laws but also of federal and state civil rights laws that protect persons with disabilities.)

Nature and Extent

No one really knows the magnitude of patient dumping in the nation. Every so often, a headline-making incident occurs. In 2006, for example, a Los Angeles hospital was criminally charged with discharging a medically unstable homeless woman from her hospital bed—and still in her gown and slippers—to a skid-row neighborhood. But quantitative analyses do not exist, in part because there is no good way to know how many people may be turned away from hospitals with no service at all. Thus, reliable statistics are lacking regarding the number of persons who may be turned away without treatment or who may be prematurely discharged from hospitals in an unstable condition for reasons unrelated to medical need. Relatively precise standards outline the duties of hospitals where emergency care is concerned, and to estimate the dumping problem accurately, incidents would need to be aligned with an array of terms and standards that, in certain aspects, also turn on medical judgment, an added confounder. The federal government does not publicly report on the number of emergency department examinations that fail to result in a finding of an emergency

medical condition, nor are there reports on the number of persons with emergency conditions who are discharged or transferred in an unstable state.

That patient dumping is a real problem is not a matter of serious debate; indeed, the legal framework for patient antidumping standards evolved from the reports of a series of spectacular incidents. Antidumping laws are controversial, in part because of the high level of stress faced by hospital emergency departments. Between 1991 and 2003, hospital emergency department visits in the nation increased by 26%, reaching a 2003 level of about 114 million visits. Of the total number of emergency department visits, about one-third were considered to be nonurgent, meaning that about 38 million visits annually are for conditions that, on examination, may be considered nonemergent. Since antidumping duties commence with the obligation to examine, the fact that many exams reveal nonemergent conditions is actually somewhat tangential. Furthermore, emergency department statistics are predicated on individuals who become registered emergency department patients. How many individuals are actually dumped—that is, turned away without any exam or diverted away from a hospital while in an ambulance—must be factored into the equation when thinking about the true reach of antidumping laws.

The Antidumping Legal Framework

The No-Duty Principle

The starting point for understanding the consequential nature of antidumping obligation is the common law principle of “no duty.” Under the common law, that is, under the long-standing principles of judicial law on which much of the U.S. legal system rests, healthcare professionals and other healthcare providers have no duty to furnish care. That is, hospitals and physicians are not considered “places of public accommodation” and thus have no legal duty to furnish care to any person they do not wish to serve. Once a provider-patient relationship is established, then, of course, healthcare providers do have a legal duty to act in a reasonable way. But this duty to behave in a reasonably professional manner does not trigger until a provider actually agrees to enter into a physician-patient relationship.

For example, a physician has no duty to come to the aid of a person suffering a medical emergency (in all jurisdictions, physicians who do provide emergency aid are covered by Good Samaritan laws that protect against all but liability for gross negligence or willful or wanton misconduct). Under common law, hospitals had no duty to treat emergencies.

Evolution of the No-Duty Principle

By the middle of the 20th century, a combination of changing emergency care technology and fundamental shifts in social values led to a fundamental legal rethinking of the no-duty principle by courts and state legislatures, at least where hospital emergency department care was concerned. (To this day, physicians have no legal duty of care.) The rise of the modern hospital, with its technologically advanced and lifesaving emergency department services, was perceived as fueling community expectations of care. The community expectation was further fueled by the considerable community support received by hospitals in the form of insurance payments, direct government support, and nonprofit tax exemptions. Indeed, the Hospital Survey and Construction Act of 1946 (more commonly known as the Hill-Burton Act) represented a national commitment to hospital construction, one that, over time, would come to be understood as creating emergency-care duties of its own.

In sum, by the middle of the 20th century, the nation's hospitals ceased to exist merely as workplaces for physicians. As complex and essential medical-care entities in their own right, hospitals were burgeoning, in great part because of a community commitment to their growth. Furthermore, this national commitment of resources took a massive leap forward with the enactment of Medicare and Medicaid in 1965.

At heart, the law is simply a highly formalized reflection of prevailing social values and beliefs. Thus, as hospitals changed as social institutions, so did their relationship to the law in many respects, including the law as it related to emergency hospital care. Similarly, as market values have come to dominate the hospital industry in recent years, the legal obligations of hospitals in response to emergency cases also have undergone a certain amount of relaxation.

The earliest patient-dumping law came from judicial decisions involving persons who died or were severely injured as a result of the denial of care. Among the principles applied to hospitals by the courts as a means of finding liability for turning people away without care under their "no duty" were the common law concepts of "detrimental reliance," "public accommodation," and "legal undertaking." A detrimental reliance claim was one in which the injured person or decedent's estate argued that the very presence of the hospital emergency department created a legal duty because the community came to rely on its presence in times of emergency; thus, the hospital could not hold itself out as the place to come for emergency care—and indeed, establish a record of furnishing such care—and then select its customers.

A public accommodation claim rested on the notion that, like innkeepers and transportation systems (which are prohibited at common law from refusing paying customers), hospitals with emergency department capacity were obligated to serve the public, even if the public could not pay at the point of service. The public accommodation theory rested on the life and death role played by inns and common carriers during the Middle Ages; thus, as hospitals came to occupy a lifesaving role in society, they came to represent a similar social good.

An undertaking claim rested on the notion that a hospital that turned someone away had actually begun to undertake care. Thus, in one celebrated court case, a hospital was found liable for essentially abandoning a patient when personnel ordered the family of a dying man to place him on an empty stretcher in the emergency department and then ignored him until he died.

In the concept of emergency care, two specific types of duties became evident from these early cases. The first was a duty to examine individuals who come to a hospital seeking care, that is, a duty to undertake care through an initial examination, regardless of factors unrelated to need. The second duty was a duty to stabilize emergency conditions in persons whose examinations revealed an emergency (typically defined as a condition that would lead to death). From the perspective of the totality of healthcare, the duty was quite narrow: Hospitals were not expected to cure or rehabilitate persons with emergencies, merely examine and stabilize them. But from the perspective of the no-duty

principle, the departure was profound, particularly because it served to establish the physician–patient relationship on which professional and corporate liability rest. Furthermore, depending on the nature of the emergency, the examination and stabilization could consume considerable resources and be quite lengthy.

The Hill-Burton Act and State Anti-Patient Dumping Statutes

As judicial law shifted, so did statutory and regulatory law. By the early 1980s a number of state legislatures had enacted emergency-care statutes that conditioned licensure on not only maintenance of hospital emergency departments but also the provision of screening and stabilization services to persons with emergency medical conditions, as defined under state law.

In addition, the Hill-Burton Act became the subject of extensive litigation surrounding the meaning of its statutory “community service obligation.” This obligation, a companion to the act’s better-known “uncompensated care” obligation, required all federally funded hospitals to provide assurances that they would serve their communities. In revised regulations issued in 1979, the U.S. Department of Health and Human Services (HHS) had interpreted the law as requiring the provision of certain emergency-related screening and stabilization services, without regard to whether individuals could pay for the care at the point of service.

The Hill-Burton regulations reached thousands of facilities built with Hill-Burton funding. But by the end of the 1970s, funding had ceased; even during its operational period, Hill-Burton excluded for-profit facilities. Thus, hospitals built over the past generation have received no Hill-Burton funds.

The Emergency Medical Treatment and Active Labor Act

Enacted in 1986, the Emergency Medical Treatment and Active Labor Act (EMTALA) was a response to the U.S. Congress’ concern over the impact of the new Medicare prospective payment system (PPS) on hospital access among indigent and uninsured patients. Its enactment followed a series of highly publicized incidents of patient dumping. In its structure and terms, EMTALA is

unique in U.S. law. Indeed, EMTALA offers the only example in which U.S. law creates a legally enforceable individual right to healthcare.

EMTALA applies to all Medicare-participating hospitals that operate an emergency department, thus pushing its reach well beyond the limits of previous federal laws applicable only to hospitals built with certain forms of public financing. It obligates a covered hospital to provide an appropriate medical examination to any person who comes to the hospital’s emergency department.

It is difficult to overstate the extent to which EMTALA departs from traditional U.S. health policy, given the no-duty principle described above. In short, EMTALA creates an affirmative duty of emergency care on the part of Medicare-participating hospitals with emergency departments, thereby overriding the right of covered hospitals and their staff to select the patients they will serve. This emergency duty of care principle, as noted, has evolved over decades, but EMTALA expands and clarifies the duty in ways not previously seen in law.

At the same time, EMTALA has real limits. EMTALA alone does not compel a hospital to maintain an emergency department (state licensure laws, laws governing the conditions of participation for Medicare hospitals, and accreditation standards might, of course). Nor does EMTALA mandate that hospital emergency departments meet certain staffing and equipment standards (again, accreditation, licensure, and Medicare conditions of participation standards might set performance levels). What EMTALA does require is the undertaking of emergency care in a fair and non-discriminatory fashion.

PATIENT-REPORTED OUTCOMES (PRO)

In clinical and translational outcomes research, the success of a patient's medical intervention or treatment has traditionally been assessed and documented by a physician or other clinician. Direct observation of response to an intervention is limited to objective measures. An outside observer cannot always measure outcomes of illness, treatment, or health promotion that minimize physical and emotional decline or loss of independence. Interventions affecting an individual's wellness, particularly in chronic disease progression, may have benefits beyond what can be objectively studied, including the preservation of functioning, pain relief, mood enhancement, and overall improvements in quality of life and well-being. With respect to more subjective outcomes, including quality of life, functioning, and symptom reduction, tools that have been validated and deemed sensitive are required to measure the impact of disease and illness from the afflicted individual's perspective. These measures are termed *patient-reported outcomes* (PRO).

Measurement of patient-reported outcomes provides valuable insight into health and illness beyond traditional efficacy or effectiveness research. In contrast to self-evident outcomes of illness such

as survival, patient-reported outcomes represent the patient's perspective on the impact of disease and its treatment on his or her everyday functioning and well-being. Instruments, typically questionnaires, can be an important measure of generic quality of life or functional status. Alternatively, they may be specific to disease, treatment, or symptom. Regardless, an instrument must be grounded in clinical and psychometric theory, be representative of domains relevant to what it attempts to measure, and have been demonstrated as valid, reliable, sensitive, and specific.

Guidance Document

Patient-reported outcomes have been defined as a measurement of any aspect of a patient's health status that comes directly from the patient (i.e., without the interpretation of the patient's responses by a physician or anyone else). Following its European counterparts, the U.S. Food and Drug Administration (FDA) released its guidance document for incorporating PRO into clinical research in 2006. This document outlines three key aspects of patient-reported outcomes that make it advantageous to include instruments in clinical and outcomes research.

1. *Some Treatment Effects Are Known Only to the Patients*

For some interventions, resulting success or failure can only be elucidated by querying the patient or subject. For example, level of anxiety and anxiety relief are the fundamental measures in understanding the benefit of cognitive behavioral therapy for generalized anxiety disorder. Also, pain intensity and pain relief are nearly exclusively subjective. There are little or no observable or physical measures that can be used to examine potential benefit related to treatment.

2. *Patients Provide a Unique Perspective on Treatment Effectiveness*

Patient-reported outcome measures can reflect what is important to a patient in terms of symptom relief, functioning, and quality of life. Thus, PRO can incorporate patient expectations related to their care. This becomes important when

clinically measurable differences related to an intervention (e.g., those quantified by a laboratory test) do not always translate into a perceivable change in health or wellness status. A widely cited example is that clinically meaningful improvements in lung function as measured by forced expiratory volume (FEV1) may not correlate well with improvements in asthma-related symptoms and their impact on a patient's ability to perform daily activities. Furthermore, significant improvements in clinically observable parameters may be correlated with a significantly negative impact on a patient's subjective response to treatment, particularly if the treatment intervention is associated with bothersome or frequent untoward side effects.

3. Formal Assessment May Be More Reliable Than Informal Interview

Obtaining information from patients on symptoms and symptom relief is not new. Clinicians informally ask questions such as, "Do you get short of breath when walking up a flight of stairs?" or "Does your pain interfere with your ability to get out of bed?" However, efforts to capture and analyze subjective answers to questions such as these are prone to inconsistency and measurement error in the absence of validated instruments. There is general agreement that scientific methods for assessing subjective outcomes (e.g., psychometrics and utility measurement) are well developed and can serve as the cornerstone for patient-reported outcomes assessment. Using existing methodology to systematically and formally gather information from patients about their symptoms and the impact of those symptoms on function is the cornerstone of PRO.

Instruments completed by patients directly measure perceived treatment response. Data captured in this manner are likely to be more reliable than those obtained through indirect third-party measurements because they are not affected by inter-rater inconsistency. Use of a well-constructed instrument is also valuable in detecting change in reported outcomes over time, particularly in progressive disease. Change in functioning may be gradual, and an instrument sensitive to this change can be useful in determining longitudinal impact on decline or improvement.

Classification of PRO Measurements

Patient-reported outcomes broadly encompass several types of instruments. These include symptom scales as well as instruments that measure health-related quality of life, functional status (e.g., ability to conduct activities of daily living), satisfaction with treatment, compliance with the intervention, and medication adherence and persistence. They may be disease specific, such as the Asthma Control Test (ACT) or the Function Living Index: Cancer (FLIC); they may be treatment specific, such as the Satisfaction With Antipsychotic Medication (SWAM) scale, or they may measure the overall status of a condition such as instruments that measure the presence or absence of depression or angina.

Alternatively to these very specific applications, patient-reported outcomes instruments may also be generic and applicable across a wide variety of disease categories. Most measurements of physical functioning and activities of daily living fall into the category of generic measures. One of the earliest and perhaps the most widely known and cited generic measure was created by John E. Ware and colleagues as an outgrowth of the Medical Outcomes Study (MOS). Known as the Short Form 36 (SF-36), this instrument encompasses 36 questions representing the domains of (1) physical functioning, (2) role functioning, (3) bodily pain, (4) general health perception, (5) vitality, (6) social functioning, (7) role-emotional functioning, and (8) mental health. Item responses within these eight domains are reported as two summary measures—physical and mental health. Generic measures such as the SF-36 have been validated within numerous disease states. Depending on the disease state, the SF-36 has been used to identify both differences in overall outcome between intervention groups and also changes within intervention groups over time.

In addition to comparing patient-reported quality of life outcomes within an individual disease state, generic measures have proven valuable for comparing health perceptions across disease states. Instruments such as the SF-36 or, more commonly, the Health Utilities Index (HUI) have been validated extensively and specifically to compare quality of life across diseases. To accomplish this comparison, results from generic measures are

converted to a 0 to 1 scale, with 1 representing perfect health and functioning and 0 representing the state nearest to death. To illustrate comparison of utilities, individuals with advanced metastatic medulloblastoma brain tumor may have a health utility of 0.31, as compared with 0.58 for an individual who is undergoing cardiac bypass surgery and 0.99 for someone without symptoms taking a cholesterol-lowering agent for hyperlipidemia. These “utilities” are used to calculate quality-adjusted life years (QALYs), which are used for policy decisions surrounding drug formulary placement and treatment reimbursement, particularly in Europe, Canada, and Australia.

Methodological Considerations in Developing PRO

The mechanism with which patient-reported outcome data is captured typically includes a questionnaire. Questionnaires may be self-administered, with a subject filling out a form with pen and paper or electronically via a computer. They may be clinician administered via a healthcare worker, social scientist, or other trained individual reading questions or through conducting a formal, structured interview either in person or telephonically. Methods available for questionnaire development generally are grounded in rigorous psychometric theory. The merit of patient-reported outcome questionnaires is determined based on three key properties. First, outcomes must be conceptually defined and be based on the most current understanding of domains of functioning and aspects of life quality relative to what is being assessed. Disease- or treatment-based instruments must also be framed within the context of a thorough review of the medical or psychiatric literature. Second, aspects of functioning, quality of life, or symptomatology must be suitably operationalized through the questionnaire. This includes using phraseology and terminology that can be understood and interpreted by the respondent. The time period that the subject is required to recall in order to respond to the question must be relevant to the health state studied but short enough to allow accurate reporting of experience. Scaling must be representative of the respondent's experience. Scaling typically measures intensity of the perceived health aspect (e.g., occurring none of

the time, some of the time, or all the time), as well as the intensity (e.g., mild, moderate, or severe) of the experience. The respondent burden, the time required to complete the instrument, must be minimized to promote willingness to complete the instrument and to facilitate the quality of the responses. The remaining, and perhaps most often overlooked, property of instrument development includes field testing to determine reliability, validity, and responsiveness (i.e., minimally detectable change). Creating and validating instruments typically encompasses creating a draft with input from leaders in the field of study, piloting the instrument in individuals afflicted with the condition of interest, interviewing pilot respondents to identify potential problems with the instrument, and finally, performing a full-scale validation study comparing responses to the instrument with recognized gold standards, where available (concurrent validity). Minimum requirements for validation of instruments includes demonstration of reliability, construct validity, responsiveness over time, internal consistency, and test-retest reliability. Measurements of validity and reliability typically make use of Cronbach's alpha coefficient and correlation or kappa coefficients. Agreement of .70 or greater is typically accepted for group comparisons. When investigator administered, a coefficient of .80 is typically acceptable to establish interrater reliability.

Other considerations in validation include that instruments should be able to discriminate between subgroups of individuals based on severity. Also, translation of instruments validated in one language should undergo linguistic validation during translation to alternate languages. Similarly, tools validated using one administration mode (e.g., self-administered) should be validated in an alternate mode (e.g., telephone interview administration) prior to incorporation into translational research.

In recent years, interest in incorporating patient-reported outcomes into clinical trials designed to meet regulatory requirements in the approval process for marketing of medicines has led to an explosion of instrument development. This development is geared toward developing tools sensitive and specific to changes in PRO related to specific pharmaceutical products. In response, regulators and harmonization groups have begun to adopt standards by which PRO measures are developed.

These measurement characteristics are grounded in solid theory and are now widely accepted. The ultimate objective is to develop and implement an instrument that is accurate and validated of the intended domains.

PATIENT SAFETY

The issue of patient safety has only gained national attention during the past decade, primarily due to the recognition that much hospital morbidity and mortality is due to medical errors. Many organizations and programs have been established to address patient safety. Most healthcare institutions have instituted patient safety measures, which are key to maintaining their accreditation and therefore to their remaining financially solvent.

Defining the Problem

Patient safety and medical errors are closely linked, and in discussing one it is often necessary to discuss the other. For this entry, patient safety is defined as freedom from accidental injury due to medical care or medical errors. *Medical error* is defined as the failure of a planned action to be completed as intended or the use of a wrong plan to achieve an aim, including problems in medical practice, products, procedures, and systems.

The term *patient safety* was first used in the name of a professional medical organization in 1984, with the establishment of the Anesthesia Patient Safety Foundation by the American Society of Anesthesiologists. Despite the recognition of patient safety issues in the field of anesthesia, the topic did not gain national attention until the late 1990s, solidified by the national Institute of Medicine (IOM) landmark report *To Err Is Human: Building a Safer Health System*, which was published in 2000. The report estimated that between 44,000 and 98,000 people die in the United States every year due to medical errors. It also estimated that the national cost of medical errors to hospitals was between \$17 and \$29 billion per year.

The IOM report cited commonly occurring errors, including adverse drug events and improper transfusions, surgical injuries and wrong-site surgery, suicides, restraint-related injuries or death, falls, burns, pressure ulcers, and mistaken patient identities. The report also cited an article in the *Quality Review Bulletin* (1993) that categorized medical errors broadly into diagnostic (e.g., error or delay in diagnosis, failure to employ tests, using outdated tests, and failure to act on results), treatment (error in performance or administration of treatment, avoidable delay in treatment, error in dose or method of using a drug, and inappropriate care), preventive (failure to provide prophylactic treatment and failure to monitor), or other (failure of communication and equipment failure) groups.

Following the IOM report, further studies were conducted to track medical errors and patient safety issues. A study published in the *Journal of the American Medical Association* in 2003 found that the greatest injury due to medical errors was postoperative sepsis leading to an excess length of hospital stay of 11 days, excess charges of \$57,727, and excess mortality of 22%.

A HealthGrades Quality Study, which was published in 2004 and investigated hospitalized Medicare patients between 2000 and 2002, found more than 1 million adverse events resulting in up to 195,000 accidental deaths per year. Based on the Agency for Healthcare Research and Quality's (AHRQ's) 20 evidence-based patient safety indicators, the study found that the three most common errors were failure to rescue (failure to diagnose and treat in time), decubitus ulcer, and postoperative sepsis. These three errors accounted for almost 60% of all patient safety incidents among the hospitalized Medicare patients, with an estimated excess annual cost of \$2.85 billion.

Addressing Medical Errors

The IOM report refuted the "bad apple" theory, which suggested that medical errors are due to specific faulty or inept practitioners; instead, it determined that errors are usually the result of faulty systems, processes, and conditions that lead people to make mistakes or fail to prevent them. Also, errors are not limited to actions but also include failure to act and avert preventable adverse outcomes.

To improve patient safety, the report recommended a four-tiered approach: (1) establish a national focus to create leadership, research, tools, and protocols to enhance the knowledge base about safety; (2) identify and learn from errors by developing a nationwide public mandatory reporting system and by encouraging healthcare organizations and practitioners to develop and participate in voluntary reporting systems; (3) raise performance standards and expectations for improvements in safety through the actions of oversight organizations, professional groups, and group purchasers of healthcare; and (4) implant safety systems in healthcare organizations to ensure safe practice at the delivery level.

Largely in response to the IOM report, the U.S. Congress allocated \$50 million to the federal AHRQ in 2000 to support efforts to improve patient safety and reduce medical errors. A follow-up report from the IOM in 2001 further advocated the rapid adoption of electronic clinical records, electronic medication ordering, and computer- and Internet-based information systems to

support clinical decisions to improve patient safety and reduce medical errors.

The development of evidence-based recommendations for specific medical conditions, termed *clinical practice guidelines* or *best practices*, has accelerated in the past few years. Also, the U.S. Congress passed the Patient Safety and Quality Improvement (PSQI) Act of 2005, establishing a database to improve patient safety by encouraging voluntary and confidential reporting of medical errors.

Public and Private Initiatives

Since the publication of the landmark IOM report in 2000, many government and private organizations have made patient safety a top healthcare priority. Government organizations with specific initiatives for patient safety include the AHRQ and the Centers for Medicare and Medicaid Services (CMS).

Private organizations concerned with patient safety include the American Society of Medication Safety Officers (ASMSO), Council on Graduate Medical Education (COGME), Institute for Healthcare Improvement (IHI), Institute for Safe Medication Practices (ISMP), Joint Commission, Leapfrog Group, National Academy of State Health Policy (NASHP), National Advisory Council on Nurse Education and Practice (NACNEP), National Patient Safety Foundation (NPSF), National Quality Forum (NQF), Safe Care Campaign, and the United States Pharmacopeia (USP).

Selected Patient Safety Organizations and Programs

The CMS currently has several demonstration projects underway, including a pay-for-performance program, which offers hospitals increased compensation for improvements in patient care coordination and the institution of quality measures. It also initiated a new disincentive rule in 2008, which stops hospitals from billing Medicare for any charges associated with eight serious preventable conditions. The eight conditions include (1) pressure ulcers, (2) urinary tract infections, (3) patient falls, (4) mediastinitis (an infection after heart surgery), (5) objects left in the patient's

bodies after surgery such as sponges, (6) incompatible blood transfusions, (7) air embolisms blocking blood flow, and (8) infections caused by leaving catheters in blood vessels and bladders too long.

The Joint Commission, which was established in 1951, is an independent, nonprofit organization that evaluates and accredits nearly 15,000 health-care organizations and programs in the nation. Most healthcare organizations seek accreditation to receive federal Medicare and Medicaid funds. Many of the Joint Commission's standards for organizations directly relate to patient safety, response to adverse events, and the prevention of accidental harm. During the past decade, the Joint Commission has established a number of programs addressing patient safety, including the National Patient Safety Goals and the Speak Up initiatives, which urge patients to take an active role in preventing medical errors. In 2005, it established an International Center for Patient Safety to collaborate with international patient safety organizations.

The Leapfrog Group, which was established in 2000, is a conglomeration of large U.S. corporations that agreed to base their purchase of health-care on principles that encouraged provider quality improvement and consumer involvement. It created the Leapfrog Hospital Rewards Program, which mandates specific quality practices such as computerized physician order entry, evidence-based hospital referral, and intensive-care unit (ICU) staffing by physicians experienced in critical-care medicine. Additionally, a Leapfrog Safe Practices Score was developed as a hospital quality ratings system to influence consumers' choices.

The NPSF is a nonprofit organization founded in 1996 by the American Medical Association (AMA), CNA HealthPro, and 3M. The foundation provides leadership training, research support, and education, and it publishes the *Journal of Patient Safety*, containing original articles and reviews on the subject.

The NQF is a nonprofit, membership organization established in 1999 to develop and implement a national strategy for healthcare quality measurement and reporting. The NQF has focused on several areas, including medical error rates, unnecessary procedures and undertreatment, and preventive care. In 2002, the NQF defined 27 events that should never occur within a healthcare facility. It

grouped the “never” events into six categories (officially called Serious Reportable Events): (1) surgical events (e.g., surgery being performed on the wrong patient), (2) product or device events (e.g., using contaminated drugs), (3) patient protection events (e.g., an infant discharged to the wrong person), (4) care management events (e.g., a medication error), (5) environmental events (e.g., electric shock or burn), and (6) criminal events (e.g., sexual assault of a patient).

Important Concepts

“First, do no harm” is an often-quoted mantra attributed to Hippocrates, the father of Western medicine. The implication is that medical professionals should try to help but at a minimum should do no additional harm. Many medical errors are the direct result of inappropriate actions such as administering the wrong dose of a medication or performing surgery on the wrong limb or patient.

Prevention is a key concept as well. Inaction is considered equally as culpable as performing the wrong action. Many medical “errors” are due to not addressing foreseeable adverse events. Examples include not instituting fall precautions (e.g., raising bedrails for patients at risk of falling out of bed), not washing hands properly (leading to transmission of hospital-acquired infections), and not giving anticoagulant medicine to prevent blood clots in bed-bound patients.

Evidence-based medicine is the idea of integrating available medical research into patient care. Many clinical practice guidelines have been established in recent years, which are consensus-based recommendations for physicians to apply to care of patients. These guidelines can help create consistent care based on the most up-to-date scientific data available.

To improve patient safety, medical errors need to be identified and studied to determine possible causes. Reporting of medical errors, including near-miss events, is paramount. A near-miss event is an unplanned event that did not result in injury, illness, or damage, but had the potential to do so. Reporting of near-miss events by observers is an established error reduction technique in other industries and has recently been applied to the healthcare sector.

Future Implications

Many medical errors have been attributed to poor handwriting, manual order entry, and nonstandard abbreviations that are misinterpreted. Electronic clinical records are a new technology that has the potential to reduce some of these errors, not only by eliminating illegibility but also by having default doses for medications and alerts for potential drug interactions or allergies. Electronic clinical records could also reduce errors by improving access to information and communication among providers.

As noted above, some organizations, including the CMS, have pilot programs which use a pay-for-performance system that includes financial incentives and disincentives relating to patient safety and the occurrence of “never” events identified by the NQF. This type of reimbursement is highly controversial. Proponents suggest that financial incentives will change behavior and encourage systems improvements. Others, primarily physician groups, argue that many complications occur despite following best practice guidelines (e.g., postoperative infections), and institutions and providers will be unfairly penalized, possibly leading to compromised patient safety if healthcare organizations are denied vital resources.

Legal reform is also seen as an area for intervention. Healthcare providers are often hesitant to report errors due to the threat of legal liability. U.S. Senators Hillary Rodham Clinton (D-NY) and Barack Obama (D-IL) jointly proposed the National Medical Error Disclosure and Compensation (MEDiC) Bill of 2005, which would create an Office of Patient Safety and Health Care Quality to administer the MEDiC program. The proposed program is designed to improve disclosure of medical errors, give physicians certain protections from liability, and help facilitate appropriate compensation for affected patients, with the overall aim of improving patient safety. The bill was referred to the Senate in September 2005 and subsequently to the Committee on Health, Education, Labor, and Pensions. Neither the MEDiC Bill nor any other recent legislation addressing medical malpractice reform has been passed by both houses of Congress, but this topic will likely resurface when a new administration

revisits the problems of healthcare costs and medical errors.

PATIENT TRANSFERS

Patient transfers can be defined by the various methods (e.g., ground or air transport) and motives (e.g., transfer to another hospital because the patient does not have health insurance) for moving a patient from one location to another. A major classification of patient transfers is whether they are intrafacility or interfacility transfers. Intrafacility transfers are patient transfers within a given healthcare facility, either between departments or between other organizations within the healthcare facility. In contrast, interfacility transfers are patient transfers from one healthcare facility to another facility. Examples of interfacility transfers include the following: (a) hospital-to-hospital transfers, (b) clinic to hospital transfers, (c) hospital to rehabilitation facility transfers, and (d) hospital to long-term care facility transfers.

Challenges to the success of interfacility transfers include the qualifications of those delivering the care, the ability to meet the clinical needs of the patient, and the aptitude to maintain continuity of care. Due to the emergence of specialty medical systems such as cardiac centers and stroke centers, the ultimate destination of a patient is now often predicated on the patient's specific medical condition rather than the proximity of the nearest medical facility. This practice has created the need for enhanced measurement and guidelines and the evaluation of patient transfers to understand and track the different circumstances under which transfers take place.

Because of this change, the number of stakeholders involved in patient transfer protocols and instrumentations has increased and diversified over the past few years. Stakeholders include physicians at both the receiving and transferring facility, the medical staff of both institutions, the patient and the patient's family and caregivers, the third-party insurance groups, the health administration and legal staff of both facilities, and the transferring bodies such as the ambulance staff. Additional stakeholders include Emergency Medical Services (EMS) organizations and the National Highway Traffic Safety Administration (NHTSA) who enter into discussions to create EMS priority issues and

establish guidelines for the EMS organization's critical-care transport. This level of transport care is provided to patients whose indication requires an expert level of provider knowledge and skills, a setting with necessary equipment, and the ability to handle the challenge of the transport.

Reasons for Patient Transfers

The rationales for transferring patients include facility capacity issues, facility or physician specialty and competency, and limitations in levels of care offered. Hospitals are often plagued with issues of overcapacity and inability to properly house and care for incoming patients. Some healthcare institutions such as clinics and nursing homes may accept only a few payment options, thereby limiting the care they provide. Additionally, many patients are transferred because the initial admitting facility is unable to support the needs of the patient. For example, some of the highest frequencies of interfacility transfers occur among obstetrics and gynecology (e.g., high-risk pregnancies) and neurology (e.g., stroke) patients, who require specialized training not available at many healthcare facilities.

Issues

Problems with interfacility patient transfers can also be unrelated to medical care. Nonclinically related issues include redundant and unnecessary transports that create financial burdens in terms of both direct and indirect costs. Direct costs may include the expenses for transport and personnel, while the indirect costs may include the expenses related to increased patient morbidity, liability issues, and overcrowding in the emergency department. Patient-related issues include the time involved, the extent of morbidity and mortality associated with wait time, lack of care continuity and poor quality of care, patient privacy issues, and patient dumping. Patient dumping occurs when unexamined or unstable patients are transferred to another facility because of nonclinical reasons, as when the patient does not have health insurance and is likely not to be able to pay for his or her care.

Public Policy

The federal Emergency Medical Treatment and Active Labor Act (EMTALA) provides broad guidelines regarding the transfer of patients after they seek care in a hospital's emergency department. EMTALA, which was passed in 1986, was designed to prevent patient dumping. It mandates that hospitals that receive Medicare and Medicaid funds provide medical screening examinations of all emergency department patients, regardless of a patient's ability to pay. If critical medical conditions are identified, EMTALA requires the hospital to stabilize the patient before transferring him or her to another facility for care. The act addresses concerns of patient safety and the ability to receive medical care regardless of demographics and socioeconomic status.

Future Implications

As the result of EMTALA, many of the nation's hospitals are changing their patient transfer protocols. They are increasingly implementing centralized transfer centers to improve overall patient flows and to control incoming patients and facility capacity. These centralized transfer centers also promise to lower costs, save time, and protect the facilities against lawsuits.

PAULY, MARK V.

Mark V. Pauly is one of America’s leading health economists. Although Pauly has conducted research in many areas of health economics, he is perhaps best known for his work on moral hazard. His classic 1968 study of the economics of moral hazard was the first to point out how health insurance may affect the behavior of the insured as well as those providing healthcare services to them. His work popularized the term.

Pauly is currently the Bendheim Professor in the Department of Health Care Systems at the Wharton School of the University of Pennsylvania. He also is professor of business and public policy and insurance and risk management at the Wharton School and professor of economics in the School of Arts and Sciences at the University of Pennsylvania. Before joining the Wharton School in 1983, he taught at Northwestern University for 16 years.

Born in 1941, Pauly earned a bachelor of arts degree in classical languages from Xavier University in 1963, a master’s degree in economics from the University of Delaware in 1965, and a doctorate in economics from the University of Virginia in 1967.

Over his long career, Pauly has studied the empirical and theoretical impact of health insurance coverage on preventive care, ambulatory care, and prescription drug use in managed care. He has investigated the various influences that determine the availability of health insurance coverage and, using cost-effectiveness analysis, determined the influences of medical care and health

practices on outcomes and costs. He also has studied and proposed ways to reduce the number of uninsured through the use of tax credits and ways to redesign the Medicare program.

Pauly is a prolific researcher and author. He has published many scholarly journal articles and books on various health economics topics. He is the coeditor-in-chief of the *International Journal of Health Care Finance and Economics* and the associate editor of the *Journal of Risk and Uncertainty*. He also serves on the editorial board of *Public Finance Quarterly*.

Pauly has received many awards and honors in recognition of his work. In 2007, he received the Distinguished Investigator Award from AcademyHealth and the John Eisenberg Excellence in Mentorship Award from the federal Agency for Healthcare Research and Quality (AHRQ). He is an elected member of the National Academy of Sciences, Institute of Medicine (IOM). He also is a member of the National Advisory Council for the AHRQ. He was the recipient of an investigator award in health policy research from the Robert Wood Johnson Foundation. And he previously served as a commissioner on the Physician Payment Review Commission (PPRC), which advised the U.S. Congress on Medicare physician payment.

He has consulted for national public policy and research centers such as the American Enterprise Institute for Public Policy Research (AEI), Mathematica Policy Research, and the Urban Institute; hospital associations, including the Greater New York Hospital Association; and pharmaceutical companies such as Amgen, Bayer, Glaxo, and Merck.

Pauly’s current interests include the economic analysis of healthcare reform, the understanding of the conceptual foundations for cost-benefit analysis of pharmaceutical drugs, and the economic incentives in managed care. His work will continue to assist health services researchers and policymakers to better understand the economics of healthcare in America.

PAY-FOR-PERFORMANCE

The linkage of financial incentives to quality and performance is a relatively new concept in healthcare. Pay-for-performance is a way to reward healthcare providers for higher-quality healthcare. In most industries, lower costs are achieved through greater production efficiency, and financial rewards accrue to firms that produce high-quality products more efficiently. In contrast, most physicians and hospitals are paid the same regardless of the quality of the healthcare they provide, producing no financial incentives for quality and, in some cases, disincentives for quality.

In its 2001 report *Cross the Quality Chasm: A New Health System for the 21st Century*, the National Academy of Sciences, Institute of Medicine (IOM) drew attention to the poor quality of the nation's healthcare as well as factors contributing

to poor quality, including the structure of the present healthcare payment system. The IOM noted that, for certain types of clinical situations, healthcare payment arrangements may actually produce disincentives for quality care. For example, in general, patients cared for under fee-for-service reimbursement systems receive more services that are under the discretion of the provider. The incentives result in overuse of services without regard to efficiency; services of high cost that are technically complex tend to be rewarded over those that are labor and time intensive, such as counseling regarding self-care of diabetes or care coordination among subspecialists. High-technology, -volume, and -cost services are preferentially rewarded over low-technology, -volume, cost preventive healthcare services.

Under fee-for-service, this imbalance in incentives for high-technology, -volume, -cost services is further compounded. When providers invest in improving outcomes of chronic diseases (such as diabetes), their income may eventually drop, as patients with excellent control of their diabetes require fewer office visits and hospital stays in the longer term, resulting in fewer opportunities to bill for services.

Other payment methods do not reimburse for services provided but pay healthcare providers prospectively. These types of payment methods may also provide disincentives for quality. For example, capitation payment methods result in lower use of healthcare services overall and may result in underuse of essential services. Furthermore, while preventive care is more likely to be rewarded under capitation than it is under fee-for-service, when patients switch healthcare plans, investments in preventive care are less likely to result in financial savings for the payer who provided and made the up-front investments in such care.

In recognition of these issues, there are increasing numbers of programs in the United Kingdom and the United States that link payment to performance. In 2004, the United Kingdom's National Health Service (NHS) began a pay-for-performance initiative. General practitioners agreed to participate in a performance program encompassing 146 quality indicators reflecting clinical care for 10 chronic diseases, organization of care, and patient experience. In return, funding for primary care was increased 20% over previous levels, permitting

practices to invest in technology and staff. A startling 90% of general practitioners now use electronic prescribing, and general practitioners increased their income by \$40,000 through the program.

In the United States, given the disincentives for high quality healthcare that exist in current payment methods such as fee-for-service and capitation, the objectives of pay-for-performance include rapid performance improvement to address ongoing quality deficits, innovation, structural changes in care delivery, and, ultimately, better outcomes of care. A number of issues are critical to the success of pay-for-performance programs in achieving these objectives and improving the quality of healthcare.

Measuring Quality

The methods used for defining and measuring quality are the fundamental building blocks of any pay-for-performance program and are critical to the success of a program in meeting its objectives. If measures of quality do not have a sound theoretical and methodological foundation, healthcare providers are not being rewarded for the behaviors that are desired and are even perhaps inadvertently being rewarded for behaviors that are undesirable. For example, if improving the numbers of patients who quit using tobacco is the desired outcome, but documentation of tobacco cessation advice is the rewarded measure, healthcare providers may merely document smoking cessation advice, without supplying any further tools to aid smokers in quitting.

Significant limitations exist in current clinical information systems in use by healthcare providers, which are often not designed to collect data valid for quality assessment. If the data sources for creating performance measures are not universally available, accurate, and reliable, healthcare providers become suspicious that their performance is not being accurately assessed. Furthermore, if the cohort of patients eligible for the measures does not reflect the actual panel of patients, healthcare providers participating in a pay-for-performance program may be inadvertently penalized for care provided (or not provided) by others.

Risk adjustment is also essential, where appropriate. Measures of quality that do not make

appropriate risk adjustments create incentives for providers to avoid treating the sickest patients or penalize healthcare providers who care for disproportionate numbers of disadvantaged patients, who may not be able to afford their medications or comply with a treatment plan.

Chronic medical conditions are the leading cause of morbidity and mortality in the United States, and treatment of patients with these conditions consumes more than three fourths of all healthcare expenditures. Yet despite the resources devoted to the treatment of chronic conditions, chronically ill patients receive only half of the appropriate recommended care overall. Thus, many pay-for-performance programs have focused on increasing the provision of guideline-recommended care.

The effect of common, chronic, coexisting (or comorbid) conditions on measures of the quality of healthcare and patient ratings of their care is of concern to healthcare providers. Coexisting conditions complicate treatment plans and patient compliance. Some studies show that patients with chronic diseases are less likely to receive treatment for unrelated disorders or to undergo preventive healthcare services, but others show that patients with coexisting conditions are more likely to receive higher quality care. However, some studies have used a simple count of conditions as a crude marker of complexity or accessed only a limited range of conditions, possibly obscuring important relationships between types of conditions. For example, in patients with diabetes, treatment of hypertension is “concordant” with the goals of treatment for ischemic heart disease, whereas the treatment of arthritis is not, or, in other words, is “discordant.” Therefore, treatment of arthritis might reduce the time available during a visit to address care for diabetes, whereas treatment of comorbid hypertension might not.

Healthcare providers are also concerned that with the increasing numbers of comorbid conditions, patient ratings of their care may suffer. This is because “high quality” care may come with a burden of large numbers of medications and healthcare use that lowers the satisfaction of patients overall. An evaluation of clinical practice guideline adherence found that a hypothetical older adult with five common comorbidities would be prescribed at least 12 medications. Also, because evidenced-based

guidelines focus on single-disease processes and fail to account for patients with multiple comorbidities, the potential risks and benefits of such therapy, particularly in elderly patients, are unclear.

Process Versus Outcome Measures of Quality

In designing performance measures for incentive programs, several issues should be noted. First, the best process-of-care measures are those for which there is evidence that better performance leads to better health outcomes. Second, it is important to note that process-of-care measures may be more sensitive to quality differences than are measures of health outcomes, because a poor health outcome does not necessarily occur every time there is a quality problem.

It could be argued that, other things being equal, individual physician-level process-based incentives will create stronger incentives for improvement in processes over which the physician can exert direct control. In turn, such individual physician incentives may produce better health outcomes (assuming that the processes receiving incentives are systematically related to improved health outcomes over time). Therefore, combining outcome-based (e.g., tobacco quit rates) with process-based incentives (e.g., documentation of smoking cessation advice) may produce even greater quality improvement overall than process measures alone, by encouraging providers to balance process with attention to results. This approach may avoid the pitfalls of process-of-care measures alone that encourage gaming the system while avoiding the disadvantage of basing incentives solely on outcomes that may be relatively rare or difficult to achieve and somewhat beyond the control of the provider. Thus, a combined approach capitalizes on the advantages and complementary nature of both types of quality-of-care measures. However, the exact combination of process-based and outcome-based incentives that could be expected to produce the highest quality of healthcare is unknown.

Careful attention to quality measurement issues is important in averting healthcare provider opposition to such programs. A scientifically sound approach to quality measurement may also alleviate concerns that pay-for-performance is primarily a cost-cutting rather than a quality improvement tool.

Effectiveness

Ideally, studies of pay-for-performance would be multi-institutional, large-scale investigations of important and common medical conditions. Ideal studies include concurrent control groups to ensure that investigators can clearly infer associations between pay-for-performance and changes in performance. However, many pay-for-performance projects are implemented in an uncontrolled fashion, making it unclear whether the benefits are truly due to the financial incentives. Concurrent controls are essential to learn whether other temporal changes in the healthcare environment are resulting in improvements in the quality care, rather than a pay-for-performance program. Quality-of-care measures should be based on high-quality evidence and accepted guidelines, so as to minimize dispute over the evidence base for rewarded measures. Outcomes of care should be assessed. Unintended effects of the incentive program on performance measures that were not financially rewarded should also be assessed. To ensure face validity, clinical data should be collected consistently. However, empirical studies of the relationship between explicit financial incentives designed to improve a measure of healthcare quality and a quantitative measure of healthcare quality are rare in the literature. Rigorous research designs and methodology are necessary to determine whether performance-based payment arrangements result in meaningful quality improvements and are cost-effective. Studies meeting all the above criteria are surprisingly rare.

Despite the limitations of the literature, the available studies in general show some significant effects of pay-for-performance in improving the quality of healthcare. In studies of preventive care, with rewards to individual physicians, investigators have documented improvements in performance ranging from 8% to 19%. Rewards to provider groups generally had effect sizes of less than 10%.

Design of Financial Incentive Reward Programs

Designing financial incentives is a complex process involving decisions about whether providers should be in a “tournament” (competitive) style

program, whether the recipient of the incentive should consist of an individual healthcare provider or a group of healthcare providers (including clerical support staff, nurses, and pharmacists), the amount of the reward, how frequently the reward should be given, and whether the reward should include some sort of nonfinancial component, such as audit and feedback or a public recognition program. Choices in any of these categories have advantages and disadvantages. As part of this decision-making process, policymakers should consider whether their goal is improving performance at the lower end of the spectrum versus maintaining best performance, or both.

Payment may be made according to relative performance (i.e., the participant's overall percentile ranking) or absolute performance (i.e., strictly according to performance relative to the quality standard). Payment may also be made on what is termed a "Pay as You Perform" schedule, so that each instance of the behavior is rewarded. Theoretical arguments for and against these designs from the fields of economics, social psychology, cognitive psychology, industrial/organizational psychology, and other behavioral disciplines can be made. The approach that works best in healthcare is an open question.

One could anticipate that with group- or practice-team-level incentives, individual physicians would not capture the full returns on their individual effort to improve the quality of their care. The potential for some physicians to "free-ride" on the efforts of others may lead them to reduce their individual efforts. However, the problem with rewarding individuals, but not the organization or group, is that the provision of the required institutional cooperation may not be present. Thus, theory suggests the potential for group-level incentives to support organizational and team-based efforts to improve the quality of healthcare. Some evidence regarding teams and groups exists from studies evaluating the chronic-care model. These suggest that multidisciplinary teams produce better patient outcomes. Group- or system-level incentives may provide the impetus to create infrastructure changes or to promote cooperation that is absent from traditional practice.

Attributing care to a provider or a group of providers can be challenging, particularly for patients who suffer from complex, chronic diseases,

such as coexisting diabetes and chronic heart failure. Patients frequently interact with more than one provider, and treatment requires consultation with multiple subspecialists. Enhancing care coordination is essential to improving quality of care. How to identify providers who act in a coordinating role and then reward them for successfully accomplishing this role is essential to improving care for patients with chronic, complex conditions. The American College of Physicians (ACP) has proposed the concept of The Advanced Medical Home as a patient-centered, physician-guided model of healthcare to address some of these communication and coordination issues.

Most programs to date have consisted of positive rewards, rather than reduction in payments. However, this is changing. In the United States, the Centers for Medicare and Medicaid Services (CMS) has proposed eliminating payments for care that results in injury or death. As of October 2008, payments would be reduced for "never events" as defined by the National Quality Forum, such as hospital-acquired infections. And other healthcare payers are exploring similar plans.

Apart from the structure of the payment plan, the size of the bonus is almost certainly important. Possible explanations for the lack of effect or small effect in some previous studies may include the small size of the bonus. Similarly, when multiple insurers pay providers, the incentive may affect too few patients, effectively diluting the size of the incentive. On the other hand, a bonus that is perceived to be too large may produce negative feelings regarding a pay-for-performance program. Some critics have wondered whether pay-for-performance programs crowd out intrinsic motivation and negatively affect professionalism. Larger bonuses are more likely to contribute to these perceptions.

The last design issue to consider is the "end-of-year" compensation, which may not influence physician behavior as much as a concurrent fee or intermittent bonus. This is because lack of awareness of the intervention and infrequent performance feedback appear to be significant potential barriers to the effectiveness of incentives.

Regardless of the choices made, incentives require very careful design and attention to possible unintended consequences. A few studies have shown that documentation, rather than actual use of the preventive service, was significantly improved

with a financial incentive. Obviously, the goal of the pay-for-performance program is to improve the quality of healthcare and not just documentation alone. Measures more likely to show evidence of unintended effects are those unrelated to reward measures, such as screening for cancer or treatment of pneumonia.

Unanswered Questions

Despite the wide adoption of pay-for-performance, research evidence of the effectiveness of pay-for-performance programs, particularly randomized trials, is very limited, and many questions remain unanswered. For example, what types of clinical conditions or healthcare services should be the target of financial incentives to improve quality—chronic diseases, acute care, and/or preventive care services? How effective (and cost-effective) are financial incentives for quality? What are the optimum magnitude, frequency, and duration of financial incentives for quality? Should insurers reward achievement of an absolute threshold of performance, improvement over baseline performance, or some combination of these? To whom should such incentives be directed—the patient, the healthcare provider, the provider group, or the hospital—or all of them? What types of quality measures should be rewarded—processes of care, health outcomes, or both? Are financial incentives for not providing inappropriate care (such as antibiotics for uncomplicated acute upper-respiratory illnesses) effective? What is the optimum “package” of nonfinancial interventions, if any, to include with financial incentives for quality—e.g., audit and feedback, recognition, clinical reminders, academic detailing, and/or information technology support? Can insurers expect that the effect of financial incentives will persist after they are stopped? Because any effective intervention will have some unanticipated effects, will important patient care activities that are not rewarded financially be neglected? Thus, despite the great enthusiasm about the potential for aligning financial incentives with high-quality healthcare, there are a number of fundamental unanswered questions about their optimal design, effectiveness, and implementation.

Rigorous research, including randomized, controlled trials and observational studies with

concurrent control groups, is needed to guide implementation of explicit financial incentives for healthcare quality and to assess their cost-effectiveness. Much more research is needed to ensure that the nation’s healthcare financing systems are effectively designed to encourage and promote the highest possible quality of healthcare for the nation’s population.

PAYMENT MECHANISMS

Payment mechanisms are the methods by which healthcare providers are reimbursed for the goods and services they provide. Payment mechanisms include those made by the patient, or *first-party payments*; health insurer, or *third-party payments*; and those payments that are assumed by the healthcare provider, or *second-party payments*. Each payment mechanism has inherent economic incentives that affect utilization.

Third-Party Payment Mechanisms

Third-party payers (i.e., insurance companies, managed-care organizations, and the government) use a number of mechanisms to pay healthcare providers for the cost of services delivered to their insured patients. Both public payers (e.g., Medicare and Medicaid) and private payers (e.g., Blue Cross and Blue Shield and other insurance plans) have similar types of payment mechanisms available. These payment mechanisms include fee-for-service, fee schedule, per diem, per stay, and capitation payments. Often, a payer uses multiple payment mechanisms within a particular insurance product. For example, physician outpatient care may be reimbursed using a fee schedule and hospital inpatient care may be reimbursed on a per-stay basis.

Fee-for-Service

A fee-for-service payment mechanism reimburses healthcare providers on a per-unit basis or for each service provided. The fee may be based on the actual charges (i.e., the amount charged by the provider) or based on a schedule that lists the dollar amount to be reimbursed for each service. Under fee-for-service payment mechanisms, providers have the economic incentive to provide more services than necessary to increase revenue, since they are paid per unit. When fee-for-service payments are based on actual charges rather than

a predetermined fee schedule, providers can also increase revenue by increasing their charges.

Fee Schedules

Fee schedules are a particular type of fee-for-service payment mechanism that establishes either a maximum amount or actual amount of reimbursement for a particular service. If the fee schedule were used to establish maximum fees, the provider would receive the lesser of the amount charged and the predetermined amount in the fee schedule. In practice, providers almost always charge more than the fee schedule amount to ensure receipt of the full amount established in the fee schedule. Providers have the incentive to provide more services than necessary as a means of increasing revenue, but they have no influence on the amount reimbursed per service as long as their fees are set above the fee schedule amount.

The most common fee schedule in the United States is the National Physician Fee Schedule Relative Value System, which Medicare uses to reimburse physicians for services provided to Medicare beneficiaries. The system is based on the Resource-Based Relative Value Scale (RBRVS), which was developed by William Hsiao and his associates at Harvard University. Specifically, this fee schedule establishes relative value units for each Current Procedural Terminology (CPT) and Healthcare Common Procedure Coding System (HCPCS) code, and it then converts the relative value units to a dollar amount of reimbursement using a conversion factor that is revised annually. Many third-party payers use this system as the basis for determining their physician fee schedules by modifying the conversion factor that translates relative value units to dollars of reimbursement.

Per Diem

Per diem is a payment mechanism that reimburses healthcare providers per day of stay and establishes a set fee per day. Per diem is most commonly used by third-party payers for acute, long-term, skilled nursing and psychiatric hospital stays. Providers have the incentive to keep patients in the facility longer than necessary to increase reimbursement, but they have no influence on the price paid per day.

Per Stay

Third-party payers may also use payment mechanisms that make one payment for each episode of care, such as a hospitalization stay. Per stay payments solve the incentive problem inherent in per diem payments of treating patients for longer durations of time than necessary, since a flat payment per episode is made. Providers do have an incentive, however, to increase the number of times a patient is admitted to increase reimbursement.

Medicare's prospective payment system (PPS) is a payment mechanism that reimburses services on a fixed amount per episode of care for some types of services, such as acute inpatient hospital stays and home health care, while it uses per diem payments for other services, such as skilled nursing care. Acute-care hospitals are reimbursed for each inpatient case based on the Diagnosis Related Group (DRG) assigned to the case, with one payment for each hospital stay. DRGs were developed by John D. Thompson and Robert B. Fetter at Yale University. Specifically, the total payment includes a base DRG payment component plus adjustments if the hospital has a high proportion of low-income patients or is a teaching hospital or if the case is an outlier in terms of being a high-cost case. Home health care is reimbursed based on 60-day episodes of care, with a base payment plus adjustments for factors such as case-mix (i.e., severity of illness, clinical condition, and services required).

Capitation

Capitation is a payment mechanism that reimburses a physician, medical group practice, or hospital a fixed amount per patient for a fixed period of time. Often capitation payments are paid for each insured member assigned to a provider for each month, or a per-member per-month (PMPM) capitation payment. Capitation payments cover a predetermined set of services provided within the defined time period and may include primary and specialty-care physician services, other outpatient services, diagnostic and laboratory tests, and hospital stays. The provider assumes the risk of the healthcare costs for the defined population of patients, and therefore, has the incentive to provide efficient care.

First-Party Payment Mechanisms

Healthcare providers also receive payments directly from patients. Self-pay is a first-party payment mechanism and includes situations in which the patient is the only payer and those in which the patient is responsible for a portion of the payment with a third party responsible for a balance of the payment.

Self-Pay

Self-pay is the patient's out-of-pocket payment obligation. Self-pay as a payment mechanism includes two types of patients—those with no source of health insurance coverage who are responsible for the entire fee (i.e., uninsured self-pay), and those with a third-party source of health insurance coverage who must pay a portion of the fee out of pocket (i.e., insured self-pay). Payments for uninsured self-pay patients have historically been based on hospital or provider charges with no negotiated price discounts. Many hospitals have been criticized for charging patients with the least financial means the most for care, and many are revising their policies for uninsured self-pay patients.

Payments for insured self-pay patients are based on the negotiated rates established between the third-party payer and healthcare provider. Insured self-pay payment mechanisms include three main types of demand-side cost sharing, namely deductibles, coinsurance, and copayments. A deductible is the amount that an insured individual must pay out of pocket before the insurer will start to reimburse the providers for services, and the individual usually must pay the deductible each year. From an insurance perspective, coinsurance is a general term that refers to the amount of a medical bill that the insured individual is responsible for out of pocket, which could be stated as a percentage of the total amount billed or as a flat dollar amount. In healthcare, coinsurance is commonly used to refer specifically to the proportion of the negotiated medical fees that the insured individual is responsible for (e.g., 20% coinsurance), with the insurer paying the remaining proportion of the fees. A copayment refers to the flat dollar amount of the negotiated medical fees that the insured individual must pay (e.g., \$20 copayment), with the insurer paying the remaining dollar amount of the

fees. The dollar amount paid out of pocket with coinsurance may vary for each visit, but the dollar amount for a copayment remains constant.

These demand-side payment mechanisms may work together in a single episode of care. For example, suppose an individual has health insurance coverage with a \$500 deductible and a 20% coinsurance once the deductible is met. At the beginning of the year, the individual receives an MRI scan. This individual's out-of-pocket expenses would be \$540 (\$500 deductible + \$40 coinsurance (20% × \$200)), while the insurer's portion would be \$160 (\$700 – \$540). Instead, if the individual has a \$500 deductible with a \$20 copayment, the individual's out-of-pocket expense would be \$520, while the insurer would pay \$180.

Provider Internal Payment Mechanisms

Hospitals, physicians, and other healthcare providers do not collect payments from all patients—either because of a decision to provide services as charity care to a patient without the financial resources to pay or because of a failure to collect payment from the patient or third-party payer. Both charity care and bad debt are classified as uncompensated care.

Charity Care

For patients without the income (or assets, in some cases) to pay for needed services, healthcare providers may render the care as charity care. Charity care includes services that are provided but for which the provider does not expect a payment. The provider does not bill the patient or insurer nor does the provider pursue collection of payment from an external source.

Bad Debt

Bad debt includes payments that are expected to be collected but are not collected from either the patient or a third-party payer. Providers attempt to collect these payments but are ultimately unsuccessful. Bad debt is an expense to providers.

Future Implications

Healthcare payment mechanisms have become increasingly diverse and complex over time. Patients undergoing the same procedure at the

same hospital often use different payment mechanisms, or combination of payment mechanisms, and pay different amounts for the same services.

Even with healthcare reforms that would expand coverage to the currently uninsured population, the U.S. healthcare system is likely to continue relying on multiple sources of coverage, which will further fuel the complex web of payment mechanisms. While nations with a single-payer system have inherently simplified payment mechanisms, many nations may consider an increase in the individual's out-of-pocket responsibilities to control their own spiraling healthcare costs.

The largest change in the United States is likely to occur with respect to the balance of payments made by the individual compared with the insurer. Consumer-driven health plans are increasing the individual patient's cost-sharing obligations as a mechanism to control costs. This shift is likely to precipitate a change in how hospitals, physicians, and other healthcare providers collect first-party payments. While copayments for outpatient visits are routinely collected at the time of service, deductibles and coinsurance amounts for hospitalizations are more likely to be billed retrospectively. These payments are often collected after treatment because providers often cannot *ex ante* calculate the cost of treatment. As the size of first-party payments increases from hundreds to thousands of dollars, providers will have a greater incentive to collect them up front to guarantee payment. At face value, this change seems relatively minute; however, it could also lead to an increase in the number of potential patients denied services until they can make payment, to prevent a surge in bad debt.

PEW CHARITABLE TRUSTS

The Pew Charitable Trusts is the single recipient of seven charitable funds initiated by the children of Joseph N. Pew, the creator of Sun Oil Company, and his wife, Mary Anderson Pew. The four founders of the Pew Charitable Trusts were Joseph N. Pew, Jr., J. Howard Pew, Mary Ethel Pew, and Mabel Pew Myrin. They established the Trusts in 1948 as a means of honoring their parents. The central aim of the Trusts is to donate to the public and add to its general health and welfare and thereby strengthen the nation's communities. Since its establishment, the Pew Charitable Trusts has stayed robust, encompassing several national organizations, while keeping its pledge to businesses and groups within the Philadelphia area.

Based in Philadelphia, with an office in Washington, D.C., the Pew Charitable Trusts provides organizations and citizens with fact-based research and practical solutions for changing issues. It investigates a large number of topics, including arts and culture, children and youth, computers and the Internet, education, environment, health, Hispanics in America, media and journalism,

public opinion, and religion and public life. Specifically in the health area, it funds a number of centers and projects, including the Pennsylvania Medicaid Policy Center, the Genetics and Public Policy Center, and the Prescription Drug Project. In 2007, the Trusts spent a total of \$248 million on its multitude of centers and projects.

Changing Political Views

Joseph N. Pew's political views were right of center, as were those of his heirs. In the beginning, the J. Howard Pew Freedom Trust felt that its goal was educating the American people regarding the bureaucratic morass in Washington and how important the free market was for freedom. For instance, Pew thought that Roosevelt and his New Deal were nothing more than a hoax designed to turn Americans into automatons doing exactly what Washington wanted. For many years, the Pew Charitable Trusts primarily funded conservative activities centered in Philadelphia. Initially, the recipients comprised organizations such as cancer research institutes, museums, and various universities (especially those that were historically Black). The conservative leaning of the Trusts changed when Thomas Langfitt, who was president from 1987 to 1994, and his hand-picked successor, Rebecca Rimel, shifted the Trusts' emphasis to a more liberal stance. Both Langfitt and Rimel thought that the views espoused by Pew and his heirs were outdated and that, thus, a new direction was needed.

According to Rimel, one central theme undergirding the Pew Charitable Trusts is to help politicians and policymakers in Washington make decisions that would lead to positive change for each American. As a result, the Trusts uses some of America's greatest scholars, scientists, and philosophers to envision and initiate sensible solutions to urgent public problems. Even though the Trusts now has a more international focus, great emphasis is still placed on the citizens and culture of Philadelphia.

Pew Projects

In 1999, a new era for the Trusts began when the Pew Internet and American Life Project was created. This project scrutinizes the societal and community impact of the Internet. Other projects

include the Pew Research Center for the People and the Press (previously called the Times Mirror Center for the People and the Press). The center measures the changing opinions and mores of the American population. Each month, it conducts at least one major national opinion poll.

Another Trusts program is the Pew Global Attitudes Project, which conducts a series of worldwide opinion polls on a wide variety of topics. Over the years, it has conducted more than 150,000 interviews in 54 countries. In 2007, in conjunction with the Kaiser Family Foundation it conducted a global health survey that included 47 countries.

In 2001, the Trusts established the Pew Hispanic Center. Its primary goal focuses on the improvement and awareness of the diverse U.S. Hispanic populations. In addition, it seeks to record Latinos' increasing influence in the nation and to enlighten policy discussions regarding the nation's largest minority population.

The Pew Forum on Religion and Public Life sponsors an in-depth appreciation of questions at the junction of religious and public affairs. Its goal is to offer appropriate, impartial information to government leaders, journalists, analysts, and various national organizations. The forum never takes sides regarding policy and/or legislation, priding itself on being a nonpartisan entity.

Since 1999, the Pew Charitable Trusts has supported Stateline.org, an online news resource that covers state politics and policy through original reporting and by collecting news stories. Its goal is to strengthen and enrich America's political news agencies by offering data about the daily political activities taking place in each of the 50 states. Stateline.org considers itself to be an unbiased and impartial news journal; thus, the information contained therein is apolitical. Each week, approximately 20,000 viewers peruse the Web site. Stateline.org also publishes an annual *State of the States Report*, and it sponsors professional development conferences and workshops for the new media.

The Pew Charitable Trusts also funds the Pew Research Center, which operates as a self-regulating, apolitical organization. One activity of the center is to support the Pew Biomedical Scholars Program. This program provides financial assistance to talented early- and mid-career scientists who are investigating fundamental and medical areas

regarding human health. Scholars are given financial support (in the range of \$240,000 for 48 months) and are encouraged to be commercial and original in their research endeavors.

PHARMACEUTICAL INDUSTRY

The pharmaceutical or drug industry historically has been one of the most innovative and profitable business sectors in the United States. Recent developments, however, portend major changes in the nation's pharmaceutical industry. Growing regulatory oversight, rising consumer distrust over advertising claims, drug safety concerns, increased cost-containment initiatives by government and private third-party payers, mandated health technology assessments to determine coverage and reimbursement policies, patent expirations of top-selling products, and the implementation of the Medicare Part D drug benefit have influenced changes in the industry's practices and strategies. This entry describes the

global sales and market share of the pharmaceutical industry, the different classifications within the industry, and the future outlook for the industry in light of the recent developments.

Global Pharmaceutical Sales

Global pharmaceutical sales grew by 7% in 2006, totaling more than \$643 billion (all data reported in U.S. dollars) in sales, according to industry estimates by IMS Health. This marked the third straight year of single-digit revenue growth for the pharmaceutical industry, after 5 years of double-digit increases from 1999 to 2003. The worldwide pharmaceutical market is dominated by the United States, with 44% of the world's market share, followed by Europe, with 28%, Japan, 10%, Asia Pacific, 7%, Latin America, 5%, the Middle East and Africa, 3%, and Canada, 3%. The largest European markets are France, Germany, Italy, the United Kingdom, and Spain. The Asia Pacific region includes fast-growing pharmaceutical companies, located in India and China, which mainly produce generic versions of drug products. Brazil is the largest market in Latin America.

Classification of the Pharmaceutical Industry

The pharmaceutical industry, or *pharma*, includes three primary sectors: (1) the traditional research-intensive pharmaceutical industry, (2) the research-intensive biopharmaceutical industry, and (3) the generic pharmaceutical industry. These sectors, however, are increasingly becoming blurred because of strategic company acquisitions, mergers, licensing agreements, and other business practices. For example, most traditional research-intensive pharmaceutical companies manufacture or license generic versions of their original products. The traditional research-intensive industry is attempting to gain market share and position in the biopharmaceutical industry. And the generic pharmaceutical industry is lobbying for legislation to facilitate the approval of *biogenerics* (i.e., similar versions of biotech pharmaceutical products).

Traditional Pharmaceutical Industry

The traditional research-intensive pharmaceutical industry is also known as the “brand-name”

or “innovator” pharmaceutical industry. The largest companies in this sector are often referred to as “Big Pharma.” They are represented by the trade association, Pharmaceutical Research and Manufactures of America (PhRMA). This sector focuses on the discovery, development, and production of new chemical entities and new biologic entities. These multibillion dollar corporations, however, are not limited solely to drug products or vaccine sales. Many of these corporations include other healthcare-related products, such as nutrition products, dietary supplements, diagnostics, medical devices, and other consumer products.

Relative rankings of the world's top pharmaceutical companies change yearly due to sales, patent expirations, mergers, acquisitions, and other practices. Based on 2007 rankings (compiled from Fortune 500 lists), 12 pharmaceutical corporations accounted for 60% of the total global pharmaceutical sales. The leading companies—based on sales, headquarters country, revenue, and profit (as a percentage of revenues)—were (1) Johnson & Johnson (U.S.), \$53.3 billion, 20.7%; (2) Pfizer (U.S.), \$52.4 billion, 36.9%; (3) GlaxoSmithKline (U.K.), \$42.7 billion, 23.2%; (4) Novartis (Switzerland), \$37 billion, 19.4%; (5) Sanofi-Aventis (France), \$37 billion, 13.6%; (6) Roche Group (Switzerland), \$34.7 billion, 18.1%; (7) AstraZeneca (U.K.), \$26.5 billion, 22.8%; (8) Merck & Co. (U.S.), \$22.6 billion, 19.6%; (9) Abbott Laboratories (U.S.), \$22.5 billion, 7.6%; (10) Wyeth (U.S.), \$20.4 billion, 20.6%; (11) Bristol-Myers Squibb (U.S.), \$17.9 billion, 8.8%; and (12) Eli Lilly (U.S.), \$15.7 billion, 17%.

Seven of the top pharmaceutical companies are American-based, and the five other top companies are headquartered in Europe. Depending on the year, other leading research-based pharmaceutical companies include Bayer (Germany), Boehringer Ingelheim (Germany), Schering-Plough (U.S.), Baxter International (U.S.), Takeda Pharmaceuticals (Japan), Procter & Gamble (U.S.), Astella Pharma (Japan), and others.

The median profit margin for the leading pharmaceutical companies was 19.5%, which is well above the median of 4% to 5% for most other industries. Median profit margins for the pharmaceutical industry have been about 17% to 18% since 2002 (with a slight dip to 14% in 2003). Industry profits increased in the United States due in part to

the passage of the Medicare Part D prescription drug benefit, which the industry helped pass.

The pharmaceutical industry asserts that its profits are in line with those of other major industries in consideration of its need for a reasonable return on its investment and adequate revenue to encourage risk and innovation in the business of drug discovery. Critics counter that it is difficult to consider such a routinely profitable industry as being risky.

The research-based pharmaceutical industry strongly supports innovative drug research, swift development and approval of drug products demonstrated to be safe and effective, strong intellectual property and patent protection, and access to medicines in an open, competitive market. It also supports federal legislation that would limit liability (e.g., limits on punitive damages and on damage awards) for drug manufacturers. On the other hand, it opposes restrictive drug formularies, prior authorization policies for prescription drug coverage, limits on prescription reimbursement, price controls, and retail-level prescription drug importation from foreign sources.

The U.S. Food and Drug Administration (FDA) is the federal agency that reviews drug products for approval in America, while patents on drug products (and related chemical compounds, processes, and other intellectual property) are granted by the U.S. Patent and Trademark Office. Patents can be granted anywhere along the development lifeline of a drug compound or product. Patents are granted for a period of 20 years from the date of filing, before patent term restoration activities and court challenges. The PhRMA states that due to lost patent time during the protracted drug approval process (estimated at 11 to 12 years by the FDA and up to 15 years by the pharmaceutical industry), the effective patent life of prescription drugs in the United States is only about 11 or 12 years, as compared with more than 18 years for nondrug products. The FDA can grant exclusive marketing rights, or exclusivity, for certain time periods (ranging from 6 months to 7 years) to help promote a balance between innovation in new chemical entities and generic competition.

Biopharmaceutical Industry

The research-based biopharmaceutical industry is the newest sector and is also referred to as the

“pharmaceutical biotechnology industry,” or “biopharma.” Its products are usually termed *biotech pharmaceuticals* or *biological medicines*. Biotech pharmaceuticals are medicines derived from living cells and proteins, the so-called large molecules. In comparison, the traditional research-based pharmaceutical industry discovers and produces drug products based primarily on small-molecule chemical substances. Examples of biopharmaceuticals include monoclonal antibodies, protein cell cultures, protein microbials, and bioengineered hormones. Biopharmaceuticals are used to treat a variety of medical conditions, though most current products are marketed as specialty medications indicated for cancers, anemia, heart disease, rheumatoid arthritis, and less prevalent diseases such as ankylosing spondylitis and Crohn’s disease. A large percentage of research and development expenses (25–50% of revenue) is invested by the biopharma industry as compared with the traditional research-intensive pharmaceutical industry (which averages about 18% of revenue).

The U.S. market for biotech pharmaceuticals was \$35 billion in 2006, a 17% increase in growth from 2005, which was about two times the rate of the traditional research-intensive pharmaceutical industry. Biotech pharmaceuticals accounted for 12% of total prescription sales, though the high costs for some of these products can make them prohibitively expensive. For example, treatment with Genentech’s Avastin (bevacizumab)—indicated for certain types of lung cancer, advanced breast cancer, or metastatic colorectal cancer—can cost \$100,000 per patient per year.

The top 10 biopharmaceutical companies, based on reported 2006 revenues, were (1) Amgen (\$14.3 billion), (2) Genentech (\$7.6 billion), (3) Novo Nordisk (\$6.5 billion), (4) Genzyme (\$3.2 billion), (5) Gilead Sciences (\$3 billion), (6) UCB Group (\$2.7 billion), (7) Biogen Idec (\$2.7 billion), (8) Serono (\$2.5 billion), (9) MedImmune (\$1.2 billion), and (10) Millennium (\$220 million). Eight of these companies are based in the United States. The exceptions are Novo Nordisk (Denmark) and UCB Group (Belgium).

Financial positions, relative rankings, and ownership can change quickly, especially in the more volatile biopharmaceutical sector. For example, Amgen’s profits of almost \$3 billion dropped by 19.7% from the levels achieved in 2005. Gilead

Sciences and Genzyme also experienced substantial profit decreases during a 1-year period. The eighth-ranked biopharmaceutical company—Serono—was acquired by Merck KGaA in 2006 and is now Merck Serono (known as EMD Serono, Inc., in the United States and Canada because Germany-based Merck KGaA is a different company from the U.S.-based Merck & Co., which has the rights to the name in North America). Similarly, AstraZeneca purchased MedImmune in 2007.

The biopharmaceutical industry has a similar product approval process to that of other pharmaceutical products. However, the approval time for a biopharmaceutical ranges between 7 and 12 years from development to approval. The development and manufacture of biologic medicines is more complex and expensive than production of small-molecule chemical entities, which is one of the reasons for their high costs. Because biologics are produced in living cells, it would be very difficult for other manufacturers to duplicate the process exactly in attempts to make generic versions of biopharmaceuticals. Thus, biosimilars may be therapeutically equivalent, rather than chemically equivalent with original products. The FDA is in the early stages of creating regulatory procedures for the review and approval of biogenerics or biosimilars, which are “generic” (or, more aptly named “similar”) versions of the innovator biotech pharmaceuticals. However, it is likely to be years before that process is completed.

The major biotechnology trade association is the Biotechnology Industry Organization (BIO), and its multidisciplinary membership includes more than 1,100 biotech companies, universities, research organizations, and affiliates. In addition to biotech pharmaceutical firms, an increasing number of PhRMA companies are branching into pharmaceutical biotechnology because of the rapid growth of the industry and the lack of current processes to enable generic competition. From 2005 to 2007, Big Pharma companies spent \$76 billion to acquire biotech companies. For example, Novartis, Wyeth, Abbot, and Eli Lilly have invested hundreds of millions of dollars each in the formation of in-house units for the development and manufacture of biotech pharmaceuticals and the building of new manufacturing facilities. Other Big Pharma companies have acquired smaller biotech firms to expand their pipelines.

The biopharmaceutical industry generally espouses similar position statements as the traditional research-intensive pharmaceutical companies with respect to support of market-based pricing for medicines, support of tax incentives to encourage investment in biotech-derived medicines, opposition to price controls for biotech drugs, and opposition to restrictive reimbursement programs. Similar to Big Pharma, the biotech pharmaceutical industry is using late life-cycle strategies to expand its product line and to extend the market life of its products, such as the second-generation anemia drug, EPO Aranesp (darbepoetin alfa), which is manufactured by Amgen. One area where the position of the biopharmaceutical industry differs from those of the traditional research-intensive pharmacy companies is with respect to policies on separate reimbursement mechanisms for drugs and biologicals.

Generic Pharmaceutical Industry

A generic drug product is defined as a product that is bioequivalent to a referenced innovator (brand name) drug product and is identical in active chemical ingredient, strength, dosage form, route of administration, quality, performance characteristics, safety, and treatment indication. Multisource generics are available for about three-quarters of drug products approved by the FDA. The generic pharmaceutical industry experienced a 22% growth in sales from 2005 to 2006. Nationally, 63% of prescriptions dispensed in the United States in 2006 were generic products, though generics accounted for only 20% of prescription drug sales. Over the past 20 years, the sustained growth in use of generic drug products has been promoted as a cost-saving measure by managed-care organizations, private health insurance companies, state Medicaid and other government programs, pharmacy benefit management companies, and others.

The pharmaceutical industry differentiates between unbranded generics and branded generics. Following approval of an abbreviated new drug application (ANDA) by the FDA, unbranded generics are manufactured by pharmaceutical companies unaffiliated (for that product) with the innovator company. The ANDA (and equivalent) process does not require the applicant firm to repeat the expensive preclinical and clinical research for the drug

ingredients and dosage forms that were approved by the FDA for the application of the innovator company. Rather, the generic product must demonstrate bioequivalence. The median ANDA approval time in 2006 was 16.6 months. Branded generics (called “authorized generics” by the industry) are generic versions of the innovator product that are manufactured by the innovator pharmaceutical industry sponsor and/or otherwise produced and distributed by one of its licensed partners. Branded generics are not required to undergo an abbreviated FDA approval process because the innovator company is selling the same product previously approved under a brand name. In 2006, the top pharmaceutical companies for unbranded generic drug products (accounting for 54% of prescription dispensed and 10% of U.S. sales) were Teva Pharmaceuticals, Novartis (Sandoz division), Mylan Laboratories, Watson Pharmaceuticals, Pfizer (Greenstone division), Apotex Corporation, Par Pharmaceuticals, Mallinckrodt, Barr Labs, Boehringer Ingelheim, Actavis US, Qualitest Products, and Hospira, Inc.

The main generic pharmaceutical industry trade association is the Generic Pharmaceutical Association (GPhA). The association states that the generic manufacturers provide consumers with safe, effective, quality drug products at lower costs. Generic drugs are estimated to save U.S. customers \$8 to \$10 billion yearly at the retail level, with more savings realized when including other pharmacy distribution outlets such as hospitals and nursing homes. The generic pharmaceutical industry supports efforts to promote free market forces and supports the development of an abbreviated regulatory approval process for biogenerics or biosimilars. The generic pharmaceutical industry wants faster FDA review times for ANDAs. It is strongly opposed to brand-name (research-intensive) drug industry efforts to extend patents and other tactics to delay market introduction of generic drug products, such as patent extensions for minor changes in formulations or processes and unsubstantiated citizen petitions to block FDA approval of generic applications. The unbranded generic industry has challenged the FDA's regulatory policies in approving authorized generics. The generic pharmaceutical industry claims that by merely changing their label, the brand-name companies compete with the first generic drug company at a period in which the first generic sponsor should have exclusive marketing

rights (for 180 days) without competition by any product other than the original brand label. It also opposes foreign importation of drug products at the retail level.

Future Implications

Mergers, acquisitions, and other consolidations among the major pharmaceutical companies are anticipated to continue, and the nature of the pharmaceutical industry is changing. Fewer blockbuster drug products (i.e., products with annual global sales of at least \$1 billion) have been approved in recent years, with drugs in the research pipelines appearing less promising for the traditional research-based pharmaceutical industry than for the growing biotech pharmaceutical sector.

It has been estimated that Big Pharma lost \$14 billion in sales as the result of patent expirations and increased generic competition in 2006. In the future, while the companies will remain profitable, revenues are likely to decline because many of their drug products are coming off patent between 2008 and 2012 (e.g., Fosamax, Valtrix, Advair, Lipitor, Plavix, and Crestor).

In light of these patent expirations, more limited pipeline resources, and declining sales, many major pharma companies are reorganizing. In recent years, many companies have attempted to have leaner operations by laying off employees and streamlining programs.

Predicted trends for the pharmaceutical industry include the increased use of outsourcing and global licensing because of reduced regulatory monitoring and decreased costs. The U.S. pharmaceutical industry (research and generic) already outsources much of its production to offshore territories (e.g., Puerto Rico) and overseas countries, especially the emerging markets of India, China, and Eastern Europe. While the FDA inspects these facilities (for drug products legitimately sold in the United States), the oversight is less stringent than the routine inspections in U.S.-based corporations.

Last, the future outlooks of the pharmaceutical industry will include increasing regulatory consideration of biosimilars. The European Commission granted Sandoz approval to market a biosimilar version of epoetin alfa, or EPO (indicated for treatment of anemia) in 2007, becoming the first biogeneric product approved in the European EPO

market. While predicted to be a potential blockbuster, the ultimate impact of this regulatory action is unknown. Sandoz's Omnitrope (somatropin, rDNA origin), a biosimilar version of Pfizer's human growth hormone Genotropin, was marketed under special rules in the United States and Europe in 2006. Its sales, however, represent less than 1% of the market. Perhaps its low market share was due to the drug's relatively high price and physician concerns about its bioequivalence. In 2007, legislation was introduced in the U.S. Congress (H.R. 1038 and S. 623, Access to Life-Saving Medicine Act) to provide for the licensing of therapeutically equivalent biological medicines, which would mandate the FDA to create an abbreviated approval process for biological products. However, Congress took no action.

PHARMACOECONOMICS

Pharmacoeconomics can be defined as the description and analysis of the costs and consequences of pharmaceutical products and services and their impact on individuals, the healthcare system, and society at large. Pharmacoeconomics as a field of research arose in the late 1970s in response to rising expenditures on prescriptions and growing concerns regarding cost containment of drug budgets. The underlying purpose of pharmacoeconomic analysis is to promote the efficient use of healthcare resources by informing treatment choices and related policy.

Background

Pharmacoeconomics has ties to both economic evaluation and health outcomes research. Many of the theoretical methods have roots in social welfare and cost-benefit analysis that are found in public finance and environmental economics. The field is also related to decision analysis and corporate finance principles often used in evaluating corporate business decisions.

Categories of Study Methods

Within pharmacoeconomics, there are four general subcategories of study methods: (1) cost-minimization analysis (CMA), (2) cost-effectiveness

analysis (CEA), (3) cost-utility analysis (CUA), and (4) cost-benefit analysis (CBA). These four subcategories are differentiated according to how health outcomes are measured: CMA requires that the health effects of the alternatives in question are equal. CEA measures health outcomes in some natural unit (e.g., life years). CUA is very similar to CEA except that the unit of health is quality-adjusted life years (QALYs). These units are formed by assigning health status (e.g., mild angina) a preference-based utility score, typically between 0 and 1, where 1 represents perfect health and 0 represents death, and then multiplying life years in a particular health state by the preference score of that health state (e.g., 10 years in a health state with a utility score of 0.7 results in 7 QALYs). The scores themselves come from survey-based methods, and there are various methodologies for obtaining the utility scores. Finally, CBA measures health effects in dollars, which often involves some means of translating health gains into a dollar value. All four subcategories consider costs measured in dollars.

Data Sources

There are numerous potential sources of data for quantifying costs and outcomes for use in a pharmacoeconomics analysis, ranging from prospective data collection to analyses of administrative databases to information based on surveys of experts. In addition, information from randomized clinical trials or from pharmacoepidemiologic studies can be examined in combination with cost information. Any pharmacoeconomic study is limited by the availability of data related to what treatments it sets out to compare. In addition, data are typically available from a particular patient population, a particular time period, and a particular setting. Consequently, studies often involve the use of models to project results across patient populations, and to project costs and outcomes into time horizons beyond the research of existing data.

Determining Costs

A key aspect of pharmacoeconomics is consideration of costs beyond just the simple cost of the drug. Examples of other costs that can be included are the personnel, equipment, or facilities used in

administering treatment, the cost of treating side effects, the costs associated with healthcare utilization (e.g., physician office visits or hospitalizations), or the cost of patient time that is spent during treatment, to name a few. Finally, the costs of pain and suffering from a treatment or disease can be considered. Note, that a central element of a pharmacoeconomic analysis is the choice of the study perspective, where a societal perspective is generally felt to be the most relevant in terms of informing national policy (other perspectives include the payer perspective, the provider perspective, and the employer perspective). The study perspective fundamentally determines what costs are included in the analysis, which is a reason that studies that take a broad perspective, such as a societal perspective, are considered to be of greater importance. However, data availability and available budgets for research may limit the perspective that research can cover. More important, it is the research question (or decision to be made) that dictates the appropriate perspective.

Decision Making

In terms of how the results inform decisions, CMA identifies the lowest-cost treatment among two or more with the same effect. CEA and CUA identify treatments that cost more and provide equal or lower amounts of a health outcome, a choice that is never favorable. CEA and CUA also measure the additional spending that is required per gain in additional units of health outcome in making a treatment switch to a higher-cost, higher-effect treatment (or *visa versa*). By identifying the cost of increasing health in particular treatment options, CEA and CUA promote efficient treatment choices. Currently, treatment adoptions with cost-to-QALYs ratios lower than \$100,000 are generally considered favorable. Cost-benefit analysis typically provides a direct calculation of the net benefit of making a treatment change, defined as the change in benefits minus the change in costs. When the change in treatment is deemed to have a positive net benefit, then that change is recommended.

Currently, CUA with a societal perspective is considered the gold standard strategy among pharmacoeconomic analysts, though this is not without controversy. While many feel that QALYs

are the best available measure of general health outcomes, many also feel that the measurement techniques to acquire QALYs are flawed and that there are too many underlying assumptions that go into aggregating QALYs (e.g., that an added QALY for an elderly person is the same as for a younger person) for them to adequately inform actual policy decisions. Suffice to say that development of appropriate measures of health outcomes and notions of how to best apply aggregated results to inform policy toward health treatments is an ongoing process.

Future Implications

Pharmacoeconomics continues to grow, as measured by the number of published articles and books, the number of researchers, as well as the number of dollars spent on research in the field. Many nations require pharmacoeconomic analyses as part of the drug approval process. Although the U.S. Food and Drug Administration (FDA) does not currently require pharmacoeconomic analyses in its approval process, a growing number of healthcare organizations are including pharmacoeconomic evidence in their decision-making processes. In addition, many of the nation's pharmacy schools require pharmacoeconomics in the curriculum of their students, and there are a number of graduate programs available that include concentrations in pharmacoeconomics.

PHARMACY

For the general public, pharmacists are often the most accessible health professionals for patients to obtain information and advice. Currently, there are about 245,000 licensed pharmacists employed in the United States, which ranks pharmacy as the nation's third-largest health profession. There are also about 285,000 employed pharmacy technicians. Pharmacists help ensure the rational and safe use of drug therapies by working to achieve positive therapeutic outcomes, improve the quality of life for patients, reduce healthcare costs, and minimize patient risk from drug-related morbidity and mortality.

Pharmacists are increasingly expanding their roles in healthcare. Specifically, they are advising physicians, nurses, and other health professionals on medication selection, dosages, use, interactions, and side effects; dispensing medications and monitoring patients for expected outcomes and adverse effects; and educating and counseling patients on prescription and nonprescription drugs, dietary supplements, self-care, and other healthcare topics.

As recognized medication-use experts, pharmacists are well educated on the composition and characteristics of pharmaceuticals (e.g., chemical, pharmacological, and physical properties), their manufacture and/or preparation, and use. Pharmacists strive to verify the quality of drugs and related ingredients in the supply chain to help ensure drug purity, strength, and proper labeling for improved patient safety.

History of American Pharmacy

The existence of pharmacists was rare in Colonial America. Drugs and “patent medicines” (i.e., cheap and supposedly curative tonics, pills, and other concoctions, which often contained large proportions of alcohol, opium, or laxatives) were readily available and hawked for sale without a prescription at general stores and by traveling salesmen. In the late 1700s, physicians compounded drugs they prescribed (i.e., prepared specially customized medicines), or their apprentices prepared the drugs under their supervision. Apothecary shops were generally owned by physicians and were located in large cities. The local drug clerk was a shop employee whose role was more akin to a wholesaler than retailer; the drug clerk primarily compounded, stocked, and distributed medicines for physicians. The job of the drug clerk was viewed as a trade occupation, which was best learned by daily application of repetitive practices. The apprentice drug clerks eventually developed more expertise in pharmaceuticals, far beyond the knowledge of most physicians, and they enjoyed a close working relationship with physicians, since they usually operated the shops on behalf of them.

Over time, the physician-owners of the shops moved away and/or sold their businesses to their former drug clerks, which began the establishment of the independent retail drugstore trade. In the early to mid-1800s, independent apothecary shops and drugstores proliferated, and the businesses became increasingly profitable. As proprietors, the former drug clerks adopted the titled of apothecaries or druggists (and a few called themselves pharmacists). The first college of pharmacy was established in Philadelphia in 1821, and a small number of other pharmacy colleges were founded, though most druggist-practitioners lacked formal training. From the mid-1800s through the early 1900s, the country lacked laws and regulations governing foods, drugs, and healthcare practice. The sale of inefficacious, possibly poisonous, and mislabeled patent medicines were sold by self-designated apothecaries and other merchants. Some 19th-century druggists diagnosed patients and dispensed medicines, which conflicted with medical practice. Physicians widely criticized the apprentice-trained employees as unknowledgeable and

unscrupulous. Many physicians continued to dispense their own medicines, and a widening rift developed between pharmacy and clinical medicine.

By the early 1900s, federal legislation and regulations helped improve safety and quality of the drug supply to some extent. Medical education, training, and practice underwent substantial change. Most physicians stopped or limited their dispensing of medicines, and druggists compromised by limiting their diagnosing to minor illnesses. During the Prohibition Era (1920–1933), drugstores were popular hangouts because druggists could dispense alcohol for medicinal purposes. Regulatory change of certain drug products to prescription-only status in the early 1900s eliminated the discretionary latitude of pharmacists in dispensing certain medications over the counter. Mass manufacturing of drug products by the pharmaceutical industry began around the same time, which greatly reduced compounding activities by pharmacists. By the 1960s, pharmacy practice started to evolve from the product-oriented distributive focus to include more patient-oriented clinical roles.

Laws and regulations, professional standards, and a professional code of ethics underpin contemporary pharmacist roles. Leaders in the profession embraced the clinical pharmacy movement in the 1970s to the 1990s, when the concept of pharmaceutical care was conceptualized. Today, pharmaceutical care is defined as assuming responsibility for providing drug therapy intended to produce outcomes that improve the patient’s quality of life. The changing healthcare marketplace, societal need, shifting of some drugs from prescription to nonprescription status, advent of computerization and other automated systems, and educational reforms help shape pharmacy practice.

Education

Throughout the 20th century, inconsistent pharmacy educational requirements resulted in disjointed perceptions of pharmacists and fragmented philosophies of practice. More formalized pharmacy education programs were established by the early 1900s, including 2-year diploma programs and a few 3-year and 4-year programs. The minimum educational requirement for pharmacy increased to 3 years in 1925 and increased to a

4-year bachelor of science degree in 1932. By the 1950s, many pharmacy schools had expanded the degree program requirements to a 5-year bachelor's degree, which became the minimum standard in 1960.

Most of the nation's pharmacy degree programs in the 1960s and 1970s were heavily science based, with curriculums focused on chemistry and other physical sciences. Clinical therapeutics courses were added to the curricula at most pharmacy programs by the 1970s. A number of pharmacy schools converted their programs to a 6-year doctor of pharmacy (PharmD) degree by the 1980s, though the majority of colleges continued to offer the 5-year bachelor's degree as the entry-level degree in pharmacy. At that time, the doctor of pharmacy degree was typically available as an advanced postbaccalaureate degree.

A protracted debate ensued among members of the profession, major pharmacy providers, and the academic community as to whether there was the need for the advanced clinical degree for all pharmacists. A dual system of pharmacy education (bachelor's degree and doctor of pharmacy) persisted for decades in a contentious atmosphere of strong support for and opposition to the all-doctor of pharmacy standard for professional education. The debate ended in 1992, when the accrediting body (now the Accreditation Council for Pharmacy Education [ACPE]) announced its intent to recognize only the doctor of pharmacy as the first professional degree. Since 2004, the doctor of pharmacy has been the only professional pharmacy degree program accredited by ACPE.

The doctor of pharmacy (PharmD) is designed to take a minimum of 6 academic years, including 2 years of prepharmacy requirements and 4 years of pharmacy school. Admission to pharmacy school is highly competitive. Applicants must have high academic achievement in courses such as biology, chemistry, physics, and calculus. More pharmacy schools are also requiring students to take various liberal arts courses such as communication and economics to have a broader education. Most pharmacy schools require Pharmacy College Admission Test (PCAT) scores and interviews before applicants are considered for admission. The pharmacy school curriculum includes strong foundations in the basic pharmacy sciences (e.g., medicinal chemistry, pharmacology, pharmacognosy, or natural

products, pharmaceuticals, pharmacokinetics, and physiology), the social, behavioral, and administrative sciences (e.g., communications, health systems analysis and services delivery, pharmacoeconomics, and management), and pharmacotherapeutics (e.g., clinical pharmacy). Early experiential education is included throughout the curriculum, and advanced pharmacy practice experiential education (i.e., clerkships) is offered during the final year of study. Graduate programs (leading to master's and doctoral degrees) are also available in specific areas of the pharmaceutical sciences, but these research-based graduate degree programs do not generally require a background in pharmacy as a prerequisite for admission. More than 100 accredited pharmacy schools exist in the United States, and these programs graduate approximately 9,000 pharmacists annually.

Optional postgraduate training opportunities exist in pharmacy. More than 1,500 pharmacists complete a residency each year. A pharmacy residency is an organized, postgraduate training program in professional practice and management activities. Pharmacy residency programs are mainly located in the hospitals or ambulatory-care settings but also include home care and long-term care facilities, managed-care facilities, community pharmacies, and other settings. The American Society of Health-System Pharmacists (ASHP) accredits more than 800 residency programs, and the training programs cover diverse practice areas, such as ambulatory care, cardiology, critical care, informatics, psychiatric pharmacy, and transplantation. Residency programs usually last 1 year (though a few are 2 years in duration), and some pharmacists complete a second, specialized residency after 1 year of general pharmacy residency training. A pharmacy fellowship, typically lasting 2 years, is a highly individualized postgraduate training program to develop research skills for pharmacists. The pharmacy fellow is under the direction of an experienced researcher-preceptor, usually in the academic or the pharmaceutical industry sector.

Licensure and Credentialing

Graduates of accredited pharmacy programs in the United States must pass state board examinations to earn a license to practice pharmacy. Initial

state licensure as a registered pharmacist is gained by passing the North American Pharmacist Licensure Examination (NAPLEX), the appropriate sections of the Multistate Pharmacy Jurisprudence Examination, both of which are administered by the National Association of Boards of Pharmacy (NABP), and/or other state requirements. Mechanisms exist to transfer NAPLEX scores (during initial licensing) and to transfer existing licenses (reciprocity) to gain licensure in more than one state or jurisdiction. A certification process is established by NABP and individual state boards to allow foreign pharmacy graduates (who pass the Foreign Pharmacy Graduate Equivalency Examination and provide documentation of sufficient foreign pharmacy education) to become eligible to take the NAPLEX. Pharmacists are expected to maintain professional competence, legal requirements, ethical standards, and continuing professional education to maintain their licensure.

At the highest recognized level of specialization, pharmacists in certain fields may become board certified through programs administered by the Board of Pharmaceutical Specialties (BPS). Board certification does not grant the recipient any legal authority. However, certification offers advantages in knowledge gained, competitive job advantages, and recognized expertise for third-party payers. BPS-specialties exist in nuclear pharmacy, nutrition support pharmacy, oncology pharmacy, pharmacotherapy (including added qualifications for subspecialists in cardiology and infectious diseases), and psychiatric pharmacy. Nearly 7,000 pharmacists (about 3% of the workforce) were board certified in 2007. In addition to BPS certification, pharmacists can develop specialized areas of practice through residency or fellowship training, certificate programs in disease state management and other areas of practice, or extensive work experience.

The role of pharmacists continues to expand, partly due to increasing numbers of pharmacists specializing in practice areas and participating in disease state management. Certain states have enacted legislation to enable collaborative practice between pharmacists and physicians based on set protocols. Through such collaborative drug therapy management agreements, qualified pharmacists may perform patient assessments, order

drug-therapy-related tests, administer medications, and order and monitor drug regimens.

Pharmacy Technicians

Pharmacists often are assisted by pharmacy technicians who provide technical support. Depending on individual state practice acts and regulations, pharmacy technicians may enter medication orders, prepare medications and supplies for dispensing (e.g., counting and labeling), stock and transport medications, purchase drugs, manage narcotics inventories, answer telephone inquiries, and conduct other administrative duties. Roles of pharmacy technicians are determined by their employer, and their work must be supervised under the direction of a registered pharmacist. There are no uniform qualifications for pharmacy technicians, and requirements vary across states and practice settings. Most, though not all, states require that pharmacy technicians be high school graduates or equivalent. Pharmacy technicians may be trained informally or formally on the job, in vocational programs, community colleges, or the U.S. military; training program lengths range from 1 day to 2 years. Increasingly, employers and some states are requiring that pharmacy technicians obtain certification, primarily by the Pharmacy Technician Certification Board (PTCB) or by the Institute for the Certification of Pharmacy Technicians (ICPT).

Pharmacist Associations

Hundreds of pharmacist associations exist to serve member needs, including government relations, public relations, continuing education, professional standards development, meetings, products and services, and other professional activities. The three largest pharmacist associations are (1) the American Pharmacists Association (APhA), (2) the American Society of Health-System Pharmacists (ASHP), and (3) the National Community Pharmacists Association (NCPA).

Founded in 1852, the APhA (formerly the American Pharmaceutical Association), which is located in Washington, D.C., is the oldest professional pharmacist society. The APhA has a membership of approximately 60,000 pharmacists, pharmacy students, and pharmacy technicians.

The ASHP (formerly the American Society of Hospital Pharmacists), which is located in Bethesda, Maryland, has the largest annual budget of any pharmacist association, at approximately \$40 million. Its membership consists of about 30,000 pharmacists whose practice settings include hospitals, health maintenance organizations (HMOs), patients' homes, and long-term care facilities.

The NCPA, which was founded in 1898 as the National Association of Retail Druggists, is headquartered in Alexandria, Virginia. It represents approximately 23,000 members who practice in independent community pharmacies.

Other major pharmacist associations represent managed-care practitioners (Academy of Managed Care Pharmacists), clinical specialists in pharmacy practice and research (American College of Clinical Pharmacy), compounding pharmacists (International Academy of Compounding Pharmacists), and minority pharmacists (National Pharmaceutical Association).

Affiliate member status is available for pharmacy technicians in most of the major pharmacist associations, but the primary group representing them is the American Association of Pharmacy Technicians (AAPT).

Other important related associations are the National Association of Chain Drug Stores (NACDS) and the Pharmaceutical Care Management Association, which represent chain drugstores and pharmacy benefit managers, respectively.

Future Implications

Currently, about 60% of pharmacists work in community pharmacies (e.g., independently owned pharmacies, chain drugstores, mass merchandisers, and supermarket pharmacies). About 20% of pharmacists work in healthcare institutions (e.g., hospitals, nursing homes, and health clinics). The remaining pharmacists work in various areas such as the federal government, academia, the pharmaceutical industry, managed-care organizations, professional associations, and public health agencies, among others.

Although salary ranges vary widely across geographic regions and practice settings, the median annual pharmacist salaries ranged between about \$83,000 and \$108,000 in 2006. And because of the

increasing demand for pharmacists, their salaries continue to rise each year.

The future employment outlook for pharmacists is very promising. Pharmacists are in increasing demand because of the greater use of prescription drugs, demographic trends such as the aging of the population, and the increasing incidence of chronic diseases. It is anticipated that there will be a national shortage of 112,000 to 157,000 pharmacists by 2020. It is also estimated that about 91,000 additional pharmacy technicians will be needed by 2016. Future workforce projections will be influenced by the attrition rate of older pharmacists, shifts in full-time-equivalent positions (currently 85% of practitioners) versus the growing part-time employment in pharmacy practice, the continued expansion of existing and new pharmacy school degree programs, and effective use of support personnel and automation.

PHYSICIAN ASSISTANTS

Physician assistants play an important role in America’s healthcare system, working in areas often not directly served by physicians. In 2008, there were about 68,000 physician assistants delivering healthcare in the nation. Physician assistants are trained to diagnose health conditions and administer therapy under the direction of a supervising physician. They are an integral part of healthcare teams. They often take patients’ medical histories, examine and treat patients within their respective range of knowledge, and order and interpret laboratory tests and X rays, as well as make specific diagnoses. They may perform simple medical procedures such as stitching cuts and splinting and casting broken limbs. Physician assistants are allowed to prescribe medications in 48 states and the District of Columbia; they may also be responsible for managerial

duties, such as ordering supplies and equipment and supervising others.

Background

During the 1960s, the United States had a shortage of physicians. During the Vietnam War, many medical corpsmen returned from their tour of duty looking for suitable employment in which to apply the skills they learned while in military service. The physician assistant vocation was viewed as a measure to aid the delivery of primary care, while extending the practice of physicians.

The first program in the nation to train physician assistants was established at Duke University in 1967. The program’s goal was to make health-care available to all people, especially those living in underserved areas. Federal grants allowed the expansion of physician assistant programs, and between 1970 and 1980 the number of programs grew from 12 to 56.

Education Programs

Today, about 12,000 students are enrolled in 141 accredited physician assistant educational programs in the nation. Most programs (121) offer students the opportunity of earning a master’s degree. The other programs allow students to earn either a bachelor’s degree or an associate degree. Each program has its own admission requirements, but all require at least 4 years of college and some healthcare experience prior to admission.

Like medical students, physician assistant students take a variety of science courses, such as biology, chemistry, and mathematics. They also take courses in various subspecialties, including pharmacology, human growth and development, and human physiology. The students receive their clinical training in various medical specialties, such as obstetrics-gynecology, general surgery, and otolaryngology. Depending on the program, some students have the option of serving on more than one clinical rotation.

Physician assistants are not bound to one specialty. That is, if a physician assistant wants additional education to gain new skills, he or she has the option of doing so. For example, it is common for physician assistants to receive additional instruction in specialties such as pediatrics or

emergency medicine. To meet common healthcare challenges found in underserved areas, many physician assistants enroll in postgraduate educational programs that emphasize disciplines critical to rural and/or inner-city communities.

Licensure

To gain licensure, each state requires a physician assistant to complete an accredited, recognized curriculum of study as well as pass a qualifying examination. Physician assistant programs typically last 2 years and require full-time attendance. Some courses in the curricula are given in university health clinics, medical schools, and traditional colleges and universities, while others are given at community colleges, in military establishments, or in hospitals.

Each state and the District of Columbia have laws specifying the requirements and qualifications needed to become a physician assistant. All require physician assistants to successfully pass the Physician Assistant National Certifying Examination (PANCE), which is given by the National Commission on Certification of Physician Assistants (NCCPA). The examination is available only to graduates of accredited physician assistant education programs. To retain certification, physician assistants need to take 100 hours of continuing medical education every 24 months. Every 72 months, they must take a recertification examination.

Scope of Work

All professional medical services provided by physician assistants are under the guidance of a physician. However, in many rural areas where there are few physicians, the physician assistants are often the primary medical-care providers. In scenarios such as this, the physician assistants discuss each case with the overseeing physician, as mandated by statutory law. Unlike many physicians, physician assistants visit patients in their home, travel to various hospitals and nursing homes to see how patients are progressing, and then report everything back to the physician.

Like physicians, physician assistants often specialize in areas such as general practice, cardiology, and psychiatry. Other specialty areas include

neurology, internal medicine, and surgery. Physician assistants with specialties in surgery provide both preoperative and postoperative treatment and are often the physician's primary assistants if major surgery is required. The physician assistant's work setting depends on his or her supervising physician. For example, some work mainly in an office, whereas others assist with surgeries. Physician assistants working in hospitals usually have a variety of schedules and are often on call. On the other hand, physician assistants employed in physicians' clinics usually work 40 hours per week.

Future Implications

The demand for physician assistants is expected to continue to grow in the future much faster than the average job growth for all occupations in the nation. The U.S. Bureau of Labor Statistics projects rapid job growth for physician assistants because of the general expansion of healthcare and an emphasis on cost containment, which will result in the increasing use of physician assistants by healthcare organizations. Job opportunities will likely be in rural and inner-city clinics because these settings have difficulty attracting physicians.

PHYSICIANS

Physicians are medical practitioners who focus on improving human health through the study, diagnosis, and treatment of disease and injury. Physicians are able to apply their knowledge and the science of medicine after much training and specialized studies. Physicians play a vital role in the nation's healthcare system, and they may work directly with patients in a clinical setting or conduct medical research. Although physicians make up less than 10% of the nation's total medical workforce, they command enormous resources, and the entire healthcare industry is usually subordinate to their professional authority in clinical matters and research.

Overview

Modern medicine in the United States dates back to the latter half of the 18th century when the first medical school was founded at the University of Pennsylvania. Quickly thereafter, there was a push to standardize the practice of medicine. In 1847, the American Medical Association (AMA) was established; with this came the initiation of licensing laws and accreditation standards for medical schools. The strength of the AMA was illustrated with the publication of the landmark report *Medical Education in the United States and Canada*, more commonly known as the Flexner Report, in 1910, which subsequently led to the closure of a number of medical schools that did not meet the AMA's criteria. Another consequence of the Flexner Report was the curtailment of the supply of physicians. Standardization of medicine continued in many ways, including the establishment of the National Board of Medical Examiners (NBME) in 1915, whose function was to administer

a standardized licensing examination to physicians, the United States Medical Licensing Examination (USMLE).

Entrance Into Medical School

Motivations to enter the field of medicine, while unique to the individual who pursues this path, generally include factors such as the desire to help others in a healing capacity, service in the context of science, technology, and research, and preference for an autonomous profession. Medical school admission requirements include successful completion of the Medical College Admissions Test (MCAT), a standardized test comprising three sections of physical sciences, biological sciences, and verbal reasoning, scored from 1 to 15 points, as well as two writing samples. An application is typically submitted through the American Medical College Application Service (AMCAS), which processes applications for the majority of allopathic medical schools, or through the American Association of Osteopathic Medicine (AACOM) for osteopathic medical schools.

This highly selective and competitive process draws serious and motivated students. Applicant data are collected annually and shows that most accepted applicants earned an average of 10 to 15 points on each section of the MCAT. Moreover, they have an undergraduate cumulative grade point average in science of 3.75 on a 4.0 scale. Recently, there have been an increasing number of female applicants to medical schools, and approximately 60% of students are female. Most applicants are White. Blacks, Native Americans, Mexican Americans, and mainland Puerto Ricans comprise about 12% of all medical students, while these groups together comprise about 20% of the nation's overall population.

On graduating from medical school, physicians enter medical residency programs to continue their training. These programs run from 3 to 8 years in length, and, generally, osteopathic physicians must complete a 12-month rotation prior to entry. After residency, physicians obtain a state license to practice medicine. Licensing laws are set by state boards of medicine that require graduation from an accredited medical school and passing the three steps of the USMLE to obtain a license. Furthermore,

these boards set certain standards for physicians, such as qualifications for a license and standards of practice, and they have authority over disciplinary action.

Allopathic and Osteopathic Physicians and International Medical Graduates

All physicians, including allopathic physicians (MDs) and osteopathic physicians (DOs) have the role of evaluating, diagnosing, and treating patients. However, these medical providers accomplish their goals in distinct roles, as most MDs are specialists whereas most DOs are primarily general practitioners.

Allopathic medicine is generally regarded as the traditional (Western) practice of medicine and its study leads to the doctor of medicine degree (MD) in any of the 126 accredited schools of medicine in the nation. These schools are accredited by the AAMC and graduate about 14,500 students per year.

Osteopathic medicine, however, has a history distinct from the allopathic school of thought. In 1892, Andrew T. Still, the father of osteopathic medicine, founded the American School of Osteopathy, which has since changed its name to the Kirksville College of Osteopathic Medicine, in Kirksville, Missouri. The school was founded on the core beliefs of osteopathy that stress holistic medicine, manipulative therapies, and the importance of the neuromusculoskeletal system. These beliefs still prevail today and are taught in conjunction with academic courses similar to those offered in allopathic schools of medicine. At the completion of their four-year education in one of the 19 U.S. osteopathic schools of medicine, osteopathic students earn a DO (or doctor of osteopathy or doctor of osteopathic medicine) degree, and they can then enter into either osteopathic or allopathic residency programs. About 2,500 students graduate from osteopathic schools of medicine annually, and about two thirds of DOs go through allopathic medical residencies. Ultimately, most DOs are in general practice, and they account for about 6% of all active physicians in the nation.

International Medical Graduates (IMGs) comprise about 25% of all residency positions and account for about a quarter of all active physicians in the nation. These individuals have graduated

from medical schools in countries outside the United States, including Puerto Rico and Canada. The Educational Commission for Foreign Medical Graduates (ECFMG) must certify IMGs prior to their entrance into U.S. graduate medical education programs. To receive certification, IMGs must pass both the Test of English as a Foreign Language (TOEFL) and the USMLE. In addition, as of 1988, IMGs must also pass the Clinical Skills Assessment (CSA) examination. Many influential organizations, including the AMA, the national Institute of Medicine (IOM), and the Pew Health Professions Commission have called for a reduction in the number of IMGs in residency programs citing the fact that they are not helping the problem of the maldistribution of physicians in the nation. Despite the fact that most IMGs train in underserved areas, most practice in nonunderserved areas.

Need for Physicians

The federal government plays an important but indirect role in the number of physicians in the United States by funding both medical school education and medical residency programs. Moreover, the government also influences the number of physicians practicing in specialties or primary care by regulating the amount of funds for training in these areas. Importantly, some believe that access to healthcare itself can be managed by exercising control over the supply of physicians.

Supply of Physicians

In the early 1960s, the ratio of physicians to the population was 140 physicians per 100,000 people in the nation. Many felt this ratio was too low and that there was a national physician shortage. To overcome the shortage, the U.S. Congress enacted the Higher Education Facilities Act (PL 88-204) in 1963, and efforts were made to both increase the enrollment of students in existing medical schools and create new schools across the nation. Eventually, 40 new medical schools were created, and many more physicians graduated from medical school. By 1980, the ratio of physicians to the population rose to 202 physicians per 100,000 people. The federal Civil Rights Act of 1964 (PL 88-352) also increased the national supply of physicians, particularly of Blacks and

women. In fact, between 1965 and 1999, the number of women graduates from the nation's medical schools increased from 7% to 43%. Similarly, there was an increase in the total number of women physicians in active practice from 7% in 1970 to 21% in 1999.

The Graduate Medical Education National Advisory Committee (GMENAC), which consisted of a panel of prominent experts, was established in 1976 to assess the success of the effort to overcome the national physician shortage problem. Commissioned by the U.S. Department of Health and Human Services (HHS), GMENAC was given the task of determining the following: (a) the number of physicians required to meet the healthcare needs of the nation, (b) the most appropriate specialty distribution of these physicians, (c) the most favorable geographic distribution of physicians, (d) appropriate ways to finance the graduate medical education of physicians, and (e) the strategies that can achieve the recommendations formulated by the committee. GMENAC published its findings in 1980 and concluded that there was no longer a national shortage of physicians. Rather, it predicted, there would be an excess number of physicians by the 1990s. Also, the committee noted concerns related to geographic and primary-care shortages, specifically in the areas of general medicine and child psychiatry, and failure to meet its suggested ratio of between 145 and 185 physicians per 100,000 people. The trend of training more physicians continued, with the number of physicians in the nation increasing by 173% between 1950 and 1990. Consequently, the Pew Commission published data in the mid-1990s predicting that there would be a surplus of physicians and called for the closing of 20% of medical schools and for a 25% reduction in the number of medical residency positions. Along with the increasing number of physicians there were also rising costs associated with their training. To curtail this, the federal Balanced Budget Act of 1997 capped the total number of medical residents funded by the Medicare program and also reduced payments to residency programs.

Demand for Physicians

The demand for physicians is a function of access to healthcare. The total number of physicians and the physician to population ratio do not present an

entirely accurate picture of access to care, as there are significant problems with the maldistribution of providers. In particular, physicians are not evenly distributed across geography or by specialty, which has resulted in shortages in rural areas and in primary care. The geographic maldistribution of physicians generally means that some areas lack adequate numbers of physicians whereas others have a sufficient number or even an oversupply. There are severe shortages of healthcare services in many rural areas, particularly in areas with populations of less than 5,000 individuals. People who reside in these areas must rely on only 5 physicians per 10,000 residents. Approximately 20% of the nation's population lives in these areas, which only have about 9% of the nation's physicians. Furthermore, although cities generally report an adequate number of practicing physicians, in many instances, they are not distributed equally within the cities. As a result, there are local communities that need more physicians. In fact, some urban areas have physician to population ratios as low as 10 physicians per 100,000 people.

Some steps have been taken to compensate for these shortages of physicians. In 1970, the federal National Health Service Corps (NHSC) was established with the mission of recruiting and retaining physicians and other health professionals in shortage areas. To entice people to join the NHSC, scholarships and loan repayments are offered, providing that the minimum 2 years of service are completed. This program has placed more than 20,000 health professionals since its inception. Additionally, guidelines were developed for the designation of Medically Underserved Areas (MUAs) in 1973. MUA status was determined by using a four part Index of Medical Underservice that looked at the percentage of the population below the federal poverty level, the percentage of the population 65 years of age or older, the infant mortality rate, and the physician to population ratio. In 1976, similar guidelines were set for the designation of Health Manpower Shortage Areas (HMSAs) under the Health Professionals Education Assistance Act. These guidelines outlined three different types of primary-care HMSAs: (1) geographic areas, (2) population groups, and (3) medical facilities. Another effort to combat the geographic shortage of physicians was the development of Community and Migrant Health Centers

(C/MHCs), which have been important in providing services to patients in rural areas. For example, in 2000, about 53% of all C/MHCs were located in rural areas and served more than 9 million people. The enactment of the federal Rural Health Clinics Act in 1977 instituted a successful reimbursement strategy to help deal with the lack of physicians in rural areas. This legislation allowed physician assistants, nurse practitioners, and certified nurse midwives associated with rural clinics to practice without the supervision of a physician. Also, this act gave rural health clinics eligibility for reimbursement from Medicaid at a higher rate, matching that provided by Medicare.

Medical schools have also taken steps toward overcoming the physician shortages in rural areas. Schools such as Philadelphia's Thomas Jefferson School of Medicine and the University of Illinois College of Medicine have implemented programs to deal with geographic shortages. A 2001 study of the Physician Shortage Area Program of the Thomas Jefferson School of Medicine found that it was successful in contributing to the supply of physicians practicing in rural and underserved areas. The study noted that the program's selection criteria, which almost exclusively favor admission for students from rural areas, coupled with its emphasis on primary care during training were the key reasons for its success.

The imbalance between specialists and primary-care physicians is another obstacle limiting access to healthcare. Reasons for specialty maldistribution include medical technology, reimbursement methods, and specialty-oriented medical education. Medical technology is expanding at a rapid pace, and it may appeal to medical students who are further attracted into specialties because their training is organized around it. Moreover, reimbursement and remuneration of specialists is higher compared to primary-care physicians, which may deflect interest in pursuing a career in primary care. These factors have been linked to fluctuations in the number of medical students who match residencies in internal medicine, pediatrics, and family care. These fields were most popular in 1998 and had a match rate of 53%, but interest has dropped, and in 2002 only 44% of students matched in these areas of practice. Specifically, rates between 1998 and 2002 decreased from 24% to 22% in internal medicine, 16% to 10% in family medicine, and

13% to 12% in pediatrics. However, it is difficult to predict the numbers of medical residents who will actually practice in primary care, since many of them enter fellowship programs and subspecialize. This dichotomy has grown larger over time, such that two thirds of physicians are specialists.

Impact of Managed Care

Managed care has greatly influenced the practice of medicine. Managed-care organizations such as health maintenance organizations (HMOs) and preferred provider organizations (PPOs) were the preferred choice of employers and the government in the 1980s as a means to contain the costs of healthcare. Managed-care organizations either contract with physicians or directly employ them. They use three principal types of payments: (1) payments to preferred providers with discounted fee schedules, (2) capitation payments, and (3) salaries. The consequence is that these organizations exercise control over physicians by way of constraints on payments, and they tend to use a capitation or discounted rate payment scheme. This approach results in disincentives for physicians to refer patients to specialists and to limit inpatient hospital stays. The use of primary-care physicians as gatekeepers to specialty care has also jeopardized patient care by imposing barriers to specialty care. On the other hand, the managed-care organizations offer incentives to physicians depending on their productivity. Despite this, the objective of cost containment has not been realized since the wide-scale implementation of managed care. And healthcare costs continue to rise.

Future Implications

In 2009, there will be about 890,000 active physicians in the United States, or approximately 295 per 100,000 people. Future projections, however, indicate that there will be a growing national shortage of physicians. According to several reports, although the total number of physicians will increase, the demand for their services will outpace supply. Factors such as the accelerating rate of retirements of older physicians, the aging of the nation's population, with associated chronic medical conditions, and restrictions on the number of hours medical residents work will contribute to

the physician shortages. To prevent the shortage, there is a push to increase the enrollment of students in medical schools across the nation. While this is a feasible solution, its effects will not be realized in the short term, because it takes 12 to 15 years to train a physician. Also, financial factors complicate this issue and influence the number of students who apply to medical school. It is problematic that the costs of education have consistently risen against a background of decreasing physician reimbursement. With an average of about \$200,000 in educational costs incurred postgraduation, coupled with less return on the investment today as compared with the past, interest in medicine has declined and so have the number of applicants to medical schools. A more immediate solution to the shortage of physicians may be achieved by having a greater number of IMGs enter residency programs. Another possibility is the greater use of nonphysician practitioners (NPPs), who represent a large portion of health-care providers. Specifically, nurse practitioners (NPs) and physician assistants (PAs) are popular medical careers that can be helpful in combating the need for care in underserved areas at a lower cost, typically 40% less than the cost of a physician. NPs, who complete registered nursing degrees in addition to extended study, are able to write prescriptions in most states. PAs practice under the supervision of a physician and also tend to practice in primary-care fields. Pooling resources from multiple areas, including more domestic medical graduates and IMGs, along with the greater use of NPPs, will help to equilibrate the imbalance between physician supply and demand and also promises to help with the problem of geographic and specialty maldistribution.

PHYSICIANS, OSTEOPATHIC

There are currently about 61,000 osteopathic physicians in the United States; they constitute about 7% of the nation's practicing physician workforce. But osteopathic physicians are responsible for

16% of patient visits in small communities with populations of fewer than 2,500 individuals. In addition, 22% of all osteopathic physicians practice in rural and medically underserved areas.

The osteopathic medical philosophy emphasizes preventive care and focuses on the unity of all body parts. Instead of just treating specific symptoms or illnesses, osteopathic physicians regard the body as an integrated whole, and they help patients develop attitudes and lifestyles that help prevent illness. Like allopathic physicians, osteopathic physicians are fully licensed to prescribe medications and practice in all medical specialty areas, including surgery.

Osteopathic physicians also receive extra medical training in the musculoskeletal system, the body's interconnected system of nerves, muscles, and bones that make up two thirds of its body mass. This training provides osteopathic physicians with a better understanding of the ways that an injury or illness in one part of the body can affect another.

Furthermore, osteopathic physicians incorporate osteopathic manipulative treatment into their medical care. With this treatment, osteopathic physicians use their hands to diagnose injury and illness and to encourage the body's natural tendency toward good health.

Background

Andrew Taylor Still (1828–1917) was the father of osteopathic medicine as well as the founder of the first college of osteopathic medicine. Born in a log cabin in Jonesville, Virginia, Still decided at an early age to follow in his father's footsteps and become a physician. As an apprentice physician to his father, he learned both from being at his father's side as well as from the course of study. Still later served in the Civil War as a surgeon in the Union Army.

It was not until the early 1870s that Still separated himself from his allopathic counterparts by his pervasive criticism of the misuse of drugs common in that day. Believing that medicine should offer the patient more, he supported a philosophy of medicine different from the practice of his day, and in its place he advocated the use of osteopathic manipulative treatment.

Still identified the musculoskeletal system as a key element of health and recognized the body's

ability to heal itself. He stressed preventive care, eating properly, and keeping fit. In 1892, Still founded the American School of Osteopathy, now known as the Kirksville College of Osteopathic Medicine of the A. T. Still University of Health Sciences, in Kirksville, Missouri.

Osteopathic Medical Education

Currently, there are 26 osteopathic medical schools in the United States. Students in these programs take courses in anatomy, physiology, microbiology, histology, osteopathic principles and practices, including osteopathic manipulative medicine, pharmacology, clinical skills, physician–patient communications, and systems courses that focus on each major system of the body, such as the cardiac and respiratory systems.

Many osteopathic medical schools have students assigned to work with physicians beginning early in their 1st year of study. This process continues throughout the 2nd year in conjunction with the necessary science courses. In the 3rd and 4th years, osteopathic medical students spend time learning about and exploring the major specialties in medicine through clinical rotations.

One unique aspect of the osteopathic medical student's education is how these rotations are conducted in community hospitals and physicians' offices across the nation. Because few osteopathic medical colleges have their own hospitals, the schools partner with community hospitals to deliver the final years of curriculum as well as internship and residency training. This model of medical education developed by the osteopathic medical profession has been touted as the new model for all medical education. Current pilot studies are being developed on a national level to evaluate this model of medical education.

Medical Licensure

Licensing boards in each state provide osteopathic physicians with licensure to practice medicine. Requirements vary by state, but there are generally three ways an osteopathic physician can become licensed. First, osteopathic physicians must successfully complete a medical licensing

examination administered by the state licensing board. State boards may prepare their own examination or administer an examination that has been prepared and purchased from a specialized agency. Today, the United States Medical Licensing Examination (USMLE) and the Comprehensive Osteopathic Medical Licensing Examination (COMLEX-USA) are the most widely used tests. The osteopathic physician can also accept the certificate issued by the National Board of Osteopathic Medical Examiners (NBOME), awarded after an applicant has satisfied the requirements, including the successful passage of a rigorous series of tests. Finally, licensure can be granted through reciprocity or endorsement of a license previously received from another state. This typically has to be issued on the basis of a written examination.

Future Implications

Osteopathic physicians are one of the fastest growing segments of healthcare professionals in the nation. By the year 2020, an estimated 100,000 osteopathic physicians will be in active medical practice. Approximately 60% of all practicing osteopathic physicians specialize in the primary-care areas of family practice, internal medicine, obstetrics and gynecology, and pediatrics. Many of these physicians will continue to fill a critical need by practicing in rural and medically underserved areas of the nation.

PHYSICIAN WORKFORCE ISSUES

The rate of change throughout the healthcare industry has had profound effects on the composition of the physician workforce. Yet while many health services researchers study issues involving the physician, including healthcare insurance and managed care, quality of care and outcomes, and malpractice and tort reform, direct evidence of changes in the physician workforce is relatively scant. Researchers, however, are able to use information from the studies that do exist to help develop efficient and effective healthcare management and policy.

Nature and Function of the Physician Workforce

More than 15 centuries ago, the Greek physician Hippocrates advocated that all physicians pay attention to the individual patient. In this rebellion against the Cnidian convention that favored diagnosis and classification of diseases, Hippocrates modernized the practice of medicine. While the physician has historically trained as an apprentice and basic responsibilities have remained the same over time, the physician is no longer simply someone who is a skilled healer. Today's physician is a healer who is formally trained—and legally qualified—to practice medicine. More stringent standards have existed only since the early 20th century, when Abraham Flexner's report on the status of medical education in North America

largely resulted in the advent of scientifically based university medical schools and teaching hospitals similar to those that had been established in Europe.

The physician workforce is presently composed of individuals educated and trained in primary care and various specialties. A primary-care physician is a Medical Doctor (MD) or Doctor of Osteopathic Medicine (DO) who, as a generalist, serves as the patient's first entry point into the healthcare system; a specialist physician is one who is qualified to diagnose and care for specific ailments or injuries. Physicians also may choose to practice in surgical specialties, which include the branches of medicine that treat injury or disease by operative procedures, or medical specialties, which include the branches of medicine that deal with nonsurgical techniques.

Various specialty boards, recognized by the American Board of Medical Specialties (ABMS) and the American Medical Association (AMA), individually certify physicians as specialists based on specific requirements, such as training, examination, and continuing education. Recognized specialties include the following: Allergy and Immunology, Anesthesiology, Colon and Rectal Surgery, Dermatology, Emergency Medicine, Family Practice, Internal Medicine, Medical Genetics, Neurological Surgery, Nuclear Medicine, Obstetrics and Gynecology, Ophthalmology, Orthopedic Surgery, Otolaryngology, Pathology, Pediatrics, Physical Medicine and Rehabilitation, Plastic Surgery, Preventive Medicine, Psychiatry and Neurology, Radiology, Surgery, Thoracic Surgery, and Urology. A majority of the specialties also acknowledge various subspecialties.

Many factors influence the choice of specialization as well as the choice to pursue a career in medicine. These factors become more defined as the individual's career, status, and function change over time. Among these factors are career opportunities; academic opportunities; practical experience during medical school; role models or mentors in the specialty; length of training required; lifestyle and work hours, especially during residency; likelihood of obtaining a residency position; concern about loans and debt; call schedules; post-training lifestyle, work hours, and financial rewards; intellectual challenges; interactions with patients; potential patient demographics; and

within-specialty gender distribution. Medical students also have expressed that receiving early exposure to positive role models and opportunities in a certain specialty is likely to influence their career pursuits in that specialty.

At the same time, lifestyle issues are increasingly and conclusively central to career choice decisions of medical school students. Measuring the determinants of specialty choice and overall satisfaction among generalists and specialists in different types of workplaces and organizations also requires the consideration of various factors, including possible postponement of family plans. And as the physician workforce experiences the introduction of younger professionals and the development of new opportunities for older ones, there is an increased need to consider the availability of role models and mentors, gender demographics, assurance in expressing emotions at work, development of personal relationships, parenthood during residency, family plans, and geographic location—all of which act as important factors in choices made by physicians throughout their careers. That is, the manner in which physicians view quality of life, both at work and at home, is of increasing importance when considering issues in and of the physician workforce.

Work Conditions

Although the majority of physicians continue to work in private offices or clinics, typically assisted by a small staff of nurses and administrative personnel, the professional lives of American physicians are increasingly—and almost entirely—being defined by group practice relationships and health maintenance organizations (HMOs). The HMO model, originated by Kaiser Permanente, is vertically integrated to link financial concerns with healthcare delivery and horizontally integrated to connect healthcare services, with the intent of providing continuity of care to patients who are members. This healthcare delivery structure is also designed to reduce scheduling and administrative by using a team approach to coordinating patient care. The model does, by definition, however, decrease the amount of independence solo practitioners experience by increasingly centralizing power within the organizational hierarchy.

Such organizational structures have had a significant impact on physician working conditions. Where excessive workloads, professional- and personal-time demands, and interpersonal communication hassles have long contributed to physician dissatisfaction at work, there are strong indications that HMO and other managed-care physicians base work satisfaction on a combination of professional expectations and characteristics of the workplace as well as whether they are working for one managed-care organization or more. As with physicians in other practice types, these physicians' satisfaction is based on the extent of autonomy, administrative issues, resources, work-related relationships, and the amount of time allotted to visit with patients. In keeping with Max Weber's early-20th-century analyses of bureaucratic organizations as fundamentally impersonal and constraining of individuals' behaviors, managed-care physicians increasingly report less job satisfaction as compared with nonmanaged-care physicians. The enjoyment that they individually sense in their daily work or career, however, is contingent on whether the physicians can accept the differences between work in the context of managed care and prior to its arrival.

Adaptation to the Work Milieu

Federal and state governments have taken interest in regulating the number of medical resident work hours, in response to growing public concerns over medical errors and the national Institute of Medicine's (IOM) seminal report, *To Err Is Human*. Although there is no conclusive evidence of a significant relationship between medical errors and the number of hours worked, the reduction in medical resident work hours has affected educational, practical, and patient care experiences. There is also a focus in government institutions and public and private organizations on modernizing information technology systems used by healthcare providers in ways that align with the implementation of service-outcome and quality improvement programs.

To further understand physicians' motivation to act on issues in the work environment, there must be an account of concerns over capitation-based income, negotiability of other work incentives, and whether physicians have autonomy when arranging work

schedules and the like. But physicians have also cited decreased control over medical decisions, decreased control over referral processes, the proliferation of malpractice lawsuits, ethical concerns due to managed-care arrangements, federal Health Insurance Portability and Accountability Act (HIPAA) compliance requirements, and reduced income as reasons for diminished satisfaction at work. Where these effects of managed care may be interpreted or overinterpreted by any human being as an affront to personal self-image, they may have a consequent effect on how physicians view their work environments and how they perform in them.

Time and Money

Irrespective of the type of organization or environment in which a physician practices medicine, the amount of time a physician spends at work may exceed an average of 60 hours per week, especially during medical residency. Physicians who are on call also have to contend with patients' concerns over the telephone and have to prepare to make emergency hospital visits; the emergence of e-mail as a physician-patient communication channel has also had an impact on physicians' time considerations. These considerations have emerged on top of the expansion of managed care, which has arguably had an adverse effect on the quantity and quality of time physicians can dedicate to patient care.

The requisite time commitments provide challenges in scheduling individually desired work shifts. In instances where physicians negotiate new and more flexible schedules, coworker resentment can emerge. Thus, physicians and the organizations for which they work are discovering that they have to amicably determine some form of compensation when desired schedules cannot be realized.

One potential trade-off to the amount of time spent in professional activities is the income generated by most physicians. The latest reports on physician distribution from the American Medical Association (AMA) and the U.S. Department of Labor (DOL) indicate that almost 900,000 active physicians in the United States practice professional activities in hospital-based, office-based, and academic medical settings. The number of physicians spread across these diverse practice settings, combined with an increasingly consumerist

healthcare system, are a cursory signal of the market forces that facilitate physician income streams. With incomes generally holding across the six-figure range, medicine remains one of the highest paid professions in the nation.

Yet physicians report that their service commitment is disproportionate to the financial reward. Physicians are seeing more patients, or have simply had to increase the price of their services, in an effort to keep pace with rising operational costs and the rate of inflation. This development runs in line with a public perception that physicians seek a “target income” that is accomplished through their increasing the volume of services. Plus, the relative disparity in income between specialists and primary-care physicians and the variability of income across the profession, combined with the implications of managed care, government reform, and the economy in general, have conceivably led many physicians to seek alternative sources of remuneration.

Malpractice and Tort Reform

Among the healthcare issues that further affect physician income is the current condition of medical malpractice litigation in the nation. The original intent of medical malpractice litigation, which first materialized in the nation during the 19th century, was to safeguard patients against sham or hazardous medical practices and to equitably compensate patients injured by such practices. Over time, and despite the medical profession having become more regulated, the per-person cost of malpractice litigation in the United States is proportionately more than that in any other country in the world. The considerable number of plaintiffs in medical malpractice cases who have received multimillion-dollar monetary awards has led to a widespread assertion that there is a national malpractice crisis. This crisis has in turn caused a great number of professionals in the healthcare field to share the belief that malpractice litigation has surpassed reasonable levels and that some correction is overdue. The concomitant fallout has profoundly affected the medical profession.

Physicians have recently experienced enormous changes with regard to professional liability insurance. These circumstances have been attributed to a systemwide failure to adopt tort reform that includes caps on noneconomic damages. This view

has been contrarily refuted by scores of plaintiff attorneys and like-minded advocacy groups. Increases in malpractice insurance premiums have nevertheless reached a point where many physicians have considered practicing without malpractice insurance coverage, while others have difficulty obtaining insurance—in some cases despite having never faced a claim. Coverage from many insurers has now become cost-prohibitive. The existing malpractice conundrum has thrown professional practices into a state of confusion.

Physicians generally function on the basis that a majority of the litigious claims are erroneous allegations made by patients whose medical cases resulted in negative outcomes. To whatever extent this belief is true, malpractice claims seem to be in large part contingent on the physician–patient relationship and how actively engaged the patient judges the physician to be when communicating during office, clinic, or hospital visits. Although effective communication between the physician and the patient is an obvious means toward reducing liability, the sheer number, financial and reputation costs, and jury awards associated with malpractice suits brought against physicians have also significantly contributed to a shift in the way physicians practice medicine.

In an attempt to avoid litigation, some physicians are said to be practicing defensive medicine, whereby patient care decisions are predicated more on reducing the physician’s liability risk than by what treatments may be considered accurately in the best interest of the patient. For example, physicians may feel compelled to order excessive tests, treatments, and services and may even avoid certain high-risk procedures and entire specializations altogether for fear of being sued for malpractice. As physicians increasingly diminish the types of procedures they are willing to perform and find their incomes being reduced by rising malpractice fees, a palpable cascade effect affects the delivery of care to patients. The decrease in income and decision-making opportunities may further help explain why physicians have been seeking out and clinging onto the vestiges of their autonomy and self-esteem.

Also striking is the finding that younger physicians are likely to seek a job as opposed to wanting to establish a practice. This trend may be due to a movement away from the less-satisfying,

productivity-based compensation of private practice, which has long been a risky but lucrative system for medical professionals. Even though production-based compensation leads to increased productivity among physicians, physicians have reported being satisfied when an emphasis is placed on quality of care and dissatisfied when productivity is emphasized in their work. This finding echoes earlier conclusions that time pressure may lead to suboptimal work performance and overall satisfaction levels, which lead to potential compromises in patient care. In today's healthcare system, the amount of time a physician spends with a patient or on a given task is regulated to an extent by the size and structure of the organization in which the physician works.

Demographic Changes

A number of economic factors have clearly influenced change throughout healthcare. Yet the central management concern in healthcare lies in two significant social transformations that have occurred with a minimum of attention: The older generation of physicians assert different expectations about their work as compared with the younger generation; and the physician workforce in the United States, which before the last quarter or third of the 20th century had been male dominated, is now becoming female dominated.

Many of the age-based changes may be seen in the contrasts between baby boomers, born between 1946 and 1964, and Generation X-ers, born between 1965 and 1981. Within the medical profession, baby boomers and the first half of Generation X comprise upward of 60% of the physician workforce, while the latter half of Generation X accounts for slightly less than 20% of the total. Physicians of the baby boomer generation experienced enormous practice management changes throughout their careers. They most likely began and spent most of their careers in private practice as solo practitioners or in small groups but are now likely to be employed by or associated with a large healthcare organization. Yet they may assert a sense of confidence about their work and are often accused of caring more about their work than their lives outside work. They convey satisfaction in their jobs because they are often at a point in their careers where they are given opportunities

to voice their opinions and make high-level decisions. And practicing medicine has provided a respectable level of affluence for most of them because of less-stringent economic constraints on medicine during the early and middle years of their careers. But younger physicians have entered the field during a time when medical-practice management has been increasingly enveloped by the bureaucratic systems of managed care.

Another change is that women now account for about half of all medical school applicants; 35 years ago, they comprised less than 1/10 of the applicant pool. While this shift may well alter the physical image of the physician in the popular imagination, the increasing number of women in the workforce has already changed things. Chief among the changes has been the growth in the number of women who join the physician workforce and who also continue to involve themselves in traditional roles at home, which has been the motive behind flexible work schedules. Female physicians born between the early 1960s and as late as 1980 were among the first physicians to demand flexibility and variety in their schedules. When these requests were accommodated by administrators, male physicians of the same generation requested similar elasticity in their schedules, and then so, too, did more senior physicians.

Information about physicians' attitudes toward work and home life is becoming more focused on illuminating physician-specific healthcare-related trends and could be integrated into plans to improve individual and organizational performance abilities and functions.

Physician Supply

There are now indications that the United States will face a shortage of physicians in the coming decades. Reasons for this supply shortage include the following: (a) the overall growth of the nation's population, (b) an increased demand for physicians' services due to economic expansion, (c) an increased demand for more medical care by aging baby boomers, (d) an increase in performance of physicians' services by nonphysician clinicians who will need to be supervised, (e) an increase in malpractice insurance premiums and concomitant legal issues, (f) insurance carriers that dictate practice methods and income, (g) salaries that lag behind

the rising rate of inflation, (h) the retirement of practicing physicians, (i) a decline in physician work effort, (j) the suddenly low number of applications to medical schools, and (k) geographically dependent lifestyle effects. As the composition of the physician workforce continues to change, and with it ideas about the length and meaning of work, questions abound as to how positions will be filled throughout the workplace.

Future Implications

Contemporary healthcare facility and medical school administrators must contend with challenges related to physician recruitment and retention, especially as the U.S. population consumes more healthcare as it moves through midlife and into old age. But complex social, economic, political, organizational, and individual factors have influenced the creation of new institutions throughout healthcare. To understand and capably manage the new aims, physicians and their employers, patients and their advocates, politicians, and the press will have to examine all facets of the physician at work. It is physicians who on a daily basis participate in healthcare more than any other stakeholder, which means that they are a valid point from which to assess the thoughts and behaviors of the people, organizations, and systems that have an impact on healthcare.

PREFERRED PROVIDER ORGANIZATIONS (PPOs)

A preferred provider organization (PPO) is a healthcare delivery system where providers contract with the PPO at various reimbursement levels in return for patient steerage into their practices and/or timely payment. PPOs differ from other healthcare delivery systems in the way they are financed as well as by providing more choice, benefit flexibility, and enrollee access to providers and medical services both in and out of network.

History

While PPOs have been in existence in some form or another for decades, the development of modern

PPOs was the result of key legislative actions at the state and national level. In the 1970s and 1980s, many states passed enabling legislation to specifically allow for the development of PPOs. In 1974, the U.S. Congress enacted the Employee Retirement Income Security Act (ERISA). A very small portion of this law gave Taft-Harley Funds and other organizations the right to self-insure their healthcare benefits. Under the new law, organizations that self-insured would not be subject to various state coverage mandates or to state premium taxes; instead, they were now free to develop employee healthcare benefit programs. Recognizing the unique opportunity, third-party administrators began providing some or all of the services required by the self-insuring companies.

As a rule, however, these third-party administrators did not develop their own delivery networks and instead looked to another fledgling group of companies—preferred provider organizations—to credential and supply networks of physicians and healthcare institutions. Insured products grew and employers and other purchasers came to see PPOs as the middle ground between health maintenance organizations (HMOs) (traditionally lower cost but more restrictive) and indemnity insurance plans (permissive but more expensive). This fueled the development of local PPO organizations in the 1970s and 1980s and—beginning in

the 1990s—encouraged the expansion of a limited number of national PPOs. The growth in PPO plan enrollment at the expense of traditional indemnity insurance and point of service plans is shown in Figure 1.

Today PPOs are tremendously popular. Over the past few years, there has been a consolidation of the PPOs marketplace resulting in fewer regional PPOs and larger national plans as regional plans merge or are bought by larger national plans.

In 2007, more than 158 million individuals were enrolled in a PPO program, which represents 64% of all Americans with healthcare coverage. One reason for this strong market share is that PPOs have delivered what the public has called for: choice, flexibility, and a balance between delivery of appropriate care and cost control.

Characteristics and Types of PPOs

There are two basic types of PPOs: a nonrisk PPO and a risk PPO. A nonrisk PPO's primary focus is to contract with providers in a geographical area to form an interconnected network of providers and services. The nonrisk PPO network leases and/or "rents" its network for a fee to insurance companies, self-insured employers, union trusts, third-party administrators, business coalitions, and associations. In contrast, a risk PPO assumes the financial risk for an enrollee's healthcare costs.

Figure 1 A Comparison of Medical Plan Enrollment, 1993 to 2006

Source: Association of Preferred Provider Organizations (2007).

Traditionally, insurance companies offer a risk PPO that includes a benefit plan and network services either provided by the risk PPO or leased from a nonrisk PPO.

Insurance companies own most PPOs. They are also owned by hospitals, hospital consortiums, individual entrepreneurs, and private equity groups.

Enrollees in PPOs typically have benefit plans that provide both in-network and out-of-network coverage. Enrollees who seek care from providers within the PPO network receive in-network coverage, generally at a greater benefit level or lower coinsurance or copayment. Enrollees may still seek care outside the PPO network, but the benefit level is usually lower, and the enrollee may incur additional costs due to balance billing from the nonnetwork provider. Enrollees can choose, each time they seek care, to use an in-network or out-of-network provider. PPOs benefit enrollees by supporting their need to take a more active role in their healthcare.

PPOs also benefit providers. The financial considerations of the PPO healthcare delivery model do not override patient care decisions but rather work in conjunction with PPO providers in delivering patient care.

Claims from providers are usually handled in several ways. The PPO can give access to its fee schedule to the claims-paying entity. This is often done by providing a computerized record of the payment amount. If the PPO does not share its fee schedule with the payer, the PPO usually reprices the claims and then sends them to the payer, which pays the bill. Claims from hospitals and professional providers are sent to the PPO. The PPO adds information to each claim about the fees that should be used to process the claim. The fee information includes the PPO's negotiated and contractual rate. The claims are then sent to the paying entity (HMO, insurance company, third-party administrator) for processing. Of course, some PPOs pay claims for all providers as well.
