In addition to comprehensive network PPOs, some PPOs are dedicated to specialty networks. Specialty network PPOs facilitate and support the delivery of specialized healthcare services, such as dental, vision, chiropractic, radiology, behavioral health, and other areas. Often, these types of providers have unique reimbursement and benefit issues.

PRESCRIPTION AND GENERIC DRUG USE

The pharmaceutical industry in the United States represents a multibillion dollar a year enterprise that has helped fuel increasing healthcare costs. In 2006, America's spending alone on drugs increased to over \$250 billion, accounting for more than

41% of worldwide expenditures. New foreign markets, primarily in Asia, have seen more drastic annual expenditure increases than the United States, however. Reasons cited for the increase in drug expenditures include the introduction of new, more expensive drugs to the marketplace, a population that is aging and requiring more pharmaceuticals for disease management, increasing prices on the manufacture of existing drugs, and the use of drugs as a substitute for other forms of healthcare services.

Historically, the pharmaceutical industry has grown with the development of new drugs, new drug therapies, and the expansion of medical knowledge and practice. This expansion has required an increased focus on new drug efficacy and safety. Tighter government scrutiny and control have been realized through the Prescription Drug Marketing Act of 1987 and the U.S. Federal Drug Administration (FDA) approval process. Many, especially within the pharmaceutical industry, view the FDA's approval process as prohibitive; others view it as necessary to ensure public safety. The length of the approval process delays a drug's entry into the marketplace and quite possibly drives the developmental costs upward. It is estimated that the total development costs for a new drug in the United States, including losses to nonapproval of previous drugs, is around \$1 billion each year. The accepted estimate is around \$860 million per new medication developed, although some recent estimates put development costs at somewhere between \$500 million and \$2 billion per new drug. Companies try to recoup these costs as quickly as possible, which leads to higher prices when the drugs arrive on the marketplace for use by the public.

Although pharmaceutical companies typically receive a 20-year patent on the new drugs they develop, the FDA approval process may take as long as 12 years in and of itself. This lengthy period considerably reduces the effective income-producing potential of any new drug produced. Because of the shortened brand name shelf life for a drug, the companies must make profits within a relatively short amount of time. When the patent expires, other companies may produce the drug in its generic form. Generic drugs represent a cheaper alternative to the branded versions of the drug when released by the companies.

This entry presents an overview of the 12-step FDA approval process and discusses orphan and generic drugs. Then, this entry discusses the factors associated with those who use prescription drugs. Next, the prescription drugs' cost dilemma is addressed; and last, future implications are considered.

The FDA Approval Process

Once a pharmaceutical company has developed a new drug, the company must apply to the FDA for approval to market and sell the drug. The FDA process involves 12 steps, beginning with animal testing. This is designed to increase the size of clinical studies until the drug has been proven to have the desired effect while being safe.

Animal testing, referred to as preclinical testing, involves establishing the efficacy of the drug before it is given to humans. Many new drugs are stopped at Stage 1 because the FDA has not deemed the drugs reasonably safe for human usage because of their side effects or their lack of desired effect on the animals tested.

If the drug shows promise and is considered safe for further testing, a protocol for human testing is developed and must be approved by a local institutional review board (IRB) and the FDA in Stage 2. The IRB is composed of scientists and researchers who must determine whether human subjects are adequately protected from possible negative outcomes. It also determines whether the study is scientifically acceptable. This stage represents the company's proposal for clinical trials, involving human subjects, of the new drug.

Once the protocol is established and approved by the IRB, the company may move on to Stage 3 of the process. Stage 3 includes what is generally referred to as Phase 1 clinical trials. Phase 1 studies involve testing the drug on a small group of human subjects. The size of the group is generally between 20 and 80 healthy volunteers. The observance and notation of negative or frequent side effects of the drug is particularly important during Phase 1. If significant side effects are not detected, Phase 2 clinical trials may begin. Occasionally, alternative uses for a drug may be uncovered at this stage. That is, it is possible that a side effect may have a significant impact on another medical condition. An example of such unintended uses of a drug is

the case of AZT. AZT was originally developed as an anticancer drug in the 1960s, but its trial results were disappointing. Twenty years later, AZT was discovered to be a viable treatment for HIV/AIDS.

Phase 2 studies, Stage 4 in the FDA approval process, increase the size of the subject panels from several dozen to a few hundred participants. The focus of Phase 2 clinical trials shifts from the safety focus of Phase 1 trials to a focus on effectiveness. Safety is continually monitored, though. Rather than testing on healthy individuals, Phase 2 trials use volunteers with the condition that the drug attempts to alleviate. These studies often involve the use of cohorts comparing the effectiveness of the drug to a placebo. A cohort study represents a type of epidemiological approach to investigating the incidence and prevalence of disease across a fixed population group over time. Investigators compare outcomes between a group of individuals who have a risk factor believed to be associated with the outcome to a group without that factor. Cohort studies can be conducted prospectively or retrospectively, but the concept of control is extremely important to determining a drug's efficacy.

Should the evidence from the Phase 2 clinical trials point to the drug's safety and effectiveness, the pharmaceutical company moves its application to Stage 5 of the approval process. In Stage 5, Phase 3 clinical trials include a larger number of participants, usually up to a few thousand subjects, and they continue to scrutinize the safety and effectiveness of the drug. On successful completion of these drug trials, the process moves to Stage 6.

Stage 6 is sometimes referred to as the pre-New Drug Application, or pre-NDA, stage. At this point in the approval process, drug company representatives meet with FDA representatives to review the proposed product. If it is determined safe and effective, the pharmaceutical company moves to the next stage of the process.

Stage 7 involves the submission of the New Drug Application (NDA) to the FDA. The NDA represents a formal request from the pharmaceutical company for the FDA's approval of the drug. The FDA has 60 days to decide whether to consider approval. The agency's decision itself is considered Stage 8 of the overall process. A positive decision leads the FDA to file the application as Stage 9. It also assigns a team to evaluate the evidence collected from the three phases of the clinical trials.

In Stage 10 of the FDA approval process, the focus is on the review of the proposed labeling of the drug. The FDA ensures that the patient instructions are clear and understandable. Its review team also visits the pharmaceutical company's production facilities and evaluates its processes to ensure quality control in Stage 11.

Finally, in Stage 12 of the process, the FDA reviews all submitted evidence and documentation. The agency arrives at a final decision of "approvable" or "not approvable." Assuming that the data indicate an acceptable risk and demonstrable benefit, the drug is ready for manufacture and sale.

The length of time between drug development and sale is obviously long. For drugs that can potentially save patients with immediate and life-threatening conditions where no drug currently exists, the FDA may allow the company to engage in an accelerated approval process. This more expedient process involves using "surrogate endpoints" or alternative data to establish the drug's efficacy. In some cases, the larger Phase 3 clinical trials may be waived based on the promise of data from the smaller Phase 2 trials. Accelerated approval, however, is relatively rare. It tends to be used on drugs developed to treat diseases with very poor projected outcomes where other treatments have been shown to be ineffective. Most recently, drugs used to treat HIV/AIDS have been approved through an accelerated process because the benefits of the drug to patients are deemed to outweigh the risks when the disease is terminal.

The entire FDA drug approval process is designed to ensure the public's safety and its confidence that these drugs achieve the results that the pharmaceutical companies maintain. It is long, arduous, and expensive to the developers of new pharmaceuticals. Even then, however, it is still possible that long-term negative effects may surface at a later date, necessitating a change in the FDA's initial ruling. Therefore, even after a drug has obtained FDA approval, it is continuously monitored for safety. This postapproval safety monitoring may cost the pharmaceutical industry an additional \$50 million annually.

Orphan Drugs

Although the FDA approval process is clearly intended to protect the public's interest and

guarantee their safety, it can become cost-prohibitive for pharmaceutical companies to use their resources to develop drugs for conditions that affect a relatively small number of patients. Relatively rare diseases are sometimes referred to as orphan diseases. Similarly, drugs developed to treat such diseases are called orphan drugs. Orphan drugs have received special federal regulations that allow for a 7-year monopoly on the production of the drugs as well as tax reductions. The orphan drug rules are in effect for diseases that affect fewer than 200,000 people in the United States.

Generic Drugs

A generic drug is a prescription drug that is produced and sold without a brand name. Once the patent for a drug expires, companies may make generic versions for sale to the public. Generic drugs are generally less expensive than their branded counterparts, primarily because they are not advertised and because of increased competition among pharmaceutical companies. Many health insurance companies encourage their beneficiaries to use generic equivalents whenever possible because they provide significant cost savings. The Congressional Budget Office (CBO) estimates that generic drugs save consumers between \$8 and \$10 billion annually.

If a pharmaceutical company wishes to sell a drug as a generic, it must file an abbreviated new drug application with the FDA prior to introducing it in the marketplace. The company must demonstrate that the generic version of the drug is identical to the brand version in order to obtain FDA approval to sell the drug. Not only must the generic version be chemically identical, but the same strict manufacturing procedures previously adhered to for the brand version must also be used to make the generic version of the drug.

Some health insurance companies require the substitution of a generic equivalent to be covered. Patients who request not to receive a generic drug may have to pay the additional cost out of pocket. Not all drugs have generic counterparts, however. Presently, only around 50% of brand name drugs have generic equivalents. Patients desiring a generic equivalent may ask their physician if an equivalent exists and whether a substitution is appropriate.

Prescription Drugs Users

As previously mentioned, age is an important factor in who uses prescription drugs. The National Center for Health Statistics (NCHS) reports that nearly 85% of all Americans over the age of 65 had at least one prescription in the previous month and nearly 52% had three or more prescriptions. The percentage of those using prescription drugs increases steadily with age.

Gender also plays a significant role in prescription drug use. The data reported by NCHS indicate that a higher percentage of women use prescription drugs than do men across every age group except those under 18. Women are more likely than men to use prescription drugs across racial/ethnic groups as well.

Whites, for both men and women, are the most likely to use prescription drugs, followed by African Americans and Hispanics, respectively. Because access to prescription drugs is restricted, disparities in their use are similar to disparities in healthcare resulting from different levels of access to physician services and medical care.

Prescription Drug Cost Dilemma

The widespread use of generic drugs represents one way in which consumer costs can be reduced. Generic drugs are lower in price because they do not incur a number of the high costs associated with brand name drugs. First, there are no new research and development costs. Once a patent expires on a brand name drug, pharmaceutical companies can make generic equivalents through a reverse engineering process. Second, they do not have marketing costs. Generic equivalents tend to benefit from previously marketed brand drugs. In addition, companies tend not to provide free samples of generic drugs to physicians. Third, generic drugs do not have the costs associated with the 12-stage FDA approval process; rather, they only have to demonstrate the biochemical equivalence of the brand version. Finally, because multiple drug companies can sell generic equivalents after the patent expires, there is greater competition, which results in lower costs to the consumer.

The elderly have been especially affected by spiraling drug costs because they often live on a lower, fixed income than younger cohorts, and

older adults use prescription drugs more frequently. In 2003, the federal government enacted the Medicare Prescription Drug, Improvement, and Modernization Act, which is generally referred to as Medicare Part D, to assist the elderly in accessing necessary prescription drugs in a more cost-effective manner. Medicare Part D was implemented in 2006 and allowed eligible elderly and disabled Medicare patients to select enrollment into one of a set of government-approved private prescription plans.

Different approved prescription drug plans tend to cover different drugs. An early complaint from Medicare recipients about the selection process was that it was too complicated. The enrollee is expected to make a plan choice by matching a list of the prescriptions they receive against the lists of approved drugs and their prices to arrive at the most cost-effective choice given their personal situation. After initial problems, however, the process has gone considerably more smoothly. Revenues from Medicare Part D premiums are expected to be nearly \$750 million by the year 2015.

Future Implications

The use, and the expense associated with that use, of prescription drugs has spiraled upward in the past and is likely to increase even more in the future. As this happens, efforts to make drugs more accessible will escalate. In some cases, this may mean that some prescription drugs may be made available over the counter if they have demonstrated very long-term efficacy and safety. This practice allows greater exposure and availability of the drug to a wider public consumer audience. It also typically reduces the unit cost because of higher expected sales.

The percentage of the population, adjusted for age, that has received at least one prescription has increased from 38% in the early 1990s to over 45% in the early 21st century. For the elderly, the increase is even more dramatic. Pharmaceutical companies strive to bring more and better drugs to the marketplace as part of their financial strategic plans. The net effect on the consumer and the physician is a wider selection of drugs that can be used to treat a wider array of conditions.

PREVENTIVE CARE

Preventive care is a set of measures taken before symptoms begin to prevent illness or injury. While the number of preventive services has expanded in recent years, particularly in the areas of cancer and ischemic heart disease, preventive care is still best exemplified by routine physical examinations and immunizations. The emphasis remains to prevent disease before it occurs. Physicians, nurses, and public health officials perform preventive services in various settings, including physicians' offices, clinics, health departments, and hospitals. Public and private health insurance plans generally pay for preventive services, and the literature and expert consensus agree that healthcare systems focused on preventive care are more cost-effective. A number of barriers to preventive care exist, and medicine, public health, and policymakers must work to eliminate them.

Background

While traditional preventive strategies of medicine and public health, such as routine physical examinations and immunizations, have been around for many years, the science of preventive care was first formalized with the establishment of the U.S. Preventive Services Task Force (USPSTF) in 1984. The task force, first convened by the U.S. Public Health Service (PHS) and since 1998 sponsored by the Agency for Healthcare Research and Quality (AHRQ), is the leading independent panel of private-sector experts in prevention and primary care. The task force ensures that the clinical guidelines for providing preventive care are evidence based. Specifically, the task force conducts rigorous, impartial assessments of the scientific evidence for the effectiveness of clinical preventive services, including health screening, counseling, and preventive medications. Its recommendations are considered the gold standard for clinical preventive services. The task force is made up of primary-care clinicians along with nurses. The task force evaluates the benefits of individual services based on age, gender, and risk factors for disease and offers recommendations that have formed the basis of the clinical standards for many professional societies, health organizations, and medical

quality review groups. Its work has established the importance of including prevention in primary care and prompted insurance coverage for effective preventive services.

Types of Prevention

Preventive care can be categorized into three levels: (1) primary, (2) secondary, and (3) tertiary prevention. Primary prevention services avert disease development and include population-based health promotion activities such as vaccination and safe water supplies. Secondary prevention services target early detection of asymptomatic disease with the goal of preventing the progression of disease (exemplified by the pap smear to detect precancerous cervical changes). Secondary prevention services may also include prophylaxis to reduce the chance of disease recurrence (e.g., aspirin, blood pressure control, and lipid-lowering medications for the secondary prevention of ischemic heart disease following an initial myocardial infarction, or heart attack). Tertiary prevention services reduce the impact of already established disease. Preventive care encompasses both therapeutic interventions, such as immunizations or antibody prophylaxis and diagnostic examinations that screen for early asymptomatic disease. Screening examinations often detect early disease at a point where interventions improve health outcomes.

Preventive-Care Services

The historical foundation of preventive care rests on routine medical history taking, physical examination, and healthy lifestyle counseling, but rapid advances in medical technology provide new devices and laboratory tests to screen for disease. Amid the rapid growth of preventive-care services, clinicians must decipher the evidence of each service. The USPSTF offers the most rigorous evaluation of preventive services and provides guidance for clinicians to make evidence-based decisions. The task force's *Guide to Clinical Preventive Services, 2007* provides recommendations on 58 services made from 2001 to 2006. These services are grouped into clinical categories, including cancer; heart and vascular diseases; infectious diseases; injury and violence; mental health conditions and substance abuse; metabolic, nutritional, and

endocrine conditions; musculoskeletal disorders; obstetric and gynecological conditions; pediatric disorders; and vision and hearing disorders.

The task force recommends that clinicians discuss the 58 preventive services, based on their strength of evidence, with their eligible patients. The services include the following: abdominal aortic aneurysm screening (one-time screening by ultrasonography in men 65 to 75 years of age who have ever smoked); alcohol misuse and behavioral counseling interventions (for men, women, and especially pregnant women); aspirin for the primary prevention of cardiovascular events (for men and women at increased risk for coronary artery disease); asymptomatic bacteriuria screening (for pregnant women); breast cancer (mammography every 1–2 years for women 40 years of age and older and discussion of chemoprevention in high-risk populations); breast and ovarian cancer susceptibility (genetic testing and counseling); promotion of breastfeeding (structured education and behavior counseling for pregnant women); cervical cancer screening (for women over 18 who are sexually active); chlamydial infection screening (for women 25 and younger and other asymptomatic women at risk of infection); colorectal cancer screening (for men and women 50 years of age and older); dental caries prevention (oral fluoride supplementation to preschool children in areas where water sources are deficient in fluoride); depression screening (for men and women within established clinical systems); diabetes mellitus (Type 2) screening in adults (for men and women with hypertension or hyperlipidemia); diet counseling (for adult men and women with hyperlipidemia and other known risk factors for cardiovascular and diet-related chronic disease); gonorrhea screening (for all sexually active women at increased risk for infection, including pregnant women); prophylactic gonorrhea treatment (including ocular topical medications for all newborns); hepatitis B virus infection screening (for pregnant women at first prenatal visit); high blood pressure screening (for adult men and women at all visits); HIV screening (for all adolescents and adults at risk for HIV infection and all pregnant women); iron deficiency anemia prevention (including routine iron supplementation for asymptomatic children 6–12 months of age who are at risk for iron deficiency); iron deficiency anemia screening (for asymptomatic pregnant women);

lipid disorder screening (for men 35 years of age or older and women 45 years of age or older, and for younger adults with other risk factors for coronary disease); obesity screening (including intensive counseling and behavioral interventions to promote sustained weight loss for obese adults); osteoporosis screening (for women 65 years of age and older and women 60 years of age or older who are at increased risk for osteoporotic fractures); Rh(D) incompatibility screening (including blood typing and antibody testing at the first pregnancy-related visit); syphilis infection screening (for persons at risk and all pregnant women); tobacco use and tobacco-caused disease counseling (including cessation interventions for those who use tobacco); and visual impairment screening (for children younger than 5 years of age to detect amblyopia, strabismus, and defects in visual acuity).

It should be noted that the task force did not make recommendations for newborn screening, which aims to identify treatable genetic, endocrinologic, metabolic, and hematologic diseases. It also did not address immunizations.

Immunizations

Immunization is the process in which the body develops a defense against foreign agents (e.g., bacteria, viruses, and fungi). Exposure to these foreign molecules prompts the immune response to protect the body. A hallmark of the immune system is its memory. After first exposure to most agents, the human body develops immunological memory, such that later exposure to the same agent will result in quick, efficient, and successful protection from the agent. A common example is the lifetime protection conferred to most people after infection with *Varicella* (chickenpox). It is this feature of the immune system that provides the basis for successful vaccines, which have become a cornerstone of public health and preventive care. Under typical conditions, immunizations expose the body to nonvirulent doses of foreign agents, enabling it to develop immunological memory, which confers lifetime protection to the specific agent. Since the original work of Edward Jenner in the early 19th century, biomedical research has developed many successful vaccines, of which many are given routinely to children and are considered compulsory for attending school.

Immunizations have led to worldwide eradication of smallpox and the dramatic decline in mortality and morbidity from diseases such as polio, measles, diphtheria, whooping cough, hepatitis B, and bacterial meningitis.

The Advisory Committee on Immunization Practices (ACIP), a branch of the Centers for Disease Control and Prevention (CDC), provides evaluation of the literature and offers evidence-based recommendations for immunization schedules for adults, infants, and toddlers, preteens and adolescents, college students and young adults, parents, pregnant women, healthcare workers, people with specific diseases/conditions, racial and ethnic populations, and travelers. The ACIP is composed of 15 experts who are selected by the Secretary of the U.S. Department of Health and Human Services (HHS). This committee provides advice and guidance to the Secretary, the Assistant Secretary for Health, and the CDC on the control of vaccine-preventable diseases. The committee develops written recommendations for routine administration of vaccines with the goal of reducing the incidence of vaccine-preventable diseases in the nation and ensuring safe use of vaccines. Under this guidance, immunizations remain one of the most valuable services of preventive care.

Providers

Primary-care physicians (i.e., internal medicine, pediatrics, family medicine, and obstetrics and gynecology), nurses, physician assistants, and nurse practitioners represent the majority of the clinicians who provide preventive-care services on a daily basis. They provide these services in various settings, including physicians' offices, outpatient clinics, public health departments, and hospitals. Importantly, these professions have incorporated preventive care into their missions of providing care and ensuring health among their patients.

While primary-care physicians provide the bulk of preventive services, as recommended by the USPSTF, the profession of medicine further formalizes and emphasizes preventive care through designated training in the specialty of preventive medicine. Preventive medicine is one of 24 medical specialties recognized by the American Board of Medical Specialties (ABMS). The specialty encompasses multiple population-based and clinical approaches

to healthcare and draws on several core competencies, including biostatistics and epidemiology, management and administration, clinical preventive medicine, and occupational and environmental health. Board-certified physicians in preventive medicine can hold many positions within a variety of healthcare settings, yet a common undercurrent of their work in all venues involves an approach to health that seeks systemic and population-based interventions to improve the health of individuals.

Preventive medicine residencies are offered at more than 75 institutions in the nation and include a general medicine internship, a year of classwork to attain a master of public health (MPH) degree, and a year of practicum work, which is often tailored to an individual's career interests and aspirations. The three specialty areas within preventive medicine residencies are (1) public health/general preventive medicine, (2) occupational medicine, and (3) aerospace medicine.

Another venue for potential preventive care that has received much attention is the school—more specifically, the role of school nurses in obesity prevention. Schools present a critical setting for addressing the significant and increasing public health problem of childhood obesity. School nurses are uniquely positioned to address obesity and offer preventive services such as height, weight, and body mass index (BMI) measurements along with healthy diet and lifestyle counseling.

Reimbursement

The USPSTF's rigorous evaluation of the literature offers authority to clinicians' utilization of many preventive services. The consensus among clinicians, researchers, and public health officials regarding the value of routine preventive services, as recommended by the USPSTF and described above, has prompted their reimbursement by both public and private health insurance plans.

The nation's Medicare program, for example, offers its beneficiaries many preventive services, including screening tests for heart disease; mammograms, pap smears, and pelvic examinations; bone mass measurements; colon cancer screening; prostate screening; diabetes testing; diabetes self-management training; foot care and supplies; flu shots; pneumonia vaccine; hepatitis B vaccine; and glaucoma screening. Despite these services,

however, Medicare falls short of providing comprehensive preventive care for its beneficiaries. One deficiency is that Medicare only covers one routine preventive physical examination that must be received within 6 months of initial enrollment in the program.

All the nation's state Medicaid programs provide inclusive preventive care for eligible recipients, who are mostly children and pregnant women, groups that benefit significantly from preventive services. The Early and Periodic Screening, Diagnostic, and Treatment (EPSDT) service is Medicaid's comprehensive and preventive child health program for individuals under 21 years of age. Defined by law in 1989, the EPSDT includes periodic screening, vision, dental, and hearing services. EPSDT guarantees that physicians will provide initial and periodic evaluations of children and assures that health problems are diagnosed and treated early, preventing complications, and improving health outcomes.

Although private health insurance coverage varies with respect to the preventive services covered, most private insurance policies provide comprehensive preventive care, especially for children and pregnant women.

Cost-Effectiveness

Intuitively, it is easy to accept the notion that prevention is more cost-effective than treatment. However, with respect to medicine and public health, this notion needs to be verified with evidence. While an emerging body of literature supports specific preventive-care interventions, no studies of the overall cost-effectiveness of preventive services have been conducted.

Recent literature tends to show that the cost-effectiveness of specific preventive services depends greatly on the particular intervention and its target population. For instance, a recent systematic review of the cost-effectiveness of preventive interventions for Type 2 diabetes mellitus suggests that primary prevention of that disease is highly cost-effective. Other interventions, such as strict blood pressure control, have also been shown to be overwhelmingly cost-effective. However, other individual interventions aimed at lowering weight, average blood glucose, and cholesterol levels varied significantly in their cost-effectiveness.

Although much more research is needed, it appears that the potential impact of preventive care both economically and with respect to improved health outcomes may be highly significant. For example, it has been estimated that about 800,000 deaths in the nation (40% of the total annual mortality) in 2000 were from preventable causes, such as tobacco use, poor diet, physical inactivity, and alcohol misuse. It also has been shown that preventive measures, such as tobacco cessation programs and screening for colorectal cancer, can reduce mortality at low cost or even at cost savings. It seems logical that if preventive services were more widely used they would lower mortality and likely lower the total cost of healthcare.

Barriers

Individuals face a number of barriers to receiving preventive care. One important barrier is lack of health insurance coverage. It is clear that individuals without health insurance often delay needed healthcare and many times entirely forgo preventive care. However, even individuals with health insurance coverage face significant barriers to receiving preventive care. Many characteristics of the physician-patient interaction have been found to hinder the delivery of preventive care, including the following: the physician's attitudes toward prevention, unfamiliarity with the USPSTF's recommendations, belief that some healthcare services do not fall under the physician's scope of care; hurried office visits and lack of time to address prevention; lack of financial incentives to provide preventive care; and patients' attitude toward preventive care. Another important dynamic of the physician-patient relationship that affects preventive services is continuity of care. Several studies confirm that identifying a regular site of care is associated with increased access to preventive services, particularly for women and children. The medical literature supports the value of both site and provider continuity in preventive care. Despite the growing rhetoric among policymakers and politicians about the importance of preventive care, the day-to-day infrastructure of healthcare delivery does not support this ideal. And a concerted effort must be made to overcome the many barriers to preventive care.

sound and socially acceptable" way; it is "universally accessible" to all in the community who seek it; it is affordable; and it is geared toward "self-reliance and self-determination." Primary care includes basic, routine, and preventive care that is often provided in an office or clinic by a provider who coordinates all aspects of a patient's health-care needs. It is often the patient's first contact with the healthcare system for a given health problem. Physicians, nurses, or other healthcare professionals can provide primary care. Primary-care physicians are generally considered to include those trained in family medicine or general practice, general pediatrics, and general internal medicine. Sometimes physicians in obstetrics and gynecology are also considered primary-care physicians. After briefly discussing problems with the U.S. health services system, this entry summarizes primary care's role in health services and how health policies can foster the provision of quality primary care to patients.

Background

Every complex organization, whether biological or social, requires a framework to support and coordinate its different functions. Healthcare systems rank among the various social systems that require a unified framework for appropriate functioning. Among industrialized nations, the United States is an anomaly because it lacks such a unified framework. A highly developed nation with well-developed and long-standing systems in many areas, such as education, it lacks any semblance of a health services delivery system with a structural framework. Historically, health services developed without any planning or regulation of their supporting structures and rules of conduct.

As a result, the United States stands alone among industrialized nations in its inability to respond to new imperatives and new challenges to public health. At the mercy of unaccountable market forces, the healthcare system reacts unpredictably, or sometimes not at all, to changing needs of the population for services of various kinds. Market-oriented organizations, including private universities and hospitals, medical-device manufacturers, pharmaceutical companies, professional organizations, and disease-oriented consumer advocacy groups, can set agendas for the operation

PRIMARY CARE

Primary health care, as defined by the World Health Organization (WHO), is "essential health-care" that is delivered in a "practical, scientifically

of health services according to the likelihood of these services furthering the interests of the group in particular ways of defining health needs. They can create unwarranted health demands, particularly among population groups whose care contributes to high rates of profit for the industry. Some in the health services research field believe that the federal and state governments have abdicated responsibility or accountability. This current system has resulted in continuing escalation of costs, proliferation of unnecessary and potentially harmful technology, and declining population health as measured by the United States' relative position in the world.

Importance of Primary Care

Numerous research studies in the United States have found that a greater primary-care physician supply is associated with a variety of positive health outcomes, including fewer instances of all-cause mortality; cancer, heart disease, stroke, and infant mortality; low birth weight; increased life expectancy; and higher self-rated health. These results were consistent across study years and geographic areas. Pooled results for all-cause mortality indicate that an increase of one primary-care physician per 10,000 people is associated with an average mortality reduction of 5.3%, or 49 fewer deaths per 100,000 deaths per year. Mortality rate reductions for the Black population were higher than those for the White population, indicating improved equity and effectiveness. At a national level, a 5.3% reduction in all-cause mortality in the year 2000 would have translated into about 130,000 averted deaths. In comparison, a decline in the number of deaths of about 2,000 is considered sufficient to justify a national focus on screening the entire adult population for colorectal cancer. An increase of one primary-care physician per 10,000 people would require a 12.6% overall increase in the primary-care physician supply, or an absolute one-time increase of 28,726 primary-care physicians, based on the supply in the year 2000.

These results are consistent with international comparisons of nations differing in the strength of primary care. Nations with strong primary-care infrastructures have lower mortality rates, with the greatest reductions for causes particularly sensitive

to primary-care interventions, such as asthma, heart and cerebrovascular diseases, and pneumonia. These results remain consistent after controlling for other important influences on health, including differences in age structure of the population, income per capita, gross domestic product (GDP) per capita, and behavioral factors such as smoking and alcohol consumption.

The evidence of the benefits of primary care is not limited to studies of the supply of primary-care physicians. There are demonstrated benefits from improving access to and use of primary-care practitioners as people's regular source of care, as well as from better experiences with the four cardinal features of primary care, which are detailed below. The greater the reported use of primary-care physicians as the regular source of care, the better the 5-year survival rates of patients, even after controlling for a variety of sociodemographic characteristics and initial health status: the better the experiences with the receipt of primary-care services, the better the self-reported health.

Beneficial Impact on Health and Costs

Primary-care services are the supporting spine of healthcare systems by virtue of four cardinal features: (1) They are generally the first contact point of access and use, (2) they are person-focused care over time instead of being disease focused, (3) they are comprehensive in the sense of taking care of all health-related needs except those too uncommon to maintain competence, and (4) they coordinate and integrate care that is more appropriately provided elsewhere.

In combination, these four functions constitute primary care. Their achievement makes it possible for care to be patient focused, family oriented, and relevant to the needs of the community in which people live and work. Primary care, when organized to carry out these functions, makes it possible to achieve more appropriate, safer, and less costly care. It helps people navigate the healthcare system so that they avoid the unnecessary or duplicated interventions that increase the risk of adverse effects and that are becoming common in the experiences of people.

Evidence for the beneficial impact of each of the four cardinal features of primary care is strong. That is, the filtering of patients by primary care,

the first-contact feature, is effective in reducing unnecessary visits to specialists that both increase costs and increase the risk of overuse and adverse effects. Moreover, the person focus of primary-care practitioners leads to better overall improvement in health. The third feature of primary care, comprehensiveness, is an important contributor to the beneficial impact of primary care. The breadth of problems that are dealt with in primary care as opposed to being provided by specialists is the most consistent distinction between nations that have strong primary care and nations with weak primary care. Both national studies and international comparisons show that the greater the number of physicians involved in caring for an individual patient, the worse the outcome. And last, the coordinating feature of primary care is responsible for reducing duplication of medical tests and adverse effects of interventions. These four features, which in combination may be referred to as “primary-care practice,” are associated with increased access to care for relatively deprived population groups, improved quality of care overall, better preventive services overall, better early interventions for health problems, fewer hospitalizations, and reductions in referrals to specialists, with resulting better population health at considerably lower costs.

A focus on achieving the combination of these four features explains why studies of people’s experiences with primary care are even more consistent in showing benefits than are studies that seek to correlate the supply of primary-care physicians to health outcomes. The mere presence of such clinicians does not assure that good primary care is being provided; some population subgroups may lack access to existing primary-care resources, and some purported primary-care practices may not be adequate in their provision of first-contact, person-focused, comprehensive, and coordinated care. Moreover, an excess of directly accessible specialists may detract from the benefits of existing primary-care resources by discouraging coordination and person-focused care, as well as by leading to unnecessary and excessive interventions in the context of the patient’s needs. Studies in the United States have shown that a greater supply of specialists available to the population does not improve the outcomes of care and, in fact, often worsens it. In 35 research studies dealing with differences between various geographic areas and rates of

mortality (total deaths, deaths from heart disease, cancer, and stroke, and infant deaths), 28 of the studies found that the greater the primary-care physician supply, the lower the mortality. And in 25 of the studies, it was found that the higher the specialist to population ratio was, the higher the mortality.

Primary Care’s Growing Importance

Four major challenges to health services delivery in the nation will make the role of primary care increasingly important in the future. First, the morbidity burden of the population will increase as a result of increased survival from individual diseases. Most people, particularly as they age, accumulate a higher burden of morbidity—that is, comorbidity. Coexisting illnesses cause the focus of medical attention and quality assessments on particular diseases to be inadequate. Clinical practice guidelines are based, at best, on randomized controlled trials (RCTs) that attempt to exclude individuals with coexisting disease, even though they may constitute the majority of people otherwise eligible to participate in the trial. Consequently, the results of the trial are not applicable to most people with the disease for which the guidelines are implemented. A major, largely unrecognized defect in the application of results of the trials is the assumption that their findings apply to all populations even though it is known that the properties of tests and interventions differ according to the characteristics of the target population: general communities, patients in primary-care settings, or patients in specialty settings. When applied in a general community, in the example of fecal blood screening for colon cancer, the proportion of false-positive tests is much greater than would be the case if the intervention were applied in primary-care settings or specialty-care settings; intervention applied to the whole population will lead to many more unnecessary interventions, with a much greater likelihood of adverse effects and greatly decreased cost-effectiveness. For most medical interventions directed at individuals in the population, it is much more effective and efficient to focus on their application to patients in primary-care settings than in community-based settings, with referral to specialists from primary care as needed.

Second, an increase in the morbidity burden of the population exists because of growing rates of

diagnosis of existing and new health problems. In the past two decades, the prevalence of diagnosed disease has increased markedly, largely due to lowered thresholds for diagnosis of individual diseases or inclusion of one or more risk factors as a proxy for a diagnosed disease. The increase has greatly expanded the market for use of medications, many of which have subsequently been shown to be dangerous. Primary care bears the burden, from increasing workloads to the challenges of dealing with adverse effects.

A third challenge is presented by an increase in the frequency of occurrence of adverse effects in medical interventions. These negative effects are estimated to precipitate more than 200,000 deaths annually in the nation. Between 4% and 18% of patient visits are also associated with adverse effects.

The rate of withdrawal of drugs from the market due to lack of safety has greatly increased since 1992, when the Food and Drug Administration (FDA) drug approval process was relaxed. Rates of nonindicated prescriptions have also increased. For example, the rate of prescribing medications for the common cold is 50% higher than the national desirable target, and the percentage of the elderly receiving a prescription for 1 of the 11 always-contraindicated drugs remains unchanged at about 3% per year. Deaths associated with medication errors increased markedly, by more than 65% in the nation just between 1990 and 1993. Only 40% of coronary angiographies are done competently; one fourth of those are erroneously read as showing severe disease; 6% of patients are informed that the test was normal although it was not; and one third of those individuals with misread tests have had surgery that was of uncertain benefit. The more physicians a patient sees, the greater the likelihood of adverse effects. Primary-care physicians, as the locus of responsibility for the ongoing care of patients, are in the best position to identify and deal with these adverse effects. Electronic health records, portable across a variety of settings, provide a way to facilitate identification of adverse effects and conduct research to establish more effective ways of dealing with these effects. However, to do this, a system of coding patients' problems, in the form of symptoms and signs, will have to become routine. Such a system exists but is not widely used in the

United States. To have it incorporated into medical practice will require considerable leadership from professional and policy-making bodies.

Finally, the imperative to reduce disparities in health resulting from avoidable differences in outcomes across different population subgroups remains a challenge to the healthcare system. In contrast to specialty services, which are distributed inequitably in most nations, primary-care services are generally equitably distributed. The exception is in the United States, however. The equity-facilitating influence of primary care is well documented, both from studies in the nation and elsewhere. The benefits of a greater supply of primary-care physicians are even greater for the Black population in this nation than for the majority White population and are greater in socially deprived areas than in more advantaged areas. Populations receiving their care from Federally Qualified Health Centers (FQHCs), which are required to maintain standards for primary-care practice, have fewer disparities in health outcomes between Black and White populations; studies in other industrialized nations such as the United Kingdom and in developing nations have had similar results. Thus, the move toward primary care can be considered a move toward equity in health.

Public Policy Directions

The supply of primary-care physicians in the nation is declining at a rapid rate, as is evident from the 45% reduction from 1997 to 2003 in the number of medical school students intending to enter a primary-care specialty. Chronic underfunding of primary-care services as compared with specialists has contributed to this decline in the attractiveness of primary-care practice, as the level of reimbursement for fee-for-services payment is set by reference to historical levels of relative reimbursement rather than to the difficulty and time requirements of practice. As a result of media focus on the technologic and pharmacologic aspects of health services, the public has come to believe that specialty care is superior to primary care; hence, population groups with rich insurance coverage and the ability to pay out of pocket have set the standard of seeking out specialty care directly. Research on the quality of care, however, is consistent in showing that primary care is superior to specialty care when the outcomes

are broad rather than focused on diseases. Recent literature reviews indicate that even outcomes for specific common diseases are at least as good if not better when care is provided by primary-care physicians, appropriately buttressed by care from specialists. Early studies purporting to demonstrate the superiority of care from specialists were fraught with methodological inadequacies, especially with regard to controlling for overall morbidity burden. Even the extensive focus on evidence-based quality of care fails to give sufficient attention to the special benefits of primary care in relation to person- and population-focused outcomes rather than disease outcomes. This failure is due to the inappropriateness of guidelines for “all-or-nothing” performance measures.

The health services research community has not been in the forefront of primary care, most of which is carried out by primary-care physicians. In view of the evidence that some health system structures and processes have a major impact on outcomes, this seems to be a notable oversight concerning an important aspect of investigations into the role and impact of health services.

Preliminary evidence indicates that at least three features of health systems and two features of practice have a notable influence on health indicators at national levels. The systemic features include (1) national efforts to distribute health service resources according to need, (2) nonuse of copayments for primary-care services, and (3) tax-based health or regulated financing systems ensuring universal benefits. The practice characteristics most consistently associated with strong primary care are (1) comprehensiveness of services within primary care and (2) family orientation of health services. None of these characteristics are covered by U.S. health policy—and practically none by health services research in the nation.

Future Implications

The way that specialists and primary-care physicians provide healthcare differs. Their roles are different and need to be separately identifiable. There are almost certainly large differences in costs and activities, and high national health services costs and poor health outcomes result at least in part from an underuse of primary care and an overuse and misuse of specialty care. Both primary

care and specialty care have important roles to play in the care of the population, and researchers can help policymakers make rational, evidence-based decisions about the relative functions and appropriate contributions of each.

PRIMARY CARE CASE MANAGEMENT (PCCM)

The Centers for Medicare and Medicaid Services (CMS) defines Primary Care Case Management (PCCM) as case management-related services, including the locating, coordinating, and monitoring of healthcare services provided by a physician, a physician group practice, or an entity employing or having other arrangements with physicians under a PCCM contract with a state. These contracts can also be with nurse practitioners, certified nurse midwives, and physician assistants. State Medicaid agencies administer PCCM programs in which primary-care providers are responsible for managing the care of Medicaid recipients, including routine primary and preventive services, coordination of care, and arrangements for specialty services, usually without network restrictions. The primary-care providers receive reimbursement on a fee-for-service basis for the services they provide as well as a flat per-member-per-month fee or an increase in their preventive service fees to compensate for care management.

History

PCCM as an approach to Medicaid was enabled by an amendment to Title XIX of the Social Security Act in the Omnibus Budget Reconciliation Act of 1981. The addition of Section 1915(b) authorized the waiver of statutory requirements that Medicaid programs offer comparable benefits statewide and offer recipients freedom of choice in obtaining services. The amendment also specified that PCCM services would be Medicaid-covered and that qualifying PCCM programs must make provisions for 24-hour emergency treatment and reasonable geographic availability delivery sites as well as have a sufficient number of physicians to

serve the Medicaid population promptly and without compromise to the quality of care.

The Balanced Budget Act of 1997 further amended the Social Security Act to include a new Section 1932 state plan option as an alternative to seeking waivers under Section 1915(b) and research and demonstration projects under Section 1115. The new authority permitted states to implement mandatory managed care without waivers and without the cost-neutrality requirements associated with Section 1115. Approval could be obtained through a state plan amendment, and there was no time limit on the approval. The managed-care state plan was also required to offer enrollees in urban areas a choice between at least two managed-care organizations or between a PCCM system and a managed-care organization. In rural areas, there could be one managed-care organization or PCCM as long as there was a choice of physicians or case managers.

Growth of PCCM Programs

By the mid-1980s, states interested in increasing access to healthcare while holding providers accountable and controlling costs began enrolling Medicare recipients in PCCM programs. These programs attempted to reduce inappropriate hospital emergency department use and other types of high-cost care. In many instances, states developed PCCM programs as a stepping stone to risk-based managed care, and these programs grew steadily during the 1990s. When commercial managed-care organizations began declining to serve Medicaid populations in many markets, even those states that originally intended to move all their Medicaid recipients to risk-based managed care began considering PCCM as a viable method for maintaining Medicaid managed-care delivery systems.

Presently, 30 states in the nation use PCCM, and it is the model of choice for rural areas, where a relative scarcity of providers and a scattered population have resulted in weaker managed-care penetration. Due to its flexibility, PCCM is also used in urban areas. It is frequently the default enrollment for Medicaid recipients who fail to make a choice of a plan. Furthermore, PCCM may be used only in specific markets and also statewide, under either voluntary or mandatory conditions. In markets where feasible, states commonly offer both PCCM

programs and risk models. The resulting competition increases recipient choice and motivates both managed-care organizations and PCCM programs to improve quality and service. However, states must be careful to apply access, quality, and reporting standards evenly to avoid encouraging managed-care-organizations' withdrawal.

In addition to the benefits associated with PCCM's flexibility from the perspective of states, it has enjoyed popularity with both patients and primary-care providers. Medicaid recipients entering PCCM programs report finding stable relationships with their physician and appreciating the lack of restrictions usually associated with managed care. And primary-care providers are pleased not to have to assume the financial risk for the care of their patients and find that they have greater control over medical decision making as well as less administrative burden. They also recognize that states are willing to take their concerns seriously and to find better ways to support them.

Comparison of PCCM Programs and Managed-Care Organizations

PCCM programs, which are legally recognized as managed-care plans, are similar to managed-care organizations in several ways. Notably, the structure of PCCM programs includes a panel of physicians, and one primary-care provider is charged with the primary responsibility for each recipient. PCCM also structures incentives for both physicians and recipients to encourage appropriate use of healthcare services. Additionally, PCCM programs typically conduct utilization reviews, patient education programs, and quality-monitoring activities.

An important difference is that states themselves are in charge of PCCM programs rather than a managed-care organization contractor, which means that state Medicaid agencies either directly administer PCCM or manage a contractor to handle administrative functions. Although such responsibilities are demanding for Medicaid agencies, this aspect of PCCM programs offers states an important opportunity to tailor programs to their policy goals in terms of populations, culture, and public health priorities. Furthermore, PCCM provides an assurance of continuity; unlike a for-profit managed-care organization, a state agency cannot consider leaving when a market turns unprofitable.

Another major difference between PCCM programs and managed-care organizations is the sharing of financial risk. PCCM physicians, with fee-for-service reimbursement supplemented by a management fee, do not take on additional risk. Therefore, PCCM programs are attractive to physicians because they are not disadvantaged when they have a sicker-than-average group of patients.

Trends in PCCM Practices

State PCCM programs differ because each state has taken a different approach that depended on its particular managed-care environment, and policy goals of states also vary. Nevertheless, several trends in the structure and operation of PCCM are apparent and reflect the significant evolution of PCCM over time.

Expanded Eligibility

In addition to enrolling a core population of individuals receiving Temporary Assistance for Needy Families (TANF), PCCM is also frequently being used to extend health insurance coverage to hard-to-serve populations, such as Supplemental Security Income (SSI) disabled children and adults, the aged, and children in foster care. Since the advent of the State Children's Health Insurance Program (SCHIP), most states have incorporated SCHIP members into their PCCM programs as well. Many states have also targeted individuals with chronic medical conditions and have integrated disease management into their PCCM programs.

Provider Recruitment and Retention

States are focusing on improving provider recruitment and retention by supporting participating providers through specially designated outreach staff, operating provider hotlines, implementing feedback mechanisms such as provider profiling, and devising strategies to gain providers' input and suggestions. Rather than second-guessing the decisions of physicians, states frequently provide tools to allow providers to police themselves and, when necessary, dedicate resources for working with outliers to improve their practices. States also have found that providing educational outreach, as by disseminating best practices and making available

online instructional models, to be an effective support for providers. Taken together, these activities may produce strong state-provider relations and ultimately result in increased commitment from a wide variety of providers.

Quality Activities

Increasingly, states are applying many of the principles commonly used in network management to ensure that Medicaid recipients receive quality care from PCCM programs. For example, states are putting tighter language into their provider contracts and dedicating staff to monitor compliance with the stricter standards. In some cases, PCCM programs also are including strict provider credentialing, member surveys, care coordinated across multiple providers and conditions, 24-hour member services and nurse advice lines, community-based preventive health campaigns, Healthcare Effectiveness Data and Information Set (HEDIS) reporting to gauge the primary-care provider's performance, member education and health needs assessment, disciplined utilization management, disease management programs, complaint log reviews, and provider profiles.

Enrollment Process

Informing prospective members about Medicaid managed care and its requirements in a manner that ensures a full understanding of the PCCM program and how to access services remains a critical challenge. To overcome the intrinsic issues associated with enrollment, private enrollment vendors or brokers are increasingly being used to conduct enrollment and other functions. A variety of enrollment strategies is used, including providing informational materials and instructions about how to enroll, holding group educational sessions, operating toll-free help lines, and offering individual face-to-face counseling.

The mobility of Medicaid recipients also presents a significant challenge, creating discontinuity between the time individuals are enrolled in Medicaid and the time they enroll in PCCM. To address this issue, states are conducting telephone outreach at the time of the initial Medicaid eligibility determination. Additionally, some state agencies responsible for Medicaid eligibility determination

are educating recipients about PCCM and encouraging timely enrollment.

Increasing PCCM Active-Care Coordination

Some states are including an active care coordination component in their PCCM programs, recognizing that the referral process is the key to managing services, and they are making significant efforts to streamline prior authorization for providers. Additionally, care coordinators who are familiar with available resources and the community are often employed to more effectively respond to questions and concerns from both members and providers. These care coordinators may also be expected to collaborate with existing services, such as the Women, Infants, and Children (WIC) program, as well as empower local communities to change their service delivery system. Care coordinators may also be deployed to work with community service agencies and other providers to coordinate resources and services on the behalf of members with special needs.

Provider Reimbursement

States with incentive payment systems have found that these systems can be very effective in reinforcing primary program goals, and some state Medicaid agencies have gone beyond the basic fee approach. To encourage the provision of certain primary-care services, some states are reimbursing primary-care providers at enhanced rates rather than reimbursing them at the standard per-member-per-month fee. Other states have adopted partial capitation for primary care, paying a capitated amount for basic office visits and an enhanced payment for targeted services. Still other states allow primary-care providers to receive a per-member-per-month payment and also participate in a bonus pool that is distributed annually based on a composite measure of the physician's Medicaid caseload, hospital emergency department use, and defined prevention and quality goals.

Future Implications

The primary goals of PCCM programs are to reduce costs while improving patient outcomes.

Few evaluations of these programs have been conducted, and those that have been conducted are dated. They tended to focus on cost saving and service utilization, but they did not address patient outcomes except to suggest that PCCM programs improved access, especially to primary care.

In general, existing evaluations of PCCM programs have recorded initial savings in the range of 5% to 15% as compared with a similar fee-for-service population. This level of savings is considered comparable to the savings achieved by managed-care organizations. Savings from PCCM programs have been reported to result from changes in utilization patterns. Costs typically increase for primary-care services and prescription drugs, but the increases are offset by decreases in the costs of hospital emergency department use and inpatient services. In addition to the positive evaluations, a few of the early evaluations were negative, and as a result some state PCCM programs were abandoned in favor of full-risk or managed-care-organization-only models. Given the millions of Medicaid recipients enrolled in state PCCM programs, much more research needs to be conducted to evaluate the long-term benefits and problems of these programs.

PRIMARY-CARE PHYSICIANS

Primary-care physicians generally serve as the first point of contact to the healthcare system for nearly all of a patient's medical and healthcare needs, including the treatment and diagnosis of health conditions and the provision of preventive and continuing care. Under the managed-care model, the primary-care physician also acts as a gatekeeper who controls access to specialists or costly procedures as a mechanism to control healthcare costs. Primary-care physicians may follow patients in a variety of healthcare settings, including outpatient clinics, offices, hospitals, long-term care facilities, and the patient's home.

Physicians trained in family medicine, general internal medicine, and general pediatrics typically are considered to be primary-care physicians. Additionally, health insurance plans may differ in regard to whether pediatricians and obstetricians/gynecologists, who specialize in the care of women, are considered primary-care physicians. Family physicians generally provide comprehensive care to patients from infancy till the end of life. Pediatricians

are considered primary-care physicians for children, adolescents, teenagers, and young adults, while internists, who are practitioners of general internal medicine, provide care to adults.

Because of the aging of the nation's population, greater focus on prevention efforts and lifestyle changes, and the prevalence of acute and chronic diseases, the need for primary-care physicians has grown substantially. In recent years however, the number of primary-care physicians in the United States and other developed nations has been declining, as most physicians tend to specialize in an area of practice. A survey conducted by the University of Missouri-Columbia and the U.S. Department of Health and Human Services (HHS) predicts that by the year 2025, there will be a national shortage of 35,000 to 44,000 primary-care physicians. As a result, the current and future shortage of primary-care physicians is of concern among policymakers and healthcare planners.

Overview

Early practitioners of the science and art of medicine were primarily generalists. The breadth of their practice included diagnosing and treating a variety of illnesses, using apothecaries, and performing surgery. The concept of primary care, however, began to be formalized in the 1960s when the term appeared in the medical literature attempting to define its content and the scope and the role of the primary-care physician. Prior to this time in the United States, a movement toward specialization beginning in the early 1900s resulted in the first medical/physician specialty board being formed in 1916. The American Board of Medical Specialties (ABMS) was established in 1933 to ensure that physicians had a certifiable body of knowledge. ABMS's mission was to establish and maintain high standards for the delivery of safe, quality medical care by certified physician specialists. The American Board of Pediatrics (ABP) and the American Board of Internal Medicine (ABIM) were later established in 1935 and 1936, respectively. Today, ABMS member boards certify physicians in more than 130 different specialties and subspecialties.

After World War II, the rise of specialized care and provider specialization continued. This growth was supported by economic and professional

incentives. And the decline in the number of general practitioners that had already begun before the war accelerated. The percentage of primary-care physicians in the nation declined from more than 80% in the early 1900s to less than 20% by 1960.

In response to the growing public concern over the reduced number of general practitioners, the American Academy of General Practitioners (now the American Academy of Family Physicians) was founded in 1947 to assist these practitioners in preserving and advancing the specialty. The American Academy of Family Physicians later joined with the American College of Physicians, representing internal medicine, and the American Academy of Pediatrics to become one of the largest organizations representing the primary-care specialty of family medicine. Eventually, in 1969, family medicine was established as the 20th primary medical specialty recognized by the American Board of Medical Specialties, and as a result of these efforts, general medicine was reborn.

Primary-Care Practice

The scope of primary-care physicians' practice generally includes the basic diagnosis of common health conditions and nonsurgical treatment and interventions. During the clinical encounter, primary-care physicians gather information about the patient's condition, symptoms, and medical history through interviewing. Primary-care physicians are also trained to order and interpret medical tests such as routine labs, electrocardiograms, and X rays. For more complicated diagnoses, however, they may refer the patient to a specialist with further specialized training or experience. After obtaining medical test results, primary-care physicians will make a diagnosis and may send the patient for further testing, referral to specialized care, therapy, diet or lifestyle changes, treatment, and/or follow-up. Primary-care physicians may also perform routine screenings and immunizations as well as counsel patients on health behaviors and self-care.

With more than 130 physician specialties and subspecialties, there inevitably exist overlapping boundaries in care. Yet the decision-making of primary-care physicians does differ from other specialized physicians who include some primary-care services in their practices.

The structure of the primary-care practice may include a team of physicians and nonphysician health professionals charged with establishing and sustaining a long-term, personal relationship and partnership with individuals and their families. Primary-care physicians and members of the healthcare team serve as advocates for the patient in coordinating the use of the entire healthcare system to benefit the patient. Additionally, primary-care physicians assist with helping patients navigate the system. For example, they may coordinate a full array of services that are essential for maintaining and improving the individuals' health status while providing nonepisodic interventions early in the disease process.

Future Implications

The ultimate goal of a healthcare system is to provide the highest quality of care, at the lowest possible cost, to the greatest number of people. Possible strategies to help accomplish this include increased financing to support primary-care practices, revitalizing primary-care education, and promoting the value of care that is accessible, comprehensive, coordinated, continuous, and accountable, provided by primary-care physicians and other nonphysician primary-care clinicians.

PROJECT HOPE

Project HOPE (Health Opportunities for People Everywhere) is a nonprofit, international organization that is dedicated to improving the quality of life of the most vulnerable members of society, with a particular emphasis on women and children. Project HOPE's mission is to attain sustainable advances in healthcare globally by implementing health education programs and humanitarian assistance. Project HOPE is well-known in the field of health services research for its health policy journal *Health Affairs*.

Background

Celebrating its 50th anniversary in 2008, Project HOPE was founded as a floating hospital by William B. Walsh. After witnessing poor health conditions, particularly of young children, in the South Pacific while serving as a medical officer during World War II, Walsh persuaded President Eisenhower in 1958 to donate a naval ship to provide charity healthcare. The ship was later transformed into the S.S. HOPE and Project HOPE was formed. In September, 1960, the S.S. HOPE set sail from San Francisco to Indonesia. Although

the *S.S. HOPE* was eventually retired in 1974, it made a total of 11 voyages to various countries around the world. Today, Project HOPE continues to operate land-based programs, including medical training and health education in more than 30 countries across 5 continents.

Project HOPE is dedicated to providing sustainable solutions to health problems by helping people assist themselves. The organization improves the local capacity to sustain improvements in health and improve access to healthcare. It has programs across the globe, in locations including Africa, the Americas and the Caribbean, Asia and the Middle East, Central and Eastern Europe, and Russia/Eurasia. Project HOPE's current programs in Africa are fighting to combat HIV/AIDS, malaria, and other diseases; poverty and hunger; infant mortality; and maternal mortality. Its programs in South American countries target access to healthcare services for women and children. And in Asia its programs are focused on addressing infectious diseases and women's health issues.

Project HOPE also provides humanitarian and emergency assistance in areas that are affected by disasters. Additionally, the organization strives to provide long-term access to essential medicines and medical supplies to underserved areas. Since 1987, Project HOPE has shipped nearly \$1 billion in humanitarian assistance globally.

The organization also maintains expertise in various health and medical disciplines and provides health professionals education through various programs, ranging from the training of rural health promoters in primary care to the establishment of specialized tertiary-care medical programs. Project HOPE's implementation of train-the-trainer methodologies has resulted in millions of healthcare professionals being better equipped worldwide. Project HOPE has also laid the foundation for a healthier future by building, and training the staff needed to operate, hospitals and clinics, especially those targeting the special needs of children. The facilities serve as national training centers for healthcare providers in addition to being an invaluable resource to improve the health of children in developing countries.

Project HOPE is a registered organization of the U.S. Agency for International Development (USAID) and is a member of the Partnership for Quality Medical Donations. The organization

maintains close collaborations with local partners to ensure that efforts are not duplicated in meeting the needs of those it serves.

Health Affairs

Project HOPE has published the leading peer-reviewed health policy journal, *Health Affairs*, since 1981. The journal consistently ranks at the top of its categories in the *Journal Citation Report*. Its founding editor, John K. Iglehart, is a member of the National Academy of Sciences, Institute of Medicine (IOM) and national correspondent for the *New England Journal of Medicine*. The idea for *Health Affairs* was spawned in the 1970s when Walsh, Project HOPE's founder, concluded that it should expand its reach by publishing a journal to focus on the U.S. healthcare system.

Health Affairs is a multidisciplinary journal that covers topics such as access, costs, and quality of healthcare; Medicare; Medicaid; healthcare reform; and prescription drug coverage. The journal is nonpartisan and publishes a wide range of timely health articles, which focus on research and commentary that are of concern both domestically and abroad.

Health Affairs is published six times a year with additional supplements and is also available online. The authors that contribute to the journal include acclaimed scholars, policymakers, and leaders in the healthcare industry. The journal averages about 33,000 readers per printed issue, and the readership includes legislators, healthcare leaders and professionals, academics and researchers, health policy analysts, and advocates. *Health Affairs* is widely cited in the national media and press, including *The Washington Post*, *The New York Times*, *The Wall Street Journal*, and CNN, and it has been referred to as the "bible of health policy." Between January and July, 2006, alone, the journal was cited 18 times in U.S. congressional testimony, which is illustrative of its policy influence.

The journal is divided into the sections of Feature Articles, Commentary, Interviews, Narrative Matters, Health Tracking, Data Watch, Grant Watch, UpDate, Book Reviews, and Letters to the Editor. *Health Affairs* also publishes thematic issues each year that explore a topic in depth as well as on "variety issues."

Future Implications

Project HOPE continues its work to improve the lives of people throughout the world, particularly among low- and middle-income countries, by educating healthcare professionals and volunteers, training community workers, providing essential supplies and medicines, and combating infectious diseases. Additionally, *Health Affairs* remains an influential force in informing the public policy debate on issues that are of particular concern in healthcare.

PROSPECTIVE PAYMENT

The manner in which healthcare organizations are paid for the services they provide can influence their organizational behavior. Healthcare

organizations are generally paid in three ways: (1) on a cost-based basis, (2) on a capitation basis, or (3) on a case-based basis. On a cost-based basis, such as fee-for-service, the organization is paid for all the services it provides, which is a powerful incentive for high levels of effort and service. Payment on a capitation basis consists of a flat payment to the organization per person cared for, with the organization assuming the risk that the payment will cover the cost of the patient's care. On a case-based basis, the organization is paid a single payment for an episode of care, and the payment does not change if fewer or more services are provided. The various payment types may be either retrospective or prospective.

Medicare's Prospective Payment System

The best-known example of case-based payment in healthcare is Medicare's prospective payment system (PPS), which was mandated by the U.S. Congress to control community hospital inpatient costs in 1983. Under this system, the Medicare program changed its mode of payment for hospital inpatient care from a retrospective cost-based system to a prospective case-based system.

After the Medicare program was established in 1965 the costs of hospital care soared. One of the major factors that led to rising costs was the retrospective cost-based payment system. Under this system, hospitals submitted their bills to Medicare after the care had been given and the costs to the hospital were known. Hospitals were then paid for the care they provided, as allowed by Medicare rules, regardless of whether the costs were high or low, excessive or appropriate. Consequently, there was little incentive for hospitals to be cost-effective.

On the other hand, the prospective case-based payment system set payment rules prior to when the care was given. By setting a fixed reimbursement level per case based on diagnosis, the PPS provided economic incentives to conserve the use of resources. Hospitals that used more resources than covered by the flat rate lost the difference. Those with costs below the rate retained the difference.

Diagnosis Related Groups

Under Medicare's PPS, the amount paid to hospitals is based on their patients' Diagnosis

Related Groups (DRGs). Specifically, each patient is assigned into one of more than 500 DRGs, based on principal diagnosis, age, and medical complications. The DRGs aggregate patients with similar resource-consumption and hospital length-of-stay patterns. Medicare then pays the hospitals a set amount for each DRG. The government calculates the payment for each DRG based on national averages. It also modifies that amount somewhat based on local wage rates, geographic location (e.g., rural versus urban area), and whether the hospital is a teaching hospital.

Effects of Medicare's Prospective Payment System

Extensive research has been conducted to examine the impact of Medicare's PPS on hospitals and patients. This research has focused on the system's impact on average hospital length of stay, access to and quality of care, financial condition of hospitals, overall effects on costs, and hospital management.

Average Hospital Length of Stay

Since Medicare's PPS pays hospitals a fixed amount based on the patient's DRG, there is an incentive for hospitals to discharge their patients as soon as possible. Given that revenue is fixed, the time a patient spends in the hospital will determine the profit or loss. As a result, one of the ways to increase profits is to reduce the number of days of care taken to treat a patient. Many studies have reported that hospital average length of stay did drop after the introduction of the system.

Access to and Quality of Care

With the introduction of Medicare's PPS, many policymakers and the general public were concerned that it would induce hospitals to save on costs by cutting corners—reducing access to care and the quality of care—by refusing to treat costly patients or by closing treatment units. Researchers have addressed these issues to some extent; however, the results have been mixed so far.

Financial Conditions of Hospitals

Because Medicare's PPS puts a degree of financial stress on hospitals, particularly on those that have higher than usual costs, there was a concern about their financial viability. When PPS was first established, its fixed payment rates proved sufficiently generous, and average hospital operating margins increased. However, over time, the rates were lowered. By the late 1980s and through the early 1990s, average operating margins for the Medicare segment of hospital patients tended to be negative.

Overall Effects on Costs

The main objective of the Medicare PPS was to control hospital costs. With regard to the effect of PPS on reducing hospital expenditures, one study found that for a sample of California hospitals, those under the strongest pressure from PPS responded by reducing expenditures. Another study found that PPS reduced Medicare's hospital costs substantially. In terms of Medicare's overall budget, the PPS appears to have been effective in slowing down expenditures. The PPS reduced the historic rates of growth in total Medicare spending. However, the reduced growth in inpatient spending was partially offset by increases in spending on hospital outpatient care, skilled nursing care, home health care, and physician payment increases.

Hospital Management

The Medicare PPS was designed to create incentives for the balancing of costs and benefits in treating patients. It led hospitals to begin to explore mechanisms for more accurate product costing. Under cost-based payment, when health-care providers were directly reimbursed for whatever costs they incurred, accurate cost measurement was of little concern. However, under PPS, the revenue per patient is not merely a reflection of reported cost but is instead a fixed amount. If the true underlying cost is substantially more than the revenue for a certain type of patient, the hospital must be aware of it. Similarly, hospitals must also be aware if the cost is much less than the revenue. Medicare's PPS encouraged the use of product-line costing, which led to more efficient hospital financial management.

Future Implications

After applying PPS to community hospitals, the federal government developed and applied similar systems in other healthcare settings. Medicare now uses PPSs for hospital outpatient services, inpatient psychiatric hospital care, inpatient rehabilitation hospital care, inpatient long-term hospital care, skilled-nursing facility care, home health care, and hospice care. It seems likely that these systems will remain in use for many years to come.

PROVIDER-BASED RESEARCH NETWORKS (PBRNs)

Provider-based research networks (PBRNs) are collaborative partnerships between academically based investigators and community-based physicians who share an ongoing commitment to developing and conducting health-related research. PBRNs provide the infrastructure and support necessary to conduct community-based clinical research studies on an ongoing basis, thus providing stability and continuity that transcends individual studies. PBRNs address many shortcomings of academic medical centers—only research and present several distinct advantages to it; most notably, these entities provide access to a much larger population of prospective clinical research trial participants.

Clinical research trials are the means by which medical researchers explore and answer specific questions about health. Clinical trials, translational research, epidemiological research, health services research, and several other categories are included in the broader definition of clinical research.

Academic medical centers (AMCs) have long been the centers of clinical research, the development of new knowledge, and the transfer of that knowledge to the next generation of researchers and care providers. There, teams of investigators develop research questions and methods for examining them and also carry out the research through voluntary enrollment of study subjects who are often patients at the centers. Having AMCs as the center of the clinical research universe has many advantages, including the presence of both clinical and research infrastructure and the synergy that can be developed among academics, researchers, and clinicians; but it also has several limitations.

In 1961, one of the founders of health services research in the United States, Kerr L. White, presented a statistical estimate with far-reaching implications for both medical education and population-based clinical research: For every 1,000 adults at risk of being ill or using health services in a given month, only one will be referred to an AMC. While the precision of this estimate has been debated and patterns of care may have shifted since 1961, the implications remain relevant today. If this estimate is accurate, although the overwhelming

majority of clinical research is conducted in AMCs, less than 1% of the relevant population is being seen at AMCs, and only a small subset of these individuals is enrolling in clinical research trials. A tremendous risk of selection bias exists then, jeopardizing the external validity of the majority of clinical research. Furthermore, limiting clinical research access to only AMCs induces a bottleneck in completing clinical research studies, consequently slowing the pace of medical progress.

In 2006, a contract research organization, Westat, completed and published the *Inventory and Evaluation of Clinical Research Networks: A Complete Project Report*, a comprehensive worldwide study of clinical research networks. This report identified 262 PBRNs with a variety of funding sources and organizational structures, and spanning multiple types of research and subject populations. The majority of these networks are less than 10 years old; however, others have been in existence for 50 years. Currently, 62% of these networks are funded by the federal government. Another 10% are funded by nonprofit organizations, 9% are funded by a government outside the United States, and 8% are funded by academia. Approximately 60% receive funding from more than one source; 52% report operations in the United States only, while 32% report operations in the United States and internationally, and 16% report exclusively international operations. Universities and AMCs continue to play a dominant role in many networks, while other network members span the healthcare spectrum and include the following: state and federal government healthcare facilities, community hospitals, individual or group physician practices, clinical laboratories, pharmaceutical companies, foundations, contract research organizations, and health maintenance organizations (HMOs).

The research areas vary widely, and include epidemiology, behavior modification, health communication, patient care, medical practice, clinical quality improvement, research-centered surveillance, and clinical process improvement, among others. Approximately 60% of the studies conducted through PBRNs are clinical trials, 24% are epidemiology and other observational studies, 6% are other interventional research, and 2% are outcome oriented. As far as the populations being studied are concerned, these research network

projects are variously organized by demographic characteristics (e.g., age group, gender, and race), disease type (e.g., AIDS, cancer, and heart disease), practice type (i.e., primary care and specialty services), and point on the care continuum (i.e., prevention, early detection, treatment, or disease survivorship).

Research Generalizability and Medical Progress

Among its many benefits, PBRNs broaden the access points between clinical research studies and the total potential participant population, helping ensure better research with more generalizable findings. PBRNs broaden clinical research's reach to include more members of the more than 99% of the population described by White as being "at risk" but not seen at AMCs, thus offering inclusion of people who would not seek care at the centers for any number of reasons, including their geographic relation to them, insurance coverage, perceived nonnecessity of AMC-based care, or other factors. By including members of this larger, more diverse population, the research is more likely to result in findings that are more broadly representative of it and therefore generalizable. More comprehensive population representation is of increasing importance with, for example, the current growth of genetics research. With striking limitations on the geographic reach of AMCs, PBRNs help give such genetics-based studies a broader reach, which may prevent the exclusion of potentially geographically clustered and genetically distinctive populations. These efforts help medical researchers improve the understanding of genetic pathways of disease and extend the applicability of research findings to these populations.

By opening the access points to a larger population, PBRNs also serve to expedite the pace of medical discovery. Simply put, patient enrollment is one of the most time-consuming components of most clinical trials. Individual studies can spend many years enrolling a sample of individuals sufficient to allow the statistical power to demonstrate an intervention's effectiveness. With PBRNs' access to a broader population, there is an increased probability of an individual with the right trial-specified clinical characteristics seeking care at a location that offers access to the trial. This greater rate of

patient-to-trial exposure can translate into more rapid overall trial enrollment and, consequently, more rapid trial completion. A prime example of this is cancer prevention research, which is often conducted among healthy populations.

Because cancer prevention trials often require a very large participant sample size to allow for statistically powerful analysis, this type of project may be impractical at an AMC. Beyond potentially limited trial access to the less than 1% of individuals at risk who seek care at AMCs, a large proportion of patients have considerable health concerns that would preclude their enrollment in the trial. PBRNs open the door to a dramatically larger, generally healthier population that sees their geographically more accessible practitioners for everything ranging from annual checkups and flu shots to symptom-induced visits for transient health issues to ongoing care needs that are not severe enough to either warrant referral to the AMC or preclude the patient from a prevention trial. Most recently, this benefit of PBRNs has perhaps been visible as a significant component of the National Institutes of Health's (NIH's) Roadmap, which is the federal plan for medical research in the 21st century.

Translating Research Into Practice

As part of NIH's Roadmap, the importance of developing new partnerships among patient communities, community-based physicians, and academic researchers is recognized. Indeed, several institutions and federal agencies are developing PBRNs or have them already in place. To this end, the NIH and other federal agencies are aware of the role PBRNs can play in both translating research results into better care and closing the gap between discovery and delivery.

For many medical-care innovations, providers often remain unconvinced that sufficient evidence exists to support the implementation of research-tested clinical services in real-world practice settings. The national Institute of Medicine's (IOM) 1998 report, *Bridging the Gap Between Practice and Research: Forging Partnerships With Community-Based Drug and Alcohol Treatment*, describes how the clinical-care community perceives an excess of "efficacy" research and a simultaneous dearth of "effectiveness" research. Many have noted that most research on clinical services takes place in AMCs, yet

most care is delivered in community settings. Consequently, for many community-based providers, evidence-based practice awaits more practice-based evidence. These observations suggest that the acceptance and implementation of evidence-based clinical services in community-based practice settings depends less on dissemination, which connotes a one-way flow of knowledge from researchers to providers, than on knowledge exchange, which involves two-way communication between researchers and providers. In PBRNs, this exchange is structurally facilitated, as community-based providers assume primary responsibility for seeing patients and for collecting research data and participating in other aspects of the research process. On the discovery-to-delivery continuum, the process of seeing patients represents the critical process of implementation, which remains a daunting challenge no matter how strong or credible the evidence.

For all but the simplest clinical services, successful implementation depends on administrative support, adequate financial and human resources, and organizational culture that values scientifically based practice. Indeed, systematic reviews indicate that multifaceted interventions that target organizational staffing, office workflow, and information systems are more effective in changing provider behavior than interventions that increase provider awareness and knowledge, such as continuing education and academic detailing. These findings suggest that the implementation of evidence-based clinical services necessitates systemic organizational changes, including the development of a supportive infrastructure and culture for both academic settings and, perhaps more important, community-based practice settings.

These systemic organizational changes are of growing importance because the recent healthcare market trends emphasize efficiency and may serve to erode the professional values and norms that emphasize scientifically based practice and the conduct of historically inefficient clinical research.

PBRNs involve both knowledge exchange and systemic organizational changes. As such, they are a promising model for both disseminating and implementing evidence-based clinical services and, ultimately, improving the quality of care. Knowledge exchange occurs through community-based participatory research (CBPR). By engaging providers in the research process, researchers gain

insight into the clinical issues and needs of community-based practice settings, obtain provider input on study design and the feasibility of implementation, and discover the tacit practice-based knowledge that exists in community-based practice settings and the acceptability of the intervention. CBPR promotes a sense of trust and ownership that enhances providers' acceptance of clinical research results and strengthens their commitment to acting on research findings. However, CBPR does not occur spontaneously or effortlessly.

Keys to Success

Substantial federal commitment exists to develop and support PBRNs as a means for improving and advancing the nation's research agenda as well as disseminating and implementing evidence-based clinical services in community settings. Yet reports indicate that PBRNs themselves are encountering challenges to implementation and sustainability. Several studies have elucidated characteristics that are associated with successful performance of PBRNs and the challenges they face, including developing a research agenda, obtaining member buy-in and sustaining member interest, consistently obtaining sufficient funding, creating a clinical research infrastructure, and coping with regulatory compliance issues.

Perhaps the most fundamental characteristics associated with PBRN success is the commitment of both the lead- and coinvestigators and their continuous active involvement in the PBRN. These individuals must establish a clear vision for the organization, typically in the form of scientific focus, goals, and priorities. They must also keep a close watch on the environment and remain open to new ideas and ways of remaining energized and at the forefront of research, including through continually developing new relationships with new investigators. They must also develop the relationship both inside and outside the PBRN, including those partners with the relevant patient populations, the prospective partners who would interact with those populations, and the funding groups or agencies that support the ongoing infrastructure necessary to conduct the research. Indeed, the sustainability of PBRNs has been strongly and directly tied to the ability to acquire ongoing sponsorship of research, which can be a very costly endeavor.

For all practical purposes, PBRNs cannot function without independent funding. Traditionally, clinical practice has cross-subsidized concomitant clinical research; however, this is no longer sustainable because the healthcare environment increasingly emphasizes efficiency as well as increasingly complex, burdensome, and resource-intensive research and regulatory requirements. Lack of such resources has had a negative impact on PBRNs' abilities to pursue specific lines of research and on some PBRNs' abilities to complete already initiated studies. The pressures and uncertainty of obtaining new and ongoing funding are ever present, and the time spent seeking funding displaces the time that could be spent performing the research. Restrictions placed on some funding sources can further limit how and where PBRN efforts are directed. Some PBRNs receive stable funding through federal support, which mitigates some of this pressure and uncertainty, and enables more consistent operations, while some PBRNs take as much of a business perspective as a research perspective when determining research agendas and carrying out research, as they constantly focus on costs and efficiency of operations.

In addition to being costly, clinical research is time-consuming. Investigators in PBRNs often experience exceptional time pressure because they are often also responsible for maintaining a viable clinical practice. These investigators often have little or no directly supported time to develop or conduct research, let alone analyze study data or develop and publish the findings. As such, their success is often tied to their ability to create an organizational infrastructure to support the many time-consuming aspects of clinical research. PBRN member provider organizations often must implement systemic changes in organizational staffing, office workflow, information systems, and reward structures to appropriately encourage staff support and participation and operational success. Some PBRNs have a more centralized model, where the research staff is funded in dedicated support of research, operate out of a central nonclinical office setting, and only interact with clinical staff to identify and enroll patients and carry out the strictly research-related aspects of study participants' otherwise usual course of care. Some PBRNs, on the other hand, employ a more decentralized model in which the same staff members support both patient

care and the requirements of the clinical research protocol. In either case, two infrastructure elements, good staffing and strong information technology (IT), remain key components to success.

Successful PBRNs consistently extol the value of a well-trained staff to carry out the many specialized functions within the PBRN. These roles include data managers and statistical support staff who assist in the development of research protocols and also help manage and analyze data, research nurses who interact with study participants, administrative staff who help ensure that all sorts of regulatory requirements, including interactions with local institutional review boards (IRBs) and government agencies such as the Food and Drug Administration (FDA), are met, and study coordinators and managers who oversee and coordinate all these roles. To fulfill these roles, PBRN staff efficiency, effectiveness, and general productivity are often influenced by having IT systems.

As it pertains both to internal PBRN operations as well as PBRN interaction with sponsors and other agencies, many recent advances in IT have been facilitators of PBRN success. With many PBRNs spread across multiple states and even multiple countries, the utility of an IT resource for communication and operations support is obvious. New government-sponsored IT resources such as the Clinical Trials Support Unit (CTSUs), cancer Biomedical Information Grid (caBIG), Network for Effective Collaboration Technologies through Advanced Research (NECTAR), and other resources have facilitated access to information on clinical trial availability, contributed to relieving the regulatory burden of trial participation for practitioners, and allowed much greater consistency and efficiency in participant enrollment and ongoing trial management. Some other, more forward-looking research programs have begun to develop patient-centric IT systems in which patients enter responses to trial-relevant questions on checking in for a clinic visit. With implications for practice at both AMCs and community-based practices, these data are stored for trial analysis with other patients' responses. Additionally, they are analyzed in real time to inform and improve practice immediately by both providing useful educational information to participants or patients and also informing the care provider regarding the most pertinent matters to address during the concomitant clinic visit.

Future Implications

PBRNs have broadly demonstrated their success in allowing access to new populations and enhancing enrollment in clinical trials. To cite just one example, a National Cancer Institute (NCI) PBRN, the Community Clinical Oncology Program, has allowed a successful expansion from cancer treatment trials into cancer prevention and control trials. In addition to effectively opening the door to prevention trials, it currently accounts for 30% of all enrollments to treatment trials sponsored by the NCI.

Although many PBRNs have shown that they can complete studies and advance medical knowledge, the extent to which PBRNs actually promote the use of evidence-based clinical services in community-based practice settings remains largely unknown. The few studies that have been done have demonstrated a benefit of enhanced utilization of new therapies for nontrial patients compared with patients in practices that do not do clinical research. The scope, details, and generalizability of these relationships largely remain to be proved, since many PBRNs are too new, too small, or lack reliable outcome data to measure their impact as a model for dissemination. With the NIH Roadmap's recent emphasis on PBRNs, a growing opportunity exists to conduct empirical evaluations of the benefits of PBRNs in terms of their ability to directly influence clinical practice and facilitate the translation of research into practice.

PUBLIC HEALTH

Public health involves promoting health and preventing disease for all people in a community. The mission of public health is to promote health and mental health and prevent disease, injury, and disability for all the inhabitants of a community or other jurisdiction. Society has an interest in protecting its population and making assurances to that population that the society will endeavor to create conditions for all people to be healthy. Public health practitioners carry out the mission of public health through assessment, policy development, and the application of the essential public health services. The vision of public health is to promote a healthy people in healthy communities agenda. At a scientific level, this means that research and practice will be oriented to preventing disease before it occurs (primary prevention), finding ways to prolong life, encouraging healthy lifestyles with individual responsibility for maintaining these lifestyles, and developing a public health system that promotes health for all its population through organized community efforts

and collaboration. This latter point is tied to a major concern about health equity for all. At a practice level, this agenda would also be pursued by preventing epidemics and the spread of disease, protecting people from environmental hazards, prevention of injuries, responding to disasters and helping people and communities in the recovery period, and assuring accessibility of health services for everyone. Public health is thus population based and not generally a provider of clinical services. Public health agencies work with other community health partners to carry out the mission of public health and a vision for a healthier future.

Major Functions and Essential Services

Public health has 3 major functions and 10 essential services that will successfully impact a local public health system. The first function is *assessment*, which involves the identification of health problems in a community and a determination of all quantitative and qualitative considerations of that problem. The function of *policy development* involves the creation of solutions and action steps with appropriate rules, regulations, statutes, and laws, and protocols related to these solutions. The final function involves *assurance*, which relates to the implementation of the solutions in the area of action.

A clarification of these core functions involves the public health system carrying out the 10 essential public health services:

1. Monitor health status to identify community problems.
2. Diagnose and investigate health problems and health hazards in the community.
3. Inform and educate people about health issues and empower them to deal with the issues.
4. Mobilize community partnerships to identify and solve health problems.
5. Develop policies and plans that support individual and community health efforts.
6. Enforce laws and regulations that protect health and ensure safety.
7. Link people to needed personal health services and ensure the provision of healthcare when otherwise unavailable.

8. Ensure a competent public health and personal healthcare work force.
9. Evaluate effectiveness, accessibility, and quality of personal and population-based services.
10. Conduct research for new insights and innovative solutions to health problems.

Structure of the American Public Health Service System

Most public health agencies in the United States are found at the state and local levels. Although the American public health system tends to be decentralized, with different structures between states and localities, it is possible to see a public health presence at the national level. The U.S. Public Health Service includes the Office of Public Health and Science (OPHS) and eight operating agencies. These agencies are (1) the Health Resources and Services Administration (HRSA), (2) Indian Health Service (IHS), (3) Centers for Disease Control and Prevention (CDC), (4) National Institutes of Health (NIH), (5) Food and Drug Administration (FDA), (6) Substance Abuse and Mental Health Services Administration (SAMHSA), (7) Agency for Toxic Substances and Disease Registry (ATSDR), and (8) the Agency for Healthcare Research and Quality (AHRQ).

There are also 10 Regional Health Administrators for the federal regions of the country. Under Section 330 of the Public Health Service Act, there are also a number of Community Health Centers (CHC) around the country that provide ambulatory healthcare in areas where there are few health services for a population or a special needs population. These centers coordinate federal, state, and local resources to deliver health and social services to a designated population. The federal government also provides funds to the states for designated program development, such as HIV/AIDS programs. In fact, the federal government is the largest purchaser of health-related services.

All 50 states have a public health presence within some state agency. State public health agencies are either freestanding or units of a multipurpose health and human services agency. These agencies are responsible for identifying and meeting the health needs of the residents of the states. They are often responsible for monitoring federal

funding in the state. However, the subdivisions within state agencies are not common among all states. For example, environmental public health programs may be in a different agency than population-based programs. In Illinois, for example, family health programs are in the Illinois Department of Human Services and not in the Illinois Department of Public Health. State health agencies are involved in a range of activities from drinking water regulation; vital statistics and epidemiologic surveillance; food safety; tobacco prevention and control; Women, Infants, and Children (WIC) programs; health professions licensing; health facility regulation; medical and forensic examination; public health laboratories; mental health; drug and alcohol abuse prevention; environmental health and regulation; and Medicaid.

On a day-to-day basis, most of the work of public health professionals is carried out at the local level. It is estimated that there are about 3,200 local health departments in the United States at the regional, district, county, or municipal level. About 60% of these local health departments are county based. The remainder are city-county agencies, multicounty agencies, or some other hybrid. In terms of governance, these entities are either a freestanding part of the local government, a local agency where all staff are part of the state agency, a mixed model with both state and local shared responsibility, a mixed pattern, or, in a few instances, a not-for-profit agency such as a hospital contracting with the local government to manage the public health programs of the jurisdiction. Most local health departments are small organizations. About 70% serve a population of 50,000 or less. More than 80% of these agencies are associated with a local board of health.

In recent years, there has been an initiative to develop an operational definition of a functional local health department. In concert with this activity, there has been an initiative to develop a voluntary national accreditation process for local health departments. Some experts believe that an operational definition may lead to a reduction in the number of local health departments as some smaller programs consolidate with other local agencies or other small agencies into some regionally based model. Regardless of structure or pattern of governance, a functional health department

would need to meet certain standards, such as the following:

- Understand the specific health issues confronting the community.
- Investigate health problems and health threats.
- Prevent, minimize, and contain adverse health effects from communicable diseases, disease outbreaks from unsafe food and water, chronic diseases, environmental hazards, injuries, and risky health behaviors.
- Lead planning and response activities for public health emergencies.
- Collaborate with other local responders and with state and federal agencies to intervene in other emergencies with public health significance.
- Implement health promotion programs.
- Engage the community to address public health issues.
- Develop partnerships with public and private healthcare providers and institutions, community-based organizations, and other governmental agencies engaged in services that affect health to collectively identify, alleviate, and act on the sources of public health problems.
- Coordinate the public health system's efforts in an intentionally noncompetitive and nonduplicative manner.
- Address health disparities.
- Serve as an essential resource for local governing bodies and policymakers on up-to-date public health laws and policies.
- Provide science-based, timely, and culturally competent health information and health alerts to the media and the community.
- Provide its expertise to others who treat or address issues of public health significance.
- Ensure compliance with public health laws and ordinances using enforcement authority when appropriate.
- Employ well-trained staff members who have the necessary resources to implement best practices and evidence-based programs and interventions.
- Facilitate research efforts, when approached by researchers, that benefit the community.
- Use and contribute to the evidence base of public health.
- Strategically plan its services and activities, evaluate performance and outcomes, and make adjustments as needed to continually improve its effectiveness, enhance the community's health status, and meet the community's expectations.

These standards are closely allied to the core functions and essential public health services discussed above. These standards can serve as guidelines for the fundamental responsibilities of the local health department. They also will be critical in any agency accreditation process.

Public Health Workforce

The public health workforce is composed of individuals from diverse backgrounds, education, and training in fields including medicine, nursing, psychology, social work, epidemiology, biostatistics, laboratory science, law, public administration, business, economics, pharmacy, veterinary medicine, social sciences, education, and public health. This diversity serves both as strength and a weakness in the definition of public health and in the dimensions of how to carry out the work of public health. The U.S. census reports about 250,000 full-time equivalent health workers employed by local governments. In 2004, there were about 550,000 full-time equivalent workers in the governmental sector at the federal, state, and local levels. In a more recent survey of the public health workforce in local public health departments, it was estimated that there were 160,000 in 2005. Managers and administrators constitute about 6%, nurses 24%, environmental specialists/scientists 10%, clerical staff 27%, health educators 3%, nutritionists 3%, and other designated health professionals such as physicians constitute about 4%; the remaining 23% are uncategorized workers. With regard to physicians, it is estimated that there will be a need for 10,000 more public health physicians in the coming decades than we have now. Currently, there are about 10,000 public health physicians.

It is also estimated that there will be critical shortages of public health nurses, environmental

health specialists, health educators, epidemiologists, and information technology (IT) specialists in the future. Since September 11, 2001, there has been an increase in the number of public health workers involved in emergency preparedness and response. As federal funding for these activities declines, it is predicted that there will be some decline in the governmental public health workforce.

Public Health Education Programs

Although there are many individuals in the public health workforce, many have not been specifically trained in public health. Schools of public health and public health programs that are accredited by the Council on Education for Public Health (CEPH) provide academic training in public health. Currently, there are 39 accredited Schools of Public Health and 67 accredited graduate public health programs in the United States. All the schools have curricula that are competency based. A credentialing process has been developed to credential master's of public health (MPH) graduates of the schools and other accredited public health programs. The first credentialing examination was held in the summer of 2008.

There are a number of core competencies that have been developed to demonstrate the skills that are needed for successful public health practice. These competencies include analytic/assessment skills; policy development/program planning skills; community dimensions of practice skills; basic public health sciences skills; communication skills; cultural competency skills; financial planning and management skills; and leadership and systems thinking.

Prior to 2002, five major curriculum content areas were designated as important for public health practice: (1) biostatistics, (2) epidemiology, (3) environmental health sciences, (4) health services administration, and (5) social and behavioral sciences. A number of educational programs also included content on community health and laboratory sciences.

During this first decade of the 21st century, the national Institute of Medicine (IOM) has strongly advocated the addition of a number of other content areas that are critical for public health practice in the new century. They have identified 11

additional content areas: (1) informatics, (2) genomics, (3) communication, (4) cultural competence, (5) community-based participatory research, (6) global health, (7) policy and law, (8) ethics, (9) leadership, (10) public health emergency preparedness, and (11) clinical and community preventive services.

Public Health Emergency Preparedness

Since the terrorist attacks of September 11, 2001, emergency preparedness and response have become major activities for local public health departments. These local entities have significantly increased their ability to address public health emergencies with federal funding from the Centers for Disease Control and Prevention (CDC). Whereas only 20% of local health departments had comprehensive emergency response plans in 2001, more than 90% have such a plan in late 2007. Funding is beginning to be cut, with concern about the ability to maintain this emergency preparedness momentum in the future. About 20% of local health departments hold that they are fully prepared now, and 77% hold that improvements have been made since 2001. Since 2005, funding has declined by almost 30%. With these funding cuts, local public health agencies have had to cut or lay off staff. Workforce training programs have been curtailed as a result. More than 55% of local public health agencies do not think that they can achieve their deliverables within the designated time frames. In addition, local public health agencies are finding it difficult to find and hire emergency preparedness planners, epidemiologists, and nurses. The only positive element has been an increase in funding for pandemic influenza planning. Staff have been redeployed to address this new health priority.

PUBLIC HEALTH POLICY ADVOCACY

Almost every decision made by policymakers influences public health. Whether a given policy is directly related to healthcare, or whether it indirectly affects human health or the environment, public health advocates must be cognizant of the policy-making process and how to influence that process. Examples of issues affecting public health range from environmental regulation to education policy and from transportation projects to consumer protection. And, of course, key to public health policy analysis are issues involving access, costs, and quality of healthcare.

Developing a Policy Action Plan

To advocate for a public health policy, a policy action plan should be developed. The basic issues for developing such a plan are discussed below.

The "Commodity" of Information

For each issue, information must be collected, analyzed, assimilated, and delivered. A Policy Action Plan should be developed to clearly and concisely provide a strategy for consensus building. Types of information to be collected include data from research-based studies, epidemiological studies, and cost-benefit analyses as well as information about previous policy approaches to addressing the issue from other jurisdictions, and adopted policies. Information about policymakers should also be collected. Who cares most about this issue? Why? Can they assist in advocacy efforts? Advocacy channels are also a key consideration. Is the issue best addressed by legislators, or should relief be sought through administrative routes?

Legislative Branch

Most policy-making venues have both legislative and executive branches. Understanding how to navigate through the policy-making infrastructure is key to effective policy advocacy. On the legislative

side, advocates need to familiarize themselves with the bill-making process, committee structures, and individual legislators and their staff. Each jurisdiction has slightly different rules for how a bill becomes law. Key legislative committees will include those relating to healthcare, public health, health disparities, education, justice reform, environment, and transportation, to name a few. Appropriations committees often operate under a different set of rules that may significantly influence how programs are funded and administered.

Executive Branch

On the executive side, policy advocates need to understand the agency structure, the rule-making process, and key administrators. Executive branches at the local, regional, state, and federal level often mirror each other. For instance, at the federal level, the U.S. Department of Health and Human Services (HHS) houses most of the key public health and healthcare agencies, including the Centers for Disease Control and Prevention (CDC) and the National Institutes of Health (NIH). At the same time, most federal funding flows through state departments of health and human services, which have subagencies for each relevant funding stream.

The administrative rulemaking process determines how funds flow to various agencies and the rules under which those funds will be distributed. At the federal level, information on the rulemaking process is found in the *Federal Register*. Typically, each state's administrative code can be accessed through the state's official Web site. While many localities also house their ordinances and local rules online, advocates may be required to make the trip to city hall to obtain a copy of relevant regulations.

Identifying Stakeholders

Effective public health policy advocacy must include an analysis of the various stakeholders. The inquiry should begin by identifying the proper venue for advocacy. Is the issue best addressed at the local, state, country, or international level? For example, if the issue concerns children's health in

school, it may be best to seek out solutions at the local school level. If the issue concerns county health departments, it may be most effective to advocate the issue with the proper county policymakers. An effective advocate will determine which local or regional policymakers chair the relevant committees, which ones are passionate about the topic, which ones have direct experience with the topic, and so on. The same analysis holds true with issues at the state, federal, and international levels.

Identifying external stakeholders is another important exercise that policy advocates must undertake. What constituency and interest groups will support or oppose the initiative? Which organizations will take a lead role in assisting in advocacy efforts? Other external stakeholders, including private-sector organizations such as hospitals, healthcare systems, insurance companies, and pharmaceutical companies, should also be catalogued as potential advocacy channels. Which organizations' Web pages, newsletters, or events can be used for advocacy? Advocates should also research private funders, including nonprofit foundations and corporate foundations, to determine opportunities to leverage funding.

Delivering Information/Direct Advocacy Channels

Often, advocates have opportunities to discuss their issue directly with policymakers. A single meeting, if handled correctly, can have a tremendous impact on the policy-making process. Direct advocacy channels range from formal meetings to happenstance encounters at, say, the pharmacy. Most often, formal meetings can occur in an elected policymaker's capital or district office. Careful consideration should be given to where the meeting occurs and who attends. Elected policymakers are often passionate about public health issues and can easily be approached to discuss a specific issue. Most direct advocacy opportunities, however, will occur in a short meeting; advocates must be well prepared to maximize the contact.

Formal and informal meetings with administrative policymakers are an often overlooked opportunity for effective issue advocacy. Regulators are generally well informed about the intricacies of the

policy-making process as well as the complexities of implementing policies on particular issues. Establishing relationships with regulators can provide unmatched advocacy opportunities, particularly when the individual has a direct interest in the issue or where the affected agency has the issue as a core competency.

Advocacy Tools

In addition to direct contact with policymakers, advocates deliver information in various written formats. The most widely used written document is a fact sheet—a one-page summary of the issue, recommended action, and rationale for the proposed action. Fact sheets should also include a messaging component as well as a clearly articulated summary of the request. Other written advocacy tools include issue papers, correspondence, letters to the editor, brochures, and Web pages, to name a few. Policymakers pay significant attention to handwritten letters from their constituents. Other types of letters include form letters signed by individuals and those listing supporting organizations. In addition to written communications, advocates sometimes use messaging tools such as pins and bumper stickers.

Future Implications

To be most effective, public health policy advocates should carefully map out a policy action plan for each issue. Methods for collecting, analyzing, assimilating, and delivering relevant information to policymakers at the local, regional, state, national, and international levels should be carefully considered. Tools for advocacy should include face-to-face meetings as well as written communication. Meetings should be short, and written documents should be clear and concise. Without question, public health policy advocates can influence the policy-making process on significant issues relating to healthcare, health disparities, and the environment, among others.

PUBLIC POLICY

Public policy represents the codification of mainstream values. Policy comes in the form of legislation, regulation, executive decisions, budget allocations, and court decisions. Public policy represents the official direction or pronouncement of governmental institutions (the legislature, executive, or judicial branches) on a particular subject or issue. In the United States, public policy is promulgated at the federal, state, and local levels of government by elected and appointed officials. As mainstream values change over time, so does public policy. This change may be the result of elections, interpretations of the courts concerning legislation, lobbying, or public opinion. Policy represents the product of a priority-setting process. Public policy in the area of healthcare, therefore, represents the official decisions of government on access, allocation of resources, delivery, financing, and organization of healthcare services.

Basic Premises

In the United States, the basic value at the foundation of public policy concerning healthcare is that

healthcare is not a legal right of citizenship. Instead, healthcare is considered to be a privilege usually associated with a benefit of employment. Only for those 65 years of age or older and those with very low incomes has the nation created a legal entitlement to health insurance coverage, thus establishing a right to healthcare for these citizens.

The basic model is that healthcare is an individual, private responsibility for all those in the age range of 18 to 65 whose incomes do not fall below the poverty line and who are not disabled, veterans, American Indians, or Alaska Natives.

The U.S. healthcare system stands out in two other ways, which also reflect mainstream values. The first is that it devotes the largest share of its gross domestic product (GDP) to healthcare in contrast to other developed nations. In the middle of the 20th century, less than 5% of its GDP was devoted to healthcare. That percentage rose to nearly 14% by the end of the century. Yet the system does not necessarily produce superior health outcomes (e.g., low infant mortality or greater life expectancy). The second unique feature of the U.S. healthcare system is that it is not based on some form of universal healthcare. The system relies, for the most part, on private healthcare providers with a mix of private and public insurance as well as extensive government regulatory intervention.

Policy-Making Process

Policy is the product of a process consisting of the following stages: (a) problem definition; (b) formulating options for consideration; (c) debate and deliberation over the available options; (d) adoption of a particular option; (e) implementation of the selected option, including appropriation of resources to support the option; and (f) assessment or evaluation. This process may vary depending on which political institution or level of government is involved.

Legal and Regulatory Foundations

Much of public policy since World War II in the healthcare area can be traced to changes in laws and regulations related to healthcare. These policies relate to access, financing, organization, and service delivery. Taken together, these laws and regulations represent public policy in American healthcare.

Hospital Expansion

After World War II, President Truman assigned a high priority to health insurance. He built on the proposals developed in 1938 and included the following components: expansion of hospitals, increased support for public health, support for maternal and child health services, increased federal support for medical research and education, and, most significantly, a single health insurance program to provide coverage for all segments of society. These reforms were defeated for the same reasons and by the same coalition that had defeated these kinds of proposals in the past.

It was, however, during the Truman Administration that part of his vision was realized: the expansion of hospitals. The U.S. Congress passed the Hospital Survey and Construction Act, also known as the Hill-Burton Act of 1946, which provided for \$1 dollar of federal funds for every \$2 spent by states in the construction of community-based hospitals.

With the defeat of the various proposals for universal health insurance coverage between 1915 and 1946, the post-World War II era in healthcare was characterized by an expansion of Blue Cross and Blue Shield and other commercial insurance products as well as an increase in prepaid, direct service plans, such as the one developed by Henry Kaiser.

Medicare and Medicaid

With the passage of the Title XVIII (Medicare) and Title XIX (Medicaid) amendments to the Social Security Act in 1965, the role of the federal government was fundamentally changed. These programs represented a major change in the government's approach to the design, financing, and delivery of healthcare. As part of the New Frontier, President Kennedy had flirted with the reintroduction of a national health insurance proposal. President Johnson, subsequently, succeeded in the enactment of Medicare, which provided an entitlement to every citizen who reached the age of 65. Part A of the Medicare program (i.e., reimbursement for inpatient, hospital-based treatment) was mandated, and Part B (i.e., outpatient care and reimbursement for physicians) was to be voluntary. Between 1965 and 1985, Medicare helped

restructure financing and reimbursement policies for all the American healthcare system and not just for this particular program, because private insurance companies adopted reimbursement policies that were indexed to Medicare.

Medicaid represented a federal-state partnership to provide medical services to low-income individuals who meet the eligibility criteria. The theory behind Medicaid was that eligible individuals should be given the buying power in the healthcare marketplace that would provide free choice of providers and open-ended reimbursement, based on reasonable costs and fee-for-service, for noninstitutional providers. The statute also provided nonhospital providers with the choice to accept or reject Medicaid patients. The program provided for a core minimum set of services that all states must provide and a second set of services that states had the option to provide.

Health Maintenance Organization Act

Subsequent to Medicare and Medicaid, the U.S. Congress enacted the Health Maintenance Organization (HMO) Act of 1973. This statute represented a new approach in federal healthcare policy: It was an attempt to gain control over healthcare pricing by encouraging the development of fully integrated healthcare organizations that imposed vertical controls on the cost of services furnished to their member providers. Congress envisioned that 1,700 HMOs would be developed by 1976, but only a fraction of that number was ultimately developed. This innovative legislation, proposed by the Nixon Administration, foresaw a trend in American healthcare that would ultimately become quite popular in the 1990s. In 1988, for example only 25% of those with employer-based insurance were enrolled in managed-care plans; by 1997, the number increased to 80%.

Emergency Medical Treatment and Active Labor Act

Federal involvement in healthcare was augmented in 1986 with the enactment of the Emergency Medical Treatment and Active Labor Act (EMTALA). This statute was a response to the growing problem of access to healthcare in the United States. This law was also in response to what appeared to be a grow-

ing trend of hospitals not providing treatment to those who could not afford to pay for the services they were receiving. EMTALA requires hospitals that are receiving any Medicare revenues (which includes almost all the hospitals in the nation) to provide treatment to all patients seeking care for emergency medical conditions regardless of the ability to pay and regardless of their eligibility for Medicare. The statute requires hospitals to provide patients with "appropriate medical screening," and patients must also be stabilized, before they can be transferred to another facility.

At approximately the same time, there was increasing concern in the public and private sector alike over the rising costs of healthcare and more intensive skepticism over the effectiveness of the traditional fee-for-service system. This system was considered to be user-friendly, allowing for flexibility and discretion for providers and patients alike. However, it did not seem that it could control costs. Health insurance premium increases, for example, of 15% to 20% per year were commonplace in the mid- to late 1980s. In 1990, when employer-sponsored group insurance premiums increased "by only 14%," this was considered to be good news, because they had risen by 24% in the previous year. This inability to control cost increases was considered to be the fatal flaw of the fee-for-service system.

This indictment led to the increased popularity of managed-care arrangements. The term *managed care* encompasses a broad range of healthcare organizational arrangements that are intended to eliminate unnecessary and inappropriate care and to reduce costs. The basic theory of managed care is to control costs by restricting access and services while maintaining quality. The basic features of managed care include contractual arrangements with selected providers to furnish a comprehensive set of healthcare services to its members, significant financial incentives to steer patients toward providers and treatments/medical procedures within the plan, and ongoing accountability of providers for their clinical and financial performance through formal quality assurance and utilization review. A central feature of managed care is the use of a limited number of providers who are selected on the basis of their clinical-practice patterns and specialty and their acceptance of financial incentives for cost conscious utilization of resources.

These managed-care arrangements allow for the provision and financing of healthcare in a structure substantially different from the accepted fee-for-service arrangement, and they enable managed-care organizations to take an active role in monitoring and controlling the amount and type of services provided to patients by physicians and other caregivers. They differ in the amount of financial risk that the managed-care organizations assume, the way they share risk with providers, the restrictiveness of the provider policies, and the level of out-of-pocket costs that the beneficiaries bear.

Health Security Act

With the growing concern over costs, the critique of the fee-for-service system, and the growing popularity of managed care, healthcare became a campaign issue in the 1992 presidential race. Following his election, President Clinton introduced a comprehensive proposal (Health Security Act [HSA] of 1993) to reform the American healthcare system. The proposed legislation began with the premise that healthcare was a legal right for all citizens. This act envisioned universal access to healthcare for all citizens. It used principles of managed competition to increase access and quality of healthcare at the same time. The plan was to restructure the financing and delivery of services through providing incentives to private insurance companies, enabling the formation of small groups and purchasing cooperatives, and by increasing the role of government in providing access and services, as required. During this same time period, at least 10 alternative proposals to reform the nation's healthcare system were introduced by members of the U.S. Congress. None of these proposals, including the HSA, were adopted.

Health Insurance Portability and Accountability Act

The debate over Clinton's proposed health plan, did, however, highlight some of the problems of the nation's healthcare system. This recognition led to the adoption of the Health Insurance Portability and Accountability Act (HIPAA) of 1996. HIPAA provides for continued health insurance coverage for individuals who might otherwise lose their coverage as part of a group plan (e.g., for leaving one

job to accept another). It also bars exclusionary practices of insurance companies that are designed to deny coverage to individuals who are bad risks because of preexisting medical conditions.

Employee Retirement Income Security Act

State government has traditionally held the right to regulate the insurance industry. Insurance law, certification, and licensing requirements have provided states with a measure of control over the healthcare industry. However, in 1974, the U.S. Congress passed the Employee Retirement Income Security Act (ERISA), a comprehensive, uniform national system for employee benefit plans, which mandated inclusion of healthcare benefits. ERISA provisions have resulted in preemption of state initiatives, especially those oriented at universal coverage provided through employer mandates. In addition, ERISA has often been interpreted by the federal courts to preempt virtually all of the vast body of state insurance, contracts, and other laws or regulations applicable to healthcare plans.

As already indicated, the focus of healthcare policy and law since 1930 has been containment of healthcare expenditures. Cost containment efforts have led to a transformation in the organization and financing of the American healthcare system, with the government-financed Medicare program serving as a standard for reimbursement. However, neither the cost-containment initiatives nor the new programmatic statutes such as EMTALA or HIPAA have addressed what many employers, consumers, and third-party payers consider to be the major flaws with the traditional fee-for-service system. This has led to the growing acceptance of managed care.

National data suggest that managed-care organizations are substantially more efficient than indemnity plans in controlling costs. The average premiums paid for by employers for health benefits decreased substantially between 1989 and 1999. Health insurance premiums began to increase again over the past several years. It could be argued that these rate increases are linked to the negative impact of regulation on managed care. In 1989, the average premium increase per year was 18%, and by 1996 it was only 1%. The sweeping changes in the organization and financing of the healthcare system can be attributed to the spread of managed care.

However, the growing reliance on managed care in the private marketplace and in Medicaid programs was also accompanied by consumer and provider dissatisfaction with these new financing, administrative, and organizational arrangements. Providers and consumers have advocated for a larger panel of providers in managed-care networks and less restrictiveness on stepping outside the network to obtain reimbursable medical services from nonnetwork providers. Consumers are looking for less restricted access to providers than they have in many managed-care plans. Providers, being shut out of selective contracting and fearing loss of income from the closed panels of managed-care organizations, are advocating for unrestricted access for patients. Providers are also demanding that the administrators of these organizations remove themselves from, in effect, making therapeutic decisions that result from financing decisions. For example, providers and consumers alike strongly object to so-called gag clauses, which prevent providers from informing patients about treatment options that the managed-care plan does not cover; to policies that limit hospital stays for childbirth; and to restrictions on patients' rights to sue managed-care organizations for denial of needed care.

In response to the growing criticisms of managed care by providers and consumers and the increasingly adverse coverage of managed care by the popular press, state legislatures and the U.S. Congress began to respond with a regulatory strategy. Since the defeat of the Clinton healthcare reform proposal, states have taken the lead in enacting a set of laws limiting the flexibility of managed-care organizations in their contracting for and delivery of services.

The specific features of managed-care regulation vary from state to state, but the types of regulation can be divided into two categories: (1) laws that regulate the relationship between managed-care organizations and healthcare providers and (2) laws that regulate the relationship between managed-care organizations and healthcare consumers.

Laws that regulate the relationship between managed-care organizations and healthcare providers affect how the organizations select, deselect, compensate, and control the physicians whom they employ directly or contract with to provide healthcare. These include laws that limit the ability

of managed-care plans to direct the flow of patients to specific providers, prohibit contracts between managed-care plans and provisions that establish exclusive relationships (contracts that do not permit providers to sign contracts with other managed-care plans), and mandate that any provider willing to meet the price terms of the health plan must be accepted into the network—the so-called Any Willing Provider legislation (statutes that stipulate that any provider who meets the criteria for inclusion in a managed-care organization's network must be given the opportunity to join the managed-care organization); at least 14 states have enacted comprehensive Any Willing Provider laws, and another 14 states have enacted more limited versions of these laws.

Proposed laws that regulate the relationship between managed-care organizations and healthcare consumers include legislation that would allow patients direct access to specialists without a referral (the so-called direct access laws), which mandates a minimum stay in hospitals for births and other procedures, and that allows enrollees to sue managed-care organizations for refusing necessary treatment.

The commonality between these various forms of managed-care regulation is that they all focus on issues of cost and access. A central feature of managed care's ability to restrain the rapid rise of healthcare costs is its restriction on access and choice. Managed care restricts access through the use of a limited number of providers who are selected to be part of the plan and through the use of financial incentives to steer patients to providers who are part of this plan. Elimination or restraint of either of these features significantly affects the ability of the managed-care organization to control costs. Issues of increased access to a broad set of providers and, hence, increased choice and cost control appear to be mutually exclusive if one is trying to adhere to principles of managed care.

The plethora of anti-managed-care regulations put forward appears to be a disjointed attempt by state legislators to satisfy disgruntled constituencies by violating the fundamental principles of managed care that can make it successful. The continued pressure on state legislatures to respond to constituent pressure for relief from managed-care restrictions is not the only issue healthcare reformers will face in the future. Insurance premium costs

are increasing after several years of slow or flat growth. It could be argued that these rate increases are linked to the negative impact of regulation on managed care. While managed-care penetration into the healthcare market increased in the 1990s, will rising costs cause employers to discontinue healthcare coverage for their employees or shift ever-larger portions of healthcare costs onto them? Growing numbers of healthcare purchasers are opting to move into self-insured plans; this is done, in part, to avoid state regulation. Self-insurance plans “protect” employers from state regulation because of the ERISA preemption.

State Policy

Public policy in the arena of healthcare has not only been formulated at the national level, but there also have been policies promulgated in the states. In the past decade or so, the majority of states have passed legislation regulating the issuance, content, and pricing of private group health insurance plans. The purpose of this legislation is to increase the number of insured persons by expanding and securing coverage and to ensure that those who are sick receive the appropriate care. A variety of factors have motivated these laws. One prominent reason for states’ aggressive regulation of the private health insurance market was the large number of uninsured individuals who were employed. In 1987, prior to the implementation of many of the regulations, there were 23 million uninsured individuals between the ages of 18 and 64, many of whom were employed. Moreover, there was a significant increase in the number of uninsured workers in small firms during the latter half of the 1980s. Many believe that insurance industry practices such as experience rating and redlining (i.e., refusing to sell insurance to firms deemed high risk) were major reasons that workers in small firms accounted for one out of every two uninsured workers. In response, many states limited these practices through legislation collectively referred to as small group reform.

The other major type of state (and federal) regulation is mandated health insurance benefits, regulation that requires that all group insurance plans pay for certain medical procedures and/or providers. These reforms have a longer history than small group insurance reform. They initially arose as a

response to lobbying pressures by provider groups and as a way to address possible market failures, but recent mandates have been primarily motivated by the rise of managed-care organizations. Regulation of the content of insurance plans is an attempt to counter managed-care organizations’ efforts to limit utilization. To ensure that people still receive appropriate care, states have specified the types of treatments and kinds of providers an insurance plan must cover. An example of such a mandate is minimum maternity hospital stays. The popularity of mandated benefits has grown dramatically over time. In the first 6 months of 1997 alone, more than 600 new state health insurance benefit mandates were introduced across the nation.

Future Implications

There have been debates over healthcare reform in the United States since the Progressive Era. However, large-scale reform has not been achieved. Future policy deliberations will need to address some fundamental tensions, such as balancing the need for cost containment while providing access to the growing number of uninsured individuals. They will also need to address many questions, such as the following: Can increased access be achieved without introducing mandates for employers or individuals? With increasing life expectancy, how can the costs of Medicare be brought under control? Will the United States ever commit itself to providing healthcare as a right of citizenship?

QUALITY-ADJUSTED LIFE YEARS (QALYS)

A quality-adjusted life year (QALY) is an outcome measurement of health over time related to a disease or condition under study. The quality of life can be determined by using various tools to measure the preference toward a health state of the general public or of a specific individual or group in a certain state of disease or wellness. This measure of the quality of life in each health state is multiplied by the time spent in each health state to obtain the QALY. The QALY is not just a measure of life years but also a measure of the quality of health in each of those years, therefore a measurement of both morbidity and mortality. A QALY will be equal to or less than the total number of life years studied.

Calculation Methods

A QALY can be calculated in several ways using various methods. The quality of life can be measured using preference scales to implicitly rate the quality of health experienced by either individuals or the public in general. These tools can be either based on general attitudes or disease specific. Preference scales commonly used are the Visual Analog Scales (VASs), or feeling thermometers, the Standard Gamble (SG), and the Time Trade Off (TTO) preferences. The use of preference scales allows for the measurement of the quality

of health from the perspective of the individuals toward whom the health system is directed.

The VASs use number or category rating scales, marked or unmarked line scales, or combinations of either. While the scales vary, the final measure is transformed into a scale of 0 to 1, where 0 is *dead* and 1 is *perfect health*. The individual is presented with two choices: One is treatment, which may result in a chronic health state leading to either a better state or immediate death; the other is no treatment, therefore remaining in a chronic health state leading to death. The assumption is that the life years are longer in the treatment state. This tool could also be used with temporary health states that do not lead to death. One such scale is the Health Related Quality of Life Scale (HQRL). The HQRL uses a vertical scale, analogous to a thermometer, from 0 to 1, 10 divisions between each integer, with 0 being *dead* and 1 being *perfect health*. The subjects are asked to indicate where on the scale they feel the quality of their health lies. Another published scale using preference scores is the Quality of Well-Being Scale (QWB). The preference scores can be plotted on the vertical axis of a graph against the time spent in each score or health state with time on the horizontal axis. Integrating the area under the plotted curve is a measure of the total QALY.

The SG method measures preferences for chronic states by presenting the subject with a choice between treatment, leading to either a healthy state or death, and no treatment, resulting in a continued chronic state until death, much like the VASs. However, the time in each state, if listed

as a probability, can be altered to determine the subject's preference. SG techniques are offered by direct interview, paper, or computerized questionnaires. Any of these can be enhanced with visual aides. Variations for temporary health states can accommodate conditions not having a fatal outcome. Examples of tools incorporating SG are the Short-Form-6D and the Health Utility Index (HUI), both of which were generated from general public preferences.

The TTO method is used by the EuroQoL Group (an organization initiated in Europe to develop a common instrument for describing and assessing health and quality of life) and is similar to the SG. In this method, subjects choose between living in a certain chronic state until death and a healthy state of shorter duration until death. Or for temporary states, the subject can choose between a poor health state or one that is worse but with treatment leading to a better state. The time spent in each state can be adjusted until the subject feels about the same toward each.

Other methods include the Rosser Index and the Person Trade-Off (PTO), which is basically a TTO with the trade-off considered for others rather than oneself.

QALY measures do not look at the monetary cost of arriving at a particular state of health quality but are used in cost-effectiveness and cost-utility analyses to determine the ratio of cost to outcome or cost per QALY. In these analyses, the cost per unit of health can be measured in several ways, one of which is the cost per life year gained. When choosing an instrument to measure QALY, consideration must be given to the population used in developing the tool. Attempting a pilot test prior to choosing, or using several tools may be advisable. The resulting cost-effectiveness or cost-utility analysis may vary greatly depending on the method used to evaluate the quality of life. A thorough analysis using several methods could yield results better suited for economic evaluations. The use of QALYs is also recommended to facilitate comparisons across studies for various medical and health-care interventions. On the individual scale, a small improvement in health over many years may yield the same QALYs as a large benefit over only a few years. Similarly on the societal level, a small improvement for many people may equal a large benefit for a few individuals.

When calculating QALYs into the future, discounting of future benefits or health states can be done to gain the relative weight in the current year. With escalating healthcare costs, increasing emphasis is placed on government and private control measures, individual contributions, and universal coverage. Developing decision models using cost per QALY comparisons could assist in public and private policy-making decisions on the allocation of resources. A limitation is the long-term observation period required for the analysis of newer treatments. The ongoing collection of data sets and league tables listing costs per QALY, available in public registries, lends convenient access for such purposes.

QUALITY ENHANCEMENT RESEARCH INITIATIVE (QUERI) OF THE VETERANS HEALTH ADMINISTRATION (VHA)

The Quality Enhancement Research Initiative (QUERI) of the Veterans Health Administration (VHA) is a multidisciplinary, data-driven, quality improvement program designed to ensure excellence in all places where VHA provides healthcare services, including inpatient, outpatient, and long-term care settings. QUERI aims to identify best practices, systematize their use, and provide the feedback necessary to maintain ongoing improvement. The National Academy of Sciences, Institute of Medicine's (IOM) seminal report *Crossing the Quality Chasm* (2001) identified QUERI as one of the nation's best examples of synthesizing the medical evidence base and applying it to clinical care.

The VHA is the healthcare delivery system for the U.S. Department of Veterans Affairs. It runs many hospitals, outpatient clinics, and long-term care facilities. One of the main offices of the VHA is the Office of Research and Development (ORD). QUERI is based within the Health Service Research and Development Service of ORD. From its onset in 1998, QUERI has been fully integrated into the VHA's strategic framework for quality management. Being within the VHA, with its central management and centralized database that is used by all its facilities, the clinicians and researchers associated with QUERI have the unique opportunity of putting their research findings into practice.

Organization

QUERI is organized into three parts: QUERI centers, a Research and Methodology Committee, and a National Advisory Council (NAC).

QUERI brings together VHA's Health Services Research and Development researchers and VHA's clinicians and administrators and provides them the unique opportunity to transfer research findings into patientwide and systemwide improvements. QUERI centers currently focus on nine conditions that are prevalent and high risk among veterans: chronic heart failure, diabetes,

HIV/hepatitis, ischemic health disease, mental health, polytrauma and blast-related injuries, spinal cord injury, stroke, and substance use disorders. Each QUERI center consists of a research and clinical coordinator and a 15-member executive committee that includes researchers and clinicians with expertise in specific areas for each center from around the country.

The Research and Methodology Committee serves as the oversight committee for the entire QUERI process. It is composed of VHA senior researchers, clinicians, and policymakers. It meets semiannually to evaluate the performance of each QUERI center by reviewing their research methods, plans, and projects. It approves requests for solicitations, and it ensures that the QUERI process is being followed by each center.

The NAC is composed of senior VHA policy leaders from the U.S. Department of Veterans Affairs' (VAs') central office in Washington, D.C. It provides general policy guidance and direction, and it ensures that QUERI is integrated into the VHA's operational policies and structure.

Process

The specific activities of the QUERI centers follow a standard process or sequence of activities that were specified at the time the centers were established. Through literature reviews and experience, six steps were identified as necessary to systematizing quality improvement in the VHA. The six steps are discussed below.

Step 1: Identify conditions associated with high risk of disease and/or disability and/or burden of illness for veterans. The QUERI leadership chose the conditions. Most of the conditions chosen were high volume and among the most common discharge diagnoses in the VHA. For two of the conditions, spinal cord injury and HIV/AIDS, the VHA is the nation's largest provider of care. The individual QUERI executive committees could choose to concentrate on specific high-priority subtopics within their condition. This was done with the approval of the QUERI leadership.

Step 2: Identify best practices. Following the identification of the disease or condition, each QUERI group identified evidence-based best-practice

recommendations and processes. For many of the QUERI conditions, a range of systematic reviews, evidence-based clinical practice guidelines, and other clinical recommendations were already available for review, refinement, and implementation. In some areas, evidence-based clinical practice guidelines were unavailable. In these cases, each QUERI center was expected to do literature reviews, evaluate care models, and use other best-practice programs. If necessary, the QUERI centers were to initiate their own research to close existing gaps in knowledge and practice. They were also encouraged to work with VHA's National Clinical Practice Guideline Council to facilitate the development of new evidence-based guidelines.

Step 3: Define existing practice patterns and outcomes across VHA and current variation from best practice. Following the identification of evidence-based best practices, each QUERI center conducted research to document and assess current VHA practice patterns and identify gaps and shortcomings in VHA policies, clinical practices, and outcomes. The VHA's national database greatly expedited this process. This process identified opportunities for improvement. Where VHA databases did not allow the collection of such data, the QUERI centers worked with VHA to refine and develop such data or tools.

Step 4: Identify and implement interventions to promote best practices. Following completion of Step 3 (which included data collection and analysis activities and the identification of important performance variations and gaps), each QUERI center worked to diagnose the cause of documented performance problems and to identify and implement programs and strategies to improve healthcare quality and outcomes. In areas where published literature provided evidence regarding promising strategies, the QUERI centers worked to adapt and implement the established strategies. In areas where such guidance was not available, the QUERI researchers designed new strategies. The specific interventions and projects conducted in Step 4 included (1) efforts to translate clinical research findings and recommendations into routine clinical practice through refinements and reorganization of clinical-practice systems and processes and (2) efforts to translate successful facility-level programs into systemwide policies and practices.

Since the field of translation research is relatively new, several coordinated efforts were launched to support and encourage the investigators associated with the QUERI centers. These included special funding and solicitations, a separate scientific review board with experience to review grant proposals from the QUERI centers, annual conferences to examine methods and processes of quality improvement and strategies for organizational behavioral change in healthcare delivery, translation consultants identified and made available to the QUERI centers, and supplemental funding made available to each QUERI center to hire dedicated translation experts (with formal training and experience in individual and organizational behavior change and quality improvement). Each QUERI center was responsible for having a plan outlining where in the six steps it was for each condition or subtopic and a separate translation plan. These plans were updated annually and reviewed by the Research and Methodology Committee.

Step 5: Document that best practices improve outcomes. An important feature of the QUERI process and a critical element in its success is its focus on measurement and improvement in patient and system outcomes. If QUERI was to promote sustained quality improvement and attain support from VHA patients, staff, managers, and external stakeholders (e.g., the U.S. Congress), it must demonstrate continued improvement in patient care and systems outcomes. Although process and structure data were also needed, outcome measurement was prioritized. Outcomes were generally measured in QUERI through a diverse set of tools and sources, including VHA's computerized data and surveys of patients, their caregivers, and VHA clinicians. Together, these sources provided a comprehensive assessment of relevant patient and system outcomes, ensuring value and helping to further refine the QUERI quality enhancement programs and other interventions implemented in Step 4. Outcomes of interest typically included mortality, morbidity, functional status, health-related quality of life (HRQOL), access, utilization, costs, and patient satisfaction. In circumstances where valid outcome measures did not exist, studies were proposed in the strategic plan, which was then reviewed, by the Research and Methodology Committee. Where appropriate, risk-adjusted

models were also developed and tested. Finally, the development of relevant feedback mechanisms was encouraged.

Step 6: Document that outcomes are associated with improved HRQOL. The final QUERI step was to link practices with improved HRQOL, functional status, and patient satisfaction. Although patient outcomes were addressed in Step 5 of the QUERI process, HRQOL measures are so important and so often neglected that they were emphasized separately in the QUERI process. Separating HRQOL in Step 6 ensured that QUERI projects emphasize this critical outcome and that adequate attention be given to its measurement and improvement.

Progress and Results

Several of the QUERI centers have already demonstrated improved patient outcomes. For example, the chronic health failure QUERI implemented a multifaceted intervention to improve the patient's outcomes and to reduce the length of stay and readmission rates, by using coordinated case management, patient education, and related tools. They have shown a significant decrease in 14-day readmission rates (from 14.2% to 4.8%) and increased patient stability on discharge and at the first outpatient visit.

The diabetes QUERI designed interventions to increase clinician awareness of diabetic-patient risk factors and to increase use of aggressive appropriate therapy. Impacts include increased provider awareness of the importance of blood pressure control and significant improvements in controlled blood pressure, lipids, and glycosylated hemoglobin (HA1c). This has led to decreasing cardiovascular events and death.

The spinal cord injury QUERI has targeted influenza vaccination of its patients. This led to a VHA-wide policy to identify and target spinal cord injury patients as a high-risk, high-priority group for flu vaccination. As a result of the policy, vaccination rates improved from 26% in the late 1990s to 74% for influenza and 89% for pneumonia in 2007.

The mental health QUERI has facilitated the spread of collaborative care for depression in VA primary-care settings.

The ischemic heart disease QUERI has implemented computerized decision support for treatment of hypertension.

In addition to the accomplishments of each QUERI center, the leadership of QUERI recognized the need to advance the field of implementation by promoting the sharing of insights and results among scientific peers. To accomplish this, it recently participated in the establishment of an online reviewed journal focused on implementation science.

QUALITY IMPROVEMENT ORGANIZATIONS (QIOs)

Quality Improvement Organizations (QIOs) are nonprofit organizations whose statutory missions are to improve and protect the quality of Medicare services while safeguarding the integrity of the Medicare Trust Fund. QIOs accomplish their mandates by working with physicians, hospitals, and other healthcare providers to ensure that Medicare beneficiaries receive care consistent with professionally recognized standards of practice, mediating complaints about quality of care, and performing utilization review to ensure that services are medically necessary and appropriate. QIOs stem from a federally mandated program aimed at improving quality through national oversight and the monitoring of Medicare services. These organizations are relevant to health services research because they investigate why costs of care are increasing and how they can be contained without jeopardizing quality.

Background

The concept of QIOs emerged soon after the passage of the Medicare program (Title XVIII of the Social Security Act) in 1965, at a time when national priorities were directed on efforts to contain rising healthcare costs. Prior to that time, hospital and medical peer groups had set the precedent in establishing quality assessment criteria and in the creation of a hospital-accrediting organization (today, the Joint Commission) to enforce quality standards. These efforts not only laid the groundwork for the standards for hospitals participating in the Medicare program, they also propelled the U.S. Congress to authorize a pilot program in 1971 for an experimental medical care

review organization (EMCRO) to assess and monitor utilization of inpatient and ambulatory services, which served as the initial model for a national quality review program. A year later, the professional standards review organizations (PSROs) were established as the first national quality assurance program to focus on utilization review of hospitals and physician outliers as a way to control costs. Physician groups, however, opposed the PSROs, because they were unable to demonstrate that results from such approaches affected cost containment. A decade later, the passing of the federal Peer Review Improvement Act of 1982 (as part of the Tax Equity and Fiscal Responsibility Act of 1982) led Medicare to replace the PSROs with peer review organizations (PROs). The PROs refocused their efforts on monitoring utilization and outcomes for specific Diagnosis Related Group (DRG) assignment, readmissions, hospital operations, complications, and mortality rates. The success of the PROs led to expanding reviews in nursing facilities, home health agencies, hospital outpatient services, physician offices, and managed-care organizations. By the end of the 20th century, Medicare shifted away from a quality assurance focus on case review to quality improvement approaches that influenced patterns in clinical-care processes and outcomes. Hence, by 2002, the PROs were renamed quality improvement organizations (QIOs) to reflect the changing definitions of quality and national priorities toward measurement and population-based improvement effects.

Evolution and Current Status

QIOs constitute the nation's foremost infrastructure for quality improvement that is administered by the Centers for Medicare and Medicaid Services (CMS) as part of a larger program financed mainly through monies from the Medicare Trust Fund. CMS contracts with QIOs to provide services in all 50 states, the Virgin Islands, the District of Columbia, and Puerto Rico, plus several QIO support centers that operate solely as national resource clearinghouses. Moreover, CMS has developed and oversees a complex communication and information systems technology service for the QIO program comprising a standard data-processing system (SDPS) that serves as a centralized repository

of clinical data information interfacing with two clinical data abstraction centers (CDAC) and all QIOs. In addition, this service operates a centralized case review information system (CRIS) to track and report on case review activities as well as a protected intranet Web site used by the QIO community to share measurement tools and resources for the SDPS used in the national measures reporting activities.

As of 1984, QIOs have operated from a statement-of-work contract, in 3-year cycles, which has transformed over the decades in three distinctive phases. In the first phase, under the first and third statement-of-work contract cycles, the PROs emphasized the utilization and case review, which was gradually extended to other provider settings. During the second phase, under the fourth and fifth statement-of-work cycles, the PROs focused on transitioning healthcare providers into measurement-based quality improvement project activity rooted in systematic data collection methods using case review to validate measurements. The second phase continued under the sixth and seventh statement of work, with the PROs transitioning into the QIOs, with quality improvement projects aimed at high-cost, high-volume medical conditions (e.g., cardiac care, pneumonia, diabetes), technical assistance to providers in building performance measurement systems, and focusing cost containment on reducing the number of payment errors in hospital settings. The third phase, under the eighth statement-of-work cycle, shifted the QIOs' role to building capacity in performance-based measurement and reporting systems, adapting health information technology, redesigning processes of care, and transforming organizational culture across all provider settings.

Future Implications

The U.S. Congress completes an independent evaluation of the QIOs' program prior to the end of each 3-year statement-of-work contract cycle to determine its effectiveness in meeting quality goals and to define future directions. Current trends indicate that under the ninth statement-of-work contract cycle, slated to begin in 2009, emphasis will remain on supporting the expansion of national systems for quality measurement and

reporting to sustain performance improvement activity and on supporting emerging changes in payment systems aimed at pay-for-performance of healthcare.

QUALITY INDICATORS

Healthcare quality indicators are tools to measure and monitor the quality of care. Quality indicators

are used to determine how well a healthcare system is performing and how it can be further improved. Because poor healthcare quality can adversely affect people's lives and lead to unnecessary healthcare expenditures, quality measurement is important.

Definition

Healthcare quality indicators are the instruments and methods for quantitatively assessing clinical processes and/or patient outcomes. They are used to document the quality of care delivered by providers, evaluate patient outcomes and institutional performance, make comparisons over time and between providers, inform and help purchasers and patients make wise decisions in selecting providers, support accountability and quality improvement efforts, and create transparency in the healthcare system.

Based on the published literature, some of the key characteristics of healthcare quality indicators are as follows: They are based on agreed definitions, described exhaustively, are highly specific and sensitive, are valid and reliable, discriminate well, are relevant, permit useful comparisons, and are evidence based. Quality indicators should be explicit statements of structure, process, or outcome dimensions.

Quality indicators should be developed in the planning and development phase. The planning phase should consist of choosing the clinical area for evaluation and organizing the measurement team. The development phase should comprise providing an overview of existing evidence and practice, selecting clinical indicators and standards, designing the measure specification, and performing pilot tests. The development of quality indicators should be closely tied to both the definition and efforts to improve the quality of care.

Quality indicators can be categorized based on the type of healthcare provided (preventive, chronic, or acute); function (screening, diagnosis, treatment, or follow-up); modality (history, physical examination, laboratory/radiological study, medication); whether they are generic or disease specific, and whether they are rate based or sentinel.

Overview

Recent reports have highlighted the major deficiencies in the U.S. healthcare system. The National Academy of Sciences, Institute of Medicine's 2000 report, *To Err Is Human*, estimated that between 48,000 and 98,000 people die each year in American hospitals from preventable medical errors. And another study (Barbara Starfield's) estimated that 225,000 deaths occur each year in the nation as the result of iatrogenic causes—unnecessary surgeries, medication errors, other hospital errors, hospital-acquired infections, and adverse effects of medications.

Studies have also shown that healthcare quality in the United States varies greatly among providers and across geographic regions. Healthcare often does not meet professional standards, with most adults in the nation only receiving about half of the recommended care for common acute and chronic conditions as well as preventive services. Additionally, studies have shown that the quality of care varies according to where an individual lives in the country. As a result, there remains significant room for quality improvement across all states.

Variation in healthcare quality is not unique to the United States. Many national and international studies on the quality of care have found that the care provided in most countries is substandard. Furthermore, many countries lack performance evaluation systems to measure the quality of care. Extensive research demonstrates that quality of care does not depend on the payment system. Even countries with single-payer systems have problems with quality. Additionally, the level of quality does not appear to depend on the level of healthcare expenditures. For example, the United States has the highest healthcare expenditures per capita, but it still does not have the best measurable outcomes. Overall, there remains a general lack of investment in measuring the quality of care.

The growing concern that healthcare provides poor value relative to the amount of resources spent have led many industrialized countries to develop and implement quality indicators to better manage health production and increase the quality of care. As a result, numerous quality improvement initiatives have been implemented in the healthcare system of

nations, since Florence Nightingale first measured infection rates at the Crimean barracks hospital in the 1860s.

Early efforts in the development of quality indicators were focused on disease-specific criteria for process-based evaluations of individual physicians. With the development of clinical practice guidelines and pay-for-performance initiatives, the focus of quality indicators has been expanded to cover organizational performance.

International Quality Indicators

The development of quality indicators by the United States has resulted in the international community adopting similar practices to address the low levels of healthcare quality. Following the lead of the U.S. Agency for Healthcare Research and Quality (AHRQ), a number of other organizations are developing healthcare quality indicators, including the World Health Organization (WHO), the Canadian Association for Health Services and Policy Research (CAHSPR), and the Organization for Economic Cooperation and Development (OECD). Through these efforts, many quality indicators have been developed and are being increasingly used to evaluate the performance of individual practitioners, hospitals, and other institutional providers. Consequently, a number of countries, including Canada, England, the Netherlands, and Denmark, have launched quality indicator programs.

In particular, the OECD countries have advanced the development of quality indicators and extended these methodologies. The OECD's Health Care Quality Indicators (HCQI) project developed a conceptual framework and a set of indicators to allow for the comparison of healthcare quality across its member countries. The HCQI integrates proven concepts and methods into a health performance framework.

The OECD's framework of health determinants consists of a comprehensive multistage hierarchical model that includes four major components: health, nonhealthcare determinants of health, healthcare system performance, and health system design and context. The OECD's healthcare quality indicators focus on the healthcare system's performance, which consists of healthcare needs and specific dimensions of healthcare performance.

Healthcare needs consist of staying healthy, getting better, living with illness or disability, and coping with end-of-life problems. The dimensions of healthcare performance consist of quality (effectiveness, safety, and responsiveness/patient centeredness), access, and costs.

The Dutch healthcare system's performance evaluation is an example of a quality indicators framework that has been implemented at the national level. The Dutch model, which is based on the Canadian Lalonde model, has the dual goals of constructing a conceptual framework for national healthcare performance and selecting quality indicators for measurement. The performance system combines population health and management information into the quality indicators. The system is based on a balanced scorecard, which provides information from the consumer, financial, internal business processes, and innovation perspectives.

The Commonwealth Fund in the United States also recently developed a scorecard method and applied it to healthcare quality indicators to allow for state, national, and international comparisons. These quality indicators consist of 37 indicators of performance. This initiative is the first comprehensive means of measuring and monitoring health outcomes, quality, access, efficiency, and equity of care.

Limitations

Many of the quality indicators currently in use have conceptual and measurement issues, as they do not provide a complete assessment of a provider's performance. Furthermore, the use of quality indicators in the practice setting requires a sophisticated infrastructure that generally includes information technology, which is lacking in many clinical environments. Some of the shortcomings of quality indicators and quality-monitoring initiatives are as follows: Many healthcare systems do not have adequate documentation of the quality of care for many diseases; there are no appropriate benchmarks; there is limited evaluation of quality management efforts; and there is a lack of outcomes assessment. As a result, quality indicators have had limited success in comparing the performance between providers and organizations.

Future Implications

In the future, the quality indicators will increasingly be developed and used to monitor the performance of healthcare systems at the regional, national, and international levels. However, many conceptual and methodological issues need to be addressed. Issues such as the differences in cultural context, healthcare delivery systems, data specifications, and data availability make comparisons of healthcare performance among organizations and countries challenging. These differences must be considered if an acceptable model is to be developed. It is hoped that as healthcare quality indicators continue to be developed, evolve, and be refined to better measure, monitor, and compare against universal standards of care, the quality chasm will be crossed.

QUALITY MANAGEMENT

Quality management can be described as a method that is used to make sure that all the aspects pertaining to the design, development, and implementation of a service or product are handled in an efficient and effective manner. Quality management is critical to ensuring that certain standards are met when there is a high production volume. In healthcare, quality management has gained significant attention because of the number of

deaths and injuries reported due to medical errors. In 2000, the national Institute of Medicine (IOM) published a highly influential report, *To Err Is Human: Building a Safer Health System*, which highlighted the large number of medical-error-related deaths that occur each year in the nation's hospitals. Although the nation's manufacturing industry has been using for many years quality management techniques that encourage teamwork and communication, the healthcare industry has only recently adopted these practices.

Overview

There is no singular widely accepted definition of quality management as there are various forms of this concept, including total quality management (TQM), continuous quality improvement (CQI), and statistical control processes. The definition of quality is relevant only to the extent that it provides value to the customer. However, the main components of quality management include quality control, assurance, and improvement.

The concept of quality management evolved from the work of several important figures in the field, including W. Edwards Deming (1900–1993), Joseph M. Juran (1904–2008), Walter A. Shewhart (1891–1967), and Frederick Winslow Taylor (1856–1915). Taylor, the father of scientific management, was one of the first to lay the foundation for quality management through standardization and to advocate improved organizational practices. Continuing to advance the field, Shewhart, the father of statistical quality control, introduced the concept of the control chart. Shewhart developed his concepts at Bell Laboratories, later describing the principles of statistical quality control in his book *Economic Control of the Quality of Manufactured Products* (1931). Statistical quality control is the discipline that involves applying statistical methods to process-related data that identify the critical variables or root causes that result in reduced variation of processes or the elimination of problems.

Following in Shewhart's footsteps, Deming shared his knowledge of statistical methods to achieve quality control during World War II as well as his 14 points that served as a basis for quality management principles. Because of Deming's extensive knowledge, he consulted with

post-World War II Japan to help that nation improve the quality of its products. Japan would recognize Deming by establishing a prize for quality achievement in his honor. Deming popularized the Plan-Do-Check-Act (PDCA) cycle developed by Shewhart, also known as Deming's Cycle, or Shewhart's Cycle, which is a four-step process in quality control. In this cycle, the Plan step consists of determining goals and targets as well as the methods of reaching these goals, Do involves implementing the processes, Check assesses the results of the implementation, and Act entails taking appropriate action to improve the processes.

Juran is regarded as one of the eminent quality experts, and he was one of the first to deal with the broad management concept of quality. Juran introduced the cost of quality concept in *The Quality Control Handbook* (1951). He advocated structured improvement initiatives, a sense of urgency, extensive training, and strong upper-level management commitment.

Quality Management Strategies

Six Sigma is a quality management technique based on statistical process control to emphasize the continuous decrease in process variation. Developed at the Motorola Corporation in 1986, Six Sigma strives to reduce and eliminate sources of errors in the manufacturing process. This concept eventually led to the concept of TQM, which is a strategy that aims to improve quality among all organizational levels and processes. Another quality management strategy that arose in corporate environments and has been implemented in healthcare is CQI. This concept focuses on a team approach to quality improvement as opposed to having a culture of blame.

One of the difficulties with quality management is how to define and ensure quality. The consumer, or payer, ultimately decides what the attributes of quality are. Additionally, quality can be used as a differentiating factor between an organization's products or services.

Quality Management in Healthcare

Quality management in healthcare only began to flourish in the mid-1980s when the healthcare

industry moved toward a more outcomes-based approach. The Hospital Corporation of America (HCA) was one of the leaders in adopting Deming's PDCA cycle as FOCUS-PDCA. FOCUS stands for F—find a process that can be improved, O—organize to improve that process, C—clarify what is currently known, U—understand why there is variation, and S—select a process improvement strategy.

Research on quality management initiatives to improve patient safety and reduce medical errors has been undertaken by many national organizations and agencies such as the Joint Commission, American College of Surgeons, Agency for Healthcare Research and Quality (AHRQ), and Centers for Medicare and Medicaid Services (CMS). Computerized physician order entry, flagging alert systems, and various provider-patient communication tools are just some of the quality management techniques that have been implemented in healthcare systems in recent years.

Baldrige Award

There are several national awards given out to recognize quality; however, in the United States, the Baldrige award is the most prestigious. To recognize achievements in quality, the Malcolm Baldrige National Quality Award is given out annually by the U.S. National Institutes of Standards and Technology (NIST). Established by the U.S. Congress in 1987 and named after former U.S. Secretary of Commerce Malcolm Baldrige, this award program, inspired by total quality management practices, highlights businesses and healthcare, educational, and nonprofit organizations that deliver quality services. The original intended purpose of the Baldrige award was to increase quality awareness, acknowledge the quality achievements of companies, and highlight successful quality strategies. Recent winners of the Baldrige award in healthcare include Mercy Health System of Janesville, Wisconsin (2007); Sharp Healthcare of San Diego, California (2007); and North Mississippi Medical Center of Tupelo, Mississippi (2006).

Future Implications

Because of the wide recognition of the significant gaps in the U.S. healthcare system, quality

management will remain at the forefront of the healthcare agenda as a way to reduce medical errors and adverse events while improving patient safety, outcomes, and overall quality. The increasing use of technology, improved communication strategies, and performance assessment will be integral to implementing quality management practices in healthcare. Quality management initiatives will continue to play an important role in ensuring the consistent delivery of high-quality care for all.

QUALITY OF HEALTHCARE

Quality of healthcare refers to the degree to which healthcare services for individuals and populations increase the likelihood of desired health outcomes that are consistent with current professional knowledge. To improve the quality of healthcare, many evaluation and standardization practices have been developed. This entry discusses several aspects of healthcare quality, including the history of healthcare quality evaluation, the major organizations and programs created to increase the quality of healthcare, the role of academe in the quality of healthcare, evaluation phases, and incentives for improving quality.

History

During the first quarter of the 20th century, a confluence of events served as a strong impetus to the institutionalized, systematic evaluation of hospital quality. Abraham Flexner’s report on medical education in the United States and Canada, published in 1912, called attention to the serious deficiencies in the training of American physicians. Ernest A. Codman successfully persuaded his fellow surgeons that the development of hospital standards, along with complete, accurate records

of care and outcomes and the development of clinical databases for the study of end results, was necessary for the improvement of medical care.

In 1917, the new American College of Surgeons (ACS), created in 1913, established its Hospital Standardization Program, fundamentally embodying Codman’s proposal. The ACS formulated a one-page “Minimum Standard” on the basis of which its volunteer member-surveyors began surveying hospitals that wished to obtain ACS accreditation, the badge of excellence. Early hospital surveys revealed that medical records were for the most part utterly inadequate as documentation. The entire medical community was alerted to the need for the formulation of standards for medical and surgical care and to the need for a system of medical records that would thoroughly and accurately document patient care.

Foundation Organizations and Programs

For 35 years the ACS conducted its Hospital Standardization Program, using as surveyors its own members who volunteered their services. Over the years, it became obvious that the logistical and financial burdens of a single-organization volunteer program had become too great for the ACS to support on its own. In 1952, the ACS was joined by the American College of Physicians (ACP), American Hospital Association (AHA), American Medical Association (AMA), and Canadian Medical Association (CMA) in forming the Joint Commission on Accreditation of Hospitals (JCAH). A few years later, the CMA withdrew to become a founding member of the new Canadian Council on Hospital Accreditation (CCHA).

With the passage of the federal Medicare program in 1965, the U.S. Congress conferred “deemed status” on JCAH-accredited hospitals in the nation, granting accredited hospitals automatic eligibility for Medicare reimbursement. In view of this delegation of federal authority, as it was perceived by many critics, it became imperative to develop objective standards for the evaluation of hospital performance. The JCAH responded by completely overhauling its research and standards development programs from 1967 to 1970 and publishing updated, more objective standards with which compliance could be measured.

In 1988, in recognition of its expansion to include mental health, long-term care, home-care, and ambulatory-care providers, the JCAH changed its name to the Joint Commission on Accreditation of Healthcare Organizations (JCAHO). Since then, it has expanded its reach to include non-hospital-based clinical laboratories and office surgery practices. As a result, it has recently changed its name to simply the Joint Commission.

The growth of health maintenance organizations (HMOs) during the 1980s spurred the development of managed-care organizations and large multispecialty group practices. In 1990, the National Committee for Quality Assurance (NCQA) was established. The mission of the NCQA was to develop performance standards and conduct accreditation surveys of managed-care organizations. Since 1992, NCQA has used the Healthcare Effectiveness Data and Information Set (HEDIS), a set of standards of organizational performance with a significant emphasis on the use of screening procedures in covered populations, as its principal tool in evaluating the performance of managed-care organizations. Over the years, HEDIS has been systematically updated and expanded.

The Role of Academe

Medical schools came to system-oriented quality management slowly. Their interpretation of the concept of quality focused on the efficacy of the individual physician's clinical performance and traditionally tended to ignore the physician's role as a member of a system for providing care. While, beginning in the 1960s, small groups of inquisitive scholars on the faculties of medical schools and colleges of nursing were beginning to study ways to measure and improve the quality of hospital care, very little information about their findings and recommendations appeared in course content. In 1987, in response to an informal questionnaire survey sent to the members of the Association of American Medical Colleges (AAMC), 20% of the responders replied that they did include some material on quality assessment in the curriculum. However, the most common offering cited, typical of the affirmative responses, was a 2-hour elective lecture in the 1st or 2nd year of medical school. When the survey was repeated in 1993, the results were essentially the same.

Some respondents commented that the curriculum was so crowded with mandatory courses that no room was left for the study of organizational quality management. In another study, researchers found that 54% of the study sample of medical residents indicated that their training had not included content on medical errors.

Phases in Evaluation

In the United States, hospital-wide patient-care evaluation has gone through three recognizable phases in its evolution. The first phase was implicit review. This, the traditional method, involved assessing care on the basis of process norms or criteria derived from the assessor's personal experiences, values, and professional opinions. The criteria used were not formulated or published in advance and often varied from one expert assessor to another.

Accreditation-driven evaluation by the JCAH prior to the early 1980s focused primarily on a hospital's organizational structure and its presumed ability to provide good care, without explicitly incorporating the outcomes of care in the evaluation equation. The Joint Commission's criteria were essentially structural, although during the 1970s, research and development were moving in the direction of process-oriented surveys. Evaluation criteria focused on the organizational structure; the presence of an organized medical staff; credentials of the medical staff members; the presence of adequate numbers of qualified nurses; and the presence of acceptable plant, equipment, and instruments.

Process-oriented patient-care audits represented the second phase in institutional healthcare evaluation. During the late 1970s and 1980s, quality assurance audits performed periodically by hospitals involved the application of preestablished hospital-generated process criteria. However, the audit system had some basic flaws that weakened its potential for stimulating improvements in patient-care outcomes. When a conventional audit was performed, it was easy to pounce on a few episodes of care that failed to meet the criteria, to conclude that the observed care was acceptable, or to dismiss the whole exercise with the notation "Audit completed." The obligation had been fulfilled. Those care episodes that failed to meet the

criteria had been identified. Although it served to identify performance flaws, this approach did nothing to help professionals understand the reasons for poor performance or to point the way toward improvement. The major contribution of this approach was the fact that the criteria were established in advance of the audit and an attempt was made to quantify the evaluation findings.

Meanwhile, the Joint Commission was laying the groundwork for new techniques focusing on assessing patient clinical outcomes. Improving outcomes entails improving the systems of care. In this third, or system-oriented, phase, the healthcare industry began applying the principles of continuous quality improvement (CQI) and total quality management (TQM) to its organizational behavior. One popular approach, the “Plan, Do, Check, Act” (PDCA) cycle, gained wide acceptance. Diagnosis-specific clinical measures came into use as criteria of good care and then gave rise to the use of end-results data in developing treatment benchmarks, related “best-practices” guidelines, and evidence-based medicine. Although they were being formulated by highly credentialed groups, such as teams formed by medical specialty societies, the concepts of best practices and benchmarks met with some early resistance on the part of traditionalists, who decried their use as “cookbook medicine.” Over time, benchmarking and best practices have become generally accepted as parts of the quality management armamentarium. Reminiscent of Codman’s emphasis on end results was the development, during this time, of the concept of evidence-based medicine as a guide to practice.

Access to Care and Patient Satisfaction

Along with the reduction of medical errors and the improvement in clinical outcomes, two additional components of healthcare quality are access to good care and patient satisfaction. Access to care is a process that usually is addressed through strategies such as insurance programs, nondiscrimination policies and laws, architectural and environmental modifications, adequate public transportation, and community health education programs. Achieving widespread access to good quality care depends on legislative and public financial support at the municipal, state, and federal levels.

Over the past quarter-century, patient satisfaction has come to be recognized as an important factor in the quality of care, subject to measurement and improvement. An active consulting industry has developed around the need for objective analysis of the needs, desires, and reactions of patients and their families with regard to many elements in their care, such as the quality of hospital food, pain control, staff courtesy and responsiveness, and environmental features. Patients routinely respond to lengthy, detailed survey instruments designed to elicit their reactions to each element in the hospital experience. On the basis of analytical study of the responses, hospital managements evaluate patient satisfaction levels and institute indicated changes.

Development of New Tools

It was not enough to formulate and publish standards of performance, such as benchmarks and practice guidelines. New sets of tools for quantifying assessment and behavioral change were necessary. The need for new tools was answered in large part by the introduction of statistical process control (SPC) to healthcare quality management during the 1980s and 1990s. Derived from the work of Walter Shewhart, W. Edward Deming, and Joseph Juran and long established in industry, SPC in all its manifestations has become solidly established in healthcare.

SPC involves the use of control charts to show the degree to which a group’s performance varies from a preestablished optimal or normative range. Investigators sought to differentiate between the special causes of variation, stemming from factors peculiar to the specific case under study, and the common causes of variation, related to factors inherent in the system of care itself. During the same period, the healthcare industry came to recognize that problems of quality and safety were system problems and that their resolution was an organizational responsibility.

The use of SPC in the healthcare industry received valuable support from the publication of two seminal reports by the national Institute of Medicine’s (IOM) Committee on Quality of Health Care in America. In the first report, *To Err Is Human: Building a Safer Health System*, published in 2000, the committee explored issues of patient

safety ranging from staff training to falls and medication errors. This report sparked universal support, on the part of both consumers and the healthcare community, for methods of ensuring the safety of patients from medication and treatment errors. In the second report, *Crossing the Quality Chasm: A New Health System in the 21st Century*, published in 2001, the committee set forth broad strategic plans for redesigning the nation's healthcare delivery system with an emphasis on patient safety, accountability, and evaluation based on objective evidence.

Another widely used transplant from industry is Six Sigma, a method for bringing about quantifiable improvement in group performance, again as measured against a charted normative level. The objective of following the Six Sigma process is to reduce errors to a rate of 3.4 errors per 1 million opportunities. Following the example set by the rest of the corporate world, healthcare organizations increasingly have retained consultants to teach executives and clinical personnel how to plan and run their own Six Sigma programs in order to attain excellence in organizational performance. An important feature of Six Sigma is "Poko-yoke, or "mistake-proofing," the designing of systems that make it easy for personnel to perform their tasks correctly without error. The mistake-proofing approach has a long history in Japanese industry. While Six Sigma can be superficially described as a quantitative method of reducing errors in patient care, applying it across a healthcare organization is a complex task. It requires problem detection (often through the use of process control charting); causal analysis; problem solving, including mistake proofing and the revision of procedures; and retraining personnel.

Evidence-Based Medicine and Electronic Tools

Nine decades after Codman's call for improving end results, the same theme—the need for concrete evidence to support assessment and guideline development—continues to shape the healthcare industry's efforts to improve the quality of care. In the late 20th and early 21st centuries, the concept was called evidence-based medicine. Researchers rely on this concept to guide studies and identify optimal diagnostic and therapeutic strategies for

dissemination to clinicians. Without the nearly universal use of electronic ordering and database building in hospitals, physicians' offices, and other sites of care, it would have been impossible to reach Codman's goal of documenting and analyzing the end results of medical care.

The development and expansion of electronic ordering and medical record systems in hospitals and other care centers, which began in the 1980s and continues today, is making it possible to build and maintain the patient databases needed for SPC and the Six Sigma approach. Using the clinical-pathway model based on critical-path analysis, tracing every phase of the patient's treatment from admission to discharge, quality investigators can determine whether the treatment of individuals or of groups was consistent with best practices. Database development on a national scale made it possible for the Joint Commission, the NCQA, and the federal Centers for Medicare and Medicaid Services (CMS) to publish national performance data.

Widespread media dissemination of the information derived from these programs, along with the development of readily accessible Internet reference sources, is providing consumers with improved access to healthcare information and stoking their interest in finding and supporting improved therapies. The existence of a critical mass of well-informed consumers, theoretically, will play a role in the widespread improvement of the quality of healthcare. However, the risks of spreading misinformation also arise from uncritical, often sensationalized media presentation of clinical breakthroughs (e.g., untested "miracle cures") and ongoing developments in patient care. In the long run, the spread of information facilitates competition, which historically results in improvements in the quality of the product or service.

Creating Incentives

Leapfrog Group

The revelations contained in the IOM's 2000 report, *To Err Is Human*, resonated with the large American corporations that provide healthcare benefits to their employees. The report focused on the prevalence of hospital-related preventable medical errors, leading to an estimated 44,000 to

98,000 deaths per year. The issue was one of simple economics: The evidence indicated that employers were not getting what they were paying for—good healthcare in return for their premiums. In 2000, a group of these large corporate employers founded an association that they named the Leapfrog Group. The name reflected the need to leap forward in developing strategies to correct the existing conditions.

A principal Leapfrog Group objective is to promote high-quality healthcare by providing incentives and rewards, through their health benefits plans, to providers that use computerized physician order entry systems; base hospital referrals on evidence-based medicine; require specialized training for physicians working in intensive-care units; and adopt the 30 Safe Practices, addressing processes across a range of areas, formulated by the National Quality Forum (NQF).

Pay-for-Performance

The CMS has conducted several incentive-based monitoring and evaluation programs under the umbrella title pay-for-performance, or as they are commonly known, P4P. The general objective of pay-for-performance is to try to ensure that providers of services to Medicare beneficiaries and Medicaid recipients meet certain standards of care consistent with those of the NQF, Joint Commission, NCQA, Agency for Healthcare Research and Quality (AHRQ), AMA, and other nationally recognized bodies involved in setting quality standards. Demonstrated, documented compliance with quality measures endorsed by pay-for-performance is rewarded through an incentive system. Managed-care groups, in particular, have been quick to recognize the value of the pay-for-performance approach and have begun to develop formal mechanisms to participate in it.

PEPPER, MACS, and the False Claims Act

Many clues to the quality and effectiveness of clinical care can be found by tracing a patient's billing record. Complications and misdiagnoses are often reflected in unusually long hospital inpatient stays and very early hospital inpatient readmissions. Another resource at the disposal of the CMS, in its efforts to improve quality and efficiency, is

the Program for Evaluating Payment Patterns (PEPPER). A PEPPER is an electronic data report containing hospital-specific billing data for 13 targeted Diagnosis Related Groups (DRGs) and discharges that have been identified as carrying a high risk of payment errors. Using a PEPPER and the associated database, the CMS and hospital reviewers can home in on admissions that resulted in extended hospital stays or early readmissions for the same diagnosis. This process can point to the occurrence of clinical complications and inadequacies—poor quality—in patient care and alert hospitals to the need for change.

One factor making it difficult to follow up on patients after discharge to assess the end results of hospital care has been the strong possibility that a Medicare patient who received poor care, resulting in a complication, may not return to the same provider and hospital but may go to another physician and another hospital. Thus, the patient's postdischarge history lacks continuity and is lost to quality evaluation research. This would not happen in the presence of a single national database of Medicare patients. Beginning in 2007, and expected to be operational by 2012, a new plan called the Medicare Administrative Contractor System (MACS) will be functioning. Under the MACS plan, data from Medicare Part A and Part B plans will be combined into a single database for each Medicare region, with the entries identified by patient. Thus, all the Medicare patient's care, whether office, ambulatory, or inpatient, will be traceable in one database, facilitating long-term study.

As purveyors of services to Medicare patients, healthcare providers are subject to the terms of the federal False Claims Act. Therefore, they can be prosecuted for defrauding the federal government if their services are shown to have been other than appropriate and of good quality. A growing body of case law reflects the successful prosecution of healthcare providers found guilty of such fraud. The severe financial and operational sanctions provided for in the amendments to the act can be a strong deterrent to clinical behavior that fails to meet established norms and standards.

Future Implications

The quality of healthcare will remain an important issue in the future. With the greater availability of

information and quality measurement tools, insurers and individual consumers will, it is hoped, be able to more wisely choose healthcare organizations and individual practitioners who provide high-quality care.

QUALITY OF LIFE, HEALTH-RELATED (HRQOL)

Health-related quality of life (HRQOL) refers to an individual's or a group's physical and mental well-being over time. Healthcare providers and health services researchers use HRQOL tools to measure patients' chronic illness and to see how these conditions affect a person's daily life. Additionally, public health professionals use HRQOL to measure disorders, disabilities, and diseases in various populations. By tracking HRQOL, groups with poor physical and mental health can be properly identified. Policies to improve the health of these groups can then be appropriately developed.

Overview

The following highlights an example of the use of HRQOL for one individual. A 5-year old girl presents at a hospital with acute lymphoblastic leukemia, the most common type of childhood cancer. For the physicians, as well as the parents, the child's current quality of life is a key concern. How much pain is the child in now? What is her emotional condition? How did she respond to earlier therapies?

Examining the HRQOL in patients is of increasing concern in the medical community, and these concerns are affecting the way new therapies are administered and randomized controlled trials (RCTs) are planned. HRQOL provides important information on the improvements that new therapies offer as well as an outcome measure for economic evaluations.

Recently developed HRQOL measures and applications are important contributions to this emerging field. Information from these tools is used to adjust therapy or improve treatment for the patient. The quality-of-life information is also

used to prevent and control disease, injury, and disability in others.

According to researchers, the domains of quality of life refer to areas of behavior that are measured. The subjective domains of quality-of-life include the following: physical functioning, occupational functioning, psychological functioning, social functioning, and perceptions about health status. Some researchers have also defined “social health” as the dimension of an individual’s well-being that concerns how he or she gets along with others, how other people react to the individual, and how the person interacts with social institutions and norms.

From an objective standpoint, health status can be measured by laboratory or diagnostic tests, psychology tests, measures of socioeconomic status, and the degree of social support. Experts note that the so-called objective measures of quality of life often bear little relationship to life satisfaction. Thus, patients’ subjective satisfaction should always be considered in routine assessment and clinical interventions as it is a useful source of information.

Clinicians have for many years had to substitute physiological or laboratory tests for the direct measurement of people’s health. During the past 20 years, however, clinicians have recognized the importance of direct measurement of how people are feeling and how they are able to function in daily activities. Investigators have now developed sophisticated methods of measuring quality of life.

Healthy Day Measures

The Centers for Disease Control and Prevention (CDC) employs what it calls Healthy Day Measures to monitor the quality of life of individuals. This measure is a survey which can be administered to any population and from which data about the individual’s state of health can be determined. These questions include the following:

1. Would you say that in general your health is excellent, very good, good, fair, or poor?
2. Now thinking about your physical health, which includes physical illness and injury, for how many days during the past 30 days was your physical health not good?

3. Now thinking about your mental health, which includes depression, stress, and problems with emotions, for how many days during the past 30 days was your mental health not good?
4. During the past 30 days, for how many days did poor physical or mental health keep you from doing your usual daily activities, such as self-care, work, or recreation?

The CDC indicates that “unhealthy days” are an estimate of the overall number of days during the preceding 30 days when the respondent felt that his or her physical or mental health was “not good.” To obtain this estimate, responses to Questions 2 and 3 are combined to calculate a summary index of overall unhealthy days, with a maximum of 30 unhealthy days. For instance, a person who reports 4 “physically unhealthy days” and “2 mentally unhealthy days” is assigned a value of 6 unhealthy days, while someone who reports 30 physically unhealthy days and 30 mentally unhealthy days is assigned a maximum of 30 unhealthy days.

The CDC reports that the majority of individuals report “substantially different” numbers of physically unhealthy days versus mentally unhealthy days. For example, according to the 1998 Behavioral Risk Factor Surveillance System (BRFSS), 68% of the 68,600 adults who reported any unhealthy days indicated only physically unhealthy days or mentally unhealthy days, while 4% indicated “equal numbers” for each measure. Additionally, evidence demonstrates that the reported days do not overlap. Just 10% of the 250 persons who reported both 15 physically unhealthy days and 15 mentally unhealthy days also reported more than 15 days of recent activity limitation due to poor physical or mental health.

History

The World Health Organization (WHO) broadly defines health as a state of complete physical, mental, and social well-being and not just the absence of disease. For two decades, the four core Healthy Days Measures have been part of the CDC’s state-based BRFSS’s sample. Beginning in 2000, the Healthy Days Measures were also incorporated by CDC’s National Center for Health

Statistics (NCHS) into the examination part of its National Health and Nutrition Examination Survey (NHANES).

The measures and data have also been used for research and program planning by CDC's Cardiovascular Health and HIV/AIDS programs. Other users have included the Public Health Foundation, the Foundation for Accountability, and numerous other academic and government programs.

Recently, several organizations have found these Healthy Days Measures useful at the national level for determining health disparities, following population trends, and creating broad coalitions around a measure of population health compatible with the WHO's definition of health.

The Healthy Days Measures and data have been employed by state and local public health departments for tracking the overall progress in achieving the two major goals of the federal government's Healthy People 2010 initiative, increasing the quality and years of healthy life and eliminating health disparities.

Major National Research Findings

The CDC has reported a number of key findings related to the nation's adult HRQOL, including the following: Americans on average report that they felt "healthy and full of energy" for only about 19 days per month; they said that they felt unhealthy—physically or mentally—for about 6 days per month; nearly one third of Americans said that they suffer from some mental or emotional problems every month—including 10% who reported that their mental health was not good for 14 or more days per month; younger American adults, between 18 and 24 years of age, said that they suffered mental health distress the most; older American adults suffered the most from poor physical health and activity limitation; Alaska Natives and other Native Americans reported the highest levels of unhealthy days among American race/ethnicity groups; those Americans with the lowest income and education reported more unhealthy days than did those with higher income or education; and Americans with chronic diseases and disabilities reported high levels of unhealthy days.

The CDC also reported on HRQOL for individuals suffering from specific diseases, including chronic arthritis, breast cancer, heart disease, and diabetes mellitus. They found the following: Adults with chronic arthritis reported 4.6 more unhealthy days per month compared with adults without arthritis; among adults with arthritis, the largest number of unhealthy days was experienced by women, younger persons, and persons without a college education; women with breast cancer reported experiencing 8.5 unhealthy days per month compared with 6.1 unhealthy days per month for women without breast cancer; individuals who had a heart attack, coronary heart disease, or a stroke reported an average of 10 unhealthy days for the previous month compared with 5 unhealthy days reported among persons not having one of these conditions; and individuals with diabetes reported experiencing 9.9 unhealthy days per month compared with 5.1 unhealthy days per month for adults without diabetes.

Controversy

Researchers typically measure HRQOL by using survey questionnaires that include questions about how individuals are feeling or what they are experiencing associated with response options such as "yes" or "no" or point scales. As discussed earlier, researchers then aggregate the responses to these questions into domains or dimensions—such as physical or emotional function—that yield an overall quality-of-life score. However, controversy exists over the extent to which individual values must be included in its measurement. Increasingly, researchers are asking if it is sufficient to know that individuals with chronic obstructive lung disease in general value being able to climb stairs without getting short of breath? Or does medical science need to establish that the individual values climbing stairs with dyspnea (difficulty in breathing)?

Additional controversy exists about the value of the scoring systems developed by the CDC and other health research organizations. Researchers are wondering whether it is enough to simply know that both dyspnea and fatigue are important to people with lung disease. Or does medicine need to establish their relative importance? Furthermore, if establishing their relative importance is necessary, which of the many available approaches should be used?

An emerging consensus indicates that medicine is ready to accept an individual's own statements about what he or she values without a very precise determination of ranking of that information on a scale. However, experts note that not all treatment and therapies lead to an improvement in HRQOL for patients. Many life-prolonging treatments have a negligible impact on the quality of life that individuals experience. This may lead them and their families to be concerned with the very small gains in life span that come at a great price. Some examples of this include chemotherapy for cancer and treating HIV disease. Although life may be prolonged, the individual may worry about how his or her quality of life may be affected.

When the physician's goal for treatment is to improve how patients are feeling rather than to merely prolong their lives, HRQOL measurement is vital. Difficult decisions occur, however, when the relationship between laboratory measures and HRQOL outcomes is uncertain. In the past, physicians have relied on substitute outcomes, not because they were not interested in making patients feel better but because they assumed a strong link between physiologic measurements and the well-being of the patient.

A recent RCT of patients with symptomatic postmenopausal osteoporosis studied the effect of sodium fluoride on bone density and vertebral fractures. The researchers reasoned that increased bone mass and fewer vertebral fractures would most definitely lead to decreased pain and increased functionality. The question to be asked, however, is does the failure of the researchers to measure the effect of treatment in areas of unequivocal importance to patients, including pain, physical function, and household and leisure activities, affect the clinical message of the results? Based on research related to HRQOL, the answer would be yes.

Fear of Recurrent Disease

The relationship between physiological and clinical measures and patients' symptoms is usually somewhat modest. Each clinician must therefore rely on his or her own threshold. However, increasing consultation with the patient is becoming the norm.

Studies of cancer survivors reveal that many of them fear the recurrence of the disease. Studies show

that HRQOL measures can also be successfully used with former as well as current cancer patients.

Future Implications

As HRQOL measures continue to be developed and expand in their use, they will likely have a growing impact on improving the health of populations. HRQOL tools hold much potential in facilitating a more effective healthcare system and enhancing patient outcomes.

QUALITY OF WELL-BEING SCALE (QWB)

The Quality of Well-Being Scale (QWB) is a widely used general health index that summarizes an individual's current symptoms and disabilities in a single number. It represents a judgment of the health problems of an individual or population, and it can be expressed in terms of quality-adjusted life years (QALY). The QWB can be used as an outcome measure to estimate present and future healthcare needs, and it can be used with any type of acute or chronic disease.

Overview

The first version of the QWB was developed in the 1970s by J. W. Bush and his colleagues at the University of California at San Diego. It was later refined to its current forms in the late 1990s by Robert M. Kaplan. The QWB is a general health-related questionnaire that measures quality of life as defined by four major domains—symptoms, mobility, physical activity, and social activity. Scores from the questionnaire are often translated into an economic assessment for studies of cost-effectiveness of treatment and also to approximate an individual's QALY. The QWB exists in two formats—self-administered (QWB-SA) or given by a trained interviewer, often a healthcare provider. Each type of QWB takes about 20 minutes to complete. The QWB has been translated into Spanish, German, Chinese, and many other languages.

Scoring

In terms of finding a person's place on the scale, the QWB combines weighted values for symptoms and functioning. Functioning is evaluated by questions that gather information about limitations over the previous 3 days, within three areas—mobility, physical activity, and social activity. In addition, symptoms are evaluated by asking simple questions about how the individual feels with regard to the presence or absence of common symptom complexes (e.g., sore throat, joint pain). The scores (which are arranged in a roughly normal distribution) from these four areas are tallied

to provide a numerical evaluation of an individual's well-being at a given point in time, somewhere on the continuum between the extremes of *death* (0.00) to *complete health* (1.00). In addition to using morbidity descriptors, the QWB also uses mortality data from life tables, clinical experience, and direct measurement to help determine quality-adjusted life expectancy (current life expectancy corrected for decreased quality of life associated with disabilities and disease states).

Validity and Reliability

Many research studies have shown the QWB to be very reliable (consistency of measurement) in the short term, especially when it is given on back-to-back days, with a 96% reliability rate in the general adult population and ranging from 83% reliability in burn patients to 98% reliability in chronic obstructive pulmonary disease (COPD) patients, when considering the population with morbidities. Many studies have also shown the QWB to be highly valid (correctness of measurement) in repeated randomized controlled trials (RCTs). One study, for example, found that individuals with Alzheimer's disease scored significantly lower on the QWB, while the degree of cognitive impairment was also found to be related in a systematic way, leading to lower QWB scores. Another study found that the QWB scores were highly correlated with performance and physiological findings relevant to the health status of those with COPD. At the same time, the QWB was capable of being translated into well-year units for studies of cost-effectiveness and also served as an outcome predictor and measure for the disease.

Criticisms

Criticisms of the QWB include the fact that there is no mental health component, which some would argue makes evaluating psychiatric patients very difficult (although Kaplan disagrees with this notion). Another difficulty with the QWB is assessing the potential impact of the interviewer on the responses of the individual. The QWB has also been criticized as being long, complex, expensive, and difficult to administer. To some extent the self-administered

QWB alleviates many of these problems. It has been shown that the self-administered version of the QWB is highly correlated with the interviewer-administered QWB and that it retains the same validity and reliability.

Future Implications

The QWB has been used in numerous RCTs and research studies to evaluate medical and surgical treatments for conditions such as arthritis, atrial fibrillation, COPD, cystic fibrosis, diabetes mellitus, and lung transplantation. In addition, the QWB was used to prioritize medical procedures and ration health resources by Oregon's Medicaid program in the late 1980s and early 1990s. The innovative, and highly controversial, Oregon Plan attempted to extend Medicaid cost-effective health services such as prenatal care but eliminated costly, ineffective services such as organ transplants. After the deaths of several individuals who required transplants, the plan was suspended. With the increase in the nation's aging population and growing concerns over the cost-effectiveness of healthcare, it seems likely that quality-of-life measures such as the QWB will be more widely used by healthcare organizations, practitioners, and researchers to measure various treatments and allocate resources.

R

RAND CORPORATION

The RAND Corporation is the largest policy analysis think tank in the United States. The RAND (a contraction of “research and development”) Corporation is an independent, nonprofit institution that conducts research and analysis for the U.S. and foreign governments, international organizations, industry, foundations, universities, professional associations, and other organizations. Headquartered in Santa Monica, California, with branch offices in Washington, D.C., and Pittsburgh, Pennsylvania, the RAND Corporation employs about 1,600 people. It annually receives over \$200 million in contracts and grants, and at any given time its staff is working on about 500 projects. Of its nine research divisions, the RAND Health division consists of over 170 employees. Each year, it produces many reports concerning various aspects of health services research.

Background

During the various military campaigns of World War II, the U.S. War Department, the Office of Scientific Research and Development, and industry identified the need for a private organization to link military planning with research and development. To establish such an organization, the U.S. Army Air Forces (USAAF) in the fall of 1945 issued a special contract to the Douglas Aircraft

Company in Santa Monica, California, to create Project RAND, which would eventually become the RAND Corporation.

A number of people participated in the creation of Project RAND, including H. H. “Hap” Arnold, U.S. Secretary of War and Commanding General of the USAAF; Edward Bowles, a professor of electrical engineering at the Massachusetts Institute of Technology (MIT) and a consultant to the Secretary of War; General Lauris Norstad, Assistant Chief of Air Staff for Plans, USAAF; Major General Curtis LeMay of the USAAF, who was in charge of the strategic bombing of Japan; Donald Douglas, President of Douglas Aircraft Company; Arthur Raymond, Chief Engineer at Douglas; and Franklin Collbohm, Raymond’s assistant.

The first report of Project RAND, which was published in 1946, was years ahead of its time. It addressed the design and possible use of an experimental, world-circling spaceship.

In 1948, with the approval of the U.S. Air Force (which was established in 1947), RAND became an independent, nonprofit corporation. And Project RAND was transferred to the new corporation. During much of the Cold War era, the RAND Corporation worked closely with the defense industry, the military, and the federal government, helping to develop policies and strategies and to improve decision making. In the 1960s, RAND expanded its scope to also include national, social, economic, political, and healthcare delivery and financing issues.

Organizational Structure

The RAND Corporation's mission is to help improve policy and decision making through research and analysis. Its core values are quality and objectivity. To accomplish its mission, RAND is governed by a 23-member Board of Trustees, which is composed of leaders from the business, academic, and nonprofit sectors. The corporation is also guided by 16 advisory boards, composed of experts in various areas. It has nine research divisions, including the following: RAND Army Resource Division; RAND Education; RANDEurope; RANDHealth; RANDInfrastructure, Safety, and Environment; RAND Institute for Civil Justice; RAND Labor and Population; RAND National Security Research Division; and the RAND Project AIR FORCE.

RAND Health Division

Originating in the 1960s, the RAND Health division currently consists of three programs: Economics, Finance, and Organization; Quality Assessment and Quality Improvement; and Health Promotion and Disease Prevention. The division also includes four strategic initiatives: Compare; Global Health; Public Health Preparedness; and Military Health. The division's research agenda is very broad, including areas such as aging and health; complementary and alternative medicine; diversity and health; end-of-life care; global health; health economics; health security; HIV, sexually transmitted diseases, and sexual behavior; informatics and technology; maternal, child, and adolescent health; mental health; military health; neighborhood influences on health; overweight and obesity; public health; quality of care; substance abuse: alcohol, drugs, and tobacco; and violence and health.

Past and Present Healthcare Research

Over the decades, the RAND Corporation has conducted a number of innovative and influential health services research studies. For example, in the early 1970s to the mid-1980s, it conducted the RAND Health Insurance Experiment (HIE). The HIE was one of the largest and most important social experiments in U.S. history. It randomly assigned several thousand families in various regions of the nation to insurance plans with various levels

of cost-sharing arrangements and then followed them for up to 5 years to evaluate the effects on healthcare expenditures and health status. The study helped shape health services research in the nation and greatly influences policies for healthcare financing.

In the late 1980s and early 1990s, RAND conducted the Medical Outcome Study (MOS), the first large-scale study attempting to measure medical outcomes in terms of how individuals feel, function, and perform. As part of the study, a brief, health-screening survey instrument was developed: the Short Form 36-Item Health Survey, or SF-36. Today, the SF-36 and other versions of it are widely used throughout the world.

In late 1990, RAND conducted the HIV Cost and Services Utilization Study (HCSUS), the first comprehensive national survey on healthcare use of persons in care for HIV. The study provided information on the barriers to access, the costs of HIV care, and the effects of HIV on quality of life.

In the 2005, RAND released the first comprehensive study of the costs and quality effects of computerizing clinical records. The study found that computerizing records dramatically increased efficiency, greatly increased safety, and led to various health benefits.

Currently, the RAND Health division is conducting research in health economics, public health, and quality of care. For example, in 2007, its researchers provided technical assistance to the U.S. Department of Health and Human Services (HHS) on how to improve the readiness of state and local health departments to respond to emergencies. They conducted research to determine what percentage of children in the United States are receiving recommended care for acute and chronic medical problems. And they helped global health officials address the threat of an influenza pandemic in Southeast Asia.

Frederick S. Pardee RAND Graduate School

The RAND Corporation established a graduate school in public policy analysis in 1970. The school, originally the RAND Graduate Institute, changed its name to the RAND Graduate School in 1987, and in 2004, its name was again changed to honor Frederick S. Pardee, a former RAND researcher and philanthropist. The graduate school,

which is part of RAND and an autonomous entity within it, primarily awards the Doctor of Philosophy (PhD) degree. It also awards a Master of Philosophy (MPhil) degree. About 25 new students are accepted each year, and currently there are about 100 students enrolled in the school. Doctoral students (called fellows) are required to take course work and qualifying examinations and to write a dissertation. They also are required to take a practicum by working on various RAND projects. To date, the school has awarded about 200 doctoral degrees, making it the world's leading producer of doctorates in public policy analysis. Graduates from the school are employed in research and public service, as well as in the private sector.

experiments in U.S. history. The HIE randomly assigned several thousand families in various geographic areas of the nation to insurance plans with various levels of copayments and then followed up for 5 years to evaluate the effects on healthcare expenditures and health status. The experiment ran from approximately 1974 to 1982. At the time, there was limited information on the impact of cost sharing or of prepaid care on health expenditures, and there was almost no information on the impact of health insurance on health status. The experiment's results encouraged the restructuring of the nation's private health insurance, and they are still widely cited today.

Background

To assess the potential economic and health impacts of decisions on what insurance coverage to provide, how generous the cost sharing should be, and how services should be delivered (traditional fee-for-service-based insurance plans versus prepaid, health maintenance organization [HMO]-style managed care), there are two research strategies. The first is to collect more and better observational data, including information on insurance structure, health status, and other confounders that could lead to biased assessment of the effect of health insurance on either expenditures or subsequent health status. The second is to design and conduct a randomized trial that would experimentally assign coverage to remove the potential bias from residual confounding or to avoid adverse selection effects. Both strategies were followed from the 1970s through the end of the century. Major observational data sets were collected under the auspices of the National Center for Health Services Research (NCHSR), the Agency for Health Care Policy and Research (AHCPR), the Agency for Healthcare Research and Quality (AHRQ), and the National Center for Health Statistics (NCHS). The RAND Corporation designed and conducted the randomized trial known as the HIE with financial support from the Office of the Assistant Secretary for Planning and Evaluation (ASPE). The health economist Joseph Newhouse was the principal investigator for the project throughout its length.

RAND HEALTH INSURANCE EXPERIMENT

The RAND Health Insurance Experiment (HIE) was one of the largest and most important social

Study Design and Sample

The HIE enrolled families in six sites—Dayton, Ohio; Seattle, Washington; Fitchburg, Massachusetts; Franklin County, Massachusetts; Charleston, South Carolina; and Georgetown County, South Carolina—starting in 1974. The last of the enrollees exited the study in 1982. The sites were selected to represent the four geographic census regions, to represent the range of city sizes to reflect the complexity of the medical delivery system, to cover a range of waiting times to appointment and physician per capita ratios (in order to test for the sensitivity of demand to non-price rationing), and to include both urban and rural sites in the North and the South.

Health Insurance Plans

Families participating in the experiment were randomly assigned to 1 of 14 different fee-for-service or 2 prepaid group practice health insurance plans. The fee-for-service plans had different levels of cost sharing that varied over two dimensions: the coinsurance rate and an upper limit on out-of-pocket expenses. The coinsurance rates (percentage paid out of pocket) were 0%, 25%, 50%, or 95% for all health services. Each plan had a stop-loss or upper limit on out-of-pocket expenses of 5%, 10%, or 15% of family income up to a maximum of \$1,000. Beyond the maximum out-of-pocket dollar expenditure amounts, the insurance plan reimbursed all expenses in full. One plan had different coinsurance rates for inpatients and ambulatory medical services (25%) than for dental and ambulatory mental health services (50%). Finally, on one plan, the families faced a 95% coinsurance rate for outpatient services, subject to a \$150 annual limit on out-of-pocket expenses per person (\$450 per family). In this plan, all inpatient services were free; in effect, this plan had an outpatient individual deductible. The coinsurance rate for this plan was changed to 95% after the 1st year of the study in the first site (Dayton, Ohio).

To illustrate how one of the plans worked, we consider a plan with a family coinsurance rate of 25% up to a stop-loss of \$1,000 in 1970s dollars (or \$3,400 in 2007 dollars, corrected by the all-item consumer price index). For the first \$4,000 of

expenditures on any health service (dental, medical, or mental health), the family pays 25% of the bill, and the insurance company pays 75%. Beyond that point (the stop-loss), the family pays nothing more out of pocket for the remainder of that year. The following year, the family again will incur out-of-pocket expenses of 25% of the bill until it reaches its stop-loss or upper limit on out-of-pocket expenses.

In addition to the fee-for-service-based health insurance plans, the HIE had two groups enrolled in a prepaid staff model HMO, Group Health Cooperative of Puget Sound (GHC). The scope of benefits was comparable with that of all the fee-for-service plans. Like the free plan, there was no out-of-pocket cost as long as enrolled individuals stayed within the plan.

All plans covered the same wide variety of services, including inpatient and outpatient medical care, mental healthcare, dental services, drugs and supplies. However, there were some benefit exclusions: nonpreventive orthodontia, cosmetic surgery, and outpatient psychotherapy services in excess of 52 visits per year per person.

The families were enrolled on their experimental health insurance plans as a group, subject to the same coinsurance rate(s) and stop-loss, with the exception of the Individual Deductible Plan with its separate individual deductible for outpatient care. Only individuals eligible for the experiment could participate. Families were either offered one experimental plan or were allowed to continue with their existing coverage. To prevent refusals, families were given a lump-sum payment greater than the worst-case outcome in their experimental plans relative to their previous plan; thus, families were always better off financially for accepting the enrollment offer. Moreover, because of a bonus for completion, they were always better off completing the study. Hence, there is a theoretical presumption of no bias from refusal or attrition. In fact, study researchers have detected negligible effects from refusal and attrition.

Families were assigned to treatments using the finite selection model. This model is designed to achieve as much balance across plans as possible while retaining randomization; that is, it reduces the correlation of the experimental treatment with health, demographic, and economic covariates.

Refusal and Attrition

There are two potential threats to the balance of health and other characteristics across insurance plans: (1) nonrandom refusal of the offer to participate and (2) nonrandom attrition from the study. Refusals of the plan offer varied across plans. However, analysis of these refusals to participate indicates that the only significant difference between those who accepted and those who rejected the offer was that the latter had lower education and income. Income is controlled for in the analysis of experimental data, and education had no detectable (partial) effect on use. There is no evidence that those who rejected the offer to participate were sicker or that there was an interaction between plan, sickness, and refusal of the offer.

Individuals on the cost-sharing plans were more likely to leave the study early than were individuals on the free plan. These early departures were also sicker on average than those who stayed. Thus, people on the cost-sharing plans at the end of the study were healthier on average than those on the free plan. This could lead to an overestimate of the response to the cost-sharing insurance plans. To correct for such a potential bias, baseline health status measures were included as covariates.

Population Sampled

The individuals enrolled in the experiment were drawn from a random sample of each site's noninstitutionalized civilian population, excluding those 62 years of age and older at the time of enrollment, those with incomes in excess of \$25,000 in 1973 (or \$115,000 in 2007 dollars—this excluded 3% of the families contacted), those eligible for the Medicare disability program, and veterans with service-connected disabilities. The HIE also included a group in GHC. A group of nonelderly individuals already enrolled in GHC were randomly selected and invited to participate as a control group. Another group of nonelderly, noninstitutionalized civilians in the fee-for-service system were randomized to be an experimental group at GHC from the same pool as those enrolled in the fee-for-service plans.

Estimation Samples

Estimation samples varied from the study groups being examined—the whole population, adults,

children, fee-for-service plans, or comparisons between fee-for-service and prepaid group plans (in Seattle only). Interim results were reported in the first two fifths of the data and final results on the full sample of those enrolled for the 3- to 5-year duration.

Outcomes (Dependent) Variables

The analysis of the economic effects of cost sharing focused on medical care utilization (inpatient hospital stays, outpatient visits, episodes of treatment) and related healthcare expenditures (including drugs and supplies), based on information collected on health insurance claims. All expenditures, including out-of-pocket payments and payments by the insurance carrier, were relevant. For the prepaid plans, medical records were abstracted in the form of claims data and assigned prevailing fee-for-service prices; these were augmented with information on out-of-plan use.

The effects of cost sharing focused on a number of health status measures developed as a part of the HIE. These included scales based on self-reported health status in a number of health domains (general health, mental and social health, physical and role limitations, pain, etc.), the presence and severity of health conditions, as well as assessments based on physical examinations that were given to a random percentage of families at enrollment and to all families at normal completion. Nearly 77% of all noncompletion cases (85% of the survivors) were located and had their health assessed.

Independent Variables

Most analyses of the HIE report simple averages by health insurance plan or by groups of plans. However, any analysis must rely on results that already control for demographic, health status, and socioeconomic measures in addition to fixed effects for study sites and the health insurance plan.

Unit of Analysis

The unit of analysis is a person-year for the analysis of utilization and expenditures, because the stop-loss is an annual limit. The researchers used the person as the unit of observation because

the major determinants of the use of services are individual (e.g., age, gender, and health status) rather than family (e.g., insurance coverage and family income).

The unit of analysis for the health status studies is the person, again because the major determinants of health are individual. Children (under age 13) were separated from adults because the instrumentation of health status was different.

Results

Healthcare Utilization and Expenditures

The results from the HIE indicate that increases in out-of-pocket cost sharing reduced healthcare use and costs. Since all these plans had a stop-loss on the financial risk incurred by the family, this is the effect of first-dollar cost sharing, not the effect of a change in out-of-pocket price throughout the year. Thus, each response is a response to price for part of the year and having free care (beyond the stop-loss or deductible) for the remainder of the year. Specifically, higher coinsurance rates reduce expenditures by about 20% for moderate levels of cost sharing and nearly 30% for high levels of cost sharing. This response corresponds to a price elasticity of approximately -0.2 once the effect of the stop-loss has been eliminated. Though less dramatic, the same response is observed for the probability of any care and for any admission during the year. Most of the response to cost sharing can be traced to the reduction in the likelihood of having any healthcare during the year.

Although children and adults exhibited similar responses to insurance plans for outpatient care, they had different responses to cost sharing for inpatient hospital care. There was little response for children but a significant response for adults. The experiment did not detect any differential response to cost sharing by income group, gender, health status, or site.

Other healthcare goods and services exhibited different or more complicated responses. The expenditures for outpatient prescriptions followed the same pattern as that for outpatient care. The response of emergency department use to cost sharing was very similar to that for general medical care, but this masked a major difference in response depending on the urgency of the diagnosis. Urgent

emergency department demand had half the response to cost sharing that less urgent care did. Dental-care demand surged on the free plan by 46% during the 1st year of the experiment. After that, plans with out-of-pocket cost sharing were about a quarter less expensive than the free plan. Outpatient mental healthcare was almost twice as responsive to cost sharing as outpatient care.

In an attempt to understand whether cost sharing had a greater effect on the appropriateness of care, the study examined the appropriateness of inpatient care for conditions other than maternity, pediatric, or psychiatric, using a methodology that indicated whether the care had to be done in a hospital or could have been done as an outpatient service. The free and cost-sharing plans had very similar and statistically insignificantly different fractions of hospitalizations that were inappropriate. Thus it appears that cost sharing is a blunt instrument for reducing inappropriate care because it reduced both appropriate and inappropriate care by approximately the same amount.

The HMO experimental group had 28% lower annual expenditures than the free fee-for-service plan. Both had the same benefits and the same out-of-pocket costs. This lower expenditure rate was achieved largely by a 39% lower admission rate at the HMO. Outpatient visit rates were comparable for both the HMO experimental group and the free fee-for-service plans. Other fee-for-service plans also had higher expenditure rates than the HMO, except for the 95% plan, which acts like a large deductible plan. That plan had significantly lower visit rates and insignificantly higher admission rates than the HMO experimental group. The individual deductible plans followed a similar pattern.

One of the concerns motivating this experiment group was that HMOs were experiencing favorable selection that would help explain the difference in utilization and costs. The experimental comparisons suggest that such an explanation did not account for the differences observed in this mature HMO. A further comparison of those HMO enrollees who self-selected into the HMO versus those who were randomized in indicates only modest differences. If anything, the controls were slightly older and sicker than the experimental group, which partially accounts for the difference in visit rates.

Health Status

Despite the substantial reduction in healthcare utilization and expenditures, there was little evidence that cost sharing had an adverse effect on the overall health status of the HIE's enrollees. There was no statistically significant effect on average for adults on general health or separately for physical, mental, or social health or on an index of the risk of dying. Nor was there an effect on the economically poorest part of the adult population. However, there was some evidence that those individuals who were both poor and sick at the beginning of the experiment had better health status at the end of the experiment if they were on the free plan rather than on the cost-sharing plans. This group constituted about 6% of the HIE population.

There were some areas of health that were better with the free plan than with cost sharing. These included hypertension control and vision; there was also a reduction in the number of decayed teeth among young adults.

There was no statistically significant effect of cost sharing on children's health status relative to the free plan. Nor was there evidence of an effect for at-risk or poor children.

For both children and adults, there was no evidence of an overall effect of the prepaid, staff model HMO compared with the free fee-for-service plan.

Policy Implications

The HIE found that health insurance plans with first-dollar cost sharing and moderate deductibles could have a major impact on total healthcare utilization and healthcare costs without having an adverse effect on the health status of nonelderly individuals. Although there were healthcare reductions, the cost sharing appeared to be a blunt policy instrument in that it reduced both medically appropriate and medically inappropriate hospitalization nearly equally. However, it is important to recognize that the word *inappropriate* has a more limited use in this and other studies of the period. Here, an inappropriate hospital stay means that the treatment could have been given in an outpatient setting, while an inappropriate inpatient stay means that the stay was inappropriate

or that the patient had unnecessary days at either the beginning or the end of the stay.

If cost sharing reduced both inpatient and outpatient care, why were the changes in health status so modest—largely limited to blood pressure control, corrected vision, and decreases in dental decay? Why weren't there more substantial changes in overall health status or mortality? Several explanations have been offered: The nonelderly population as a whole is healthy relative to the elderly or the disabled, and thus there is less room for improvement; the similar effect on appropriate versus inappropriate care may mean that there are offsetting effects of cost sharing; the data are from the 1970s and early 1980s, before the major drops in inpatient utilization in the nation, and thus there may have been more discretionary care in the healthcare system than has been the case in the past decade; and the presence of a stop-loss on the plans means that cost sharing was never large enough to deter any major or important utilization (none of the health plans involved unlimited cost sharing or left the family completely uninsured). Finally, it is worth remembering that one of the major benefits of health insurance is to protect risk-averse individuals against the uncertainty involved with large healthcare bills, especially ones that may be sufficiently large to impoverish the individuals. All these explanations are plausible to some degree. A single study, even one as well designed and executed as the HIE, is not sufficient to answer these questions.

There were some findings from the HIE that raise concerns. There was some evidence that cost sharing could have an adverse effect on the health of those who were *both* sick and poor—not sick *or* poor, but having both characteristics. This could provide an argument for differentially lower cost sharing or the elimination of cost sharing for this group.

The prepaid versus fee-for-service findings suggest that large drops in inpatient use can be achieved without major adverse effects on the overall populations. This was consistent with the major drops in inpatient use during the 1990s and the spread of managed care and managed indemnity plans. However small the differences in health status, there were major differences in patient satisfaction, which is consistent with the widespread reaction to the spread of managed care.

If cost sharing coupled with stop-losses can reduce healthcare costs without much risk to the health of the general nonelderly population, then is the long-term decrease in cost sharing responsible for a large part of medical care inflation? The answer is “Probably not.” It is true historically that more generously covered services have experienced more rapid inflation than less generously covered ones. But the magnitude of the post-HIE changes in healthcare utilization (visits and stays) is not enough to account for medical care inflation; it is not the demand response to cost sharing per se that increased healthcare expenditures. That part is too small. It appears that the relation of costsharing to the rapid growth in healthcare expenditure is more complex and involves linkages to more rapid rates of technological progress and adoption of more generously covered service plans by institutions.

RANDOMIZED CONTROLLED TRIALS (RCTs)

In medicine, a clinical trial is an experimental study conducted on human subjects to answer or confirm a research question. Clinical trials can be designed at the discretion of the researcher and must meet certain ethical criteria to ensure the protection of human subjects. Of the many research design options for clinical trials, the randomized controlled trial (RCT) has evolved as the gold standard in the investigation of several types of treatments, including (but not limited to) new therapies, community interventions, and diagnostic techniques. The RCT is often referred to as a randomized clinical trial, and the terms are used interchangeably throughout the literature.

Historical Beginnings

The earliest reference to research that meets the definition of a controlled trial dates back to 605–562 BC, when King Nebuchadnezzar II carried out the first controlled trial by ordering that a strict diet of meat and wine be followed by a small group of children for 3 years while four

children of royal blood were allowed to exchange bread and water for the required meal. After only 10 days, those who had switched to bread and water appeared healthier than those who ate only wine and meat.

In 1537, the French Renaissance surgeon Ambroise Parè (1510–1590) blended a mixture of oil of rose, turpentine, and egg yolk as a replacement for the accepted regimen for treating open wounds. One day after the unintentional trial, Parè observed that the wounds treated with the traditional formula were swollen and extremely painful, while the wounds treated with the experimental mixture were not painful, indicating that the new balm was more favorable than the oil usually applied.

Active Controls

The Scottish naval surgeon James Lind (1716–1794) is often credited with originating controlled trials, since he was the first to introduce a control group into his experiments in approximately 1747. A control is when the investigator, or the individual conducting the study, controls the treatment or stimulus to be received by the subject. In this context, one can study the treatment or stimulus, defined as the experimental group, by comparison with (or as a supplement to) the standard of care, defined as the control group. Lind studied the great sea plague, scurvy, of the time. On long naval voyages, it was not uncommon for scurvy to kill two thirds of a ship's crew. To prevent scurvy, Lind conducted the first planned, controlled trial, supplementing the diet of a small number of sailors with fresh citrus fruit and lemon juice (the experimental group). He then compared the incidence of scurvy among those men with that among other sailors on the same ship who ate the normal vitamin-poor naval diet (the control group). Finding that citrus fruit prevented the disease, Lind recommended dietary changes for all sailors, which ultimately resulted in the eradication of scurvy from the British navy. Hence, British sailors are still referred to as "limeys."

Blinding and Placebo Control

By 1863, controlled trials began to evolve with more rigorous study designs, including the use of

placebo treatments. A placebo can be considered a type of control in which no active treatment or stimulus is introduced, but rather subjects assigned to a placebo receive an inactive or sugar pill if the treatment is a pill medication or an injection of salt water if the treatment is a fluid injection, or they go through the routine of having an X ray without the instrument being activated. The placebo has the broadest indication in medicine, as it is effective to a greater or lesser extent in almost all medical settings, necessitating additional design enhancements to minimize bias addressing this phenomenon, known as the placebo effect.

The introduction of a matching placebo allows for the blinding or masking of what treatment, if any, the subject is receiving. In controlled (clinical) trials, treatments are often compared to assess the experimental treatment's effect as compared with what should be the noneffective treatment of the placebo. Participants in the control group receive a placebo instead of an active treatment, and the results from the placebo group are then compared with the results from the experimental group, which received the treatment. Blinding can also be used when comparing different active treatments. The process of blinding, with or without the use of a placebo, helps control for bias that is introduced if the subject or the researcher (or both) is aware of the treatment group to which the subject has been assigned. In a single-blind design, the subjects do not know what treatment they are receiving. In a double-blind design, neither the person delivering nor the one receiving the therapy knows which treatment has been assigned.

Randomization

In 1912, the U.S. Congress passed the Sherley Amendment to the 1906 U.S. Food and Drugs Act, prohibiting labeling medicines with false treatment claims. This amendment ultimately raised experimental standards to the level of requiring the conduct of controlled trials for new treatments. This stimulated the growth of the RCT and further added to the design rigor expected to prove the effectiveness and safety of drugs approved for marketing in the United States.

Generally, a researcher uses randomization to indiscriminately allocate subjects between or among the different treatments or stimuli, thus

performing a “randomized” controlled trial. The major strength of this approach, known as random assignment, is a theoretical equal distribution of potential confounding factors that are known, unknown, or not measurable. Without this, the treatment groups may be different and not comparable. Because biases are minimized by randomization and the treatment groups are directly comparable as a result, associations demonstrated in RCTs are more likely to be causal associations than those demonstrated using other research study designs. If the study is powered sufficiently (i.e., is sufficiently large to detect true differences), the assigned treatment is the most likely explanation of any observed differences in the outcomes, whether an improvement or a worsening of the disease state, between the treatment groups.

The English statistician Sir Ronald Aylmer Fisher (1890–1962) first introduced randomization in the 1920s in the science of agriculture. In Fisher’s experiment the assignment of a plant strain to a plot of land was made randomly. In a controlled (clinical) trial, the same principle results in the assignment of a treatment to subjects by chance, by placing the subjects randomly into three treatment groups (i.e., subjects are assigned to the active treatment group, to the nonactive treatment group, or to the placebo group). In this example, effective randomization would give a subject a 50% chance of being in any one treatment group or arm. This technique deliberately introduces noise into the study such that, over all RCTs that could have been conducted with the experimental treatment, each subject has an equal chance to be in any one treatment group or arm. Therefore, Fisher’s technique, adding the noise of randomization to a controlled trial, allows for a fair comparison to be made between treatments.

In 1879, while at Johns Hopkins University, the American mathematician Charles Peirce (1839–1914) may have been the first to use randomization in a research study, to see if blindfolded people could notice the difference between a 1- and a 2-kilogram weight. Peirce would add or remove weight based on a specially designed deck of cards so as to remove the bias from the researcher making the weight adjustments.

Among the earliest randomized trials was one by the American physician James Burns Amberson Jr. (1890–1979). Amberson, an international

authority on chest disease and tuberculosis, conducted a controlled (clinical) trial from 1926 to 1927 (published in 1931) of sanocrysin, a gold preparation, in pulmonary tuberculosis. The study used a flip of a coin to assign treatment to groups receiving either sanocrysin (active group) or distilled water (control group). Subjects were not aware of which treatment was administered.

A subsequent study, often referenced as the first documented trial to correctly use randomization to assign subjects to treatment and control groups, was carried out by the British Medical Research Council (MRC) in 1948 and involved the use of streptomycin to treat pulmonary tuberculosis. The British statistician Sir Austin Bradford Hill (1897–1991) played a major role in designing the trial, which featured a double-blind assignment to treatment groups, where neither the researchers nor the subjects knew which treatment group each subject was in during the conduct of the study, enabling unbiased analysis of the results.

Randomizations are usually balanced to ensure that, overall, the same quantity, or number, of subjects receives each of the available treatments; this is referred to as a simple or nonstratified randomization. A stratified randomization can be used to minimize the risk of imbalance or bias occurring because of the preponderance of a particular factor relative to the disease or its treatment in one of the treatment groups. To do this, the subjects are separated into groups (or the groups are predefined if the subjects have yet to be identified) according to the factors that are important, such as age, duration of illness, laboratory value, etc. A separate randomization plan or schedule is then prepared for each predefined group.

Multicenter Trials

Multicenter RCTs were first used in the 1940s. Multicenter studies are conducted at several different sites or locations, but all use the same research protocol. When numerous subjects are necessary to detect a meaningful difference in treatment, multicenter studies are typically conducted, making the studies large in scale. Data collected from subjects treated at each site can be pooled so that the greater numbers give increased statistical “power” to the overall results found. Multicenter RCTs are most commonly conducted by government and industry

researchers and in some instances also by not-for-profit health organizations.

Trial Design

When comparing different treatments in an RCT, subjects may be given only one of the treatments prospectively as part of a parallel group design, or all treatments, each on different occasions, as part of a crossover design (also called within-subject comparison).

In the parallel-group study of treatments, each subject would be randomized to receive only one treatment. In the crossover study of treatments, each subject would receive each treatment one after the other. With the crossover design, the order in which the treatments are given is random to avoid the best or worst treatment always being taken first, thereby minimizing any bias in the results obtained from the alternative treatment. Depending on the type of treatment, there may also be a washout period (e.g., a period when the drug is shed from the body until there is no trace of the drug) between crossover design treatments such as placebo, no treatment, or an alternative noncompeting treatment (e.g., one that satisfies the needs of the subject in minimizing discomfort). The crossover study design typically requires fewer subjects than the parallel-group design, but the disease itself may have changed over the time of the treatment period, confounding the results, and the studies typically take longer to conduct, making the crossover study less favored and the parallel-group design the most commonly used.

Human-Subject Protection

RCTs should be carried out adhering to accepted standards of safety, subject welfare, and data interpretation. However, history shows that subject welfare was not always a high priority. To prevent atrocities such as those that occurred in World War II, the Nuremberg Code was developed in 1947. With it, the mid 20th century witnessed a period of protectionism for human subjects. The protection of human subjects has had an impact on the conduct of RCTs, as represented in the World Medical Association's development of the Declaration of Helsinki (first released in 1964, and subsequently amended in 1975, 1983, 1989, 1996, 2000, and 2001).

Most recently in 2001, the Declaration of Helsinki was revised to reaffirm its position that extreme care must be taken in conducting a placebo-controlled trial and that in general this methodology should only be used in the absence of existing proven therapy. However, a placebo-controlled trial may be ethically acceptable, even if proven therapy is available, if there are compelling and scientifically sound methodological reasons for its use—for example, if it is necessary to determine the efficacy or safety of a prophylactic, diagnostic, or therapeutic method or if a prophylactic, diagnostic, or therapeutic method is being investigated for a minor condition and the subjects who receive the placebo will not be subject to any additional risk of serious or irreversible harm. An investigator must propose and defend such research to an institutional review board (IRB)/institutional ethics committee for review to gain conduct approval.

Problems

RCTs are not without their problems. Conducting an RCT often has potential problems inherent in the study design and can be ethically and logistically challenging to perform. Examples of ethically problematic RCT designs include the use of a placebo when an alternate therapy is available, the use of a surrogate end point when the target end point is not reasonably attainable, or the establishment of a short-term follow-up period when the treatment may be intended for long-term application. In addition, randomized controlled (clinical) trials are expensive and artificial. The RCT results are applicable to efficacy (the effect of the treatment or stimulus in a controlled environment) but may not demonstrate effectiveness (the effect of the treatment or stimulus in an uncontrolled environment). This can be further explained by assuming that the severity of a disease is normally distributed, whereas an RCT is designed to include eligible subjects typically represented at the extremes from the mean, median, or mode to demonstrate a pronounced effect of the treatment or stimulus as compared with the control. Thus, the RCT does not represent a typical response expected from the majority of subjects that lie within a few standard deviations of a disease state distribution. However, when an RCT is robustly designed and of sufficient size, the

results of the trial can be applied to the general population.

Future Implications

RCTs continue to be the gold standard for demonstrating safety and efficacy and will continue to be the model by which other experimental designs are judged, but they likely will continue to be critiqued. In the future, there will be continued scrutiny of the controlled (clinical) trial and its inherent design efficacy as opposed to effectiveness, especially considering public concerns over pharmaceutical treatment risks not fully elucidated until after FDA approval for use among the general population, leading to product withdrawals and black-box warnings. Additionally, U.S. policymakers have not fully endorsed the 2001 amendment to the Declaration of Helsinki and its limits on the use of placebos, in terms of the conduct of RCTs for novel treatments. It is important to note that regulatory agencies are beginning to make changes in their standards for approval of new drugs for the good of public health, but further discussions and development of policies are needed. There will be continued examination of the increasing expenditures for the development of novel treatments and of the development costs of conducting the RCTs necessary for approval, estimated at more than \$1 billion for every new treatment in the United States. While there should always be a balance between medical progress and public health, the regulation and policy analysis of controlled (clinical) trials must ensure that this balance is acceptable and reasonable.

RATIONING HEALTHCARE

Rationing typically refers to the distribution of some good or service insufficient in supply to meet the available demand for it. Most people think of rationing as a situation when scarce commodities such as fuel during wartime are not sufficiently

available. The fuel available could be rationed by price and given to the highest bidder, but such price rationing is seen as unfair. Thus, a system of allocation is designed that seeks to incorporate broader values such as equity, need, potential benefit, fair share, positioning in the queue, and so on.

The situation best exemplifying such scarcity in contemporary America is the lack of available hearts, kidneys, livers, and lungs for transplantation, where need in many cases far exceeds supply. Almost everyone regards price rationing for such available organs as unfair, so an alternative distribution system must be designed. Such distributions have been called “tragic choices” because there is no correct answer on how to do this.

Some analysts note that many of the instances in medicine referred to as rationing do not involve scarcity in that the needed supply is available but consumers are unwilling or unable to pay the price demanded. However, most instances of scarcity are imposed by policy choices reflecting culture and ethical values. There are numerous ways to increase the availability of scarce organs were we not bound by our values and norms. These include allowing people to buy and sell them, paying relatives to agree to the use of organs of their loved ones who no longer have brain function, or appropriating the organs of people who are brain dead by fiat regardless of family wishes. Or we can do what occasionally has been done in China—take the organs of prisoners following execution or soldiers killed in war. We can even imagine societies where people are bred for spare organs. Most societies view all the above solutions to scarcity as unethical.

Price Rationing

It is commonly asserted that healthcare is not rationed in America. This might be substantially true if price rationing is excluded. Our healthcare system has the capacity to provide an adequate level of care to all who need it. But many lack access because they are uninsured or have little of the disposable income needed to purchase care. Thus, many people forgo needed care because of cost and as a consequence have poorer health. To most economists, allocation by price is simply an instance of supply and demand. Most people would not think that luxury cars are rationed simply

because many persons cannot afford to buy them. But societies think differently about some necessities such as healthcare than about ordinary commodities. The special claims for healthcare stem from the belief that adequate health is a precondition for fair competition.

Levels of Rationing

Most nations seek to control the resources devoted to healthcare relative to other societal needs. The United Kingdom, for example, establishes a central health budget each year and seeks to live within it, while other nations use a variety of price controls and other regulations to hold healthcare expenditures in check. Since no nation provides all the care the population would wish, all must have some rationing rules to determine the distribution of available health resources.

The rationing context is established in most countries by macro decisions that shape the amounts and types of care available: decisions concerning the number and types of health professionals trained; the distribution of funds among varying types of technologies, services, and specialists; the numbers and locations of hospitals and clinics built; the definition of reimbursable providers; the amounts of payment for varying kinds of services; the distribution between primary-care physicians and specialists and among different types of health professions; and the distribution of funding among types of providers and geographic locations. These decisions may be more or less centralized and involve fierce politics and interest-group advocacy. The history and culture of each country shapes the design of benefits and the extent to which patients are expected to share in the costs. Definitions of care services will vary among nations. In some, respite care in spas is covered under the basic health plan.

Some planning decisions may remain highly centralized, such as decisions about overall budgets, new hospital buildings, or acquisition of new, expensive technologies, while others may be delegated to regions or local entities and provider organizations, such as insurance plans, hospitals, clinics, and provider groups. Managers in these more decentralized settings make many intermediate decisions, such as how to distribute their available funding, the numbers and types of reimbursable

facilities and providers, the balance between general practice and specialty care, the numbers of specialists in each type of service, and the like. These decisions will make care more or less available in varying categories, such as cardiac care or mental health, and make rationing more or less needed, depending on the resources allocated to each function.

Many rationing decisions are predetermined by benefit design and coverage decisions by the purchaser (government) of the healthcare plan. Important services may or may not be covered or may be restricted in various ways, such as dental care, prescription drugs, long-term care, certain preventive services, specified surgical interventions, some appliances and devices, and so on. All healthcare systems exclude some services seen as less important or too expensive, such as various cosmetic surgical interventions, some reproductive services, "lifestyle" drugs, psychoanalysis, and the like. These decisions may be controversial and politically contested, but they are part of the overall design process. Decisions made at the point of service are much more difficult, because people cannot access care or are denied services they believe they need at the point where they believe their health is at stake.

Explicit and Implicit Rationing

A central issue is the extent to which rationing should be allowed at the point of service delivery and whether it should be explicit or implicit. One advantage of implicit rationing, where clinicians make discretionary judgments about what services to provide, is that it more readily takes account of differences in medical and social circumstances, patient preferences, and situations that cannot be known beforehand, given the iterative nature of patient care and decision making. Thus, it is flexible and readily adaptable to different and changing situations. Its strengths are also its weaknesses, in that it makes decision making less transparent and opens greater opportunities for personal bias and discrimination under the guise of clinical decisions. Physicians sometimes make care decisions on the basis of age, gender, race, and other prejudices and may respond differently if they like or dislike particular patients.

Critics of implicit rationing seek more transparent decision making and clear, explicit rules about who should have access to varying interventions. They also see this as a way to ensure professional accountability. They commonly advocate having such rules established through public participation so that decisions reflect the dominant values of the community. The most publicized effort to develop rules for explicit rationing was the Oregon Health Plan, which sought to provide healthcare coverage to more people by rationing the services available. Efforts were made to distinguish between more and less useful interventions in order of priority as a way of defining the services available within that state's Medicaid program. Oregon began with a series of public meetings and meetings of various advisory committees, to develop consensus on priorities. Through this exercise, medical services were classified into a number of condition-treatment pairs that were ranked and prioritized through judgments of medical efficacy and community values. Initially, 700 categories were established, but it was determined that the state budget could only support the first 588.

When the rankings were examined, there were a variety of seemingly bizarre outcomes. Tooth capping, for example, ranked higher than surgery for ectopic pregnancy or appendectomy, interventions that save lives. Thus, the rankings were criticized for failure to give the "rule of rescue" sufficient priority and for other reasons. The list was then reordered to give more influence to clinical understanding. The public was involved, but most participants in the various meetings and committees were health professionals. Observers viewed the process as a rational and fair way to make difficult decisions about allocations of limited budgets. The system was never really implemented as expected, and relatively little rationing actually took place. All such efforts function in a broader political, organizational, economic, and social context, and implementation depends on factors that may have little to do with the approach itself.

The psychometric techniques used are uncertain because of the difficulty of rating needs and experiences one has not personally encountered. The general public makes different assessments from those who actually have the illnesses in question. Moreover, explicit rationing has many problems beyond the technicalities of developing rational

and evidence-based priorities. Given the complexities of people's lives and their medical histories and varying social situations, it is impossible to anticipate all the issues that may arise in caregiving. Explicit decisions can be inflexible and misdirected. It is also difficult to modify them in a timely way as new knowledge and understanding evolves.

In the United States, rationing has largely involved excluding many services in the benefit design, requiring cost sharing when using services, and requiring waits to get appointments to see the physician. Most denials do not occur at the point of service, and patients commonly do not think of these access limitations as rationing. Managed care changed this a great deal in the 1990s by explicitly denying care at the point of service. The rationing approaches used by managed-care organizations included utilization review (precertification for and concurrent review of inpatient care and other expensive interventions), requiring clients to enroll with a primary-care physician from a predetermined list, and requiring formal referrals for specialty care. Prescription plans similarly developed drug formularies and required substitution of generic for brand-name medications. They sometimes limited the number of prescriptions a patient could fill in a month (as in some state Medicaid programs) and limited the number of pills a patient could receive per month (as in coverage for lifestyle drugs such as Viagra). This was the first major experience American patients and physicians had with explicit rationing at the point of service, and they disliked it, resulting in a major backlash. Many of these controls were then relaxed, contributing to a new cost spiral.

Explicit rationing at the point of service is "rationing in your face" and is less acceptable than more impersonal types of explicit rationing, as in benefit design. The most successful types of rationing are often those that people don't perceive as rationing at all. When people and their loved ones are seriously ill, most will use every means to get the services they believe they need. Thus, rational efforts under managed care to limit some types of care resulted in public attacks and litigation, leading managers to back down in order to avoid bad publicity. One example was bone marrow transplants in patients with advanced breast cancer, a treatment ultimately proven to have no value in such instances. But explicit rationing is inherently political, and the transparency of decision making

encourages confrontation and public acrimony. Although implicit rationing is less fair and more easily open to favoritism, it allows people's preferences to be met when some feel more strongly than others. But it also gives advantages to those who are more educated and sophisticated and who know better how to manipulate bureaucratic systems. Nevertheless, explicit rationing at the point of service is extraordinarily difficult to sustain politically. Few successful examples exist beyond organ transplantation.

Types of Rationing

The easiest types of rationing are often those where the public fails to perceive it. Rudolf Klein and his associates have described seven types of rationing. The most apparent is denial of service because individuals lack health insurance or cannot pay the required cost or because the managed-care reviewers do not believe that the service is justified. Rationing by selection refers to the choice of individuals among competing patients because of assessments of likelihood of benefit, place on a queue, or some rule about what is fair. Rationing by deflection refers to sending patients elsewhere because of heavy load, as often occurs in ambulance deflection from emergency departments or "turging" what are seen as undesirable patients (because of age, chronicity, or social characteristics) to some other service. Rationing by deterrence involves making it difficult to receive a service by unresponsive telephone systems, inaccessible locations, dismissive receptionists, dismal surroundings, and making people feel unwelcome. A related type of rationing is by delay, making it difficult to obtain an appointment or very long waiting times in the clinic or office. A particularly serious form of deterrence involves marketing efforts by health plans that avoid enrolling people with serious illness by making program enrollment less accessible to them. Rationing also occurs by dilution, involving short consultations with little content and the need to make repeated visits for basic services that could be provided in fewer visits. Finally, some patients face rationing by termination when they seek services but are told that nothing more can be done for them and health personnel withdraw. Such rationing commonly occurs at the end of life.

Setting Limits Fairly

It is inevitable that more rigorous rationing will be needed as new technologies and rapidly developing biomedical science provide new and expensive possibilities for treating disease. Some believe that given the large amount of waste in the U.S. health-care system, it will be possible to improve access and quality without rationing care by introducing new organizational rationalities, restructuring physician and hospital payment and other incentives, and emphasizing evidence-based treatment. However, this may be wishful thinking. Healthcare in America has always been rationed in the ways described and likely will be rationed even more as new possibilities pose enormous cost demands. The hope is that we can ration in constructive and health-promoting ways rather than simply allocating care to those with the greatest ability to pay. Rational allocation schemes require significant changes in healthcare practice organization and broad implementation of information technology, but American medicine has been slow to make these changes. The experience of large practice systems such as the Veteran's Affairs (VA) health-care system and large health maintenance organizations (HMOs) such as Kaiser-Permanente suggests that change is feasible.

One major challenge is to have the capacity to make evidence-based assessments credible to the public and insulated from everyday political pressures and influences. One example is the United Kingdom's National Institute for Health and Clinical Excellence (known as NICE), which makes such judgments and gives advice to the National Health Service (NHS). A number of models have been proposed for such a function in the United States, including one fashioned like the U.S. Federal Reserve System, which makes monetary policy significantly insulated from everyday political pressures. Some large organizations such as the VA and Kaiser-Permanente have their own processes to make such judgments, building on evidence from sophisticated databases such as those maintained by the Cochrane Collaboration, a large effort to bring together and assess the findings from randomized controlled trials and other research from all over the world.

Knowing the evidence, however, does not ensure a fair and credible allocation process. Norman

Daniels and James Sabin have developed a rationing approach to achieve legitimacy with patients. They call their approach "accountability for reasonableness" and define four necessary elements. First, they argue, decisions and their underlying rationales must be public and easily accessible. Here they endorse, as do many ethicists, explicit rationing. Second, the decisions must be based on evidence, principles, and justifications that all participants see as relevant to decisions about how best to allocate resources that are too few to give everyone whatever they might demand. Third, they recognize the uncertainties in medical care and do not demand certainty but maintain that the evidence and decision making should be plausibly consistent. Fourth, any decisions should be open to challenge and revisable when new information becomes available. In short, there must be clear organizational mechanisms in place to appeal against and revise decisions. Finally, there must be organizational mechanisms in place to ensure that the aforementioned conditions are met. No system has implemented this approach in full, although some of the elements have been used in particular kinds of decisions in some organizations. It is not clear, however, if this explicit rationing approach can be implemented to its full extent for the reasons discussed earlier. However, such thoughtful theory is helpful as we go forward.

Rationing remains an unbroachable topic in discussions of American healthcare, and professionals and patients commonly believe the myth that healthcare is not rationed. If we are to make thoughtful and prudent decisions, the public must understand rationing realities. The question is not whether to ration but how to ration more thoughtfully and effectively. This will be a continuing challenge.

REGULATION

Regulation is the formal process through which health policy governs behavior. It takes the form of rules, procedures, adjudications, and administrative actions implemented by a regulatory authority. Such an authority can function at the federal, state, or local governmental level or through numerous private organizations. Because of the breadth of the healthcare industry, the regulatory framework is particularly complex.

Health services researchers study the effects of regulation as a tool for achieving policy goals. Such investigations are often referred to as program evaluations, as they evaluate the effectiveness of regulatory programs. The outcomes of health services research may also influence the development of regulations and of legislation that forms its legal basis. Research findings are often cited by members of the U.S. Congress, state legislators, members of private bodies, and courts in the development and evaluation of regulatory policy.

Health services research is itself subject to regulation. The National Research Act of 1974 requires that all federally funded research involving the use of human subjects be approved and supervised by an institutional review board (IRB) at the sponsoring institution. IRBs are composed of professional peers of the investigators and members of the community at large, and their role is to ensure that subjects are adequately protected, in particular through procedures for obtaining informed consent concerning possible research risks. The federal Health Insurance Portability and Accountability Act of 1996 (HIPAA) limits the use and distribution of medical information that can identify individual patients. Health services researchers who rely on clinical data must either use information from which patients cannot be identified or obtain the consent of the patients involved.

Purpose and Functions

The primary purpose of government regulation is to develop and enforce the detailed rules that effectuate statutes. When the U.S. Congress or a state legislature enacts a law, it cannot account for all the technical aspects of implementation, as legislators do not have the time or the expertise to do so. Statutes typically set overall policy guidance in a field and direct an agency to bring it to fruition. For example, the U.S. Congress mandated that the Food and Drug Administration (FDA) ensure the safety and efficacy of all new drugs and devices but left it to the agency to determine the manner in which clinical testing will be conducted. The legislature in every state has required that physicians be licensed by a medical board to practice and directed these boards to set the actual qualifications for licensure.

In a private context, regulation implements policy decisions of professional and industry organizations. For example, the hospital members of the Joint Commission seek to have all institutions function at a uniform level of quality. Committees within the organization devise the actual standards that must be met to exhibit quality and the procedures for enforcing them. Similarly, the physician members of medical specialty societies seek to ensure that practitioners display minimum levels of skill and competence. Committees of these bodies develop examinations and practice guidelines to assess these attributes.

Government regulators serve four main functions. First, they promulgate rules and standards that fill in the details of legislation, as when the FDA specifies the procedures for testing a new drug. This activity is known as rulemaking. Second, they conduct adjudications that enforce those rules and that grant rights and privileges under them, such as the right to practice medicine. Third, they administer government functions, such as hospital operations in the Veterans Administration (VA). Fourth, they disperse funding for targeting purposes—for example, support for biomedical research by the National Institutes of Health (NIH).

In performing these tasks, regulators take on the roles of each branch of government. Rulemaking extends the reach of the legislative branch by adding detailed directives to the general guidance contained in laws. Adjudication mimics the activity of the judicial branch by resolving disputes over regulatory enforcement. Administration of government operations and of funding programs carries out functions of the executive branch by directly managing government activities.

Regulatory authority may be vested in bodies known as boards, commissions, agencies, or departments. They are headed by officials who are appointed by the president or, for state-level programs, the governor, and who are generally subject to confirmation by the Senate or the state legislature. When there is a single agency head, leadership changes with each new administration. Members of boards and commissions are often appointed for fixed terms that are staggered to extend beyond election cycles in order to provide for continuity of leadership across administrations. Senior agency officials just below the top leadership also tend to be political appointees. Their role

is to provide overall policy guidance. Most of the day-to-day work of regulatory agencies is conducted by a permanent professional staff.

In cutting across the traditional divisions of responsibility between branches of government, regulators play an anomalous role. They derive their authority from legislative enactments, yet they are directly accountable to the executive that appoints their leadership, and all their actions are subject to review by the courts for consistency with the underlying statutes and with the federal or state constitution. The mixing of governmental roles has at times proved controversial, in that it can be seen to blur the conventional separation of powers.

Process

Under the constitution, basic legal powers are vested in the states unless one of several enumerated national concerns is involved. Therefore, most regulation of routine aspects of healthcare, such as medical practice, hospital operations, and sanitation, fall under the jurisdiction of state agencies. States may delegate some of these functions to municipal and county governments, as is the case, for example, for restaurant inspections. Most federal regulation of healthcare falls under the constitutional authority to regulate interstate commerce, as seen in the regulation of drugs by the FDA, or under the power to spend funds to address national needs, as is done in the Medicare program.

Private regulators are usually sponsored by the regulated industry or the profession itself, as in the examples of the Joint Commission and medical specialty boards. They do not exercise actual legal authority to govern behavior and cannot impose legal sanctions for violations of their rules. Their power derives from their ability to influence reputations and professional recognition. The Joint Commission does not determine whether or not a hospital may legally operate, but accreditation by the Joint Commission adds essential credibility to an institution's claim to quality, and it is required for reimbursement by virtually all governmental and private payers. Board certification does not control the legal right to practice medicine, but it exerts similar effects on credibility and reimbursement eligibility.

Government regulators are subject to the restrictions on authority contained in the federal constitution. In particular, they may not violate the rights of those whom they oversee to due process when life, liberty, or property are at stake. Healthcare regulation affects property interests in many ways—for example, by controlling a physician's ability to earn a living, determining when a drug company can sell a new product, or deciding when a hospital can construct a new facility. Due process requires that such actions be taken only after full consideration of all relevant factors and after all affected parties have had a chance to be heard. As a guide to ensure that these steps are taken, the U.S. Congress in 1946 enacted the Administrative Procedures Act (APA), which imposes standards that federal regulators must follow. Most states have similar laws.

To meet the Administrative Procedures Act's requirements, regulatory actions must be preceded by a series of prescribed steps. The agency involved must conduct a thorough fact-finding effort that builds a record to support the action. Adequate notice must be provided to the general public of pending activities, which is generally accomplished through publication in a regular journal of the federal government known as the *Federal Register*. Particular care must be given to notifying parties who may be directly affected by an adjudication. Those with a direct interest in the outcome must also be afforded the opportunity for input through written comments or at a hearing, and after an initial decision is made, they must be able to bring an appeal. At the end of the process, a regulatory action is considered final, but appeal to the courts is still possible. They can review regulatory actions for consistency with the APA, the underlying statute that authorized the action, and the Constitution.

Private regulators are not components of the government, so they are not subject to the Administrative Procedure Act. However, there are several legal rules that circumscribe their actions. They may not discriminate based on impermissible factors such as race, religion, or national origin. In many states, they are subject to a requirement of "fundamental fairness" in their actions. They may also be held accountable for complying with their own internal rules and bylaws. Some private organizations that exercise regulatory powers, such as hospitals that grant staff privileges to physicians, are considered by

the courts to be "quasi-governmental" actors because of their tax-exempt status and receipt of government funding. This brings with it a requirement to provide due process for parties affected by their actions. Beyond these legal dictates, private regulators also have a strong interest in safeguarding their own reputations for fairness, if they are to remain credible as arbiters of professional competence and quality.

History

Over the course of the past 150 years, the focus of healthcare regulation has expanded, so that it now covers almost every aspect of the field. For the most part, each regulatory program addresses one of three key policy concerns—enhancing quality, ensuring access, or controlling costs. As the focus of policy has shifted over the years, new programs have been added by a range of different authorities, and in many instances sets of regulatory requirements are layered, one upon another.

The earliest regulation of healthcare in America addressed public health concerns. As science first revealed the role of germs in causing disease and as the means of contagion, state and local governments responded with preventive measures. These included sanitation, clean drinking water, food inspections, mandatory vaccinations, and quarantine in the face of epidemics. At the start of the 20th century, the quality of healthcare services and products became the focus as states imposed licensure requirements for physicians and private bodies affiliated with the umbrella professional organization for the medical profession, the American Medical Association (AMA), instituted procedures for accrediting the medical schools at which their members trained. In 1906, the U.S. Congress passed the first national drug safety law and established the FDA. The law was overhauled and strengthened in 1938 and again in 1962. In overall effect, these actions improved the level of quality in American healthcare and to a sufficient extent that by the 1920s the country could claim a credible system.

During the mid 20th century, the focus of regulatory activity turned largely to enhancing access. State laws passed in the 1930s facilitated the first Blue Cross and Blue Shield plans that provided insurance on a nonprofit basis. A federal ruling in

1943 helped link insurance to employment. The War Labor Board exempted employer-paid insurance premiums from a freeze on wage and price increases during World War II and permitted firms to add health coverage as a fringe benefit without restriction. Further encouragement for this benefit came after the war, when the Internal Revenue Service (IRS) ruled its value to be exempt from the calculation of income for purposes of taxation. In 1946, the U.S. Congress passed the first major federal healthcare spending initiative in the form of the Hill-Burton Act, which allocated billions of dollars for hospital construction, especially in rural areas.

The most significant regulatory expansion of access occurred in 1965 with the enactment of Medicare and Medicaid. These programs offered insurance to millions of citizens who lacked eligibility for employer-sponsored coverage—Medicare to the elderly who were no longer working and Medicaid to several categories of the poor who lacked employment. The programs were supplemented in 1997 by the state Children's Health Insurance Program (SCHIP), which permits states to extend coverage to children of families with incomes that are low but not low enough to qualify for Medicaid. In exercising its spending power through these programs, the U.S. Congress has added various regulatory restrictions over the years. For example, to receive reimbursement, institutions and practitioners must meet quality criteria embodied in the conditions of participation. Hospitals that operate emergency rooms, a category that includes almost all, must provide open access regardless of ability to pay. All providers must structure their financial dealings to avoid the exchange of remuneration in return for the referral of patients.

Not surprisingly—to many healthcare analysts—the expansion of access that Medicare and Medicaid achieved imposed tremendous pressure on costs, and healthcare spending in the United States began to accelerate rapidly in the late 1960s. In response, many regulatory programs enacted over the next 30 years focused on different kinds of cost control strategies. In 1973, the U.S. Congress passed the Health Maintenance Organization Act to encourage the use of managed care. The next year, it passed the Employee Retirement Income Security Act (ERISA) to assist

large, multistate employers in self-insuring for employee healthcare expenses. During the 1970s, all states passed, with federal encouragement, certificate-of-need (CON) programs to limit the expansion of healthcare services and facilities that were deemed superfluous. In 1983, the U.S. Congress changed the mechanism for reimbursing hospitals under Medicare to a prospective payment system based on Diagnosis Related Groups (DRGs) to eliminate incentives for overtreatment.

The actual effectiveness of these programs in stemming the rise in healthcare spending has been a matter of debate among health policy analysts and health services researchers. Costs for healthcare services continue to rise relentlessly and represent more than 16% of the gross domestic product (GDP), more than the proportion in any other country. However, from a research perspective, cost control programs have provided considerable fuel for studying the effects of economic incentives on the behavior of institutions, practitioners, and patients.

More recent regulatory programs address a range of concerns. Various federal and state reporting laws require that government authorities be informed of medical errors, which have been found to represent a major threat to quality, especially in hospitals. The U.S. Congress has empowered the FDA to take more assertive action when safety hazards are discovered in approved drugs. Access to prescription medications was expanded for the elderly with the enactment of Part D of Medicare. HIPAA restricts the ability of insurers to refuse coverage based on preexisting conditions to members of employer-sponsored groups.

In separate provisions, HIPAA also protects the privacy of patient medical information. This last regulatory thrust may be a harbinger of much future health policy. Healthcare has been slower than many other industries to adopt information technology, but substantial efforts are under way to accelerate the computerization of many aspects of the industry. This trend will raise new kinds of concerns, particularly regarding threats to patient privacy, that regulatory policy will have to address. Other applications of information technology, such as electronic medical records, telemedicine, and Internet-based services, will undoubtedly also command the attention of policymakers to an increasing extent as inevitable issues and conflicts arise.

Current Regulatory Structures

With a history of over 100 years of expansion, regulation today affects almost every aspect of American healthcare. In most cases, a variety of regulators, rather than a single authority, is involved. Each sphere of the industry is subject to its own complex structure, characterized in most cases by a dynamic interplay between oversight bodies and programs that have arisen at different times.

Physicians and other healthcare professionals are subject to licensure at the state level. Many healthcare professions also maintain a certification process through which expertise in a specialty is recognized. To achieve a financially viable practice, most kinds of practitioners must also meet the conditions for participation in Medicare and Medicaid and abide by the requirements for participation in the provider networks of private managed-care organizations should they wish to qualify for reimbursement. Physicians who seek to practice at or admit patients to a hospital are also subject to review and supervision by that institution's credentials committee.

Hospitals and other healthcare institutions are similarly subject to licensure by the states. Most also seek accreditation by the Joint Commission. About two thirds of all states maintain CON laws, which restrict the ability of hospitals to add new services or facilities without state approval based on a demonstration of community need. Hospitals must also abide by the numerous requirements that go with receipt of Hill-Burton funding, including nondiscrimination, indigent care, and maintenance of emergency rooms, and by additional rules that accompany participation in Medicare.

Healthcare finance in America has substantial components at both the private and the governmental level, both of which function within a complex regulatory framework. The business of insurance is regulated by the states, but ERISA preempts state authority over some aspects of employer-sponsored coverage, which represents over 90% of the market. In its place, this law provides for minimal oversight of health plan finances by the U.S. Department of Labor. The premiums paid for employment-based health insurance receive favorable tax treatment, which effectively creates a large government subsidy for this kind of coverage.

The federal government finances healthcare directly for the elderly, the totally disabled, and those suffering from end-stage renal disease through Medicare. Government financing is shared jointly between the federal and state governments for those categories of the extremely poor who are covered by Medicaid and for SCHIP. All these programs rely on regulatory mechanisms to operate.

Drugs and other healthcare products are regulated primarily by the FDA. This agency administers a regulatory structure that oversees all aspects of drug and device testing and determines whether test results indicate sufficient safety and efficacy to justify approval for marketing. Once a drug is on the market, the FDA oversees the advertising and promotion of approved products and evaluates postmarket safety data. Manufacturers must also obtain patents from the federal Patent and Trademark Office to protect new discoveries from competition. The federal Drug Price Competition and Patent Term Restoration Act of 1984 determines when generic copies of patented drugs and devices may be manufactured, tested, and sold.

Public health in America, the oldest subject of governmental regulation, is today one of the most disjointed. Most basic public health regulatory functions, such as oversight of sanitation, restaurant inspections, and epidemic investigations, are handled at the state or local level. The federal government takes the lead with regard to food safety. It also coordinates state efforts, monitors national disease trends, and develops recommendations through the Centers for Disease Control and Prevention (CDC). Environmental pollution is addressed by the federal Environmental Protection Agency (EPA) and by similar bodies in many states. Occupational safety and health is primarily a federal concern, subject to oversight by the Occupational Safety and Health Administration (OSHA).

Business relationships between healthcare entities are regulated in distinctive ways that do not apply to other industries. Antitrust laws are enforced by the federal U.S. Department of Justice, the Federal Trade Commission, and many state attorneys general. Federal guidance has been issued to advise healthcare providers that compete with one another on permissible forms of collaboration. Payments that providers exchange to encourage

the referral of patients are strictly prohibited by federal law, and the boundaries of legitimate financial relationships are defined in regulations issued by the Office of Inspector General of the Medicare program. Tax exempt hospitals must abide by the rules of the IRS regarding charitable activities. All healthcare providers are subject to regulations issued under HIPAA concerning the privacy of patient data.

Biomedical and other health-related research is regulated by various government agencies that provide funding and also by the FDA when results are used to support applications for approval of new drugs or devices. The National Institutes of Health (NIH), the largest single research-funding source in the world, reviews proposals of private investigators, as do the National Science Foundation (NSF), the Agency for Healthcare Research and Quality (AHRQ), and other agencies. Scientists who receive support must abide by IRB oversight concerning the use of human subjects and by numerous accounting rules.

Future Implications

Regulation is the force that translates health policy into action. Its scope is broader with regard to healthcare than with regard to most other industries. Healthcare regulators operate at all levels of government and in private settings, and they address, in one form or another, each of the three key policy concerns of enhancing quality, controlling costs, and ensuring access.

To those within the industry, regulation represents a complex and often bewildering array of restrictions. However, it has also helped foster the industry's growth over the past century. Regulatory programs have channeled much of the country's healthcare activity, for example, through the National Institutes of Health (NIH) support for basic biomedical research; enhanced the public's respect for the field, for example, through the licensure of healthcare professionals; and served as the conduit for injecting huge amounts of federal money into the system, for example, through the Medicare program. As a result, regulation serves as both a fertile ground for health services research and an outlet for implementing research findings. Because of the importance of healthcare to the nation's well-being and to its economy, regulation

will always play a central role in determining the industry's shape and in guiding its functioning.

REINHARDT, UWE E.

Uwe E. Reinhardt is a well-known and highly respected health economist and health services researcher. Reinhardt is an insightful, and often humorous, commentator on economic, political, and public policy issues in healthcare. He frequently writes on the uninsured and compares healthcare in the United States with that in other countries.

Born in 1937 in Germany, Reinhardt immigrated to Canada. He earned a bachelor's degree in commerce and economics from the University of Saskatchewan, Canada, in 1964 and was awarded the Governor General's Medal as the Most Distinguished Graduate of his class. He did his graduate work at Yale University, earning a master's degree and a doctorate in economics in 1970.

Reinhardt has taught at Princeton University since 1968, rising through the academic ranks from assistant professor of economics to his current position of James Madison Professor of Political Economy and professor of economics and public affairs. At the university, he has taught courses in micro- and macroeconomics, accounting, financial management, and health economics and policy.

Reinhardt has served on a number of government committees and commissions. He served on the National Council on Health Care Technology of the U.S. Department of Health and Welfare from 1979 to 1982. He was a member of the Special Medical Advisory Group of the Veterans Administration (VA) from 1981 to 1985. He also

served as a commissioner on the Physician Payment Review Commission (PPRC), which advised the U.S. Congress on reforms of Medicare policies for paying physicians, from 1986 to 1995.

He has also served as a member of many private-sector organizations, including the Council on the Economic Impact of Health Reform, the National Leadership Coalition on Health Care, and the National Institute for Health Care Management. He is currently on the board of trustees of Duke University Health System and the Teachers Insurance and Annuity Association. And he is the chairman of the Coordinating Committee of the International Program in Health Policy of the Commonwealth Fund.

Reinhardt is a prolific researcher and writer who has authored or coauthored over 200 journal articles, books, and editorials. He also has served on the editorial boards of many prestigious medical and health services research journals, including *Health Affairs*, *Journal of the American Medical Association*, *Journal of Health Economics*, *Milbank Quarterly*, and the *New England Journal of Medicine*.

In recognition of his work, Reinhardt has received many awards and honors. For example, he was elected to the National Academy of Sciences, Institute of Medicine (IOM), in which he has been a member since 1978. He is a past president of the Association of Health Services Research and the Foundation for Health Services Research. In 2004, he received the Distinguished Investigator Award from AcademyHealth.

Reinhardt has been a consultant to many organizations, including the World Bank, as well as to various federal legislators. He frequently is called to testify before the U.S. Congress.

RELMAN, ARNOLD S.

Arnold S. Relman is Professor Emeritus of Medicine and of Social Medicine at Harvard Medical School. He has been a medical research scientist, a clinical practitioner and consultant, a medical-school teacher and department head, a university and medical-school trustee, the editor of two influential medical journals, a writer on medical and healthcare policy issues, and a member of a state board of licensure and discipline.

Born in New York City in 1923, Relman graduated from Cornell University in 1943 and received his medical degree from Columbia University in 1946. After residency training at Yale-New Haven Hospital, he moved to Boston in 1949 to be a National Research Council Fellow in the Medical Sciences at Boston University School of Medicine. He remained on the Boston University faculty, rising to the position of Conrad Wesselhoeft Professor of Medicine and Director of the Boston University Medical Services at the Boston City Hospital. From 1962 to 1967, he served as the editor of the *Journal of Clinical Investigation*. In 1968, he

moved to Philadelphia to become the Frank Wister Thomas Professor of Medicine and chair of the Department of Medicine at the University of Pennsylvania School of Medicine and Physician-in-Chief at the Hospital of the University of Pennsylvania. In 1975–1976, he was a Macy Foundation Faculty Scholar at Oxford University, England, and a visiting scientist in biochemistry at Merton College, Oxford. In 1977, he returned to Boston to become the editor of the *New England Journal of Medicine*, professor of medicine at Harvard Medical School, and senior physician at the Brigham and Women's Hospital. In 1991, he became Editor Emeritus of the *New England Journal of Medicine* and professor of medicine and of social medicine at Harvard University. In 1994, he became Professor Emeritus. From 1995 to 2001, he was a member of the Massachusetts State Board of Registration in Medicine and chair of its committee on quality.

Relman began his career as a medical research scientist and clinical practitioner and teacher. His research focused on renal disease and physiology and on fluid and electrolyte metabolism. He published many original studies that contributed to the understanding of the regulation of acid-base balance by the kidney, the renal effects of potassium depletion, and the diagnosis and treatment of kidney disease. He became a leader in academic medicine, serving as president of major national organizations such as the American Federation for Clinical Research, the American Society of Clinical Investigation, and the Association of American Physicians (the only person to hold all three positions) and as a member of the Council of the National Academy of Sciences, Institute of Medicine (IOM).

When Relman assumed the editorship of the *New England Journal of Medicine* in 1977, his primary interest shifted to healthcare policy and issues of medical professionalism. Since then, he has written widely on the economic, ethical, legal, and social aspects of healthcare and the practice of medicine. In 1980, he published a seminal article, "The New Medical-Industrial Complex," which first called attention to the growing commercialization of medical care in the United States and its consequences. In many articles since then in professional journals and in the lay media, he has continued to explore this theme. Relman has also

been interested in the ethical and professional principles that govern the writing, editing, and publishing of medical research reports. He was a cofounder, in 1978, of the International Committee of Medical Journal Editors, which has promulgated influential guidelines in this area.

In 1966 and 1974, Relman was a coeditor of two volumes of *Controversy in Internal Medicine*. In 2007, he published *A Second Opinion: Rescuing America's Health Care*, which summarizes his assessment of the problems of healthcare in the United States and proposes major reforms in both the insurance and the delivery systems. In this book, he says that the uniquely high costs of the nation's healthcare are due primarily to the investor-owned businesses that own most of the private insurance system, most of the ambulatory services and facilities, and a large fraction of the short- and long-term inpatient facilities. He argues that investor ownership demands continued growth of income and this has changed all of the system into an expanding commercial market that has become unaffordable. As a solution, he proposes a publicly regulated single-payer insurance system and a not-for-profit delivery system based on prepaid multispecialty medical groups with salaried physicians.

RESOURCE-BASED RELATIVE VALUE SCALE (RBRVS)

The Resource-Based Relative Value Scale (RBRVS) is the method used to construct Medicare's physician payment schedule for ambulatory services. The RBRVS transformed the way physicians were reimbursed by establishing a method of standardization of payment. Other nations have also used the method to reimburse their physicians.

Background

The method and rate of physician payment constitute powerful incentives under which physicians make clinical decisions, such as how much time to spend with patients and hours of work supplied. Fee-for-service is the dominant payment method for physician services in most countries, including the United States, Germany, Canada, Japan, Australia, and Singapore. Their fees are largely based on what physicians have charged in the market place. In a market economy, prices are determined by supply and demand and by competition. However, nations have learned from experience that the market for physician services does not satisfy the conditions that define a reasonably competitive market. These imperfections in the market often distort the payment rates for different services.

First, widespread health insurance coverage reduces patients' sensitivity to fees. Physicians can overcharge patients, particularly for the diagnosis and treatment of urgent and life-threatening medical conditions. Moreover, there is an asymmetry of information between physicians and patients.

While in a few specialties, such as family medicine and pediatrics, patients may be able to make reasonably informed choices, in others, such as oncology and neurosurgery, patients have to rely primarily on physicians' decisions. Consequently, physicians can induce demand and raise their fees. Finally, legal restrictions specify who can provide medical services, admit patients to hospitals, and prescribe drugs. Although such restrictions protect patients from unqualified providers, they also tend to grant monopoly power to the medical profession. Physicians can use this monopolistic power to raise their fees.

These market distortions result in the fees for some specialties being higher than those for other specialties. A distorted fee schedule can cause an under- or oversupply of physicians by specialty and therefore also a lack of medical services in areas where there is an undersupply, excess service provision (which can be harmful to patients) in areas where there is an oversupply, and higher health expenditures when unnecessary services are rendered. To avoid distorted fees, policymakers in the United States and several other advanced economies have sought a systematic and rational foundation for determining physician fees.

Once a nation decides to move away from paying physicians according to their charges, the question becomes, "What rational foundation and methodology can be used to develop a relative value scale and set the conversion factor?" Equally important is the question of whether the medical profession will accept a new approach to administering their fees. The RBRVS was developed when the United States was grappling with these questions.

Theoretical Foundation

In 1979, William C. Hsiao and William B. Stason published an article that outlined a rational foundation for setting a physician fee schedule. It was to be based on the theory of competitive markets, whereby the price of a service would be equal to the cost of the input resources required to produce it efficiently. A fee schedule based on the price that a perfectly competitive market would yield has the advantage that the fees will allocate resources efficiently and services will be produced efficiently.

In 1986, the U.S. Congress requested and appropriated funds for developing a new method to set physician fees for the nation's Medicare program on a more rational basis. A Harvard University research group, headed by Hsiao, was selected from several competing organizations to conduct the study. Hsiao proposed to develop the new fees based on the principles of his earlier work. A year later, the U.S. Physician Payment Review Commission (PPRC), an advisory body to the U.S. Congress, also endorsed the method based on input resource costs. The commission reasoned that a resource-cost basis would reflect estimates of what relative values would be in a hypothetical market that functions perfectly and that in such a market, competition drives relative prices to reflect the relative costs of efficient producers.

Method and Data

The Harvard research group identified three main resource inputs required to produce physician services: (1) the total work input by the physician (TW); (2) the relative practice costs, including professional liability insurance premium (RPC); and (3) the amortized value of the opportunity costs of postgraduate specialty training (AST). These three components are combined to produce the RBRVS. Specifically, $RBRVS = (TW)(1 + RPC)(1 + AST)$. The TW, RPC, and AST are each expressed as an index. The total work is divided into pre-, intra-, and postservice work. The intraservice period is the time when a physician sees the patient or performs a procedure, while the preservice and postservice periods represent the time spent on the patient before and after the intraservice period.

To investigate the work and other costs, the RBRVS study relied on the Physician's Current Procedural Terminology (CPT-4), a coding system designed by physicians, to identify more than 7,000 distinct services, visits, and procedures.

In their study, the Harvard research group found that physician work consists of two key components: time and intensity of time. The intensity has four dimensions: mental effort and clinical judgment, technical skill, physical effort, and stress due to risk. The study employed the magnitude estimation method to measure work inputs for a given service. Magnitude estimation method is a way of measuring subjective perceptions and judgments;

its usefulness in obtaining reliable, reproducible, and valid results for work input has been repeatedly demonstrated.

The Harvard research group randomly selected 6,841 physicians from the American Medical Association's Physician Masterfile and surveyed them by telephone. They were asked to estimate the time and intensity of the work of selected services performed by that specialty. The survey covered 33 specialties. The overall response rate was 69%, ranging from a high of 84% for nuclear medicine to a low of 56% for obstetrics and gynecology. The responses were tested for reliability, consistency, and validity with different statistical methods such as the intraclass correlation method and regression analysis. The study found the results from the surveys to be reliable, consistent, and reproducible. A panel of more than 200 practicing physicians who served as consultants to the study, representing the 33 specialties, then reviewed the results. The research group found that the results had face validity.

In the national survey, physicians in each specialty used a different service as a standard against which to rate the work of other services. To create a common scale for all specialties, the research group had to link the separate scales. They developed a method whereby their physician consultant panels identified pairs of services from different specialties that required approximately equal amounts of intraservice work. They connected each specialty to others by at least four of the pairs, creating a set of linkages. They then used a weighted-least-squares method to find the best-fit location for each link. A jackknife analysis of the residual sum of squares suggested that the choice of links was appropriate.

Practice costs can vary widely between different specialties and different services. Such costs would include compensation for supporting staff, office space, equipment, and supplies. The RBRVS study divided practice costs into direct and indirect costs. The identification of direct costs is straightforward—these are the resources used to render a service. In contrast, indirect costs consist of all the remaining costs; they are allocated based on commonly accepted allocation methods used in cost accounting, such as time or space occupied.

Physicians master their clinical judgment and skills through post-medical school residency training, which can range from 3 to 7 years depending

on specialty. To undertake residency training, the physicians forgo the compensation they could have earned as medical school graduates. This loss in earnings constitutes the opportunity cost of residency training. The RBRVS study developed an index of the opportunity costs for different specialties by calculating the opportunity costs for each specialty and amortizing these costs over their working lifetime.

Last, the three components of the RBRVS are combined into one index.

Epilogue

The RBRVS study was completed for all specialties in late 1991. On its completion, the U.S. Congress immediately passed a law to adopt its use for the nation's Medicare program by January 1, 1992. Many private insurance plans in the nation adopted it as well. Responsibility for updating the RBRVS was given to the American Medical Association (AMA). Subsequently, several other nations, including Australia and France, and private insurance plans in England also adopted the RBRVS method to set their physician fees.

RICE, DOROTHY P.

Dorothy P. Rice is a noted health economist and statistician who developed and applied methodologies for estimating the cost of illness and directed the federal National Center for Health Statistics (NCHS).

Rice was born Dorothy Rebecca Pechman in Brooklyn, New York, in 1922. Her parents had immigrated from Poland about a decade before. She attended Brooklyn College for 2 years and then transferred to the University of Wisconsin, where she earned a bachelor's degree in economics in 1941.

Immediately after college, she began her career as a federal civil servant—as an assistant statistical clerk for the Railroad Retirement Board, and in 1942, she moved to the War Production Board. There, she met her future husband, John D. (Jim) Rice, whom she married in 1943 and remained married to until his death 62 years later. In 1946, she worked as a health economist for the U.S. Public Health Service on the Hill-Burton Act, which supported the post–World War II growth of hospitals. Thereafter, she had three children, Kenneth, Donald, and Thomas and was out of the labor force, raising them and volunteering for various nonprofit organizations, from 1949 to 1960.

Rice reentered the labor force in 1960 and joined the U.S. Public Health Service. There, she helped develop, refine, and apply a methodology

for estimating the cost of a human life. Called the "human capital method," it approximates the economic value of life by calculating the discounted value of future earnings. One of her innovations was developing and refining methods for imputing values for those not in the labor force, such as housewives. One purpose of calculating the value of a life was to estimate the aggregate cost of disease. Rice estimated the costs of cardiovascular disease and cancer (1965) and then the overall cost of illness in the United States (1966).

She became Chief of the Health Insurance Research Branch of the Social Security Administration (SSA) in 1965 and then Deputy Assistant Commissioner for Research and Statistics at SSA in 1972. During the early 1960s, much attention was being devoted to national health insurance. She analyzed data from a comprehensive survey of the aged and found that more than half of the citizens aged 65 and older did not have adequate health insurance. These data were used in developing proposals that resulted in the Medicare program.

In 1976, Rice was appointed the director of the National Center for Health Statistics (NCHS). NCHS is the leading national agency that oversees the collection, analysis, and dissemination of health data. Her stewardship lasted until 1982, when she retired from the federal government and moved to California.

In 1982, Rice was appointed as a professor in the Department of Social and Behavior Sciences in the School of Nursing and at the Institute for Health and Aging at the University of California, San Francisco (UCSF). At UCSF she revisited her work on estimating the cost of illnesses, applying it to injuries, aging, mental illness, and AIDS. She devoted considerable attention to the cost of smoking and contributed to the Tobacco Settlement of \$246 billion between the state attorneys general and the tobacco companies.

Rice's honors include election to the national Institute of Medicine (IOM); the American Public Health Association's Sedgwick Memorial Medal for Distinguished Service in Public Health; the Presidential Award for Leadership and Contributions to Health Services Research from the Association for Health Services Research (now AcademyHealth); and the Jack C. Massey Award for Achievement in Health and Related Sciences. She also holds an

honorary doctorate of science from the College of Medicine and Dentistry at New Jersey. Rice is the author of more than 250 articles, chapters, books, and monographs. In 1999, the University of California, San Francisco, established the Dorothy Pechman Rice Center for Health Economics.

a particular (typically negative) event or, more generally, to a magnitude that is a combination of the probability of a negative event and the magnitude of loss associated with the given event. The more likely the event is to occur and the more harsh and costly the results if the event occurs, the greater the overall risk.

Risk in Epidemiology and Biostatistics

In the context of epidemiology, the term *risk* refers to the probability that some event will occur within a particular time period. Typical events are death (mortality) or disease (morbidity) incidence. The fixed time period is essential for defining the probability. Related measures of risk per unit time are instead referred to as *rates*. In the area of biostatistics, risk also refers specifically to the probability of the occurrence of a particular event during a defined time period. Biostatistical analyses along with epidemiologic study designs have been used extensively to analyze risk in this sense. Estimation of risk can be done based on a random sample of the population for whom the status of the given event is defined during the given time period; the estimate is then simply the number who experience the event divided by the total. It is essential that the entire sample be at risk of the outcome event. For example, if the event is the incidence of some disease, the population at risk is the subset of the population that has been diagnosed with the disease. It is also essential that each individual in the population can be properly classified as either having the event or not having the event during the given time period. Statistical theory addressing estimation of probabilities of risk is based on the binomial distribution. Confidence intervals can be computed that reflect the variation in the estimate due to sampling, based on the sample size and the assumption of a random sample.

An area within biostatistics known as survival analysis addresses the problem of incomplete information, or censoring, in the estimation of risk. Right censoring occurs when an individual known to be at risk of the event for some time period is then lost to follow-up or when the individual's subsequent status is unknown for some reason. The latest time the individual is known to still be at risk, or has still had the event, is his or her right-censored time. Such persons are said to be at risk

RISK

Risk refers to the potential negative impact of some event or exposure. It can refer to the probability of

of the event until they are right-censored. Given a sample of right-censored observations at any time point, the subset that is still known to be at risk is called the risk set. The product-limit estimate, or Kaplan-Meier estimate, is a method of estimating the cumulative risk of an event at any time point, based on conditional probabilities within the risk set. The entire set of risk estimates for different time points is the estimated survival curve.

Often risk is studied in terms of an instantaneous rate per unit time, which is then applied to a time interval to compute a risk or probability. Specifically, the rate is the potential for change in a numerator quantity—in this case, event occurrence, or change from no event to an event—relative to change in a denominator quantity—in this case, time. Under the assumption of a constant rate across time, the rate can be estimated easily from a sample of observations with varying amounts of time at risk. For example, a study of disease incidence might record disease status across time for a sample of persons initially free of the disease, and the observed time at risk might vary. If time is measured in months, the total person-time for the study is the sum of the number of months observed at risk across all individuals in the study. The average rate is then the number of events divided by the total person time and will be the event rate per month. This estimate is also known as the average incidence density.

Risk Factors and Risk Markers

A factor demonstrated to be associated with the risk of a particular outcome is called a risk factor. Examples of risk factors include environmental exposure, personal behaviors or lifestyles, or inborn or inherited characteristics. A risk marker is something shown to be associated with a particular health outcome but not necessarily as a causal factor. A factor that does seem to cause the given health outcome is referred to as a determinant of the health outcome. A determinant that can potentially be altered with intervention is a modifiable risk factor.

Risk Ratio, Odds Ratio, and the Risk Difference

There are three statistical measures used to summarize the association between a binary exposure

or other factor and risk of a given outcome; these are the risk ratio, the odds ratio, and the risk difference. The risk ratio is the risk of the outcome in those who are exposed divided by the risk of the outcome in those who are not exposed. A risk ratio of 2.0, for example, suggests that the exposure doubles the probability of the outcome. Similarly, the odds ratio is the ratio of the odds of the outcome in those who are exposed relative to those who are not exposed, where *the odds* is defined as the risk probability divided by 1 minus the risk probability. The odds ratio has become popular with researchers because, unlike the risk ratio, it is not altered when the proportion with exposure or disease is fixed in the sample by design. Considering a two-by-two table that is a cross-tabulation of exposure by disease outcome, another way of stating this property is that the odds ratio remains constant if the marginals of the table are altered. In case-control studies of disease outcomes that are rare in the population, the estimated odds ratio from the sample provides a reasonable estimate of the risk ratio in the population.

The risk difference is the risk of the outcome in those who are exposed minus the risk of the outcome in those who are not exposed. This measure of association is preferred by some researchers because its interpretation is directly tied to the number in the population affected by the exposure. There are several more variations on the risk difference. The rate difference is a difference in rates, rather than risks tied to a particular time period, between the exposed and unexposed. The population risk difference is the risk in the entire population minus the risk in the unexposed population, which corresponds to the theoretical improvement in the population risk if the exposure were entirely eliminated. The attributable risk is the population risk difference divided by the risk of disease in the population, or the proportion of risk that could theoretically be eliminated if exposure in the population were eliminated. The attributable risk among the exposed is the risk difference divided by the risk of disease given exposure, or the proportion of risk within the exposed population that could theoretically be eliminated.

Use of Statistical Regression

Epidemiological study designs along with statistical regression modeling have been used extensively

to identify factors related to risk. Logistic regression and Poisson regression are both used to model risk of disease, or any other binary variable, as the outcome measure. Logistic regression assumes linear effects on the logarithm of the odds of the outcome and produces a simple estimate of the odds ratio, whereas Poisson regression assumes linear effects on the logarithm of the risk of the outcome and produces a simple estimate of the risk ratio. Multiple regression, either logistic or Poisson, is used to adjust for confounders as additional independent variables and obtain a more accurate estimate of association of a given factor with disease risk. Inclusion of interactions as independent variables can allow for the magnitude of association between a factor and the outcome to vary with other characteristics. Factors or exposures under study are concluded to be risk factors for the outcome if the model coefficients representing their effects are statistically significantly different from zero, typically using the criterion of Type I error rate equal to .05. A statistically significant association in this case means that there is less than a 5% probability that the observed association arises only due to the particular random sample and that there is really no association in the population.

The epidemiologic literature refers to the following criteria for deciding that something is a risk factor: strength of the association, as elaborated above; dose-response effect (more exposure is associated with higher risk); lack of temporal ambiguity (the risk factor precedes the outcome); consistency of findings across different studies; biological plausibility; coherence of evidence; and specificity of the association.

Risk Assessment

Risk assessment is the estimation of risk of adverse effects resulting from negative exposures to health hazards or from absence of beneficial or positive exposures. Specifically, the amount of risk is estimated in terms of a probability and in terms of different magnitudes or doses of exposure. In the context of negative environmental exposures, or ecological risk assessment, the process typically consists of four steps. The hazardous negative exposure, conditions of exposure, and the potential target population must be identified (hazard

identification), and the resulting adverse events to be investigated must be described (risk characterization). The exposure to the relevant population must then be quantified and measured (exposure assessment); this could be done based on measures of emissions or environmental levels of the toxic substance, reflecting potential exposure in a particular area, or directly from biological monitoring of subjects from a representative sample. The final step (risk estimation) consists of combining information to make a statement about expected health effects in the target population.

Health risk appraisal is a form of risk assessment that addresses individual behaviors or lifestyles that play the role of exposure. In this case, the purpose of the risk assessment would be to identify high-risk people and motivate them to change their negative exposures or behaviors. Promoting awareness of negative effects would hopefully create a tension in high-risk individuals. There is a vast literature addressing numerous intervention programs designed to motivate change in high-risk behaviors.

The process of taking steps to reduce levels of risk is called risk management. Typically, this refers to an active hazard and control process to deal with environmental agents of disease such as toxic substances. There are three steps involved in risk management: risk evaluation, exposure control, and risk monitoring. Specifically, *risk evaluation* refers to the determination of acceptable versus unacceptable risk by comparing risk estimates with some standard for level of acceptable risk. *Exposure control* refers to actions taken to keep exposure below the acceptable maximum level. *Risk monitoring* is the process of measuring reduction in the risk as a result of exposure control.

Risk-benefit analysis refers to the process of analyzing and comparing the benefits, or expected positive outcomes, with the costs, or expected negative outcomes, of a particular action. When this is done on a single scale, results can be summarized as a risk-benefit ratio, defined as the ratio of risks to benefits. For example, the single measurement scale could be dollars.

In the context of economics, financial risk is often defined as the unexpected variability of returns, including both worse than expected and better than expected outcomes. In this case, the process of assessing risk involves predicting the

range or variability of possible outcomes of a given action.

ROBERT WOOD JOHNSON FOUNDATION (RWJF)

Located in Princeton, New Jersey, the Robert Wood Johnson Foundation (RWJF) is the largest U.S. foundation exclusively funding health-related activities and research. It played a major role in creating the new field of health services research, and because of its large size and the number of

projects it funds, the foundation continues to have an important impact on the field.

Robert Wood Johnson II (1893–1968), who built the family firm of Johnson & Johnson into one of the world's largest health and personal-care products entities, established the foundation in 1936. On his death, he left the vast majority of his personal fortune to the foundation. Since that time, the RWJF has funded research, education, and services in a wide variety of areas but with the priorities of access to affordable primary care, medical and nursing education, and quality-of-care initiatives. The foundation does not fund direct care or biomedical research. Hospitals, universities, public schools, professional associations, research organizations, community groups, and state and local governments are eligible for funding.

In 2006, the RWJF awarded over 900 grants and contracts totaling \$403 million. Grants from the foundation average \$300,000 for a project period of 3 years. Many types of organizations have been funded; priority is given to public agencies, public charities, and organizations deemed tax-exempt under Section 501(c)(3) of the U.S. Internal Revenue Code. Only projects located in the United States are funded; no international projects are supported. Many types of projects are funded, including service demonstrations, surveillance, data collection and analysis, secondary data analysis, public education (including health professions training programs), policy development and analysis, health services and public health services research, technical assistance, communication activities, and evaluation projects.

Background

In 1952, the foundation, which was originally located in New Brunswick, New Jersey, and called the Johnson New Brunswick Foundation, moved to Princeton, New Jersey, and changed its name to the Robert Wood Johnson Foundation. At this time, it also expanded its scope and began funding projects throughout New Jersey; previously it only funded local projects in New Brunswick.

In its early decades, the Johnson Foundation developed a set of priorities that still guide its funding: hospitals and healthcare; scholarship support, primarily in the health professions; and community service programs focusing on vulnerable

and underserved populations. In its early years, over half of all its grant funds went to support hospitals and healthcare, primarily in New Brunswick. It also established a large number of educational scholarships for medical, dental, nursing, and pharmaceutical students from low-income backgrounds; approximately 25% of its funds were spent in this area. The remainder of the foundation's spending was directed to community agencies serving indigent people, particularly youth. This included secular organizations such as the Boy Scouts and Girl Scouts as well as religion-affiliated organizations such as the Hillel Foundation and the Christ Church of New Brunswick.

In 1968, when Robert Wood Johnson II died, the foundation had a net worth of over \$53 million. In his will, he bequeathed \$300 million in Johnson & Johnson stock to the foundation. In the 3 years it took to probate his estate, the value of the stock increased to more than \$1 billion. This radically changed the foundation, making it the largest health-focused philanthropy in the nation. In 1971, the foundation's policy committee decided that the foundation's grants would have a national focus and that its primary purpose would be to contribute to the advancement of healthcare in the United States. Three specific objectives were adopted: expand access to medical care services for underserved populations through large-scale testing of promising approaches; improve the quality of medical care through measures including funding health professions training programs, especially those designed to increase minority representation in the primary-care disciplines; and develop approaches designed to allow the objective analysis of health-related public policies. Broadly speaking, the RWJF has kept this focus while continuing to maintain a more diverse giving strategy in the New Brunswick, New Jersey, area.

In 1971, the foundation had \$1.2 billion in assets, and in the next funding year, it dispersed \$45 million; this compares with a total of \$4.4 million in giving during the previous 34 years. Faced with the responsibility of managing this large grant program, the foundation leadership set several priorities for giving. They decided that the foundation would provide seed money to test new programs and ideas, especially in the areas of access to care for underserved populations, improving the quality of health and medical care, and developing methodologies

that would lead to objective analysis of policy interventions. They also decided to fund outcomes over process, positioning the foundation to be an early leader in the area of program evaluation. Finally, they committed the foundation to devoting significant resources to communication, thereby ensuring that their findings would be well-known and available to researchers, academic leaders, elected officials, and government policymakers.

Many of these basic approaches and areas of interest have stood the test of time. The RWJF continues to fund communications and evaluations, health professions training, and testing of new ideas through large demonstration projects. Specific issues and strategies have changed over time and will continue to evolve as the health-related needs of the nation change and develop.

Current Priorities

Specific information regarding the foundation's current funding priorities is available on its Web site. Funding is available through specific calls for proposals (CFPs); unsolicited proposals are rarely accepted except in three program areas: human capital, vulnerable populations, and pioneer projects. Proposals can include funding for service demonstrations, gathering and monitoring of health statistics, public education, health professions training and fellowship programs, policy analysis, health services and public health services research, technical assistance, communications activities, and evaluation activities. The foundation does not fund general operating expenses, existing deficits, endowment or capital campaigns, biomedical research, research on drug therapies or devices, direct support of individuals, or any kind of lobbying activities. As of 2008, the foundation no longer accepts proposals related to long-term care, end-of-life care, physical activity for adults over 50, and specific chronic conditions not otherwise covered in their priority areas.

Affordable Primary Care, Access to Care, and Health Professions Education

The giving practices of the RWJF show that it views these three issues as intertwined. From its earliest days, the foundation sponsored programs to expand health insurance and access to care, to

explore the efficacy of prepaid group plans, and to promote primary care. Between 1972 and 1975, the foundation provided over \$50 million to academic medical centers to improve the delivery of primary care and to train health professionals in the primary-care disciplines. The Clinical Scholars Program was also initiated during this time. During the mid-1970s, the foundation funded a demonstration project to improve dental care for disabled persons, a project that permanently changed the standard-of-care and service delivery approach for this population. In the late 1990s, the foundation targeted efforts toward health insurance coverage for children. In 1997, it launched Covering Kids and Families at a cost of \$13 million. A month later, the U.S. Congress passed the \$20 billion State Children's Health Insurance Program (SCHIP). The foundation added \$34 million to help states enroll children in the program.

This area of grant making is driven by CFPs issued by the foundation; unsolicited proposals are not accepted. In 2006, a wide variety of projects received funding, including 47 proposals totaling \$19.6 million designed to address affordable healthcare coverage through the development of policies and programs to expand healthcare coverage and maximize enrollment in existing coverage programs.

Quality Initiatives

During the 1970s, the foundation funded Georgetown University to develop a methodological tool to measure the quality of diagnostic services and follow-up care. Since that time, the foundation's interest in this area has broadened. In 2006, 133 grants totaling \$43.1 million were awarded. Many projects are designed to assist communities—especially communities facing lower standards of care—to improve the quality of healthcare in ways that matter to their residents. These efforts take a variety of approaches, including coalition building, developing performance measures, and encouraging public disclosure of healthcare quality measures and quality improvement projects. Program and policy evaluation are also funded under the foundation's quality initiative. The foundation also uses its national resources to ensure that results are effectively communicated to all stakeholders.

Health Services Research and Public Policy

Historically, the foundation's commitment to health services research has been embedded in its commitment to evidence-based public policy. In the 1990s, the foundation became interested in understanding and accessing the changes wrought by managed care in terms of access, cost, and quality. To facilitate this interest, the foundation established a new organization, the Center for Studying Health System Change. This organization, located in Washington, D.C., continues to design and conduct research on the nation's healthcare system to inform policymakers in government and private industry.

During the 2001 decade, the RWJF increased its efforts in this area, coming forward and espousing a need to refocus the national health services research agenda to include public health services and systems research. It is the intent of the foundation to direct more private and public dollars towards building a strong public health research infrastructure, one that continues to generate epidemiological data as well as address the social and community conditions that promote physical and mental health in the population. In announcing its increased interest in this area of research, the foundation expressed concern over the fragility of the nation's public health system and stated that, in its estimation, the best remedy is to increase the science base and ensure that recommendations are based on findings, not political expediency. While in terms of grant-making dollars this is a new initiative, it is consistent with the foundation's longstanding interests and builds on its activities to support the 1988 National Academy of Sciences, Institute of Medicine (IOM) report, *The Future of Public Health*, participation in the Turning Point Initiative, and the goals and objectives of Healthy People 2010.

Funding under this giving area is in response to specific CFPs issued by the foundation. In 2006, 137 projects were funded, totaling \$43 million. Most of these projects were designed to improve the performance of public health agencies, increase advocacy for public health resources and policy changes, and, to these ends, build an evidence base for public health policy and practice. Funding to build the evidence base included assessing the potential of a public health accreditation system

and other quality improvement efforts; projects that actively engage public health research partners; support for survey research concerning public health activities; and research to assess the potential health impacts of a variety of projects and policies.

Of note, the National Association of City and County Health Officials (NACCHO) and the Association of State and Territorial Health Officials (ASTHO) were among the public health organizations funded to create a national public health accreditation system to serve as the basis for ongoing quality assessment, greater transparency, and increased accountability.

A variety of advocacy initiatives were also funded in 2006. They included tobacco control measures, including smoke-free-air laws and tobacco taxes.

Healthy Communities and Lifestyles

Beginning in the 1990s, the RWJF became interested in the nonmedical factors that influence health. Since that time, it has funded many approaches to ensuring healthy communities and to encouraging healthy lifestyle choices. Projects have been funded on a broad array of topics, including smoking, diet, sexual behavior, substance abuse, and environmental exposures. Beginning in 2006, the foundation specifically directed efforts toward the childhood obesity epidemic in the belief that the long-term consequences of childhood obesity will negatively affect the health status of an entire generation and will further stress systems of primary care and limit resources. In that year, 128 grants totaling \$41.8 million were funded to support the priority of reversing the epidemic by 2015 by improving access to affordable healthy foods and increasing opportunities for physical activity in schools and communities across the nation. Three integrated strategies guide this area of grant making. The foundation prioritized funding projects that will build an evidence base to ensure that the most promising efforts are replicated throughout the nation. It also funds action strategies for schools and communities, including coalition building to disseminate promising approaches at the local level. Advocacy efforts also receive funding under this initiative.

The foundation funds the Leadership for Healthy Communication initiative, which works with national organizations that represent elected and appointed officials—such as the National Conference of State Legislatures and the U.S. Conference of Mayors—to educate their members about successful approaches to increasing physical activity and healthy eating among children and young adults.

In 2008, the foundation announced a new initiative in this area, the Commission to Build a Healthier America. This commission, funded for 2 years, is charged with identifying proven interventions capable of successful replication, especially those interventions that take into account economic, social, and physical environment factors. This program area accepts unsolicited proposals.

Vulnerable Populations

This area of giving is designed to support promising ideas and strategies to overcome health disparities. Unsolicited proposals are accepted. In 2006, 154 grants totaling \$83.7 million were approved. This area of giving supports promising new ideas to help overcome long-standing health challenges for groups that bear an excess of the burden of disease. Projects often address poor health status in the context of other factors such as housing, education, and poverty. Changes in healthcare service delivery and organization are funded, as are initiatives to improve policy, financing, and service integration among local service providers and state and federal agencies. The Community Oriented Correctional Health Services project funds continuity-of-care approaches to connect the healthcare provided in local correctional centers with healthcare providers in the community.

This giving area also funds projects that bring together nontraditional partners and multiple-service systems to address health disparities and care for vulnerable populations. As an example, the Green House Project is taking a new approach to skilled-nursing homes and assisted living facilities by creating residences for small groups of individuals who require skilled nursing care in a homelike setting.

The foundation also funds projects to address rapid demographic changes occurring in the nation,

including the Community Partnership for Older Adults and the New Routes to Community Health projects.

Human Capital

This giving area funds a wide variety of training programs and leadership development programs. In 2006, 195 grants totaling \$115.1 million were awarded. Unsolicited proposals are accepted. This area includes some of the foundation's most long-standing programs, such as the Clinical Scholars Program. It also funds programs to increase the racial and ethnic diversity of the health professions, train people in specific subdisciplines such as quality improvement, ameliorate the nursing shortage, and involve scholars from a variety of fields (e.g., business, engineering, and law) in research studies on the policy issues in health and health-care. Diversity training and cultural-competence projects are also funded. The foundation maintains many midcareer awards, including its Health Policy Fellowship Program, Community Health Leaders Program, and the Executive Nurse Fellows Program.

Pioneering Projects

This area of giving allows the foundation to be an early participant in new approaches to important problems, approaches deemed capable of developing breakthrough improvements in health, healthcare, and public health. The foundation tends to fund projects that it feels have the potential to become long-term foundation initiatives. Unsolicited proposals are accepted. In 2006, 29 grants totaling \$8.3 million were made in this area. This included funding for new approaches to fighting drug-resistant diseases; improving the public health system's ability to predict influenza outbreaks; a national program to reform medical liability by developing a system of specialized health courts; the Myelin Repair Foundation, to develop a fast-track process for "bench to bedside" translational research; and Project Health Design, which is designing strategies to expand the use of personal health records and develop a "smart" system capable of helping individuals comply with treatment guidelines and engage in preventive measures.

Science Evaluation

Beginning in the 1970s, the foundation became committed to program evaluation. It has consistently funded evaluation components for its projects. Over the years, the foundation has remained interested in program evaluation, outcome evaluation, and the evaluation of specific policy initiatives. Funding for evaluation is embedded in all successful grant proposals. However, specific evaluation projects are also funded.

Impact on Health Services Research

The RWJF's commitment to health services research has been consistent throughout its history. It has supported research, evaluation, and the dissemination of results toward the end of supporting an evidence-based approach to the development and evaluation of public policy. Health services research is a major focus of the foundation; this is clearly evident in its rhetoric, its requests for proposals, and the allocation of its grant funds. In many ways, its support of other issues such as building healthy communities, supporting health professions education, and addressing discrete issues such as childhood obesity is toward the end of evidence-based public policy. The foundation will likely continue to play a dominant role in the funding of the field of health services research in the future.

ROEMER, MILTON I.

Milton I. Roemer (1916–2001) was a pioneer in health services research, a health administrator, and a teacher. Roemer was a scholar in the areas of international health, primary care, rural health, and healthcare organization. He was the first to identify, in the early 1960s, the phenomenon of supplier-induced demand. Specifically, he found that when health insurance is widespread in a community, increased utilization of services results in an increase in the supply of hospital beds, or, in short, a hospital bed built is a bed filled. This finding became known as the *Roemer effect* or *Roemer's law*. It would contribute in the 1970s to the enactment of federal certificate-of-need (CON) legislation and comprehensive health planning.

Born in Paterson, New Jersey, in 1916, Roemer earned a master's degree in sociology from Cornell University in 1939, a medical degree from

New York University in 1940, and a master's degree in public health from the University of Michigan in 1943.

In the early 1940s, Roemer was a county health officer for Monongalia County, West Virginia. Later, he was a medical officer for the New Jersey State Health Department. During World War II, he joined the U.S. Public Health Service, where he served as a medical officer for the War Food Administration and the Medical Care Administration of the States Relations Division. In 1951, Roemer began his international work when he was appointed Chief of Social and Occupational Health at the newly formed World Health Organization (WHO). At the WHO, he was responsible for a wide range of services, including hospital administration, occupational health, and the organization of medical care, among others. However, he was forced out of his position when the U.S. government withdrew its approval of his appointment under pressure of McCarthyism. In 1953, Roemer moved to Canada, where he worked for the Saskatchewan Department of Public Health as the Director of Medical and Hospital Services. He eventually returned to the United States and taught at Yale and Cornell universities. In 1962, Roemer joined the faculty of the School of Public Health at the University of California, Los Angeles (UCLA). He taught courses in comparative national health systems, hospital administration, medical care, and public health. And he served as the chairman of the Department of Health Services for 8 years. While at the university, he undertook extensive work in Asia and Latin America. In 1986, Roemer retired from the university and became Professor Emeritus.

During his 60-year career, Roemer conducted a wide range of research projects in international health, and he was a prolific writer. He worked in 71 countries and authored or coauthored 32 books and 430 scholarly articles. One of his best-known publications is *National Health Systems of the World*, a monumental two-volume comparative analysis of international healthcare systems.

Roemer received many awards and honors in recognition of his work. He was a member of the National Academy of Sciences, Institute of Medicine (IOM). He received the International Award for Excellence in Promoting and Protecting the Health of People in 1977, the Sedgwick Memorial Medal for distinguished service in public health in 1983,

and the Lifetime Achievement Award in 1997 from the American Public Health Association (APHA). He also received the Joseph W. Mountain award from the Centers for Disease Control and Prevention (CDC) in 1992 and the Distinguished Career Award from the Association for Health Services Research in 1997. Roemer died in 2001 at the age of 84.

ROOS, LESLIE L.

Leslie L. Roos is a Distinguished Professor at the University of Manitoba (Canada), the founding

director of the Population Health Research Data Repository, and Senior Researcher at the Manitoba Centre for Health Policy. Roos is a recognized expert in the use of administrative databases in conducting health services research.

Roos received a bachelor's degree with honors in psychology and biology from Stanford University in 1962. With awards from the National Science Foundation and Social Science Research Council, he earned a doctoral degree in political science from the Massachusetts Institute of Technology (MIT) in 1966. He then completed a postdoctoral fellowship in political science at MIT. Following academic appointments at Brandeis and Northwestern Universities, in 1973, Roos joined the University of Manitoba as an associate and was subsequently full professor in the Faculty of Administrative Studies (now the Asper School of Business). His early research resulted in three books and numerous papers on social science methods and organizational behavior. Roos moved to the University of Manitoba's Department of Community Health Sciences, Faculty of Medicine in 1990.

Roos's substantive work includes a number of papers comparing health and healthcare in Canada and the United States, looking at primary and secondary prevention among socioeconomic groups over time, and analyzing alternative approaches to funding Canadian Medicare. Roos's studies have helped transform research approaches in health services, health policy, and population health. Recent papers are expanding the applicability of his work in epidemiology, economics, and sociology. Current research has been examining the effects of family and place on well-being.

Roos has received over \$20 million in research support (several grants have been in collaboration with researchers based across Canada as well as at several U.S. universities), and he has been invited to venues as diverse as Australia and Spain to give short courses on his work.

Roos's contributions in health services research have been recognized nationally and internationally and through the ongoing success of the Manitoba Centre for Health Policy. He has published approximately 186 peer-reviewed papers and book chapters with collaborators from leading universities. Roos has been honored as a "Highly Cited Investigator" by the Institute of Scientific Information. His citations recently tallied almost

2,800, the highest number of citations by any Canadian social scientist. Journals in which he has published include *Health Affairs*, *Health Services Research*, *Journal of Clinical Epidemiology*, *Journal of the American Medical Association*, *Medical Care*, *Milbank Quarterly*, *New England Journal of Medicine*, and *Social Science and Medicine*.

Roos received career funding from the National Health Research and Development Program for over 20 years. He is a fellow of AcademyHealth and an associate of the Canadian Institute for Advanced Research. His work contributed substantially to the Manitoba Centre for Health Policy's receipt of the 2001 Health Services Research Advancement Award from the Canadian Health Services Research Foundation (CHSRF) and the 2005 regional Knowledge Translation award from the Canadian Institutes for Health Research.

Roos has received awards from the University of Manitoba for research excellence, outreach, and graduate student mentorship.

ROOS, NORALOU P.

Noralou P. Roos is a professor at the University of Manitoba (Canada) and the founding director of the Manitoba Centre for Health Policy, where she is a senior researcher, having stepped down from the directorship in 2004. Her research interests include the use of administrative data for managing the healthcare system; the relationship between healthcare use and population health; and, most recently, the impact of early childhood experiences, education, community environment, and healthcare interventions on the health of children.

Roos received a bachelor's degree with distinction and departmental honors in political science from Stanford University in 1963. As a Woodrow Wilson Fellow and a Woodrow Wilson Dissertation Fellow, she earned a doctoral degree in political science from the Massachusetts Institute of Technology (MIT) in 1968. Her first academic appointment was in political science at MIT. She then moved to a faculty position in the Graduate School of Management at Northwestern University,

followed by a year as a medical program specialist and Sears-Roebuck Foundation Federal Faculty Fellow at the National Center for Health Services Research Development. In 1973, Roos joined the University of Manitoba as an associate and subsequently full professor in the Faculty of Administrative Studies (now the Asper School of Business) (1973–1988) and the Faculty of Medicine (1973 to present).

As founder of the Manitoba Centre for Health Policy and Evaluation (later called the Manitoba Centre for Health Policy), Roos established a prototype for successfully conducting research using administrative data. The Centre holds anonymized and linkable health administrative data for all health services provided within the province of Manitoba. Using these data, Roos and her colleagues have addressed many important questions about the health and healthcare of Manitobans, and their findings have been valuable not only in Manitoba but in other healthcare systems in Canada and elsewhere around the world.

Roos is an Institute for Scientific Information Highly Cited Researcher, placed in the top half of 1% of published scientists with over 2,800 citations. Her early work built on her doctoral research and focused on public administration in Turkey. Subsequently, she shifted her scholarship to evaluation and to evaluating health programs in particular. She has published over 200 scholarly articles and academic reports and has collaborated extensively with authors throughout North America and elsewhere in the world. She has published in journals such as *American Journal of Public Health*, *Health Affairs*, *Health Services Research*, *Medical Care*, *Milbank Quarterly*, the *New England Journal of Medicine*, and *Social Science and Medicine*.

Over the course of her career, Roos has received over \$45 million in research support, including being continuously funded as a National Health Research Scientist from 1973 to 1998, an associate with the Canadian Institute for Advanced Research from 1988 to 2002, and a Tier 1 Canada Research Chair in Population Health Research from 2001 to the present. She was a member of the Prime Minister's National Health Forum from 1994 to 1997 and a member of the Medical Research Council from 1997 to 2000.

Her work and collaborations were recognized in 2001 through the Canadian Health Services Research Foundation (CHSRF) awarding the Manitoba Centre for Health Policy the Health Services Research Achievement Award. In 2005, Roos was the recipient of the Order of Canada in recognition of her lifetime of outstanding achievement, dedication to the community, and service to the nation.

ROEM, C. RUFUS

The field of health economics was still in its infancy when C. Rufus Roem (1894–1988) was asked to join the landmark Committee on the Costs of Medical Care (CCMC) in 1929. From that time onward, Roem’s groundbreaking work established his reputation as a pioneer in this new field. Along the way, Roem proved to be an innovative and influential advocate for group medical practice, hospital prepayment, uniform hospital accounting, and areawide health planning.

Born in Radcliffe, Iowa, in 1894, Roem was the son of Norwegian immigrant parents who were members of the Religious Society of Friends, or Quakers. Roem attended Oberlin College, majoring in political science. After graduation, he accepted a position with the Goodyear Tire and Rubber Company. But he soon left to join the U.S. Army for service in World War I. After the war, Roem decided to pursue a career in education, and he took a position teaching accounting and business courses at Earlham College, a small Quaker college in Richmond, Indiana. To establish his credentials in accounting, he passed the Indiana Certified Public Account (CPA) examination. At that time, Roem saw where his future lay, for he enrolled in graduate studies at the University of Chicago. He received an instructorship in accounting, and he completed a master’s and a doctoral degree in economics. Soon Roem was promoted to assistant professor at the university, and in 1928 was appointed assistant dean of its School of Commerce and Administration. And in 1929, he became an associate professor.

While at the University of Chicago, Roem developed a friendship with a colleague who had a lasting influence on his life. In 1928, he met Michael M. Davis. Davis was a major figure in the nation’s medical-care circles; he was the director of medical services at the Julius Rosenwald Fund and an executive committee member of the CCMC. The CCMC was organized in 1927 and supported by a number of large foundations to conduct a 5-year study of the financing and delivery of medical care in the nation.

In 1929, Davis asked Roem to become the associate director of medical services at the Rosenwald Fund. He also asked Roem to lead a study of hospital capital investment for the CCMC,

which had not been studied previously. The project appealed to Roem because of his background and his interest in public finance and nonprofit corporations. It was not long before Roem was a full-time staff economist for the CCMC. In 1930, he moved to Washington, D.C., where he assisted in preparing a number of CCMC reports, including the landmark *Final Report of the Committee on the Costs of Medical Care*, which was published in 1932.

While at the University of Chicago, Roem also met Isidore S. Falk. Falk would become widely recognized in medical-care circles for his work on health and Social Security issues. Eventually, Falk became the associate director of the CCMC research staff, linking him professionally with both Roem and Davis.

Roem’s work at CCMC led to his interest in the prepayment of healthcare. He became associate secretary of the American Hospital Association (AHA) and later, executive secretary of the Committee on Hospital Service, where he assisted in the approval of prepaid group hospitalization in 1934. It has been said that Roem more than anyone else shaped the movement of prepaid healthcare. Ultimately, Roem’s activities at the AHA helped enormously in laying the foundation for the formation of Blue Cross and Blue Shield plans around the nation. In his work, Roem was influenced by E. A. Filene’s emphasis on applying the principles of scientific management to the healthcare field and by his advocacy for group prepayment and regional health planning.

In 1946, Roem testified before the U.S. Senate Committee on Education and Labor, describing the rapid growth of Blue Cross plans in America as having “enrolled more participants in less time than any voluntary movement in the history of the world.”

Among the principles Roem supported were not-for-profit operation in healthcare, appointing physicians and community leaders to hospital governing boards, patients’ choice of physician and hospital, financial integrity, and “dignified promotion.” He believed strongly that health is wealth and access to health services is a basic right, essential to the effective pursuit of happiness. He also held the opinion that while healthcare is an economic commodity, it differs sharply from other commodities.

Rorem was a prolific writer. His first publication on medical care costs was *The Public's Investment in Hospitals* (1930). In the book, he underscored the fact that most hospital capital came from public rather than from private sources. He also published *Private Group Clinics* (1931). Rorem contributed to 5 of the 28 reports issued by the CCMC, and he was the author of numerous other publications.

Rorem remained at the American Hospital Association for 10 years, leaving in 1947 to take the position of executive director of the Hospital Council of Greater Philadelphia. He remained there until 1960, when he took a post in Pittsburgh as the director of the Hospital Planning Association of Alleghany County.

During his long career, C. Rufus Rorem received many honors, including membership in the Health Care Hall of Fame. He was admired for his soft-spoken and self-effacing manner and respected for his view of healthcare as more than just a business. He had no sympathy for the view of many hospital spokesmen and physicians who described their activities as an "industry." He was a gentle and wise man who made an indelible mark on American health economics and medical care.

ROSENBAUM, SARA

Sara Rosenbaum is a leading health policy expert whose professional accomplishments have transformed the lives of ordinary Americans by advocating for more equitable and effective policies to increase access to healthcare for low-income, minority, and medically underserved populations. Rosenbaum has been pivotally involved in designing national and state legislative and regulatory health policies in a variety of areas, including Medicaid, private health insurance, employee health benefits, health services for medically underserved populations, maternal and child health, civil rights, and public health.

Sara Rosenbaum is the Harold and Jane Hirsh Professor of Health Law and Policy and is the founding chair of the Department of Health Policy at the George Washington University School of Public Health and Health Services in Washington, D.C. She is also the director of the Hirsh Health Law and Policy Program and the Center for Health Services Research and Policy at the university.

Rosenbaum received her bachelor's degree from Wesleyan University in 1973 and her Juris Doctorate degree from the Boston University School of Law in 1976. She began her career as a community legal services attorney in Vermont and California and also worked at the Children's Defense Fund in Washington, D.C.

Rosenbaum's research interest focuses on the ways in which the law intersects with the nation's healthcare and public health systems, with a

particular interest in quality of care, managed care, insurance coverage, and civil rights. She has published extensively and is coauthor of the widely used health law textbook *Law and the American Health Care System*.

Rosenbaum serves on many boards and committees, including AcademyHealth, the National Board of Medical Examiners, and the Committee on Child Health Research of the American Academy of Pediatrics and on study committees of the national Institute of Medicine (IOM), and she serves in an advisory role to the March of Dimes and the Centers for Disease Control and Prevention's (CDC) National Center on Birth Defects and Disabilities. During the Clinton administration, from 1993 to 1994, Rosenbaum worked for the White House Domestic Policy Council, where she directed the drafting of the Health Security Act and oversaw the development of the Vaccines for Children program.

Rosenbaum has received numerous accolades for her work, including the Investigator Award in Health Policy from the Robert Wood Johnson Foundation, and has been recognized by the U.S. Department of Health and Human Services for distinguished national service on behalf of Medicaid beneficiaries. In addition, she has been named one of the nation's 500 most influential health policy-makers by McGraw-Hill.

Rosenbaum has advised the U.S. District Court for the Middle District of Tennessee in *John B. v. Groetz*, a class action suit that challenges the adequacy of health services for children in that state. She also continues to champion the needs of the most marginalized members of our society and mentors students interested in improving health-care for the poor.

RTI INTERNATIONAL

RTI International is an independent, nonprofit research organization dedicated to improving the human condition by turning knowledge into practice through cutting-edge study and analysis in health and pharmaceuticals, education and training, surveys and statistics, advanced technology, democratic governance, economic and social development, energy, and the environment. Founded in 1958 by three universities (Duke University, North Carolina State University, and the University of North Carolina) in North Carolina's Research Triangle Park, RTI was the initial research organization and focal point for research in the Park; its first projects included applied statistics and environmental research. Today, with a staff of more than 2,600 individuals, RTI conducts research in 40 countries. Headquartered in North Carolina, RTI has seven U.S. regional offices and eight international offices. Its clients include most federal cabinet departments (particularly the U.S. Department of Health and Human Services), numerous state and public health agencies, and a variety of private foundations.

Health Services Research

Health services research encompasses investigations into healthcare delivery and interventions from prevention and screening through diagnosis and treatment to rehabilitation; a broad set of health policy issues concerning access to care, costs of care, and quality of care; health insurance; effectiveness and efficiency of care processes; patient outcomes, including quality of life and satisfaction; workforce issues; and a wide array of social problems with health implications, including domestic violence and criminal justice, substance use and abuse, and environmental toxicities. Health services research at RTI concerns individuals, families, organizations and institutions, communities, and populations.

RTI's research portfolio is highly multidisciplinary and applies sophisticated quantitative and qualitative methods from many fields, including social sciences such as sociology, psychology, anthropology; statistical, economic, and mathematical sciences including advanced modeling techniques; epidemiologic and public health fields that employ community-based methods; and biological and life sciences, particularly medicine, nursing, and pharmacy. RTI projects employ advanced survey techniques based on both traditional and modern measurement theory, all possible administration modes, and program evaluation and policy analysis.

Exceptionally strong survey and computer processing capabilities support health services research at RTI. Healthcare surveys may be small area, national, or international in scope, and they may be either cross-sectional or longitudinal in nature. RTI specializes in recruiting and following hard-to-reach populations, such as children in the foster care system, the low-income elderly, and homeless persons. RTI has an outstanding capacity for using administrative data, with programmers able to link claims and enrollment data from multiple sources to create episodes of care or to follow cohorts of patients over time.

Principal Areas of Research

RTI research is heavily oriented toward improving the health and well-being of individuals and populations (both domestically and internationally),

enhancing healthcare and social programs, and strengthening public policy through an extensive health services research and policy analysis portfolio. Particular emphasis is placed on applying multiple disciplines, methods, and theoretical frameworks to healthcare financing and payment; healthcare quality; aging and persons with disabilities; child, adolescent, and family well-being; early childhood development; women's and reproductive health; and health and social organizations. RTI conducts research on substance abuse, mental health, and criminal justice issues using a wide range of multidisciplinary social science methods on broad topics of behavioral health and related policy issues. Research foci include substance abuse prevention and treatment; HIV/AIDS; problems of the urban poor; risk behaviors and family research; and transdisciplinary research that links genetic, neurobiological, and behavioral factors in the study of substance abuse, crime, and violence.

RTI also conducts a broad range of applied research and evaluation in health promotion, disease prevention, health and environmental economics, and technology transfer, with special emphasis on individual, social, and environmental factors that affect modifiable health behaviors and human welfare. A growing collection of research focuses on health communications, including literacy and health literacy. Among social and environmental factors of interest are public policies and regulation, media and communications, communities, schools and workplace, and interpersonal and individual psychology.

Special Areas of Focus and Strength

Economic research covers healthcare costs and cost-effectiveness, behavioral health economics (especially substance abuse and mental health), prevention effectiveness economics, and payment and reimbursement issues. Particular emphasis is placed on healthcare financing, insurance, payment, and reimbursement issues, especially those affecting Medicare and State Children's Health Insurance Programs (SCHIPs). RTI conducts extensive evaluation and research for the Centers for Medicare and Medicaid Services (CMS). RTI's Medicare payment research includes developing risk adjustment algorithms for managed care and Medicare Part D (prescription drug) plans, implementing and evaluating

competitive bidding and pay-for-performance demonstrations, redesigning provider payment systems (e.g., for post-acute-care providers and for psychiatric hospitals and units), and making technical refinements of prospective payment systems and physician fee schedules. Medicaid and SCHIP research has focused on enrollment and retention, managed care, long-term care, and evaluations of 1,115 waiver demonstrations, including the Oregon Health Plan. Many of these studies are mandated by the U.S. Congress and are used to support new federal policies and regulations.

RTI performs cost-of-illness studies and cost-effectiveness analysis. This work includes designing and evaluating interventions to prevent obesity, diabetes, coronary heart disease, cancer, infectious diseases, injuries, and other preventable causes of disability and death. Related research evaluates strategies to boost positive health behavior and reduce risky behaviors such as smoking, substance abuse, and domestic violence.

Research on access to healthcare, apart from the wide variety of projects concerned with public and private insurance schemes, focuses on vulnerable populations such as minority or low-income populations; on patient populations defined by substance use and abuse, tobacco use, mental illness, and HIV/AIDS; and on incarcerated persons. Many studies focus on subsets of these vulnerable populations, such as low-income children and elderly persons belonging to racial and ethnic minority groups. Health and healthcare delivery for active-duty military populations and dependents are expanding targets of RTI research. Numerous projects concern the elderly and disabled, especially with respect to long-term care and rehabilitation. Health and healthcare disparities represent a growing portion of the health services research portfolio, with particular emphasis on access to cancer screening and treatment, family planning services, preventive and primary care, high-tech surgery, and prescription drugs. Geospatial analysis (e.g., for breast cancer) and complex modeling techniques are increasingly being applied.

RTI addresses quality of healthcare through several broad programs, including an Evidence-Based Practice Center (EPC) for conducting systematic and comparative effectiveness, a Developing Evidence to Inform Decisions About Effectiveness Center (DEcIDE) for projects related to the

comparative effectiveness of therapies and delivery systems, and an Accelerating Change and Transformation in Organizations and Networks (ACTION) to study change within healthcare organizations; all are supported by the U.S. Agency for Healthcare Research and Quality (AHRQ). RTI researchers develop and evaluate quality measures and indicators of patient safety such as injury detection triggers, refine and apply methods for detecting adverse drug events, develop and test methods for public reporting of quality performance, and analyze the effect of payment policy on quality of healthcare. Applying methods to assess quality of life and patient-reported outcomes is a growing feature of RTI research. Research involving clinical measures of quality, processes of care, and outcomes addresses issues for the U.S. Department of Health and Human Services, the Department of Defense, and international pharmaceutical clients and foundations.

Virtually all health technologies and interventions fall within the purview of RTI health services research: counseling and behavioral interventions, diagnostic and screening tests, prevention activities such as immunization or chemoprevention, all forms of therapeutics (especially pharmaceuticals), and rehabilitation services. Similarly, virtually all types of chronic diseases (e.g., cancer, cardiovascular diseases, depression, and obesity), many prevalent and emerging infectious diseases (e.g., HIV/AIDS, avian influenza), genetic conditions (e.g., Fragile X), and various lifestyle behaviors (e.g., smoking, poor nutrition, physical inactivity, obesity, smoking, and the use of alcohol and licit or illicit drugs) figure prominently in the RTI research portfolio.

RURAL HEALTH

What constitutes rural in healthcare depends on the definition being used for rurality, and that is sometimes dependent on the type of healthcare being delivered. There currently is no consensus definition of what rural is in the United States, either for health or for other policy domains. Since 1910, the U.S. Census Bureau has used a threshold of 2,500 people living in an incorporated place as its definition of rural; that definition remains in place today, but it is seldom used except for classification purposes in the census. A more widely used and recognized definition is the "metropolitan" designation process developed by the U.S. Office of Management and Budget (OMB), the White House office responsible for devising and submitting the president's annual budget proposal to Congress. The OMB classifies counties as metropolitan if they include a central city of at least 50,000 people or contain an urban cluster of that size or if they are closely tied to central metropolitan counties by commuting or economic trade patterns. The OMB originally identified only metropolitan counties but later designated core and other metro counties. In 2000, the nonmetropolitan counties with small urban centers were classified as "micropolitan." The U.S. Department of Agriculture (USDA) has created several different classifications of nonmetropolitan counties (non-Core Based Statistical Areas, functional regions based around an urban center of at least 10,000 people) that are often used to scale the degree of rurality of counties. These include the Rural Continuum Code and the Urban Influence Codes. An alternative, fine-grained classification system based largely on commuting patterns, the Rural Urban Commuting Areas (RUCA) codes, is based on clusters of census blocks or block groups; it has been adapted to apply to U.S. Postal Service ZIP

code areas. Federal and state policies that apply to health programs and regulations often specify one or more of these classification systems to guide the allocation of funds or application of rules to rural communities and populations.

The Rural Population in the United States

The United States was, for most of its history, a rural, agricultural nation. It was not until the 1920 census that the urban population of the nation exceeded the rural for the first time. In that year, the rural population was 50,866,899, or 48.1% of the total U.S. population. Since that time, the nation's rural population has remained relatively stable, growing to 59,274,456 in 2000. However, the rural proportion dropped to just over 20% of the total population of the nation. Alternatively, since the 1950s, the OMB chose to develop the metropolitan statistical areas designation to separate urbanized or city-oriented from other counties. In 2005, a total of 1,090 counties in the nation were metropolitan and constituted 83.2% of the U.S. population; 693 counties were micropolitan, 10.3% of the nation's population; and 1,358 counties were non-Core Based Statistical Areas, 6.6% of the total population. In 2005, the estimated total U.S. population living in nonmetropolitan counties was 54,566,948.

Rural Health Services Research

Rural health services research grew out of social and policy concerns with access to medical care and the health consequences of poverty that are closely associated with many rural areas. The problem of the relative deprivation of rural areas and its effects on health was noted in the 1920s, with structural assessments completed by the Farm Security Administration (FSA), a product of the New Deal. The FSA promoted prepaid medical group practice cooperatives as one way to meet the healthcare access needs of rural areas. This laid the foundation for the development of the staff model managed-care systems and health maintenance organizations (HMOs). The FSA also supported analysis of these programs and their outcomes and impacts, and this work was an early forerunner of health services research.

Plans for regionalization of healthcare services were proposed early in the 20th century as one way to ensure that rural places would receive the necessary care. In Great Britain, the work of Lord Dawson of Penn in his plans for a hierarchical system of clinics and hospitals stimulated future American healthcare planners associated with the Committee on the Costs of Medical Care (CCMC), which met from 1927 to 1932. The committee began work to estimate the necessary minimum population that could support what were termed "primary" medical centers that would provide medical services in the smaller towns and villages. The idea of a hierarchical structuring of regionalized medical services became part of the federal Hospital Survey and Construction Act, also known as the Hill-Burton Act, which supported the construction of hospitals in many rural communities from 1946 through the 1960s. The basic planning methodologies developed in the process of implementing the Hill-Burton Act formed the structure for later analytic work attempting to balance place-based needs with services. The subsequent federal planning legislation of the 1970s supported the development of methods to allocate resources, project supply, and anticipate demand. This work formed the underpinnings for determination of appropriate levels of utilization of services, a theme that later emphasized the ability of populations to gain access to healthcare.

The relative supply of physicians between rural and urban places was a concern of Milton I. Roemer and Frank G. Dickenson of the American Medical Association. Their work in the 1950s was centered on the development of appropriate geographic service areas to properly assess and guarantee distribution of care. This assessment of geographic distribution and variations in supply anticipated the later work of John E. Wennberg at Dartmouth Medical School.

In the 1950s and early 1960s, the problems of overall physician supply were apparent, and rural-focused research emphasized the analysis of health manpower needs as well as the development and assessment of alternatives to resolve that problem. The economics of physician workforce distribution with a specific emphasis on rural places developed in the emerging field of health services research with the work of health economists

including Rashi Fein, Uwe E. Reinhardt, and Frank A. Sloan. The primary-care needs of rural places became one of the principal reasons for the development of the new professions of nurse practitioner and physician assistants, and evidence supporting their efficacy was collected in many rural communities. These same economists tackled the issues of substitution and complementarity of clinical roles as these “new health professionals” found political acceptance.

The late 1960s and 1970s saw the emergence of subsidized primary care programs and clinics in the form of comprehensive community health centers, hospital-based clinics, nurse practitioner-staffed clinics, outreach programs, and physician leadership programs. Given the relative shortage of resources, many of the clinics were established in rural places, and a number of programs stimulated their development. The variety of organizational structures of rural primary-care systems stimulated a series of studies that compared the relative efficiency and effectiveness of these organizational forms via work led by Stephen M. Shortell and Cecil G. Sheps with funding from various foundations and the federal government.

The Medicare program based its payments for hospitals and physician services partly on the location of the provider during this period. The system recognized wide geographic differences in costs and charges in the “usual, customary, and reasonable” payment system that was eventually modified into a system that differentiated between cities and the rural parts of states and regions. Medicare structured its payments to hospitals using a geographic modifier to account for past payment patterns and underlying labor costs. This created a pattern of inexplicably and dramatically different payment levels between seemingly similar adjacent counties but a relatively consistent gradient between urban and rural areas, with providers in metropolitan areas receiving higher payments than those outside those places. This differential was especially apparent with the release of payment indexes for managed-care organizations after the passage of the federal Tax Equity and Fiscal Responsibility Act (TEFRA) of 1982. The system created an average adjusted per capita cost (AAPCC) mechanism to guide managed-care payments; these created very large gaps between urban and rural payment levels. This formalized

system generated an organized political response that, in turn, unified the several differing advocacy organizations representing rural interests into the National Rural Health Association (NRHA), which, in turn, pressed for a lead federal agency to promote the cause of rural healthcare in the federal government. Legislation creating the federal Office of Rural Health Policy (ORHP) was passed in 1987 and was organized in the following year. The authorizing legislation for the ORPH called for a research agenda, which led to the funding of a group of rural research centers in 1988.

One of the first issues the rural research centers investigated was the viability of small, rural hospitals. In the 1980s there was concern that these institutions would not be able to weather the effects of a rural economic downturn. The Inspector General’s Office in the U.S. Department of Health and Human Services noted that there was an alarming trend toward closure of small rural hospitals, which could be attributed to aggressive competition from urban hospitals and the demands of rapidly developing technologies that required significant economies of scale. The problems of rural hospitals were identified in various research studies as lack of technology and gaps in management and leadership as well as a fundamentally skewed payment system in Medicare. A demonstration of a new form of provider, the Medical Assistance Facility (MAF), was fielded in Montana in 1987. The MAFs were scaled-down hospitals that restricted their size and range of services but maintained emergency and limited inpatient facilities in remote, frontier communities. The Health Care Financing Administration (now the Centers for Medicare and Medicaid Services [CMS]) granted a waiver allowing Medicare payments to these institutions. That was followed by a seven-state demonstration of the Essential Access/Rural Primary Care Hospital provider type authorized under the federal Omnibus Budget and Reconciliation Act of 1989, which was replaced in the Balanced Budget Act of 1997 by the Medicare Rural Hospital Flexibility Program, which created critical-access hospitals (CAH). These demonstrations were accompanied by evaluation and research that showed the viability of the concept of a limited-service rural hospital. By 2007, there were over 1,250 CAHs dispersed through all but two states in the nation.

Rural healthcare systems have used several options to guide their structure, with networks and consortia being the primary organizational tool. Early rural hospital cooperatives and consortia were created in the upper Midwest, which allowed many smaller hospitals to share resources and promoted their survival. Networks are promoted by federal legislation, including the Medicare Rural Hospital Flexibility Program, which requires the CAHs to link with a larger, more complex hospital as well as emergency services and policy development partners. The trend toward networking and collaboration was given a boost by the Institute of Medicine (IOM) in a 2005 report that found that cooperation among providers allowed for better access and quality of care.

Health Services and Vulnerability

Data from the National Health Interview Survey (NHIS) and the Medical Expenditure Panel Survey (MEPS) indicate that self-reported health status is generally worse among rural residents than among urban residents and that this situation has persisted over the past two decades. After adjusting for differences in age, NHIS respondents living in nonmetropolitan counties were more likely than metropolitan residents to rate their health as only fair or poor. Similar patterns in self-reported health status were also found among MEPS respondents. Likewise, most chronic diseases have been, and continue to be, more prevalent in rural areas. Data from the NHIS also confirm these patterns for chronic conditions such as various types of joint pain, low back and neck pain, and vision and hearing problems. In addition, data from the U.S. Centers for Disease Control and Prevention (CDC) show higher rates of obesity, cigarette smoking, and total tooth loss in nonmetropolitan counties.

During the past decade, rural areas have seen a steep decline in manufacturing jobs (which tended to offer higher rates of employer-sponsored health insurance coverage than other jobs), accompanied by a rise in service-sector employment, where access to health insurance has been much lower. This has resulted in a greater percentage of rural residents being uninsured than urban residents. In 2001–2002 nearly 4 million rural families (30%) had at least one uninsured member. And many

rural residents with private health insurance may face large out-of-pocket costs for care as a result of being underinsured.

Some of the earliest research on rural healthcare focused on the geographic distribution of physicians. That has continued in studies of the distribution of primary-care practitioners as part of policies intended to identify the places with the fewest health professional resources, either as health professional shortage areas (HPSAs) or as medically underserved areas (MUAs). These designations are used by the federal government to qualify localities for a multiplicity of programs that allow them to seek grants for clinics, placement of practitioners, and special payment regimes under Medicare and Medicaid. Underserved areas are defined and designated by the Shortage Designation Branch of the Health Resources and Services Administration's (HRSA) Bureau of Health Professions. Both geographic areas and population groups can be classified as either shortage or underserved areas. The percentage of both metropolitan and nonmetropolitan counties with either a single-county or a part-county primary-care HPSA designation increased from 1987 to 2004. Over 75% of nonmetropolitan counties were designated as HPSAs by 2004.

Other Health Professions and Services

The geographic distribution of health professionals in rural areas has long been identified as a problem; more than half of all the nation's counties have no licensed psychiatrist or psychologist, and virtually all these counties are rural. As of 2004, 79% of nonmetropolitan counties and 55% of metropolitan counties were identified as being either single- or part-county mental health HPSAs. Counties with mental health HPSA designations have a shortage of psychiatrists and/or other core mental health professionals such as clinical psychologists and clinical social workers.

Rural communities have proportionately fewer dentists than urban places. In 2004, there were 3.8 general practice dentists per 10,000 urban residents but only 2.3 per 10,000 rural residents. The geographic distribution of registered nurses in nonmetropolitan counties is proportional to the general population distribution, but in the least populous and most isolated rural counties, the

numbers are below the general population share. Public health agencies in rural places also tend to have smaller staffs, lower budgets, and less technical capacity than in urban areas.

Persistent Problems

The nature of rural places makes them less attractive to many professionals and less able to invest in high-technology, high-cost healthcare services. This economic reality presents a challenge to public policies that attempt to equalize access to services in government programs such as Medicare and Medicaid and for the regulation of private health insurance. A constant challenge to researchers and policymakers is to identify optimal minimums of healthcare services that should be provided to small and isolated populations. The same problems of scale affect the diffusion of clinical as well as organizational innovations. Rural communities often have less access to newer medical technologies and specialized treatments. Health reform programs that depend on market forces, such as managed-care programs or group practices, often do not work well in rural places.

Rural communities and rural health policies remain an important part of national healthcare policy due to the structure of the U.S. Congress, which gives proportionately greater power in the U.S. Senate to the residents of the more sparsely populated states of the West and Midwest. This political reality has provided a balancing force to even out the market forces that often leave rural communities at a disadvantage.

S

SACKETT, DAVID L.

David L. Sackett is widely regarded as one of the originators of evidence-based medicine (EBM), which is the integration of the best research evidence and clinical expertise in the care of individual patients. Evidence-based medicine has revolutionized the thinking of many clinical practitioners.

Over the years, Sackett has developed and mentored a cadre of applied clinician-scientists who have disseminated the practice of evidence-based medicine throughout the world. These research teams have been at the forefront of medicine. They were the first to validate the efficacy of aspirin and carotid endarterectomy for patients with threatened stroke. They developed strategies for hypertensive patients to comply with their drug regimes. And they found compelling evidence for the effectiveness of nurse practitioners.

Sackett was the founding chair of the Department of Clinical Epidemiology and Biostatistics at McMaster University in Hamilton, Ontario. He rose through the academic ranks at the university and became professor and chair of the Division of Internal Medicine. After nearly 27 years at McMaster University, Sackett moved to Oxford University in 1994 to become founding director of the Centre for Evidence-Based Medicine and professor of Epidemiology in the Nuffield Department of Clinical Medicine. He also was founding chair of the Cochrane Collaboration Steering Group, which is an organization dedicated to the dissemination of

systematic reviews of the effects of healthcare interventions.

Sackett has authored many books in the field of epidemiology, including *Clinical Epidemiology: A Basic Science for Clinical Medicine* and *Evidence-Based Medicine: How to Practice and Teach EBM*. He has also authored or coauthored over 300 journal articles. Sackett has been involved in hundreds of randomized controlled trials (RCTs) as a principal investigator, consultant, or member or chair of a data safety monitoring board.

Sackett has received numerous honors and awards, including the Trillium Clinical Scientist Award, the Zinkoff Honor Award, the J. Allyn Taylor International Prize in Medicine, and the Health Services Research Prize from the Baxter International Foundation, and he was elected to the Canada Medical Hall of Fame. He is a fellow of the Royal College of Physicians of London and Edinburgh. He is also an elected member of many learned societies, including the Royal Society of Canada, the American and Canadian Societies for Clinical Investigation, the Association of American Physicians, the Canadian Society for Internal Medicine, and the Pan American Health Association.

Born in Chicago, Sackett earned a bachelor's degree from Lawrence College in 1956. He earned a second bachelor's degree from the University of Illinois in 1958. He then went on to earn his medical degree from the University of Illinois College of Medicine, followed by a medical residency at the University of Illinois Research and Educational Hospital. Sackett then completed a postdoctoral

fellowship in nephrology and earned a master of science degree in epidemiology from the Harvard School of Public Health. He also was awarded a doctor of science degree from the University of Bern.

Currently, Sackett resides in Canada, where he continues to write and teach. He is the founder and director of the Kilgore S. Trout Research and Education Centre in Hamilton, Ontario, an organization dedicated to training young researchers.

populations. Some responses reflect governmental mandates, while others represent institutional missions or charitable initiatives to offer free or reduced-fee care. In its 2000 report, *America's Health Care Safety Net: Intact But Endangered*, the national Institute of Medicine (IOM), arrived at a two-tiered definition of safety net providers. Most broadly, it defines the safety net as including those organizations that provide healthcare services to the uninsured, Medicaid recipients, and other vulnerable populations. In addition, it singled out a subset of core safety net providers with two distinguishing characteristics: (1) by legal mandate or explicitly adopted mission, they maintain an "open door," offering access to services to patients regardless of their ability to pay, and (2) a substantial share of their patient mix is composed of uninsured, Medicaid recipients, and other vulnerable patients. Taken together, these providers and the resources that support them constitute a distinct system of care for the nation's most vulnerable individuals.

This entry provides an overview of how the safety net emerged as the nation's healthcare system evolved. Subsequent sections describe components, sources of financing, threats to stability, and resources for monitoring the safety net. Health services researchers and policymakers have become increasingly interested in and concerned about the nation's safety net as healthcare costs rise and the number of uninsured persons continues to grow.

History

At the beginning of the 20th century, medical care was neither particularly costly nor effective for most conditions. Middle- and upper-middle-income families typically received medical care in their home. The major economic concern associated with illness was lost wages. Hospitals were most often charitable institutions supported by local government appropriations predominantly serving as respites for the poor. Private donations and fees supported a smaller number of religious or ethnically affiliated institutions. However, as services became more sophisticated and costs rose—with the advent of modern anesthetic techniques, antiseptics, and antimicrobial agents—medical care became a valuable and costly commodity. Health insurance began to emerge during

SAFETY NET

The nation's healthcare safety net is a patchwork of responses to the health needs of underserved

the Great Depression as prepaid hospital plans. During World War II, at a time when the U.S. Congress had instituted wage and price controls, employers competed for scarce labor by offering health insurance benefit packages. In addition, the federal government waived payroll taxes for employer contributions to employee health insurance plans. These incentives established the linkage between employment status and access to private health insurance that characterizes the United States today.

Government support of private approaches to insuring healthcare coverage evolved in the context of several failed attempts to institute a universal health coverage program dating back to the early years of the 20th century, again during the Great Depression, and following the election of President Harry S. Truman in 1948. The continued rise in healthcare costs accompanied by incremental rather than universal expansion of health insurance created serious gaps as more Americans found themselves in need of services they could not afford. In 1946, the U.S. Congress passed a law called the Hill-Burton Act, which gave health facilities grants and loans for construction and modernization. In return, the facilities agreed to provide a reasonable volume of services to persons unable to pay for care. The 1960s saw the emergence of Medicare to improve access for the elderly and disabled and Medicaid to improve access to those most impoverished and ill.

Despite governmental incentives and subsidized programs, there existed no guarantee of basic care to those without coverage for an emergency condition. It was not until 1986 that the U.S. Congress passed the Emergency Medical Treatment and Active Labor Act (EMTALA) to prevent hospitals that have entered into provider agreements under the Medicare program from denying medical services to patients with emergency medical needs because of their inability to pay. The essential provisions of the statute are that every patient must receive a medical screening examination and obtain appropriate stabilizing treatment or be transferred to another facility, if clinically indicated, for an emergency condition. The law applies to any hospital-based provider, including off-site clinics and primary-care centers that operate under the name, ownership, and financial and administrative control of the institutions that contract with Medicare.

An important difference between EMTALA and other incremental reforms to improve access, however, is that EMTALA is an unfunded mandate. In other words, the law provides no financial support for the required services. As a result, it places an enormous burden on patients who are shouldered with bills they cannot pay and on the hospitals that serve them and accrue the resulting bad debt.

In sum, over the past century incremental reforms to broaden access to healthcare have followed failed attempts to establish any system of universal healthcare coverage, resulting in federal and state programs, incentives, and statutes that benefit some individuals but not others. The emergence of a safety net system of providers has been an outgrowth of this process.

Components

As noted above, the IOM has distinguished between core providers and other providers in the healthcare safety net system. Core providers include two groups. First, there are “essential community providers,” defined by the U.S. Congress in 1993 as those located in federally designated Medically Underserved Areas (MUAs); these include Community Health Centers/Federally Qualified Health Centers (FQHCs), FQHC Look-Alikes (FQHC-LA), and many public hospitals and local public health departments. These facilities are typically eligible for various federal and state grants or subsidies. Second, there are mission-driven organizations that may not meet the criteria for essential community provider but nevertheless serve a disproportionately poor and uninsured population. Although the care of the uninsured is concentrated among core providers, the absolute volume of uncompensated care is larger across the many, primarily not-for-profit community hospitals and academic medical centers, private practitioners, and school-based health centers that make up what has been called the hidden safety net. Finally, although considered distinct from the safety net system because they serve two narrowly circumscribed populations, the Veterans Health Administration (VHA) and the Indian Health Service (IHS) provide care to two large groups that include many otherwise uninsured Americans.

Geographic regions of the nation vary greatly in their dependence on core versus noncore healthcare safety net providers. New York, Los Angeles, Chicago, and Atlanta all have major public hospitals or healthcare systems that cater primarily to the indigent and underserved. At the other end of the continuum are regions that rely on mainstream private institutions. Instead of directing low-income patients to a public hospital system, indigent patients are dispersed across a subset of private hospitals and clinics with a mission that includes them. Philadelphia, for instance, has not had a public hospital since 1978, and inpatient services for the uninsured are distributed across the 25% of mostly private hospitals in Pennsylvania that provide more than half of all services to the state's Medical Assistance Program. Proponents of the former emphasize the specialized services (e.g., assisting patients with language and cultural barriers) and focus of core providers. Proponents of the latter emphasize that mainstreaming safety net care avoids a potentially two-tiered healthcare system.

In differentiating core from noncore safety net providers, it is also useful to distinguish between the two types of uncompensated care: charity care and bad debt. Whereas the former refers to free or discounted health-related services to individuals deemed unable to pay, the latter relates to charges that hospitals or other providers have not collected from patients who are expected to pay. While both core and other safety net providers deliver unusually high amounts of uncompensated care, core providers typically stand out for their willingness not to bill many of their patients and to employ generous sliding-fee scales, thereby providing much charity care. Unfortunately, there has been a lack of available data about the proportion of uncompensated care that is due to bad debt versus charity care at many institutions—mainly due to inconsistent hospital bookkeeping and reporting practices, but core safety net providers are clearly the major source of the latter. Whereas the distinction has not, historically, been so significant to providers since both represent unreimbursed costs, for patients the inability to pay medical bills or even the fear of accruing such debt can significantly affect access to needed care. Health services-related bad debt is now the leading cause of personal bankruptcy in America.

In recent years, there has been a public outcry over the aggressive collection practices of many hospitals attempting to reduce bad debt while at the same time reporting high levels of uncompensated care. In the case of not-for-profit hospitals, the issue is that these entities receive considerable tax benefits with the expectation that they will “give back to their communities” an amount that is at least commensurate with those benefits. The concern is that hospitals that claim high uncompensated care costs but are primarily accruing those losses because of bad debt are not really serving a safety net function. An alternative argument, however, is that the willingness of some of these hospitals to provide certain services—such as trauma care—at a predictable loss in poor communities, to care for many publicly insured or uninsured patients despite their inability to pay at cost, and to write off losses from the latter without using overly aggressive collection practices constitutes an essential safety net function even if there is little documented charity care.

Financing

To care for some patients at a loss while still remaining in business, healthcare providers must be able to offset those losses from the revenues generated by other payers—a process known as cost shifting, from private donations, or from government funds or government-mandated charity-care pools. Alternatively, they must cut their expenses. Historically, prior to World War II, most charity care was financed by private donations. Then, with rising healthcare costs and the growth of indemnity health insurance, cost shifting became an important presumed mechanism to finance the care of the poor. More recently, however, economists have questioned the role of cost shifting. Empirical analysis of hospital charges to private insurers provides little evidence that markups have correlated with or offset rising uncompensated care costs, even during the pre-managed-care era, when hospitals were thought to have the capacity to raise prices. Instead, in the absence of other sources of revenue, such as federal subsidies, providers with a high indigent care burden cut costs by reducing personnel, limiting charity care, eliminating service lines that are loss leaders, and putting off pay increases for staff.

Because of the limited capacity of providers to shift costs, they depend on a variety of funding sources at the federal, state, and county levels. One important source has been Medicaid disproportionate-share (DSH) hospital payments. Established in 1981 by the U.S. Congress, the Medicaid DSH program requires state matching funds. Initially this dampened its appeal, until states adopted a number of ways to count various state expenses from other agencies to justify federal dollars in the 1990s, through a process known as Inter-Governmental Transfers (IGT). Unfortunately, some states misdirected the funds obtained toward ineligible healthcare or even non-healthcare-related expenses. Another problem was that since DSH payments were linked to Medicaid volume rather than to the volume of uninsured, an increasingly poor correlation between these two payer groups (as more and more upscale providers competed for Medicaid dollars but not for the uninsured) diluted the program's benefit to the safety net. As a result, the U.S. Congress passed laws limiting DSH payments to states (state DSH allotments) and to hospitals (hospital-specific DSH caps), the latter linked to the hospital's overall uncompensated-care costs. States and their hospitals must also currently comply with new auditing requirements that demonstrate that DSH payments are in fact offsetting the costs of care of indigent patients receiving medical services.

Although Medicaid DSH payments were originally established to fund hospitals, a number of states have found innovative and legitimate strategies to direct the funds toward primary- and preventive-care services, often with hospitals' support. In Maine, unused state DSH funds contributed to a Medicaid expansion for uninsured adults without dependent children called Access Health. In Georgia, DSH hospitals contribute funds to extend primary-care services through a program called the Georgia Indigent Care Trust Fund, which includes case management for the uninsured chronically ill and for pharmaceutical support. In Massachusetts, an uncompensated-care pool that supports both inpatient and community-based care is financed with DSH funds in addition to assessments on hospitals and health plans. In sum, Medicaid DSH funds are being successfully stretched across the safety net in many locales to cover a broader range of services than was originally intended.

Medicare DSH payments have also been an important source of additional revenue for safety net providers. Also dating to the 1980s, this adjustment was originally intended to compensate those hospitals serving a disproportionate number of low-income Medicare patients, who tend to be sicker and therefore more costly to serve than others with the same diagnosis. Specifically, the DSH payment is an add-on to the Diagnosis Related Group (DRG) payment, established 2 years after Medicare's prospective payment system (PPS) began in 1983. Although Medicare's PPS was established with no new money—by lowering the basic DRG rate and decreasing indirect medical education (IME) payments to teaching hospitals (which benefit from the DSH payments)—the program grew in the 1990s as the U.S. Congress added money for various categories of hospitals, particularly safety net providers. More than 95% of Medicare DSH payments goes to urban hospitals. Hence, while the original intention of the Medicare DSH payment was to offset the higher costs of caring for poor Medicare patients, it has come to serve the broader purpose of financially assisting hospitals serving low-income populations in order to preserve access to care.

DSH payments represent just one mechanism of many for funding safety net providers that rely on a patchwork of support from federal, state, county, and other sources. These include, at the federal level, funding from the Ryan White Care Act, which supports the unmet healthcare needs of individuals living with HIV; the Public Health Service Act, which provides Section 330 grants to eligible community and migrant health centers, homeless programs, and public housing primary-care programs; the Rural Health Clinics program, which allows enhanced Medicare and Medicaid reimbursement to encourage nurse practitioners, physicians, and physician assistants to work together in provider shortage areas; and the Critical Access Hospitals program, which provides cost-based reimbursement in an effort to reduce hospital closures in medically underserved areas.

Although states support the safety net primarily with federal matching programs, the presence of state-only programs can broaden access by extending coverage to residents who would otherwise fall through the cracks. For instance, MediKan in Kansas covers individuals trying to get Social Security

disability benefits but who are not yet approved; Wisconsin's General Assistance Medical Program (GAMP) covers indigent Milwaukee County residents who are not eligible for Medicaid or the State's Children's Health Insurance Program (SCHIP); and Minnesota Care and Basic Health (in Washington state) both provide subsidized insurance to Medicaid-ineligible residents not covered by other programs. Such state-only programs are relatively few and far between because of the challenge of enacting adequate financing mechanisms, usually through new taxes or cuts in other services.

In some states, counties contribute substantial funds and services to safety net care, while in others they do not. In Texas, for instance, counties are legally responsible for funding indigent care. Uninsured individuals receive services through county hospitals or local public health departments. In regions of the state without public hospitals or health systems, counties are required to administer an indigent healthcare program for eligible residents by funding services in the private sector. Counties receive state subsidies or matching funds depending on the cost and volume of the indigent care services they provide. As in Texas, the 58 counties in California play a crucial and state-mandated role in financing and delivering safety net services. Within these states, counties have substantial discretion in how they interpret requirements, so services vary widely. In contrast, in Alabama and Mississippi, few county programs exist for indigent care beyond those funded by Medicaid.

Finally, in addition to the federal, state, and county support, the safety net receives some support and resources from foundation grants, managed-care companies, and manufacturer's indigent drug programs. For instance, the Virginia Health Care Foundation was initiated in 1992 as a public-private partnership to raise private funds to supplement public indigent care services.

Challenges

The challenges affecting the nation's healthcare safety net include the rising numbers of uninsured individuals needing care and the changing structure and environment of the healthcare marketplace. The impact of these challenges and the resilience of the safety net vary regionally, based on local support and structural factors that affect

the safety net providers. Structural factors include the degree to which safety net services are concentrated among providers, such as a few public hospitals versus a wider network; the extent to which the burden is shared by both public and private entities; and the overall price competitiveness of the marketplace.

Equally important is the purposefulness with which healthcare administrators and policymakers have responded to local challenges to develop or maintain robust safety net systems. In some cases, adaptation has led to mergers, as in the joining of publicly owned Boston City Hospital and the private Boston University Hospital to establish Boston Medical Center. There have also been conversions of public hospitals to not-for-profit private status to facilitate joint ventures or improve efficiencies, as in the creation of the non-profit Cambridge Hospital, previously an agent of city government. And there have been restructured relationships within the public system resulting in administratively independent entities such as Denver Health, which consists of an extensive horizontally integrated system that includes a medical center with Level 1 trauma services, nine family health centers in underserved communities, 11 school-based clinics, and a wide range of detoxification, correctional-care facilities and behavioral health services that have provided over \$100 million in charity-care services annually. In addition, Denver Health established the vertical integration of insurance, hospitals, and clinicians to create a large and financially viable Medicaid HMO called Colorado Access.

Other geographic regions of the nation have been less successful in building viable safety net systems or are greatly struggling to meet the growing needs of a large indigent population. Such locales typically lack strong core providers or mainstream health systems that are able and willing to provide substantial inpatient and outpatient safety net capacity. Little Rock, for instance, has struggled with inadequate safety net infrastructure and growing poverty, individuals without health insurance, and an influx of undocumented immigrants. A generous public insurance program for children has helped, as well as the engagement of faith-based charities and the participation of the city's academic medical center, where waits for specialist appointments for uninsured patients

average 6 to 9 months. Even the most evolved safety net systems, however, remain vulnerable to the vicissitudes of public revenue streams, particularly Medicaid funding. For example, although it has been successful for over a decade, Colorado Access was forced to drop its physical health Medicaid contract in 2006 because of a 15% drop in the state's reimbursement rate. It has adapted by focusing on providing access for low-income children and for those needing behavioral health services and on Medicare Part D products; but 65,000 individuals lost their Medicaid coverage. In sum, success depends on adopting good business models that improve productivity, collections, economies of scale, and technical expertise and diversifying revenue streams—but with a mission to providing care for the poor.

Monitoring

Given the precarious nature of the healthcare safety net, with its wide variation across geographic regions of the nation, the IOM recommended a monitoring system for tracking its stability and performance in meeting the needs of vulnerable populations. Beginning in 2000, the federal Agency for Healthcare Research and Quality (AHRQ) and the Health Resources and Services Administration (HRSA) embarked on a joint safety net monitoring initiative with three strategies: to provide baseline information on hundreds of local safety nets throughout the nation, to establish and disseminate a standardized methodology for regional analysts to monitor the ongoing status of their safety nets, and to provide specific tools for assessing local capacity and performance. Initially, two data books were produced that described the status of safety nets in over 1,800 U.S. counties, with information on demand for safety net services (based on measures of poverty, individuals without health insurance, and illness), financial support for indigent care (including funding for Medicaid, DSH payments, and community health centers), descriptions of safety net structure, and measures of outcome of safety net performance (such as preventable hospitalizations and barriers to accessing care). A subsequent publication detailed how to estimate local demand for uncompensated care, assess safety net provider financial status, and measure performance

and outcomes, among other strategies to aid regional analysts. Finally, the project generated Web-based tools, including a worksheet for evaluating an entity's financial risk relative to a distribution of other safety net providers.

Future Implications

America's healthcare safety net is a complex patchwork of institutions, providers, and funding streams that offer medical services to individuals who lack the financial resources to pay for the care they need. Although various federal initiatives fund safety net programs, there are wide regional differences that reflect local variations in funding, political priorities, and demand for uncompensated care. Recently, a growing number of states have been leading innovators in identifying ways to reduce the burden on the safety net by expanding health insurance coverage. For the foreseeable future, however, the safety net will remain a vast but limited resource for many in America who must try to access it when they need healthcare.

SATISFACTION SURVEYS

Obtaining information on how patients rate a health-care facility and its providers and how satisfied they are with the care they receive has become a major focus of healthcare organizations. Although healthcare providers have been collecting such information for decades, in the past, it was viewed as a routine function with little practical utility. Patients were plentiful, and a consumerist approach was not in vogue. Patient satisfaction was not seriously considered as a method to improve quality and reduce costs.

Today, healthcare organizations are increasingly aware of the importance of keeping their patients satisfied as a way of preventing their shifting to other providers for their healthcare needs. As revenues become scarcer and competition more acute, many healthcare organizations are using patient satisfaction data to improve their services, increase revenue, and attain a superior market position.

Many healthcare providers view the delivery of care differently from their patients. They often view care as "fragmented," or being provided in "silos." Patients, on the other hand, tend to evaluate their total care experience as an integrated whole. Thus, the way patients view and evaluate their experiences may be completely different from the isolated view of providers and healthcare

organizations. The implication, of course, is that low satisfaction levels for one or two aspects of care may result in significantly lower subjective assessments of the quality of the entire organization. And one or two positive experiences, on the other hand, may not be generalized to the whole experience.

Background

In the past, many healthcare organizations viewed patients as an unlimited resource. If patients became dissatisfied with their health care, and chose to switch their source of care, most healthcare facilities firmly held the attitude that there were "plenty more where they came from." Patient satisfaction therefore was of neither practical nor theoretical interest. However, in the 1970s, patient satisfaction became a phenomenon of theoretical interest to health services researchers. Patient satisfaction was used as a subjective measure of realized access to care. As such, satisfaction with care became a dependent variable of research interest as well as a predictor of other healthcare outcomes, including compliance with medical advice and return visits for care.

Today, there is an unprecedented revolution in healthcare. The informed consumer, who through an information explosion propelled by scientific and technological advances, mass media coverage, and the Internet better understands treatment options, is not afraid to challenge healthcare providers if the care does not meet his or her standards. Since patients can no longer be viewed as an unlimited resource, consumers have taken control and, in some cases, have more information regarding their specific diagnosis than some of their healthcare providers. Information flow helps set the standards for individual health behavior and for patient involvement in the diagnostic, treatment, and curative processes. Properly analyzed, patient satisfaction data can point to areas of patient concern, which when corrected will improve quality, reduce costs, and bring the patient back into the process of care.

Importance of Patient Perceptions

There are many reasons why all healthcare organizations should be concerned about patient perceptions of quality and their level of satisfaction. First,

satisfied patients are more compliant, which results in better medical outcomes. That is, they will follow treatment protocols, such as completing drug regimens. Second, satisfied patients are more likely to return for follow-up visits. Third, patient satisfaction data provide managers with useful information regarding the outcomes of care themselves. Since satisfaction can be viewed as a proxy measure for the outcome of care, patient perceptions can point out process areas needing improvement. Fourth, patient satisfaction is a subjective measure of access to care. Fifth, patients who are satisfied tend not to file lawsuits. Sixth, satisfied patients, even if the medical outcome is not positive, tend to view the healthcare they were provided as a quality experience if they were satisfied with the level of care provided. Finally, patients, like all consumers, want and deserve to be satisfied with the products and services they purchase.

The Joint Commission recognizes patient satisfaction as part of its ORYX performance measurement system requirements. In addition, the National Committee for Quality Assurance's (NCQA) Healthcare Effectiveness Data and Information Set (HEDIS), ISO 9000, many state agencies, and the Malcolm Baldrige National Quality Award competition all consider patient satisfaction to be of very high importance. All contain regulations and guidelines for the measurement and reporting of specific satisfaction indicators. Many hospitals, health systems, and business cooperatives are publishing report cards with the same patient satisfaction indicators.

Data Collection Methods

The main way to collect data on patients' perceptions of the care they receive is to ask them. Doing so requires the use of a questionnaire and a survey process. Healthcare organizations use different survey techniques to collect their data. They must decide whether to interview their patients retrospectively at some time after they received care or to use a more prospective, point-of-service approach to capture patient perceptions as close to the time when they received care as possible. They also must decide the specific data collection strategy they will use. In general, there are three choices: a self-administered questionnaire, a personal interview, or a telephone survey. Each approach has its

own set of advantages and disadvantages that affect cost, response rates, and ease of follow up. Personal interviews of past patients tend not be used because they are very costly to conduct.

Using mail surveys can be the most cost-effective and reliable method to collect patient satisfaction information. Response rates should generally be in the 50% range. Major costs in conducting a mail survey include the printing of the survey and cover letter; postage, including survey return postage; follow-up reminder letters or postcards after the first mailing; and a second mailing letter and survey for a portion of the original sample. Staff time is needed for the process as well. Time must be allocated for assembling the cover letter and survey, addressing the envelope package, mailing the package, compiling return surveys, and preparing the responses for analysis. Information-system time is also required to generate a random sample of patients to be surveyed and to produce their addresses and mailing labels. In terms of time, as many as 40 hours per survey may be required to successfully complete the process. If a healthcare organization uses a third party vendor to conduct the survey, it should compile and distribute regular reports within the organization. If the survey is being conducted in-house, resources necessary to generate reports should also be considered.

Advantages of conducting mail patient satisfaction surveys include the following: the healthcare organization maintains control of the process; costs are limited to printing, postage, and staff time to administer the surveys; the result of the surveys are likely to be reliable; ongoing investment in the process of conducting the surveys can be constant and predictable for budgeting purposes; the surveys can be customized without much effort; the results from the surveys can produce data for benchmark comparisons; the surveys may provide actionable results within acceptable statistical variance; and they may be less expensive to conduct than using an outside company.

Disadvantages of conducting mail satisfaction surveys include the following: intensive internal staff effort is required to prepare the surveys for distribution; there is loss of control over individual questionnaires once they are mailed; the functional illiteracy rate in the United States is high, and patients may not understand the language used in the survey; it may be difficult to locate patients

such as those who are homeless; foreign-language-speaking patients may not be able to respond; return rates may vary greatly given the population being sampled; the lag time of results reporting can be from 30 to 60 days post survey mailing; if the survey is changed, it must be reprinted, thus increasing the costs; increases in postal rates can negatively affect the survey's budget; and staff departments involved in the survey process may stop or delay the timing of the survey.

The main difference between a mail survey and a telephone survey approach is the use of an interviewer. Using a telephone as the delivery mechanism, rather than the mail, means that an interviewer is necessary to ask the questions once a respondent is contacted. Interviewers are useful because they can circumvent the illiteracy problem, they can establish a sense of personal relationship, and they can assist the respondent if the questions are unclear.

Advantages of telephone patient satisfaction surveys include the following: there is immediate response and feedback, as it is a relatively fast process; callbacks are easy and inexpensive; it generally produces a greater response rate; no staff time is involved in data collection; standard questions are available; sample size and response by demographic group are more controllable; they produce reliable statistical results; they can produce large comparative benchmark databases; and they produce actionable reports and results.

Disadvantages of telephone patient satisfaction surveys include the following: they are more costly than mail surveys; customized questions may be available but at a premium price; patients receiving the telephone calls may view them as intrusive; individuals conducting the calls may be inconsistent in their presentations; some patients may not have a telephone; patients with multiple telephone numbers may be called several times; there may be multiple callbacks to obtain a response; the results of the survey may be difficult to compare with other survey methods if change is implemented; and comparative databases are generally unavailable for customized questions.

Point-of-service strategies include exit or discharge surveys, bedside surveys, or surveys of patients at any time during their visit or hospital stay. These data collection approaches are relatively simple for organizations to implement

in-house, but if done on a large scale, they can become complicated.

The advantages of point-of-service patient satisfaction surveys include the following: there is immediate feedback; the patient can enter information via a kiosk or a computer terminal; any problems or concerns presented can be immediately addressed; they are cost-effective in that the patient does the work with little direct staff involvement; reports can be computer generated from the database; it is easy to change or add questions; the surveys can be used as an ongoing method to acquire information; computer software to conduct the surveys is easily updated; and data from the surveys can be continuously collected.

Disadvantages of point-of-service patient satisfaction surveys include the following: responses to the survey's questions may be biased due to the patient's medical condition; patients may perceive a lack of confidentiality and/or anonymity; the data collection method usually involves nonprobability samples, making any generalizations difficult; the initial costs of point-of-service systems are generally high; no comparative database may be available; there is no method to control respondents, which may result in oversampling of population groups; patients may respond more than once during their stay; the results may not be statistically reliable; patients may be fearful of computers; and there is the potential problem of safeguarding electronic information.

The method by which an organization chooses to measure patient satisfaction will be based on issues such as cost, philosophy toward satisfaction, and how the results will be used. Perhaps the most frequently used strategy is a self-administered questionnaire approach. Usually, healthcare organizations rely on a mail survey approach because of its low cost and low pressure on patients to respond. Another approach, growing in popularity, is to use kiosks located around the healthcare facility. This allows patients to stop at their convenience to assess the level and quality of care received. The problem with this approach is that the resulting sample of patients is not random and may not include all patients in the population base. Should the sample not be indicative of the total population of patients, the results may be biased and not nearly as useful to administrators.

No matter what data-gathering approach is used, the heart of the process is the questionnaire itself. Those using patient satisfaction surveys should be concerned about their validity and reliability. Making meaningful quality and cost improvements requires high-quality, valid, and reliable data. *Validity* refers to whether a survey's question actually measures what it is intended to measure. *Reliability* refers to whether a survey's question measures the same thing each time it is used. Validity ensures reliability, but a reliable question is not necessarily valid. That is, a survey's question may be measuring the same thing each time it is used, but it is not measuring what it is intended to measure. Obviously, when it comes to using patient satisfaction data for improving the quality of care an organization provides, both issues are key. In addition, issues such as sample size, response rate, generalizability, and statistical significance must also be recognized to generate usable results.

To make quality decisions regarding improvement strategies, it is important that the data used to make such decisions is of high quality. The old data processing adage of "garbage in-garbage out" (GIGO) is relevant and applicable to using patient satisfaction data for quality and performance improvement.

Many healthcare organizations currently outsource patient satisfaction data collection to proprietary companies. The reasons for outsourcing the data collection are usually related to cost, convenience, and organizational competence. That is, some healthcare organizations feel that it is less expensive to outsource the work than to maintain a qualified staff of survey and statistical experts. Others organizations may feel that receiving satisfaction data from a proprietary company on a regular basis is convenient and reduces the non-clinical functions within the organization. Still others may feel that they do not have the necessary level of competence within the organization to carry out the tasks associated with collecting their own patient satisfaction data.

Even if a healthcare organization outsources its patient satisfaction data collection process, it would be unwise to haphazardly select a company without considering several key factors. The fact that a company is in the business of collecting data for hospitals and other healthcare organizations does not automatically ensure that it provides a

quality product. Before selecting any data collection company, issues surrounding two key questions must be satisfactorily addressed. First, is the data collection instrument valid and reliable? Second, what specific questions are asked?

Measuring Patient Satisfaction

There are two general approaches to measuring patient assessment of care. The first is to ask questions directly related to satisfaction levels. For example, "How satisfied were you with the overall quality of care at your last visit?" The respondent selects a response from a list of possible answers, such as very satisfied, somewhat satisfied, somewhat dissatisfied, and very dissatisfied.

An alternative approach is to use a patient rating system. An example of this strategy is to ask, "How would you rate the overall quality of the care you received at your last visit?"—with the possible responses of "excellent," "good," "fair," and "poor." Although it could be argued that these two strategies tap into different perceptions, they tend to be viewed within the healthcare industry as interchangeable.

A strategy that is used to accumulate data on the patient's experience with care is to divide the visit into its component parts. For example, questions pertaining to waiting time, appointment time, staff and physician communications, and so on are presented as separate items. This allows an analysis of the various parts that make up the whole visit or hospital stay. Usually, the last question asks about the overall satisfaction with the visit or stay. This approach permits the relative importance of each item to be measured against the patient's overall perception of the care, and it will identify where problem areas exist. The approach allows healthcare managers to focus intervention strategies for quality improvement where they are most needed. It also can be used to highlight areas where the providers do an especially good job, which allows the opportunity to establish best-practices protocols that can be used across the organization.

Future Implications

Querying patients about all dimensions of the care they receive across the health system provides the

opportunity to identify areas where the process of care fails to provide an encompassing, satisfying experience. Satisfaction is a valuable weapon that provides an organization an edge in a highly competitive marketplace. If a hospital or other health-care organization is not using available tools to understand and interpret patient satisfaction data, it is missing a valuable opportunity for improvement. Patient satisfaction data reflect the voice of the customer. That voice provides a very personal view of the process of care within the organization.

It is important that the patient's input be taken seriously when attempting any improvement strategies. Early on, patient satisfaction surveys were conducted primarily to show the patient that the health-care organization "cared," with little practical use for the results. With the move by health-care-accrediting organizations, insurance companies, and government agencies to obtain and use more patient outcome measures, health-care organizations are now being required to demonstrate how patient satisfaction survey results are used to improve care.

SCOTT, W. RICHARD

W. Richard (Dick) Scott has made significant contributions to the field of organizational theory and the application of this theory to health-care organizations. He has conducted extensive research on professional organizations, with particular emphasis on social welfare, educational, and medical organizations. Scott is Professor Emeritus of Sociology, with appointments in the Graduate School of Business, the School of Education, and the School of Medicine at Stanford University.

Scott has spent his entire academic career at Stanford University, where he was the founding director of the Stanford Center for Organizations Research. Scott's early research focused on the sociological study of authority and control relations in organizations. Along with his colleagues John W. Meyer and James G. March at Stanford, Scott soon became a key theorist of organizational analysis within the school of neoinstitutionalism. This school examines how organizations operate in institutional and societal environments that govern behavior beyond market forces.

Scott is well-known for his historical study examining changes in the health-care delivery system of the San Francisco Bay Area over a 50-year period. The study, which is published in *Institutional Change and Healthcare Organizations: From Professional Dominance to Managed Care* (2000), examines the profound transformation of health-care organizations in the Bay Area. It charts changes since World War II in the number and types of organizations delivering health-care services as these have been affected by changes in the resource environment—for example, demography, financing, supply of health professionals—and in the

institutional environment—for example, changes in institutional logics and governance systems.

Scott has authored or coauthored many books and has published over 150 scholarly articles. Specifically, he has authored three widely used textbooks on organizations, *Formal Organizations: A Comparative Approach* (1962), *Organizations and Organizing: Rational, Natural and Open Systems* (2007), and *Institutions and Organizations: Ideas and Interests* (2008).

Scott has received many awards and accolades throughout his distinguished career. He is an elected member of the National Academy of Sciences, Institute of Medicine (IOM), and was a fellow of the Center for Advanced Study in the Behavioral Sciences. Scott also received the Distinguished Scholar Award from the Management and Organization Theory Division of the Academy of Management as well as the Richard D. Irwin Award for a career of distinguished scholarly contributions to management. In 2000, the American Sociological Association, Section on Organizations, Occupations, and Work created an award in Scott's name to recognize his contributions to the field of organizational sociology. The award is given annually to honor the most outstanding article contributing to the advancement of the field.

Scott was born in 1932 in Parsons, Kansas. He graduated from Parsons Junior College with an associate degree in 1952. He went on to receive a bachelor's and a master's degree from the University of Kansas and later completed his doctoral degree in sociology at the University of Chicago in 1961. While at the University of Chicago, he studied under Peter M. Blau, one of the founders of the field of organizational sociology. Scott has received honorary doctorates from the Copenhagen School of Business (2000) and the Helsinki School of Economics (2001).

Scott continues to teach doctoral-level seminars and conduct scholarly work at Stanford. He is currently engaged in the theoretical work of combining institutional theory in organizations with social movement theory as well as conducting research on institutional change at the community and the transnational level.

SELECTIVE CONTRACTING

Selective contracting is when an insurer, usually a managed-care plan, contracts with some but not all healthcare providers in a market. In essence, the insurer trades patient volume in return for lower provider prices. Selective contracting has been the comparative advantage that managed-care plans have used to enter and eventually dominate the nation's private health insurance market during the past 20 years. The selective contracting process was successful in introducing price competition into healthcare markets in the 1990s. The rapid increase in health insurance premiums in the past several years can be attributed, at least in part, to the erosion of selective contracting.

Overview

The basic idea surrounding selective contracting is that insurers contract with hospitals, physicians, pharmacies, and other healthcare providers based on factors such as services, quality, amenities, location, and, potentially, price. In the 1970s and 1980s, competition in healthcare was characterized as a medical arms race. More competitors in a market, measured as more hospitals in a geographic area, were associated with higher, not lower, prices as simple economic theory would predict. In as much as consumers were reasonably well insured and insurers entered into contracts with all local providers, there was little reason for a provider to offer a lower price. A lower price would garner little additional patient volume. Instead, more services, greater quality, and additional amenities attracted physicians and their patients. Thus, costs were higher in areas with greater nonprice competition.

Empirical Evidence

Efforts largely beginning in California began to change the medical arms race. California's state legislature passed laws that made it clear that insurers did not have to contract with all licensed providers in a market. Prior to the laws, hospital costs were higher in highly competitive markets in California. However, after enactment of the laws, cost increases were much smaller in the more competitive hospital market areas—the opposite of the medical arms race scenario.

Even more compelling evidence was found in an analysis of the hospital prices that were negotiated by the Blue Shield of California preferred provider organization (PPO). An analysis of the medical-surgical price per day that the PPO negotiated with 190 California hospitals showed that the PPO was able to obtain a lower price when there were fewer hospitals in the market; when the PPO had a larger share of a hospital's admissions; when a hospital had only a small share of the PPO's local book of business; and when there was idle capacity in the hospital or, indeed, in the local hospital market. These findings were strong evidence that the standard economic model was functioning in the hospital market. A number of other recent studies have generalized these findings beyond California.

Managed Care

The success of managed care in reducing healthcare costs is attributed to selective contracting and the reduction of expensive services on the part of managed-care plans. There is substantial evidence that managed-care plans, particularly health maintenance organizations (HMOs), have attracted lower utilizers of healthcare. It is less clear, however, whether this reduction comes about as a result of actions that the health plans take to enroll lower utilizers and shun high users or whether their enrollment reflects individuals who disproportionately like the concept of health maintenance and who dislike interacting with the healthcare system. The evidence that managed-care plans discourage the use of expensive services is scarce.

There is some evidence that sorts out the relative impacts of selective contracting, favorable selection, and treatment intensity on the lower use of healthcare in the case of managed care relative to conventional plans. Researchers examining the per-enrollee expenditures for eight medical conditions (acute myocardial infarction, live birth, four types of cancer, and Types 1 and 2 diabetes) among Massachusetts state employees in the mid-1990s found that the HMOs offered by the state had per-person claims costs that were \$107 lower for these conditions than the analogous claims costs for the same conditions in the conventional plan offered. Fifty-one percent of the difference was attributable to favorable selection. The HMOs attracted younger enrollees and people with a lower incidence of the medical conditions. An additional 5% was attributable to lower treatment intensity. Selective contracting accounted for 45% of the lower claims costs. As an example, the HMOs on average paid \$20,302 for an angioplasty procedure, while the conventional plan paid \$37,330.

Increase in Insurance Premiums

Selective contracting also provides a potential explanation for the more rapid increase in health insurance premiums that the country has observed during the past decade. Two explanations are typically advanced for this increase. One is a backlash against managed care. The other is a consolidation among providers. Both suggest an

undermining of the comparative advantage that was offered by selective contracting.

The managed-care backlash is said to consist of physician and patient complaints about the nature of the restrictions that managed-care plans imposed on access to healthcare. These include restrictions on self-referral and the use of various utilization management techniques. In addition, patients seem to be concerned about the quality of the providers potentially available to them in their managed-care panel. As a consequence, there has been growth in the preferred provider organization (PPO) model of managed care at the expense of HMOs. PPOs allow subscribers to use a wider set of healthcare providers if they are willing to pay higher copays to use non-panel providers. Whatever the merits of this shift, it has the consequence of undermining selective contracting. By expanding their networks and allowing subscribers to step outside the established network of providers, managed-care plans are unable to trade patient volume for lower prices. As a result, health insurance premiums continue to increase.

The consolidation explanation for higher health insurance premiums holds that hospitals have combined through mergers and acquisitions and physician groups have entered into larger groups and formed marketing networks to negotiate with managed-care plans. These activities also have the potential to undermine selective contracting. Consolidations and marketing networks reduce the number of competitors, remove idle capacity from the market, and increase the share of the insurer's subscribers using the new entities. All these actions have the potential to raise the prices that managed-care firms could negotiate through selective contracting.

SEVERITY ADJUSTMENT

A common problem with comparing performance among healthcare providers is how to adjust for differences in the disease severity of patients. For example, the mortality rate of patients in Hospital A may be higher than in Hospital B, but unfair and misleading conclusions may be drawn if patient characteristics in the two hospitals are not taken into consideration. Perhaps Hospital A is more likely to serve a large number of indigent patients, who lack health insurance coverage and tend to delay care until later stages of the disease, while Hospital B serves a large number of upper-middle-class patients, who have access to routine and preventive care. When assessing the relative performance of these two hospitals, these patient differences must be accounted for in some way, a process referred to as severity adjustment.

Although severity adjustment might initially appear to be straightforward, the process may be very complex. Methods of severity adjustment depend on the availability of data, the accuracy of the data, and the costs of data collection. A large number of factors may affect the outcomes of care, including the patient's age, gender, race and ethnicity, coexisting diseases, and psychosocial and socioeconomic characteristics. There are also a number of different severity adjustment methods and models available that often do not lead to similar conclusions.

History

The first attempts to measure patient severity took place in the 1970s. Later, particular attention was paid to severity adjustment in 1983, when the nation's Medicare program adopted a Diagnosis Related Group (DRG)-based prospective payment system (PPS) for hospitals. Hospitals were concerned that the new system would not pay for the provision of care to "sicker" patients. There was also concern about the accuracy of the DRG concept, since it assigns patients based mainly on principal diagnosis codes. Since compensation levels were at stake, critics argued that diagnosis severity could be exaggerated by hospitals in an attempt to improve their "bottom lines." These issues prompted debate over the use of code-based versus medical record surveys to assess patient complexity; thus, there were considerable efforts by developers of severity measures to explore and test a number of systems, such as disease staging, severity scores of Patient Management Categories (PMCs), and All Patient Refined Diagnosis Related Groups (APR-DRGs).

Selection of Performance Outcome

In the process of severity adjustment, healthcare managers and researchers must decide on a performance outcome of interest. Outcome measures that could be attributable to healthcare quality include morbidity, mortality, readmission rates, complication rates, functional status, and patient satisfaction. By far, mortality has been the most frequently used generic measure of hospital performance. Advantages of using mortality include the wide availability of this information, its clearly definable end point, and its importance. Further decisions about the mortality outcome measure may include whether to use in-hospital mortality, 10-day mortality, 30-day mortality, or 1-year mortality.

While a generic measure of hospital performance such as all-cause mortality may be used, it may be of greater interest to evaluate a disease- or procedure-specific mortality (e.g., in-hospital mortality among patients with congestive heart failure or in-house mortality after abdominal aortic aneurysm repair). Instead of mortality, healthcare managers and researchers may be interested in performance indicators such as the number of cesarean deliveries among high-risk women,

urinary-catheter-associated infections, or postoperative sepsis. Sometimes, selection of performance indicators may be hampered by small sample size, leaving inadequate statistical power to properly assess priority outcomes.

Selection of Severity Indicators

Fundamental to risk adjustment strategies is the selection of specific indicator variables that will help healthcare managers and researchers arrive at an adequate disease severity measure. If disease severity is poorly represented, then differences in healthcare performance outcome may be inaccurately estimated.

The selection of risk adjustment variables may be made on an individual level, the hospital or organization level, or both. For example, common variables to control for at the patient level include demographic factors such as age, gender, and race. Obviously, a hospital that treats more elderly patients will likely have a high mortality rate. Examples of health status variables at the patient level include the presence of coexisting diseases such as congestive heart failure, cancer, or chronic renal failure. An example of a health status indicator at the hospital level is the all-payer, DRG-based case mix index. Socioeconomic indicators at the county level, which could help adjust for case-mix differences among organizations, may also be incorporated into adjustment models. Variables might include per capita income, unemployment rate, or college graduation rate.

Data Sources

Decisions regarding the manner in which data are collected for severity adjustment may vary. For example, it may be less costly and less time-consuming to use routinely collected data already present in a hospital's computer system. However, this type of data may be very limited in nature and have questionable accuracy, depending on the habits of individual healthcare providers within the settings of interest. For these reasons, some experts have advocated going directly to medical records to extract relevant information. However, data extraction alone for a single hospital can cost tens of thousands of dollars and may therefore be prohibitive and not worth the net gain in added precision.

Severity Adjustment Methods

There have been numerous attempts to design the most ideal disease severity adjustment method, which have resulted in a variety of commercial products that are compared and contrasted in the literature. Due to the complexities of severity adjustment, practical limitations, and the evolving nature of the field, selection of an appropriate severity measure can be difficult. Different adjustment models require different inputs. Some models use clinical information that may only be extracted from the medical record, while others may require coding data that are already available in an electronic format.

Examples of severity measurement models include Acute Physiology and Chronic Health Evaluation (APACHE III—APS), MedisGroups Score, Severity Scores on Patient Management Category Severity Scales (PMCs), Disease Staging, Charlson Severity Score, and the All Patient Refined Diagnosis Related Groups (APR-DRGs).

SHAPIRO, SAM

Sam Shapiro (1914–1999) was both a founder and an exemplar of health services research as a recognized field of inquiry in public health and medical care. He was an innovative researcher, a dedicated teacher of a generation of health services researchers, a generous mentor to younger researchers, and a valued partner in research to colleagues.

Shapiro is widely recognized for research begun in the 1960s with Drs. Philip Strax and Louis Venet that demonstrated the effectiveness of screening mammography, combined with a clinical examination, in reducing breast cancer mortality. At the time, Shapiro was director of Research for the Health Insurance Plan of Greater New York. He, Strax, and Venet initiated a clinical trial that, between 1963 and 1968, enrolled 62,000 women aged 40 to 64 who were randomly assigned screening mammography and clinical examination versus regular care. Ten years later, cumulative mortality among women randomized to screening was about 30% lower than in the regular care group. In recognition of the importance of this work, Shapiro and Strax were awarded the Charles E. Kettering Prize for outstanding contributions to cancer diagnosis or treatment in 1988. Shapiro was the first public health researcher to receive this prize.

Shapiro was born and raised in Brooklyn, New York, and attended Brooklyn College, where he earned a bachelor's degree in mathematics in 1933. In the 1934–1935 academic year, he did graduate work in mathematics and statistics at Columbia University but left to work in Home Relief, a Depression-era program in New York City. In early 1943, he went to Washington, D.C., where he worked for the Selective Service System. In 1944–1946, he served in the U.S. Navy.

After being discharged from the Navy in 1946, he joined the National Office of Vital Statistics (now the National Center for Health Statistics), a component of the Public Health Service. It was there he began his work in public health, with responsibility for birth and infant death statistics. Among his earliest published papers are several concerned with the development and completeness of birth registration data and applications of these statistical data to answer public health questions.

He spent a year (1954–1955) as senior study director at the National Opinion Research Center (NORC) in Chicago, developing research designs and questionnaires for national and local studies on health services use. He joined the Health Insurance Plan (HIP) of Greater New York in 1955 as associate director of Research and Statistics and was promoted to vice president and director of Research and Statistics in 1959.

His research at HIP focused initially on the effects of prepaid group practice on health outcomes. With Paul Densen and others, he authored two research papers in 1958 and 1960 comparing prematurity and perinatal mortality among HIP members and the general population; he reported that women in the HMO began prenatal care earlier and had lower prematurity and perinatal mortality rates and that this occurred for both White and non-White groups. Differences were also observed between women seeing private physicians and those seeing “general-service” physicians.

Concurrently with the perinatal-care work, he and Densen examined patterns of ambulatory services utilization and hospitalizations. They designed and implemented one of the very early, if not the first, routine collections of encounter data in a prepaid group practice plan to support research on patterns of service utilization. His work in mental health began with analyses of prescriptions for psychotropic medications and patterns of medical care related to mental illness. Shapiro also conducted research showing that encounters for elderly patients took more time than for adults under age 65. This provided the basis for higher capitation payments by Medicare for elderly enrollees.

Under Shapiro’s direction, HIP launched a longitudinal study of the course of newly diagnosed coronary heart disease among its members in the early 1960s, taking advantage of the plan’s enrolled population, ready access to medical records, and extensive information on procedures and treatments available from the encounter data system. Over the next 10 years or so, a number of research papers were published describing, for instance, analyses of factors associated with the incidence of myocardial infarction and angina, lifestyle changes after a diagnosis of myocardial infarction or angina, and the disease course for women as compared with men.

In March 1973, Shapiro accepted the position of director of the Health Services Research and Development Center (HSRDC) at Johns Hopkins University. During the next 9 years, he developed an interdisciplinary team of health services researchers that competed successfully for a 5-year core support grant for the HSRDC from the National Center for Health Services Research and Development and for project grants from foundations and several of the National Institutes of Health (NIH).

His own research during this period addressed several disparate topics, including surveys of defined populations in Baltimore concerning utilization of health services for chronic and preventive care; the development of statistical procedures for measuring health status in geographic areas using vital statistics and hospital discharge data; evaluation of a Maryland statewide initiative to improve blood pressure control; and, with Ellen Mackenzie, reliability testing of the Injury Severity Scale (ISS) and its underlying Abbreviated Injury Scale (AIS) for evaluating trauma injuries.

In 1974–1976, with support from the National Center for Health Statistics (NCHS), Shapiro and Richard Yaffe conducted a pilot study to assess the costs and effectiveness of alternative methodologies for obtaining survey data on medical expenditures. The results of that work influenced the design of the 1977–1978 National Medical Care Expenditure Survey (now the Medical Expenditure Panel Survey).

Continuing his interest in perinatal care issues, he undertook between 1975 and 1981, with Marie McCormick and Barbara Starfield, an evaluation of the effects of Robert Wood Johnson Foundation (RWJF)–supported regionalized networks for high-risk pregnancy care. They found that while the program’s regions did not show better outcomes than nonprogram regions, its implementation coincided with increased centralization of high-risk pregnancy care nationally so that the decrease in neonatal mortality was accompanied by a decrease in selected morbidity overall.

In 1979, Shapiro joined with Morton Kramer and Ernest Gruenberg to lead the Eastern Baltimore Mental Health Survey, one of five sites for National Institute of Mental Health’s Epidemiologic Catchment Area Survey, which developed population-based estimates for the incidence and prevalence of mental

disorders in the United States and for met and unmet needs for mental health care among people with mental disorders.

Shapiro stepped down as HSRDC director in 1982, at the age of 68, but continued his active research career, publishing more than 55 research papers and two books over the next 15 years. In 1992, at the age of 78, he began his last major investigation, with Dr. Janet Hardy. The study traced the biological and social conditions experienced by a cohort of children born at Johns Hopkins Hospital between 1960 and 1965 and assessed their status at ages 27 to 33 years with regard to their health, educational attainment, employment experience, and family formation.

In the course of his long career at Johns Hopkins University, Shapiro was advisor to a large number of students, many of whom have gone on to make major contributions in health services research. He was also a mentor to many young faculty members who are now leaders in the field in their own right.

Shapiro received many awards in recognition of his unique contributions. The American Public Health Association gave him its Award for Excellence in Promoting and Protecting the Health of People in the Domestic Field in 1977, citing the breadth and groundbreaking nature of his contributions to our knowledge of health services and their contribution to the public's health. He was elected to the national Institute of Medicine (IOM) (1974); received the Distinguished Achievement Award of the American Society of Preventive Oncology (1985); was selected to give the American Public Health Association Lowell Reed Lecture (1989); was chosen to present the 14th Wendell G. Scott Memorial Lecture of the American College of Radiology (1992); and was made an honorary fellow of the American College of Radiology (1993). Shapiro was a key participant in the formation of the Association for Health Services Research (now AcademyHealth) in 1981, in recognition of which he was given the first Distinguished Investigator Award in 1985.

Shapiro's research defined standards for preventive services and provided new epidemiologic information on major risk factors for coronary heart disease. His research on organization and finance demonstrated that HMOs could provide care of equal or better quality than the alternatives.

He developed one of the first information systems to capture utilization and diagnostic information on each physician visit and demonstrated its potential value. Today, we rely on administrative data systems that are built on this experience, including Medicare and Medicaid. One of their uses is to analyze variations in medical-practice patterns and their relationship to patient outcomes and costs as a way to identify opportunities to improve the effectiveness and efficiency of health care. His work spanned pregnancy to old age, included physical and mental health problems, focused on prevention of disease and disability, and examined alternative approaches to the organization and payment of services to ensure that those who need care receive it. His contributions to the development of this new field of knowledge, health services research, were recognized by the Johns Hopkins University in 1998 with an honorary doctorate in humane letters, "for changing the face of American health care in this half-century." Shapiro died in Baltimore in 1999 at the age of 85.

SHEPS, CECIL G.

Cecil G. Sheps (1913–2004), one of the founders of the field now known as health services research, was the Taylor Grandy Distinguished Professor of Social Medicine and Epidemiology at the University of North Carolina at Chapel Hill (UNC-CH), the university's former Vice Chancellor for Health Affairs, and founding director of UNC-CH's Health Services Research Center (renamed in 1991 as the Cecil G. Sheps Center for Health Services Research), where he maintained an active presence until his death in 2004.

Sheps spent two different periods of his long career as a member of the UNC-CH faculty. He first came to Chapel Hill in 1947, shortly after having completed his public health training at Yale University. He was born and had grown up in Winnipeg, Canada, and he took his medical degree at the University of Manitoba. At UNC, he was first employed in the Office of Planning for the newly created Division of Health Affairs, and he was on the campus as the School of Medicine expanded to become a 4-year curriculum and the School of Public Health was made a distinct academic unit. He taught basic courses in public health administration, biostatistics, and epidemiology in the latter school until he departed for Boston in 1953 to become director of the Beth Israel Hospital, one of the principal teaching hospitals affiliated with the Harvard Medical School, where he held a faculty position.

In 1958, he left Boston to become professor of Public Health and head of the graduate program in medical care administration at the Graduate School of Public Health at the University of Pittsburgh. After only 5 years in that position, he was lured back into an administrative position as director of the Beth Israel Hospital in New York and as a professor at the Mount Sinai School of Medicine.

In 1968, the University of North Carolina at Chapel Hill received one of five major grants from the U.S. Public Health Service to begin a multidisciplinary center for health services research. A search for an initial director of this new center began, and several faculty members suggested that an approach be made to Sheps to return to Chapel Hill to launch this new multidisciplinary center. Sheps and his wife decided to accept separate offers to return to North Carolina, he as director of the Health Services Research Center and as professor of family medicine and she as professor of Biostatistics in the UNC School of Public Health.

Sheps had developed a keen interest in multidisciplinary problem-focused research, especially research focused on the issues of concern to the field of healthcare. He had formed a multidisciplinary unit to carry out this sort of research at Beth Israel in Boston, one of the first hospital-based research institutes of its kind. Several of the investigators he attracted to work in that unit later became the leading figures in the emerging field of health services research, a field he helped to create and name. He was the first chairperson of the initial study section of the U.S. Public Health Service, giving grants to support the work of scholars in what was then called healthcare studies.

Sheps believed that the problems in assuring access to quality medical care for everyone were surmountable. He believed that one of the challenges of health services was to discover ways of converting an array of disconnected healthcare services into coherent and consumer/patient-centered programs of healthcare serving defined populations by offering clearly defined and needed care.

Throughout his career, Sheps had a strong interest in international healthcare issues and in the development of both research and educational programs addressing healthcare issues. He traveled and was actively involved in health services research in the United Kingdom, and he was one of the consultants involved over a number of years in the

development of a new community-oriented medical school at Ben Gurion University of the Negev in Israel.

Sheps published over 140 articles in scientific journals and wrote or edited nine books, including *Needed Research in Health and Medical Care: A Biosocial Approach* with Eugene E. Taylor and *The Sick Citadel: The American Academic Medical Center and the Public Interest* with Irving J. Lewis. Sheps passed away on February 7, 2004.

United States, Stephen M. Shortell has had a very productive and influential career. His groundbreaking, interdisciplinary research projects have sought to identify and understand the interactions among business strategies, organizational structures, quality improvement processes, and performance of healthcare systems. One important outcome of Shortell's research has been a typology of healthcare systems alliances. His research also has focused on organizational attributes of physician group practices, with an ongoing interest in quality, outcomes of care, and strategic alliances between physicians and other healthcare entities. Woven throughout his ongoing program of research are questions about the effectiveness of total quality management (TQM), strategic change in the healthcare sector, and ways to enhance community-based initiatives to improve health. At the heart of his scholarly and intricate studies is a concern for improving the organization of health services as a means to improve the health of populations.

After receiving his bachelor's degree in business from the University of Notre Dame, Shortell completed a master of public health degree from the University of California at Los Angeles. Next, he received a master of business administration and a doctoral degree in behavioral science from the University of Chicago. In 1998, Shortell became dean of the University of California, Berkeley, School of Public Health; Blue Cross of California Distinguished Professor of Health Policy and Management; and a professor of Organization Behavior at the Haas School of Business. He concurrently holds appointments in the Department of Sociology at Berkeley and the Institute for Health Policy Research at the University of California, San Francisco. For the 16 years prior to arriving at Berkeley, Shortell was A. C. Buehler Distinguished Professor of Health Services Management in the Kellogg Graduate School of Management at Northwestern University.

Over his long career, Shortell has received numerous distinguished awards for his various contributions. He received the Baxter-Allegiance Prize for innovative research and the Gold Medal from the American College of Healthcare Executives (ACHE). He was elected to the National Academy of Sciences, Institute of Medicine (IOM), in 1986 and served two terms on the Governing Council. He has served as editor-in-chief of *Health Services*

SHORTELL, STEPHEN M.

A highly distinguished scholar and well-respected leader in health services delivery systems in the

Research, president of the Association for Health Services Research, and chair of the Accrediting Commission for Graduate Education in Health Services Administration. More recently, Shortell was a fellow at the Center for Advanced Study in the Behavioral Sciences at Stanford University. He has received three “Book of the Year” awards from professional associations ranging from the American Nurses Association to the Academy of Management. The textbook Shortell wrote with Arnold D. Kaluzny is now in its fifth edition. It was one of the first textbooks written specifically for health services managers and researchers.

The extent of Shortell’s accomplishments is a testament to both his keen intellect and his ready willingness to engage with others in the pursuit of knowledge.

SHORT-FORM HEALTH SURVEYS (SF-36, -12, -8)

The Short-Form Health Survey (SF-36) is a generic, multipurpose, 36-item survey that is widely used to measure the health status of general and specific populations for a variety of purposes. Specifically, the SF-36 survey instrument measures eight health domains, including the following: general health, physical functioning, role limitations due to physical health problems, role limitations due to emotional problems, social functioning, bodily pain, vitality, and mental health. The survey is usually self-administered and takes only 5 to 10 minutes to complete. Shorter versions of the SF-36 are available. The SF-36 has been translated into dozens of languages, and its use has been documented in thousands of published studies. Applications of SF-36 include comparing and evaluating health outcomes related to specific medical treatments, estimating and/or comparing the burden of different disease states, and comparing health status over time.

Survey Development

Most of the items used in the SF-36 have evolved from other survey instruments applied over several decades, but its immediate roots can be traced to the development of a 149-item Functioning and Well-Being Profile (FWBP) developed by researchers

involved in the RAND Corporation's Health Insurance Experiment (HIE) and Medical Outcomes Study (MOS). The 149 items used in the FWBP were taken and modified from a variety of other survey instruments, including the General Psychological Well-Being Inventory and the Health Perceptions Questionnaire. An initial version of the SF-36, the SF-20, was published in 1988 but received criticism for being too short and lacking sensitivity to health status changes. The SF-20 was therefore transformed into the SF-36, which has withstood considerable evaluation and scrutiny since then.

The SF-36 is currently published and coordinated by QualityMetric, Inc., a company that develops and markets patient-reported outcome instruments that measure health-related quality of life. The company publishes several manuals that contain detailed information pertaining to the survey's administration and scoring, as well as comparisons with other tools.

Due to time and cost constraints on the amount of data that can be collected for many studies, even shorter versions of the SF-36 have been developed that provide acceptable degrees of information for certain applications. The SF-12, a 12-item survey that fits on a single page, consists of a subset of the SF-36. Although it improves efficiency and lowers research costs, the shorter survey has limitations. Similarly, the 8-item SF-8 also has limitations, and it may be used in lieu of the SF-36 and SF-12.

Description and Content

The SF-36 contains 11 numbered sections, some of which have multiple items (Table 1). Each "item" is essentially a specific question; therefore, as the survey's name implies, there are 36 total questions or items that address eight health domains. Depending on needs and preferences, some variation may be applied to the scoring and analysis of the SF-36. The fundamental information provided, though, consists of two sets of scores, including eight individual domain scores and two summary scores. One summary score is calculated for the "physical health component" function and the other for the "mental health component." The physical health component summary score is derived from the physical-functioning domain, the role limitation due to

physical health domain, the bodily pain domain, and the general health domain. The mental health component summary score is derived from the general mental health domain, the vitality domain, the role limitation due to emotional problems domain, and the social-functioning domain.

All the items in the current version of the survey instrument (SF-36 Health Survey Version 2.0) have three or more Likert Scale responses (i.e., data that are categorical in nature yet have a hierarchical sequence). For example, for the question that asks how much pain the individual has experienced during the past 4 weeks, the possible ordered responses are "none," "very mild," "mild," "moderate," "severe," and "very severe." This type of question format provides more data than the older version of SF-36, which used simple "yes" and "no" responses. And the greater number of response categories in lieu of the dichotomous response options has resulted in greater measurement precision as well as a reduction in "floor" and "ceiling" effects whereby the survey instrument may fail to differentiate responses at the margins.

Although the SF-36 contains eight of the health domains most frequently used in other popular surveys, symptoms and problems connected to a specific medical condition are not included among the questions. Thus, it does not encompass content areas such as self-esteem, sleep adequacy, and cognitive functioning.

Survey Administration

The overall purpose of the SF-36 is to measure aspects of a person's health for those 14 years of age or older in a manner that is relatively comprehensive and from the individual's perspective. It is also intended to be brief. The survey instrument is designed to be self-administered, but it may also be administered through face-to-face or telephone interview. Computerized administration is also possible. When the survey is administered, individuals are not "coached," or provided with advice relative to its interpretation. Rather, instructions are limited to those printed on the survey. If any assistance is required, due to poor visual acuity, for example, it is limited to reading the survey verbatim.

Table 1 Short-Form 36 Health Survey

Your Health and Well-Being

This survey asks for your views about your health. This information will help keep track of how you feel and how well you are able to do your usual activities. *Thank you for completing this survey!*

For each of the following questions, please mark an X in the one box that best describes your answer.

1. In general, would you say your health is:

Excellent	Very good	Good	Fair	Poor
▼	▼	▼	▼	▼
<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5

2. Compared to one year ago, how would you rate your health in general now?

Much better now than one year ago	Somewhat better now than one year ago	About the same as one year ago	Somewhat worse now than one year ago	Much worse now than one year ago
▼	▼	▼	▼	▼
<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5

3. The following questions are about activities you might do during a typical day. Does your health now limit you in these activities? If so, how much?

Yes, limited a lot	Yes, limited a little	No, not limited at all
▼	▼	▼

- a. Vigorous activities, such as running, lifting heavy objects, participating in strenuous sports 1..... 2..... 3
- b. Moderate activities, such as moving a table, pushing a vacuum cleaner, bowling, or playing golf 1..... 2..... 3
- c. Lifting or carrying groceries 1..... 2..... 3

Table I (Continued)

9. These questions are about how you feel and how things have been with you during the past 4 weeks. For each question, please give the one answer that comes closest to the way you have been feeling. How much of the time during the past 4 weeks...

	All of the time	Most of the time	Some of the time	A little of the time	None of the time
	▼	▼	▼	▼	▼
a. Did you feel full of life?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
b. Have you been very nervous?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
c. Have you felt so down in the dumps that nothing could cheer you up?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
d. Have you felt calm and peaceful? ...	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
e. Did you have a lot of energy?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
f. Have you felt downhearted and depressed?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
g. Did you feel worn out?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
h. Have you been happy?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
i. Did you feel tired?.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5

10. During the past 4 weeks, how much of the time has your physical health or emotional problems interfered with your social activities (like visiting friends, relatives, etc.)?

All of the time	Most of the time	Some of the time	A little of the time	None of the time
▼	▼	▼	▼	▼
<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5

11. How TRUE or FALSE is each of the following statements for you?

	Definitely true	Mostly true	Don't know	Mostly false	Definitely false
	▼	▼	▼	▼	▼
a. I seem to get sick a little easier than other people.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
b. I am as healthy as anybody I know	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
c. I expect my health to get worse	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
d. My health is excellent.....	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5

THANK YOU FOR COMPLETING THESE QUESTIONS!

QualityMetric, Inc., the Medical Outcomes Trust (MOT), and the Health Assessment Laboratory (HAL) are co-copyright and trademark holders of the SF-36, -12, and -8 surveys. Use of them requires a commercial license or permission for use in scholarly research.

When using the SF-36 to measure health status repeatedly over time, the standard form is designed for a 4-week recall. An acute (1 week) recall version is also available when it is desirable to measure health status weekly or biweekly. The 1-week recall version is more sensitive to recent changes in health status than the standard 4-week recall version. The 1-week recall form was created by changing the words “in the past four weeks” to “in the past week” in the health domain questions for which this is applicable.

Scoring the Survey

As with many other survey instruments, although the raw recorded data may appear straightforward initially, there are important considerations, and choice of analysis method may depend on the specific applications. There are many considerations, including whether health status is being compared among different populations or within the same population over time. Detailed manuals are best consulted for in-depth explanations and scoring options. Computer software is also available to assist with scoring, but expertise is required nonetheless.

Fundamental to the SF-36 is that it yields eight scale scores, one for each health domain, and two summary scores, one being a physical component score (PCS) and the other a mental component score (MCS). An initial step in the process of scoring requires some transformation of the data such that “better health” is represented by consistently higher values (on the original survey form, the numeral 1 may correspond to the “best” health response or the “worst” health response). Each item is then scored on a 0 to 100 scale such that the score 0 represents the poorest health option and 100 represents the best health option. Thus, an item’s answer represents the percentage of the maximum achievable score. Because the intervals in a Likert Scale are not typically proportional, an item that has five possible responses cannot simply be assigned 0, 25%, 50%, 75%, and 100%.

Instead, special weights that have been determined from Likert analyses must be used.

Domain scores are calculated by using averaging methods of the scores from each domain’s relevant items. Similarly, the summary scores (i.e., the PCS and the MCS) are derived using averaging methods applied to the relevant domain scores. During the scoring process, unanswered items may simply be ignored altogether while averaging a domain’s remaining items, but this can be handled in several different ways. Commercial software designed specifically for the survey instrument can be used to create imputed values to replace “missing” data if desired.

To make it easier to compare the eight domain scores, different populations, and survey results acquired using the SF-36, Version 2.0, with published results using the SF-36, Version 1.0, norm-based scoring algorithms were developed that yield standardized scores (with a mean score of 50 and a standard deviation of 10). This type of standardization allows an interpretation such that scores 0 to 49 are below average and scores 51 to 100 are above average.

Reliability and Validity

Developing an in-depth understanding of the reliability and validity of the SF-36 is complex, and assistance from someone familiar with the voluminous SF-36 literature and with expertise in survey research is desirable. Although the appropriateness of the short-form surveys must be considered in relation to specific applications, the survey instruments are generally both reliable (yield consistent results) and valid (accurately measure what is being tested). Numerous studies, using both internal consistency and test-retest methods, support the reliability of the eight health domain scores as well as the two summary measures. In particular, the physical and mental summary scores usually have exceeded median reliability coefficients. Reliability trends have been found to span many different sociodemographic groups and medical diagnoses.

Systematic comparisons of the SF-36 content validity with that of other widely used surveys show that the health domains addressed are some of the most frequently used for similar purposes. There are many different health domains, or

content areas, that are used in other surveys, but the SF-36 is designed to be a nonspecific, generic health survey. Thus, it will not indicate condition-specific problems, nor should it be expected to do so, because of its general nature.

Shorter Versions of the Survey

Both the SF-12 and SF-8 were developed as shorter alternatives to the SF-36. Having these shorter survey instruments to measure health status in a manner that is reasonably as accurate as the SF-36 is frequently necessary when there is a need to also collect other information that adds to cumulative testing time.

The initial version of the SF-12 was published in 1995, and it has been widely used. It contains only 12 items extracted from the SF-36, it fits on one page, and it takes only about 2 minutes to complete. Each of the eight health domains is addressed with only one or two items. Similar to the SF-36, the SF-12 has evolved so that all items have more than just a “yes” or “no” response, and this has improved the possible conclusions from the survey. Version 1.0 of the SF-12 was developed so that two summary scores, the PCS and the MCS, could be calculated with about 90% of the accuracy of the SF-36.

The SF-8, the shortest questionnaire, has only one item for each of the eight health domains. Unlike the SF-12, the SF-8 has only one item that has the same language as the SF-36. Scores from the SF-8 can be compared directly with scores from other SF surveys. Similar to the SF-36, the SF-8 is available in 1-week and 4-week recall formats. The SF-8 has also been modified into a 24-hour recall format.

SINGLE-PAYER SYSTEM

The term *single-payer system* refers to any health-care scheme in which a sole source of funding provides payments to physicians, hospitals, laboratories, and other providers for services rendered to patients. While healthcare reform advocates often propose single-payer systems as a means to achieve universal healthcare, the terms should not be considered synonymous. Single-payer systems may serve patients grouped by government constituency (e.g., national citizens or state citizens) or by patient community. By this standard, the U.S. government currently manages several single-payer systems, including Medicare, for individuals 65 years of age and older, and the Veterans Health Administration (VHA), for eligible armed services veterans.

The payer in such a system may be a government entity or other designated insurance organization. But typically, when policy analysts refer to the United States moving to a single-payer-based healthcare system, they envision a system of national health insurance, implemented similarly to the system currently employed in Canada. Canada’s national health insurance scheme works according to a federal model, with mandates and guidelines set by the national government; it is implemented and provided by the individual provincial governments. Just as in the United States, Canada’s healthcare providers exist as a mix of

public, private not-for-profit, and for-profit, investor-owned organizations. Approximately 70% of Canada's healthcare expenditures run through its national health insurance plan, with the remaining expenditures made up of out-of-pocket costs and supplementary private insurance payments.

Canada's system originated with provincial-level programs, starting with Saskatchewan in 1946, and some advocates have proposed a similar approach to instituting single-payer systems in the United States. To date, state legislatures have evaluated proposals for state-level single-payer systems in California, Oregon, Massachusetts, and Illinois. Of these, only one bill, the 2006 Health Care for all Californians Act, passed the state legislature, but it went down to veto by California's Governor Arnold Schwarzenegger.

Advantages

Advocates of a single-payer approach to reforming the U.S. healthcare system point to several assumed advantages, chiefly cost reductions through administrative efficiency and bargaining power; increased access to insurance and healthcare; and improved healthcare quality and outcomes.

Approximately 31% of U.S. healthcare spending goes to overhead costs and profits. In contrast, Canada's national health insurance program spends a little more than 1% of its budget on overhead, and in the United States, the federal government keeps Medicare's administrative costs to less than 4% of the total spending. U.S. hospitals devote roughly one quarter of their budgets to administration and billing, while Canadian hospitals only spend about half as much for the same functions. In theory, a single-payer system would enable these savings on a nationwide basis. Policy analysts speculate that further cost reductions would come from the bargaining power a nationalized insurance plan would have to negotiate prices with service providers, drug companies, medical-device makers, and other suppliers.

While single-payer systems need not require individual coverage, most proposals for implementing national health insurance in the United States include either mandates or strong economic incentives to include as many persons in the pool as possible. Advocates of this approach point to lower costs of entry for individuals, as

well as reduced costs for those people currently insured, by virtue of enlarging the risk pool. The resulting equality of coverage should break down many of the current barriers to care experienced in the United States, particularly by persons of lower socioeconomic status, persons at high risk for disease or injury, and other populations that have trouble securing insurance, such as the self-employed.

With the massive spending outlays on billing and administration by hospitals and other healthcare providers comes a great drain on human resources. Advocates of the single-payer approach highlight the amount of time spent by U.S. physicians dealing with insurance paperwork and bureaucracy and suggest that moving to a simplified national insurance program would free providers to spend more time with their patients, improving quality of care.

Disadvantages

Even some advocates of single-payer systems criticize the Canadian model as preserving what both they and some critics see as a problematic fee-for-service delivery model. By itself, implementing the single-payer system in the United States would do nothing to address the broader quality-of-care issues that many analysts link to fee-for-service delivery.

More specifically, opponents of single-payer systems often argue against them on broad economic or philosophical grounds that sometimes have more to do with the means than the ends of such reform proposals. But in terms of the specifics of implementing a single-payer system in the United States, critics identify some potential pitfalls: healthcare rationing, insufficient redress of healthcare inequality, illusory cost savings, and the general repercussions of reducing competition in healthcare.

Many single-payer system plans operate on a global budget, specifying a maximum government outlay for healthcare during a given year. To remain within those budgets, countries such as Canada enforce limitations on resources, such as the number of appointments available, and on implementation of expensive technology, such as magnetic resonance imaging scanners. Opponents note that for the covered population, these limitations can

result in increased waiting times for nonemergency services and noncoverage of some services readily available in third-party-payer systems.

Despite assertions that a single-payer model would address health disparities, critics point out that even in nations with single-payer-based universal coverage, serious health disparities remain. One study, for example, found that Canada's system increased access to psychiatric services for persons in higher socioeconomic groups with lower morbidity while failing to address the needs of persons in lower socioeconomic groups with greater need for care.

Opponents of single-payer models argue that the cost savings seen in existing systems do not represent true savings but actually cost-shifting from patients and payers to caregivers and vendors. In other words, if a single-payer entity negotiates the fee for a service from \$1000 down to \$750, the payer may "save" \$250, but this transaction "charges" the provider \$250, leaving the social cost the same.

Finally, critics of single-payer systems suggest that reducing competitive payment from the U.S. healthcare system will ultimately harm patients by eliminating incentives for providers to compete through lower fees, increased convenience, and innovations in products and services. These policy analysts offer examples such as Lasik surgery and fee-based telephone physician consultation as the types of services that would not emerge and thrive under a monopolistic single-payer model.

Future Implications

With growing healthcare costs, swelling ranks of the uninsured, and increased global competition, few policy analysts would argue that the U.S. healthcare system does not require some kind of intervention and reform. But like so many issues of national policy, the question of whether or not to implement a single-payer system hinges on political and philosophical questions at least as much as questions concerning its potential economic and social impact. Most opponents of a single-payer system favor market-based solutions that minimize government's role in healthcare. In many ways, single-payer versus market reforms perfectly represents the broader fault lines in American politics.

For decades, policymakers have tried to sidestep the broader questions embedded in the healthcare debate by implementing incremental changes that both expand government's role as single payer for some populations (e.g., as in Medicare Part D) and use incentives to make healthcare more like traditional markets (e.g., as in health savings accounts). But while few analysts seriously propose eliminating government's role as a payer entirely, advocates on both sides of the debate increasingly acknowledge that these incremental, balanced approaches do not yield satisfactory results. At the same time, despite a growing sense of crisis about U.S. healthcare, observers find scant evidence that the political will exists to fully embrace either approach.

Despite the growing size and power of its national government, the United States remains a federalist nation. Just as Canada's national health insurance system originated in a single province, one or more U.S. states may pass single-payer legislation and thus serve as laboratories for a single-payer experiment. Success on the state level could well lead to a national tipping point for the single-payer system or, in the event of failure, a backlash favoring market-based solutions.

SKILLED-NURSING FACILITIES

Skilled-nursing facilities play a vital role in the continuum of healthcare services, providing care in one of the most intensive healthcare settings outside hospitals. Skilled-nursing facilities meet the short-term care needs of individuals with intensive medical and rehabilitation needs or needs for hospice or respite services, and they provide more continuous long-term care for persons with disabilities, chronic conditions, and custodial care needs. For individuals with short-term care needs, skilled-nursing facilities play a transitional role in facilitating care that is less intensive than that provided in acute care settings and more intensive than care provided at home. For individuals with long-term care needs, skilled-nursing facilities provide services that may be rendered until the end of their lives.

The Nature of These Facilities

A skilled-nursing facility is a specific category of nursing home. A nursing home is defined as an establishment of three or more beds that provides individual care and services to the aged, infirm, and chronically ill. Nursing homes are licensed institutions that have the option to pursue

additional certification as skilled-nursing facilities. Nursing homes without skilled-nursing facility certification provide a less intensive, custodial level of care. Skilled-nursing facilities may be either independent, freestanding facilities or distinct units within a larger nursing home, hospital, continuing-care retirement community, or long-term care hospital.

There are approximately 15,000 skilled-nursing facilities throughout the United States. The majority of these facilities are proprietary (for-profit), followed by not-for-profit facilities, with the smallest number of facilities being government owned. Regardless of ownership, most skilled-nursing facilities are affiliated with a chain, while a smaller number are independent facilities. The majority of skilled-nursing facilities in the nation are located in the Midwest and South. And most facilities are located in metropolitan areas. The average size of these facilities is about 100 beds. Most skilled-nursing facilities are certified by both Medicare and Medicaid, although a small number of them are certified by only Medicare. Smaller facilities and those certified by only Medicare are often designated distinct units within larger institutions such as hospitals.

Problems

While the number of skilled-nursing facilities in the nation has been on the rise, the overall occupancy rate of these facilities has been declining. The decline in occupancy rate is the result of shorter lengths of stay and alternative options for care. Shorter lengths of stay are spurred by many factors, including changes in financing mechanisms and advances in medical treatment. Consumer interests, changes in financing mechanisms, and the development of various technologies are creating alternative options of care. Alternative settings to nursing facilities include the patient's home (in-home care), assisted living and supportive living facilities, and continuing care retirement communities.

Criteria for Care

Most individuals who are admitted to skilled-nursing facilities for short-term transitional needs

must meet the criteria established by Medicare, private health insurance companies, and/or the states. The criteria individuals must meet under Medicare and insurance companies typically include medically necessary nursing and therapy services provided by a licensed practitioner such as a physical, occupational, respiratory, or speech therapist or a licensed, vocational, or registered nurse. These services must be ordered by a physician and initiated and executed within specific time frames. With the qualifying criteria met, Medicare will pay for services rendered in a certified skilled-nursing facility; however, this benefit is limited to 100 days and may be discontinued prior to 100 days if the individual no longer meets the qualifying criteria. Financial coverage through private health insurance companies follows similar guidelines; however, the full extent of the coverage is specific to each individual insurance policy.

Individuals may be admitted to a skilled-nursing facility and not meet the qualifying criteria for coverage through Medicare or private health insurance. They may continue to live in a skilled-nursing facility after they no longer meet the qualifying criteria for financial coverage under Medicare or private insurance. They may also no longer meet qualifying coverage because they have exhausted their coverage benefit or because they no longer demonstrate a need that qualifies them for coverage.

Qualifying criteria associated with long-term care in a skilled-nursing facility vary from state to state. The criteria may correlate to payment for skilled-nursing facility care under the individual state's Medicaid payment program. This criterion often uses two variables associated with an individual's capacity in the areas of cognition and independence. An individual is scored to have a qualifying level of cognitive impairment through the administration of various tests, such as the Folstein Mini-Mental State Examination (FMSE). Criteria that measure an individual's independence are typically scored through the Activities of Daily Living (ADL) or the Instrumental Activity of Daily Living (IADL). These tests measure an individual's level of independence in a number of categories, including bathing, grooming, ambulation, shopping, and housekeeping.

Services Provided

Skilled-nursing facilities may provide a wide range of services. These services may be organized into dedicated units within the facility or offered as standard levels of care throughout the facility. These services may include intensive nursing care associated with ventilator care; intensive rehabilitation associated with postacute, postsurgical, or neurological needs; and complex medical care emphasizing the intensive combination of both nursing and rehabilitation. These varieties of highly skilled care may be referred to as subacute care. Skilled-nursing facilities may also offer specialized services for persons with Alzheimer disease, those in need of hospice care, or persons with respite-care needs. Other services provided include education of the individual patient and family, meals, medications, social services, activities, and dietary consultation.

As skilled-nursing facilities become more competitive and occupancy rates continue to decline, they are increasingly looking toward specialization in one or more of these services, to maintain or develop a position in the marketplace.

Future Implications

Skilled-nursing facilities play an important role in the delivery of healthcare services in the nation. They provide some of the most intensive settings for medical care outside hospitals. Providing both short-term and long-term care, skilled-nursing facilities meet the transitional needs of individuals who require care between the hospital and their home. They also play an important role in the provision of long-term care for individuals who are cognitively impaired or are dependent in a significant number of activities of daily living. A number of financing mechanisms pay for care in a skilled-nursing facility; however, individuals must often meet qualifying criteria to be admitted to the facility. As the need for skilled-nursing facilities evolves, more of them are developing specialized services or units focusing on specific conditions, treatments, and services.

STARFIELD, BARBARA

Barbara Starfield is an internationally recognized health services researcher who is known for her work in primary care. She has devoted much of her career to studying the role and impact of primary care on health systems and the health of populations. She is also a strong advocate for the greater use of primary care as a way to improve quality and lower healthcare costs. Many of her publications are seminal works in the field. Two of her best-known publications are *Primary Care: Concepts, Evaluation, and Policy* and *Primary Care: Balancing Health Needs, Services, and Technology*.

Born and raised in New York City, Starfield earned her bachelor's degree from Swarthmore College in 1954, her medical degree from the State University of New York (through the Health Sciences Center in Brooklyn) in 1959, and her master of public health degree from Johns Hopkins University in 1963.

Starfield has been at Johns Hopkins University for most of her career. From 1959 to 1963, she was a fellow in the pediatrics department at the university's medical school. From 1963 to 1966,

she was an instructor in the pediatrics department and medical director of the pediatric medical care clinic. From 1966 to 1975, she was a professor in the department of medical care and hospitals at the university's School of Public Health. From 1975 to 1994, she was the head of the Division of Health Policy in the Department of Health Policy and Management. She is now University Distinguished Service Professor in the Department of Health Policy and Management and director of the Primary Care Policy Center at Johns Hopkins University.

Starfield is a prolific researcher and writer. She has authored or coauthored over 200 journal articles, 15 books and monographs, and 57 book chapters.

In recognition of her work, Starfield has received numerous awards and honors. She has been a member of the National Academy of Sciences, Institute of Medicine (IOM) since 1977. She received the Distinguished Investigator Award from the Association of Health Services Research in 1996 and the Baxter International Foundation Prize for Health Services Research from the Association of University Programs in Health Administration (AUPHA) in 2004. She was awarded the John G. Walsh Award for Lifetime Contributions to Family Medicine by the American Academy of Family Physicians (AAFP), and she received an honorary doctoral degree from the University of Montreal in 2005. She received the Annual Award for Excellence and Innovation and Value Purchasing from the National Business Group on Health and the Avedis Donabedian Award for Quality Improvement from the American Public Health Association in 2007.

Starfield was the cofounder and first president of the International Society for Equity in Health, a scientific society devoted to equity in the distribution of health care services.

STARR, PAUL

Paul Starr is a noted professor of sociology and public affairs at Princeton University, where he holds the Stuart Chair in Communications and Public Affairs at the Woodrow Wilson School of Public and International Affairs. Starr was awarded the Pulitzer Prize for Nonfiction and the Bancroft Prize in American History in 1984 for his book *The Social Transformation of American Medicine*. This seminal work details the history of the nation's healthcare system over the past centuries. The book stimulated many scholars and students in history, political science, and public health to take stock of medicine's historical and future directions.

The Social Transformation of American Medicine documents the transformation of the nation's healthcare from a household service to one that has become dominated by market forces and the emergence of private medical practice. In the book, Starr details the institutionalization and professionalization of American medicine and the rise in influence of the medical profession and its authority over healthcare. He elaborates how physicians have

been able to exert their control over almost every aspect of the healthcare system and how hospitals have served as the medical workshops of physicians, subsidized by various government programs. As a result of the dominance of physician control, healthcare costs have risen dramatically, and the public has become increasingly frustrated. This also has led to corporate conglomerates exerting greater influence over the burgeoning healthcare system.

Starr also authored the book *The Logic of Health Care Reform*, which advocated a national health insurance system and managed competition based on President Clinton's healthcare reform proposal. During 1993, Starr served as a senior advisor to the White House and was the chief architect of the Clinton administration's proposed healthcare reform plan. Starr laid out a variation of a managed-competition scheme to cover all Americans, regardless of employment status or pre-existing conditions, which was to be funded through employer contributions and government subsidies.

Starr has published extensively on issues in politics, American society, and domestic and foreign policy. His most recent book, *Freedom's Power: The True Force of Liberalism*, argues that modern democratic liberalism is the only viable solution to the challenges confronting our modern society. Starr also is the coeditor of *The American Prospect*, a liberal monthly magazine about politics, policies, and ideas that he cofounded in 1990 along with Robert Kuttner and Robert Reich.

Starr previously served as the project director for the Center for the Study of Responsive Law from 1971 to 1972, and he was the director of the Century Institute from 1999 to 2003. Starr was assistant professor of sociology from 1978 to 1983 and associate professor of sociology from 1983 to 1985 at Harvard University. He received his bachelor's degree in 1970 from Columbia University and a doctoral degree in sociology from Harvard University in 1978. Starr also received in 1986 an honorary Doctor of Humane Letters from the State University of New York.

STATE-BASED HEALTH INSURANCE INITIATIVES

Many states in the nation, including Illinois, Maine, and Massachusetts, have created state-based health insurance initiatives to expand coverage. These state-based initiatives have incrementally expanded existing health insurance programs as well as created new programs. Their varied attempts have resulted in equally varied results and outcomes. These varied outcomes mirror the states' diverse populations and situations. Their successes have been limited by federal laws, financial constraints, and political wills.

In 2006, approximately 47 million Americans, or about one in six residents, did not have health insurance coverage. Nationally, 15.8% of the population were uninsured, but the variation across states ranged from a low of 8.5% for Minnesota to a high of 24.1% for Texas. Individuals without health insurance receive no care, inadequate care, or care paid for by a third party such as the government, a charity, or involuntary subsidy. Inadequate healthcare often means more expensive care. Healthcare for the uninsured is

often delivered after a disease has progressed, when the disease is more difficult and expensive to treat. Preventive healthcare is likely to be the first type of care that uninsured people do without. When uninsured Americans finally do receive healthcare, other citizens and businesses ultimately pay for the cost of that care.

Individuals, businesses, and governments all have incentives to create an efficient and equitable health insurance coverage system. The federal government addresses this problem through several insurance entitlements and funding mechanisms. However, the federal government programs have not been able to provide all Americans with guaranteed health insurance. The unmet cost of healthcare for these uninsured Americans then falls to local charities and governments, and these entities have tried to meet this demand.

Many states are attempting to expand healthcare coverage in spite of the continued rise in the cost of health insurance and the decline in employer-sponsored health insurance coverage. The health insurance landscape creates many challenges. The states themselves, faced with budgetary constraints, political interest groups, and federal regulations, find their attempts to provide health insurance difficult. No state has been able to provide universal health coverage. In addition to the financial and political hurdles the states must face, they must also conform to federal laws. And federal law prevents them from mandating businesses to provide health insurance benefits.

Health Services Research Issues

State-based health insurance initiatives must address three health services research issues: access, cost, and quality of care. However, access issues have been their primary focus. State-based initiatives have mainly attempted to expand health insurance coverage through improved financing (increasing state funds) and lowering the cost of health insurance premiums. Funds for these goals can come from state taxes or from federal government programs and grants.

Access

State governments can increase access to healthcare by expanding eligibility to state-sponsored

health insurance (largely Medicaid and State Children's Health Insurance Programs, or SCHIP). They can encourage employee-sponsored insurance by providing subsidies to businesses that offer it or by providing premium assistance to employees who elect to take the insurance. The states can modify eligibility rules, and they also can attempt to increase access by lowering the costs of health insurance premiums. Lower health insurance premiums may increase the number of people who opt to purchase insurance.

Cost

Many states have attempted to lower the cost of health insurance by creating high-risk pools that organize high-risk individuals (individuals with preexisting medical conditions, individuals employed in small businesses, and others) into larger groups, thereby spreading the risk of insurance across the larger group of people. These high-risk pools do require higher premiums, but they provide insurance access that would otherwise not exist. The states have also provided liability protection to insurance companies (reinsurance) to limit the insurance companies' exposure from high-risk individuals' insurance claims. The states also have lowered health insurance costs by allowing decreased benefits (however, this can decrease quality). However, states have limited means to actually decrease the costs of healthcare.

Quality

Many states have attempted to increase the quality of care via expanded coverage within the state-sponsored entitlement programs or through rules mandating specific coverage benefits that insurance products must offer. Some states have set up commissions to address the quality of healthcare.

Types of State Initiatives

The individual states have taken several specific initiatives to increase health insurance coverage. These initiatives include the following: expanding eligibility for Medicaid and other federal programs, offering reinsurance, creating high-risk pools, establishing mandated and limited-benefit plans,

imposing individual mandates, allowing group purchasing arrangements, adding dependent coverage, and providing administrative assistance.

Medicaid and Other Federal Programs

Medicaid is the nation's largest health insurance program for the poor, covering over 40 million Americans. Medicaid is a joint federal-state government program. It is financed by both the federal government and the individual states. The federal government matches state spending on qualified Medicaid recipients.

Both the federal government and the states set the rules for Medicaid eligibility. The Medicaid program was created by the federal government to provide health insurance to needy members of society—impoverished families with children, the disabled, and elderly individuals. As a federal program, Medicaid is not a purely state-based coverage initiative; but the states define eligibility (within limits) and administer their own Medicaid programs. The federal government establishes some minimum and maximum eligibility criteria, but the states have some flexibility in determining who qualifies for Medicaid. Additionally, multiple waivers are available to allow the states to expand coverage beyond their historical limits. As a result, state control of the Medicaid program is the most important means for a state to provide coverage for its uninsured residents.

The states may expand Medicaid eligibility beyond the federal criteria, but matching federal funds will not be provided unless the state has a waiver for the expanded coverage. Certain groups are eligible for Medicaid, including children living under a specific federal poverty level, parents of children living under a specific federal poverty level (which differs from state to state), pregnant women below the poverty level, elderly and disabled social security insurance beneficiaries with incomes less than the poverty level, some working disabled, and Medicare buy-in groups. Other groups, if designated by the state, are allowed to be covered with-outspecial waivers. These optional Medicaid-eligible groups include some subsets of the same groups (children, parents of children, disabled, and elderly) that exceed the specific federal poverty limits—for example, children over the age of 6 who live over 100% of the federal poverty level but are still

impoverished by state-set standards. Other groups, such as the medically needy, may be permissible. The federal government sets specific guidelines for these groups, but multiple avenues exist for states to try to expand coverage and still receive matching funds. The flexibility of coverage criteria results in a wide range of eligibility standards from state to state. This range of eligibility variability will likely continue to expand.

The federal Personal Responsibility and Work Opportunity Reconciliation Act of 1996, better known as the Welfare Reform Act, created options for the states to expand Medicaid. The provisions in Section 1931 of the act require states to continue to cover families with incomes below the 1996 Aid to Families With Dependent Children (AFDC) income limits regardless of whether they receive cash assistance. More important, Section 1931 gives states greater flexibility to extend eligibility to more low-income families. The states are allowed to disregard some of an individual's income or assets. By ignoring some income or assets, many additional individuals meet the federal criteria for poverty.

Federal SCHIP allows states to provide health insurance coverage to uninsured children in low-income families that are not otherwise eligible for Medicaid. The states are allowed to include children from families with higher income levels than otherwise allowable. Additional funds were designated for this program, and additional rules for copayments and benefits are allowed. The federal matching rate is higher for this program than for traditional Medicaid, but the total SCHIP funds available to all the states, in aggregate, are capped, and new funds will determine the future of this program.

The federal Ticket to Work and Work Incentives Improvement Act of 1999 provides another way to increase Medicaid eligibility. Under this law, states may permit working individuals with disabilities to maintain their Medicaid eligibility.

Another major initiative of the federal government to encourage the states to explore novel ways to expand coverage is Section 1115 of the Social Security Act. This law allows the federal government to waive certain Medicaid requirements in order to conduct pilot, experimental, or demonstration projects that expand or improve health insurance coverage.

In 2001, the Health Insurance Flexibility and Accountability Act expanded Section 1115. It encourages new comprehensive state approaches to increase the number of individuals with health insurance coverage with current-level Medicaid and SCHIP resources. However, these new initiatives cannot increase a state's federal matching funds.

Reinsurance

Reinsurance, insurance for insurance companies, provides an avenue for insurance carriers to lower their risk and therefore lower the premiums they charge. The state is likely to be the source of the reinsurance, but reinsurance can be a private enterprise that is encouraged by the state. The reinsurance is specifically created to cap the risk exposure from high-risk health insurance policies. The reinsurance premium is paid by the insurance carriers in exchange for limiting their risk. For example, maximum 1-year claims may be capped at a predetermined figure. Any claims higher than the capped amount would be covered by the state reinsurance fund. Limiting the insurance carriers' liability should entice the carriers to offer policies to higher-risk individuals, groups, or small businesses. Only a few states currently have reinsurance plans.

High-Risk Pools

High-risk pools create a source of health insurance to high-risk individuals who could otherwise not access it. The high-risk pools attempt to create an option for individuals who are the most difficult to insure—those who do not qualify for entitlement programs, have preexisting medical conditions, and do not have access to group insurance policies. The high-risk pools are state associations specifically created as a last option for health insurance. Most states have created high-risk pools. The federal Health Insurance Portability and Accountability Act of 1996 (HIPAA) requires that people leaving a group health insurance policy be able to access an individual policy. Each state sets its own premium rates (usually significantly higher than group insurance rates) and then uses specific insurance carriers to administer the health insurance. High-risk pools usually require additional funds to cover the claims expenses, as many of the

covered individuals have costly healthcare needs. Most states view high-risk pools as a last resort and establish strict guidelines on accessing them to encourage individuals to seek other options first.

Mandated and Limited-Benefit Plans

State legislatures require health insurance policies to offer specific benefits. Each state has its own list of mandated benefits. Most of these mandated benefits are essential and needed safeguards, while a few of the mandates emerged as reactions to isolated public events. These mandates generally increase the quality of healthcare, but they also increase overall healthcare expenses. In an attempt to make health insurance more affordable, and thereby increase coverage, many states have allowed (and/or encouraged) insurance carriers to offer bare-bones policies. These policies usually suspend the state mandates and frequently offer a reduced set of healthcare benefits, such as catastrophic coverage only.

Several states have limited-benefit plans, but their effectiveness in expanding coverage has been small. The limited-benefit plans tend to be only slightly less expensive than comprehensive plans; they do not sell well, and insurance companies do not like to market them. Additionally, when individuals who previously had a comprehensive plan purchase limited-benefit plans, many of them actually reduce their health coverage, creating an unintended effect.

Individual Mandates

Individual mandates require individuals to obtain health insurance coverage. Presumably a financial penalty (added to an individual's state tax obligation) would ensue for those failing to obtain health insurance. Individual mandates have been passed by a few state legislatures, but they have not been effective. Impoverished or low-income individuals, those most likely to be uninsured, do not generally pay state income taxes.

Group Purchasing Arrangements

Group purchasing arrangements are small groups or individuals who join together to purchase health insurance. The goal is to create a large

group that can qualify for lower health insurance premiums. Group purchasing arrangements can be formed outside state governments, but many states have organized these groups to facilitate individual purchase of health insurance. Little evidence exists, however, that these groups actually have access to less expensive health insurance.

Dependent Coverage

Dependent coverage allows minors to receive health insurance through their parent or guardian. Young people older than 18 years often go without health insurance. Several states have changed laws to allow these individuals to continue qualifying for dependent coverage past age 18 and school enrollment. These arrangements are quite effective as the dependent coverage can be reasonably priced and involves no expense for the states.

Administrative Assistance

Some states encourage their residents to access health insurance by providing various kinds of administrative assistance. For some states, this means offices to enroll residents in Medicaid, but for other states the assistance can be quite extensive. Some states attempt to find private insurance or offer additional state financial benefits for individuals who use local government medical services.

Federal Limits on State Power

The federal Employee Retirement Income Security Act (ERISA) of 1974 created employer mandates for health insurance coverage. This federal law sets guidelines for companies offering health insurance coverage. The states may not pass laws with additional health benefit rules for specific companies. As a result, no state can expand health insurance coverage by placing the burden on business enterprises. However, the states are allowed to raise revenues from businesses and individuals to pay for state health insurance coverage schemes. Several states have implemented "play or pay" laws that force businesses to pay additional taxes if they do not provide additional state-mandated coverage. These laws seem to be allowable by the courts if the businesses are given a real option between the tax and employer-sponsored insurance. If the tax

poses a choice that is not much better than providing employer-sponsored insurance, it is unlikely to be considered legal under ERISA.

Future Implications

Increased globalization and the competitive economy are pushing many companies to decrease employer-sponsored health insurance. Without a national health insurance program, the states are being forced to develop expanded coverage systems. The states have implemented and proposed a wide variety of health coverage initiatives. State-based coverage initiatives have explored a range of proposals, but no state has successfully eliminated the problem of the uninsured. Many proposals are being tested, and many remain to be explored. As some states are finding ways to expand coverage, other states may follow their lead.

STATE CHILDREN'S HEALTH INSURANCE PROGRAM (SCHIP)

The federal Balanced Budget Act of 1997 created the State Children's Health Insurance Program (SCHIP) as part of Title XXI of the Social Security Act. SCHIP is the single largest expansion in health insurance coverage since the enactment of Medicaid in 1965. The goal of SCHIP is to increase the medical coverage of low-income, uninsured children up to the age of 19 by extending eligibility for public insurance to children in families earning too much to qualify for Medicaid yet earning too little to afford private health insurance, which generally includes families earning between 100% and 200% of the federal poverty level. The SCHIP legislation apportioned more than \$40 billion in federal matching funds over 10 years beginning in FY1998. States are allowed to use these funds to expand Medicaid eligibility, develop new insurance programs, and increase outreach for children already eligible for public coverage.

Program Design

Like Medicaid, SCHIP is a joint federal-state program, though SCHIP offers states more flexibility with respect to eligibility criteria, program design, and benefits. States had three broad options for

implementing SCHIP. They could expand their Medicaid programs by either increasing income eligibility thresholds or extending coverage to age groups that were not eligible for Medicaid previously, create a new separate health insurance program for children, or do both. At the time of implementation, a key argument for expanding Medicaid was that states could build on existing infrastructure for administration, enrollment, and processing of claims. The main disadvantages of this approach were the requirement of conforming to existing federal rules that some states considered burdensome as well as the effect of any negative reputation associated with Medicaid. The main argument for creating a new insurance program for children was that it would allow greater flexibility in designing a program that better met the needs of children in a particular state. However, a separate program must contend with the potentially higher costs associated with start-up and outreach.

Unlike Medicaid, the law creating SCHIP included specific provisions that mandated states to include outreach efforts as a part of their expansion. As part of this effort, states created television, radio, and print advertising campaigns to increase awareness about the programs. Toll-free information lines and Web sites were also established. In California, for example, the outreach campaign included two main components, (1) the use of community-based "application assistants" to reduce the process and outcome costs of enrolling and (2) a media campaign to increase awareness of the program and reduce the information costs of enrolling, with roughly \$7 million devoted to each component in the 1st year. Nearly every state also instituted a number of administrative reforms, such as simplifying application forms and eliminating face-to-face interviews, which had previously been required of Medicaid applicants.

Another innovative aspect of SCHIP is the explicit attempt to limit the degree of substitution from private insurance in favor of public insurance, or crowd-out. The most common strategy taken by states to reduce crowd-out was the requirement that children be without health insurance coverage for some period of time (typically 3–6 months) prior to enrolling in the program. In addition, a few states used sliding-scale premium contributions for families with incomes above 150% of the federal poverty level and subsidies to

encourage parents to take up employer-based health insurance coverage when it was available.

Like Medicaid, SCHIP financing features a federal matching rate for state dollars contributed to the program. The federal medical assistance percentage (FMAP) is the rate at which the federal government shares the expenditures associated with each state's Medicaid program. The FMAP formula is calculated annually and is a function of the average per capita income of the state relative to the national average. States with lower average per capita incomes receive a higher FMAP, while states with higher per capita incomes receive a lower FMAP. To encourage state participation in SCHIP, states receive an enhanced FMAP for their SCHIP expenditures. While the Medicaid FMAP ranges from 50% to 76% in FY2006, the enhanced SCHIP FMAP ranged from 65% to 83% across states.

Title XXI of the Social Security Act specifically states that children with insurance, including children with Medicaid coverage, are not eligible to enroll in SCHIP. To prevent states from shifting enrollees from Medicaid to SCHIP to take advantage of the more generous federal matching rates, the legislation requires that children who apply for SCHIP be screened for Medicaid eligibility and those found to be eligible only be enrolled in Medicaid. Because of this rule, it is possible that SCHIP "marketing" may have indirectly increased the Medicaid enrollment of children who were already eligible for but not covered by that program.

The benefit package for SCHIP enrollees was mandated to contain at least the benefits required for Medicaid recipients, though additional benefits could be added by states if they chose.

Implementation

States implemented SCHIP at various times and in various ways. Thirty-four states enacted their programs in 1998. Eleven states did so in 1997, and the remaining six states began in 1999 or 2000. Nineteen states have expanded their Medicaid programs to include SCHIP, 15 states created a separate new program, and 17 states implemented a combination of expanded Medicaid and the new program. States that implemented both Medicaid expansions and a separate SCHIP expansion were

able to start these components at different times, usually expanding Medicaid eligibility first.

States differed in their initial preprogram eligibility criteria, and within states, rules tended to be more generous for younger children. Prior to SCHIP, states were required to cover children 6 years of age and under up to 133% of the federal poverty level and were allowed to expand coverage up to 185% and still receive federal matching dollars. As of 1996, several states had used their own funds to expand eligibility beyond 185% of the poverty level. Since eligibility increases were larger in states that previously had lower eligibility limits for Medicaid, the SCHIP expansions have reduced the cross-state variation in public insurance eligibility standards. Likewise, in many states, prior to SCHIP, income eligibility limits were substantially higher for younger children than for older children. By increasing income limits more for older than for younger children, the SCHIP expansions largely eliminated this within-state variation in eligibility.

Effects on Insurance Coverage

The early experience with SCHIP was fraught with some degree of anxiety that enrollment was not meeting expectations. Some of this concern might have been rooted in the ambitious nature of many state expansion plans. A large number of studies have examined the impact of SCHIP on children's health insurance coverage. Fewer studies have examined the effect of SCHIP on children's health.

The best available evidence points to a modest effect of SCHIP on the health insurance coverage of children. Studies have found that about 8% to 10% of children meeting eligibility standards for SCHIP enrolled in the new program.

Recent Developments

In 2007, SCHIP came up for reauthorization. Considerable disagreements were apparent between those who wanted to expand the income eligibility limits for the program and those who wanted to maintain the status quo with respect to the program. Several expansion bills were passed by the U.S. Congress but were vetoed by the President. Ultimately, the program was not expanded.

In December 2007, the U.S. Congress passed—and the President signed—the Medicare, Medicaid,

and SCHIP Extension Act to continue SCHIP coverage through March 2009. This legislation maintains the current federal SCHIP funding level at \$5 billion a year. The bill also includes additional funds for states with projected shortfalls.

The ongoing reauthorization debate over SCHIP has created uncertainty among states regarding their programs. Several states, anticipating a lack of federal funding, are operating on contingency plans. Others have established enrollment caps and implemented more cost-sharing measures, including increasing premiums.

STEVENS, ROSEMARY A.

Rosemary A. Stevens is a well-known and highly respected social medical historian. She began her career as a National Health Service (NHS) hospital administrator in Great Britain, and much of her subsequent academic work describes comparatively the orientation of healthcare in the United Kingdom and the United States. In her various scholarly works, Stevens has described how American hospitals are unique: a combination of public and private institutions that are at once charities and businesses, social welfare institutions and icons of American science, wealth, and technical achievements. This rare combination of public and private is different from hospitals in other advanced nations, especially her native United Kingdom. American hospitals have little concern with improving public health. Also, many professional healthcare organizations function largely as interest groups, jostling with others for political favors. Stevens' work is an alternative vision—one in which professionals, healthcare institutions, and government serve the public interest. She describes the American healthcare system without bitterness or anger. According to Stevens, this is how it is; it is not all bad, but it could be better.

Born in Lincolnshire, England, in 1935, Stevens attended Oxford University as an undergraduate, majoring in English literature. Later, she pursued graduate studies at Yale University, earning a master of public health degree in hospital administration and medical care in 1963 and a doctoral degree in epidemiology in 1968. After graduation, she taught at Yale University for 8 years, followed by a 2-year appointment at Tulane University. In 1979, she joined the University of Pennsylvania, where she has spent most of her career. Stevens served as chair of the department of history and sociology of science from 1980 to 1983 and again from 1986 to 1991, when she was appointed the first woman dean of the University of Pennsylvania's School of Arts and Sciences. In 2002, she moved to Cornell University. Currently, she is the DeWitt Wallace Distinguished Scholar at the Weill Cornell Medical College in New York City.

Stevens's scholarly works include *Medical Practice in Modern England: The Impact of Specialization and State Medicine* (1966) and

American Medicine and the Public Interest (1971). In 1974, in conjunction with Robert B. Stevens, she published *Welfare Medicine in America: A Case Study of Medicaid*. This was followed by *In Sickness and in Wealth: American Hospitals in the Twentieth Century*—arguably her best-known work. Stevens organized and coedited *History and Health Policy in the United States: Putting the Past Back In*. Her most recent book, *The Public-Private Health Care State: Essays on the History of American Health Policy*, includes 17 of her essays, spanning a 40-year period, from 1961 to 2001.

Stevens has received many awards and honors. For example, she received the Robert Wood Johnson Foundation Investigator Award in Health Policy Research for the years 1998–2003. In 2003, she received the Lifetime Achievement Award from the American Association for the History of Medicine. She also has been given four honorary doctoral degrees.

Stevens has served on numerous boards and committees, including the American Board of Medical Specialties, the Educational Commission for Foreign Medical Graduates, and the Milbank Memorial Fund. She has been a member of the National Academy of Sciences, Institute of Medicine (IOM), since 1973.

STRUCTURE-PROCESS-OUTCOME QUALITY MEASURES

Avedis Donabedian (1919–2000), a physician and professor of public health at the University of Michigan, first proposed the conceptual model of assessing the quality of healthcare using structure-process-outcome measures in the 1960s. Donabedian's model continues to be widely used for evaluating quality within healthcare. Structure measures in the model include the characteristics and traits of the healthcare providers, their tools and resources, and their physical and organizational work settings. Process measures include the set of activities that occur with and between the providers and patients. Outcome measures include the change in a patient's current and future health status due to the care he or she received. Each of these measures is discussed in more detail below, along with the methods used to obtain information, research studies using this model, and future implications.

Structure Measures

Structure measures refers to the conditions under which care is provided, with the notion that if the structure is appropriate, good-quality medical care will follow. Material resources such as adequacy of facilities and equipment are taken into consideration, as are professional and organizational resources that support and direct provision of care (e.g., staff credentials, facility-operating capacities, performance review, and fiscal organization). Donabedian's concept of structure is especially relevant for organizational learning, in terms of encompassing the more stable characteristics of the care delivery system: staffing, equipment, facilities, and the way these are organized to deliver care. It also includes formalized organizational routines, such as the process of passing patient information across shifts.

Using structure to measure the quality of care leads to relatively concrete and accessible information. Structure data are essential to system-level organizational learning and improvement. The primary limitation in using structure is that the relationship between structure and process or structure and outcomes is rarely well established.

Process Measures

Process measures of quality refer to things done to or for the patient by practitioners in the course of treatment, including clinical history taking, the appropriateness and thoroughness of physical examinations, the number and type of diagnostic tests given, and technical competence in diagnostic and therapeutic procedures such as surgery. Other process measures include preventive management, coordination and continuity of care, referral criteria, and patient education. Estimates of quality obtained through process measures are not as stable or final as those obtained from outcome measures. Many times, process measures are used to identify whether medicine was practiced properly or not. Process-of-care evaluation has several advantages. It is directly related to the practice of medicine and is relatively easy to conduct. Many diseases have established, peer-reviewed models on which to base evaluations. In addition, data can be analyzed for population studies or health delivery systems where computerized data networks are available. Such measurements provide direct indicators to the areas needing quality improvement.

Two methods are used to measure process quality: explicit and implicit review. Explicit review is based on analyzing medical care from medical records. Under ideal circumstances, the analysis should be based on a set of concrete values formulated by experts or recognized professional organizations such as the American Heart Association. The measurement criteria are developed after careful evaluation of clinical trials, cohort studies, and established practice protocols to produce evidence-based quality indicators. Explicit reviews suffer some drawbacks in that the complexity and variety of medical care makes congruency in formulating such indicators difficult, and each organization can have different criteria. Also, they can be incomplete and fail to reflect the totality of care offered to a patient, as not only physicians are involved in care. To make explicit reviews more meaningful, there is a need to identify the processes that truly improve outcomes and correlate them with clinical judgments individually and not collectively, as each person can have unique factors that can influence outcomes.

In contrast, implicit review involves a personalized, critical appraisal of the quality of care

received and has no set protocols as yet. It is particularly relevant to physicians, as it takes into consideration the exigencies and limitations of the situation while administering care. Medical errors are commonly subjected to implicit reviews, which can be expensive and time-consuming. There can be significant differences in assessments between reviewers due to divergence of views in the absence of set protocols. Attempts to improve the quality of implicit reviews include the creation of standard review forms and coding criteria, aggregating scores, and making statistical adjustments for bias. Other changes include the process of simplifying the clinical factors under review to eliminate reviewer bias and the tendency to give credence to outcomes over process.

Quality improvement research suggests that process measures are more sensitive than outcome measures to differences in quality across providers and/or time. Process measures are easier to interpret, partly because accountability is clearer.

Outcome Measures

Outcome measures are the desired states resulting from care processes. Outcome measures such as recovery, restoration of function, and survival have been frequently used as indicators of the quality of medical care. Technical outcomes encompass the physical and functional aspects of care, such as the absence of postsurgical complications and the successful management of chronic conditions, while interpersonal outcomes encompass dimensions of the “art” of medicine, such as patient satisfaction with care and the influence of care on the patient’s quality of life as perceived by the patient.

Outcome measures can also be divided into five broad categories: death (mortality), disease (morbidity), disability (days of disability, work loss), discomfort (pain), and dissatisfaction (patient dissatisfaction, compliance with treatment regimens, provider retention). Excessive focus on the worst outcomes, such as death and severe disability, could lead to insufficient attention to prevention of minor disabilities, discomfort, and dissatisfaction.

Theoretically, lower mortality and morbidity rates, fewer readmissions or hospitalizations, and higher quality-of-life measures are equated with better quality of care. However, blind acceptance

of these statistics is not justified, as these numbers may not adequately reflect the case-mix differences in various categories of hospitals. For example, a large inner-city public hospital may treat patients with more complications, due to delays in seeking care because patients lack health insurance coverage, as compared with a suburban private hospital. To compare outcomes without accounting for these differences may lead to biased and false conclusions. Such measures act as disincentives to offering treatment to disadvantaged and more severe patients, to preserve rankings, and they also perpetuate disparities in care. There are few case-mix computerized data models available on which a fair evaluation of surgical and medical outcomes can be made. To improve quality-of-care outcomes research, it is imperative to create and use such assessment tools. In the absence of such tools, limited case-mix models are being used to judge whether quality of care was optimal at all levels: emergency department, inpatient, outpatient, and follow up.

Outcome measures can be viewed from several different perspectives, depending on the objectives of a study. Long-term, intermediate, and short-term outcomes need to be judged on different criteria. Consider, for example, patients suffering from heart attacks; for these patients, prevention of death soon after the attack is a short-term outcome involving different levels of care, while the long-term morbidity, quality-of-life, and mortality outcomes are viewed differently. Health outcomes are governed considerably by many factors outside the clinical domain, including social, psychological, environmental, socioeconomic, and personal factors, which need to be accounted for when studying health outcomes. Patients’ preferences for treatment and adherence to it, their will to recover, and their assessment of quality of service are difficult to quantify, though these may significantly influence health outcomes.

Outcome measures tend to have more face validity than process measures and are more meaningful in the discussion of patient safety. Outcomes tend to be concrete, and the use of outcome measures lends itself to precise measurement where validity is rarely questioned.

The advantages of outcome measurement include the ease of measuring concrete factors such as death or functional recovery from strokes or

injuries. They can be used as screening tools to indicate the areas that need process measurement to improve the quality of outcomes. The disadvantages of outcome measurement are that they tend to be focused on aggregate data rather than on individual cases. They are therefore not equipped to change individual behaviors. Second, they are retrospective, so that on-the-spot treatment decisions cannot be analyzed and changed for the better. Third, outcome measures have scant correlation to process measures in many areas, thus limiting reliance on outcome measures exclusively. Last, most patients receive care from several different physicians and facilities over their lifetimes, thus blurring the clear delineation of entry to and exit from care and the fixing of responsibility. The high costs of conducting such evaluations also act as barriers.

Several limitations exist in using outcome as a quality-of-care measure. Sometimes a particular outcome measure is irrelevant, or the outcome measure is not the most relevant measure. Factors outside medical care, such as genetic factors and personal history, can influence the outcome. Some outcomes are not clearly defined or can be difficult to measure: patient attitudes and satisfactions, social restoration, physical disability, and rehabilitation. The limitations of outcome measures do not mean that they are inappropriate indicators of quality; they just simply must be used carefully.

Sources and Methods of Obtaining Information

Patient medical records are often used for assessing the quality of healthcare. However, questions arise about how thorough or appropriate these records are as a source of information. For example, are the records complete, is the record or the care provided being rated, and should the entire record or only the abstracted information be used for evaluation purposes?

Patient medical records are often not adequate to serve as a basis for evaluation in general practice. Observation of a physician by a qualified colleague is the best alternative, though some dimensions of care are not observable and would not be included in the evaluation. The major limitation of direct observation is the change of usual practice by those who know that they are being observed.

Studying behaviors and opinions is an indirect method of obtaining information about quality. For instance, in seeking care for themselves and their families, physicians exhibit critical and valid judgments concerning the capacity of their colleagues to provide a high quality of care. An *auto-reputational* approach is one in which hospital personnel (managerial, profession, and technical) and knowledgeable community members rank and rate the hospital's quality of medical care.

Patient evaluation constitutes the consumer's perspective of the quality of care. Healthcare organizations and practices exist to serve patients, and their objective is to satisfy consumer needs and aspirations to the best of their ability. Collecting patient feedback provides valuable insights into perceived shortfalls in treatment and care and is gaining increasing acceptance as a way to evaluate quality of care. Patient evaluations are also able to provide feedback on organizational shortcomings in structure and process measures, such as long waiting times, unsatisfactory clinical care, or wrong billing. Constant review of patient evaluations is helpful in initiating changes to improve the overall quality of care.

Research Studies Using the Model

Most research studies using the structure-process-outcome model examining ambulatory care have focused on structure and the process of care rather than the outcomes of care. Physician characteristics that were found to be associated with greater conformity to standards of care are length of training, primary-care specialization, practicing area of specialty training, and continuing education.

In terms of inpatient hospital care, evidence supports a volume-quality relationship; that is, mortality rates are lower in high-volume facilities. A variety of structural measures have not been conclusively associated with outcomes, including: public versus private institutions, teaching hospitals and patient satisfaction, physician capabilities (board certification, years of experience), and nurse to patient staffing ratios. Higher registered nurse staffing and years of nursing experience have been found to be associated with better postsurgical outcomes but not with mortality rates.

Studies of the association between nursing home structure and resident-care outcomes focus

on capacity and capability measures. Outcome-centered studies demonstrate the lack of a consistent relationship between bed size and measures of mortality, discharge status, patient functioning, patient satisfaction, and quality of life. Registered nurse to resident ratios have been found to be associated with better physical functioning, lower mortality rates, higher likelihood of discharge back to the resident's home, and less unnecessary hospitalization.

A serious lack of information exists concerning whether structural characteristics make a difference in outcomes of home health care services.

The structure-process-outcome model is frequently used for assessing internal quality-of-care measures, which do not need to be very stringent. There is a lack of computerized systems that provide data on the continuum of care, so essential in managing chronic diseases, which now form the bulk of medical care. The use of integrated health systems that have community outreach is necessary to really assess quality outcomes in healthcare. This is now the focus of many health services researchers who are implementing such models.

Future Implications

Health services research using structure-process-outcome quality measures focuses on organizational capacity and capability. Concepts of structure and outcome are evolving as perspectives on what constitutes meaningful measures have changed.

The accrediting organizations, the government, and the general public are increasingly demanding quality and patient safety data from healthcare organizations. Clinical practice guidelines designed to capture the essence of state-of-the-art and evidence-based care have become more prevalent. And efforts to measure patient satisfaction have grown.

However, many challenges remain in identifying excellent quality of healthcare. Clinical knowledge is constantly changing; therefore, the definition of quality healthcare must evolve. Furthermore, individual patients tend to value different aspects of care. Researchers suggest

broadening the current quality measurement lens, specifically incorporating patient preferences, and adding a focus on the organization. Encouraging the development and use of integrated, computerized systems that can provide data on parameters of quality of care in its continuum will likely help improve the quality of healthcare at all levels.

SUBSTANCE ABUSE AND MENTAL HEALTH SERVICES ADMINISTRATION (SAMHSA)

The Substance Abuse and Mental Health Services Administration (SAMHSA) is a unit of the U.S. Department of Health and Human Services (HHS). Established in October 1992 as a result of Public Law 102-321, SAMHSA has as its statutory mission the provision of prevention and treatment services for people at risk of or suffering from mental or substance abuse disorders. SAMHSA works in partnership with states, communities, and private organizations to address the needs of people with substance abuse and mental illnesses as well as the community risk factors that contribute to these illnesses. SAMHSA's most recent strategic plan describes its vision as providing a life in the community for everyone and its operating mission as the building of resilience and facilitating recovery. A matrix of priorities based on cross-cutting principles and programs and issues delineates the overall scope of its services and program expectations.

Background

Prior to the creation of SAMHSA in 1992, the Alcohol, Drug Abuse, and Mental Health Administration (ADAMHA) was charged with both drug and alcohol research and the provision of treatment services. A study in early 1992 led to the decision to separate the research function from the treatment function to more efficiently and effectively use resources. As a result of this study, SAMHSA was created to provide treatment and mental health services, and research funding was moved to the National Institutes of Health (NIH), where two institutes—the National Institute for Drug Abuse (NIDA) and the National Institute on Alcohol Abuse and Alcoholism (NIAAA)—serve as the repositories for research into alcohol and drug abuse. A third NIH institute, the National Institute of Mental Health (NIMH), conducts and supports research on mental health and mental illnesses.

In the decade leading to the restructuring and creation of SAMHSA, efforts to use a public health

model with community treatment options for mental health issues were slowly being included in state health plans for services. Efforts also evolved to move services, particularly in mental health, from institutional models to community-based care. In addition, a core value in the creation of SAMHSA was to link services more closely to the results of research models validating an evidence-based framework for service delivery.

Structure and Function

SAMHSA is organized into three centers and an office. The units are the Center for Mental Health Services (CMHS), the Center for Substance Abuse Treatment (CSAT), the Center for Substance Abuse Prevention (CSAP), and the Office of Applied Studies (OAS).

Specifically, the CMHS is charged with improving the quality of and access to mental health services, particularly for those who are underserved. The CSAT promotes the quality and availability of community-based substance abuse treatment services for individuals and families. The CSAP works with states and communities to develop comprehensive prevention systems that create healthy communities in which people enjoy a high quality of life. The OAS serves as a focal point for data collection and analysis and for dissemination of critical public health data to assist policymakers, providers, and the public in making informed decisions regarding the prevention and treatment of mental and substance abuse disorders.

The CMHS leads government efforts to treat mental illnesses by promoting mental health and by preventing the development or the worsening of mental illnesses if at all possible. The center currently has initiatives in the areas of adults with severe mental illnesses, including those who are homeless; services to children and adolescents; emergency mental health and traumatic stress services; and work with jail and prison populations. It also works collaboratively with the other two SAMHSA centers to study the impact of managed care on services to individuals with substance-abuse-related needs. Public health education, advocacy, and data collection and analysis round out the scope of initiatives that are the primary responsibility of the center.

The CSAT works with states and community-based groups to improve and expand existing substance abuse treatment services under the Substance Abuse Prevention and Treatment Block Grant Program. The center supports a free treatment referral service to link people with the community-based substance abuse services they need. Programs and initiatives supported by the center embrace the philosophy that treatment and recovery work best in a community-based, coordinated system of comprehensive services. This philosophy is based on research and a consensus of experts in the addiction-care field. The center also supports the nation's effort to provide multiple treatment modalities, evaluate treatment effectiveness, and use evaluation results to enhance treatment and recovery approaches so as to reach the greatest number of individuals in need of services.

The CSAP provides leadership in the federal effort to prevent alcohol, tobacco, and other drug problems. The center has developed a model for prevention called the Strategic Prevention Framework (SPF), which aims to promote youth development, reduce risk-taking behaviors, build assets and resilience, and prevent problem behaviors across the individual's life span. The SPF is a five-step process—assessment, capacity, planning, implementation, and evaluation—and is designed to create sustainable and culturally relevant prevention services. Programs supported by the center's funds must use the SPF and be based on or adapted from recognized model programs.

Last, the OAS is responsible for providing data to the public related to the incidence of alcohol and drug use, drug-related emergency department treatment and deaths, and the treatment network of services. The data provided help support planning and budget efforts and validate the outcomes of efforts by SAMHSA-funded programs.

SUPPLIER-INDUCED DEMAND

Traditional economic theory assumes that the market for health services is characterized by an upward-sloping supply curve and a downward-sloping demand curve. Patients are assumed to be rational consumers who make informed utility-maximizing choices, while physicians are profit maximizers. The theory predicts that an excess supply of physicians in relation to the population will result in an outward shift of the physician supply curve, lower fees charged for services, and lower revenues. To avoid the loss of revenues, most economists believe that physicians exploit the information asymmetry (a result of patients' lack of clinical knowledge) in the market for their services and shift the demand curve up, resulting in higher revenues. This phenomenon is termed supplier-induced demand. It occurs when a physician has a financial incentive to recommend treatments whose medical benefits are outweighed by

the costs. Supplier-induced demand is equated with unethical behavior because of the social welfare loss associated with inefficient treatment. Due to the prominent role physicians play in the healthcare industry, cost control measures will be difficult to implement under supplier-induced demand. By studying this phenomenon, policymakers will be able to design and develop relevant tools to minimize waste and improve access to healthcare.

Traditional economic theory predicts that when physicians have mixed patient caseloads (Medicare, Medicaid, and privately insured patients), a decrease in the fees charged to Medicare and Medicaid patients will result in substitution and income effects. Under the substitution effect, physicians will reduce their Medicare patient caseload and treat more privately insured patients. The income effect will result in the delivery of more services to both the Medicare and the privately insured patients to make up the income lost from the reduction in fees paid by Medicare patients. The observed increase in services to privately insured patients is consistent with both physicians' profit-maximizing behavior and demand inducement.

Why is demand inducement an interesting problem for economists to study? In addition to the waste involved, the existence of demand inducement contradicts the predictions of neoclassical economic theories of demand and supply, where the excess supply of physicians should lead to fee reductions. Proponents believe that if the market does not work as expected for physician services, the practitioners must be inducing demand. While this observation may be true, it does not consider the uncertainties involved in medical decision making.

The Demand Inducement Literature

Under the competitive model, physicians are expected to be perfect agents for their patients and should not induce demand for personal financial gains. An increase in physician density relative to population must result in decreased fees and utilization. Researchers have investigated the impacts of physician density, fee changes, physician monopoly power, and target income on the existence of supplier-induced demand.

Impact of Physician Density on Demand Inducement

The evidence of demand inducement using physician density has been ambiguous. Most of the researchers did not control for quality in their studies. If physician density increases, physicians could respond to market competition by differentiating the services delivered based on quality. Under normal circumstances, quality of care is an increasing function of time spent per patient during visits. Patients who value quality must be willing to pay more for higher-quality care. Using time per patient visit as a proxy for quality care, some researchers found that physicians react to increased competition by increasing the time spent per patient visit. Patients were also willing to pay more for longer time spent during visits. This result is attributable to improvements in the quality of care under competition rather than demand inducement. One study found that as the number of competing physicians increases in a given location, fees decline if quality is not controlled for. However, physicians reduce the time spent seeing Medicaid patients (substitution effect) when there is increased competition, while spending more time with the privately insured patients. In general, to survive in physician-dense areas, providers must deliver higher-quality care at higher fees and earnings per patient. This evidence is consistent with nonprice (quality) competition and does not necessarily reflect demand inducement.

Impact of Fees on the Supply of Services

An alternative method of testing for demand inducement relies on the relationship between the fees paid to physicians and the supply of services. Traditional economic theory predicts that when payments to physicians are reduced, they should not induce or create unnecessary demand in order to maintain their previous income levels. Supply of services must be reduced as predicted by the competitive-market model (upward-sloping supply curve). Here too, the evidence on demand inducement according to physician payments has been mixed. One study found that when California froze Medicaid payments in the early 1970s, physicians reacted by increasing the quality of services delivered. The same evidence of demand inducement was found among physicians in urban areas

of Colorado in response to Medicare fee reductions. Health services researchers also found that Canadian physicians responded to slow raises in physician payments by increasing the quantity and intensity of the services they delivered. However, other researchers using Canadian data found no significant relationship between fees and the utilization of certain medical procedures. The major critique of using fee reductions to test demand inducement is that fee reductions simultaneously result in lower patient copayments. A utility-maximizing consumer must react to reduced out-of-pocket payments by increasing service utilization.

The physician is assumed to be a utility maximizer where utility is a function of income. However, if leisure is an additional argument in the physician's utility function, the joint optimization of income and leisure will result in a backward-bending supply curve. This implies that depending on the level of fees, payment reductions could lead to increased delivery of services. Therefore, the evidence from using physician payments to test demand inducement is consistent with both supplier-induced demand and predictions of traditional economic theory. It is likely that physicians, acting as agents, make their decisions based on their assessment of patients' utility from treatment. The uncertainty involved in physicians' assessment of patients' utility from treatment may explain some of the lack of consensus in clinical decision making.

After controlling for fees, income, gender, and other socioeconomic factors, some researchers found a wide variation in the use of well-known medical procedures between small geographic locations. For example, in some studies, the actual variation exceeded the predicted utilization of total hip replacement by a factor of 110%; and in the case of colonoscopy, the actual variation exceeded the predicted utilization by 2,000%. The argument is that practice patterns may not strictly reflect an established set of well-defined clinical guidelines. These patterns may instead depend on the multiplicity of factors that influence clinical decision making, such as training, peer behavior, location, conference attendance, direct-to-consumer advertising, use of the Internet by patients, personal temperament and experience, financial incentives, time, age, and infrastructural capacity. Without a clear appreciation of the

uncertainties involved in medical decision making, it will be inappropriate to base cost-control or reimbursement policies on the estimated magnitude of demand inducement.

Target Income and Monopoly

The target income hypothesis postulates that physicians use their monopoly power to induce demand in order to satisfy a predetermined target income. Physicians are capable of exercising monopoly power because reputation, location, treatment style, patient preferences, and payment types combine to produce strong bonds among patients and their physicians. These bonds make it difficult for patients to easily substitute one physician for another and provide physicians with some degree of monopoly power. The target income hypothesis implies that an individual physician's behavior may be influenced by relative income. When physician density relative to population increases, physicians may exercise monopoly power by increasing their fees to achieve a target income. Since insured consumers pay only a small fraction of the cost of their treatment, physicians can raise prices without losing their patients. This behavior is aided by the fact that medical care is a credence good, where the utility impact is difficult to ascertain even after consumption. Reputation and price are possible indicators of quality for credence goods. Physicians with established reputations can exercise monopoly power and raise fees and utilization. Critics of the target income hypothesis argue that it has no foundation in economic theory. In addition, it is not known how these targets are set. Results of studies of the effects of target income on physician pricing decisions are mixed.

Future Implications

Studies aimed at identifying supplier-induced demand have resulted in contradictory or mixed results. Critics of these studies have based their arguments on the misspecification of the economic models used in many of them. The outcomes from these studies can oftentimes be justified by supplier-induced demand behavior, rational utility, and profit maximization models and by uncertainties in medical decision making. The

only study that controlled for quality found that when physician density in relationship to population increases, physicians react by differentiating their products based on quality improvements.

Few studies have addressed the uncertainties involved in medical decision making. Is there a set of gold standard guidelines that physicians have to strictly adhere to under all circumstances? If a physician's treatments deviate from the guidelines, is he or she necessarily a biased and unethical agent? Under supplier-induced demand, physicians recommend treatments whose benefits are outweighed by the costs. Medical decision making is characterized by uncertainty, and practice patterns reflect economic and noneconomic factors, including motivation, judgments, altruism, and professionalism. Therefore, there will be significant variability in observed treatment patterns and outcomes based partly on noneconomic factors. Health services researchers have documented wide variances in outcomes within specific locations after controlling for socioeconomic factors.

It has been proposed that an alternative test of the availability of supplier-induced demand is to observe the health services utilization of well-informed patients, namely, physicians. However, the findings by some researchers that physicians and their families do not use fewer medical services than their patients suggest that physicians also self-induce demand. If inducement is for private gains, then this result contradicts the accepted definition of supplier-induced demand. The ambiguity in supplier-induced demand research suggests that physicians, so as to do the best for their patients and themselves based on their medical knowledge, may overtreat or consume excessive amounts of medical services. While some physicians may exploit the gap in information for private gains, there is little evidence that this behavior is pervasive.

Membership in social networks embedded in healthcare-purchasing groups, as well as health literacy education, may diminish the information asymmetry between physicians and patients and lead to more optimal utilization of health services. Future research on supplier-induced demand must include the factors that motivate physicians to

deliver excessive healthcare services to their patients. Governments should not base cost-control policies on the concept of supplier-induced demand without understanding the uncertainties involved in medical decision making. In addition, governments must control direct-to-consumer advertising of drugs to prevent consumer-induced demand from being a confounding factor in supplier-induced demand research.

T

TARLOV, ALVIN R.

Alvin R. Tarlov is a physician, educator, and researcher whose vision and leadership have influenced physician workforce structure and training, thinking about what constitutes effectiveness in healthcare, and theory and research on the relationships between and among health and its multiple determinants.

Tarlov earned a bachelor's degree at Dartmouth College (1951) and a medical degree from the University of Chicago (1956). He completed a residency in Internal Medicine at the University of Chicago and spent 5 years conducting hematologic research.

Tarlov joined the faculty of the University of Chicago in 1964. As chairman of the Department of Medicine (1968–1981), he established the first academic division of general internal medicine in the country to address the growing problem of fragmented medical care caused by overspecialization of the physician workforce. In 1978, the Secretary of the U.S. Department of Health Education and Welfare appointed Tarlov chairman of the Graduate Medical Education National Advisory Committee (GMENAC) to advise the secretary on the most desirable number, specialty distribution, and geographic placement of physicians in each specialty. GMENAC's report stirred controversy because it refuted the commonly held belief that the geographic maldistribution of physicians and the poor health of large segments of the population could be effectively addressed by increasing the physician supply.

Struck by the lack of evidence comparing the effectiveness of medical specialists, surgical specialists, and generalists in treating specific conditions, Tarlov cofounded the Medical Outcomes Study to develop and apply measures of patients' functional capacity, well-being, and quality of life as the principal indicators of the effectiveness of medical services. This work became a bellwether in health services research as it led to a paradigm shift in thinking about the aims of medical care, the establishment of outcomes as the centerpiece of health services research, and spawned new fields of inquiry, including methodological research on functional status and quality-of-life measurement.

As President of the Henry J. Kaiser Family Foundation in Menlo Park, California (1984–1990), Tarlov developed a national program on community-based health education and disease prevention. Questioning the assumption that the substandard health of disadvantaged Americans could be explained by inadequate access to medical care, Tarlov began an interdisciplinary collaboration with sociologists, economists, psychologists, neuroscientists, and other scholars to explore the question of how social factors influence health. He convened an international conference on the social determinants of health, which led to the first book published on this topic.

Moving to Boston, Tarlov was appointed professor of medicine at Tufts University and professor of health promotion at the Harvard School of Public Health (1990–1999). He was director of The Health Institute at the New England Medical Center, devoted to research on the outcomes of medical care and on the

relationship of societal characteristics to population health. At Harvard University, he was chairman of the Mind/Brain/Behavior Society and Health Interfaculty Initiative. During this time, he developed and published a theoretical framework to describe the relationship between social inequality and social, psychological, and biological responses.

Tarlov served as director of the multiuniversity Texas Program for Society and Health in Houston (1999–2005) where he also was a professor in the University of Texas School of Public Health, professor of medicine at the Baylor College of Medicine, and Sid Richardson and Taylor and Robert H. Ray Senior Fellow in Health Policy at the James A. Baker III Institute for Public Policy, Rice University. While there, he received three statewide awards from community organizations in Texas for contributions to public policies to enhance early-childhood development and education.

Tarlov is a former Markle Foundation Scholar and National Institutes of Health (NIH) Research Career Development Awardee. He served as president of the Association of Professors of Medicine. He was elected to the national Institute of Medicine (IOM) and selected a master of the American College of Physicians. In 1992, Tarlov received from the Society for General Internal Medicine the Robert Glaser Award for Distinguished Contributions to the Advancement of General Internal Medicine. He was named Distinguished Internist of 1997 by the American Society of Internal Medicine. In May 2000, he was made an honorary fellow of University College London.

Tarlov, who is currently a professor of medicine at the University of Chicago, is completing as editor a book examining the evidence that public investment in early childhood development has greater promise and cost-effectiveness for improving population health, reducing health disparities, enhancing human capital formation, and promoting economic development than other public policy interventions designed for those purposes.

TAX SUBSIDY OF EMPLOYER-SPONSORED HEALTH INSURANCE

One explanation for the structure of health insurance in the United States is the federal tax code. The nation's tax code excludes from taxation compensation received by employees in the form of employer-sponsored health insurance. This implicit subsidy encourages people to purchase insurance through their employers and to buy more health insurance coverage than they otherwise would. Thus, the tax treatment encourages both broader and deeper coverage by individuals. A case can also be made that the tax treatment, by encouraging generous health insurance coverage, increases healthcare utilization and prices. This leads to higher health insurance premiums and to many people forgoing private health insurance coverage.

History

Private health insurance in the United States essentially began with the Great Depression and grew

through the 1930s and into the early years of World War II. However, the federal tax code was silent on whether employer-provided health insurance was to be considered income that was subject to income tax. Employers increasingly used health insurance as a means of attracting and paying scarce workers during the war years. In 1943, the Internal Revenue Service (IRS) issued a private ruling holding that employer-sponsored health insurance benefits were not subject to federal income or payroll taxation. Over the years, a series of contradictory private rulings emerged, and in 1954, the U.S. Congress passed legislation making employer-sponsored coverage exempt from federal income taxes. With the enactment of Medicare in 1965, the exemption was expanded. The states have also followed the federal lead in the definition of income subject to state income taxes and similarly exclude employer-sponsored health insurance.

Impact of the Exclusion

The tax exclusion of employer-sponsored health insurance is not a trivial matter. It was estimated that in 2006, the combined federal and state income tax and federal payroll tax exclusions reduced tax collections by \$208.6 billion. Nearly 54% were the result of exclusion from the federal income tax, and more than 35% were from the exclusion of Social Security and Medicare payroll taxes. To put these values in context, in 2006, total Medicare spending was \$402 billion. The tax subsidy for employer-sponsored health insurance is slightly over one half as much as was spent on Medicare.

The tax exclusion provides strong incentives for workers and their employers to shift the form of employee compensation. From the employer's perspective, the tax exclusion is largely irrelevant. Whether the employer compensates its employees with money wages or with health insurance, both are legitimate business expenses, and both are deducted from revenue before computing the employer's tax liability.

From the worker's perspective, the form of compensation matters. Consider a single individual, who after claiming one exemption and taking the standard deduction has a taxable income of \$45,000. Under the federal tax laws and assuming

a 5% state income tax, the individual faces a marginal tax rate of 32.64%. That is, on the last \$100 earned, the individual owes combined taxes of \$32.64. Suppose that instead of taking all the compensation as money income, the individual took some as employer-sponsored health insurance. For every \$100 of coverage the individual took through his or her employer, the individual would reduce the tax liability by \$32.64. Stated another way, the \$100 of insurance coverage effectively cost the individual only \$67.36. If the individual had taken the average insurance bundle offered to insured workers in 2006, he or she would have effectively "purchased" \$4,248 worth of coverage for only \$2,860.60. The individual can be viewed as purchasing the coverage because he or she gave up money wages that would otherwise have been received as compensation for labor.

It is worth noting that this example is in no way extreme. It is estimated that the average tax subsidy for employer-sponsored health insurance is approximately 35% of the premium.

The tax subsidy for employer-sponsored health insurance provides incentives for people to buy insurance coverage that they otherwise might have ignored. They would do this by seeking out jobs that offered health insurance and lower wages rather than just higher wages. In addition, the tax subsidy provides incentives for people to take jobs that offer more generous health insurance packages than would otherwise be the case. They might do this by seeking out employers who offer better benefits or by encouraging their employers to expand the health benefits offered.

Empirical Evidence

A number of studies have attempted to estimate the effects of differences in tax rates on the prevalence and generosity of employer-sponsored health insurance. The difficulty is in marshalling data that contain information on the relevant household tax rate and the nature of the coverage available.

One study, by Jonathan Gruber and Michael Lettau, provides the most exhaustive analysis to date. It used wage and nonwage compensation data from the 1983 to 1995 Bureau of Labor Statistic's Employment Cost Index (ECI), augmented with data on individual workers from the Bureau of the Census's Current Population Survey

(CPS) and data on family taxes from the Department of the Treasury's Statistics of Income (SOI). The ECI provided information on some 203,000 jobs in more than 48,000 firms. The compensation data were the average for all workers holding the sampled type of job. The average worker could be single or married and file an itemized or nonitemized tax return. For each of these possibilities, the study imputed the average spousal and unearned income based on the state in which the firm was located, its industry, the occupation classification of the job, and the wage rate using data from the CPS and SOI. Given these characteristics and family incomes, the study computed the relevant marginal tax rate for the household. Then, using the proportions of married people and itemizing deductions, married and not itemizing, and single itemizing and nonitemizing, it was able to compute the marginal tax and the marginal "tax price" of health insurance for the average worker in each firm. The tax rate is analogous to the 32.64% marginal rate in the example above; the tax price is the 67.36% of the insurance premium that the employee would pay after the tax exclusion. The computation of the tax price allowed the study to estimate whether or not a firm offered coverage, based on the tax status of their average employee and the generosity of the coverage, if offered.

The study concluded that a 10% increase in the tax price (a cut in taxes) reduced the probability of a firm offering coverage by 3.1%. This is in the lower tail of the range of prior estimates. Thus, the tax subsidy does encourage firms to offer coverage. The study estimates suggest that it is the workers in small firms who are the most tax-price sensitive to buying coverage through their employers.

The effects of the generosity of coverage were much larger. The study estimated that the same 10% increase in the tax price would lead firms that currently offer coverage to reduce their expenditures on that coverage by approximately 11%. This is in the middle of the earlier estimates. Based on insurance theory, such reductions would likely be achieved by eliminating coverage on things that are of lesser value to employees, such as first-dollar coverage of physician services and prescription drugs and perhaps the elimination of dental- and vision-care coverage.

The tax treatment of employer-sponsored health insurance stands in marked contrast to the

treatment afforded to individually purchased coverage. Individuals are allowed to deduct for federal income tax, but not payroll tax purposes, the portion of their health insurance premiums (plus other medical expenses) that are in excess of 7.5% of adjusted gross income. This is a very modest subsidy compared to that afforded by employer-sponsored coverage.

Consider again the individual with \$45,000 in taxable income and a marginal tax rate of 32.64%. If the individual bought insurance directly from a broker and paid the same average premium of \$4,248 as in the original example, the individual would receive a tax subsidy of less than \$300, compared with nearly \$1,400 for employer-sponsored coverage. In addition, the individual would get this only if he or she itemized the tax return.

Self-employed individuals can do somewhat better. They can deduct all their health insurance premiums prior to computing their adjusted gross income. However, the deduction may not exceed their profits, and they are not eligible to claim the deduction in any month in which they or their spouse was eligible for employer-sponsored coverage.

Proposed Changes

A number of approaches have been proposed to change the nature of the tax treatment of employer-sponsored health insurance. Of course, one could simply abolish the exclusion and treat employer-sponsored health insurance as taxable employee compensation. The study described above suggested that a total elimination would reduce spending on employer-sponsored coverage by 45%, combining both the reduction in the probability that coverage was offered and the reduced generosity. However, healthcare spending likely would be reduced by considerably less than that amount because many people would pay higher deductibles and copays out of pocket.

In 2007, the Bush administration proposed a standard deduction of \$7,500 for individuals and \$15,000 for families in place of unlimited tax exclusion of employer-sponsored coverage. This deduction was to apply whether one purchased health insurance directly or through an employer. The amount of the deduction would be fixed each year regardless of how much was actually spent on

insurance as long as they bought a qualified health plan. However, no action was taken on the proposed plan.

Such a plan could change health insurance incentives in several ways. First, by limiting the size of the deduction, it would provide incentives for those with very generous plans to cut back on their health plans. Effectively, anyone with insurance premiums above the size of the deduction would receive no further tax subsidy. Second, because the size of the deduction would be available to anyone who had a qualified health plan, it would provide incentives for people to consider reducing their benefit package even if the premium was below the size of the deduction. The tax on the difference between the deduction and the premium would be a tax refund. The individual with the \$45,000 in taxable income who took the least costly insurance plan, a health maintenance organization (HMO), offered by the employer would receive a tax refund of approximately \$450. Third, because the standard deduction applied on any qualified health plan, the tax subsidy would apply to those who purchased individual coverage as well as those who purchased coverage through an employer. Thus, there would be a new tax subsidy for non-employer-based coverage. Finally, if the standard deduction were tied to general inflation rather than medical-care inflation, it would gradually reduce the tax subsidy relative to the costs of medical care.

Both before and after the Bush proposal, a number of policy experts had proposed that the tax exclusion be replaced with a refundable individual tax credit. Under the current exclusion and under the Bush proposal, the value of the tax subsidy depends on one's marginal tax rate. Those with higher taxable incomes face higher tax rates and therefore receive higher tax subsidies for purchasing health insurance through their employers. A tax credit fundamentally changes this. The recipient of a tax credit receives a reduction in tax liability in the amount of the credit. Thus, a \$1,000 tax credit reduces one's tax liability by \$1,000 regardless of one's marginal tax rate. A refundable tax credit allows one to receive the full tax credit even if one's tax liability is less than \$1,000. Moreover, because the tax credit would not be tied to employer-based coverage, it would be available to those who purchased nongroup coverage.

Advocates tend to favor such a general tax credit for several reasons. First, because it expands the tax subsidy for purchasing coverage to all individuals, not just those with employer-sponsored coverage, more people would be likely to buy coverage. Second, because the tax subsidy does not increase with income, it reduces the incentive for those in higher tax brackets to shift more of their income into more generous health insurance plans. Third, in principle, a tax credit could be tailored to the health status of recipients, thereby providing larger subsidies to those with substantial health problems.

In addition to the replacement of the tax exclusion with a general tax credit for the purchase of health insurance, some have proposed targeted refundable tax credits for those with incomes below some level. The argument is one of providing a subsidy to the targeted group to allow them to buy coverage in the private market.

Changes in the tax treatment of employer-sponsored health insurance are not without challenges. First, if nothing else is changed, eliminating its exclusion would constitute a substantial increase in taxes that would be felt by virtually all income tax payers who have employer-sponsored coverage. Second, replacement of the tax exclusion with a standard deduction or a tax credit implies potentially large numbers of winners and losers. Such shifts are always politically difficult. Finally, the introduction of a generous standard deduction or tax credit implies that the tax subsidy will be larger than the current subsidy, suggesting substantial increases in domestic governmental spending. Nonetheless, while politically challenging, reform of the tax treatment of employer-sponsored health insurance offers the potential for both a more efficient and a fairer tax and insurance system.

TECHNOLOGY ASSESSMENT

Technology assessment is a form of policy analysis and evaluation that poses the question "What will be the social, economic, environmental, ethical, and political impacts of the introduction of a new technology?" In this sense, it is an analytic tool that is designed to provide decision makers with scientific information about the potential impacts of technology that might be introduced in the future. A technology assessment consists of three parts: (1) identification of problems, issues, and applicable technologies; (2) identification of relevant effects and impacts; and (3) development and evaluation/assessment of policy and decision alternatives. In the United States, one of the most important federal agencies to conduct technology assessment was the former Office of Technology Assessment (OTA). Today, several government agencies and private organizations conduct health-care technology assessment.

History

The technology assessment movement of the 1970s grew out of the history of trying to link the research and policy-making communities.

Technology assessment is a form of systems analysis that attempts to apply rational, systematic approaches to an area of public policy. Specifically, technology assessment represents a class of policy studies that systematically examines the effects on society that may occur when a technology is introduced, extended, or modified, with special emphasis on those consequences that are unintended, indirect, and delayed.

Technology assessment is known for its focus on not limiting impact studies to first-order consequences (e.g., the effect of canceling the Clinch River project on the nuclear power industry) but, instead, concentrating on discovering and predicting as many second- and larger-order effects as possible (e.g., environmental impacts of breeder reactors, the effects of research and development on the other breeder reactor technologies).

In other words, technology assessment represents a new form of evaluation that will allow officials to estimate (forecast) what the consequences of their potential actions are likely to be; as such, technology assessment represents an especially attractive source of expertise within a political environment in which decisions are made through bargaining and minimization of risks.

Office of Technology Assessment

Future-oriented systems analysis became very popular in scientific and government circles in the 1960s and 1970s. In recognition of the importance of this type of analysis, the U.S. Congress created the OTA in 1972 (PL 92–484). This office was designed to provide the Congress with the best scientific and technical information available on emerging technologies. This information was to be presented in a form that was understandable to lay audiences. During its 24 years of existence, the OTA produced 750 studies on a wide range of topics, including healthcare, acid rain, global climate change, and many new technologies that were being introduced (e.g., imaging medical equipment such as CAT scanners, and MRIs).

When the original bill was being drafted for the creation of the OTA, the staff of the House Science and Technology Committee took the tenets of technology assessment methodology quite seriously. The board overseeing the operations of the OTA would consist of citizens, representatives of

industry, scientists, and members of the U.S. Congress. However, Congress would not maintain the majority of votes on this board. The theory was that all stakeholders should have equal representation; and Congress was simply one stakeholder.

Clearly, as the history of the OTA indicates, this plan was fine in theory but inconsistent with the realities of politics. This original bill was not acceptable to Congress. If Congress was to have full trust and confidence in this body, then it should also control it. Furthermore, Congress argued that if the results of the OTA studies were to be useful to it, then Congress should also set and control the research agenda. Citizens, and other public representation, were important, but they should be on agency advisory councils or on project advisory committees.

When Harold Brown (then President of the California Institute of Technology) resigned as the first chairman of the OTA's Advisory Council, the strains between researchers/technicians and politicians over the creation of the OTA were evident. In his letter of resignation, Brown noted that few members on the council were satisfied with what had been accomplished, compared with what was hoped for and possible. Specifically, Brown felt that the OTA had failed to provide an early warning system for Congress so that it could consider the social and other impacts of technological advances. He blamed this failure on the tendency of the OTA to squander its energies on routine tasks for congressional committees. The OTA, according to Brown, should be in the position of turning down committee requests, particularly those that did not call for technology assessment but rather sought technical feasibility studies, reviews of existing programs, and literature searches—jobs that might be better performed by other research agencies with greater resources.

Presumably, the tendency to respond to short-term committee needs would not have been as prevalent under the original conception of the OTA first proposed by the House Science and Technology Committee staff. At the same time, Congress would not have supported this version of an OTA. In 1972, when the OTA was created, Congress was concerned with creating some of its own analytic capabilities that would provide information independent of the executive branch. However, Congress did not want to be responsible

for creating large, unwieldy bureaucracies. For example, Texas Democratic Congressman Olin E. Teague, Chairman of the House Science and Technology Committee and one-time chairman of the OTA board, indicated that the OTA was always supposed to be a contract operation with a small but highly capable in-house staff. Teague believed that OTA would not have been created without these assurances.

When the 104th U.S. Congress withdrew funding for the OTA, it had a full-time staff of 143 employees with an annual budget of \$21.9 million. The OTA closed on September 29, 1995.

At the time when the OTA was most active, there was also the creation of technology assessment capabilities within many executive branch agencies—most notably with the U.S. Departments of Commerce, Agriculture, and Energy, as well as the creation of the National Science Foundation Program designed to sponsor and develop technology assessment methodology.

The Professionalization of Technology Assessment

The development of technology assessment as a methodology was accompanied by the creation of several professional associations and groups of researchers and technicians who were promoting the technology assessment movement.

From a strictly methodological perspective, technology assessment represents an information resource that, by design, requires the following: boundary spanning and coordination among various disciplines; multidisciplinary work; a coordinated, planned, exploratory approach that is structured to acknowledge the uncertainty of the task; and the conscious and planned involvement of all parties who might be affected (stakeholders) by the adoption of the technology under study.

Each of these facets of technology assessment raises fundamental questions about control, institutional responsibility, and coordination; yet, from the perspectives of researchers, each is critical for attempting to provide the comprehensive analyses at the heart of the technology assessment movement. If they are to be translated into institutional terms, technology assessments would seem to implicitly require coordination at the inter- and intra-organizational levels. However, bureaucrats

traditionally have resisted this form of coordination. There have been attempts made at creating lead agencies, which are responsible for coordinating a particular substantive task in government (e.g., coordinating career-planning research). Interagency task forces have also been experimented with. Except for times of crisis, this type of coordination has encountered severe problems, which ultimately have led to failure.

However, as already outlined, the technology assessment movement represented a potentially powerful and useful tool for government officials. This is especially true given the pressure that is being put on government officials to reform their day-to-day operations by being more rational—in a formal, scientific sense of the term; using scientific information—or at least using the results of research funded through public funds; and relying considerably less on intuition than officials have been inclined to do in the past.

Technology Assessment as a System of Analysis

As it evolved, technology assessment was not just another form of research output or a bit of social science knowledge but is instead a system of analysis designed to inform the public-policy-making process.

System of analysis can be thought of as both formal and informal. The critical (essential) distinction between systems of analysis and more routine knowledge or information is that a system of analysis is associated with a set of general rules, procedures, and processes that guide the production of the end product. In recent history, examples of these kinds of systems have included the Program-Planning-Budgeting System (PPBS), the Environmental Impact Statement system, and the attempts by some federal agencies to build a routinized survey capacity into their policy-making process.

Technology assessment, as a system of analysis, is based on a general process that provides a systematic and rational input to societal decision making and management. These particularized policy studies attempt to account for direct and indirect effects as well as indirect and delayed impacts involved with technological change. To this end, technology assessment brings together multidisciplinary approaches, recommendations,

and the perspectives related to a new technological development. Although there is no single methodology common to all technology assessments, there are a number of common or generic elements involved in the creation of virtually every comprehensive technology assessment. When a decision maker reads a technology assessment, he or she can expect that each of these elements or perspectives has been taken into account and is documented in the technology assessment study.

It is important to distinguish systems of analysis from other, more routine information, whether generated in-house or sent to the organization free of charge, because the process that accompanies the creation of a technology assessment, which ensures the introduction and reporting of many different perspectives, may be just as important in understanding the ultimate impact of this class of policy studies on decision makers as the substance of the study itself.

Other Systems of Analysis

Technology assessment is not the only form of policy analysis or evaluation that represents a system of analysis. At the same time that technology assessments were becoming popular, environmental impact statements were also being developed and were also seen as attractive by government officials, because they know what to expect; they know the form (generally defined) in which they will receive the information; each environmental impact statement contains specific kinds of information and/or covers (accounts for) a set of perspectives; and there are few unexpected results that emerge from an environmental impact statement because of the process that was followed (i.e., set of procedures predetermined by the bureaucracy) in creating the environmental impact statement.

Future Implications

In the future, technology assessments, especially in healthcare, will likely increase and become a more important factor in evaluation. As new, enormously expensive medical equipment and drugs are introduced, federal and state governments, insurance companies, and consumers are increasingly questioning their value. Although the federal OTA no longer exists, other federal government agencies

currently conduct healthcare technology assessments (e.g., National Institutes of Health [NIH] and the Food and Drug Administration [FDA]). Furthermore, several private associations (e.g., Blue Cross Blue Shield Association [BCBSA], and the University HealthSystem Consortium [UHC] also conduct technology assessments for their members. Outside the United States, the best-known organization that conducts healthcare technology assessments is the United Kingdom's National Institute for Health and Clinical Excellence (NICE).

TELEMEDICINE

Telemedicine is the application of clinical medicine through the exchange of medical information from one site to another via electronic networks to improve patients' health. The number of existing telemedicine networks in the United States is approximately 200, and it involves nearly 2,000 medical institutions throughout the nation. Furthermore, it is estimated that about half, or nearly 100, of the telemedicine programs are actively providing patient care services on a routine daily basis. The American Telemedicine Association (ATA) reports that the total amount of federal grants and contracts for telemedicine is about \$270 million. More than one third of these funds are for research contracts with the U.S. Department of Defense (DOD), which allow for equipment and service delivery.

Overview

An elderly female patient presents at a rural hospital with cardiac problems and depression. The medical staff at this hospital prescribes a course of therapy for her heart troubles, and the patient is seen for regular, routine follow-up visits with a cardiologist. However, there is no psychiatrist on staff at this small facility. To ensure that the patient's depression, a serious comorbidity which can exacerbate the heart problems, is properly treated, the physicians connect her with a home-monitoring service. Every quarter, the service rings the patient and administers a telephone-based, interactive voice recording (IVR) screening using a health questionnaire as a way to monitor the patient's mental status.

A study by Carolyn Turvey and colleagues at the University of Iowa, whose parameters were outlined above, indicated that 90% of patients completed this telemedicine screening. The researchers found that a regular telephone IVR screen for depression could be used in a standard illness protocol. This program could potentially serve as a model for incorporating technology in the management of chronic illness with comorbid depression.

Chronic illnesses, like depression, account for most of the healthcare expenses in the United

States. Cutting-edge telemedicine projects like the one described above are increasingly being developed to decrease the burden of these illnesses on the medical system, to treat comorbidities, and to improve patient care and outcomes.

The term *telemedicine* appears frequently in news media reports and is often mentioned at medical conferences. Although telemedicine is not yet recognized as a separate medical specialty, technologies used for telemedicine are often part of a larger investment by healthcare institutions in either information technology or the delivery of clinical care. The new technologies involved in the practice of telemedicine include IVR, videoconferencing, transmission of still images over the Internet, online patient portals, remote monitoring of vital signs, and continuing medical education delivered online.

For clinical care, there are several applications of telemedicine that are becoming well established. Some of the applications include referral to a specialist, consultation with a patient, remote monitoring, networking hospitals, continuing education, and consumer education.

Referral to a specialist typically occurs when a specialist assists a general practitioner in arriving at a diagnosis. This often involves a patient seeing a specialist over a live network. But it can also happen with transmission of diagnostic images and/or video along with patient data, for later viewing by the specialist. Radiologists make the greatest use of telemedicine, with thousands of images read by remote providers each year. Other major specialties that rely on telemedicine include dermatology, ophthalmology, psychiatry, cardiology, and pathology. According to reports and studies, almost 50 different medical subspecialties have successfully used telemedicine.

Using telecommunications, which includes audio, still or live images, or the Internet, a primary-care health professional can consult with a patient to render a diagnosis and develop an appropriate treatment plan. Devices can be used to remotely collect and send data to a monitoring station for interpretation. The home-based applications may include the collection of vital signs, blood pressure, and blood glucose levels, an EKG, or an array of other health indicators. These services can be used to supplement visiting nurses.

Networking hospitals involves linking urban hospitals and clinics with clinics and community

health centers in suburban and rural areas. These networks include dedicated high-speed lines or the Internet for telecommunication links between sites. Additionally, this involves linking primary-care providers, specialists, and nurses with remote patients over single-line telephone-video systems for interactive clinical consultations. This can be used for monitoring of cardiac, pulmonary, or fetal signs. Generally, conventional telephone lines are used to communicate directly between the patient and the center. Using point-to-point private networks, hospitals and clinics also deliver services directly or contract out specialty services to independent medical service providers at ambulatory-care sites. These include specialties such as radiology, psychiatry, and even intensive-care services.

Using the Internet, physicians and other healthcare professionals can receive continuing medical education credits. For example, Harvard Medical School offers courses online for physicians for \$20 or less per class.

In terms of consumer education, using online access, consumers may seek out specialized health information and participate in online discussion groups that provide peer-to-peer support for conditions such as cancer and cancer aftercare.

Investment in Telemedicine

Spending on telemedicine in the United States involves both the private and the public sector. The expenditures for telemedicine are composed of three segments: grants for demonstrations and research, direct telemedicine services by federal agencies for covered populations, and reimbursement for remote medical services under Medicare. Although the amount of spending on telemedicine services provided directly by federal agencies is not tracked, the Veterans Health Administration (VA), the largest provider of remote medical services, delivers annually approximately 350,000 patient services remotely. Other federal providers of direct services include the Department of Defense, the Indian Health Service (IHS), and the Bureau of Prisons in the Department of Justice.

Medicare spending for telemedicine is also not accurately tracked. According to the ATA, the largest source of Medicare expenditures for telemedicine is for teleradiology. A Medicare program supporting videoconference-based patient services

in nonmetropolitan areas is rapidly growing, but it reimburses less than \$1 million a year. Medicare reimburses services for remote cardiac monitoring services, and in some areas for telepathology, and remote screening for diabetic retinopathy. Home telehealth applications fall under Medicare's prospective payment system (PPS) and may be used as part of a patient's plan of care, although no specific Medicare funds may be used to pay for home telehealth delivery.

Limited Growth and Acceptance

Telemedicine has slowly emerged from the fringes of medicine to mainstream use. However, there are still concerns among advocates about its pace of growth and general acceptance. Studies have clearly shown that telemedicine can increase the availability of healthcare services, decrease the amount of travel and related expenses, and enhance patient outcomes. Thus, with all these advantages, the slow take-up of telemedicine poses a dilemma.

Despite a 40-year history and the past 10 years of intensive activity, telemedicine is neither a household word nor secure in clinical use. It is estimated that less than 300 nonradiology programs are in use, with some ceasing operation each year.

Several factors contribute to the slow growth of telemedicine. First, there are reimbursement issues, concerns over whether physicians will be paid for their services rendered online rather than in person. This issue could be remedied if the patients paid for these services. However, there are other issues as well. There are concerns in the medical community about practicing virtual medicine across state lines and whether or not this is legal. Finally, the technology for telemedicine is somewhat complicated. Although physicians are technical specialists, they may not be computer specialists, which may limit the acceptance of telemedicine.

It has been noted that the slow pace of change in medicine is not unusual. The adoption of electronic health records has also been a slow process, despite its touted utility and long history.

There are several possible ways to facilitate the adoption of telemedicine technology. For example, standardization of the technologies and applications could be required by the federal government

through regulation, perhaps through additions to the Health Insurance Portability and Accountability Act of 1996 (HIPAA), which mandates privacy of personal health records. There could also be federal and state financial incentives for hospitals and healthcare providers to adopt the technology, including tax reductions. Last, the Medicare program could announce a major spending program on telemedicine technologies, which would influence technology markets in the nation. Ultimately, the use and transformation of telemedicine may be a public policy decision even broader in scope than those envisioned. Some researchers have indicated that the public health benefits of telemedicine are so great that they justify a massive expansion of the investment in the field. The public health concerns raised by the global war on terror and homeland security concerns are becoming drivers of spending in this area. This is particularly salient with the concerns about domestic biological or dirty bomb attacks on American civilian populations.

Currently, most disease reports received by state public health departments originate from clinical laboratories. It has long been recognized that the paper reporting methods used in public health surveillance are unreliable and tremendously slow, which leads to late submission of reports and substantial underreporting of communicable diseases. A recent project undertaken by researchers at the Indiana University medical school automated the reporting of diseases to local public health authorities from clinical laboratories. Reports are sent out overnight and disseminated much more quickly than paper or fax-based transmissions. When an outbreak of shigella occurred in Indianapolis, the electronic reporting system was able to notify public health officials much earlier with greater information.

Imagine the implications of such a telemedicine system in the event of a terrorist biological attack on a major urban public transportation system. The information about this occurrence could be disseminated quickly, including information on the type of attack, the means of detonation, and the type of biological agent involved—and it could be used to prevent further attacks using the same techniques.

THOMPSON, JOHN DEVEREAUX

Familiarly known as Tommy, John Devereaux Thompson was a nurse, health administration educator, and health services researcher. Thompson along with Robert B. Fetter developed Diagnosis Related Groups (DRGs) as a tool to standardize hospital cases for studies of quality and cost, subsequently changing the way the

nation's hospitals were reimbursed when Medicare adopted DRGs for its prospective payment system (PPS). Thompson's passions for studying the history of hospital operations as well as nursing resulted in a creative and respected book that focused on the social and architectural history of hospitals.

Born in Franklin, Pennsylvania, Thompson was raised in Canton, Ohio. Thompson's stepmother, a nurse, encouraged him to also become a nurse. Following her advice, he completed his nurse training program in 1939. With World War II imminent, he enlisted in the U.S. Navy and served as a pharmacist's mate, eventually achieving the rank of warrant officer. After the war, he enrolled in the City College of New York in 1948, working nights as a nurse riding ambulances and doing psychiatric nursing. Thompson received his bachelor's degree with distinction in business. Subsequently, he enrolled in the new hospital administration program at Yale University and undertook the required administrative residency training at Montefiore Hospital in New York City. Thompson completed this praxis experience in 1950 and remained at Montefiore Hospital for 6 years, becoming one of the hospital's assistant directors. Albert W. Snoke, then director of the hospital administration program at Yale and senior administrator at the then Grace-New Haven Hospital, had received a federal Hill-Burton grant to study hospital function and design, and he was successful in recruiting Thompson back to Yale in 1956.

Thompson's directorship of the hospital administration program at Yale University was novel in its emphasis on public health, yielding students who recognized that their actions as health services managers must be related to improving the health status of communities. He was beloved as a teacher and mentor.

Much of Thompson's research was based on his underlying philosophy that clinical and administrative data must be brought together to identify and solve both operational and financial problems. Thompson was instrumental in creating the Connecticut Hospital Information Management Exchange (CHIME), one of the first of 34 statewide databases built from hospital billing systems that form the foundation of large data sets, which are often used for health services research.

Thompson studied operations research with Russell A. Nelson and Charles D. Flagle at the Johns Hopkins University School of Engineering. This interest in data and their use for management decision making as well as for policy formulation and analysis led Thompson to develop a research and teaching relationship with Robert B. Fetter, then in Yale University's Department of Administrative Sciences. With others, they were important in developing the Center for Health Services Research in Yale University's Institute for Social and Policy Studies; the Center was among the first in the country.

Thompson's published articles include topics such as hospital operations, including nursing services and nursing intensity, hospital function and design, application of operations research to hospital studies, costs of care, economics of care, education for health services administration, emergency medical services, chronic hemodialysis, the role of schools of public health, hospital architecture, case-mix cost accounting, regulation, DRGs and hospital prospective-based payment, quality appraisal, and cost funding.

Thompson epitomized the adage "He who dares to teach must never cease to learn" (Anonymous). Thompson received numerous awards and honors. He shared the Baxter Prize (now the William B. Graham Prize for Health Services Research) with Robert B. Fetter in 1992; this award is the highest distinction that health services researchers can achieve. Various awards have also been named in his honor, including the John D. Thompson Prize for Young Investigators, sponsored by the Association of University Programs in Health Administration (AUPHA), and the John D. Thompson Distinguished Visiting Fellow at the Yale University School of Public Health. In addition, the teaching arm of the Connecticut Hospice was named after him—the John D. Thompson Hospice Institute for Education, Training, and Research.

TIMELINESS OF HEALTHCARE

Timeliness is one of the six key dimensions of healthcare quality identified by the National Academy of Sciences, Institute of Medicine (IOM). Timeliness can be defined as the healthcare system's capacity to provide care quickly after a need is recognized. Timeliness is a measure of a continuum ranging from an intervention that is too early, in which the diagnosis cannot be made, through a delayed intervention, in which treatment may no longer be effective. There are many reasons why timeliness as a quality measure is critical to the effectiveness of a well-functioning healthcare system, and a great deal of research exists showing its positive and negative repercussions on emergent, urgent, and chronic conditions as well as preventive services. There are also many direct and indirect factors that play a significant role in the aspect of timeliness, including cost, proper access to medical resources, and even individual patient attributes.

There has been increasing attention given to this topic in recent years, and thus, there has been a shift in ideology and the organization of hospitals, primary-care offices, and public health departments to continually improve the timeliness of healthcare.

Benchmarks

Many benchmarks are valuable in the evaluation of timeliness of healthcare, including morbidity, mortality, cost, and patient satisfaction. Quality assurance programs in ambulatory-care and emergency department settings are increasingly implemented and used to monitor timeliness assessments. This is important not only to observe and improve patient outcome data but also to give attention to the service aspects of the healthcare industry. For example, patient visits may be evaluated by the length of wait times, and no-show rates. Wait times, in particular, may be monitored closely as patient satisfaction decreases as perceived wait times increase. Many benefits such as the shorter duration of illness, the decreased likelihood of complications, reduced anxiety on the part of the patient, and reduced activity limitation are linked to receiving timely care.

Contributing Factors

Many contributing factors may affect the aspect of the timeliness of healthcare on multiple levels and points of intervention. These contributing factors, in turn, could have, separately, or in conjunction, large ramifications on the outcomes of care. For example, transportation to and between medical facilities can have a large impact. Ease of scheduling an appointment within a given target time is also essential. In addition, patient individual characteristics such as age, gender, and race may play a role in the diagnosis of some chronic conditions. Attributes such as good communication skills, motivation, positive attitude, good learning capacity, and willingness to seek timely care may be critical factors that result in the early diagnosis of illnesses. The significance of provider judgments in accurately assessing the severity of the presenting problem and patient prognosis has been shown to affect outcomes. After diagnosis, efficient communication within and among providers and medical establishments also play a decisive role in outcomes of care.

These aspects include timely documentation, reliable physician orders, ease of referral, clear prescriptions, and assurance of patient follow-up. Communication between the medical establishment and the public health system is paramount. Timely physician reporting of communicable diseases, obviously, could have far-reaching consequences. Articulation of established clinical practice guidelines and public health initiatives to medical practitioners is also very important. Of course, there are a vast number of contributing factors that should be considered in the evaluation of timeliness within the medical and health systems; however, all influence, ultimately, efficiency, precision, and patient flow.

Range of Medical Settings

The critical nature of the timeliness of healthcare spans the range of care provided within the United States, including emergency department visits, surgical procedures, primary-care visits, specialty-care visits, and public health initiatives. Some research has shown that as many as half of all hospital emergency department visits in the nation are for nonurgent care. This is notable as it illustrates the possibility of emergency department congestion threatening timely care for urgent cases and demonstrates the importance of access to healthcare services. Studies have found that Medicaid patients in urban areas (who are often not accepted by many primary-care offices) are more likely than others to seek nonurgent care at hospital emergency departments.

Timeliness is also a critical aspect in primary healthcare. However, a growing number of individuals are delaying their care because of its cost. The National Center for Health Statistics (NCHS) estimates that about 7.7% of the nation's population in 2005–2006 delayed receiving care because of its cost, up from 6.9% of the population in 1997–1998. This can have devastating effects on patient care, especially in consideration of chronic disease states for which proper care also involves timely specialist referral and ready access to care. For example, a late evaluation by nephrologists of patients with chronic kidney disease results in a significantly greater burden and severity of comorbid disease and a shorter duration of survival. Lack of health insurance plays an important role in individuals delaying care.

As increasing attention is placed on the significance of timeliness, healthcare organizations are changing to address it. In particular, clinical practices are converting to more flexible scheduling systems that allow for a greater number of walk-in appointments and same-day scheduling. These alternative models are sometimes referred to as the carve-out model and the advanced-access model and are being shown to provide more patient satisfaction, shorter wait times, and lower no-show rates. The advanced-access model also creates the possibility for the preservation of the continuity of care. This is of note as the ability of the provider and patient to establish a consistent and reliable relationship has a great impact on the quality of care, in particular the measure of timeliness.

Future Implications

Timeliness is critical to the effectiveness of a well-functioning healthcare system, in particular emergent, urgent, and chronic conditions as well as preventive measures at multiple levels of intervention. There is increasing attention being given to this topic, including major shifts in ideology and organizations to continually improve this measure as the nation strives toward improving the quality of care within the healthcare system.

TOBACCO USE

Tobacco use is one of the biggest public health challenges of the 21st century. It is the single most preventable cause of disease and death. It is estimated that worldwide tobacco use causes about 4 million deaths a year. And the number of deaths caused by tobacco use is expected to rise to about 8.4 million by 2020.

Tobacco use imposes a significant burden on society. People who use tobacco in its various forms face multiple health risks. Moreover, they impose a heavy burden on society by increasing the nation's medical expenditures of treating many costly tobacco-related diseases as well as through an enormous loss in productivity. Sustained public policy efforts, as well as the provision of cessation counseling as a part of routine healthcare, may contribute to the decline of tobacco use in the United States.

Background

The use of tobacco as a stimulant goes back many thousands of years. It is estimated that the cultivation of the tobacco plant began as far back as

6000 BCE in the Americas. The indigenous people of the Americas were using leaf-wrapped cigarettes long before the arrival of Columbus, and from the late 1400s onward, tobacco was used in various other forms such as cigars and pipes, snuff, and chewing tobacco. However, it was not until the 1880s, when the first cigarette-making machine was invented in the United States, that natural-leaf cigarettes made from domestic tobacco began to dominate the consumer market. This development led to machine-rolled butts replacing the hand-rolled varieties, consequently making cigarettes more affordable and thereby more accessible. By World War I, cigarettes had become immensely popular, and troops in both World Wars I and II used smoking as a means of relieving the physical and psychological stress of war.

Public Health Challenge

Smoking continued to gain widespread public acceptance until 1964, when the first U.S. Surgeon General's report on smoking and health brought to the fore the many health risks associated with tobacco use. Although tobacco use has declined by more than 50% since the initial Surgeon General's report, there are still more than 40 million smokers in the United States. Tobacco use in the nation generally begins in early adolescence, and the earlier young people begin using tobacco, the more heavily they are likely to use it as adults. The addictive properties of nicotine ensure that many adolescent smokers will become regular users of tobacco as adults, leading to the eventual development of chronic health problems.

In the general population, tobacco use is associated with many diseases such as cancers of the lung, throat, pharynx, and esophagus and contributes to the development of cancers of the pancreas, cervix, kidney, and stomach. It is also associated with chronic bronchitis, emphysema, and chronic obstructive pulmonary disease (COPD). Specific to female smokers are health risks such as primary and secondary infertility and delays in becoming pregnant. With respect to pregnancy outcomes, women who smoke are at increased risk of premature rupture of membranes, low-birth-weight babies, and preterm delivery. Smoking is also a major cause of coronary heart disease among women.

Economic and Social Costs

Tobacco use not only imposes a heavy toll on health, but it also is associated with a significant economic burden by way of medical expenditures and the loss annually of billions of dollars in lost productivity. Coupled with the high medical costs of treating diseases caused by tobacco is the lost productivity from the shortened lifespan of those who use tobacco regularly. Tobacco users are also less productive while they are alive due to increased sickness and absenteeism from work.

Smokers impose costs on society that are distinct from their private costs of using tobacco. These costs include costs borne by families of tobacco users, health costs borne by governments, and the costs of environmental tobacco smoke. Smokers impose direct health costs on nonsmokers, such as low-birth-weight babies born to mothers who smoke during pregnancy. Furthermore, nonsmokers who are chronically exposed to secondhand smoke are at increased risk of diseases such as asthma and lung cancer along with other adverse health effects. Nonsmokers also end up bearing, at least partially, the higher medical costs incurred by smokers through smokers' increased use of medical-care facilities. Most medical care in the United States, specifically care associated with hospital treatment, is financed through public and/or private health insurance programs. Unless smokers contribute to these financing mechanisms by paying differentially higher insurance premiums or taxes, nonsmokers are in effect partly subsidizing medical care for smokers.

Control Measures

While smoking has been identified as a serious health hazard among healthcare professionals, economists and policymakers are still debating the many aspects of tobacco control measures, including the economic costs and benefits of tobacco consumption, the relative merits of different methods of tobacco control, and how efficient and equitable they prove to be. In the past, efforts were focused on individual-level interventions, such as clinical and small-group interventions. However, current tobacco control measures focus more on population-level strategies,

such as normative change of the social acceptability of tobacco use, higher taxes on cigarettes, advertising and marketing restrictions, countertobacco marketing, prevention and cessation services, media campaigns, and other policy and legislative actions. The shift from individual- to population-level interventions has occurred not only because of the realization that large-scale change can only be achieved through concerted public policy efforts but also because of the growing awareness of the rights of nonsmokers.

TRANSPORTATION

There are many forms of transportation available to transport the ill, the injured, and the disabled to and from various healthcare facilities. Medi-vans, helicopters, and ambulances are some of the ways by which patients are transported to receive needed healthcare. The lack of access to reliable individual and public transportation, however, continues to be one of the largest and most widely recognized barriers to receiving healthcare in the United States. Although patients no longer have to rely on physicians to make routine house calls, rural residents, minorities, the elderly, children, and the indigent are more likely to experience travel burden or transportation barriers to healthcare.

Overview

Studies have shown that people with a driver's license have two and a half times more visits for chronic care and almost two times more visits for regular check-up care than those who do not have a driver's license. Additionally, people with access to affordable public transportation have four more chronic-care visits annually than those who do not. Transportation barriers have also been linked to lower rates of preventive care, compliance with treatment regimens, and accessing emergency care. In 2006, it was estimated that 3.2 million people (4% of the population) either missed a scheduled visit or did not schedule a visit to a healthcare provider because of transportation issues. This estimate increased to 7% for families with an income of less than \$50,000 per year.

Urban areas in the United States have tremendously benefited from the vast amounts of healthcare resources available, ranging from ambulatory and air transportation to a choice of medical facility.

Although efficient transportation services in urban areas allow those with an emergent condition to choose from various acute-care facilities, many more individuals fail to receive adequate transportation to even primary healthcare. Urban health departments are using multi-million-dollar government grants to coordinate emergency transportation for thousands of people to receive medical care in the event of a mass casualty; however, more than half of some rural residents cannot find any transportation to receive immediate medical care. Furthermore, if transportation becomes available, many still cannot afford to pay for it.

Inaccessibility

While transportation has certainly eased the suffering of many, it is still an inaccessible resource to many—namely, the elderly, children, minorities, the indigent, and the rural population. The elderly use a variety of transportation methods to access the healthcare system, including driving themselves, depending on someone else, or using public transportation. Due to health problems with aging, the elderly may be unable to access healthcare because of travel burdens.

For children, the lack of transportation may mean missing out on routine medical care such as immunizations and well-child care, in addition to the increased suffering from chronic illness. Because children miss out on routine medical care, they are often transported to emergency rooms when the need for care is urgent—resulting in an increased use of emergency rooms and hospitalizations. These emergency room visits may be prevented with better access to transportation to primary care. As late as 2001, one in five children living in families at or below the poverty level in the United States was unable to access routine medical care due to the lack of transportation. (Though Medicaid recipients are entitled to transportation to receive care, many are unaware of this benefit.) Additionally, almost 50% of families reported that public transportation was not a viable option to travel to medical facilities. In rural areas, this figure was almost 75%.

Racial and ethnic minorities also have a greater likelihood of experiencing transportation barriers to healthcare. Minorities are more likely to use public transportation and travel longer distances than Whites.

The lack of transportation is not merely an option for people without any means of accessing medical care. Transportation becomes a large barrier for people with few financial resources. For the indigent, timely, reliable, and affordable transportation to healthcare can be difficult.

Rural residents are more likely than urban residents to experience travel burden or transportation barriers. This is the case because there are not as many healthcare facilities located in rural areas, and therefore residents must generally travel farther to receive their care. It is not uncommon for families to travel 20 miles or more to receive their primary care in rural areas. Rural areas also typically lack public transportation systems. It has been shown that as the distance traveled increases, healthcare utilization decreases. Because of transportation barriers, people in rural areas access healthcare at later stages of illness and, as a result, have poorer outcomes. Furthermore, many individuals in rural areas are unable to access any care, or they have to wait for a long period of time, resulting in a decline of health status. Public health and medical prevention and intervention efforts rarely reach rural areas because they are so difficult to get to. Additionally, even when present, healthcare providers have limited access to needed resources to modify lifestyles.

Future Implications

Transportation options are pivotal in opening up channels of access to healthcare. Adequate transportation to healthcare is a vital factor in access to care for a large portion of the population. If proper transportation options are not provided, it may not only make it more difficult for patients to access care, but it may also ultimately prove to be more costly for the U.S. healthcare system.

TRICARE, MILITARY HEALTH SYSTEM

TRICARE is the U.S. Department of Defense’s (DOD’s) medical entitlement program that covers eligible uniformed services beneficiaries for medically necessary care. Eligible beneficiaries may

receive care either at a DOD military treatment facility or from a TRICARE authorized civilian provider. TRICARE is the health benefit for all seven uniformed services: Army, Navy, Marine Corps, Air Force, Coast Guard, Public Health Service, and National Oceanic Atmospheric Administration.

The TRICARE healthcare program serves active-duty service members, retirees and their families, survivors, and certain family spouses worldwide. As a major component of the Military Health System (MHS), TRICARE brings together the healthcare resources of the uniformed services and supplements them with networks of civilian healthcare professionals, institutions, pharmacies, and suppliers to provide access to healthcare services while maintaining the capability to support military operations.

The plan comprises insurance and care services. The TRICARE Management Activity (TMA) unit of the DOD administers the program. Currently, the system serves 9.2 million beneficiaries at an annual cost of \$39 billion.

History

Since 1956, the DOD has been permitted to provide civilian healthcare to dependents of military service members as a result of the U.S. Congress passing the Medical Care Act. Over the years, that Act was amended, and the Civilian Health and Medical Program of the Uniformed Services (CHAMPUS) was created. As of October 1, 1966, only the family members of active-duty personnel were eligible. On January 1, 1967, retired service members and their dependents became eligible. Thus, since 1967, the DOD has funded care by civilian providers to dependents, retirees, and dependents of retirees who are under age 65 and unable to obtain access in a military health facility.

After several demonstration projects in the 1980s, the U.S. Congress and the DOD made numerous changes to the CHAMPUS Program. TRICARE was organized as a separate office under the Assistant Secretary of Defense and replaced CHAMPUS in 1994. Benefits covered under CHAMPUS are now covered under TRICARE Standard.

After 1991, the DOD began, with congressional support, moving toward managed-care arrangements under the TRICARE program that include

greater use of civilian healthcare providers even for active-duty personnel. Since then, TRICARE has undergone several restructuring initiatives, including realignment of contract regions, base realignment and closure, and the addition of TRICARE for Life benefits in 2001 for those who are eligible and TRICARE Reserve Select in 2005.

Options

For eligible persons under age 65, TRICARE consists of TRICARE Prime, a managed-care option; TRICARE Extra, a preferred provider option (PPO); and TRICARE Standard, a fee-for-service option. TRICARE partners with civilian companies, Health Net Federal Services, Inc., Humana Military Healthcare Services, Inc., and TriWest Healthcare Alliance, Corp., as well as military hospitals and clinics, to provide healthcare services and support.

TRICARE Prime is a plan similar to a civilian HMO that provides the lowest out-of-pocket cost, in return for the requirement that enrollees use only physicians, hospitals, and other healthcare providers that are part of the TRICARE network. Enrollees are assigned a primary-care physician, known generally as a “gatekeeper,” who supervises all medical care and is the one who authorizes referrals for specialty care. Active-duty and reserve service members are automatically enrolled in TRICARE Prime. However, military dependents and retirees must choose the TRICARE option that best suits their needs. Active-duty service members and their dependents have no enrollment fee. Retirees pay an annual enrollment fee and enroll for 1 year at a time.

Eligibility

TRICARE Prime is available to the following beneficiaries as long as they are not entitled to Medicare Part A and Part B due to age (65 years of age or older): active-duty service members and their families; retired service members and their families; eligible former spouses; National Guard and reserve members and their families when the National Guard or reserve member is activated for more than 30 consecutive days; retired National Guard and reserve members and their families; and Medal of Honor recipients and their families.

TRICARE Extra is the PPO. It offers choices of civilian physicians and specialists from a network of healthcare providers. It is often chosen by individuals and families whose regular physician lives too far away from a military hospital. The government shares the costs of healthcare. For using this network of preferred physicians and specialists, the government will pay an additional 5% of medical costs incurred (85% for dependents of active duty). There is no annual enrollment fee to participate in TRICARE Extra.

TRICARE Standard is the healthcare option formerly known as CHAMPUS. Eligible beneficiaries have the greatest flexibility in choosing a healthcare provider, and the government will pay a percentage of the cost. It is chosen most often by individuals and families having established relationships they wish to maintain with civilian physicians. There is no annual enrollment fee to participate in TRICARE Standard.

TRICARE for Life (TFL)

On October 1, 2001, a new TRICARE entitlement for Medicare-eligible uniformed-service retirees, eligible family members, and survivors referred to as TFL came into effect. TFL is TRICARE’s Medicare-wraparound coverage available to *all* Medicare-eligible TRICARE beneficiaries, regardless of age, provided they have Medicare Parts A and B. TRICARE acts as a second payer to Medicare. TRICARE pays the remaining out-of-pocket expenses (Medicare deductibles and cost shares) for services paid by Medicare and covered by TRICARE. Under TFL, a beneficiary will currently not pay more than \$3,000 per family per year in TRICARE-allowable expenses. After that, TRICARE pays 100%. In most cases, TFL-eligible beneficiaries have little need for other health insurance besides Medicare and TFL.

Other Coverage

The TRICARE senior pharmacy benefit provides Medicare-eligible retirees of the uniformed services, their family members, and survivors the same pharmacy benefit as retirees who are under age 65. It includes access to prescription drugs not only at military treatment facilities but also at retail pharmacies and through the TRICARE mail

order pharmacy program. The current pharmacy cost-share structure—meaning the percentage of fixed amount that the beneficiary pays toward the cost of the medication—is based on whether a prescription medication is a generic, formulary, or nonformulary pharmaceutical. The copayment is the same for all TRICARE beneficiaries (except active-duty service members, who receive medications free of charge) depending on where the beneficiaries choose to fill their prescription.

Vision Care

TRICARE vision benefits vary depending on beneficiary status (i.e., active-duty member, active-duty family member, retired service member, or retired family member) and enrollment in TRICARE Prime. TRICARE Prime enrollees aged 3 and older are authorized a comprehensive eye examination once every 2 years. Prime enrollees may receive the services from any TRICARE network provider without a referral or authorization from the primary-care manager, healthcare finder, or any other authority. If the beneficiary receives services from a nonnetwork provider that has not been authorized, the beneficiary is responsible for the entire amount of the bill. Pediatric vision screening is available at birth and at approximately 6 months of age. Diabetic patients, at any age, are allowed annual comprehensive eye examinations.

Behavioral and Mental Health

The behavioral health program now provides a locator and assistance service, which is especially helpful for those who may find it hard to locate a behavioral healthcare provider in the network. Active-duty service members must have a referral from their primary-care physician for behavioral healthcare. TRICARE Prime active-duty family members can receive the first eight outpatient behavioral healthcare visits per fiscal year without a referral, but they must receive the care from TRICARE network providers to avoid point-of-service cost-sharing charges.

Skilled Nursing

Skilled-nursing coverage typically covers the following: medically necessary skilled nursing

care, rehabilitative therapies, room and board, prescription drugs, laboratory work, supplies, appliances, and medical equipment. There are four admission criteria for skilled nursing care. First, the beneficiary must be treated in a hospital for at least 3 consecutive days, not including the day of discharge. Second, he or she must be admitted within 30 days of hospital discharge (with some exceptions) to a skilled-nursing facility. Next, a physician's treatment plan must demonstrate the need for medically necessary rehabilitation and skilled services. And finally, the facility must be Medicare certified and a participating provider.

Hospice

Hospice is available for terminally ill patients expected to live 6 months or less if the illness runs its normal course. A Medicare-approved program must provide the hospice care.

Funding and Cost Containment

In addition to revisions in military planning, nationwide changes in the practice of medicine have also affected the DOD. In particular, managed-care initiatives and capitated budgeting that are widely adopted in the civilian community are being implemented in the DOD's TRICARE program. TRICARE is also designed to coordinate the medical-care efforts of the three military departments in three geographical regions, each under a single military commander known as a lead agent. The lead agents are responsible for managing care provided by all military medical facilities in their respective regions and for contracting for additional care from civilian providers. These competitively bid, regionwide contracts represent a significant change in the delivery of defense healthcare and will, it is anticipated, result in cost savings.

The U.S. Congress, as is the case with all federal entitlement programs, determines the funding of TRICARE in the National Defense Authorization Act. The dollar amounts allocated to healthcare in the budget of the DOD have doubled during the past 5 years, from \$19 billion in FY2001 to more than \$37 billion in FY2006,

even as the size of the active-duty force has remained relatively steady. The DOD's projections for healthcare indicate that even further growth can be realistically anticipated, perhaps reaching \$64 billion in 2015. In 1990, according to the DOD estimates, healthcare expenses constituted 4.5% of its budget; by 2015 it could reach 12%. This growth in healthcare costs could have a substantial effect on spending for other defense programs and/or the overall size of defense spending within the federal budget.

There are complex considerations with regard to any of the various approaches to dealing with the growth of military medical spending. To some extent, they reflect larger healthcare issues affecting the entire country. In the case of retired service members and their dependents, most recognize a special responsibility for the nation to provide healthcare after retirement, which is an important incentive for those who follow a difficult and often dangerous career.

U

UNCOMPENSATED HEALTHCARE

Uncompensated healthcare is care provided by physicians, hospitals, and other medical personnel *pro bono*, a shortened form of *pro bono publico*, a Latin phrase meaning “for the public good.” In 2008, about 47 million Americans lack health insurance coverage, and many of the uninsured are indigent. Their only health services come from physicians, hospitals, and other medical personnel who provide uncompensated healthcare *pro bono*. Public debate concerning the uninsured continues, so it is important to examine why medical personnel provide uncompensated healthcare, its role in American politics and beliefs about healthcare for the poor, issues in defining uncompensated care, how to estimate the amount of uncompensated care, and the future implications of uncompensated healthcare.

History

Uncompensated healthcare, and the general issue of how to care for the poor, has been an important issue in America since colonial times. Reflecting English practice and law, such as the 1601 Statute of Charitable Uses, some colonies emphasized public support for the poor. However, other colonies placed greater emphasis on each community’s need to take care of its own poor, the efforts of voluntary charities and mutual benevolent societies, and the private efforts of individual providers. The need for uncompensated healthcare grew during the 19th century, as

urbanization and immigration separated many of the poor from traditional sources of support, such as extended families, while exposing them to the health risks of concentrated urban poverty. These developments continued into the 20th century and became part of the new problem of the “uninsured” and “underinsured.”

While other nations adopted universal, government-supported medicine, the United States provided healthcare for the poor through private charity, either through institutions such as charitable hospitals or through the charity care provided by physicians and other medical providers who otherwise would be paid for their services. Throughout much of the 19th century, Americans who could afford care paid a physician to come to their home, while the poor went to hospitals or clinics (almost all of which were charitable). Hospitals were founded as charitable institutions, and many held that physicians had an ethical requirement to provide charity care, as part of their accepting the Hippocratic Oath.

Throughout, the 19th century governmental activities were limited primarily to local government (especially cities) establishing public hospitals and clinics. Many of these facilities became part of the safety net of facilities that continue to provide care to the indigent. The federal government did not expand its role in healthcare beyond providing care to merchant seamen, military personnel, and American Indians until the 20th century, when it partnered with states to pay for care to the categorically needy, such as the poor elderly. States administered these programs with

financial support from the federal government. While these programs were expanded during the Great Depression, the federal government did not assume a major role in healthcare until these categorical programs became part of Medicare and Medicaid in 1965.

The reliance on the private sector to provide charity care had several sources. American tradition since the Revolutionary War emphasized each person's responsibility to take care of himself or herself ("the rugged individual") and the belief that local governments and private charities, rather than the national government, should care for those who needed and deserved help ("the deserving needy"). The national government's role was seen during most of the 19th century as dealing with issues that involved more than one state—interstate issues rather than local or intrastate issues such as healthcare. During the latter part of the 19th century, the emphasis on private charity, donated services, and local government assumed new importance as an alternative to socialism, especially the Marxism espoused by some immigrant groups and workers' organizations.

After slowly expanding health-related programs during the Great Depression, the U.S. Congress passed the Hospital Survey and Construction Act, commonly called the Hill-Burton Act (PL 725), in 1946. This act provided federal funds to help states construct and modernize nonprofit hospitals, nursing homes, and other health facilities. These facilities were then obligated to provide a reasonable amount of charity care for 20 years afterward. The last Hill-Burton grants were awarded in 1997, and approximately 300 hospitals and nursing homes still have Hill-Burton obligations.

More recently, some states have attempted to require nonprofit hospitals to provide charity care in order to retain their tax-exempt status. Since 1986, the federal government through the Emergency Medical Treatment and Active Labor Act (42 USC 1935), commonly called EMTALA, requires that the hospitals that participate in the Medicare program provide pro bono emergency care to all patients, even if they are not Medicare beneficiaries.

Definitions

Uncompensated healthcare has many definitions, depending on the perspective of the observer. It

can be defined narrowly to mean totally uncompensated healthcare (charity or pro bono care) given by those who normally charge for their services. The American Institute of Certified Public Accountants (AICPA) requires that financial statements use this definition, and the Healthcare Financial Management Association (HFMA) recommends it. The American Hospital Association's definition of uncompensated healthcare comes close to this definition, although it includes bad debt as well as charity care. On the other hand, uncompensated healthcare has also been defined to include services provided at less than full charges, such as services to Medicaid recipients, and even services provided on a sliding scale.

The definition of the cost of uncompensated healthcare also can be restricted to the marginal cost to provide that care—the additional cost that the provider incurred by treating that additional patient, or it can be defined to include the full cost of that care, which includes the marginal cost and a share of the fixed cost. This distinction is especially important because healthcare has a substantial fixed cost, which makes the marginal cost much less than the total cost. The marginal cost of 1 day of hospital care is mainly food, linen, drugs, and the marginal cost of a physician's visit. Those costs are much less than the full cost of a day of care, which includes capital costs, salary costs, and maintenance costs. The marginal cost of an outpatient visit to a physician's office can be almost zero, compared with the full cost, which includes physician's capital costs, practice expenses, and so forth. From an accounting perspective, valuing charity care at its marginal cost is more logical when it is only a small percentage of total expenses, such as 3% (or less), versus when it is a larger percentage of total expenses, such as 10%.

These differences in definition determine not only how to measure uncompensated healthcare but also its significance in the American healthcare system. Charity care represents a true cost to the provider, a cost that represents a contribution to society. Including all services provided at less than regular charges can include services that reflect a business decision as much as good intent. A hospital might accept Medicaid recipients because they can serve as patients for its residency programs or because Medicaid's limited payments will still contribute to the hospital's total profits or surplus if it

has already covered its fixed costs. Measuring uncompensated healthcare at its marginal cost makes the care burden much smaller than measuring the care at its full cost.

Amount of Uncompensated Healthcare

The American Hospital Association (AHA) reports that community hospitals provided \$28.8 billion of uncompensated care in 2005, about 5.6% of total expenses, compared with \$3.9 billion in 1980. This change is an increase of 638% unadjusted for inflation and an increase of about 100% adjusting for general inflation. Community hospitals include both nonprofit and for-profit hospitals but exclude long-term hospitals and hospitals that provide only one type of healthcare, such as psychiatric care, rehabilitation care, or orthopedic care. Between 1980 and 2005, uncompensated healthcare ranged between 5.1% and 6% of total expenses. The percentage was constant despite economic fluctuations during this period, which included recessions and changes in the percentage of managed care. The Federation of American Hospitals reported that in 2005, the average acute-care for-profit hospital provided \$15.4 million in uncompensated healthcare.

Using data from the Center for Studying Health System Change's Community Tracking Study (CTS), which included a telephone survey of physicians, researchers found that during 2004–2005, 68% of responding physicians had provided charity care during the month prior to their participating in the survey. This estimate is conservative, however, since it includes only the charity care provided during the previous month. During that month, these physicians had provided an average of 10.6 hours of charity care, which represented 6.3% of their practice time. Surgical specialists were more likely to have provided charity care than other physicians, because they were assigned charity care by the hospitals where they have admitting privileges. Physicians in solo practice or in other physician-owned practices were also more likely to have provided charity care than physicians such as those working in hospital-owned practices. The percentage of group practice physicians who provided charity care declined with the size of the practice. In small-group practices, 78%

of physicians provided charity care, compared with 62% of physicians in practices with more than 50 physicians.

Using cost survey data from the Medical Group Management Association (MGMA), the researchers also found that 43% of group practices reported having given charity care during 2005, and the average amount of charity care was 1.7% of gross charges, or a median of \$180,000 per practice. Preliminary research by the MGMA indicates that this estimate understates the amount of charity care since some practices that reported no charity care actually provided free services but did not include the services in their financial or billing records.

In 2005, the Pharmaceutical Research and Manufacturers of America (PhRMA) helped organize the Partnership for Prescription Assistance (PPA), which provides prescription medications to patients either at no cost or at reduced cost. The American Academy of Family Physicians (AAFP), American Autoimmune Related Diseases Association (AARDA), Lupus Foundation of America (LFA), National Association for the Advancement of Colored People (NAACP), National Alliance for Hispanic Health (NAHH), and National Medical Association (NMA) also collaborate with this program. The PPA directs patients to other sources of pharmaceutical assistance such as Medicaid. It also helps consolidate assistance programs sponsored by individual drug manufacturers, some of which had been in existence for 50 years. Since 2005, the program has helped approximately 3.6 million people, and PhRMA estimates that the program has already provided billions of dollars in pharmaceuticals.

In 1999, the American Dental Association (ADA) reported that 69.7% of dentists provided free or discounted charity care. The ADA also has described the charity care individual dentists have provided and has called attention to the need to enable indigent patients to afford dental care.

The American Health Care Association (AHCA), which represents long-term care facilities, has studied the differences between Medicaid payments and the cost to provide healthcare to Medicaid patients. That study estimated that unreimbursed nursing home Medicaid allowable costs were \$4.5 billion in 2006, a 4% increase over the previous year.

Trends in Supply and Demand

As noted above, the percentage of hospital revenue allocated to charity care has remained stable over the past 20 years. However, there is evidence that charity care is becoming more concentrated in a smaller number of hospitals. Some hospitals, especially those that are not a part of the safety net of hospitals that provide healthcare to the indigent, are trimming services commonly used by indigent patients. However, safety net hospitals, especially publicly owned hospitals, will likely face increased financial pressures, while at the same time local governments may seek to avoid tax increases.

The number of physicians providing charity care also appears to be declining. Researchers have found that the percentage of physicians who provide charity care declined from 76% during 1996–1997 to 68% in 2004–2005. They attribute this decrease primarily to the decline in physicians' practice income during the period. MGMA data also show that the percentage of medical groups reporting charity care appears to be declining.

The demand for uncompensated healthcare, however, will almost certainly continue to increase. The reasons include the continued increase in the number of uninsured, increased deductibles and copayments among insured patients, and the increasing age of the nation's population. People with chronic diseases such as diabetes and HIV/AIDS are living longer, and others (especially members of the baby boomer generation) expect to be healthier longer.

Future Implications

A number of factors will likely shape the future of uncompensated healthcare in America. These factors include economic, life style, and health insurance trends, changes among healthcare providers, and the increasing use of nonphysician providers.

Economic Trends

General economic trends will be a major factor in uncompensated healthcare. The adage "It's the economy, stupid" applies to uncompensated care as well. Economic downturns increase the number of unemployed (and therefore uninsured), increase

the number of jobs that do not provide health insurance, and increase the number of workers in low-paying jobs who cannot pay for healthcare. Downturns also increase the number of people living in poverty, especially urban poverty, and the health risk factors that poverty brings. The links between poverty and illness are well established.

Life Style Trends

Preventable illnesses are becoming an increasingly large percentage of all illnesses, especially among the poor, who are the most likely to need uncompensated care. Increasing exercise alone could reduce illnesses such as heart disease and diabetes, which are costly to treat and are becoming more frequent. Yet the poor have the least access to opportunities for exercise, including health clubs and parks. Changing lifestyles, especially among vulnerable populations, can do much to reduce the need for uncompensated healthcare.

Health Insurance Trends

While the current health insurance system emphasizes choice, including the choice to have no insurance coverage, it creates coverage gaps that uncompensated healthcare is asked to fill. In recent years, deductibles (the amount that the individual must pay before the insurance starts) and copays (the amount or percentage the individual must pay after the insurance starts) have increased, and a smaller percentage of employers offer health insurance coverage. The current system leaves many poor and low-income people with no health insurance. The Medicaid system covers only the "deserving needy," such as dependent children, and in most states, Medicaid does not pay enough to encourage a large number of physicians, dentists, and therapists to accept Medicaid recipients. The uninsured poor present a substantial burden to safety net providers and to all providers of charity care. Because of this, there have been calls for universal coverage, either through a single-payer system, such as the Canadian system, or through a multipayer/universal enrollment system, such as the one found in Ireland, Japan, and the Netherlands. The poor can be included in a universal health system, or they can be included in community-based programs. Such

efforts to change the American health insurance system to a universal system have not succeeded in the past.

Changes Among Healthcare Providers

Changes among healthcare providers may also affect the amount of charity care. Physicians are moving out of solo practice into groups, which are less likely to provide charity care, and the percentage of medical practices not owned by physicians is increasing. Both of these practices are much less likely to offer charity care than physician-owned practices. Whether these trends continue will affect how much uncompensated healthcare is provided. Additionally, hospitals are increasingly becoming part of multihospital systems, although it is too early to tell what these changes mean for the provision of charity care. Not-for-profit hospitals will continue to face debates on whether their tax-exempt status requires charity care or general community benefit.

Use of Nonphysician Providers

Nonphysician providers, especially therapists, are becoming increasingly important in patient care. For example, stroke patients may need physical, speech, and occupational therapy in addition to physician and hospital care to return to normal life. Many patients also need laboratory and diagnostic procedures. Hospitals and physicians have long traditions of providing charity care. In the past, many therapists and laboratory technicians were employed by hospitals and therefore provided charity care as part of the hospital's charitable activities. However, they are increasingly practicing outside hospitals in settings without a strong charity care tradition and no legal charity care obligation. Nonphysician providers may face similar charity care decisions in the future to those hospitals and physicians already face.

Uncompensated care will likely remain an important issue as medical care continues to expand and the categories of personnel providing healthcare continue to increase. Hospitals, physicians, dentists, therapists, and other providers will have to decide how much charity care to provide, society will have to decide how much care to provide to those who cannot afford to pay, and

patients who cannot afford to pay will have to find providers that will treat them pro bono.

UNINSURED INDIVIDUALS

The number of people who do not have any type of health insurance—that is, they are not covered by private policies or public programs such as Medicare and Medicaid—has been steadily increasing since the late 1970s, when the first federal surveys began asking about the coverage of individuals rather than just the head of a household. The uninsured as a percentage of the population has also been increasing. In 2006, the most recent year for which data are available, 47 million Americans did not have any type of health insurance. This was 2.2 million more people than in 2005, and it was the largest 1-year increase in the number of uninsured since the U.S. Census Bureau started collecting insurance status data in 1979. The fraction of the nation's population who were uninsured in 2006 stood at 15.8%, and among the population under age 65, 17.8%—one in six people—are uninsured.

Being without health insurance places a person at risk for potentially catastrophic expenses if he or she develops a disease, such as cancer, or a chronic medical condition, such as multiple sclerosis, or survives a major car accident or stroke. Such expenses can cause families to declare bankruptcy. Equally concerning is that the lack of health insurance can limit a person's access to healthcare. Many physicians and hospitals will not provide nonemergency services to people who are uninsured. Furthermore, people without health insurance who are treated often are not given the newer, most effective treatments, including newer pharmaceuticals, because they cost more. Thus, being uninsured involves serious risks.

Because private health insurance coverage is strongly tied to having an employer that sponsors group coverage and Medicaid coverage is tied to meeting eligibility criteria that include a low income, there are dynamic aspects to being uninsured.

Losing a job is often a trigger for losing health insurance, and likewise, changing jobs to one with a company that offers insurance can enable a person to gain coverage. Similarly, individuals can work in low-wage jobs and qualify for Medicaid, but if their employer asks them to work overtime, they can earn too much to still be eligible for Medicaid. These scenarios play out every day—people lose and gain jobs, and some lose or gain health insurance coverage, and some people lose eligibility for Medicaid, while others become eligible because of some misfortune.

These dynamics mean that over a period of time—say a year—there are people who are uninsured for part of the year while others are uninsured the entire year. Research on the dynamic aspects of health insurance coverage shows that although the median length of time that people are uninsured is about 6 months, a significant fraction (between 25% and 30%) of uninsured spells last more than a year. The implication of these studies is that surveys that ask about people's insurance situation at a point in time are not capturing the full extent to which being uninsured is a problem for people over a year or several years' time. Over the course of 2 years, the number of people who have at least 1 month without health insurance is perhaps one and a half times the number of people who are uninsured in any given week during the year when a survey may occur. Thus, the estimate of 47 million people without health insurance in any given week in 2006 could indicate that between 2005 and 2006, closer to 70 million people spent at least a month without health insurance coverage.

The dynamics of health insurance coverage point up a third risk that uninsured people face even if they are uninsured for only a short time: They may have a medical problem while they are uninsured, and then they are in trouble if they ever want to obtain self-purchased health insurance coverage. Insurers in the individual (or nongroup) market are very wary of adverse selection. In many states, insurers can reject applicants who have had medical problems, place restrictions on what medical services will be covered, or medically underwrite (i.e., increase the usual premium based on the medical history) the premium a person would have to pay. Thus, even being uninsured for a short time creates a risk for people.

Descriptions of the uninsured generally rely on annual surveys of the general population and do not include the dynamic aspects of health insurance coverage. This discussion of the uninsured follows that convention, but it is important to note that many people change their health insurance status over the course of a year.

Major Subgroups

People without health insurance coverage do not fit a single description—and the composition of the uninsured in terms of large subgroups of people has changed considerably since the late 1970s. The reasons for these changes are discussed in a separate section below. Before examining why people are uninsured, however, it is useful to know where the uninsured live and the characteristics that describe major subgroups of the uninsured. Using U.S. Census data from 2006, only slightly more than half are poor by official federal poverty standards, and the uninsured include a substantial number of middle-class people. Certain subgroups stand out: 20% are children, and another 40% are younger adults, 25 to 44 years old. One fifth are foreign-born, legal residents who are noncitizens. The primary reason these people are uninsured is that they lack access to employer-sponsored health insurance and most cannot afford to buy it in the individual market. The doubling of healthcare spending in the past decade has driven premiums to the point that an increasing number of companies are limiting their insurance costs and even individuals with middle-class incomes cannot afford individual coverage.

Where the Uninsured Live

As Figure 1 and Table 1 show, the uninsured are concentrated in the South and Western regions of the nation. More than half live in the South Atlantic, West South Central, and Pacific states. The regions with the highest proportions of their population who are uninsured are the West South Central (26%), Mountain (21%), South Atlantic (20%), and Pacific (19%). In contrast, New England has the lowest proportion of its population who are uninsured (11%). The fact that there is such variation in the proportion of the regions' populations who are uninsured is important

because those areas with the higher proportions of uninsured face a more difficult financial situation in their efforts to expand health insurance coverage to their residents.

The Poor and the Middle Class

It is commonly believed that everyone who has an income below the federal poverty level (\$10,294 for a single individual and \$20,614 for a family of four in 2006) is covered by Medicaid. However, Medicaid covers many of the poor but not all: 11.5 million people—a quarter of all the uninsured younger than 65 years of age—had family incomes in 2006 that were officially in poverty. Another 13.5 million people (29% of the uninsured) were near poor, with incomes between the poverty level and two times the poverty level. Together, just over half of the uninsured—25 million people—had incomes that were poor or near poor by official standards. In terms of simple chances of being uninsured, one third of the people with incomes below two times the poverty level were uninsured in 2006.

Figure 2 shows the family incomes of the uninsured in dollars rather than in comparison with the federal poverty level. Half of the uninsured have family incomes less than \$30,000. But almost 30% of the uninsured are middle-class people. The middle class can be defined as anyone with a family income above the median household income (i.e., the income level above which half the households in the nation have incomes). In 2006, the median household income was \$48,201. By this definition, 13.5 million uninsured people were middle class.

The simple probability of being uninsured for a working-age adult (23–64 years of age) has increased significantly during the past 25 years. In 2006, a third of all working-age adults with incomes below the middle-class threshold were uninsured. This fraction is again half as large as it was in 1979, when a fifth of lower-income adults were uninsured. For middle-class adults, the simple probability of being uninsured is significantly lower. However, it has increased from just 6% in 1979 and throughout the 1980s to between 10% and 11% in 2005 and 2006. The fact that 1 in 10 working-age middle-class adults is uninsured signals a significant problem with health insurance for a substantial portion of the middle class.

Adults 25 to 44 Years of Age and Children

As can be seen in Figure 3, two out of five uninsured in 2006 are 25 to 44 years old. More significantly, as Figure 4 shows, the percentages of all people in these age cohorts who are uninsured are at all-time highs: More than a quarter of all 25- to 34-year-olds and a fifth of all 35- to 44-year-olds were uninsured in 2006. These fractions of each cohort are twice what they were in 1979.

Twenty percent of the uninsured in 2006 were children younger than 19 years of age. This fraction of the uninsured is half what it was in 1979, when 40% of the nonelderly uninsured were children. The major explanation for the drop in the percentage of the uninsured who were children is that the Medicaid income eligibility cap for children was raised starting in the late 1980s and in 1997 the State Children’s Health Insurance Program (SCHIP) for near-poor children was implemented. In the early 2000s, the number of uninsured children stopped falling, and between

2005 and 2006, the number increased by 700,000, so that in 2006, 9.4 million children were uninsured. The fraction of all children who were uninsured was 12.1%, which was a slight increase over the past few years.

People With Less Formal Education and Occupations

Having low levels of formal education is a significant handicap for finding a job with employer-sponsored health insurance, and it is a major predictor of someone being uninsured. As Figure 5 shows, almost two thirds of uninsured adults 23 to 64 years of age have not gone past high school for formal education. Among adults who have not completed high school, 44% were uninsured; and a quarter of all adults who have high school diplomas but no further formal education were uninsured. This is a shift from a generation ago, when high school graduates could find well-paying jobs with large manufacturers. In 2006, five of the eight occupations that had the largest numbers of workers did not have high education requirements, and more than a

fifth of the people in each of these occupations were uninsured.

Foreign-Born Status

Immigrants who respond to U.S. Census surveys are almost all legally in the country; undocumented immigrants tend to hide from census interviewers. Immigrants are now a large subgroup of the uninsured. Just over a fifth of the uninsured in 2006—10 million people—were not born in the country and were not citizens. Another 2.3 million uninsured were foreign-born and were naturalized citizens. To see these numbers from another angle, not quite half (46.6%) of the foreign-born population who were not yet citizens were uninsured. This is in contrast to 15% of Americans born in the country and 19.8% of naturalized citizens who were uninsured.

The foreign-born who are not citizens include people who have not yet lived here long enough to apply for citizenship and people who may expect to return to their country of origin sometime in the future. Foreign-born residents who have been in the country for longer periods of time are less

likely to be uninsured than people who immigrated within the past 5 years.

A majority of foreign-born noncitizens are younger adults with low levels of formal education, earn low wages, and do not have employer-sponsored insurance at their jobs. Most of these uninsured immigrants live in the three regions of the country with the highest rates of uninsured. But even middle-class and well-educated foreign-born noncitizens are more likely to be uninsured than their native-born counterparts. Two out of five noncitizens have middle-class incomes, yet 28% of middle-class noncitizens are uninsured.

It is too simple to say that the immigrants from Latin America (which is where half the foreign-born population in 2000 came from) are uneducated and that explains the increase in the number of uninsured. Instead, the growth in the number of less educated immigrants in the past 20 years has to be seen as contributing to the imbalance between the demand for and supply of unskilled workers, enabling firms to hire low-wage workers without offering employer-sponsored health insurance.

To sum up, the 47 million people without health insurance coverage are a group of people with

Figure 5 Education of Uninsured Adults (19–64 Years Old), 2006

Source: U.S. Census Bureau. Current Population Survey, March 2007.

many characteristics. Although it is tempting to say that many uninsured have several of the characteristics described above, that is not the case. In 2006, there were 3.1 million adults 19 through 34 years of age who had incomes below the poverty level, had not gone beyond high school for formal education, and were uninsured, but they accounted for only 17% of all uninsured adults 19 to 34 years of age. Thus, it is important to understand why an increasing fraction of the population are uninsured and why the uninsured today consist of different types of people compared with 25 years ago.

Reasons People Are Uninsured

Decline in Employer-Sponsored Health Insurance

The large increase in the number of uninsured between 2005 and 2006 reflects a now almost decade-old decline in the percentage of people with employer-sponsored insurance. In 2000, 68.3% of

the population younger than 65 years of age had employer-sponsored coverage, in 2006, the fraction was 62.9%. During the same time period, there was a steady decline in the fraction of firms that sponsored health insurance (from 69% in 2000 to 61% in 2006). In practice, the shrinking of employer-sponsored group coverage is greater than these statistics suggest. Firms that offer health insurance to “regular” employees are increasingly using workers hired through contract houses (often known as contract workers) and temporary agencies, and other self-employed people who work on specific tasks for long periods of time. When companies hire workers in these ways, the workers are not technically employees and are not included in the fringe benefit plans the firms offer. Younger adults are particularly likely to be employed as contract workers, which helps explain their significant representation among the uninsured.

The decline in the proportion of firms offering health insurance and the increased use of contract workers indicates the extent to which companies are moving to limit their financial risk of increases in healthcare costs over which they do not have direct control. For employers, the fastest rising labor cost has been health insurance. Since 1996, premiums for employer-sponsored coverage (both actual policies purchased from insurers and premium-equivalent costs for self-insured plans) have grown every year; the increases reflect the doubling of healthcare spending since 1996. Between 2001 and 2007, premiums for firms with more than three employees increased 78%—outpacing general inflation, which rose 17%. These increases occurred in spite of most employers shifting more out-of-pocket costs onto the workers in the form of higher deductibles and copayments and implementing more restrictions on pharmaceuticals and mental health benefits. In addition, although the average employee share of premiums has remained constant since 1999, there is great variation in the share of premiums paid by employees. A major survey of employer-sponsored health insurance premiums found that workers in firms with a high proportion of low-wage workers (i.e., firms where 35% or more of the workers earn less than \$21,000 a year) pay a higher share of family policy premiums than do workers in firms with lower proportions of low-wage workers. Although the rate of increase

in premiums between 2006 and 2007 (6.1%) was the smallest since 1999, it is still larger than the rate of inflation.

Employer attitudes toward the costs of employer-sponsored coverage also reflect the labor markets in which they hire workers. Most of the growth in employment over the past two decades has been in the services sector, in particular healthcare services, professional business services, and leisure-hospitality-entertainment services. Many of the companies in these industries are small and employ large numbers of low-wage, less skilled workers. Immigrant labor is particularly prevalent in these markets. As long as the supply of workers willing to work in these service jobs is much larger than the demand for them, the firms can keep wages low and not offer health insurance to attract or keep the workers. Moreover, the demand for the services provided by these industries is very price sensitive, so firms are not in a position to charge higher prices in order to provide higher wages and group health insurance coverage.

High Premiums for Individual Insurance

People who do not have access to employer-sponsored coverage have only one choice for purchasing health insurance: the individual insurance market in their state—the market in which insurers sell policies covering individuals (and their dependents) rather than policies covering groups of people. Individual insurance is far more expensive than is employer-group coverage because insurers face the risk that a disproportionate number of people who want to purchase individual policies are at higher risk of having high medical costs than the general population. This risk is known as adverse selection. As a result, premiums for family policies in individual markets typically cost more than \$700 per month and have a deductible of \$5,000 or more.

In spite of the fact that many younger adults do not have employer-sponsored coverage and are good candidates to purchase individual coverage, the growth in healthcare costs has driven up premiums and the risk of adverse selection in the individual market. Increasingly, the people who purchase individual insurance are 45 and older—ages when healthcare spending tends to increase. It

is not uncommon for those who are older or have medical conditions to face premiums in the individual market of \$12,000 or more per year or to be offered policies that do not include care related to their conditions. Those who are younger and healthy also generally face premiums that are higher relative to what they think healthcare costs are likely to be because insurers expect that adverse selection is occurring also among the younger adults. The result is that individual policies are unattractive and unaffordable to younger adults. Even younger adults who are earning middle-class incomes may decide that any “normal” medical care they might use would cost less than the premiums they would face in the individual market.

Low Income

The third major reason why many people are uninsured is that they have low income. A little more than half of the uninsured have family incomes below \$30,000, and people with incomes below \$30,000 (or below three times the federal poverty level) cannot afford insurance in the individual market. To have an income above the poverty level, a person must be working (or be a dependent of someone who is working). Thus, a majority of the low-income uninsured are employed or dependents of someone who is employed, but they do not have access to employer-sponsored coverage, and they cannot afford to purchase insurance on their own.

Future Implications

People without health insurance are at risk for a financial catastrophe and for not obtaining medical care that could save their lives and improve the quality of their lives if they have chronic medical conditions. One in six nonelderly people in the nation now faces such risks, and a fifth of them are children who do not have a choice in their insurance status. Furthermore, almost 80% of the uninsured are younger than 45 years of age. They would be relatively inexpensive to insure since the vast majority of them are healthy and use little medical care. The fact that more than a quarter of 25- to 34-year-olds and a fifth of 35- to 44-year-olds are uninsured is not good for them or the nation's private health insurance system. Insurers

need younger, healthy people among their insured to counterbalance the risks of higher medical costs of older people. For these reasons, many believe that a new strategy for reducing the number of uninsured in the United States is needed.

UNITED KINGDOM'S NATIONAL HEALTH SERVICE (NHS)

One of the most contentious and complex issues in health services research is defining and assessing the appropriate role of government in delivering healthcare. Great Britain has developed what is widely recognized as the most advanced system of healthcare based on management and delivery by the government through tax financing. The history and experience of the healthcare system in post–World War II Great Britain is a robust example of state control and delivery of healthcare services based on the premise of universal coverage and access. Recently, the National Health Service (NHS) in England has embarked on a program of reform and modernization that is being observed with interest by researchers concerned with questions of access, implementation of technology, health outcomes, and cost controls. The NHS comprises separate organizations in England, Scotland, Wales, and Northern Ireland, but each operates on the same principles of universal access and essentially free care, funded by national tax revenues. This entry focuses on the English NHS.

History

The NHS was created in 1948 (implementation of the NHS Act occurred in 1946), but there were a number of policy debates and developments in the preceding half-century that laid the groundwork for the comprehensive system launched following the end of World War II. In the decades preceding the war, public hospitals grew to be the major treatment centers in the United Kingdom. Although there were few public general hospitals, a diverse collection of specialty public hospitals focused on infectious diseases, mental health, and maternity

services, resulting in two thirds of patients being treated at public hospitals by the late 1930s.

Voluntary (not-for-profit) hospitals—originally charity societies—began to charge for services in the two decades before the war, which paralleled the development of health insurance, beginning with the National Health Insurance (NHI) plan created in 1911. This compulsory system provided sickness benefits to the employed working class, including primary care and drugs. By 1939, the NHI, despite excluding the unemployed, married women who did not work, and children, covered 43% of the population. Ninety percent of general-practice physicians participated in the NHI, although specialist services were not covered.

Although there were a number of studies and proposals made with regard to reforming the fragmented British healthcare system in the decade prior to the creation of the NHS, the 1942 Report to Parliament on Social Insurance and Allied Services provided the impetus for the creation of a nationalized healthcare system. Known as the Beveridge Report, after its author Lord William Beveridge, the document proposed a comprehensive social security system, including a national health service to provide tax-funded comprehensive medical care for everyone in the United Kingdom. The Beveridge report became the Labor Party's platform for a social welfare state following the war.

The NHS came into existence in 1948 as the centerpiece of the Labor Party's plan for rebuilding the British economy. There was little opposition at the time, in part because of the clear victory of the Labor Party in the 1945 parliamentary elections and a national consensus that some type of social security program was necessary for rebuilding a stable workforce following the trials of the war.

Evolving Structure

The original structure of the NHS was designed in part to overcome the objections of several important interest groups to a nationalized system of healthcare. The most significant objections came from the medical profession, particularly general practitioners, who feared the loss of their professional autonomy, restrictions on practice, and inadequate compensation. The Minister of Health, Aneurin Bevan, agreed to a number of provisions designed to overcome those objections. Many of

the objections mirrored the Labor Party's internal debate over whether to focus on providing comprehensive health services based on local authority control or whether there should be a national system of healthcare controlled by the central government. Bevan insisted on nationalization of the entire hospital sector, as one element of a tripartite system of providing healthcare services. The social element was the creation of local health authorities to provide primary and specialized services, including mental health clinics, ambulance services, and related public health and social services.

A third element was intended to overcome the objections of the most vocal critics of a national health service, the general-practice physicians. Bevan agreed that these physicians would be independent contractors, rather than salaried employees, and would provide services based on contracts negotiated with representatives of their profession, primarily the British Medical Association. The contracts would be administered by separate administrative units, called executive councils, which would include representatives of the medical profession. The principle that primary-care physicians are contractors, rather than employees, has survived to this day.

The nationalization of hospitals themselves was less contentious than other issues, largely because of the support of specialty physicians and surgeons, called consultants in the United Kingdom. Unlike general practitioners, specialists were largely supportive of the NHS even though they would practice primarily in the newly nationalized hospitals. Their professional organizations, including the Royal College of Physicians and the Royal College of Surgeons, supported the creation of the NHS after Bevan made some important concessions relating to hospital structure and operations, particularly with regard to teaching hospitals. Hospitals would be coordinated by regional hospital boards and would be operated by local hospital management committees, including representation from the medical profession. In addition, teaching hospitals, at which many of the top consultants practiced, would have separate boards of governors, again with representation from the medical profession. In addition, consultants could continue to have private practices and would benefit from generous compensation plans.

The NHS began operation in 1948 based on this tripartite model of separate structures for

hospitals, physicians, and local health services, all reporting ultimately to the national Minister of Health. This structure remained largely intact until the mid-1970s, when problems that were evident from the earliest days of the NHS reached a critical stage. Through its many changes over the past 60 years, the principle on which the NHS was founded continues to guide the system today: universal and comprehensive healthcare services based on clinical need, not on the ability to pay.

The 1974 Reorganization

At the time the NHS was created, it was assumed that there would be heavy demands on its services for the first few years of operation as patients used services that were unavailable or inaccessible prior to the creation of the nationalized system. It was suggested that the demands on the services would decrease over time as these deferred health issues were addressed. In fact, demand was heavy and did not diminish over time.

Although the NHS enjoyed great public support from its creation, it soon became apparent that there were problems with duplication and overlap of management and coordination functions within the three-part structure that were affecting the ability of the NHS to respond to demands on its operations. The NHS Act of 1974 was intended to address these concerns by reorganizing the NHS to provide a more coordinated system of regional planning and local administration of all health services. At the top level, regional health authorities were created to provide overall planning. Ninety area health authorities were created with responsibility for overall coordination of health services, and several hundred districts were created to manage the actual health services provided.

Unfortunately, it soon became clear that these additional layers of management were not resulting in more efficient utilization of resources and delivery of services. There were several other reorganizations between the mid-1970s and 2002, when the current structure of the NHS was adopted.

Current Structure

The NHS Reform and Health Care Professions Act of 2002 marked the beginning of a major modernization effort for the English NHS and its

constituent units. Twenty-eight regional strategic health authorities (SHAs), serving populations of between 1.5 and 2.4 million people were created. The number of SHAs was reduced to 10 in 2006. The SHAs report directly to the Department of Health. The SHAs are responsible for allocating budgets, strategic planning, and oversight of services within their particular region, but they do not have operating responsibilities. Reporting to each SHA is a range of agencies, called trusts, that provide the actual healthcare and ancillary services. The principal trust types are primary-care trusts (PCTs), NHS (hospital) trusts, and NHS foundation trusts. The SHAs and trusts have a similar structure. They are public corporations governed by a board, which consists of operating executives and outside nonexecutive members appointed through a Department of Health selection process. Each authority and trust is headed by a nonexecutive director, who is appointed after public advertisement and selection by the respective board.

Primary-Care Trusts (PCTs)

Most health services are provided by PCTs. Originally, there were 303, but these were consolidated into 152 PCTs in 2006. The PCTs have responsibility for outpatient services, dental services, mental health services, pharmacies, ambulance and emergency services (through contracts with separate NHS Ambulance trusts), and, through contracts with separate NHS trusts, most hospitals within their defined geographic region. More than 80% of the NHS budget is controlled by the PCTs. The PCTs are also responsible for contracting for primary-care services with general practitioners. Patients select their general practitioner from a list provided by their PCT. Other healthcare services are selected by the general practitioner in consultation with the patient, although this is changing with the Patient Choice initiative discussed below.

NHS (Hospital) Trusts

The NHS trusts operate the majority of hospitals in England. There are approximately 150 hospital trusts that operate several hundred hospitals. These geographically designated hospital trusts contract with the PCTs to provide services for

patients within a defined area. They employ physicians for hospital-based care as well as contracting for specialists (consultants). Until recently, patients were required to use a hospital within their geographic region. This will change dramatically with the full implementation of the NHS Choice Plan announced in 2005.

The possibility of competition among hospitals because of the recent NHS initiatives has focused attention on the question of quality differences within the NHS. Until the 1980s, allocation of NHS budgets to local authorities was based almost solely on the previous year's budget allocation. Since that time, there have been a number of attempts to tie budgets to medical needs within a region, but inequities continue to exist. Therefore, there is concern that with choice there will be underutilization of hospitals that are perceived as having lower quality than higher-quality hospitals (which include most of the country's university-related teaching hospitals).

A quality measurement program is being implemented that will financially reward hospitals with better clinical outcomes in the hope that such an incentive will promote quality improvements in the worst-performing hospitals. However, it is acknowledged that this may not be sufficient within the current financing structure, in which there is limited capital for investment in equipment and facilities. One solution has been the creation of NHS foundation trusts.

NHS Foundation Trusts

Beginning in 2004, hospital trusts have had the option to convert to foundation trusts, which have a unique legal status within the NHS. Foundation trust hospitals are independent legal entities, owned by their members (who are patients, staff, and any local individuals who desire to be members). A foundation trust hospital is governed by an independent board of governors elected by the membership and is licensed by an independent regulator outside the NHS and the Department of Health. Unlike other NHS hospitals, a foundation trust hospital may borrow from private-sector financial sources, retain surpluses and proceeds from the sale of assets, contract with NHS entities and private providers for services, and provide pay and benefits different from the NHS schedules.

The most significant change is that the foundation trust hospitals may charge for treatment of private pay patients. The private health insurance market covers almost 15% of the healthcare expenditures in England, and foundation trust hospitals, like private hospitals, are permitted to treat privately insured patients. There is a cap on the percentage of income permitted to be derived from private pay patients. Essentially, the hospitals are required to maintain the level of NHS services provided at the time of conversion to foundation trust status.

The foundation trust program started in 2004 with 10 hospitals. In 2007, more than 70 hospitals had converted to foundation trusts. The government's plan is to have all NHS hospitals convert to foundation trust status within a decade. The government's expectation is that with greater access to private capital, greater operational autonomy, and accountability to its staff and patients, hospitals will be able to overcome the limitation on resources that has plagued them since the creation of the NHS. In addition, the government is no longer financially and operationally responsible for the hospitals that are foundation trusts.

Financing the NHS

Since its inception, the NHS has been funded through a combination of general taxation and a separate national insurance tax contribution from employers and employees. The national insurance funds a range of social benefits, including the NHS and the pension system. In 2007, more than 80% of the NHS budget comes from general taxation and about 12% from the national insurance funds. The balance of revenues comes from fees (less than 3%) and debt instruments. In recent years, the NHS has accounted for about 85% of healthcare expenditures in the United Kingdom. A growing private insurance sector has fostered the growth of private physician practices and private healthcare facilities.

In 2006, government expenditures for the NHS approached \$200 billion. The per capita expenditure on healthcare in 2004 was about \$2,500, about average for the 30 nations that are members of the Organization for Economic Cooperation and Development (OECD) and substantially less than the \$6,100 per capita for the United States. For the same year, healthcare spending in the United

Kingdom was 8.1% of the gross domestic product (GDP), while it was 15.3% in the United States. The median among OECD members was 8.8%.

One of the criticisms of the NHS's financing system is that there is little transparency since taxpayers do not readily know what percentage of their taxes actually goes to the NHS. In addition, each PCT has broad authority to use its devolved budget as it determines, with the principal government control being that the PCTs are not permitted to incur deficits.

The Modernization Initiative

Reacting to criticisms about perceived declining service and lack of investment in the NHS, Prime Minister Tony Blair commissioned a reform program for the NHS that was announced in 2000 ("The NHS Plan"). The plan called for a number of measures to modernize the NHS and improve its services. Central to the implementation of the plan was a promise made in 2002 to increase the expenditures on the NHS from 7.7% of GDP to 9.4% by 2008. Three of the most important initiatives relate to patient waiting times, modernization of information technology, and providing patients with greater control over their healthcare through choice of providers.

Patient Waiting Times

By 1997 the waiting time for treatment after diagnosis was as long as 18 months because of the lack of personnel, equipment, and facilities. One result of this was increased patient dissatisfaction with the NHS. A 1999 poll found that 42% of the British public were fairly or very dissatisfied with the NHS. The long patient waiting times became a primary political issue in successive parliamentary elections. The Blair administration made waiting times the most critical improvement promised in the NHS Plan. The wait time for treatment fell to a maximum of 9 months by 2004, with the government's goal being 18 weeks, from the first appointment with a general practitioner through treatment by 2008. Although it appears that such an ambitious goal may not be met, there has been decreased public attention directed at the NHS waiting times in recent years as they have noticeably decreased.

Modernization of Information Technology

The most ambitious element of the NHS Plan was to increase substantially its investment in information technology, with the goal of creating the most modern infrastructure in healthcare. The Blair administration proposed a national program estimated to cost more than \$32 billion over 10 years for electronic medical records, electronic imaging archives, and patient appointment and management systems, along with the necessary infrastructure improvements. By 2007, the actual expenditures were more than \$20 billion, but none of the major initiatives had been fully implemented. Technical issues and cost overruns have delayed the program, which is the largest information technology program ever attempted in the country. However, it appears likely that the effort to implement electronic medical records across the NHS will be completed by 2012.

Patient Choice

A major element of the NHS Plan is to increase patient options for treatment. Called Patient Choice, this program has become the major visible change in the NHS over the past 5 years. In addition to the creation of the NHS foundation trust program, the government's plan is to allow patients to choose among several treatment facilities within the country, whether or not part of the NHS. If the facility meets NHS quality and performance standards and the charges do not exceed the maximum price that the NHS pays for such treatments, a patient may choose care at an independent treatment center for specified procedures. To date, approved procedures include many outpatient surgical procedures. In some cases, foundation trusts have entered into contracts with privately operated outpatient treatment centers to provide such services. Several non-British companies, including at least one U.S. healthcare provider, have opened treatment centers in England. Patients can now choose any NHS foundation trust hospital for treatment; in addition to the approved private-sector treatment centers, there are at least four local NHS hospitals that have contracts with the patient's PCT. Before Patient Choice, a patient was assigned to the closest local hospital that provided the prescribed treatment.

To assist patients with making choices, the Department of Health requires the collection of patient outcome data on specified medical conditions, which are published. Patients may use this information to select their treatment center or hospital.

Future Implications

The NHS is one of the most cherished of British institutions. The NHS Plan recognizes that a number of problems need to be addressed if public support and confidence are to be maintained. Foremost among these is the pressing need for modern facilities and improved access to medical technologies. Although the NHS has technologies available that rival those of any health system in the world, the dispersal of those technologies varies depending on the region and other factors that are not based on medical need.

In addition, many parts of the country depend on hospitals with outdated facilities. Although capital investment has tripled in the past 5 years, there is a need for substantial upgrading of facilities in many parts of the country. This is an area in which the NHS's efforts to develop public/private partnerships will likely be most visible. Rather than assuming the entire burden of building new facilities, it is probable that the successful experience with private independent treatment centers will provide the impetus for more ambitious partnerships to develop healthcare facilities.

Finally, there is general recognition both inside the NHS and within the government that the NHS has not developed a culture that encourages innovation in operations. Although a network of NHS innovation centers has been created to help promote the development of innovative approaches to healthcare delivery, critics have suggested that there has been little evidence of an impact to date.

UNITED KINGDOM'S NATIONAL INSTITUTE FOR HEALTH AND CLINICAL EXCELLENCE (NICE)

Within the United Kingdom's National Health Service (NHS), the National Institute for Health and Clinical Excellence (NICE) is the agency charged with the task of developing and disseminating clinical, public health, and healthcare technology guidelines to be followed by all NHS providers and provider organizations. Its objective is to develop ways to standardize treatment

approaches at the highest levels among NHS providers in order to try to ensure uniformly good-quality healthcare.

Background

NICE came into being on April 1, 1999, as part of an initiative designed to eliminate perceived historical inequities in access to the best in healthcare. The present agency is an outgrowth of the National Institute for Clinical Excellence (also known as NICE), with an expanded role and mission. In April 2005, another NHS agency, the Health Development Agency, was folded into NICE, expanding the latter agency's scope to include public health. NICE's jurisdiction extends to all NHS providers. Providers that do not belong to the NHS generally meet the standards and guidelines as well, although they are not required to do so.

Organizational Structure

A 15-member board governs NICE. The board's standing committees are the Audit Committee, the Citizen's Council Committee, and the Remuneration and Terms of Service Committee. In addition, NICE calls on the expertise of the NHS and the broad healthcare community to assist in its work. It relies on several independent advisory committees, including those on interventional procedures, public health interventions, research and development, and technology appraisal.

Role

National standards ("frameworks") that essentially define access to and eligibility for specified types of care and services are formulated by the National Service Frameworks (NSFs) body. Typically, the NSFs set up one new framework per year. While frameworks have some resemblance to clinical pathways, they are less detailed. In their annual process called the annual health check, the healthcare commissions serve as the system regulators. The commissions evaluate the system's performance against the core standards that apply to existing performance and the developmental standards that reflect the capacity to

improve. The role of NICE is to develop the working guidelines (guidances) that will be followed by the NHS provider organizations in complying with the frameworks. Currently, NICE's guidance on health technologies and clinical practice only applies to England and Wales, while its guidance on the safety and efficacy of interventional procedures applies to England, Wales, and Scotland. NICE's guidance on public health practices applies to England alone.

In evaluating technology and technological approaches, NICE works with a wide variety of consultative and advisory bodies, including several independent academic centers representing universities and other academic groups. In developing clinical guidelines, the royal medical and nursing colleges, professional bodies, and provider organizations work with NICE. When more information is needed before guidance can be developed on an interventional procedure, NICE convenes an advisory committee composed of experts in the aspect of care being studied. This development process is funded by the NHS Department of Health, which commissions NICE to develop guidelines applying to clinical practice, public health, and healthcare technology.

NICE guidelines reflect and embody the principles of evidence-based medicine as well as cost-effectiveness. Guidelines on a particular subject are developed in response to needs as perceived and articulated by the public, the healthcare community, and professional and technology-oriented organizations and proposed by them to NICE for action. NHS providers to whom a NICE guideline, or guidance, applies are then expected to follow this guideline in their practice, taking it fully into account when deciding what treatments to give people. The healthcare commissions survey and evaluate provider performance with reference to the guidance.

In one sense, the NICE guidances show a superficial resemblance to the advisories published by the U.S. Agency for Healthcare Research and Quality (AHRQ), although NICE publishes specific implementation templates to support its guidances, listing the steps in the implementation process.

When NICE issues a guidance covering a treatment measure addressed in a core standard, the budget provisions needed by the NHS member organization to support practitioner and provider

compliance with that guidance must be in place within 3 months. In the case of a guidance reflecting a developmental standard, provider organizations are allowed more than 3 months for implementation.

UNIVERSITY HEALTHSYSTEM CONSORTIUM (UHC)

Established in 1984, the University HealthSystem Consortium (UHC) is a nonprofit alliance of more than 100 academic medical centers and 170 of their affiliated hospitals, representing approximately 90% of the nation's nonprofit academic

medical centers. Based in Oak Brook, Illinois, the consortium offers its members specific programs and services to improve clinical, operational, financial, and patient safety performance.

Mission and Vision

The mission of the UHC is to advance knowledge, foster collaboration, and promote change in order to help members succeed in their respective markets. Its vision is to be a catalyst for change, accelerating the achievement of clinical and operational excellence.

Products and Services

The UHC's various products and services provide support and resources for effective and efficient management of clinical, operational, and financial performance of an academic health system's enterprise through comparative data analytics, implementation assistance, educational and developmental resources, and networking and collaboration opportunities. Easy-to-use online reports and other Web-based tools blend clinical, operational, administrative, and financial data, enabling UHC members to benchmark and compare their performance with that of their peers and act on opportunities to improve. Product examples include the Funds Flow Collaborative, a database and reporting system of the economic interdependencies of academic medical centers, schools of medicine, and faculty practice plans; the UHC Patient Safety Net, an online data collection tool for reporting, tracking, and trending of adverse medical events; the Faculty Practice Solution Center, a database used to examine clinical productivity, plan physician incentive compensation, perform workforce analysis, and promote revenue cycle improvement; and the Managed Care Contracting Compass, an interactive database and packaged pricing model that compares various managed care contracts on a regional or national basis. Additionally, the consortium provides a variety of other services and products in areas including quality and risk, technology assessment, business strategy and tactics, and value analysis.

The UHC's supply chain optimization program is another exclusive, integrated offering of services designed to help its members make the best possible

decisions when addressing their organizations' supply chains. Novation, LLC, is the group purchasing organization for consortium's participants.

Membership

There are two categories of UHC membership: member and related organizations. For the membership category, an applicant for membership in the consortium must be a nonfederal teaching hospital or health system that has a documented affiliation agreement with a medical school by the Liaison Committee on Medical Education and fulfils one of the following conditions: (a) it is under common ownership with a medical school; (b) the majority of the medical school department chairs serve as the hospital's chiefs of service, or the chairman is responsible for appointing the hospital chief of service; or (c) it has a reputation for excellence in service, teaching, and research as determined at the discretion of the UHC Member Board of Directors, or its designee, based on consideration of clinical support of undergraduate medical education and an employed clinical faculty with a centralized practice plan.

System membership has two or more clinical entities that serve the same medical school and independently meet the criteria for full membership. Each category contains several classes of participation, with the following designations: (a) associate—an acute-care hospital that is sponsored by a consortium member or organizational member; (b) organization—an affiliated organization invited by the consortium's Governing Board to join the UHC (e.g., National Association of Public Hospitals); (3) international—a non-U.S. alliance of teaching hospitals (like the UHC) or a teaching hospital that meets the above membership criteria; (4) faculty practice plan—a faculty group practice organization associated with a medical school and organized with a unified corporate governance structure, which provides identifiable and functionally integrated practice management services and is accountable for the clinical, financial, and operational performance of its member physicians.

In addition, full UHC members and associate members may sponsor entities that provide health-care services (other than an acute-care hospital) as an affiliate or an alternate shipping location. Other consortium member-sponsored providers, including

faculty practice plans, ambulatory clinics, medical schools, universities, and others can access the power of group purchasing through the consortium's affiliate purchasing program.

Implications for Health Services Research

The UHC's major contribution to health services research is its provision of data to researchers from member organizations. Data from the consortium enable researchers to compare clinical practice patterns and the outcomes of care at academic medical centers across the nation. Because of such a large number of medical centers and the large number of patients they treat, data from the consortium can be used to study critical and emerging issues of clinical and strategic importance. Data from the consortium have been used to study the outcomes of bariatric, colon, and other surgeries; various pharmaceutical and disease state evaluations; intensivist physician staffing patterns; and outcomes of various medical education programs, including nurse residency programs.

URBAN INSTITUTE

The Urban Institute is a nonprofit, nonpartisan policy research and educational organization established in Washington, D.C., in 1968. Its multidisciplinary staff investigates the social, economic, and governance problems confronting the nation, evaluates the public and private means to alleviate them, and helps other countries build local government capacity, improve public service delivery, and nurture civil society.

Through work that ranges from broad conceptual studies to administrative and technical assistance, Institute researchers contribute to the knowledge available to guide decision making in the public interest and strive to deepen citizens’ understanding of the issues and trade-offs policy-makers face.

The Institute’s genesis came in the mid-1960s, when many U.S. cities were in turmoil and tatters. President Lyndon B. Johnson, seeing the need for independent, unbiased analysis of the problems facing urban America, created a blue-ribbon

commission of civic leaders who recommended chartering a center to do that work. The Urban Institute became that center.

Today, the Urban Institute is home to 10 policy centers and more than 230 economists, demographers, statisticians, sociologists, political scientists, educators, and other researchers and analysts. Its Health Policy Center, inaugurated in 1977 and now one of the Institute’s largest research centers, uses rigorous methods to bring objective evidence to the panoply of health service concerns, including community-based care, disabilities, health insurance, hospital and physician payments, long-term care, Medicaid, Medicare, the State Children’s Health Insurance Program (SCHIP), and uninsured and uncompensated care. Center scholars also address cost containment, managed care, liability and tort reform, the financing and delivery of health services, and their quality and appropriateness, among other issues.

Much of the Health Policy Center’s work is on who gets needed health coverage, who doesn’t, what the ramifications are of not having health insurance, and what can be done to secure access to care. A review of a quarter-century of studies found strong evidence that the uninsured receive fewer preventive and diagnostic services, tend to be more severely ill when diagnosed, and receive less therapeutic care, resulting in poorer health outcomes and higher mortality rates. Research on why 46 million people lack health insurance found that nearly all of them believe that they need coverage but more than half say that they can’t afford it. Perceptions about cost matter, the study determined, whether the uninsured individual is old or young, healthy or disabled, with high income or income well below the poverty level.

Another analysis determined that the number of nonelderly people without health insurance climbed by 1.3 million between 2004 and 2005, bringing this group’s uninsurance rate to nearly 18%. Eighty-five percent of this increase was among those with family incomes below 200% of the federal poverty level. The analysis showed that job-based insurance is dropping because of significant increases in premium costs; job shifts away from medium and large firms and those in the manufacturing, finance, and government sectors, employment environments that traditionally have high rates of employer-based insurance coverage; and

population movement toward the South and the West, regions with lower rates of employer-based health insurance coverage.

At the 10th anniversary of the SCHIP in 2007, the Institute estimated that the program had signed up close to 70% of its target population, but 1.8 million eligible children nationwide were yet to be enrolled. Federal funding for SCHIP, which was enacted in 1997 to expand health coverage to low-income uninsured children who do not qualify for Medicaid, will have to increase substantially, the study noted, if these children are to join the approximately 3.9 million children with SCHIP coverage.

Health Policy Center researchers also analyze local and regional healthcare circumstances and services, glean data, lessons, and insights that are often useful across the country. Legislation enacted in Massachusetts in 2006 aimed at bringing near-universal healthcare coverage to the state. The bipartisan legislation drew partly on the center's extensive analysis and practical policy recommendations on costs and mechanisms for covering the state's 530,000 uninsured residents. As healthcare costs soar nationwide and more businesses trim employee coverage, Institute staff are working with other states to define their range of policy options.

New York State's medical providers cared for 2.5 million uninsured individuals in 2005, a Health Policy Center research team found. Federal, state, and local governments transferred billions of dollars to hospitals and other providers in a number of complex ways, of which \$3.5 billion was deemed to relate to uninsured care. After Hurricane Katrina devastated the Gulf Coast, a Health Policy Center white paper examined what happened in New Orleans's hospitals, especially the 11 flood-bound institutions in the most desperate circumstances, why experiences varied for the hospitals and their patients, and how to avoid the most serious shortcomings in planning by hospital and public authorities.

The U.S. Congress, executive branch agencies, and state officials often call on the Urban Institute researchers to present their research or testify on legislative matters. At a U.S. House subcommittee hearing, for instance, legislators were told that developing meaningful universal health insurance coverage within a private insurance system requires

four elements: (1) comprehensive subsidized insurance benefits for low- and modest-income individuals, (2) a guaranteed source of coverage for all potential purchasers, (3) a mechanism for spreading across a broad population the costs of covering those with the greatest need for healthcare services, and (4) either a mandate for individuals to obtain coverage or that mandate combined with a "light" employer mandate.

Health policy researchers frequently call on the expertise of other Institute centers. The Transfer Income Model (TRIM), maintained and developed by the Income and Benefits Policy Center under primary funding from the U.S. Department of Health and Human Services (HHS), can illuminate the effects of changes in Medicaid, SCHIP, or employer-sponsored health insurance as well as assess participation rates and cross-program interactions. With the nation spending more than \$250 billion annually on tax incentives for workers to buy health insurance, the Urban-Brookings Tax Policy Center investigates how income tax deductions, vouchers, and similar mechanisms can meet healthcare challenges.

Health policy has been a cornerstone of the Institute's biggest research project ever. Started in 1996, *Assessing the New Federalism* monitored and analyzed the well-being of American children and families as states assumed major responsibility for healthcare, income security, social services, and job-training programs for low-income Americans. Caseloads dropped precipitously after 1996's landmark welfare overhaul, but the Institute research revealed that 1 year later, 49% of mothers who had left the rolls and 29% of their children had no health insurance.

Looking ahead, the Institute's projects will report on the condition of and changes in the healthcare delivery system throughout the United States; estimate the risk, timing, and amount of lifetime disability and long-term care, including both nursing home care and care at home; model health insurance costs and the impact of reinsurance, with technical assistance to states considering health reforms with a reinsurance component; and look at the path from the Food Stamp and school meal programs and family food behavior to child obesity.

U.S. DEPARTMENT OF VETERANS AFFAIRS (VA)

The U.S. Department of Veterans Affairs (VA) operates the nation's largest integrated healthcare system providing services and benefits to veterans, active-duty military personnel, and their dependents through a nationwide network of 155 hospitals, 881 outpatient clinics, 135 nursing homes, 46 residential rehabilitation treatment programs, 207 readjustment counseling centers, 57 veterans benefits regional offices, and 125 national cemeteries. In 2006, it provided care to nearly 5 million unique patients and 54 million outpatient visits.

Established in 1930 as the Veterans Administration, it was elevated to U.S. Cabinet-level status in 1989, becoming the U.S. Department of Veterans Affairs. Today, the VA is the second largest Cabinet department, employing more than 235,000 individuals. It is composed of a Central Office (VACO), which is located in Washington, D.C., and field facilities throughout the nation administered by its three line organizations: (1) Veterans Health Administration (VHA), which provides healthcare services; (2) Veterans Benefits Administration (VBA), which determines eligibility-level and benefits; and (3) the National Cemetery Administration (NCA), which provides burial services for veterans.

The VA plays a major role in improving the public's health as well as conducting clinical research. Additionally, it is the nation's largest provider of healthcare education and training for medical residents and other trainees and is one of the 10 largest research and development agencies in the federal government. In FY2006, the VA's appropriated budget was \$73.6 billion.

History

The early tradition of caring for our nation's veterans can be traced back to colonial times. For more than 140 years, care for the country's veterans was provided by a patchwork of various federal agencies. In 1930, however, the U.S. Congress authorized the President to consolidate all government activities that affected war veterans, combining the Veterans Bureau, the Bureau of Pensions of the Department of Interior, and the National Home for Disabled Volunteer Soldiers within the new Veterans

Administration. After World War II, a large number of veterans needing medical care inundated the VA's rudimentary healthcare capabilities. As a result, in 1946, the U.S. Congress formally authorized a healthcare system for veterans, creating the VA Department of Medicine and Surgery.

Additionally, the VA was given the responsibility of administering the GI Bill, which was passed in 1944. The GI Bill provided education and training for all veterans. Since its passage, more than 21 million veterans, service members, and their dependents have received nearly \$27 billion in benefits. In 1973, the VA also assumed the primary responsibility for the National Cemetery System from the Department of the Army. As a result of its increasing responsibility and importance, in 1989, the VA was elevated to an executive-level department with membership in the President's Cabinet.

Today, the VA provides a comprehensive and coordinated system of assistance for all the nation's veterans and their families. It operates national programs providing healthcare, financial assistance, and burial benefits, as well as supporting a large research program. Approximately 63 million individuals are potentially eligible to receive VA benefits and services because they are veterans, dependents, or survivors of veterans.

Medical Care

Because all veterans are potentially eligible for care at the VA, providing access to healthcare and other benefits has long been a challenge. To meet the healthcare needs of America's veterans, the VHA provides a broad range of primary-care, specialized-care, and related medical and social support services. The VHA healthcare facilities provide a broad spectrum of medical-surgical and rehabilitative care. Beginning with a system of 54 hospitals in 1930, the VHA has expanded to 155 medical centers—with at least one medical center in each state, Puerto Rico, and the District of Columbia. It also operates ambulatory care and community-based outpatient clinics, nursing homes, residential rehabilitation treatment programs, veterans centers, and comprehensive home care programs.

To ensure that veterans continue to receive needed medical care in the future, the U.S. Veterans Administration runs the largest medical education and health professions training program in the

nation. More than one half of the physicians practicing in the United States had some of their professional education in the VHA healthcare system. VHA facilities are affiliated with 107 medical schools, 55 dental schools, and more than 1,200 other schools across the country.

Costs

The annual spending of the VA in FY2005 was \$71.2 billion. A total of \$31.5 billion was allocated for healthcare, with the largest portion of the budget used for benefit payments. In FY2006, the budget was increased by \$1.8 billion for additions in healthcare and disability compensation.

The President's proposed budget for FY2008 seeks funding for an expansion of the services provided to veterans, including \$36.6 billion for medical care, \$1.3 billion for more prosthetics and sensory aids, \$3 billion for needed mental healthcare, and \$750 million for the construction of medical facilities. Much of the rapidly increasing budget costs of funding the VA are attributable to national increases in healthcare costs.

Quality

The quality of healthcare given by the VHA has been examined very closely. Recent studies conducted by Harvard Medical School concluded that federal hospitals, including those operated by the VHA, provided superior care for some of the most common medical conditions, including heart attack, heart failure, and pneumonia. The researchers found that patients who were treated in federal facilities were more likely to receive high-quality care than those in for-profit hospitals. Another study conducted by the RAND Corporation found that the VHA outperformed all other sectors of healthcare in the United States across a spectrum of 294 measures of quality in disease prevention and treatment.

Research

The U.S. Veterans Administration is one of the 10 largest research and development agencies in the federal government. Specifically, it has the eighth largest research and development portfolio in the FY2008 budget. The entire research and development budget

is allocated to a nationwide network of VHA hospitals and Centers of Excellence (COE).

The VHA advances medical research and development in ways that support veterans' needs by pursuing research in areas that most directly address the diseases and conditions that affect veterans, including combat-related trauma. The knowledge gained from research conducted at the VHA contributes to the public good through improving the understanding of diseases and disabilities. The advances in technologies from research at the VHA, intended primarily for veterans, also lead to gains in medical education, patient care, and public health. Some notable research conducted at the VHA includes construction of the first artificial kidney, development of the cardiac pacemaker, the first successful liver transplant, and development of prosthetic devices such as hydraulic knees and the robotic arm.

The major areas of research and development at the VHA include biomedical laboratory science, clinical science, rehabilitation research, and health services research. The biomedical laboratory science is the largest budgeted area of research, and it focuses on aging, chronic disease, and environmental exposures. Clinical science research funds clinical trials and other medical research using the large patient population in VHA medical facilities. Rehabilitation research focuses on improving the quality of life of veterans with disabilities, such as developing improved prosthetics. Health services research focuses on improving the effectiveness and efficiency of healthcare services and translating research into clinical practice. The objectives of health services research at the VHA include improving clinical decision making and care, informing VHA policy making, evaluating changes in the healthcare system, measuring health outcomes, and informing patients and the public interested in healthcare research.

One of the most significant transformations in the research portfolio at the VHA is the development of the COE, established by the VHA Health Services Research and Development (HSR&D), which provides for 15 centers across the country. Each center, which is affiliated with a VHA medical center, develops its own research agenda and collaborates with local universities and schools of public health to fulfill its mission. The research at each center serves to energize the facility and network with which it is affiliated and is designed to provide a constant source of innovation.

Women Veterans' Healthcare

Of the nation's 27 million veterans, about 6% are women, with the number expected to rise to 10% by 2010. And women constitute the fastest growing segment of eligible VHA healthcare users. Women veterans have their own unique healthcare needs, and the VHA seeks to make sure that they receive the best available care to meet those needs. Research studies conducted or funded by the VHA are mandated to include women veterans as a way of ensuring that their specific health needs are taken into consideration. In the past decade, there has been an expansion of biomedical, clinical, health services and rehabilitation research with the goal of improving the health status of women veterans. Recent initiatives through the VHA Women's Health Research and Development (ORD) commenced a VHA Women's Health Research Planning Group to develop a comprehensive research agenda for women veterans and to position the VHA as a national leader in women's health research.

Organizational Transformation

With the rapid changes in the nation's healthcare system and the aging of the nation's population, the U.S. Department of Veterans Affairs found itself in need of change. In 1995, the VA underwent a significant organizational transformation. The overarching goals of the reorganization were to optimize the value of VHA healthcare and to ensure the consistent and predictable provision of high-quality care throughout its system.

Among the major changes that took place were that the VHA went from a centralized system to a decentralized national network of facilities and 21 Veterans Integrated Service Networks (VISN) were established. These decentralized regional networks of care were created to better focus the needs of veterans in a specific region of the country. Under this new system, each network of providers and facilities assumes responsibility for the health of a specific population of eligible veterans.

Another significant change was the move to increase access to care through ambulatory settings. During this period of restructuring, 28,886 (55%) of inpatient acute-care beds closed, while the outpatient capacity increased with the opening of 302 community-based outpatient clinics.

A shift in the management style also occurred during the VA's organizational transformation with the creation of a performance management program that emphasized quality improvement and quality innovation. Managers were held contractually accountable to achieving predefined targets within a specified time frame. In addition, several best practices were implemented to improve clinical care.

Another major innovation at the VA was the implementation of a systemwide electronic health record called the Veterans Health Information Systems and Technology Architecture (VISTA). The VISTA system is designed to network the health records at all the VHA's inpatient and outpatient healthcare facilities nationwide. Because of VISTA, a wealth of information is available to conduct clinical and health services research studies on the VHA. The VHA also implemented the Quality Enhancement Research Initiative (QUERI), a systemized quality innovation program that links the aspects of clinical care, teaching, research, and the continuous measurement of outcomes to ultimately improve patient care.

Current and Future Direction

The VA has extraordinary responsibilities to meet the healthcare needs of veterans and their families and undertakes research to improve healthcare services. The VA, by necessity, meets new standards of care, the rising drug costs, technological innovations, and labor concerns. Through its radical reengineering and transformation, the VA has become a pioneer in coordinating and systematizing healthcare. Today, the VA continues its legacy of caring for our nation's veterans, conducting research that improves their healthcare, and providing vital education and training to medical professionals. The VA will continue its mandate of serving veterans and their families in the future.

U.S. FOOD AND DRUG ADMINISTRATION (FDA)

The U.S. Food and Drug Administration (FDA) is an agency of the Department of Health and Human Services (HHS) with massive and broad-ranging

consumer protection responsibilities. The mission of the FDA is to protect the public's health through the provision of information and regulation (including the manufacturing, importing, transporting, and sale) of human and veterinary drug products, biological products, medical devices, food products (other than traditional meat, poultry, and egg products, which are regulated by the U.S. Department of Agriculture), cosmetics, and radiation-emitting electronic products. The average American consumer spends more than 20 cents of every dollar in the purchase of FDA-regulated products, which total more than \$1 trillion in annual sales. The FDA's far-reaching authority and global influence rank it as among the most influential regulatory agencies in the world. Yet the FDA faces critical challenges in meeting its mission because of leadership transitions and lack of funding.

History

The evolution of the FDA has been described as a series of crisis-legislation-adaptation cycles. A consistent pattern marks historical milestones in societal and governmental responses that affected the FDA: crisis mode following public outcry from a well-publicized public health tragedy, passage of congressional legislation in response to public pressures, and adaptation by the FDA or its predecessors to implement new laws.

Prior to the 20th century, states and local governments were the primary regulatory authorities for foods and drugs, and there were loose oversight and many problems pertaining to the adulteration (contamination) and misbranding (mislabeling) of foods and drugs. The U.S. Congress passed a small number of individual laws pertaining to specific foodstuffs sold in interstate commerce, but these laws were of very limited scope. Early federal legislative efforts that influenced the later establishment of the FDA included the following: the Vaccine Act of 1813, which was enacted to prevent fraudulent marketing of smallpox vaccine and provided for the preservation of a reference standard of smallpox vaccine against which other purported vaccines could be compared (the act was repealed in 1822, after an outbreak of smallpox thought to be related to a contaminated lot supplied for the reference standard and the belief that vaccine regulation should be locally based rather

than federally based); the Drug Importation Act of 1848, which prohibited the importation of adulterated drugs following suspected mortality of U.S. soldiers from contaminated quinine and other drugs imported during the U.S.-Mexican War; and the Biologics Control Act of 1902, which required licensing of establishments that produced and marketed vaccines and antitoxins, following the deaths of almost two dozen children who were inoculated with a diphtheria antitoxin that was later found to be contaminated with tetanus bacillus.

A series of events, based on actuality and hyperbole, revealed disturbing problems of food adulteration in the 1800s and early 1900s, when advances in chemistry enabled increased detection of contamination. The origins of the FDA date back to President Lincoln's appointment of Charles M. Wetherill (as a one-man staff) in the Division of Chemistry of the U.S. Department of Agriculture in 1862. His appointment began the scientific foundations for activities now under the jurisdiction of the FDA, although commensurate regulatory authority was not established for decades to come. Later, Harvey W. Wiley was appointed Chief Chemist from 1883 until 1912 for the Division, which became the Bureau of Chemistry in 1901. In 1927, the Bureau changed its name to the Food, Drug, and Insecticide Administration, and in 1930, it shortened it to the Food and Drug Administration (FDA).

With political acumen, a knack for sensationalizing events and garnering media attention, the ability to form alliances, and an unwavering tenacity, Wiley spearheaded efforts to revolutionize the power of his office. His initiatives included the highly publicized 1902 Poison Squad, which consisted of noncontrolled experiments to assess the effects of chemical preservatives on healthy volunteers and other tactics. Wiley's efforts coincided with accounts of fraudulent and toxic medicines in many magazines, and the publication of Upton Sinclair's novel *The Jungle*, a horrifying and outrageous exposé on the nation's meatpacking industry. This provided the impetus for enactment of the 1906 Pure Food and Drugs Act (nicknamed the Wiley Act). The Pure Food and Drugs Act prohibited the interstate transport of misbranded and contaminated foods, drinks, and drugs; required labeling of a select list of ingredients (if included) and their amounts in patent medicines; and prohibited false

and misleading advertising of the ingredients (but not therapeutic claims) of patent medicines on product labeling. Loopholes in the act included the exclusion of advertising materials as part of product labeling and enforcement difficulties due to lack of funding and onerous legal requirements to prove adulteration and misbranding.

Several bills were introduced in the U.S. Congress in an attempt to remedy the shortcomings of the 1906 Pure Food and Drugs Act, but there was no change until another public health crisis occurred. In 1937, in an attempt to improve the flavor, the S. E. Massengill Company of Bristol, Tennessee, added the solvent diethylene glycol to lots of the antibiotic Elixir Sulfanilamide. Given the toxic properties of the solvent (similar to antifreeze), 107 individuals (mostly children) died as the result of ingesting the formulation before the problem was contained. Public uproar prompted congressional passage of the 1938 Food, Drug, and Cosmetic Act. This act provided for the following: requirement of scientific testing to establish drug safety (with the burden imposed on the product manufacturers) prior to marketing; regulation of cosmetics and devices used for therapeutic purposes; authorization of the FDA to inspect manufacturing facilities; virtual prohibition of poisonous additives in foods; authorization to stop false drug claims; and expanded legal options that the FDA could pursue, including product seizures, criminal prosecutions, and federal court injunctions. The 1938 act and its amendments underpin the FDA's current regulatory authority, including amendments regarding pesticides (Miller Pesticide Amendment of 1954), additives (1958 Food Additives Amendment and the Color Additive Amendment of 1960), and drugs. Of note, the 1951 Durham-Humphrey Amendment to the 1938 act specified the FDA classification of prescription drugs (or legend drugs) and nonprescription or over-the-counter drugs; previously, drugs could be purchased much like any other commodity. Attempted legislative efforts that called for the FDA to establish drug product safety and efficacy were unproductive until the thalidomide tragedies.

Thalidomide was marketed in Germany as a sedative and antinausea medicine from 1957 until 1961, during which time it was found to cause thousands of congenital birth defects and malformations, disabilities, and deaths of babies whose

mothers took the drug during pregnancy. While the United States experienced only 17 confirmed birth defects from thalidomide, the incident helped bring about the enactment of the Kefauver-Harris Drug Amendments to the 1938 act. The 1962 Kefauver-Harris Drug Amendments mandated demonstration of drug product safety and substantial evidence of efficacy (including review of drug products approved between 1938 and 1962 solely on the basis of safety), FDA authority over well-controlled drug trials, regulation of prescription drug advertising, and establishment of good manufacturing practices. The Medical Device Amendments of the 1938 act were enacted in 1976, based on the findings of more than 10,000 injuries and 731 deaths from faulty devices, such as contraceptive intrauterine devices.

Another legislative milestone was the 1984 Drug Price Competition and Patent Term Restoration Act (also known as the Waxman-Hatch Act), which enabled the FDA to accept abbreviated new-drug applications (ANDAs) for generic drug products and increased the effective patent term of drug products, which had been eroded by the length of the drug approval process. More federal laws were passed pertaining to foods, drugs, devices, or cosmetics over the past 25 years, including the 1990 Nutrition Labeling and Education Act, which required uniform labeling information of nutritional content and allowed for validated scientific health claims, and the 1994 Dietary Supplement Health and Education Act (DSHEA), which greatly restricted the FDA's jurisdiction in regulating dietary supplements (e.g., orally administered vitamins, minerals, herbs, amino acids, metabolites, and other substances) unless the agency found them to be unsafe after marketing them.

One of the more controversial statutes affecting the FDA in recent years was the 1992 Prescription Drug User Fee Act (PDUFA) and its subsequent amendments in 1997 (PDUFA II), 2002 (PDUFA III), and 2007 (PDUFA IV), as well as the 2002 Medical Device User Fee and Modernization Act and its subsequent amendment. The PDUFA legislation established user fees for human drug and biologic products on submission of an application and fees on an annual basis. The additional funding from user fees was designed to enable the hiring of additional FDA staff, which would shorten review times for product approval. Enactment of

the PDUFA provisions, however, was met with controversy (accusations of conflict of interest between the FDA and its regulated industries that paid the user fees), increased FDA staff reviewer workloads, compromised staff morale and increased staff turnover, and unresolved questions about increased withdrawal rates of marketed drug products under the tighter product approval times.

Organization and Staffing

The FDA was transferred to different cabinet-level departments throughout the 20th century (from the U.S. Department of Agriculture to the former Federal Security Agency in 1940, which became the U.S. Department of Health, Education, and Welfare [DHEW] in 1953; FDA was reorganized as part of the U.S. Public Health Service [USPHS] within the DHEW in 1968). DHEW was renamed the Department of Health and Human Services (HHS) in 1980, and the FDA remains based in that department.

Under the leadership of the FDA commissioner, the agency has a staff of more than 9,000 employees with about two thirds in the Washington, D.C., area headquarters (i.e., Rockville, Maryland, with an anticipated consolidation of FDA facilities located at a Silver Spring, Maryland, site by 2009). FDA's headquarter staff focus on product review, regulatory policy, and consumer information. The other third of FDA staff are located in field offices and laboratories across the nation, and their responsibilities are concentrated more on inspections, surveillance, and education. Globally, the FDA works with foreign governments to help ensure the safety and quality of imported products.

The FDA employs staff in the physical sciences, medicine, public health, and many other areas. Its professional staff includes physicians, biologists, chemists, veterinarians, animal scientists, toxicologists, pharmacologists, biomedical engineers, nurses, pharmacists, epidemiologists, statisticians, communications experts, business people, consumer safety officers, and public affairs specialists.

Major FDA Centers

The FDA is organized into the Office of the Commissioner (leadership, management, and operations), the Office of Chief Counsel (litigators

and counselors), the Office of Regulatory Affairs (Food, Drug, and Cosmetic Act compliance, and field agent activities), and five major centers, described below. Some regulated products are referred to as "combination products" (e.g., a combination of drugs and devices, or a biologic and a device). Assignment of combination products to one of the centers may first require referral from staff in the Office of Combination Products.

Center for Drug Evaluation and Research

The FDA's Center for Drug Evaluation and Research (CDER) reviews, approves, and monitors the safety and efficacy of prescription and nonprescription drug products that are marketed in the United States. More than 10,000 drug products are currently being marketed in the nation. The FDA assumes enormous responsibility in the paradoxical duty of benefit-to-risk judgments regarding timely approval of drug products (especially for serious or life-threatening conditions where no therapeutic options are available) and continued market availability when serious problems are noted.

The drug development and approval process in the United States involves a series of rigorous steps that can take from 11 to 12 years (FDA estimate) to 15 years (industry estimate) to go from initial laboratory testing to product approval. These processes start with preclinical testing of biological activity and safety evaluations for the compound (laboratory tests, animal studies, and computer models). After promising preclinical testing, the sponsor can file an application (i.e., Investigational New Drug Application, or IND) to begin three phases of clinical testing in people (with greater numbers of subjects in each subsequent stage). If the data demonstrate safety and effectiveness, a New Drug Application, or NDA, can be submitted to the FDA for review and possible approval of the product for commercial availability as a new molecular entity. However, very few compounds—estimated to be as few as 1 out of 10,000—make it through the process from preclinical testing to final market approval at costs to the sponsors of hundreds of millions of dollars. Regulatory agencies may also call for postmarketing surveillance and additional studies after drug product approval to evaluate the long-term effects.

Generic drug applications undergo an ANDA process. For approval, the generic product must contain the same active ingredient as the innovator product; be identical in strength, dosage form, and route of administration; list the same indications for treatment; and demonstrate bioequivalence. The median ANDA approval is about 16.6 months.

Center for Biologics Evaluation and Research

The FDA's Center for Biologics Evaluation and Research (CBER) regulates biological products such as blood and blood products, vaccines, allergenic products, and protein-derived bioengineered drug products (e.g., monoclonal antibodies, cytokines, and enzymes). The biotechnology pharmaceutical industry has a product approval process similar to other research-intensive pharmaceutical products, including discovery; preclinical studies; IND and Phase I (safety), Phase II (safety and efficacy), and Phase III (large controlled studies on safety and efficacy) clinical trials; NDA and FDA review; drug product approval; and postapproval monitoring. The approval time for a biopharmaceutical ranges between 7 and 12 years from development to approval. The center also regulates human gene therapies, xenotransplantation of organs from animals to humans, cellular and tissue transplants (including stem cell therapy) and other products derived from living organisms.

Center for Devices and Radiological Health

The FDA's Center for Devices and Radiological Health (CDRH) regulates new medical devices and provides for postmarketing surveillance. A few examples of medical devices include tongue depressors, thermometers, contact lenses, glucose level monitors, blood pressure monitors, surgical robotic-arm tools, laboratory tests, and technologically complex devices such as pacemakers, heart defibrillators, and dialysis machines. The center classifies medical devices based on proposed risk and intended use. Class I medical devices (e.g., examination gloves, bandages) represent the least risk, Class II devices (e.g., X-ray machines, electronic wheelchairs) intermediate risk, and Class III devices (e.g., heart valves, breast implants) the highest risk. With some exceptions, premarket approval is generally required for Class III medical

devices. In the majority of cases where premarket approval is not required, medical devices are regulated subject to premarket notification requirements from Section 510(k) of the Food, Drug, and Cosmetic Act. The U.S. Government Accountability Office (GAO) is currently reviewing whether there is a need for revising the 510(k) process in consideration of the possible need for more evaluation of clinical safety.

Additionally, the center establishes performance safety standards for radiation-emitting electronic products such as microwave ovens, television sets, cellular telephones, X-ray equipment and systems (including airport-scanning equipment), laser products, medical imaging techniques, sunlamps, and other products. It also provides accreditation of mammography facilities.

Center for Food Safety and Applied Nutrition

The FDA's Center for Food Safety and Applied Nutrition (CFSAN) regulates the safety and labeling of foods (except meats, poultry, and egg products) and bottled water. The center strives to ensure that food products are uncontaminated, approves food additives, and regulates the contents of medical foods and infant formulas. Within the limits of the 1994 DSHEA, the center is responsible for regulating the safety of dietary supplements. It also monitors the safety and labeling of cosmetics, which do not require premarket approval (with the exception of color additives). The agency cannot require safety testing of cosmetics. The FDA is authorized, however, to pursue enforcement actions when product violations are found regarding the adulteration and misbranding of cosmetics.

Center for Veterinary Medicine

The FDA's Center for Veterinary Medicine (CVM) regulates the safety of animal food products and the improvement of the health and productivity of food-producing animals. Drugs administered to livestock must meet safety standards for the animals and humans who may eat such animal products. Specifically, the center regulates pet food production, feeds for livestock, and the approval and marketing of drug products (prescription and over the counter) used to treat animals. It also regulates the safety, effectiveness, and labeling of veterinary

devices, which do not require preapproval before marketing, unlike human medical devices.

National Center for Toxicological Research

The FDA's National Center for Toxicological Research (NCTR) conducts scientific research and provides technical expertise on mechanisms of toxicities, human exposure, susceptibility and risk involving chemicals and pharmaceuticals, food contamination, and biomarkers for chemical and biological terrorism.

Information Provision

Much information from the FDA is provided on its Web pages, which receive more than 1 million hits per day. The FDA publishes numerous consumer resources (e.g., magazines, brochures, fact sheets, and other materials) providing product and health information. It also administers two drug information centers, one in the CDER and the other in the CBER, to provide FDA-approved prescribing information on products and regulatory guidance. Inquiries come from a range of diverse constituents, including patients, consumers, health professionals, trade associations, insurance companies, regulated industries and other sponsors, advertising agencies, attorneys, investment companies, academia, law enforcement, government agencies, and the media. Information is provided by FDA staff on clinical information, adverse events, clinical investigations and trials, electronic regulatory application submissions, review processes, regulations pertaining to imports and exports, patents and exclusivity, product recalls and shortages, and product identification.

Challenges

The FDA faces a number of major challenges, including leadership, funding, and improving the nation's drug safety system. Each is discussed below.

Leadership

The FDA commissioner is appointed by the President of the United States on confirmation by

the U.S. Senate. A major challenge to the agency is the lack of stable leadership, highlighted by the fact that no commissioner has served longer than 2 years since 1997. And the position of commissioner has been vacant for many months at various times.

Funding

With small increases in congressional appropriations, the FDA budget has increasingly become dependent on user fees. Its FY2009 budget requested almost \$2.4 billion, representing about \$1.77 billion in appropriations and \$628 million generated from industry-provided user fees. Many researchers and policy analysts believe that the FDA budget is inadequate given its comprehensive regulatory authority and that more public funding is needed. While user fees increased the funding available for drugs and biologics reviews under the PDUFA mechanisms, programs that were not supported by the PDUFA fees (including drug, food, and medical device initiatives) lost about 1,000 FDA staff members since 1992 as the result of diminished funding.

Drug Safety System

In a 2007 report, the National Academy of Sciences, Institute of Medicine (IOM) summarized some of the FDA challenges and needed improvements in the nation's drug safety system. In addition to recommendations for increased funding, the report identified organizational problems in the FDA culture that contribute to the inadequate integration of premarket and postmarket safety review data; technical limitations in the ability of the current passive postmarketing surveillance system to detect signals and analyze safety systems adequately; and unclear regulatory authority over manufacturers postapproval. The report recommended more joint authority for postapproval regulatory actions within the FDA; systematic approaches in benefit-risk judgments; and the establishment of private-public partnerships and collaborative efforts among federal agencies, pharmaceutical and biotechnology companies, and managed-care organizations to consolidate stakeholder data that can support postapproval drug safety monitoring.

U.S. GOVERNMENT ACCOUNTABILITY OFFICE (GAO)

The U.S. Government Accountability Office (GAO) is an independent, nonpartisan agency that works

for the U.S. Congress. Often called the "congressional watchdog," the GAO investigates how the federal government spends taxpayer dollars. GAO's mission is to support the U.S. Congress in meeting its constitutional responsibilities and to help improve the performance and ensure the accountability of the federal government. This includes performance and accountability related to federal health programs and spending in areas including public health, Medicare and Medicaid, defense healthcare, veterans health, long-term care, disaster preparedness, and pandemic health issues.

The GAO advises the U.S. Congress and the heads of executive agencies about ways to make government more efficient, effective, ethical, equitable, and responsive. The GAO's work is done at the request of congressional committees or subcommittees or is mandated by public laws or committee reports. The agency also undertakes research under the authority of the head of the GAO, the Comptroller General of the United States. The President appoints the Comptroller General to a 15-year term from a slate of candidates the U.S. Congress proposes. The Comptroller General cannot be reappointed and has a mandatory retirement age of 70. However, the President cannot remove the Comptroller General; only the U.S. Congress can through impeachment or joint resolution for specific reasons. GAO's main headquarters is located in Washington, D.C., and it maintains 11 field offices in various cities throughout the nation. It employs more than 3,100 individuals and has an annual budget of approximately \$490 million.

History

The GAO has focused on governmental accountability from the time it began operations. Signed into law by President Warren G. Harding in 1921, the GAO was created by the Budget and Accounting Act (Pub. L. 67–13, 42 Stat. 20), which was aimed at improving federal financial management after World War I. The statute transferred to GAO the auditing, accounting, and claims functions previously carried out by the Department of the Treasury; made GAO independent of the executive branch; and gave it a broad mandate to investigate how federal funds are spent. While the agency always has worked for good government, its mission and organization have changed over

time to keep up with congressional and national needs. In July 2004, the agency changed its official name from the U.S. General Accounting Office to the U.S. General Accountability Office. The name change better reflects the agency's modern organizational purpose while retaining its well-recognized acronym—GAO.

Health Research

The GAO supports congressional oversight of federal healthcare programs by reporting on how well programs and policies are meeting their objectives; performing policy analyses and outlining options for congressional consideration; auditing agency operations to determine whether federal funds are being spent efficiently and effectively; investigating allegations of illegal and improper activities; and issuing legal decisions and opinions, such as bid protest rulings and reports on agency rules.

Much of the GAO's work on federal healthcare programs relates to the agency's Strategic Goal No. 1: to provide timely, quality service to the U.S. Congress and the federal government to address current and emerging challenges to the well-being and financial security of the American people. For example, in FY2007, the GAO provided information that helped highlight ways to address problems affecting the delivery of health and disability services for injured soldiers and veterans, improve the U.S. Food and Drug Administration's (FDA's) process for removing dangerous drugs from the marketplace, and identify inefficient physician practice patterns to improve performance of the Medicare program.

The agency's best-known products include reports, testimonies, correspondence, and legal decisions and opinions, which are all available to the press and the public from GAO's Web site. The GAO also produces special publications to assist the U.S. Congress and executive branch agencies by recommending corrections to problems in government programs and operations, identifying long-term trends, and raising concerns about the nation's fiscal status. Among its recent special reports is *21st Century Challenges: Reexamining the Base of the Federal Government*. This report is intended to help the U.S. Congress in reviewing and reconsidering the base of federal spending and tax programs, including healthcare-related spending.

The GAO's work also seeks to analyze and monitor changes in the long-term fiscal outlook, including the effects of demographics and health-care costs, as well as other federal fiscal commitments. As the baby boomer generation (those individuals born between 1946 and 1964 who make up about 75 million individuals) retires, federal spending on retirement and health programs—Social Security, Medicare, and Medicaid—will grow dramatically. A long-term model of the federal budget and the economy, maintained by the GAO, simulates the effect of such changes. This model was adapted from work done at the Federal Reserve Bank of New York. For over a decade, the GAO has published the results of its long-term budget simulations in reports, testimonies, and other products. The model's results dramatically illustrate the need for action sooner rather than later to address the long-term fiscal imbalance.

Medicare Payment Advisory Commission

The Comptroller General of the United States and head of the GAO is responsible for appointing individuals to serve as members of the Medicare Payment Advisory Commission (MedPAC). The commission, which was established by the Balanced Budget Act of 1997, is an independent congressional agency that advised the U.S. Congress on issues affecting the Medicare program. The commission consists of 17 members who serve 3-year terms (subject to renewal). Its commissioners include actuaries, lawyers, physicians, and policy experts.

U.S. NATIONAL HEALTH EXPENDITURES

Published yearly by the National Health Statistics Group of the Office of the Actuary at the Centers for Medicare and Medicaid Services (CMS), the U.S. National Health Accounts (NHA) is the definitive source on the nation's past, current, and future healthcare expenditures. The NHA describes the total national amount spent on healthcare by type of services (e.g., hospital care, physician services, and prescription drugs), source of funds (e.g., private health insurance, Medicare, Medicaid, and out-of-pocket costs), and type of sponsors (e.g., businesses, households, and governments). Finally, the NHA presents trends in healthcare expenditures, and it makes various projections and estimates of the future healthcare expenditures.

Historical Trends

Using data from the NHA, Figure 1 shows the annual national health expenditures, the nation's

gross domestic product (GDP), and the percentage of the GDP spent on healthcare for the period 1960 through 2005. During the period, the percentage of the nation's GDP spent on healthcare increased dramatically. In 1960, healthcare accounted for 5.2% of the nation's GDP, but by 2006 it had grown to 16.0%. In 1960, total healthcare spending was \$27.6 billion, or \$143 per person, but by 2006, total healthcare spending had increased to \$2.1 trillion, or \$7,026 per person.

Types of Services Delivered

Hospitals accounted for the largest share of the nation's health expenditures. In 2006, they accounted for 30.8% of the total spending, down from a peak of 40.6% in 1982. Physician and clinical services accounted for 21.3% of the total spending in 2006, with a peak of 22.4% in 1991. Prescription drug spending reached a peak of 10.1% in 2006 from a low of 4.5% in 1982. Nursing home care accounted for 5.9% of the total spending in 2006, down from a peak of 7.3% in 1978.

Sources of Funds

The distribution of health expenditures by source of funds during the period 1960 through 2005 is shown in Figure 2. In 2006, private payers paid 54% of the nation's total health expenditures compared with 46% paid for by public payers (i.e., federal, state, and local governments). In the period 1960 through 1965, before the federal Medicare and the federal/state Medicaid programs started, private payers paid for 75% of the nation's total health expenditures. Since then, the private share has gradually declined to 54% in 2006. The actual private share may be lower because the calculation does not include the tax subsidy for private health insurance and healthcare spending. The subsidy takes the form of business and individuals deducting health insurance and healthcare spending from their taxable incomes.

The decline of the private share of expenditures was primarily due to the falling share of out-of-pocket spending. The share of out-of-pocket spending declined from nearly half the total healthcare expenditures in 1960 to 12% in 2006. While out-of-pocket spending fell, private

Figure 1 U.S. National Health Expenditure Figures, 1960 to 2005

Source: Centers for Medicare and Medicaid Services, National Health Expenditure Accounts.

health insurance expenditures as a share of total healthcare expenditures grew steadily over the decades.

The public share of healthcare expenditures, which includes Medicare, Medicaid, and the State Children's Health Insurance Program (SCHIP), has grown over the decades. In 2006, the public share totaled \$725 billion, accounting for 34% of the nation's healthcare expenditures.

Type of Sponsors

Categorizing healthcare expenditures by source of funds—such as private health insurance, Medicare, Medicaid, and so forth—does not identify the true payers of healthcare costs. In the late 1980s, the NHA started presenting data to identify the underlying entity financing the

healthcare bill—households, businesses, and governments. This structure allows a better understanding of who pays the healthcare bills and what burdens these costs are placing on each sponsor.

Individual households pay healthcare costs in various ways, including private health insurance premiums, payroll taxes such as the Medicare tax, and out-of-pocket costs. Private businesses pay for employer-sponsored health insurance premiums and part of employees' Medicare tax. The federal government pays for healthcare through federal employee health insurance premiums; Medicare taxes; and the Medicare, Medicaid, and other programs. Likewise, state and local governments pay similar taxes and premiums, and state governments pay their portion of the Medicaid program. In 2006, the total amount paid by private sponsors

Figure 2 National Healthcare Expenditure by Source of Funding, 1960–2005

Source: U.S. National Health Accounts, 2007.

accounted for 60% of health services and supplies spending, compared with 40% by the combined federal, state, and local governments.

As implied by the spending categorized by sponsor, Medicare is not financed solely by the federal government but by all sponsors—households, businesses, and governments. For example, in 2006, households paid 36% of Medicare spending. The combined households and businesses paid 56% of Medicare spending, and the remaining 44% was paid mostly by the federal government (38%). Unlike Medicare, the Medicaid program does not have its own dedicated tax as a funding source. In 2006, using general revenue funds, the federal government's contribution accounted for 56% of total Medicaid spending, with the remaining 44% being paid for by the states.

Employers have faced rapid increases in healthcare costs. Between 1987 and 1993, the growth rate of health insurance premiums, the largest component of business healthcare costs, averaged 11% per year. Beginning in 1998, the growth in employer-sponsored healthcare premiums accelerated, largely

because managed-care plans tried to cover benefit-cost increases and boost profit margins by increasing premiums.

The Burden of Healthcare Costs

The burden of healthcare costs faced by sponsors can be more adequately measured by comparing healthcare costs relative to income revenues. The share of federal revenues funding healthcare has almost doubled, from 17.3% in 2000 to 32.5% in 2004. In 2005, the burden decreased slightly to 30.0% as overall federal spending decelerated from 9.8% to 7.1%.

For state and local governments, healthcare spending as a percentage of revenues rose from 14% in 1987, to 22% in 2000, to almost 25% in 2005. Much of the increase was driven by increases in Medicaid expenditures.

For households, the share of spending compared with personal income increased from 4.9% in 1987, to 5.3% in 2000, to 6.0% in 2005. This increase appears to be mainly due to increases in

insurance premiums and out-of-pocket healthcare spending. It should be noted that there are important disparities among households in overall spending on healthcare as a share of income. The poor and the elderly tend to spend a larger share of their income on healthcare.

Projected Healthcare Expenditures

National Health Expenditures

According to the latest NHA projections for the time period 2007 through 2017, national health expenditures are expected to average a growth rate of 6.7% per year. In 2017, the projected total healthcare expenditures will be about \$4.3 trillion and will constitute 19.5% of the nation's GDP.

Public-Private Share

It is expected that the public-private share of national healthcare expenditures will be significantly altered in the future by the Medicare Part D prescription drug program. The program, which was implemented in 2006, lessens the burden that households face in paying for prescription drugs. Employers and state governments may also benefit from the program. Employers may not have to pay the costs of prescription drugs for their retired employees. States can reduce their contributions for prescription drugs for Medicaid recipients. These changes will shift more costs to the federal government. These additional costs may hurt the long-term sustainability of the entire Medicare program.

The growth in public personal healthcare spending is projected to greatly increase, while the growth of private personal healthcare is expected to slow. Specifically, public personal healthcare spending is projected to grow at an average of 7.2% per year compared with 6.5% for private personal care spending during the period 2007 through 2017. The acceleration in public spending will largely be driven by faster growth in Medicare enrollment as the baby boomer generation becomes eligible for coverage. Also, overall out-of-pocket spending growth is expected to slow, flattening out below 10.9% by 2017.

Medicare

The annual reports of the Medicare Board of Trustees to the U.S. Congress represent the federal government's official evaluation of the financial status of the Medicare program. According to the 2007 report, Medicare expenditures are expected to increase at a faster rate than workers' income. As a result, the Hospital Insurance Trust Fund used to pay for Medicare Part A services (i.e., hospital, home health, skilled-nursing facility, and hospice care) will not be adequately financed. Taxes paid into the fund are projected to fall short of expenditures in future years. Between 2007 and 2016, the trust fund's assets are projected to decrease from \$305 billion to \$221 billion. Because this amount is less than the recommended minimum level of 1 year's expenditures, both the 2006 and 2007 reports issued a "Medicare funding warning."

The second Medicare fund, Supplementary Medical Insurance (SMI), pays for Medicare Part B and D services. Medicare Part B pays for physician, outpatient hospital, and home healthcare, as well as other services. Medicare Part D pays for prescription drugs. Medicare Parts B and D are both voluntary programs, and enrollees pay for them through premiums. The SMI trust fund is financed by beneficiary premiums and general government revenue funds. According to intermediate projections, Medicare Part B's growth rate will average about 8% to 9%, and Medicare Part D's annual growth rate will average 12.6% through 2016. Thus, Medicare Part B and D expenditures will grow significantly faster than the nation's economy, which is projected to grow at 4.8% on average during the same time period.

Future Implications

In the future, the nation's healthcare expenditures will likely continue to grow at a faster pace than the general economy. This growth will be driven by increases in the nation's population, the growth of the elderly, inflation within the healthcare sector, and new medical technology. This growth will continue to strain the nation's Medicare and state Medicaid programs. Taxes may have to be increased in order to pay for the growing expenditures, and

new public policies will have to be developed and implemented in order to control healthcare costs.

V

VOLUME-OUTCOME RELATIONSHIP

The volume-outcome relationship refers to the association between the number of patients with a specific diagnosis or surgical procedure treated at a hospital or by a surgeon and the outcomes experienced by those patients. Outcomes typically refer to mortality, but they can include other quality measures such as complications or health status. Although high volume has been shown to be associated with better outcomes across a wide range of conditions and procedures, the magnitude and nature of this association are highly variable. Moreover, the reasons for the observed associations are often unclear, and the policy and clinical implications of these studies are often confounded by important methodological issues regarding volume-outcome research.

Background

Training and repetition are necessary to learn the skills needed to expertly accomplish a surgical procedure or become familiar with protocols and organizational nuances in any particular hospital setting. However, the “practice makes perfect” hypothesis raises a series of questions when applied to the real world. How high is the threshold necessary to acquire competency? Once one achieves that threshold, for example, through rigorous training, do the skills deteriorate over time if not maintained? Does quality continue to get better with experience (or volume) above the

threshold—that is, should one seek out the highest-volume provider or just avoid those below a threshold level? For surgical procedures, is it just the volume of the primary surgeon, or do the skills of the anesthesiologist and other members of the team matter? In a set of procedures, such as coronary artery bypass graft (CABG), does volume matter for all cases or just for a subset of cases, such as the most risky patients or cases when an unexpected event occurs? An entirely different perspective on the simple association between volume and outcome is that the conventional wisdom is backward. That is, perhaps some physicians are just better than others and receive more referrals because of their better outcomes and thus have higher volumes; this is known as the selective-referral hypothesis. If so, are there subtle techniques and protocols that can be taught so that others with lower case volumes can also achieve better outcomes? There is no reason, moreover, to believe that both practice makes perfect and selective referral may not occur simultaneously, perhaps with differential importance for various conditions and procedures.

Harold Luft and colleagues’ 1979 article in the *New England Journal of Medicine* was the first to examine the volume-outcome relationship across a series of surgical procedures. This study examined the 1974–1975 discharge data from 1,498 hospitals on 12 surgical procedures. A volume-outcome relationship was observed for certain procedures, including open-heart surgery, coronary artery bypass, and vascular surgery, in which high-volume (defined as more than 200 procedures per year)

hospitals were associated with significantly lower mortality. However, for other services, such as colectomy and hip replacement, mortality also decreased with increasing hospital volume but stabilized at a much lower volume, between 10 and 50 procedures per year. Other procedures, such as cholecystectomy and vagotomy, showed no relation between volume and outcome.

Over the next 30 years, hundreds of studies in the health services research and clinical literature surfaced confirming the volume-outcome relationship for both hospitals and individual providers, although the evidence is stronger for the former. Those procedures and conditions that have been most studied include vascular surgery, cancer, and cardiac care. Important questions have surfaced regarding the volume-outcome relationship: What constitutes adequate volume, and how is this determined? Which procedures are the most sensitive to volume? To what extent is hospital volume—as opposed to physician volume—the key variable? How does one account for severity of illness of patients? Might there be selective biases in referral patterns? To what extent does accumulated experience, versus volume (or “throughput”) at a given point in time, account for good outcomes? What are the clinical and other implications of various policies potentially derived from the observed relationship? After three decades of work, these questions remain at the heart of volume-outcome research.

In 2000, Ethan Halm and colleagues conducted a literature review of 135 studies covering 27 different procedures. They found that the hospital-volume relationship was strongest for pancreatic cancer surgery, esophageal cancer, pediatric cardiac surgery, the treatment of AIDS, and abdominal aortic aneurysms. Weaker volume-outcome relationships were found for coronary artery bypass surgery (CABG), coronary angioplasty, orthopedic surgery, and some forms of cancer. In the largest volume-outcome study, published in 2002, John Birkmeyer and colleagues reviewed the experience of 2.5 million Medicare patients who had 1 of 14 procedures between 1994 and 1999. Mortality and volume were inversely related; however, there were large differences between high- and low-volume settings for esophagectomy and pancreatectomy and smaller differences for CABG and carotid endarterectomy. While the volume-outcome relationship has

been confirmed by many studies, the relationship varies significantly by clinical situation. Methodological issues, however, greatly influence the results and implications of the studies.

Methodological Issues

Various methodological issues are central to both understanding the volume-outcome relationship and drawing valid policy and clinical recommendations from the available studies. Such recommendations need to be based on a comprehensive assessment of the causal linkages (not just correlations) between volume and outcome, of the separate effects of hospital and physician volume, and of their effects over time as volumes change. Without an understanding of the potential weaknesses of studies, it is easy to overinterpret reported findings.

One of the most fundamental issues in assessing the volume-outcome relationship is that it is about outcomes—typically rare ones such as death—rather than quality as measured by process—that is, measuring whether the right thing was done for each patient in each circumstance. Health professionals rarely know the optimal processes of care and the mix of skills required to achieve the best outcomes, but instead they are seeking to identify the characteristics of physicians or hospitals—such as volume—that are associated with the best outcomes for their patients and then attempt to understand why or how they achieve those differentially better outcomes.

The focus on outcomes has several important implications for the underlying methods and approaches. Patient care is not like manufacturing; the results of an episode of care or treatment reflect not only the processes and skills of the providers and organizations but also the exact nature of the clinical problem (severity), what other medical problems the patient may have (comorbidities), and how that person reacts to treatment. These are issues commonly faced in the assessment of new drugs, for example, but the methodological solution there is to take a large number of reasonably similar patients and randomly assign them to the new drug and an alternative. Assuming that the samples are large enough, and in theory replicated, the randomization ensures that differences in the exact nature of the clinical problem, comorbidities,

and patient-specific effects are balanced between the two groups and any residual differences observed must be due to the effects of the drugs. There are no large-scale volume-outcome studies that have applied randomization techniques (it is difficult to imagine how one would do so), so statistical adjustments are needed to account for potential alternative explanations.

The last component—individual variability in response to identical treatment—controlling for all the potential measurable risk factors—is a problem of random variation that raises the statistical problems discussed later. The first two categories of problems, severity and comorbidities, are often addressed through what is termed *risk adjustment*. Risk adjustment involves the inclusion of various measures of disease severity and preexisting conditions to account for differences in outcomes apart from volume-related effects. There is a large literature on how to do risk adjustment, but statistical risk adjustment will most likely not be good enough to satisfy those who see randomization as the gold standard. Most volume-outcome studies are based on large numbers of patients and hospitals (or physicians), so the real concern is not the precision of the risk adjustment but the potential for the failings of risk adjustment to be plausibly associated with the key variable of interest—volume.

For an example of how this bias might occur, consider the following situation. Patients in teaching hospitals tend to have more thorough workups and documentation of their comorbidities simply because workups are a part of house-staff training. A patient admitted for a surgical procedure to a teaching hospital is likely to have more comorbidities coded than if admitted to a community hospital, where only the diagnoses directly related to the procedure may be recorded. Most risk adjustment models depend on the conditions coded, so this differential coding will make the patient appear to be sicker based on the information reported by the teaching hospital. With a higher expected risk of a bad outcome, the ratio of observed to expected outcomes across many such patients would be better in teaching hospitals than in community hospitals even if the bad-outcome rates were identical. As teaching hospitals tend to have higher volumes than community hospitals, this simple bias in reporting and coding could lead to the spurious observation of a volume-outcome effect.

The potential for biased estimates of the volume-outcome effects is heightened if one takes into consideration the selection of providers or patients. In many healthcare situations, the patient (or his or her referring physician) has a choice of specialists and sometimes hospitals to provide care. It is plausible that given the opportunity, some patients will seek out the most skilled clinicians; this would yield the observation of higher volume among the best providers, even if volume itself had nothing to do with the outcomes—the selective referral effect. However, when the risk factors of patients are assessed, it sometimes appears that the low-volume hospitals attract a mix of sicker patients—precisely the ones who would benefit the most from the expertise. This seems inexplicable until one realizes that the observed behavior may reflect the selective choice by those patients well enough to have the time to choose a facility. They will seek out the sites with the best reputations, leaving the low-volume ones with the sickest patients, who are not able to “shop.” If the risk adjustment models are not perfect, then the low-volume sites may appear to have worse risk-adjusted outcomes than they warrant.

These examples are not intended to suggest that there is no evidence for a true relationship between volume and outcome (although the causality may be unclear) but that inattention to careful risk adjustment and the potential for selection may overestimate the true relationship. Careful testing of the risk models and searching for hints of selection are important. Likewise, one should be sensitive to when these issues are likely to be problematic. For example, treatment of patients for heart attack, when emergency medical teams typically take the patient to the nearest hospital, is not likely to be subject to a great deal of selective referral. Surgical treatment of advanced cancer, however, may be highly sensitive to both selective referral by patients and even refusals by specialists, who may argue that there is little that can be usefully done.

Turning to the implementation of the studies, assessing the impact of volume on rare events such as death creates straightforward, yet often overlooked, statistical issues. Suppose that death occurs 5% of the time after a surgical procedure—actually a rather high mortality rate for most volume-outcome studies. With 20 patients, one would expect 1 death if quality was just average. This “average figure,” however, is the result of some

hospitals with 20 patients having 0 deaths, some having 1, and some having as much as 2, 3, or 4 deaths. The observed death rates are 0, 5%, 10%, 15%, and 20%, yet all are consistent with a true average quality of 5%. The deviations are simply due to chance, just as a fair coin when flipped 10 times will not always produce exactly 5 “heads.” Unfortunately, some observers point to the observation of 0 deaths in low-volume hospitals as evidence that “some low-volume hospitals have very good outcome rates.” This may be true, but it cannot be inferred by the observation of 0 deaths when only a small number are expected.

Another problem when examining the volume-outcome relationship is assessing the independent effects of physician (usually surgeon) and hospital volume. High-volume hospitals may have both high- and low-volume surgeons, and some high-volume surgeons may spread their patients over two or more hospitals. Overall, however, surgeon and hospital volume are probably highly correlated at the low end; low-volume hospitals are probably staffed mostly by low-volume surgeons, but there are many ways high-volume hospitals can achieve their patient loads.

The nature of the volume-outcome relationship is often subjected to only minimal testing. Some researchers simply test whether outcomes are better for patients using high-volume providers, but it is more important to understand the “shape of the relationship.” That is, if one were to plot mortality on the vertical axis and volume on the horizontal, does the curve look like a \backslash , an L, or a U? If mortality continues to fall as volume increases over the relevant range, only then will the highest-volume providers have the best outcomes. On the other hand, if outcomes cease improving after a certain point, it is critical to know that point. Even worse, there may be volumes above which outcomes actually get worse, and it is critical to know whether that is the case and also the volumes at which the best outcomes occur. Few studies use methods that allow the assessment of which of these alternative explanations best fit the data, yet the methods used often determine the findings.

Policy and Clinical Implications

Many studies assess the presence of a volume-outcome relationship, but this work is primarily

of interest because of the potential clinical relevance and policy implications. Are there particular processes or techniques that can be learned from the high-volume settings that can be transferred to those with lower volume? Should patients seek the hospital or physician with the highest volume, or should they simply avoid providers with less than a certain threshold of procedures? Should volume be used as a criterion in the development of preferred referral networks? What are the potential risks and benefits of regionalization? Should there be policies requiring a minimum volume of procedures or cases?

There are several approaches to disseminating volume-outcome data. Insurers and consumer groups have recently taken an interest in public dissemination of data on hospital volumes for specific surgical procedures, recommending that health plans and consumers use the data to choose high-quality hospitals. As discussed above, however, only some procedures have a significant volume-outcome relationship, and volume per se is hardly the optimal measure because it may lead providers to increase the number of cases done even if the care is unnecessary. It is far better to report risk-adjusted outcomes, but reporting outcomes can be quite complicated and controversial.

Physician education about the volume-outcome association is another option. Few physicians really know about the outcome rates (risk adjusted) of their own patients, let alone the outcomes of the specialists to whom they refer. A better understanding of the volume-outcome relationship may lead them to consider referring their patients to high-volume centers or at least ask about the quality of care of their colleagues. The Leapfrog Group advocates volume-based referral strategies, partially because other methods of improving quality of care are impractical or have other restrictions. For instance, process measures are unclear or controversial, regulatory approaches are unpopular, and health report cards have not been very successful in altering consumer behavior. Others, such as R. Dudley and colleagues, support referral strategies to either mandate or encourage the use of designated hospitals, guide professional training, justify restrictive licensing and certification of referral centers, and take a lead in the diffusion of new services.

Last, some view the volume-outcome relationship as suggesting minimum procedure volumes.

Minimum volume regulations, however, may result in more liberal surgical policies in hospitals that are at the fringe of meeting minimums or may be used as a rationale to preclude entry of competing providers. Insurers may also opt to engage in selective contracting to high-volume hospitals, which could have broader implications for low-volume hospitals because they may lose patients not only in the targeted procedure areas but in others as well.

Regionalizing specialty services is often justified by the volume-outcome relationship. High-volume hospitals, however, may be unable to sufficiently increase capacity to maintain capacity, and low-volume hospitals may suffer from being given a bad reputation, closing related services, or struggling with financial viability. In urban areas with many hospitals capable of offering services, concentrating care may not be problematic. In more sparsely served areas, however, regionalization may imply long travel times, and patients may delay or avoid care. Regionalization may lead to better outcomes for cases that can be scheduled but may actually worsen outcomes for emergencies because of the travel time needed to reach a “capable” site.

In summary, volume-based referral strategies have been advocated for procedures with the greatest outcome differences between low- and high-volume providers and for certain high-risk patient subgroups. Thirty years of research have shown that better outcomes are associated with higher volumes among hospitals and physicians, albeit varying greatly with condition and procedure. Methodological issues, however, are central to better understanding these questions and drawing meaningful policy and clinical implications. The volume-outcome relationship is best seen not as an end in itself but as an intermediate step toward better understanding how to achieve improved patient outcomes.

VULNERABLE POPULATIONS

Vulnerable populations are groups of people whose health needs are not addressed by conventional service providers. Vulnerable populations can include the very young; the elderly; women; racial minorities; those of low socioeconomic status; those experiencing geographic, lingual, or cultural isolation; limited- or non-English-speaking people, those who are incarcerated; immigrants, refugees, and those with undetermined legal status; transient and homeless people; the uninsured; people with

disabilities; people with psychiatric, cognitive, or developmental disorders; substance/alcohol abusers; those who have to deal with abusive families; and people living with HIV/AIDS. This list is not all-inclusive, as society is in a constant state of flux. However, vulnerable populations are usually composed of people who have been marginalized by society. It is because of their inability to access, understand, and/or act on health information or obtain medical treatment that is available to the general population that these populations are considered vulnerable.

The aging process leads to mental, physical, hearing, and vision impairments, as well as a decline in physical mobility. Women are slightly more prone to physical, emotional, or mental limitations than men, and they are nearly twice as likely to require help with personal care as men after age 65. Rural residents are disadvantaged by virtue of having higher rates of reported poor health, physical activity limitations, and remoteness from healthcare than metropolitan residents. Those with transportation challenges include the disabled, the elderly, the poor, and those living in remote areas. Vulnerable populations are more likely to live and work where environmental factors expose them to a higher risk of poor health. Vulnerabilities are often compound, leading to additional unmet needs.

The federal Healthy People 2010 initiative earmarked the elimination of health disparities as second on its list of goals, drawing attention to the stark reality that despite the great strides made in improving population health, a void still exists in providing equitable healthcare to all segments of the nation's population. When compared with their more privileged counterparts, disadvantaged or vulnerable populations have higher prevalence, morbidity, and mortality rates for most conditions. Rising healthcare costs in the 1990s led to increased health disparities and raised political interest in healthcare reform.

The aftermath of Hurricanes Katrina and Rita exposed the disparities faced by vulnerable populations in accessing healthcare and emergency medical relief in times of environmental disasters. It fueled an interest in public health preparedness to avoid such disasters. In 2005, the U.S. Environmental Protection Agency (USEPA) defined *vulnerability* as susceptibility or sensitivity, different exposure, differential preparedness, and/or

differential ability to recover. The National Environmental Justice Advisory Council (NEJAC) of 2006 recommended that, to avoid such contingencies in the future, vulnerable populations need to be identified and their environmental and/or public health needs assessed through the use of tools such as the Environmental Justice Geographic Assessment Tool. It recommended greater coordination of all resources, including the vulnerable groups, in planning and implementing new disaster response procedures.

The Office of Minority Health and Health Disparities (OMHD) is responsible for eliminating health disparities and improving the health of all ethnic and racial minority populations, who largely constitute vulnerable populations. Fifteen special programs, administered by the U.S. Department of Agriculture (USDA), cater to the health and nutritional needs of vulnerable populations, especially children, pregnant women, the elderly, rural residents, and the poor. Nearly 20% of Americans use at least one food assistance program per year. About half of all infants and 25% of children between the ages 1 and 4 participate in the Special Supplemental Nutrition Program for Women, Infants, and Children (known as the WIC program), and school nutrition programs provide healthy meals to about 30 million children nationwide. The Food Stamp program assists about 30 million low-income Americans in meeting their nutritional needs.

Vulnerability in Healthcare Research

Vulnerable populations are particularly susceptible to exploitation in healthcare research, exemplified by the horrendous experiments conducted by the Nazis on Jews in concentration camps in World War II. The Nuremberg Code of 1947 was established to prevent such exploitation: It laid down the code of informed consent, whose critical components were that all participants must have adequate knowledge of, and comprehend, the proposed research and must be enrolled without duress. Subsequently, the Belmont Report, the National Research Act, and the National Bioethics Advisory Commission (NABC) have created mandatory rules to protect all segments of society from harmful inclusion in research protocols. Institutional review boards (IRBs) are responsible

for ensuring that the tenets of American biomedical ethics—autonomy, nonmaleficence, beneficence, and respect for persons in the research context—are followed in all research protocols. The 2001 NABC report identified six groups as “caution areas” for inclusion in health research: those with institutional, deferential, medical, economic, or social vulnerability and people with communication/cognition problems.

The 2007 *National Healthcare Disparities Report* points out persistent, even increasing, disparities in healthcare among all minority populations, even after accounting for demographic and insurance factors. And nearly half of the nation’s population is predicted to consist of “minority groups” by 2050. A large percentage is composed of people who have limited skills in understanding and/or speaking English. The elderly population is expected to rise briskly as longevity increases, bringing in its wake vulnerability to disability, disease, and dependence. The number of uninsured, illegal residents, and refugees continues to increase annually. These factors will add to the number of people considered vulnerable to inequitable healthcare. It is imperative that policymakers consider steps to improve healthcare provision to this growing segment of the nation’s population. The use of community-based, culturally and linguistically appropriate, interventions is thought to be the most effective approach in improving the health of vulnerable populations.

W

WARE, JOHN E.

John E. Ware, Jr. is a pioneer in the area of quality-of-life assessment and an internationally recognized expert in the field. Ware is noted for being the principal developer of the Short Form 36 (SF-36) Health Survey, one of the most widely used quality-of-life assessment tools in healthcare research. Ware is the founder and president and chief scientific officer of Quality Metric, Inc., an Internet-based healthcare technology company that uses the latest innovations in measurement technology to monitor health outcomes of consumers. Ware is also executive director of the Health Assessment Laboratory and a research professor at the Tufts University School of Medicine.

Ware received his bachelor's and master's degrees in psychology from Pepperdine University in California and completed his doctoral degree in educational measurement and statistics at Southern Illinois University in 1974. While working toward his doctorate, Ware became director of the Measuring Health Concepts Research Project at the University of Southern California School of Medicine and director of the Postgraduate Division in the Department of Psychiatry. In 1972, Ware was appointed assistant professor at the Southern Illinois University School of Medicine, and in 1975, he became a senior research psychologist at the RAND Corporation in the Behavioral Sciences Department and Health Sciences Program. Following this, Ware joined the faculty at Pepperdine University as an instructor and was an

adjunct professor and research advisor for the Clinical Scholars Program at the University of California, Los Angeles, Schools of Medicine and Public Health. In 1988, Ware became senior scientist at the Health Institute at Tufts New England Medical Center in Boston, and eventually, he took on the role of director of the International Quality of Life Assessment Project at Tufts University.

As a result of a research program at the Health Institute of New England Medical Center, the Health Assessment Laboratory was founded in 1988 as a nonprofit organization, located in Waltham, Massachusetts, where Ware is the executive director. The Health Assessment Laboratory conducts basic research on patient-reported outcomes and works in close association with the Health Institute.

Ware was the principal investigator for the Medical Outcomes Study (MOS), which developed the SF-36 Health Survey as well as other widely used health assessment tools. The experience of the SF-36 Health Survey has been cited in nearly 7,500 publications and used in approximately 1,000 clinical studies, and it was judged to be the most widely evaluated patient-assessed health outcome measure.

Ware is a member of many advisory groups, including the Social Security Administration's Disability Evaluation Study, the Joint Commission's Council on Performance Measurement, and the National Committee for Quality Assurance's Technical Advisory Group. He is an elected member of the National Academy of Sciences, Institute of Medicine (IOM). In 2003, he received the

International Society for Quality of Life Research President's Award for his pioneering and tireless work in advancing the ability to assess health-related quality of life.

Ware has made transformative contributions to the field of health related to psychometric theory and improving the measurement of patient outcomes. He is currently developing computer software and Internet applications to assess risk and monitor the health outcomes of patients.

WENNBERG, JOHN E.

John E. Wennberg is a pioneering health services researcher who is perhaps best known for his focus on geographic variations in medical care. He was one of the first researchers to document that geographic variations in medical care, which affect the cost and quality of patient care, are primarily due to physician treatment styles. His work is best exemplified in his major ongoing project, *The Dartmouth Atlas of Health Care*. By attracting the U.S. Congress's attention to outcomes research, Wennberg also helped shape the federal legislation that established the Agency for Health Care Policy and Research (now the Agency for Healthcare Research and Quality [AHRQ]).

Wennberg earned his bachelor's degree from Stanford University (1956) and his medical degree from McGill University (1961). He trained in internal medicine, followed by a fellowship in nephrology, at Johns Hopkins University. While there, he became interested in epidemiology, which led him to earn a master of public health degree from the Johns Hopkins University School of Hygiene and Public Hygiene (1966).

In the early 1970s, Wennberg along with Alan Gittelsohn developed the methodology of small-area analysis for analyzing healthcare utilization based on population and geographic area. Anecdotally, he was able to refine his research questions on seeking care for his son's tonsillitis: His local Vermont pediatrician recommended tonsillectomy, while the one in a neighboring town across the state border into New Hampshire counseled "watchful waiting." Wennberg was puzzled why medical practice could vary so dramatically over such a short distance. When he compared data on other medical procedures in other locales, other startling differences emerged: Not only does medical intervention and thus spending vary by region, but Wennberg's analyses also showed that different hospitals within the same region often have drastically different healthcare utilization patterns. Most strikingly, what at first seemed heretical has now been well accepted: More medical spending and more healthcare services are not associated with better patient outcomes.

Wennberg has been a professor in the Department of Community and Family Medicine at Dartmouth University since 1980 and in the Department of Medicine since 1989. In 1988, he became the founding director of the Center for the Evaluative Clinical Sciences, now called the Dartmouth Institute for Health Policy and Clinical Practice. In 1989, Wennberg cofounded the Foundation for Informed Medical Decision Making, based on the idea that a better-educated patient will have a safer and more positive experience in the healthcare system when engaged in shared decision making with his or her physician. In 1994, he became the Peggy Y. Thomson Professor of the Evaluative Clinical Sciences, the nation's first endowed chair in clinical evaluative sciences, the field he created. In 1996, Wennberg published the inaugural *Dartmouth Atlas of Health Care*. Updated every 2 years, the *Atlas* is a

compendium of color-coded thematic maps dividing the United States into geographic regions based on relative rates of health service utilization in a given time period.

During his distinguished career, Wennberg has received many awards and honors in recognition of his work. He is an elected member of the national Institute of Medicine (IOM). He has received the Association for Health Services Research's Distinguished Investigator Award, the Baxter Foundation's Health Services Research Prize, the Richard and Hinda Rosenthal Foundation Award in Clinical Medicine, and the Picker Institute Award for Career Achievement in Patient-Centered Care. In 2007, he was named the most influential health policy researcher of the past 25 years by the journal *Health Affairs*, and he received the Joint Commission's Ernest Amory Codman Award for his leadership in using outcome measures to improve healthcare quality.

WHITE, KERR L.

Kerr L. White is arguably the founder of the discipline of health services research in the United States. Throughout his long and distinguished career as a researcher, university professor, and government and foundation administrator, he developed the conceptual framework of health services research, established and shaped government health services research programs, and funded the emerging discipline of health services research.

White was born in Winnipeg in 1917, and he grew up in Ottawa, Canada. His father was a foreign correspondent for the London *Times* and the *Economist*, and his mother operated a lending library that emphasized various medical topics. He majored in economics and political science at McGill University, followed by graduate study in economics at Yale University. During World War II, he interrupted his graduate studies to serve in the Royal Canadian Army. After the war, he undertook medical training at McGill University, graduating in 1949. White completed his residency in internal medicine at Dartmouth College's Hitchcock Clinic and Hospital and a fellowship at McGill's Royal Victoria Hospital in the departments of medicine and psychiatry. He then joined the Department of Internal Medicine at the University of North Carolina–Chapel Hill as an assistant professor of medicine and preventive medicine. In 1962, White was appointed chair of the Department of Epidemiology and Community Medicine at the University of Vermont. In 1965, he moved to Johns Hopkins University to establish the Division of Hospitals and Medical Care, which later became the Department of Health Care Organization. In 1978, he became the deputy director for health sciences at the Rockefeller Foundation. White retired in 1984, remaining active in the health research community as a thought leader and as a mentor.

White's professional legacy can be divided into three domains: (1) scholarship, which defined the field of health services research; (2) training and mentoring leaders in this new field; and (3) the development of programs and other initiatives that have a sustained impact on the research on healthcare quality and the delivery of quality medical care.

While he was a 2nd-year medical student in 1947, White published his first article, which predicted many of the methodological and substantive domains of health services research and their relation to what would eventually be known as evidence-based medicine. At the University of North Carolina, White formulated the key ideas, which he expounded in 1961 in a seminal *New England Journal of Medicine* article that he coauthored, "The Ecology of Medical Care." White stressed, in addition to the appropriate use of methodological tools to conduct health care research, that society has an obligation to allocate healthcare resources as efficiently and effectively as possible to improve the quality of medical outcomes, benefiting both patients and providers. Moreover, he stressed that healthcare research was concerned with medicine as a social institution. White has authored or coauthored some 250 publications, including 11 books.

White proved instrumental in institutionalizing health services research, both through his editorial influence in journals such as *Medical Care* and *Health Services Research* and ensuring funding for the *International Journal of Health Services*, and through his vision in developing the organizational framework for the National Center for Health Services Research (NCHSR), which eventually became a federal agency and in 1999 was reauthorized as the Agency for Healthcare Research and Quality (AHRQ).

In recognition of White's role in establishing the field of health services research, Emory University dedicated a new center, the Kerr L. White Institute for Health Services Research, in his honor in 1996, and the Agency for Healthcare Research and Quality (AHRQ) established the Kerr White Visiting Scholars Program in 2000.

WILENSKY, GAIL R.

Gail R. Wilensky is a well-known and highly respected health economist. She has been associated with Project HOPE (Health Opportunities for People Everywhere) for many years, she was the administrator of the Health Care Financing Administration (HCFA), and she serves on many important national and international healthcare committees.

Born in 1943 in Detroit, Michigan, Wilensky attended the University of Michigan, where she

earned a bachelor's degree in psychology (1964), a master's degree (1965), and a doctoral degree in economics (1968).

After graduation, Wilensky served as a staff economist on the President's Commission on Income Maintenance Programs until 1969, when she became executive director of the Maryland Council of Economic Advisers. In 1971, she served as a senior research associate at the Urban Institute until 1973, when she accepted the position of visiting assistant professor and associate research scientist at the University of Michigan. In 1975, she worked for the National Center for Health Services Research (now the Agency for Healthcare Research and Quality), where she was a health service fellow and senior research manager. In 1983, she joined Project HOPE as vice president of health affairs. In 1990, President George H. W. Bush appointed her administrator of the Health Care Financing Administration (HFMA) (now the Centers for Medicare and Medicaid Services [CMS]). In 1992, she became deputy assistant to the President for policy development at the White House. She returned to Project HOPE in 1993 as the John M. Olin Senior Fellow, where she continues to analyze and develop healthcare policies, advise government and private-sector agencies, and write and lecture on various healthcare topics.

Wilensky has served on a number of important healthcare committees, including the Advisory Committee on Health of the General Accounting Office (GAO), the Physician Payment Review Commission (PPRC), the Medicare Payment Advisory Commission (MedPAC), and the President's Task Force to Improve Health Care Delivery for Our Nation's Veterans. She also has served on many committees of the National Academy of Sciences, Institute of Medicine (IOM).

Currently, she serves as a member of the President's Commission on Care for America's Returning Wounded Warriors; Commissioner of the World Health Organization (WHO) Commission on Social Determinants of Health; vice chair of the Maryland Health Care Commission; member of the Board of Trustees of the University of the Sciences in Philadelphia; member of the National Campaign to Prevent Teen Pregnancy; director of the American Heart Association; trustee of the National Mineworkers of America's Combined Benefits Fund; trustee of the National Opinion

Research Center (NORC) at the University of Chicago; director, chair, and vice chair of AcademyHealth; cochair of the Task Force on the Future Health Care at the U.S. Department of Defense; and member of the board of directors for Cephalon Corporation.

Wilensky has received numerous awards and honors, including the Darrel J. Mase Distinguished Leadership Award from the University of Florida (2000), the Latiolais Honor Medal from the American Managed Care Pharmacy Association (1996), the Dean Conley Award from the American College of Healthcare Executives (1989), and the Alumna in Residence Award from the University of Michigan (1989). She has received honorary degrees from the University of the Sciences (2002), Rush University (1997), and Hahnemann University (1993). She was named Marshall J. Seidman Lecturer at Harvard Medical School (2003), John D. Thompson Distinguished Visiting Fellow at the Yale Health Management Program (2003), TeKolste Scholar at the Indiana Hospital and Health Association (1997), and Flinn Foundation Distinguished Scholar in Health Policy and Management (1986). Additionally, Wilensky is listed in *Who's Who in America* and *Who's Who in American Women*. She was named as one of the 100 most powerful people in healthcare in 2003 and 2004, and in 2005, she was named as one of the top 25 women in healthcare by *Modern Healthcare*.

WILLIAMS, ALAN H.

Alan H. Williams (1927–2005) was an eminent health economist in the United Kingdom. Williams was a professor of economics at the University of York. At York, he was instrumental in establishing the university's Centre for Health Economics and its graduate program in health economics. During his long and distinguished career, he studied two broad research areas: ways of valuing health and the equity of health and healthcare. Williams is perhaps best known as the originator of the concept of quality-adjusted life years, or QALYs, a measure of health benefits. Today, QALYs are widely used by researchers to measure and compare healthcare technology and treatments.

Williams was born in Birmingham, England, in 1927. He was educated at the Birmingham King Edward's School. After graduation in 1945, he served in the Royal Air Force for 3 years. In 1948, Williams attended the University of Birmingham, where he graduated in 1951 with a bachelor's degree in economics. He continued his education doing graduate work at the Universities of Uppsala and Stockholm. From 1954 to 1963, Williams was a lecturer in economics at the University of Exeter, where he taught courses in public finance. During sabbaticals he taught at the Massachusetts Institute of Technology (MIT) and Princeton University. In 1964, he moved to the newly established University of York, where he was appointed a senior lecturer and reader in economics. Williams would teach and conduct research at that university for more than 40 years.

Besides his academic career, Williams also worked occasionally for the government. From 1966 to 1968, he was seconded (a temporary move or loan of an employee to another organization) to

Her Majesty's Treasury as the director of economic studies. At the Treasury, he developed courses in economics for civil servants. He also worked with the Ministry of Health, where he investigated its hospital building program. In 1976, Williams was appointed to the Royal Commission on the National Health Service (NHS). However, in 1978, he resigned over a dispute on the role of researchers working for the commission.

In 1987, Williams convened a meeting in Rotterdam, The Netherlands, of his colleagues and challenged them to determine how the value of health might be measured and how such values might be studied across nations. The group eventually became the EuroQol Group, which developed the EQ-5D, a series of health status measures that are widely used throughout the world.

In his later years, Williams became increasingly interested in the ethical issues determining priorities in healthcare. He expounded the concept of "fair innings." The concept reflects the general belief that everyone should achieve a long life and that if someone dies at a young age, the person is somehow cheated—death at 20 is clearly viewed very differently from death at 80. Williams argued that entitlement to healthcare ought to take into account such differences in perspectives. And more resources should be given to the young who have not had their fair innings.

Williams died in 2005 at the age of 77. In 2006, the University of York's Centre for Health Economics established the Alan Williams Health Economics Fellowships as a lasting tribute to his work and achievements.

WOMEN'S HEALTH ISSUES

Women are often the healthcare takers and decision makers of their family's health. During the past several decades, women's health issues have broadened from a focus primarily on reproductive and social issues to include research on gender differences in disease prevention and response to treatment. Although many advances have been made in improving women's healthcare and in understanding women's unique role in the healthcare system, there are significant gaps in areas such as access to healthcare, ability to pay for care, and healthcare outcomes. Several key issues for women's health remain, including the need for further studies, changes in public policy, and increased advocacy.

Health Maintenance

There is overwhelming evidence that preventive healthcare services, particularly among women, favorably affect health outcomes. However, many women often underuse the preventive services. Screening tests are an important tool for the early detection and treatment of various diseases, yet the use of some screening tests by women is declining. A national survey conducted by the Kaiser Family Foundation in 2004 indicates that screening rates for mammograms, pap smears, and blood pressure have decreased slightly since 2001.

Additionally, reproductive care is a significant part of healthcare for women. One of the goals of the Healthy People 2010 initiative of the U.S. Department of Health and Human Services (HHS) is to increase the proportion of pregnant women who receive early and adequate prenatal care to 90% of all pregnancies in the nation. While there has been an overall steady improvement, statistics show a slower rate of increase among minority women, particularly in obtaining early prenatal care.

Being overweight or obese increases adverse health risks, including high blood pressure, diabetes, heart disease, stroke, arthritis, cancer, and poor reproductive health. According to the Centers for Disease Control and Prevention (CDC), 61.5% of all women and 69.6% of men in the nation were overweight or obese in 2003–2004. Furthermore, regular physical activity has been shown to promote health, prevent disease, and facilitate maintenance of a healthy body weight. In 2005, only 50.9% of women reported engaging in at least 10 minutes of moderate leisure-time physical activity per week, and only 32.0% reported at least 10 minutes of vigorous activity, which was significantly less than that reported by men. In contrast, smoking was less common among women 12 years of age or older (22.5%) compared with men of the same age group (27.4%). In addition, women were more likely than men to try to quit smoking (44.8% vs. 40.7%).

Access to Healthcare

Access to quality healthcare services directly affects many aspects of women's health. Numerous studies have found that women who have a usual source of healthcare are more likely to receive preventive care, to have access to care, to receive continuous care, and to have lower rates of hospitalization and lower healthcare costs than those who do not have a usual source of care. Women of all racial and ethnic groups are more likely than men to have a usual source of care. However, access to healthcare is a greater challenge for women who are members of racial or ethnic minority groups with low incomes and who are uninsured. Regardless of family structure, women are more likely than men to live in poverty. Uninsured women consistently fare worse on multiple measures of access to care, including

contact with providers, obtaining timely care, access to specialists, and utilization of screen tests.

Many studies have also shown that women who lack economic resources or are from racial or ethnic minorities are more likely to report poor health status and greater chronic health problems and are more likely to confront obstacles to receiving adequate and timely care. Women not only have financial barriers to accessing healthcare but also may experience logistical barriers, such as problems with transportation, childcare, and lack of free time. Among women with family incomes at 300% or more above the federal poverty level (FPL), 73% reported excellent or very good health status compared with 42% of those with family incomes below 100% of the FPL. Women who are Latinas, of low economic status, single, and young are particularly at risk of being uninsured.

Healthcare Costs

There is a significant gender gap in health insurance coverage and the ability to afford medical care in the United States. Women are disadvantaged by greater healthcare needs and lower incomes than men. Men are more likely than women to be uninsured in every age group; however, there are an estimated 16 million uninsured women in the nation. Many studies have shown that women are more likely than men to go without healthcare services because of the costs of healthcare and also because they have higher out-of-pocket expenses. A 2005 survey by the Kaiser Family Foundation indicates that 33% of insured women and 68% of uninsured women do not get the healthcare they need because they cannot afford it as opposed to 23% of insured and 49% of uninsured men who avoid care because of the costs. Researchers also found that 16% of women are underinsured, meaning they have high out-of-pocket costs compared with their income, while only 9% of men are underinsured. Among workers, women are less likely than men to be eligible for and to participate in their employer's health insurance plans. The overall take-up rate for employer-sponsored coverage is 80% for women workers compared with 89% for men. This is in part because women are more likely to work part-time, have lower incomes, and rely more on spousal coverage.

Uninsured women are more likely to suffer serious health problems, partly because they tend to

wait too long to seek treatment or preventive care. The lack of health insurance can even be deadly, as research has shown that uninsured adults are more likely to die earlier than those who have insurance. According to the Kaiser Family Foundation survey, in 2004, one in six women nationwide who had health insurance delayed or went without needed care. Reproductive healthcare services accounted for much of this discrepancy. Thirty-nine percent of women with insurance reported difficulty paying their medical bills compared with 29% of men. The gender gap in healthcare insurance coverage and access to care has other contributing factors: For instance, women are more likely to purchase coverage in the more expensive and less comprehensive individual health insurance market and are more likely than men to take prescription drugs.

Quality of Healthcare

The report *Making the Grade for Women's Health: A National and State-by-State Report Card*, published in 2007 by the National Women's Law Center, on the status of women's healthcare in the United States, based on the goals set by Healthy People 2010, gave the nation an overall grade of "unsatisfactory" because it met only 3 of the 23 benchmarks for women's health. The report found that no state met the goal for access to health insurance. Additionally, the report highlighted the many regional differences in the health status of women. In 2005, fewer women were satisfied with how well their physicians communicated with them (81.0%), compared with men (84.3%). Men were also more likely than women (67.0% vs. 62.5%) to be satisfied with their ability to get necessary care from physicians or specialists, including obtaining treatments and tests.

Cardiovascular disease is the leading cause of death for women in the United States. Despite advances in the evaluation and management of heart disease, it is estimated that more than 240,000 women die annually from this condition. In 2005, adult women below 45 years of age had a higher rate of heart disease than men of the same age (50.9 vs. 35.2 per 1,000 adults, respectively), but men had a higher overall rate of heart disease than women. The highest rate of heart disease was among non-Hispanic White women (128.7 per

1,000), followed by non-Hispanic Black women (107.1 per 1,000). Asian women had the lowest rate (51.1 per 1,000) of heart disease among all ethnic groups. Although non-Hispanic White women experience the highest rates of heart disease, deaths from heart disease are highest among non-Hispanic Black women.

According to the Kaiser Family Foundation survey of 2005, women largely underused preventive healthcare measures, such as lifestyle modifications. Although major risk factors for heart disease can often be prevented or controlled through lifestyle changes, physicians are less likely to counsel women than men about diet, exercise, and weight reduction.

In 2004, the American Heart Association (AHA) released the first evidence-based guidelines for cardiovascular disease prevention for women. Embedded in its recommendations are lifestyle interventions that have become the cornerstone of many preventive programs. The current prevention efforts have shifted away from individual disease-specific targets to assessment of "global," or overall, risk. The lifestyle interventions have received the highest level of recommendation from the AHA (Class 1) and include the following: (a) encouraging cessation of cigarette smoking; (b) encouraging daily physical activity for a minimum of 30 minutes at moderate intensity; (c) consumption of a heart-healthy diet—restriction of intake of trans-fatty acids and saturated fat to less than 10% of calories; and (d) weight maintenance/reduction with a target body mass index (BMI) between 18.5 and 24.9 kg/m² and a waist circumference of less than 35 inches.

Cancer is the second leading cause of death of women in the United States. Furthermore, the most common cause of cancer deaths in women is lung cancer. It is estimated that more than 70,000 women in the nation die of lung cancer each year, with the majority of these deaths linked to cigarette smoking. Breast cancer is the second leading cause of cancer death in U.S. women, resulting in nearly 40,000 deaths each year, but it is the most common type of cancer among women. For each of the sex-specific cancers, such as breast, uterine, and ovarian cancer, survival rates are higher for White women than for Black women.

Stroke is a major cause of morbidity and mortality and the third leading cause of death of

women in the United States. Nearly 160,000 people in the country die of stroke each year, and almost two thirds of them are women. There are important racial and ethnic disparities in the incidence, severity, and mortality of stroke. Minority ethnic groups have higher rates of more severe strokes. In addition to the roles of primary and secondary prevention, it has been suggested that to address these disparities in stroke outcomes, initiatives that foster cultural competence must be a prominent component of a targeted approach. Primary prevention of stroke includes adequate blood pressure control and the reduction and treatment of elevated cholesterol.

In 2005, the CDC estimated there were 10,774 new cases of AIDS in the United States among adolescent and adult women, compared with 29,766 new cases among males of the same age group. AIDS has disproportionately affected men, but the rate among women is increasing at a faster pace. Since 2001, new AIDS cases have increased by 7.2% among women compared with a 6.7% increase among men. Women are biologically more susceptible to HIV infection during sexual intercourse and experience different clinical symptoms and complications. Many studies have shown that women with HIV not only face limited access to care but also experience disparities in access compared with men. Women with HIV are less likely to receive combination drug therapy and fare more poorly on other access measures than men. Compared with men, women with HIV are more likely to postpone care because of lack of transportation and more likely to be too sick to go to the physician.

Minority women also are disproportionately affected by a number of diseases and health conditions, including HIV/AIDS, sexually transmitted infections, diabetes, and overweight or obesity. In 2004, HIV/AIDS was the leading cause of death among non-Hispanic Black women 25 to 34 years of age.

Mental health is an often overlooked but critical aspect of women's healthcare. One of the biggest threats to a woman's overall health is impairment of her mental health. Studies have shown a positive relationship between the frequency and severity of negative social factors and occurrences and the frequency and severity of mental health problems experienced by women.

Despite the increasing prevalence of mental illness among both men and women, there are remarkable gender differences in patterns of mental illness. Slightly less than a quarter of women (23%) in the nation report having been diagnosed with depression or anxiety, over twice the rate of men (11%). Women attempt suicide three times more often than men, but men are much more likely to be successful in taking their lives. Risk factors for the more common mental disorders include the following: gender-based violence, socioeconomic factors, low income and income inequality, inferior social standing, and unalleviated responsibility for the welfare of others. Women now have the highest rates of post-traumatic stress disorders, a direct result of the increasing prevalence of sexual violence against women. The lifetime prevalence rate of violence against women ranges from 16% to 50%.

Healthcare Utilization and Outcomes

Over the course of a woman's life, her use of the healthcare system mirrors her changing healthcare needs, from reproductive health in the younger years to a surfacing of chronic illness during middle age and increased rates of physical limitations with advanced age. Most women in the nation are in good health, with 8 in 10 reporting excellent, very good, or good health, according to a 2005 Kaiser Family Foundation survey. There are, however, racial and ethnic disparities in these statistics. In 2005, 62.3% of non-Hispanic White women reported themselves to be in excellent or very good health, compared with only 53.6% of Hispanic women and 51.6% of non-Hispanic Black women. Men were more likely than women to report being in excellent or very good health (63.0% vs. 59.9%), and this result holds across every racial and ethnic group. However, a considerable number of women—nearly 20%—are in fair or poor health. The proportion of women reporting that they are in fair to poor health increases with age to nearly one third of women 65 years of age or older. Slightly more than a third of women reported a chronic condition requiring ongoing medical attention compared with 30% of men. As women age, there is an associated increase in the incidence of chronic conditions.

Medical outcomes research has determined that women are disproportionately affected by chronic

diseases for which clinical data are not easily generalized and traditional medical measures are inadequate. Historically, women have faced unequal treatment, with numerous studies reporting that women on average have fewer medical interventions than their male counterparts. There is evidence in the medical outcomes literature to suggest increasing ethnic disparities in incidence, severity, and mortality for a number of prevalent diseases. In the past decade, there has been a move from defining outcomes using traditional measures of morbidity and mortality to a greater emphasis on quality of life, function, patient satisfaction, and health status. The use of gender-sensitive outcome measures is essential to bridge the discrepancy between quality initiatives at the global level and what actually works at the grassroots level for improving women's healthcare. Such a shift is empowering for women and should translate into comparable health outcomes between men and women in the future.

Future Implications

It is important to understand the current issues concerning women's health and the unique role women play not only as consumers of healthcare but also as leaders in their families in healthcare decision making, as these have salient implications for public health and public policy advocacy. Significant strides have been made in recent decades in understanding not only the physiological but also the sociological health issues faced by women. Despite these advances, however, there is more work to be done in reducing the gender gap in access to healthcare, ability to pay for care, and quality of healthcare outcomes.

WORLD HEALTH ORGANIZATION (WHO)

The World Health Organization (WHO) is the directing and coordinating authority for health within the United Nations (UN). The WHO was officially constituted at the International Health Conference held in New York City from June 19

to July 22, 1946. WHO began operating on April 7, 1948.

The WHO is an intergovernmental organization (IGO), and its members are the states (countries) recognized by the UN. The 193 member states of the UN pay regulated contribution fees, which partially fund the WHO. In addition, many member states also pay voluntary contributions to fund regular or extrabudgetary programs. Member states also contribute technical expertise either through personnel quotas or through work carried out by national collaborating centers or experts who take active roles in research and technical or advisory committees and extrabudgetary activities.

The total biennial budget for the WHO in 2006–2007 was approximately \$3.3 billion. Those funds were allocated into four major areas: (1) about half of the funds (53%) are spent on essential health interventions (i.e., HIV/AIDS prevention and treatment, child and adolescent health, communicable disease prevention and control, malaria control and prevention, mental health and substance abuse programs, reproductive health, tuberculosis control and prevention, and emergency and epidemic preparedness programs); (2) about one fifth of the funds (21%) are spent on effective support for member states (i.e., WHO's core presence in countries, direction, external relations, governing bodies, planning resource and coordination, knowledge, budget and financial management, and infrastructure and logistics); (3) about 1/10 of the funds (13%) are spent on health policies, systems, and products (i.e., health financing and social protection, health information, evidence and research policy, essential health technologies, health systems policies and service delivery, human resources for health, policy making for health, and essential medicines); and (4) about 1/10 of the funds (11%) are spent on the determinants of health (i.e., food safety, women and health, health and environment, health promotion, nutrition, violence prevention, injuries and disabilities, and communicable disease research).

Through its globally recognized functions, the WHO provides leadership on health matters worldwide, and it sets norms and standards on health issues. The WHO's organizational structure allows it to perform a major global role in shaping a health research agenda, articulating evidence-based policy options, and channeling technical support

to countries, as well as monitoring and assessing global health trends.

In the 21st century, the WHO performs a critical role in an effort to ensure that health becomes a genuinely shared responsibility, involving equitable access to essential healthcare and a collective defense against transnational threats to health. Traditionally, the WHO's collective knowledge expressed through officially supported research results has been the reference base for member states to establish regulatory measures.

The Concept of Health

In conformity with the Charter of the United Nations, the WHO constitution proposes that to attain basic happiness, harmonious relations, and security for all people in the world, the principles that determine health are essential. Thus, for the WHO, health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.

Furthermore, WHO constituents affirm that the accomplishment of the highest possible standard of health is one of the fundamental rights of every human being regardless of race, religion, political belief, and economic or social condition. In addition, the health of all people is fundamental to the attainment of peace and security and depends on the fullest cooperation of individuals and countries. The WHO constitution states that the achievement of any country in the promotion and protection of health is of value to all and that unequal development in different countries in the promotion of health and control of disease, especially communicable disease, is a danger for all.

The WHO constituents also affirm that the healthy development of the child is of basic importance and that people's ability to live harmoniously in a changing total environment is essential to such development.

In addition, they affirm that the benefits of medical, psychological, and related knowledge are essential for the fullest attainment of health, but only if extended to all people, and that informed opinion and active cooperation on the part of the public are of utmost importance in the improvement of the health of the people.

The WHO constitution concludes that countries have a responsibility for the health of their people,

which can be fulfilled only by the provision of adequate health and social measures. All countries that become members of the WHO accept these principles for the purpose of cooperation among themselves and with others to promote and protect the health of all peoples.

World Health Assembly

All member states are represented in the World Health Assembly. Each member has one vote but may send three delegates. According to the WHO constitution, the delegates are to be chosen for their technical competence and preferably should represent national health administrations. Delegations may include alternates and advisers. The assembly meets annually, usually in May, for approximately 3 weeks. Most assemblies are held at WHO's headquarters in Geneva, Switzerland.

The World Health Assembly determines the policies of the organization and deals with budgetary and administrative questions. By a two-third vote, the assembly may adopt conventions or agreements. While these are not binding on member governments until accepted by them, the member state must take action leading to their acceptance within 18 months of their adoption, even if its delegation voted against a convention in the assembly, by submitting the convention to its legislature for ratification, and it must notify the WHO of the action taken. If the action is unsuccessful, it must notify the WHO of the reasons for nonacceptance.

In addition, the assembly has quasi-legislative powers to adopt regulations on important technical matters specified in the WHO constitution. Once the assembly adopts a regulation, it applies to all WHO member countries (including those whose delegates voted against it, except those whose governments specifically notify WHO that they reject the regulation or accept it only with certain reservations).

The WHO is empowered to introduce uniform technical regulations on the following matters: (a) sanitary and quarantine requirements and other procedures designed to prevent international epidemics; nomenclature with respect to disease, causes of death, and public health practices; (b) standards with respect to diagnostic procedures for international use; (c) standards with respect to

the safety, purity, and potency of biological, pharmaceutical, and similar products in international commerce; and (d) advertising and labeling of biological, pharmaceutical, and similar products in international commerce.

Current Role

Currently, the WHO fulfils its objectives through its core functions, which are (a) providing leadership on matters critical to health and engaging in partnerships where joint action is needed; (b) shaping the research agenda and stimulating the generation, translation, and dissemination of valuable knowledge; (c) setting norms and standards and promoting and monitoring their implementation; articulating ethical and evidence-based policy options; (d) providing technical support, catalyzing change, and building sustainable institutional capacity; and (e) monitoring the health situation and assessing health trends.

These core functions are set out in the 11th General Programme of Work, which provides the framework for the organization-wide program of work, its budget, resources, and results. Titled *Engaging for Health*, it covers the 10-year time period 2006–2015.

Scientific Conferences and the World Health Assembly

The WHO supports or sponsors numerous scientific conferences throughout the world. Each year, the World Health Assembly also sponsors a scientific conference on a specific topic of worldwide health interest. Discussions at this conference are held in addition to assembly business. They enable the delegates, who as a rule are top-ranking public health experts, to discuss common problems more thoroughly than formal committee debates would permit. Governments are asked to contribute special working papers and studies to these discussions and, if practicable, to send experts on the matters that are discussed.

Executive Board

The World Health Assembly may elect any 32 member countries to participate in the Executive

Board for 3-year terms as long as the representation complies with equitable geographic distribution. Each of the elected countries must designate one person “technically qualified in the field of health” as a member of the Executive Board. The countries are elected by rotation, one third of the membership being replaced every year, and members may succeed themselves. Board members serve as individuals and not as representatives of their governments.

The Executive Board meets twice a year for sessions of a few days to several weeks, but the board may convene a special meeting at any time. One of the board’s functions is to prepare the agenda for the World Health Assembly. The WHO constitution authorizes the board to take emergency measures within the functions and financial resources of the organization in order to deal with events requiring immediate action. In particular, it may authorize the Director-General to take the necessary steps to combat epidemics and to participate in the organization of health relief to victims of a calamity.

Structure and Areas of Work

Much of the WHO’s work is concentrated on supporting research and providing technical advice to governments. The WHO and its staff work and interact with ministries of health, health-related academia, research centers, the private healthcare sector, and pharmaceutical manufacturers.

The WHO’s staff consists of more than 8,000 health experts, including physicians, epidemiologists, scientists, managers, administrators, and other professionals. The staff provides services from the WHO’s global headquarters, located in Geneva, Switzerland, and six regional offices—namely, (1) WHO Regional Office for Africa (AFRO), located in Brazzaville, Republic of the Congo; (2) WHO Regional Office for the Americas (AMRO)/Pan American Health Organization (PAHO), located in Washington, D.C.; (3) WHO Regional Office for the Eastern Mediterranean (EMRO), located in Cairo, Egypt; (4) Regional Office for Europe (EURO), located in Copenhagen, Denmark; (5) WHO Regional Office for South-East Asia (SEARO), located in New Delhi, India; and (6) WHO Regional Office for the Western Pacific (WPRO), located in Manila, the Philippines.

In addition, the WHO has local offices located in 147 countries.

The WHO's organizational structure is very dynamic as it has to rapidly adapt to ever changing health conditions around the world. The WHO's regional offices and local country offices tend to follow changes in structure from the organization's headquarters, adapting them to the existing health situations and needs of their own geographical areas.

The WHO headquarters structure consists of the Director General's Office, which includes the Deputy Director General, the Executive Director, advisers, governing bodies, internal oversight services, legal counsel, communications, ombudsmen, official institutional links with other international structures and partnerships, operational links with regional offices, and a special unit for polio eradication. WHO's headquarters also includes

(a) organizational and operational structures for health security and environment; (b) HIV/AIDS, tuberculosis, malaria, and neglected tropical diseases; (c) health systems and services; health technology and pharmaceuticals; (d) health action in crises; information, evidence, and research; (e) family and community health; (f) noncommunicable diseases and mental health; and (g) general management.

Milestones in the History of the WHO

The WHO has continuously adapted to changes in scientific, medical advances and world healthcare needs. It has provided the background support for the improvement of health around the world, contributing either directly or indirectly to major achievements in health that include the following:

1948	The WHO takes on the responsibility of developing and implementing the International Classification of Diseases (ICD), which has become the standard clinical and epidemiological tool used worldwide.
1952	Jonas Salk in the United States develops the first successful polio vaccine.
1952–1964	The WHO/UNICEF Global Yaws Control Program reduces the prevalence of the crippling disease, yaws, from 50 million in 1950 to approximately 2.5 million cases in 1965.
1967	South African surgeon Christian Bernard succeeds in conducting the first heart transplant.
1967–1979	The WHO coordinates the smallpox eradication campaign, and for the first time in the history of humankind, a major infectious disease that killed millions is eradicated from the world.
1974	The World Health Assembly creates the Expanded Program for Immunization to bring basic vaccines to all children worldwide.
1974–2004	The WHO's Onchocerciasis Control Program prevents 600,000 cases of river blindness, and 18 million children are spared from the disease. And 25 million hectares of abandoned river land becomes productive again.
1977	The WHO publishes the first <i>Essential Medicines List</i> , providing countries with a national list of essential medicines.
1978	The WHO's International Conference on Primary Care in Alma-Ata, Kazakhstan, sets the historic goal of "Health for All."
1983	The Pasteur Institute in France identifies the human immunodeficiency virus (HIV), the causative agent of acquired immunodeficiency syndrome (AIDS).
1988	The WHO's Global Polio Eradication Initiative is established. As a result, 5 million children are prevented from suffering from disability, and 1.5 million childhood deaths are averted.
2003	Severe acute respiratory syndrome (SARS) is first identified and controlled.
2004	The WHO adopts the Global Strategy on Diet, Physical Activity and Health.
2005	The World Health Assembly revises the International Health Regulations.

In the near and distant future, the WHO will continue to promote and protect the health of all the peoples of the world.

I. Health Services Research

Health services research is the emerging field that addresses the complex issues related to the healthcare system and informs health policy and practice. Health services research examines important issues such as access, costs, quality, and outcomes of healthcare.

II. Access to Healthcare

Access to healthcare is the ability to establish contact with and use the healthcare system and its services. There are about 47 million uninsured individuals in the United States, many of whom are unable to afford health insurance coverage and thus are unable to access the healthcare system.

III. Costs, Economics, and Financing of Healthcare

Costs, economics, and financing of healthcare refer to the expenditures, scarcity in the allocation of healthcare resources, and the way healthcare is paid for. Economic principles are a useful tool to better understand how to control rising healthcare costs and how to finance healthcare.

V. Organizational Behavior and Structure of Healthcare

Organizational behavior and the structure of healthcare provide a theoretical basis for understanding the dynamic relationships between individuals and groups in health-care organizational settings and how they operate within the structural components of an organization.

VII. Health Policy

Health policy is the stance of the government that is aimed at improving health and healthcare. Many researchers, organizations, and advocacy groups work to shape health policy by using evidence-based studies and various resources to aid in policy guidance.

VIII. Health Professionals and Healthcare Organizations

Health professionals are the individuals who work to ensure the smooth functioning and operation of the healthcare system, and they are the primary

deliverers of healthcare services. Healthcare organizations are the entities that provide essential healthcare services.

XII. Aging, Disability, and Long-Term Care

Aging is the process of getting older, and it is concerned with issues of the elderly. Disability is the lack of ability as compared with a normal group of individuals. Long-term care is the care that is provided to the chronically ill and the disabled.

This section includes a potpourri of selected topics in health services research and provides an amalgam of informative readings.

111. Bioterrorism

- Antosia, Robert E., and John D. Cahill, eds. *Handbook of Bioterrorism and Disaster Medicine*. New York: Springer, 2006.
- Butler, Adrienne Stith, Allison M. Panzer, and Lewis R. Goldfrank, eds., and Committee on Responding to the Psychological Consequences of Terrorism, Institute of Medicine. *Preparing for the Psychological Consequences of Terrorism: A Public Health Strategy*. Washington, DC: National Academies Press, 2003.
- D'Arcy, Michael, Michael O'Hanlon, Peter Orszag, et al. *Protecting the Homeland 2006/2007*. Washington, DC: Brookings Institution Press, 2006.
- Demuth, Julie L. *Countering Terrorism: Lessons Learned From Natural and Technological Disasters: A Summary of the Natural Disasters Roundtable*. National Academy of Sciences Conference, Washington, DC (February 28–March 1, 2002). Washington, DC: National Academies Press, 2002.
- Greenberg, Michael I. *Encyclopedia of Terrorist, Natural, and Man-Made Disasters*. Sudbury, MA: Jones and Bartlett, 2006.
- Griset, Pamala L., and Sue Mahan. *Terrorism in Perspective*. Thousand Oaks, CA: Sage, 2002.
- Henderson, Donald A., Thomas V. Ingelsby, and Tara O'Toole, eds. *Bioterrorism: Guidelines for Medical and Public Health Management*. Chicago: American Medical Association, 2002.
- Levy, Barry S., and Victor W. Sidel, eds. *Terrorism and Public Health: A Balanced Approach to Strengthening Systems and Protecting People*. New York: Oxford University Press, 2002.
- McGlown, K. Joanne, ed. *Terrorism and Disaster Management: Preparing Healthcare Leaders for the New Reality*. Chicago: Health Administration Press, 2004.
- Pilch, Richard F., and Raymond A. Zilinskas, eds. *Encyclopedia of Bioterrorism Defense*. Hoboken, NJ: Wiley-LISS, 2005.
- Trotter, Griffin. *The Ethics of Coercion in Mass Casualty Medicine*. Baltimore: Johns Hopkins University Press, 2007.

112. E-Health and Telemedicine

- Bashshur, Rashid. *State of the Art: Telemedicine/Telehealth Symposium: An International Perspective: Abstract, Executive and Final Report of Symposium*. Rockville, MD: Agency for Healthcare Research and Quality, Center for Research Dissemination and Liaison, 2001. (The symposium was held at the University of Michigan in 2001)

- Demiris, George, ed. *E-Health: Current Status and Future Trends*. Washington, DC: IOS Press, 2004.
- Goldsmith, Jeff. *Digital Medicine: Implications for Healthcare Leaders*. Chicago: Health Administration Press, 2003.
- Hersh, William R., and James A. Wallace. *Telemedicine for the Medicare Population*. Rockville, MD: U.S. Department of Health and Human Services, Public Health Service, Agency for Healthcare Research and Quality, 2001.
- Lingle, Virginia A., and Eric P. Delozier, eds. *World Wide Web and Other Internet Information Services in the Health Sciences: A Collection of Policy and Procedure Statements*. Chicago: Medical Library Association, 1996.
- Maheu, Marlene M., Pamela Whitten, and Ace Allen. *E-Health, Telehealth, and Telemedicine: A Guide to Start-Up and Success*. San Francisco: Jossey-Bass, 2001.
- Norris, Anthony Charles. *Essentials of Telemedicine and Telecare*. New York: Wiley, 2002.
- Schrimsher, Robert H., and T. Harmon Straiton Jr. *Health Data on the Internet: An Annotated Bibliography and Guide*. Chicago: Medical Library Association, 1999.
- Tan, Joseph, ed. *E-Health Care Information Systems: An Introduction for Students and Professionals*. San Francisco: Jossey-Bass, 2005.
- Telemedicine and Telecommunications: Options for the New Century: Program Book*. Bethesda, MD: National Institutes of Health, National Library of Medicine, Lister Hill National Center for Biomedical Communications, Office of High Performance Computing and Communications, 2001.
- Whitten, Pamela, and David Cook, eds. *Understanding Health Communication Technologies*. San Francisco: Jossey-Bass, 2004.
- Wootton, Richard, John Craig, and Victor Patterson, eds. *Introduction to Telemedicine*. 2d ed. London: Royal Society of Medicine Press, 2006.

113. Fraud and Abuse

- Baumann, Linda A., ed. *Health Care Fraud and Abuse: Practical Perspectives*. Washington, DC: Bureau of National Affairs Press, 2002.
- Nathanson, Martha Dale, and Carel T. Hedlund. *Home Care Fraud and Abuse: Critical Questions, Essential Answers*. Gaithersburg, MD: Aspen, 1999.
- Sparrow, Malcolm K. *License to Steal: How Fraud Bleeds America's Health Care System*. Boulder, CO: Westview Press, 2000.
- U.S. Department of Health and Human Services and Department of Justice. *Health Care Fraud and Abuse Control Program Annual Report for FY2005*. Washington, DC: U.S. Department of Health and Human Services/Department of Justice, 2006.
- U.S. General Accountability Office. *Health Care Fraud and Abuse Control Programs: Results of Review of Annual Reports for Fiscal Years 2002 and 2003: Report to*

- Congressional Committees. Washington, DC: U.S. Government Accountability Office, 2005.
- U.S. General Accountability Office. *Medicaid Fraud and Abuse: CMS's Commitment to Helping States Safeguard Program Dollars Is Limited: Testimony Before the Committee on Finance, U.S. Senate*. Washington, DC: U.S. Government Accountability Office, 2005.

114. Future Trends

- Berwick, Donald M. *Escape Fire: Designs for the Future of Health Care*. San Francisco: Jossey-Bass, 2003.
- Ellis, David. *Technology and the Future of Health Care: Preparing for the Next 30 Years*. San Francisco: Jossey-Bass, 2001.
- Enthoven, Alain C., and Laura A. Tollen, eds. *Toward a 21st Century Health System: The Contribution and Promise of Prepaid Group Practice*. San Francisco: Jossey-Bass, 2004.
- Geisler, Eliezer, Koos Krabbendam, and Roel Schuring, eds. *Technology, Health Care, and Management in Hospitals of the Future*. Westport, CT: Praeger, 2003.
- Institute for the Future. *Health and Health Care 2010: Forecast, the Challenge*. 2d ed. San Francisco: Jossey-Bass, 2003.
- Institute of Medicine. *Informing the Future: Critical Issues in Health*. 3d ed. Washington, DC: National Academies Press, 2005.
- Institute of Medicine. *2020 Vision: Health in the 21st Century*. Institute of Medicine 25th Anniversary Symposium. Washington, DC: National Academy Press, 1996.
- Lutz, Sandy, Woodrin Grossman, and John Bigalke. *Med Inc.: How Consolidation Is Shaping Tomorrow's Healthcare System*. San Francisco: Jossey-Bass, 1998.
- Morrison, Ian. *Health Care in the New Millennium: Vision, Values, and Leadership*. San Francisco: Jossey-Bass, 2002.
- Showstack, Jonathan, Arlyss Anderson Rothman, and Sue Hasmiller, eds. *The Future of Primary Care*. San Francisco: Jossey-Bass, 2004.
- Silberglitt, Richard, Philip S. Anton, David R. Howell, et al. *The Global Technology Revolution 2020: Bio, Nano, Materials, Information Trends, Drivers, Barriers, and Social Implications*. Santa Monica, CA: RAND Corporation, 2006.
- Society for Healthcare Strategy and Market Development and American College of Healthcare Executives. *Futurescan: Healthcare Trends and Implications, 2006–2011*. Chicago: Health Administration Press/Society for Healthcare Strategy and Market Development, 2006.
- Styring, Willams, and Donald K. Jones. *Health Care 2020: The Coming Collapse of Employer-Provided Health Care*. Washington, DC: Hudson Institute, 1999.
- Chapman, Audrey R., and Mark S. Frankel, eds. *Designing Our Descendants: The Promises and Perils of Genetic Modifications*. Baltimore: Johns Hopkins University Press, 2003.
- Childs, Barton. *Genetic Medicine: A Logic of Disease*. 2d ed. Baltimore: Johns Hopkins University Press, 2003.
- Davies, Kevin. *Cracking the Genome: Inside the Race to Unlock Human DNA*. Baltimore: Johns Hopkins University Press, 2002.
- Guttmacher, Alan E., Francis S. Collins, and Jeffrey M. Drazen, eds. *Genomic Medicine: Articles From the New England Journal of Medicine*. Baltimore: Johns Hopkins University Press, 2004.
- Hernandez, Lyla M., ed., and Committee on Genomics and the Public's Health in the 21st Century, Board on Health Promotion and Disease Prevention, Institute of Medicine. *Implications of Genomics for Public Health: Workshop Summary*. Washington, DC: National Academies Press, 2006.
- Holtzman, Neil A., and Michael S. Watson, eds. *Promoting Safe and Effective Genetic Testing in the United States: Final Report of the Task Force on Genetic Testing*. Baltimore: Johns Hopkins University Press, 1998.
- Jorde, Lynn B., ed. *Encyclopedia of Genetics, Genomics, Proteomics, and Bioinformatics*. Hoboken, NJ: Wiley, 2005.
- Khoury, Muin J., Julian Little, and Wylie Burke. *Human Genome Epidemiology: A Scientific Foundation for Using Genetic Information to Improve Health and Prevent Disease*. New York: Oxford University Press, 2003.
- Lindee, Susan. *Moments of Truth in Genetic Medicine*. Baltimore: Johns Hopkins University Press, 2005.
- Milunsky, Aubrey, ed. *Genetic Disorders and the Fetus: Diagnosis, Prevention, and Treatment*. 5th ed. Baltimore: Johns Hopkins University Press, 2004.
- National Academies Keck Futures Initiative. *The Genomic Revolution: Implications for Treatment and Control of Infectious Disease: Working Group Summaries*. Conference held at the Arnold and Mabel Beckman Center of the National Academies, Irvine, CA (November 10–13, 2005). Washington, DC: National Academies Press, 2006.
- Ness, Bryan D., ed. *Encyclopedia of Genetics*. 2 vols. Pasadena, CA: Salem Press, 2004.
- Nys, Herman. *Genetic Testing: Patient's Rights, Insurance, and Employment: A Survey of Regulations in the European Union*. Luxembourg: Office for Official Publications of the European Communities, 2002.
- Ott, Jurg. *Analysis of Human Genetic Linkage*. 3d ed. Baltimore: Johns Hopkins University Press, 1999.
- Parens, Erik, Audrey R. Chapman, and Nancy Press, eds. *Wrestling With Behavioral Genetics: Science, Ethics, and Public Conversation*. Baltimore: Johns Hopkins University Press, 2005.
- Parthasarathy, Shobita. *Building Genetic Medicine: Technology, Breast Cancer, and the Comparative Politics of Health Care*. Cambridge: MIT Press, 2007.

115. Genetics

- Alper, Joseph S., Catherine Ard, Jon Beckwith, et al., eds. *The Double-Edged Helix: Social Implications of Genetics in a Diverse Society*. Baltimore: Johns Hopkins University Press, 2004.

- Peltz, Gary, ed. *Computational Genetics and Genomics: Tools for Understanding Disease*. Totowa, NJ: Humana Press, 2005.
- Reilly, Philip. *Is It in Your Genes? The Influence of Genes on Common Disorders and Diseases That Affect You and Your Family*. Cold Spring Harbor, NY: Cold Spring Harbor Laboratory Press, 2004.
- Thomas, Duncan C. *Statistical Methods in Genetic Epidemiology*. New York: Oxford University Press, 2004.
- Tokar, Brian, ed. *Redesigning Life? The Worldwide Challenge to Genetic Engineering*. New York: Zed Books, 2001.
- Wailoo, Keith, and Stephen Pemberton. *The Troubled Dream of Genetic Medicine: Ethnicity and Innovation in Tay-Sachs, Cystic Fibrosis, and Sickle Cell Disease*. Baltimore: Johns Hopkins University Press, 2006.

116. Health Planning

- Green, Andrew. *An Introduction to Health Planning in Developing Countries*. New York: Oxford University Press, 1999.
- Hayward, Cynthia. *Healthcare Facility Planning: Thinking Strategically*. Chicago: Health Administration Press, 2005.
- Hodges, Bonni C., and Donna M. Videto. *Assessment and Planning in Health Programs*. Sudbury, MA: Jones and Bartlett, 2005.
- Issel, L. Michele. *Health Program Planning and Evaluation: A Practical, Systematic Approach for Community Health*. Sudbury, MA: Jones and Bartlett, 2004.
- Thomas, Richard K. *Health Services Planning*. 2d ed. New York: Springer, 2003.
- Zuckerman, Alan M. *Healthcare Strategic Planning*. 2d ed. Chicago: Health Administration Press, 2005.

117. Physician–Patient Relationship

- Defining the Patient-Physician Relationship for the 21st Century*. Third Annual Disease Management Outcome Summit, Phoenix, AZ (October 30–November 2, 2003). Nashville, TN: American Healthways, 2004.
- Katz, Jay. *The Silent World of Doctor and Patient*. Baltimore: Johns Hopkins University Press, 2002.
- Levi, Benjamin H. *Respecting Patient Autonomy*. Champaign: University of Illinois Press, 1999.
- Ramsey, Paul. *The Patient as Person: Explorations in Medical Ethics*. 2d ed. New Haven, CT: Yale University Press, 2002.
- Rosenblatt, R. A., G. E. Wright, L. M. Baldwin, et al. "The Effect of the Doctor-Patient Relationship on Emergency Department Use Among the Elderly," *American Journal of Public Health* 90(1): 97–102, January 2000.
- Smith, James Monroe, ed. *Producing Patient-Centered Health Care: Patient Perspectives About Health and Illness and the Physician/Patient Relationship*. Westport, CT: Auburn House, 1999.
- Thurston, Jeffrey M. *Death of Compassion: The Endangered Doctor-Patient Relationship*. Waco, TX: WRS, 1996.

- Watts, David H. *Bedside Manners: One Doctor's Reflections on the Oddly Intimate Encounters Between Patient and Healer*. New York: Harmony Books, 2005.

118. Privacy, Confidentiality, and the Health Insurance Portability and Accountability Act of 1996 (HIPAA)

- Beaver, Kevin, and Rebecca Herold. *The Practical Guide to HIPAA Privacy and Security Compliance*. Boston: Auerbach, 2003.
- Black, Nick. "Secondary Use of Personal Data for Health and Health Services Research: Why Identifiable Data Are Essential," *Journal of Health Services Research and Policy* 8(3 Suppl. 1): 36–40, July 1, 2003.
- Chaikind, H. R., J. Hearne, B. Lyke, et al. *The Health Insurance Portability and Accountability Act (HIPAA): Overview and Analysis*. New York: Novinka Books, 2004.
- Committee on the Role of Institutional Review Boards in Health Services Research Data Privacy Protection, Division of Health Care Services, Institute of Medicine. *Institutional Review Boards and Health Services Research Data Privacy: A Workshop Summary*. Washington, DC: National Academies Press, 2000.
- Dennis, Jill Callahan. *Privacy and Confidentiality of Health Information*. San Francisco: Jossey-Bass, 2000.
- Herdman, Roger, and Harold Moses, and National Cancer Policy Forum, Institute of Medicine. Effect of the HIPAA Privacy Rule on Health Research. In *Proceedings of a Workshop Presented to the National Cancer Policy Forum*. Washington, DC: National Academies Press, 2006.
- Roach, William H. *Medical Records and the Law*. 4th ed. Sudbury, MA: Jones and Bartlett, 2006.

119. Program Evaluation

- Aday, Lu Ann, Charles E. Begley, David R. Lairson, et al. *Evaluating the Healthcare System: Effectiveness, Efficiency, and Equity*. 3d ed. Chicago: Health Administration Press, 2004.
- Grembowski, David. *The Practice of Health Program Evaluation*. Thousand Oaks, CA: Sage, 2001.
- Steckler, Allan, and Laura Linnan, eds. *Process Evaluation for Public Interventions and Research*. San Francisco: Jossey-Bass, 2002.
- Telfair, Joseph, Laura C. Leviton, and Jeanne S. Merchant. *Evaluating Health and Human Service Programs in Community Settings: New Directions for Evaluation*. San Francisco: Jossey-Bass, 1999.
- Timmreck, Thomas C. *Planning, Program Development, and Evaluation*. 2d ed. Sudbury, MA: Jones and Bartlett, 2003.
- Wynn, Barbara O., Arindam Dutta, and Martha I. Nelson. *Challenges in Program Evaluation of Health Interventions in Developing Countries*. Santa Monica, CA: RAND Center for Domestic and International Health Security, 2005.

120. *Technology Assessment*

- Acemoglu, Daron, et al. *Did Medicare Induce Pharmaceutical Innovation?* NBER Working Paper No. 11949. Cambridge, MA: National Bureau of Economic Research, 2006.
- Aspden, Philip, ed., Board on Science, Technology, and Economic Policy, Policy and Global Affairs, Board on Health Care Services, Institute of Medicine, and National Research Council. *Medical Innovation in the Changing Healthcare Marketplace: Conference Summary*. Washington, DC: National Academy Press, 2002.
- Becker, Karen, and John J. Whyte, eds. *Clinical Evaluation of Medical Devices: Principles and Case Studies*. 2d ed. Totowa, NJ: Humana Press, 2006.
- Coddington, Dean C., Keith D. Moore, and Elizabeth A. Fischer. *Strategies for the New Health Care Marketplace: Managing the Convergence of Consumerism and Technology*. San Francisco: Jossey-Bass, 2001.
- Duesterburg, Thomas, David Weinshropp, and David Murray. *Health Care Reform, Regulation, and Innovation in the Medical Device Industry: A Study of Competitiveness in a Vital U.S. Industry*. Washington, DC: Hudson Institute, 1996.
- Eaton, Margaret L., and Donald L. Kennedy. *Innovation in Medical Technology: Ethical Issues and Challenges*. Baltimore: Johns Hopkins University Press, 2007.
- Ellis, David. *Technology and the Future of Health Care: Preparing for the Next 30 Years*. San Francisco: Jossey-Bass, 2001.
- Epstein, Richard A. *Overdose: How Excessive Government Regulations Stifles Pharmaceutical Innovation*. New Haven, CT: Yale University Press, 2006.
- Garber, Alan M., and Victor R. Fuchs. "The Expanding Role of Technology Assessment in Health Policy," *Stanford Law and Policy Review* 3: 203–209, Fall 1991.
- Gedeon, Andras. *Science and Technology in Medicine: An Illustrated Account Based on Ninety-Nine Landmark Publications From Five Centuries*. New York: Springer, 2006.
- Geisler, Eliezer, Koos Krabbendam, and Roel Schuring, eds. *Technology, Health Care, and Management in the Hospitals of the Future*. Westport, CT: Praeger, 2003.
- Gelijns, Annetine C., and Holly V. Dawkins, eds., and Committee on Technology Innovation in Medicine, Institute of Medicine. *Adopting New Medical Technology*. Washington, DC: National Academy Press, 1994.
- Halley, D. *Australian Experience in the Use of Economic Evaluation to Inform Policy on Medical Technology*. West Heidelberg, Victoria, Australia: National Centre for Health Program Evaluation, 1996.
- Hanna, Kathi E., Frederick J. Manning, Peter Bouxsein, et al., and Roundtable on Research and Development of Drugs, Biologics, and Medical Devices, Board on Health Sciences Policy, Institute of Medicine. *Innovation and Invention in Medical Devices: Workshop Summary*. Washington, DC: National Academies Press, 2001.
- Jeffrey, Kirk. *Machines in Our Hearts: The Cardiac Pacemaker, the Implantable Defibrillator, and American Health Care*. Baltimore: Johns Hopkins University Press, 2001.
- Lantos, John D., and William L. Meadow. *Neonatal Bioethics: The Moral Challenges of Medical Innovation*. Baltimore: Johns Hopkins University Press, 2006.
- Mohr, Penny E., Curt Mueller, Peter Neumann, et al. *The Impact of Medical Technology on Future Health Care Costs*. Bethesda, MD: Center for Health Affairs, Project HOPE, 2001.
- Patlak, Margie, Sharyl J. Nass, I. Craig Henderson, et al., eds., Committee on the Early Detection of Breast Cancer, National Cancer Policy Board, Institute of Medicine, and Commission on Life Sciences, National Research Council. *Mammography and Beyond: Developing Technologies for the Early Detection of Breast Cancer: A Non-Technical Summary*. Washington, DC: National Academy Press, 2000.
- Rosenau, R. V. "Managing Medical Technology: Lessons for the United States From Quebec and France," *International Journal of Health Services* 30(3): 617–39, 2000.
- Schacter, Bernice Zeldin. *Issues and Dilemmas of Biotechnology: A Reference Guide*. Westport, CT: Greenwood, 1999.
- Schlich, Thomas, and Ulrich Trohler, eds. *The Risks of Medical Innovation: Risk Perception and Assessment in Historical Context*. New York: Routledge, 2006.
- Silberglitt, Richard, Philip S. Anton, David R. Howell, et al. *The Global Technology Revolution 2020: Bio, Nano, Materials, Information Trends, Drivers, Barriers, and Social Implications*. Santa Monica, CA: RAND Corporation, 2006.
- Sloan, Frank A., and Chee-Ruey Hsieh, eds. *Pharmaceutical Innovation: Incentives, and Cost-Benefit Analysis in International Perspective*. New York: Cambridge University Press, 2007.
- Spekowitz, Gerhard, and Thomas Wendler, eds. *Advances in Healthcare Technology: Shaping the Future of Medical Care*. New York: Springer, 2006.
- Stelzer, Irwin, ed. *Innovation in the Medical Technology Industries: Regulation, Competition, Reimbursement, and the Availability of Venture Capital*. Washington, DC: Hudson Institute, 2002.
- Turisco, Fran, and Jane Metzger. *Rural Health Care Delivery: Connecting Communities Through Technology*. Oakland: California HealthCare Foundation, 2002.
- U.S. Congress, Office of Technology Assessment. *Tools for Evaluating Health Technologies: Five Background Papers*. Washington, DC: U.S. Congress, Office of Technology Assessment, 1995.
- Wailoo, Keith. *Drawing Blood: Technology and Disease Identity in Twentieth-Century America*. Baltimore: Johns Hopkins University Press, 1999.
- Webster, John G., ed. *Encyclopedia of Medical Devices and Instrumentation*. 2d ed. 6 vols. Hoboken, NJ: Wiley, 2006.

121. Women's Health Issues

- Ammer, Christine. *The Encyclopedia of Women's Health*. 5th ed. New York: Facts on File, 2005.
- Clark, Rebecca A., Robert T. Maupin, and Jill Hayes Hammer. *A Women's Guide to Living With HIV Infection*. Baltimore: Johns Hopkins University Press, 2004.
- Collins, Catherine Fisher, ed. *African American Women's Health and Social Issues*. 2d ed. Westport, CT: Praeger, 2006.
- Coward, Raymond T., Lisa A. Davis, Carol H. Gold, et al., eds. *Rural Women's Health: Mental, Behavioral, and Physical Issues*. New York: Springer, 2006.
- Gay, Kathlyn. *Encyclopedia of Women's Health Issues*. Westport, CT: Oryx Press, 2002.
- Health Resources and Services Administration. *Women's Health USA 2006*. Rockville, MD: U.S. Department of Health and Human Services, 2006.
- James, Genie. *Winning in the Women's Health Care Marketplace: A Comprehensive Plan for Health Care Strategists*. San Francisco: Jossey-Bass, 1999.
- Kishor, Katherine Neitzel. *The Status of Women: Indicators for Twenty-Five Countries*. Calverton, MD: Macro International, 1996.
- Kramer, Elizabeth J., Susan L. Ivey, and Yu-Wen Ying, eds. *Immigrant Women's Health: Problems and Solutions*. San Francisco: Jossey-Bass, 1998.
- Kuh, Diana, and Rebecca Hardy, eds. *A Life Course Approach to Women's Health*. New York: Oxford University Press, 2003.
- Loue, Sana, and Martha Sajatovic. *Encyclopedia of Women's Health*. New York: Kluwer Academic Press/Plenum Press, 2004.
- Mastroianni, Anna C., Ruth Faden, and Daniel Federman, eds., and Committee on the Ethical and Legal Issues Relating to the Inclusion of Women in Clinical Studies, Division of Health Sciences Policy, Institute of Medicine. *Women and Health Research: Ethical and Legal Issues of Including Women in Clinical Studies*, vols. 1–2. Workshop and Commissioned Papers. Washington, DC: National Academy Press, 1994.
- Middleberg, Maurice I. *Promoting Reproductive Security in Developing Countries*. New York: Springer, 2003.
- Montz, F. J., Robert E. Bristow, and Paula J. Anastasia. *A Guide to Survivorship for Women With Ovarian Cancer*. Baltimore: Johns Hopkins University Press, 2005.
- National Center on Addiction and Substance Abuse at Columbia University. *Women Under the Influence*. Baltimore: Johns Hopkins University Press, 2005.
- O'Leary, Ann, and Loretta Sweet Jemmott. *Women and AIDS: Coping and Care*. New York: Springer, 1996.
- Olson, James S. *Bathsheba's Breast: Women, Cancer, and History*. Baltimore: Johns Hopkins University Press, 2005.
- Wallach, Edward E., and Esther Eisenberg. *Hysterectomy: Exploring Your Options*. Baltimore: Johns Hopkins University Press, 2003.
- Weisman, Carol S. *Women's Health Care: Activist Traditions and Institutional Change*. Baltimore: Johns Hopkins University Press, 1998.
- World Health Organization. Women and Health: Better Health and Welfare Systems, Women's Perspectives. In *Proceedings of a WHO Kobe Centre International Meeting, Awaji Yumebutai International Conference Centre (April 5–7, 2000)*. Kobe, Japan: World Health Organization, 2000.

Appendix: Web Resources

This listing contains useful resources that are available on the Internet for selected topics of health services research. It contains a brief description of each topic and links to Web sites based on particular categories of interest. These links are current as of the publication date.

1. Academic Medical Centers

Academic medical centers are teaching hospitals that are generally affiliated with a medical school or university. These hospitals have a broad mission that includes teaching, clinical research, and medical education, and they may offer the latest advancements in medical technologies and treatments.

Alliance of Independent Academic Medical Centers (AIAMC) <http://www.aiamc.org>

Association of Academic Health Centers <http://www.ahcnet.org>

Association of Canadian Academic Healthcare Organizations (ACAHO) <http://www.achao.org>

University HealthSystem Consortium (UHC) <http://www.uhc.edu>

See also Hospitals; Medical Residents and Interns; Physicians

2. Accreditation, Certification, and Licensing

Accreditation, certification, and licensing are ways of credentialing healthcare providers and facilities to ensure that a minimum professional standard has been met. Several private organizations carry out credentialing activities in healthcare.

Accreditation Association for Ambulatory Health Care (AAAHC) <http://www.aaahc.org>

Accreditation Canada, formerly known as the Canadian Council on Health Services Accreditation <http://www.accreditation-canada.ca>

American Board of Medical Specialties (ABMS) <http://www.abms.org>

Association of American Medical Colleges (AAMC) <http://www.aamc.org>

Association of Faculties of Medicine of Canada (AFMC) <http://www.afmc.ca>

Commission on Accreditation of Rehabilitation Facilities (CARF) <http://www.carf.org>

Commission on Dental Accreditation of Canada <http://www.cda-adc.ca/cdacweb>

Commission on Osteopathic College Accreditation (COCA), American Osteopathic Association <http://www.osteopathic.org>

Council on Accreditation (COA) <http://www.coanet.org>

Federation of State Medical Boards of the United States (FSMB) <http://www.fsmb.org>

Healthcare Facilities Accreditation Program (HFAP), American Osteopathic Association https://www.do-online.org/index.cfm?au=D&PageId=edu_main&SubPageId=acc_main

Joint Commission <http://www.jointcommission.org>

Canadian Physiotherapy Association
<http://www.physiotherapy.ca>

National Rehabilitation Association
<http://www.nationalrehab.org>

See also Case Management; Medical Technologists

10. Alzheimer's Disease

Alzheimer's disease is the most common form of dementia and it is an incurable and terminal condition. Several organizations have led efforts to promote research and care for those afflicted with this degenerative disease.

Alzheimer's Association (ALZ) <http://www.alz.org>

Alzheimer's Disease Education and Referral (ADEAR) Center <http://www.nia.nih.gov/alzheimers>

Alzheimer Society of Canada <http://www.alzheimer.ca>

National Institute on Aging (NIA) <http://www.nia.nih.gov>

See also Aging; Disability; Gerontology; Nursing Homes

11. Ambulatory Care

Ambulatory care is medical care that is provided on an outpatient basis. Ambulatory care can be delivered in doctor's offices and clinics, emergency departments, and urgent care centers.

Academic Pediatric Association, formerly known as the Ambulatory Pediatric Association <http://www.ambpeds.org>

Accreditation Association for Ambulatory Health Care (AAAHC) <http://www.aaahc.org>

See also Ambulatory Surgery Centers; Community Health Centers (CHCs); Physicians

12. Ambulatory Surgery Centers

Ambulatory surgery centers are healthcare facilities that provide same-day surgeries on an outpatient basis that do not require a patient to be hospitalized.

American Association for Accreditation of Ambulatory Surgery Facilities (AAAASF) <http://www.aaaasf.org>

American Association of Ambulatory Surgery Centers (AAASC) <http://www.aaasc.org>

See also Ambulatory Care; Surgery and Surgeons

13. Anesthesiology

Anesthesiology is a medical speciality that focuses on administering anesthesia to patients and monitoring vital bodily functions during a medical procedure such as surgery.

American Society of Anesthesiologists (ASA)
<http://www.asahq.org>

American Society of Regional Anesthesia and Pain Medicine (ASRA) <http://www.asra.org>

Society of Cardiovascular Anesthesiologists (SCA)
<http://www.scahq.org>

See also Ambulatory Surgery Centers; Dentistry; Hospitals; Surgery and Surgeons

14. Antitrust

Antitrust is an area that promotes competition in healthcare to benefit consumers. At its core, competition serves to improve healthcare quality, reduce costs, and increase access.

American Antitrust Institute <http://www.antitrustinstitute.org>

Antitrust Coalition for Consumer Choices in Health Care <http://www.healthantitrust.org>

Health Care Antitrust Division, U.S. Department of Justice

Spinal disorders and injuries are conditions that affect the spinal cord.

American Paraplegia Society (APS) <http://www.apssci.org>

National Spinal Cord Injury Association (NSCIA)
<http://www.spinalcord.org>

North American Spine Society (NASS) <http://www.spine.org>

Spinal Cord Society (SCS) <http://scsus.org>

See also Chronic Diseases; Disability; Physical and Rehabilitation Medicine

207. State and County Data Sources

State and county data sources are sources of health and demographic information at the state or county level.

Area Resource File (ARF) <http://www.arfsys.com>

Dartmouth Atlas of Health Care
<http://www.dartmouthatlas.org>

State Health Facts Online
<http://www.statehealthfacts.org>

See also Health Statistics and Data Sources; Health Surveys; Vital Statistics

208. State and County Government Organizations

State and county government organizations represent groups of state and county-level government employees.

Association of State and Territorial Dental Directors (ASTDD)
<http://www.astdd.org>

Association of State and Territorial Health Officials (ASTHO)
<http://www.astho.org>

Information for State Health Policy
<http://www2.umdnj.edu/ishppweb/homepage.htm>

National Academy for State Health Policy (NASHP)
<http://www.nashp.org>

National Association of County and City Health Officials (NACCHO) <http://www.naccho.org>

National Association of State Budget Officers (NASBO)
<http://www.nasbo.org>

National Association of State Medicaid Directors
<http://www.nasmd.org>

National Conference of State Legislatures (NCSL)
<http://www.ncsl.org>

National Governors Association (NGA) <http://www.nga.org>

State Health Facts Online (This website is produced by the Kaiser Family Foundation)
<http://www.statehealthfacts.kff.org>

Stateline.org (This site is produced by the Pew Center on the States) <http://www.stateline.org>

See also Health Statics and Data Sources; Public Health

209. State Children's Health Insurance Program (SCHIP)

The State Children's Health Insurance Program is a federal health program that provides funding to the states to insure families with children that have a modest income but do not qualify for Medicaid.

Centers for Medicare and Medicaid (CMS)
<http://www.cms.hhs.gov/home/schip.asp>

Medicaid/SCHIP, Henry J. Kaiser Family Foundation (KFF) <http://www.kff.org/medicaid/index.cfm>

See also Centers for Medicare and Medicaid Services (CMS); Child Development and Health; Health Insurance; Medicaid

210. Stroke

Stroke is a condition when the blood flow to the brain is disrupted either because of a blockage or hemorrhage of the blood vessels. Stroke can result in the loss of brain function and paralysis of the body.

American Stroke Association (ASA) <http://www.strokeassociation.org>

Division for Heart Disease and Stroke Prevention, Centers for Disease Control and Prevention (CDC) <http://www.cdc.gov/DHDSP>

The Internet Stroke Center, Washington University, St. Louis, MO <http://www.strokecenter.org>

National Institute of Neurological Disorders and Stroke (NINDS) <http://www.ninds.nih.gov>

National Stroke Association (NSA) <http://www.stroke.org>

The Stroke Association <http://www.stroke.org.uk>

See also Aging; Disability; Chronic Diseases; Hypertension; Physical Medicine and Rehabilitation

211. Substance Abuse

Substance abuse is the overuse or dependence on a drug or chemical that results in negative physical or mental health consequences that may affect the welfare of others. Substance abuse can result in drug addiction and physiological or behavioral problems.

American Society of Addiction Medicine (ASAM) <http://www.asam.org>

Association for Addiction Professionals (NAADAC) (The association was formerly the National Association of Alcoholism and Drug Abuse Counselors) <http://www.naadac.org>

Center for Substance Abuse Prevention (CSAP) <http://www.prevention.samhsa.gov>

National Clearinghouse for Alcohol and Drug Information (NCADI) <http://www.health.org>

National Institute on Drug Abuse <http://www.nida.nih.gov>

See also Alcoholism; Federal Government; Public Health; Tobacco Use

212. Surgery and Surgeons

Surgery is a specialty of medicine that uses both manual and invasive techniques to treat or explore disease or injuries to the body, help the body to improve in its form or function, and other reasons. Surgeons are healthcare providers who perform surgeries.

American College of Surgeons (ACS) <http://www.facs.org>

Association for Academic Surgery (AAS) <http://www.aasurg.org>

International College of Surgeons (ICS) <http://www.icsglobal.org>

Tests and Procedures, MedlinePlus <http://www.nlm.nih.gov/medlineplus/tutorial.html>

See also Health Disparities; Health Insurance; Healthcare Financial Management; National Health Insurance

217. United Kingdom Healthcare Organizations

The United Kingdom (UK) healthcare organizations include organizations in the UK that are related to health and healthcare.

National Electronic Library for Health <http://www.library.nhs.uk>

National Health Service (NHS) <http://www.nhs.uk>

National Institute for Clinical Excellence (NICE)
<http://www.nice.org.uk>

Nuffield Trust for Research and Policy Studies in Health Services <http://www.nuffieldtrust.org.uk>

The Stroke Association <http://www.stroke.org.uk>

UK Health Informatics Society (UKHIS) <http://ukhis.org.uk>

See also International Health Systems; World Health Organization (WHO)

218. Veterans Health

Veterans health includes healthcare programs that are targeted to veterans of the military.

Department of Veterans Affairs (VA) <http://www.va.gov>

National Association of State Veterans Homes (NASVH)
<http://www.nasvh.org>

National Center for Health Promotion and Disease Prevention <http://www.prevention.va.gov>

VA National Center for Patient Safety
<http://www.patientsafety.gov>

Veterans Health Administration (VHA)
<http://www1.va.gov/health>

See also Federal Government; Hospitals; Military Health Systems

219. Vital Statistics

Vital statistics are the records of births, deaths, marriages, and divorces.

Birth Data <http://www.cdc.gov/nchs/births.htm>

Fetal Deaths <http://www.cdc.gov/nchs/about/major/fetaldth/abfetal.htm>

Marriage and Divorce <http://www.cdc.gov/nchs/pressroom/96facts/mardiv.htm>

Mortality Data <http://www.cdc.gov/nchs/deaths.htm>

National Death Index <http://www.cdc.gov/nchs/ndi.htm>

National Vital Statistics System, National Center for Health Statistics (NCHS) <http://www.cdc.gov/nchs/nvss.htm>

See also Epidemiology; Public Health; Public Health, State Departments of; State and County Data Sources

220. Women's Health Issues

Women's health represents the unique health needs of women and it works to address the disparities in health between men and women.

Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN) <http://www.awhonn.org>

Canadian Women's Health Network (CWHN)
<http://www.cwhn.ca/indexeng.html>

Foundation for Women's Health Research and Development (FORWARD) <http://www.forwarduk.org.uk>

Global Alliance for Women's Health (GAWH)
<http://www.gawh.org>

Institute for Women's Policy Research (IWPR)
<http://www.iwpr.org>

International Women's Health Coalition (IWHC)
<http://www.iwhc.org>
