Post-egocentricity: This is also a perspective characterized by concreteness and centering, but it underlies a slight increase in sophistication of representations and meanings. Pupils' statements are somewhat decentered, referring to the specific experience of a pupil's immediate environment (e.g., family), centered on simple units, not justified and generally formulated in "we" form (including self and others) or possessive "he/she" form. Here are examples of post-egocentricity as manifested in creative thinking.

> (Pupil of 5–6 years): *Me too my dad he does the same.*
> (Pupil of 10–11 years): *(. . .) for example my grandfather he died, for sure my friend he will understand me.*

Pre-relativism: In this perspective, representations and meanings starts to become more sophisticated. Pupils describe their point of view to peers. These points of view underlie the beginnings of generalization, but remain grounded in familiar surroundings or contexts. Statements are centered on units and generally formulated with a general "we" or with a generalized "they." Below are examples of pre-relativism as manifested in creative thinking, as pupils add a different viewpoint to the group's perspective or present more than one side of a problem.

> (Pupil of 5–6 years): *I don't agree because babies they have brains like humans (. . .) because babies can think because they know they're in their mother's belly.*
> (Pupil of 7–8 years): *Sometimes there are people on boats who play at shoving each other and sometimes someone gives a big shove and the other person can fall into the water.*

Relativism: This is an epistemological perspective that presupposes a rupture in the groups' representations. Pupils seem to become aware that the world is not so simple (good/bad, right/wrong). They seem to be aware that others have different beliefs, points of view, etc., as they listen to others more actively. On the other hand, they want others to understand the meanings of their ideas, hence their statements are more elaborate than in the previous perspectives and they include a justification explicitly articulated (e.g., *because*. . .). Justifications are stated in the form of concrete and/or incomplete explanations with underlying simple relationships between points of view or contexts (vs. units that are independent from each other); justifications are still grounded in experience, but with the beginnings of generalization; they are generally formulated in "you," "we," or generalized "they" form. Below is an example of relativism as manifested in creative thinking, as pupils agree with their peer's viewpoint but add an element that complements the peers' viewpoint in order to further develop it.

> (Pupil of 9–10 years): *I agree with F. I find it's true you have to take your responsibilities. Often parents will want the child to have responsibilities to help out in the house because when you're a large family you have a bigger house so everyone has to help out and all that.*

Post-relativism/pre-intersubjectivity: This perspective illustrates the continuation of the process of decentering and abstraction that began in the previous perspectives. It implies that statements are generalized and show the beginnings of conceptualization; they include a justification that is explicitly articulated, presented in the form of a "good reason" (supposing an underlying inference rather than linked to a practical experience), related to peers' points of view. Statements imply the beginnings of a constructive evaluation. Below is an example of post-relativism/pre-intersubjectivity as manifested in creative thinking, as the pupil brings in a different perspective which he justifies with a good reason that was not previously developed in the group.

> (Pupil of 11–12 years): *Well I don't really agree with M (that adults are more intelligent than children) because it's not just adults who are intelligent (there are) also children who are intelligent and these children become adults.*

Intersubjectivity: In this perspective, representations and meanings are complex, as statements are conceptualized, are presented in the form of questioning or as a constructive evaluation of points of view, premises, etc., underlying a search for different meanings (vs. for a single truth) that include argumentation expressed in negotiation form. Statements include justifications that are explicitly articulated, are presented in the form of criteria (subjective or objective), are well developed although not comprehensively, and are linked to peers' points of view. Statements are centered on social or ethical concerns, and sometimes explicitly include self-correction. Below is an example of intersubjectivity as manifested in creative thinking, as pupils present evaluative relationships that contribute to increasing the sophistication of, or even to transforming, the group's perspective.

> (Pupils of 11–12 years): Pupil 1: - *If it's about intelligence, I think humans are at the top of the list. I think humans are the only ones that can do mathematics. Humans invented English and mathematics. Math is like another language we invented. We use it to understand things, to do the things we have to do well, to understand the reasons behind things. Like why the sky is blue and why can't we float or fly. So we invented mathematics to explain these things. But animals, they just think "sky" and they don't really think, they don't really think about the sky. Because they have, if for us eating and mating are an instinct, for them it's their principal instinct. (...)* Pupil 2: - *I do not quite agree with what Pupil 1 said. Well, it does depend, because we invented maths and you can't blame them (animals) for not doing it (...) And people just think they're dumb because they don't know our ways, but they probably think we're dumb, if they do think. So I kind of, I don't know. (...) And look at us, we have massive holocausts over land and we kill thousands of people but they'll just have one old fight and then it'll be over. I kind of think animals are smarter in their own way and we're smarter than them in our own way.*

Conclusions and Future Directions

Dialogical critical thinking is a process of evaluating an object of thought (whether concrete or abstract) in cooperation with a community of peers in an attempt to reach meaningful representations of that object that are more complex and valid than representations used at the beginning of the inquiry. Dialogical critical thinking is a developmental process that manifests itself through cognitive skills and attitudes that focus on conceptualization, transformation, categorization, and (self-)correction. DCT therefore presupposes the development of four thinking modes: logical, creative, responsible, and metacognitive. These thinking modes increase in complexity through the operation of six epistemological perspectives: egocentricity, post-egocentricity, pre-relativism, relativism, post-relativism/pre-intersubjectivity, and intersubjectivity. As this definition emerged within the P4C context, further contributions could be to explore its components with pupils who have no experience with P4C, that is, in other school disciplines or in the context of informal exchanges.

Digital Economy and Business Creation

Alain Philippe Batsale
University of Paris 12, Paris, France

Synonyms

Digitization; Information technology (IT)

Digital economy is the convergence of computing, communications, and contents. The two main components are computer industry and information treatment. It might be said that hardware is too physical to be discussed on a topic about digital, but the software cannot be considered without the hardware, and the hardware is of no use without its software. As far as business creation is concerned, the computer industry has led to the emergence of a huge industrial sector which continues to innovate. But, taking the example of France, if 1.2 million jobs have been created by the Internet, the estimated number of jobs destructed by this innovation is around 500,000 in this country. And regarding the information technology, the consequences may still be more equivocal: in matter of businesses, the process of creative destruction is engaged and is supposed to last long before a new equilibrium is reached.

A Case of Creative Destruction

The computer industry has gone through several revolutions (mainframes, minicomputers, personal computers, cloud computing) that led each time to new businesses. This industry is very emblematic of that process. Just include Microsoft, Apple, Google, and Facebook to illustrate the outstanding capabilities of the computer industry to generate start-ups that quickly become major global companies. New products, new devices, and new software, since the times of mainframes to the days of the Internet, have naturally involved the creation of new businesses.

Schumpeter (1942) separates several types of innovations that lead to business creation. The innovations set up by the computer industry consist mainly in the occurrence of new products. Mainframes, minicomputers, microcomputers, and smartphones have appeared over time, and the list is not supposed to be closed. In the computer industry, even software, which is also a kind of digital hardware, does not usually replace an existing product and frequently establishes a new kind of good. On the contrary, regarding the information treatment, it is rather a matter of new process of production or more precisely of reproduction. So the information treatment has driven a history more disturbed. The underlying process of digitizing leads to products of replacement more than real novelty. For instance, files of data instead of books, records, or films. So the information treatment has generated a new way of reading books or the press, a new kind of films and unknown types of musical records, and, in general, a new way of transmitting information. The materiality of these products has changed drastically: no more atoms, now, just bits. And this transformation involves definite economical consequences.

So besides the problems of creative destruction yielded by the emergence of new types of products in the computer industry, the proper nature of the information technology files of bits gives place to new economics: the digital economy. The economical pattern of a file of bits as a digital product is constant fixed costs and zero marginal costs (Varian 2004), so it is difficult to apply the neoclassical principle of a price equal to the marginal cost of production. This particular cost structure is the "baseline case" (Varian 2004) for information goods, particularly for digitized ones, while it is rather unusual for physical products with capacity constraint in the production process. So, in digital economy, good compliance with the laws of economics may lead to sale prices close to zero or to free. The confrontation between the new digital products and the old physical ones is therefore a very conflictual meeting, and the development of piracy is a big concern for firms implied in these markets.

New Businesses: Downsized Hardware and Digitalized Contents

The computer industry and the telecoms sector, on the hardware side, have known rather a traditional evolution; based on hardware downsizing on size and price, thanks to major innovations: transistor, integrated circuits, and microprocessor. A train of disruptive innovations (Christensen 1997) has generated a large number of new businesses. The first computer firms used to be large companies from the mechanographical (IBM) or the electric/electronic sectors. The personal computer revolution and the emergence of the Internet enabled lots of start-ups to emerge, some of them eventually becoming major companies. This was done mainly through new products downsizing traditional ones. On this hardware side of the industry, the traditional laws of industrial economics still apply generally, and the evolution of the sector has been rather similar to the one of other sectors.

The computer industry, on the software side, has known a slightly different trend which is also the logic of information technology. In the real sense, this is the digital economy which is based on the very nature of digitizing. While the hardware side leads to new products and new businesses by downsizing, there is a large freedom in the price level for digital products which sharpens the competition with traditional products, as it is the case for digital information goods. Since a digital product (generally a non-tangible public good) lacks of physical constraints in reproduction, its structure of costs (high fixed cost and low marginal cost) enables three specific pricing discrimination strategies: market for one, with highly personalized products; versioning, with different prices for different market segments; and selling at different prices to different groups of consumers. These strategies give to digital products a big competitive advantage over the (traditional) physical ones, strengthen the process of creative destruction, and threaten seriously the old firms.

In the beginning, the competitive advantage or the innovative product enables the creation of numerous firms. A lot of businesses are created, as we have seen, for instance, about digital music or social networks (information technology) or around new devices as smartphones or tablets (computer industry) by the emergence of small firms whose usual pattern is the start-up. This moment is followed by a standardization process which organizes the industry. In the meantime, firms of the previous periods are mostly weakened.

A Specific Process of Standardization

So another important feature of the digital economy, inherited from the computer industry, is the specificity of its standardization process. It is proper to the information technology sector and influences deeply the market structure, the number and the nature of the firms, and the way businesses are created all along the life cycle of products. This process was developed by IBM with the 360 machine, and it combines openness and modularity. This kind of routine, as the evolutionary economists might say, was verified for several products.

The digital economy is a network economy regulated by what is called increasing returns of adoption (Arthur 1989), which means the greater the number of costumers, the greater the utility of the product. The first period of the process of standardization is a time of trial and error during which many businesses are created around products following different protocols not compatible with one another. There is a second period when one of these products is able to reach the status of standard, be it for quality reasons, market power reasons, agreement between firms, or whatever. If a business wants to survive, it has to join the standard, when it is possible, or perish. A big amount of the young firms that have been created during the period of trial and error are supposed to disappear with the emergence of the standard. Then a third period begins, and the standard product may develop a kind of ecosystem and give birth to a new set of businesses connected with that standard. The standardization process was experienced for the IBM 360, the operating systems by Microsoft, the microprocessors by Intel, but also for the search engine by Google or (presumably) the social network by Facebook. Meanwhile, the firm that has set up the standard becomes usually a global major company.

We can detect several economical leverages behind the standardization process (Varian 2004), for instance, the switching costs that affect a customer who tries to change after having adopted a product. Moving from one operating system to another, from one social network to another, and from one Internet Access Provider (IAP) to another is not that easy and generates significant costs. The switching costs and the increasing returns of adoption may cause a virtuous circle in favor of a standard. There is also an economical concept which is called "lock-in" to describe strategies used by firms to prevent customers to escape. These forces help a successful product, a dominant design, to supplant the other ones and stay almost alone on a market. Moreover, the victory of a winner product is still strengthened by the network externalities yielded by the complementary products that other firms may find it profitable to produce in order to make use of the ecosystem created. The network externalities are also a way to set up new businesses.

In the Search of a New Model: The Protection of Contents

The total balance sheet between new firms and businesses destructed by the development of the digital economy is still difficult to set precisely, especially concerning the digitization of contents. Even if we can anticipate that the final figures will be positive, there is a deep concern about the classic media. The regulation may be made using the law, for instance, through property rights.

The cost structure of digital products was first an issue with the development of the software industry. Large firms in the computer industry were converted experts in the management and use of property rights to cope with the ease of copying software. This is even more accurate with the growing digitization of contents over the Internet. If Facebook creates a new kind of ecosystem, pieces of music downloaded eliminate the use of a CD-ROM. Until a viable economic model is found, new businesses will be set up for the lawyers as well.

Conclusion and Future Directions

The digital economy may create many businesses, but many companies are threatened by the digitization of the economy. This is the consequence of two processes. Firstly, inside the computing sector itself, on the hardware side, by the creation of new products, mainly by downsizing and secondly, as a threat against the firms of other sectors, on the software side and with the information treatment, by digitizing processes and contents.

Regarding the hardware aspect, the traditional laws in economics still apply. For instance, Apple succeed in managing several lines of products with an astonishing marketing, a very efficient brand policy, and reduced costs of production made possible by overseas units of production. The processes engaged for this achievement are described by traditional industrial economics.

On the software side, when the information is effectively digitized, this is the very domain of digital economy. There, the marginal cost is frequently close to zero, the selling price is difficult to determine, and the virtuality of the digit seems to have attacked the economical reality. Even the price of firms seems to be affected, a young company which has not made any profit may value billions of dollars; the rise of Apple's market capitalization seems to have no ending. But, with Hal Varian, we can consider that in the economics of information technology, the old principles still work remarkably well. Only, effects that were not quite usual in the industrial economy, network effects, switching costs, or differentiated prices are the common law in digital economy. So we need to focus on these peculiarities more than to change for a new economy.

What political and economical authorities must cope with is a traditional process of creative destruction, while this process is sharpened by the extraordinary power of digitizing. The organization of a new industrial paradigm has to be set up. In the past, this process has always established the grounds of a new era of prosperity. Why would it be different this time?

Moreover, we can see a kind of new innovation ecosystem around the Internet which can be compared with the mechanical one during the nineteenth century and what happened around the combustion engine in the beginning of the twentieth century and the integrated circuit in the 1960s. These are examples of combinatorial innovation which boosted the all economy and as it is now question of bits and not atoms, at the speed of light all around the world, the development of this new paradigm may be very much faster than the former ones.

Directed Evolution® Technology

Boris Zlotin and Alla Zusman
Ideation International Inc., Farmington Hills, MI, USA

Synonyms

Guided evolution; TRIZ forecasting

Definition

Directed Evolution® is a technology involving systematic processes for building a sustained competitive advantage through the effective management of the evolution of various artificial (man-made) systems by utilizing evolutionary patterns for technologies, markets, business, social systems, etc.

Directed Evolution is a result of integration and further development of *technological forecasting* and the *Theory of Inventive Problem Solving*.

Technological forecasting was introduced in the mid-1950s as a collection of non-related techniques based on probabilistic modeling of future characteristics of various systems. While proven being useful for short-term predictions, the method failed to deliver reliable long-term results, primarily due to the tools that were utilized to develop the forecasts.

The Theory of Inventive Problem Solving originated in the mid-1940s by Genrich Altshuller is based on the assumption that inventions in technological systems appear not randomly but rather in compliance with certain statistically recurrent *patterns of technological evolution* that could be revealed and utilized for organized and structured innovation. Typically, each pattern of evolution includes multiple *lines of evolution* – more detailed descriptions of how this pattern could be realized step-by-step.

By the mid-1970s, the discovery of patterns of evolution has enabled the introduction of *TRIZ forecasting*. Unlike traditional technological forecasting, it is based on utilization of predetermined patterns offering new directions together with proven ways how they could be realized. However, while providing valuable insight on the nature of the next generations of the given systems, TRIZ forecasting could not provide reliable answers when these new generations would come to existence.

The Directed Evolution (DE) technology was introduced in the early 1990s by Ideation International's research group as a proactive approach to the evolution of technology. Instead of making a prediction and waiting for it to be confirmed, the DE process uses numerous patterns and lines of evolution for the purpose of identifying possible scenarios, selecting the most promising ones, then building a road map and planning the process of implementation. In other words, DE is a method to predict future generation of a system by inventing it. To date, DE can be applied to various aspects of human life, including product and process development, evolution of technologies, markets, organizational development, and more. Later, significant progress has been made with the introduction of Directed Evolution® software, which incorporated powerful analytical tools and substantial knowledge base for predicting and solving various problems and more.

Typical results of a DE project include:

1. A comprehensive diagnostic analysis of the DE subject, including identifying problems hindering the evolution of the given system, revealing the system's evolutionary potential and evaluation of the applicable intellectual property
2. Solving selected problems, generating new ideas, and building futuristic concepts for the short-, mid- and long-term
3. Predicting possible mistakes and undesired events associated with further evolving the system and developing recommendations for their timely detection and prevention and possibly capitalization on them
4. Providing recommendations for the effective growth of intellectual property, structuring an IP portfolio, and increasing the company's creative potential

To date, over 100 of DE projects have been completed. The list of selected DE projects includes automotive, petrochemical, oil, medical instrumentation, electronic and other industries, consumer products, and business organizations.

Note. Directed Evolution is a registered trademark of Ideation International Inc. The name was suggested by Dr. Gafur Zainiev.

Divergent Thinking

Mark A. Runco
University of Georgia, Athens, GA, USA

Synonyms

Creative potential; Flexibility; Fluency; Ideation; Originality

Introduction

The theory of divergent thinking is among the most useful in all of creativity studies. Many people equate divergent thinking with creativity tests, which is not an accurate view since (a) divergent thinking is useful outside of assessment and testing and (b) divergent thinking is not synonymous with creativity. That being said, tests of divergent thinking are the most commonly used estimates of the potential for creative thinking. But divergent thinking tasks are also useful as exercises, even when there is no need or interest in measurement, and the theory of divergent thinking is useful when attempting to understand creative thought, even when there is no need for application, data, or assessment. It is a good theory. It stands up when the criteria for what makes a good theory (e.g., broad coverage, testable hypotheses, parsimony) are used to evaluate it. This entry starts with a summary of the theory of divergent thinking and then moves to how that theory led to measurement and assessment.

Theories of Divergent Thinking

The theory of divergent thinking was developed almost entirely by two people, J. P. Guilford (1968) and E. Paul Torrance (1995). Guilford was interested in creativity and in fact pushed the entire field of creativity studies into the scientific realm when presented his 1949 Presidential Address to the American Psychological Association. It was titled "Creativity" and contained a compelling argument for why creativity could and should be examined empirically. Guilford saw that creativity is "a natural resource," an idea that is being renewed today. Of more immediate influence was his Structure of Intellect model which attempted to delineate cognitive ability. It started with approximately 80 distinct skills and capacities but after years of empirical work grew such that it included 120 of them. Right before his death, Guilford proposed that there were in fact 180 identifiable and distinct skills and capacities.

There were questions about Guilford's statistical preferences, and these brought the orthogonality of the distinct skills into question. But the distinction Guilford offered between convergent and divergent thinking proved to be enormously useful. It fit well into theories of creativity and allowed the construction of reliable tests of creative potential. Guilford himself developed dozens of tests of divergent thinking, as did E. Paul Torrance. In fact, Torrance's (1995) battery of assessments, *The Torrance Tests of Creative Thinking*, remains the most commonly used measure in creativity studies.

Note, however, in the first paragraph the idea that tests of divergent thinking should be viewed only as estimates of potential. This point must be underscored since it allows us to avoid the mistake that tests of divergent thinking measure creativity. What they do is *estimate* creative *potential*. They are estimates because there is measurement error. Of course, that is true of any test or measure (thus characterizes all research in the behavioral sciences). As a matter of fact, the reliability and validity of divergent thinking tests, when they are administered and scored in accordance with the latest procedures, are as high or higher than many other behavioral tests. They are at least as reliable and valid as IQ tests, for example, and more reliable and valid than most tests of personality. Still, they are not perfectly accurate. There is no such thing as a perfectly accurate test. Tests are predictions. They sample behavior and then predict future behavior. Tests of divergent thinking do offer reasonable predictions of future creative performances – at least certain creative performances.

Some of the original tests did not offer very good predictions. Indeed, many people rejected divergent thinking tests in the 1970s because the predictive validity studies at that time were less than impressive. But the tests have improved. In fact, both the predictors (i.e., the tests of divergent thinking) and the criteria have improved. The older studies showing poor predictions used criteria that were available at that time, but these either focused on personality traits or on socially recognized creative accomplishment. They did not focus on what tests of divergent thinking actually assess, which is ideation. Tests of divergent thinking provide information about *ideational fluency* (the number of ideas a person gives when asked an open-ended question), *ideational originality* (the tendency to give unusual or novel ideas), and *ideational flexibility* (the variety of ideas given or the number of conceptual categories in the ideational output). Sometimes *elaboration* is used (the tendency to exploit one conceptual category) but not often. The only appropriate criteria when checking the predictive validity of tests of divergent thinking must also focus on idea. One measure was designed for exactly that (the *Runco Ideational Behavior Scale*, or RIBS) and studies using it are the ones that give reliability and validity in excess of what is found for IQ tests or personality inventories.

Additional Indices and Tests of Divergent Thinking

Tests of divergent thinking have been scored for *appropriateness* of ideas, as well as fluency and so on. This is notable because of the claim that tests of divergent thinking only estimate creative *potential*. They do not guarantee actual creative *performance*. Of course, if you want to measure actual creative performance, it is easy to administer an inventory of creative accomplishment. These are self-reports and as such are open to certain biases, but they do reliably index how many specific creative performances (e.g., "How many times have you had something published?" "How many patents have you been awarded?" "How many public recitals or concerts have you given") and accomplishments. The distinction between potential and actual performance is a critical one, especially for educators or anyone choosing a measure of creativity. It is discussed in detail in this same volume ("► Four Ps in Organizational Creativity").

The appropriateness index was developed for tests of divergent thinking because although they offer good information about originality, creativity is more than originality. Creativity requires some sort of appropriateness, effectiveness, or fit. It an idea is just original, it is not creative. In fact, highly original ideas that lack effectiveness may be crazy and not at all creative. Originality is necessary but not sufficient for creativity. Other newer indices and scores for divergent thinking tests focus on the metaphorical impact or degree of transformation, but none of these has been studied extensively. Most research uses only fluency since it is highly correlated with originality and flexibility, but this is a mistake. There is reliable variance to originality and flexibility scores, even when fluency scores have been statistically controlled, and even more importantly, originality is more critical for creativity than is productivity. If only one score was to be used, it should be originality and not fluency. The best technique is to look to a profile, with fluency, originality, and flexibility.

It is not just the scores from tests of divergent thinking that determine the reliability and validity. The tasks themselves are also important. In fact, some tests insure that creativity is especially well and realistically sampled. Consider in this regard tasks that assess *problem generation* as well as problem solving. All tests of divergent thinking are open-ended. Unlike tests of convergent thinking, which require that the individual find the one correct or conventional answer, divergent thinking tasks allow multiple answers and ideas. Most of them present a problem, such as "name all of the strong things you can think of" or "list as many uses as you can for a toothbrush." Others are realistic (e.g., "you forgot a hat and the sun just appeared from behind the clouds.... what can you do to avoid sunburn?"). Yet others go beyond problem solving and tap problem generation. This is tied to the problem-finding abilities that are so critical for actual creativity. Often there is more creativity to identifying and defining a problem than there is to solving it! For that reason, some tests of divergent thinking ask the individual to list as many problems as they can (e.g., "list problems faced by a typical student at your school."). Thus, the examiner gets an estimate of both problem-finding and problem-solving originality.

Problem generation tasks were used in one study that had especially impressive predictive validity. This investigation used realistic (presented) divergent thinking problems as well as realistic problem generation tasks in a study of the relationship of each with suicide ideation. The rationale relied on the large literature on psychopathology and creativity (e.g., the "mad genius controversy"); there is a long-standing interest in the relationship of creativity with clinical and subclinical tendencies. Suicide ideation is thought to precede actual suicide attempts. It is especially troubling when it is paired with depression. If that occurs, there is a high likelihood of an actual suicide attempt. The impressive part of this research was that a combination of the divergent thinking tests actually predicted suicide ideation better than depression! In fact, the association between depression and suicide ideation was determined and then statistically controlled, and still the divergent thinking tests were significantly related to (and predictive of) suicide ideation. Very importantly, it was a statistical interaction that was the accurate predictor of suicide ideation. In particular, suicide ideation was likely among individuals who had both (a) fluency with problem generation (they saw many problems) and (b) low flexibility (a kind of rigidity of thought) when solving problems.

A Technology of Ideation

One attraction of divergent thinking is that it applies to so much of our behavior. Think for a minute how often ideas are involved in our actions! Ideas are involved for all of our mindful behavior (we have an idea, think about it, and perhaps act on it), and depending on how an idea is defined (see this volume, the entry on "▶ Ideas and Ideation"), they may be involved in everything except reflex. One conclusion of the recent volume, *Divergent Thinking and Creative Ideation* (Runco 2012) was that the divergent thinking research has given us a "technology of ideation." The idea here (pun intended) was that ideation is an important and broadly applicable process and divergent thinking methods provide us with a reliable method for studying ideas. Note that this again implies a separation between ideation and creativity. Creativity sometimes depends on original ideation, but ideation is important outside of creativity.

The breadth of applicability is reinforced by a quick look at all of the populations who have been involved in the divergent thinking research. Virtually all age groups have been studied, for example. Preschool children who cannot yet write can still be assessed by giving them 3D objects and having them talk about what the object could be. They will talk freely and their discourse can be scored for all of the typical indicators, including originality. Older adults have been studied, and interestingly, they have an idiosyncrasy: They seem to suffer, with age, specifically in their flexibility. They rely more and more on routine and habit and their ideas become less and less varied and diverse. One last example of a population which has been studied was that of entrepreneurs. The divergent thinking tests designed for them asked for ideas concerning the strengths, weaknesses, opportunities, and threats to their businesses. This SWOT model is often used in studies of entrepreneurs and was adopted for the divergent thinking tasks in an attempt to insure that the participants in the research – highly successful entrepreneurs – would be engaged in the tasks.

That is an important point and reinforced the argument that tests of divergent thinking are merely estimates of potential. Just because someone does well at one point, on any test or sample of behavior, does not guarantee that they will do the same in the future. Insuring that individuals are engaged in the tasks does help in this regard because those individuals are much more likely to perform at their highest level when motivated. This is actually a benefit of all realistic tests of divergent thinking. There is a drawback, however, in that realistic tests seem to allow individuals to look back on their experience and find ideas by searching long-term memory. As a result, originality scores are often low in realistic tests.

Another way to engage individuals when assessing divergent thinking is to insure that they do not treat the tasks as typical tests. If divergent thinking tasks are presented such that they appear to be tests, examinees focus on convention and correctness. They are not nearly as original as they are if the tasks are called games instead. Originality is much more likely if the tasks have directions which de-emphasize spelling, grades, points, correct answers, or evaluations of any sort. Originality is likely if the tasks are called games and examinees are told to have fun. If divergent thinking tests are not administered in this game-like fashion, the same individuals who do well on traditional tests, like those in school, will be the only ones who do much. Other students may have creative talents, but their originality will not be clear unless they are assured that divergent thinking tasks are not convergent nor academic tests. If divergent thinking tasks are administered in a game-like fashion, students who do not receive high grades may very well stand out and excel in their ideation.

Conclusions and Future Directions

Additional research is needed to insure that tests of divergent thinking are used most effectively. Research in progress is testing new indices, to go along with originality, flexibility, and fluency, for example. Other work is manipulating the instructions given with these tests, the idea being that results are only valid if respondents and examinees are interested in generating ideas. Of most importance for future research may be techniques that will allow tests of divergent thinking to be used but used such that the information obtained is indicative of creative performances that occur in the natural environment. Too often, tests are only indicative of behavior that can be elicited in controlled settings. What is most important, however, is behavior as it occurs in the natural environment. Headway is being made (e.g., with realistic tests of divergent thinking) toward testing that will predict behavior in the natural environment with great accuracy.

There are other ways, besides divergent thinking tests, to estimate creative potential. Note, however, that tests of divergent thinking capture the most important part of creativity – originality – and do so in a reliable fashion. There is a sizable literature on divergent thinking, which means that plenty of data and results can be found to aid and support interpretations. They are theoretically justified, by the Structure of Intellect model as well as various associative theories. Tests of divergent thinking can be used with a broad range of populations. And they allow the individual to produce something – to create. The creation or product is an idea, but ideas are of enormous value, for world-changing inventions and everyday coping. Divergent thinking tests must be viewed as *estimates* of the *potential* for creative thinking, but they are good estimates, and there are few things that should be invested in as heavily as creative potential.

Key Concepts and Definition of Terms

The concept of divergent and convergent thinking was created by J.P. Guilford to term different types of psychological operations while problem solving. **Divergent thinking** is defined as producing a diverse assortment of appropriate responses to an open-ended question or task in which the product is not completely determined by the information. So, divergent thinking concentrates on generating a large number of alternative responses including original, unexpected, or unusual ideas. Thus, divergent thinking is associated with *creativity*.

Convergent thinking involves finding only the single correct answer, conventional to a well-defined problem. Many facts or ideas are examined while convergent thinking for their logical validity or in which a set of rules is followed. Convergent thinking focuses on reaching a problem solution through the recognition and expression of preestablished criteria. Standard *intelligence* tests are similarly believed to measure convergent thinking.

Divergent Versus Convergent Thinking, Table 1 Differences in characteristics associated with convergent and divergent thinking

Characteristics	Convergent	Divergent
Problem type	Well-defined	Poorly defined
Responses	Single	Multiple
Psychometric index	Intelligence	Creativity
Attention	Focused and local	Defocused and global
Mood	Negative	Positive
Predominating thinking strategy	Analytical and rational	Intuitive and irrational
Specific strategy of response selection	Deductive retrieval	Insight
Brain activation	High-level and localized	Low-level and widespread
Hemisphere dominance	Left	Right
Domain of specific giftedness	Science	Art
Adaptation to constant environment	Mental health	Mental diseases

Theoretical Background and Open-Ended Issues

The differences between convergent and divergent thinking in information processes, psychological operations, and brain activity are presented in Table 1 and in Figs. 1, 2.

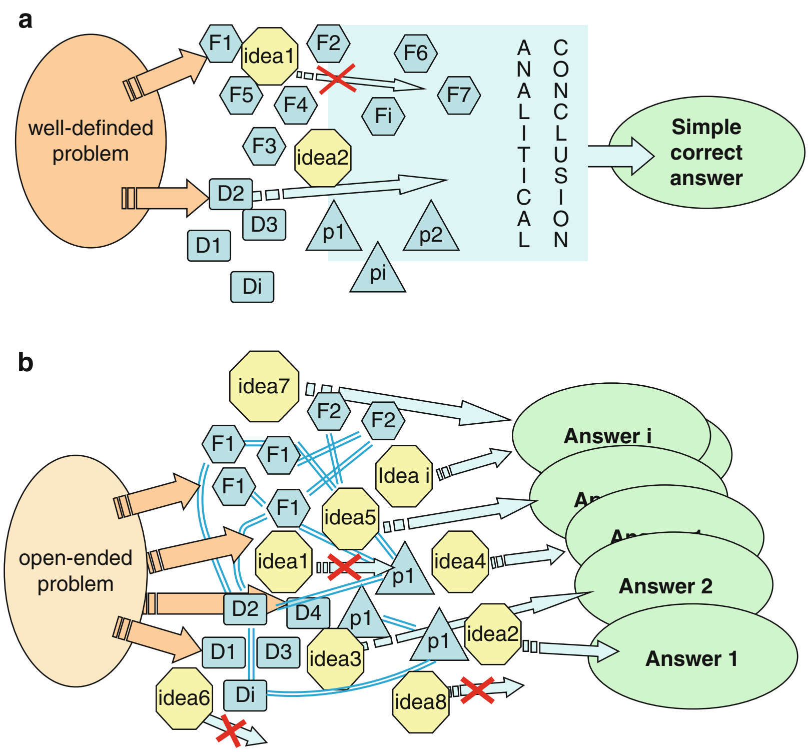
Three basic indices of divergent thinking have been offered of Guilford:

- *Fluency* (total number of the generated ideas)
- *Flexibility* (the number of categories in the ideas)
- *Originality* (the number of unique or unusual ideas)

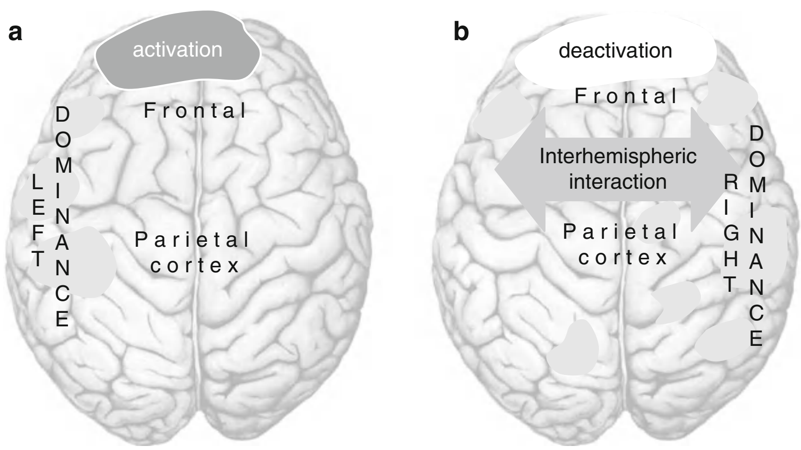
Effectiveness of divergent thinking suggests a combination of knowledge, good memory, and fluency in associations between sensory and semantic information, as well as richness of ideas, imagination, and fantasy.

The basic index of successful convergent thinking is high speed of the right answer finding. The same condition is due to measurement of mental abilities or well-known *intelligence quotient* (IQ). Intelligence, as measured on many commonly used tests, is often separated into verbal, figural, and numerical, which can be combined to produce a full-scale intelligence score. Also social, emotional, motor, and other components of intelligence are differentiated. Successful convergent thinking required a perceptual exactness in observation, great volume of general and domain-specific knowledge, good memory, analytic-abstract reasoning, and finally fast acceptance of the logical decision.

So, main contrary characteristics of convergent and divergent thinking are a quantity of task solution (simple vs. multiple, respectively), time of answer finding (short vs. long), and concept mapping of idea search (specific vs. widespread associations). However, convergent and divergent thinking have also some **similarity characteristic** in psychological processes while difficult problem solving as it presented in Table 2. These different types of thinking are important components of creative process including the formulation of a problem (dominance of convergent thinking), widespread search of variable ideas of a problem solution (function of divergent thinking), and choice of the final decision based on critical comparison of generated ideas (again convergent thinking phase). So, convergent thinking dominates while domain-relevant knowledge and data are identified and analyzed but divergent thinking – during



Divergent Versus Convergent Thinking, Fig. 1 Scheme of organization of convergent (**a**) versus divergent (**b**) thinking. F1. . .I, D1. . .I, and p1. . .i sign different semantic categories in multiple knowledge structures



Divergent Versus Convergent Thinking, Fig. 2 Model of hemispheric organization of convergent (**a**) versus divergent (**b**) thinking

information transformation and generation of both ideas collection and many possible criteria for reviewing these ideas.

Organization of Divergent Versus Convergent Thinking

Semantic transformations of information and ideas exploring as well as one important source of wit and humor are evidence of divergent thinking. Associational knowledge reflects regularities in experience based on probabilistic linkages among stimuli. Traditionally, *associational knowledge* has been held to give rise to new original thought through variable interconnections of remote concepts (see Fig. 1b). Extensive knowledge provides an information basis for flexible search of different

Divergent Versus Convergent Thinking, Table 2 Similarities in characteristics associated with convergent and divergent thinking

Sensory processes	Careful observation of their environments to gather information through the senses
Memory	Large working memory capacity
	Implicit and explicit memory resources
Knowledge	Effective application of requisite processing operations to relevant domain-specific and general knowledge
Task types	Verbal, figural, numerical, and social
Cognitive structures and abstraction	Using different concept maps and abstract models to understand the world
Emotional regulation	Negative emotions induce increased motivation to task performance, but positive emotion facilitates associative and semantic priming and supports the processing of global perceptual information
Brain activity	Interaction of specific and associative brain areas in line with individual strategies of problem solving
Adaptation to variable environment	Integration of intellectual and creative abilities to introduce change, innovation, or improvement over what exists

and similar features of objects and processes from various semantic categories that contributed to the generation of many new concepts and creative problem solutions. A *heuristic* or *insight* is a strategy that ignores part of the information, with the goal of making creative decisions after incubation period.

On the contrary, convergent thinking is defined as creating of completely determined product. *Linear logic*, schematic knowledge, and mapping operations are contributed to arrive at a firm conclusion based on relevant information. The theory of mental models is widely accepted as the explaining theory in relational reasoning (e.g., Goodwin and Johnson-Laird 2005). In line with this theory, humans construct internal representation of objects and relations in working memory, matching the state of affairs given in the premises. Convergent thinking narrows the available responses with the goal of selecting the single correct response (Fig. 1a) and can inhibit creative though as stops on one most probable idea.

However, as the stage model predicts, sometimes, convergent thinking may be necessary for final selection of original and acceptable problem solution. Two complementary subsystems are required to reach the desirable results: (1) an idea generation subsystem that embeds semantic knowledge and whose dynamics generates ideas as conceptual combinations and (2) a critic, which receives the generated ideas and produces evaluative feedback based on its domain knowledge about the given context.

Involvement of multiple knowledge structures, the capability to memorize which answers and categories have been produced, as well as the accessibility of memory traces in general should be helpful in acquiring both high creativity and intelligence test scores. The large variety of data resulting in an average correlation between divergent thinking and intelligence tests has been found using a meta-analysis of 21 studies and 45,880 participants (Kim 2005). This relationship was moderated by age, gender, specific abilities, personality, and other factors. However, patterns of relationships between these factors and the convergent and divergent thinking organization still should be studied.

So, paradoxical complementary combinations of contrary kind of thinking occur in different phases of novelty production: convergent thinking might dominate in the phases of preparation and verification, but divergent thinking in that of illumination.

Neuronal Mechanisms of Divergent and Convergent Thinking

Understanding of neuronal mechanisms of divergent and convergent thinking may not only improve a performance of different cognitive tasks but also provide new insights into regulation of innovation activity. Possible brain correlates underlying divergent and convergent thinking are found in neuroscientific studies. As example of convergent thinking, mathematics operations can be tested.

Neuropsychological as well as brain imaging studies converge on the view that *arithmetic processing* is subserved by frontoparietal areas and the basal ganglia (Dehaene et al. 1996). The left angular gyrus, perisylvian language areas, and the basal ganglia are assumed to mediate the retrieval of overlearned arithmetic facts, such as the multiplication tables, from long-term memory. The stronger activation within frontal areas in calculation tasks (Fig. 2a) has been interpreted as reflecting working memory demands, as well as error monitoring and strategic organization. There are evidences that numerical information is represented and processed by regions of the prefrontal and posterior parietal lobes, with the intraparietal sulcus as a key node for the representation of the semantic aspect of numerical quantity. The intraparietal region seems to be associated with an abstract, amodal representation of numbers in as much as it can be activated by numbers presented in various culturally learned symbolic notations. Exact arithmetic depends more on left lateralized, possibly language-related structures, while approximate arithmetic is tied to a quantity representation in bilateral intraparietal areas.

Deductive reasoning as variant of convergent thinking is the attempt to reach secure conclusion from prior beliefs, observations, or suppositions. Some reports have characterized deduction as predominantly left hemispheric, variously recruiting regions in inferior frontal, frontotemporal, and occipito-fronto-temporo-parietal cortices (Goel and Dolan 2004). Core deduction area is the left rostro-lateral prefrontal cortex, a region implicated in tasks involving goals/subgoals.

It can be concluded that the *specific network* involved in skilled arithmetic performance (i.e., convergent thinking) has been established. The inferior parietal sulcus and prefrontal cortex are assumed to mediate a common representation of quantity, and both arithmetic and sentence processing activated large sets of areas strongly lateralized to the *left hemisphere* (Fig. 2a).

On the contrary, divergent thinking and creativity are associated with widespread interconnections between *multiple brain regions* and relative dominance of the *right hemisphere* (Razumnikova 2005; Arden et al. 2010) (see Fig. 2a). A meta-analytic review of the literature to establish how creative thinking relates to hemispheric dominance revealed no difference in predominant right-hemispheric activation for verbal versus figural tasks, holistic versus analytical tasks, and context-dependent versus context-independent tasks (Mihov et al. 2010).

Right-hemisphere dominance in divergent thinking is caused to the facts that the right temporal and parietal cortices may provide a crucial nonlinguistic component needed for the intuitive generation of novel ideas using semantic knowledge in terms of features, concepts, and categories as well as verbal operations, such as the metaphor and humor creation or semantic operations that require a wide net of associations.

Semantic information in the brain is represented at several levels, ranging from combinations of sensorimotor features, through amodal concepts, to semantic categories. Considerable evidence now supports the idea that semantic processing involves several cortical functional networks including the left temporal lobe, the prefrontal cortex, the anterior cingulate cortex, the orbitofrontal cortex, and parts of the occipital cortex. Thus, if great volume of knowledge is necessary for difficult task performance, integration of functions of both hemispheres is required often for a finding of the best decision.

Many investigators have proposed that the ability to generate novel ideas or divergent thinking is associated with increased hemispheric cooperation. In line with this, hypothesis studies of patients with callosal resection have revealed a decrement in complex cognitive ability and EEG coherence studies suggest an association between effectivity of divergent thinking and interhemispheric coupling (Bogen 2000; Razumnikova 2005). Decreased callosal connectivity enhances hemispheric specialization, which benefits the incubation of ideas that are critical phase of creativity, and it is the momentary inhibition of this hemispheric independence that accounts for the illumination (Moore et al. 2009). Alternatively, decreased size of corpus callosum may reflect more specific localization of selective hemispheric processes, thereby facilitating efficient intrahemispheric functional connectivity. So, the corpus callosum is necessary for transferring earlier integrative aspects of divergent thinking from the right hemisphere to the left one, which would be essential for creative output, that is, verbal and motor answer.

The lateralized processing of the different forms and types of knowledge stored in the right and left hemispheres may be particularly important during different types of divergent thinking (verbal, figural, or social). The right hemisphere is dominated at exploring for new possibilities while the left hemisphere is more likely to result in the application of a previously learnt concept or pattern to a new problem.

An important aspect of cognitive fluency and flexibility is inhibitory control, the ability to dynamically modify or cancel planned actions in response to changes in the sensory environment, or task demands. The control and planed functions are performed in the prefrontal cortex which is deactivated during divergent thinking according to divergent task-induced alpha rhythm synchronization (Fig. 2b). This effect can be interpreted as congruent with idea that *defocused attention* and *inhibitory control decrease* is associated with effective search of original ideas.

Implication for Theory, Policy, and Practice

Successfulness in both divergent and convergent thinking can be considered within the more comprehensive concept of cognitive competence. This concerns the complex achievement forms of problem perception, information processing through learning transfer, and divergent/convergent thought processes in various situations and in different field of activity. There are findings that generally supported the view of convergent scientists and divergent artists. Scientific eminence requires high level not only intellectual but creative abilities and manifests itself in development of solution-relevant hypotheses regarding scientifically unsolved problems, the development of new theories and methods, and original problem solutions. Creativity is generally expressed, for example, in technical areas through original processes, new methods, useful inventions, and valuable products. Analysis of creativity and intelligence scores with regard to extracurricular activities shown that highly creative versus highly intelligent students dominated in art, literature, technology, and social skills whereas in science these scores were equivalent (Perleth and Sierwald 2001).

D

According to a neural plasticity model, it is expected that environmental interventions in the different form of training in divergent and convergent thinking would improve both creative and intellectual abilities. Schooling and specific intervention programs do affect relative intellectual or creative performance. A well-known tool to enhance divergent thinking in groups is brainstorming. There are many techniques for individual development of ability to generation of original ideas: challenge facts, analogies, random word and picture, and others.

It should also be noted that the magnitude of the thinking score increase would be a function of the underlying differences in neural plasticity. If there are large individual differences in neural plasticity, then even relatively large interventions would not be sufficient to overcome differences in this factor.

Conclusion and Future Directions

So, divergent thinking concentrates on producing a large number of appropriate and adequate alternative responses and often is associated with creativity which involves the generation of varied, original, or unusual ideas in response to an open-ended task. On the contrary, convergent thinking involves finding the single correct answer, and standard intelligence tests are similarly believed to measure convergent thinking.

A major question for further research is a studying individual variability in complex neuronal mechanism of divergent versus convergent thinking depending on sex, age, personality, intelligence, handedness, etc. It is necessary to unify neuroimaging methods and psychometrical testing of different components of thinking designed to provide greater spatial localization of function in brain. The future of primary creativity research would perhaps be focusing not only on the specialization of the hemispheres but on particular brain areas that are in constant interplay and communication. There is also open-end question on a role of interhemispheric or anterior and posterior cortex interaction in information selection during creative activity. Further research using techniques that can provide information about the nature of white matter connections, such as diffusion tensor imaging, will help to explain the mechanism by which effectivity of divergent thinking relates to size of corpus callosum.

Recently, more and more attention is given to the use of psychological knowledge in the politician and ordinary life. In this connection, studying of functional mechanisms of social creativity or implications of divergent and convergent thinking concepts on work, at home, or in complete adaptation to the world represents a great interest.

Diversity and Entrepreneurship

Laurice Alexandre-Leclair

Synonyms

Clusters; Cultural diversity; Environment; Ethnic entrepreneurship; Gender; Immigrants; Minority

Every society is composed of social and cultural groups. For researchers, diversity has become increasingly important. Diversity means variety. This variety can be evaluated along the dimensions of race, ethnicity, gender, sexual orientation, socio-economic status, age, physical abilities, religious beliefs, political beliefs, or other ideologies (Baycan-Levent et al. 2003). Disabilities are sometimes also included among these variables.

According to Hampden-Turner and Chih (2010), diversity includes visible characteristics such as nationality, ethnicity, gender, and age, and also invisible characteristics such as creativity, beliefs, and tastes. These authors state that there is an important connection between fixed diversity and voluntary diversity. In this discussion, the focus is on *fixed diversity*, such as ethnicity and culture, because these variables are directly linked to entrepreneurship. *Voluntary diversity* is more a strategy of human resources recruitment, adopted by firms in order to improve their image and their reputation amongst their stakeholders and demonstrate that they practice corporate social responsibility.

Diversity is considered by some authors as a factor of competitiveness. Amin and Graham (1997) (in Eraydin et al. 2010) state that cities have never been homogeneous entities; social, cultural, and ethnic forms of diversity have always been key items on the urban research agenda. As a result of processes of globalization, neoliberalization, and economic restructuring, most urban centers in advanced economies have faced significant increases in migration (Eraydin et al. 2010). From an economic perspective, debates about diversity have entered the competitiveness literature (Thrift and Olds 1996; Storper 1997; Florida 2005). Eraydin et al. 2010 cite Fainstein (2005), who argues that "the competitive advantage of cities and thus the most promising approach to attaining economic success, lies in enhancing diversity within the society, economic base, and built environment." Zachary (2000), Florida (2001), and Boodar and Rath (2005) also highlight the positive role of diversity in achieving a competitive economy.

Diversity is a core factor that leads to entrepreneurship. Hampden-Turner and Chih (2010) quote Saxenian (1999), who declares that "immigrants have created a very large proportion of the world's wealth. Moreover, Vecania (1999), quoted by Baykan-Levent (2003), raised the point that for individuals who are unable to adapt to a social system, such as those in ethnic and migrant minority groups, their marginal social position is a driving force to become self-employed. Self-employment in this case is not only a means to earn a living, but it is also a way of obtaining recognition and social acceptance.

Many studies have demonstrated that, despite their investments in human capital, minority workers (including immigrants) are systematically excluded from employment that offers high salaries, job security, and promotion opportunities (Yoon 1997) (in Bogan and Darity 2008). A number of other authors claim the positive relationship between diversity and entrepreneurship. Thuse, the aim of this discussion is to explore diversity and entrepreneurship. As mentioned before, diversity encompasses a wide variety of characteristics. This discussion focuses on ethnicity and culture because these characteristics directly affect entrepreneurship. Culture and entrepreneurship will be discussed first, followed by ethnic entrepreneurship.

Culture and Entrepreneurship

Sowell (1981) has claimed that different economic outcomes across different ethnic groups are due to culture rather than market or institutional discrimination. For instance, the relative success of black West Indians, compared with other black Americans, is attributed to their distinctive cultural values.

In their work, Sobel et al. (2010) present the definition of Lavoie (1991) of culture and entrepreneurship: "It pointed that entrepreneurship necessarily takes place within culture, it is utterly shaped by culture, and it fundamental consists in interpreting and influencing culture. Consequently, the social scientist can understand it only if he is willing to immerse himself in the cultural context in which the entrepreneurial process occurs."

Hofstede (1980, 1993) declares that national cultural values influence the conduct of business in particular countries. Sobel et al. (2010) tried to measure the relation between cultural diversity and entrepreneurial activity using five different measures of entrepreneurship (average business start-up rate, net business creation rate, venture capital per capita, patents per capita, and measure of productive entrepreneurship) in a cross-state analysis. They found that the states with the most diversity in their cultural makeup have higher rates of entrepreneurial activity.

Moreover, Sobel et al. (2010) discuss cultural capital. They state that different geographic areas across the globe are characterized by their own unique cultures. When people migrate from one country to another, they bring some of their unique cultural capital with them. Because entrepreneurship is about coming up with new and unique combinations of resources, this interchange of ideas may lead to more innovations, new products, and generally a higher rate of entrepreneurial initiatives.

Along the same lines, according to the cultural hypothesis, the inclination of some immigrant and ethnic groups toward entrepreneurship can be explained by their ethno-national attributes (Yoon 1997) (in Bogan and Darity 2008), however, Bogan and Darity (2008) argue that one must take into consideration other factors contributing to the entrepreneurial role of minorities, such as class resources, urban racial segregation patterns, and immigrant disadvantages. The experience of Chinese and Japanese immigrants in the American labor market prior to World War II is a good example of return migration. The immigrants initially were welcomed when they came to fill the labor shortages on sugar plantations, in the mines, and in railroad construction camps on the West Coast. But when labor competition developed during economic depressions, they became the targets of anti-Asian campaigns and institutional discrimination (Yoon 1997) (in Bogan and Darity 2008).

In order to validate these characteristics, Bogan and Darity (2008) took the example of Korean immigrants. For example, Korean immigrants' class resources for their business activities not only include financial capital but also human capital. Korean immigrants with middle class backgrounds possess the knowledge and motives that are required for successful entrepreneurship. College-educated Korean immigrants have advantages in terms of management skills and attitudes over native-born, non-Korean small business owners, who usually have less education (Min 1988b) (quoted by Bogan and Darity 2008).

Korean entrepreneurs have benefitted from discrimination against blacks. The reluctance of corporations to invest in inner-city, minority areas and the retirement of white business owners from these areas created a small business void that was happily filled by Korean immigrants (Min 1988b; Light and Rosenstein 1995) (in Bogan and Darity 2008); a void that black entrepreneurs were unable to fill due to lack of resources, capital, and so on.

Bogan and Darity (2008) note that, for Korean immigrants, their situation as disadvantaged immigrants may be a more significant influence on their business behavior patterns than the cultural influence of their Korean background.

Other factors should be taken into consideration in order to better understand the role of culture in entrepreneurship. For instance, Ibrahim and Galt (2011) highlight the importance of human capital determinants such as schooling, education, and other features that determine productivity (Chiswick 1983). Knocke (2000) (in Ibrahim and Galt 2011) challenged the argument that intrinsic cultural factors are obstacles to labor market integration by showing that integration, segregation, or discrimination against ethnic minorities results from economic needs and structural labor market characteristics.

Ethnic Entrepreneurship

Ethnic entrepreneurialism can only be understood as a multi-dimensional organism existing in an external context that needs to be properly specified.

According to Baycan-Levent et al. (2003), ethnic minorities are gradually becoming a majority in some European cities. The influx of foreign migrants has brought about economic advantages, but it has also caused a multiplicity of social and economic tensions. With a few exceptions, ethnic groups belong, in general, to the lower socio-economic segment of European cities, mainly as a result of their lack of education and skills, which led them toward self-employment. On the other hand, some authors (Bates 1997; Borjas 1999) (in Pecoud 2010) maintain that immigrant entrepreneurship is related to class resources, because entrepreneurship requires financial and human capital and, consequently, self-employment would not modify immigrants' socio-economic conditions.

Ram et al. (2010) note two problems in comparative research about ethnicity and entrepreneurship. The first is the tendency to focus on a single ethnic group in isolation from the wider small business population, which can accentuate perceived differences (this idea is also proposed by Jones et al. 1992; and Mulholland 1997). They also cite Zimmer and Aldrich (1987, p. 422), who declares that "the comparative study of immigrants and native groups shifts the focus from group differences to group similarities. Studies examining only immigrants may find apparently distinctive characteristics, but in fact many traits are common to all small business owners."

The second problem argued by Ram et al. (2000) is the ignorance of influence of sector on business activity in the frame of ethnic entrepreneurship. When cross-section comparisons are taken into account, inter-communal differences are often less acute than imagined. They give the example of Jones et al. (1994), who confirm that South Asian owners work significantly longer than others; this was found to be largely due to the overwhelming concentration of South Asian firms in labor-intensive sectors like food retailing and confectionery, tobacco, and newsagents.

Consequently, Ram et al. (2000) conducted research on ethnic minority business in the catering sector in the UK, because this sector is one of the niches traditionally occupied by ethnic minorities when they are offering their own unique national foods. According to their findings, the family plays a role in the formation and management of the enterprise across *all* ethnic groups, although it can take different forms. Even though the South Asian business owners, the same as white and African-Caribbean owners, declared that they would not want their children to enter the family business, the researchers noticed that South Asian children found their employment in the family business. This is an example of the importance of family among South Asian groups, but it emerged from economic necessity rather than notions of solidarity (Metcalf et al. 1996).

Pecoud (2010) provides a definition from Zhou (2004, p. 1040): "Ethnic entrepreneurs are often referred to as simultaneously owners and managers of their own businesses whose group membership is tied to a common cultural heritage or origin and is known to out-group members as having such traits; more importantly, they are intrinsically intertwined in particular social structures in which individual behavior, social relations, and economic transactions are constrained."

Ethnicity-based explanations of entrepreneurship coexist with two arguments (Pecoud 2010). The first, mostly developed by British scholars, sees self-employment as the product of the context in which migrants live and work: blocked opportunities, unemployment, and discrimination leave no choice to migrants but business (Barrett et al. 1996) (in Pecoud 2010). Migrants also invest in sectors whose unattractive conditions (long working hours, low return on investments, etc.) put off their previous owners.

Baycan-Levent et al. (2003) present different factors leading ethnic people to self-employment and entrepreneurship: motivations and orientation, labor and capital conditions, customer relationships, and gender and generational differences. We add to this list racial background and contingency factors, which play a role in differentiating and encouraging or discouraging entrepreneurship.

Motivation and Orientation

In addition to the classical motives that push minorities towards entrepreneurship, the existence of ethnic and social networks also plays a major role in motivating immigrants towards entrepreneurship (Delft et al. 2000; Johnson 2000; Kloosterman et al. 1998; Masurel et al. 2002; Ram 1994a, 1994b; Wilson and Portes 1980) (in Baycan-Levent et al. 2003).

Normally, ethnic companies start with a focus on clients from their own ethnic group, with traditional products, services, and communication channels. This internal orientation and the mutual trust within the ethnic network provides a protected market and a ready labor force (Baycan-Levent et al. 2003) and creates a loyalty between the ethnic firm and its clients (Dyer and Ross 2000).

Labor and Capital Conditions

Through their networks of relatives, co-nationals, or co-ethnics, new firms have a privileged and flexible access to information, capital, and labor (Basu 1998; Kloosterman et al. 1998) (in Baycan-Levent et al. 2003)

Customer Relationship

According to Baycan-Levent et al. (2003), several studies refer to an intra-cluster ethnic loyalty, while highly intensive communication behavior within the ethnic community offers potential competitive advantages for ethnic firms (Donthu and Cherian 1994; Dyer and Ross 2000).

Gender and Generational Differences

Baycan-Levent et al. (2003) emphasize that age and generation can affect the kind of entrepreneurship. The first generations involve more pull factors, whereas the second generation may exhibit more pull factors. First-generation ethnic entrepreneurs are more motivated by discrimination, problems with the transferability of their diplomas, and obtaining status, compared with their second-generation counterparts. In other words, while first-generation immigrants may be more frequently "forced entrepreneurs," second-generation immigrants may act more frequently as "voluntary entrepreneurs" (Baycan-Levent et al. 2003), which supposes that the second generation is free to invest in new markets outside the internal market.

Baycan-Levent et al. (2003) note that this difference also exists for gender difference. Female ethnic entrepreneurs involve more pull factors, their motivation stemming from their education level and work experience and skills, business goals, and management styles and personal value system. Most female ethnic entrepreneurship belongs to services sector; the businesses are small and the owners are relatively young. The social network plays a role also in entrepreneurship. In their study of South Asian people, Ram et al. (2000) noticed that women's work was often not acknowledged, despite its importance to the business.

Racial Background and Entrepreneurship

Researchers examining the success or failure of ethnic entrepreneurs who share the same racial and national backgrounds found that they perform differently in different countries (Ibrahim and Galt 2011). Indeed, some authors make the difference between immigrant entrepreneurship and Black American entrepreneurship. According to Butler (2005) (in Bogan and Darity 2008) and others, the primary difference between black and immigrant entrepreneurs was that black business owners were forced to develop separate enterprises and sell in a restricted marketplace while immigrants were allowed to operate in the economic mainstream. Bogan and Darity (2008) quote the survey of Bearse (1984), who found that foreign-born blacks are more likely to be engaged in entrepreneurship than U.S.-born blacks. The same study's fundamental finding is that the likelihood of black being entrepreneurs is significantly lower than for other groups. Nevertheless, Boyed (1991b) reinforced the view that black immigrants and native blacks share race-related disadvantages.

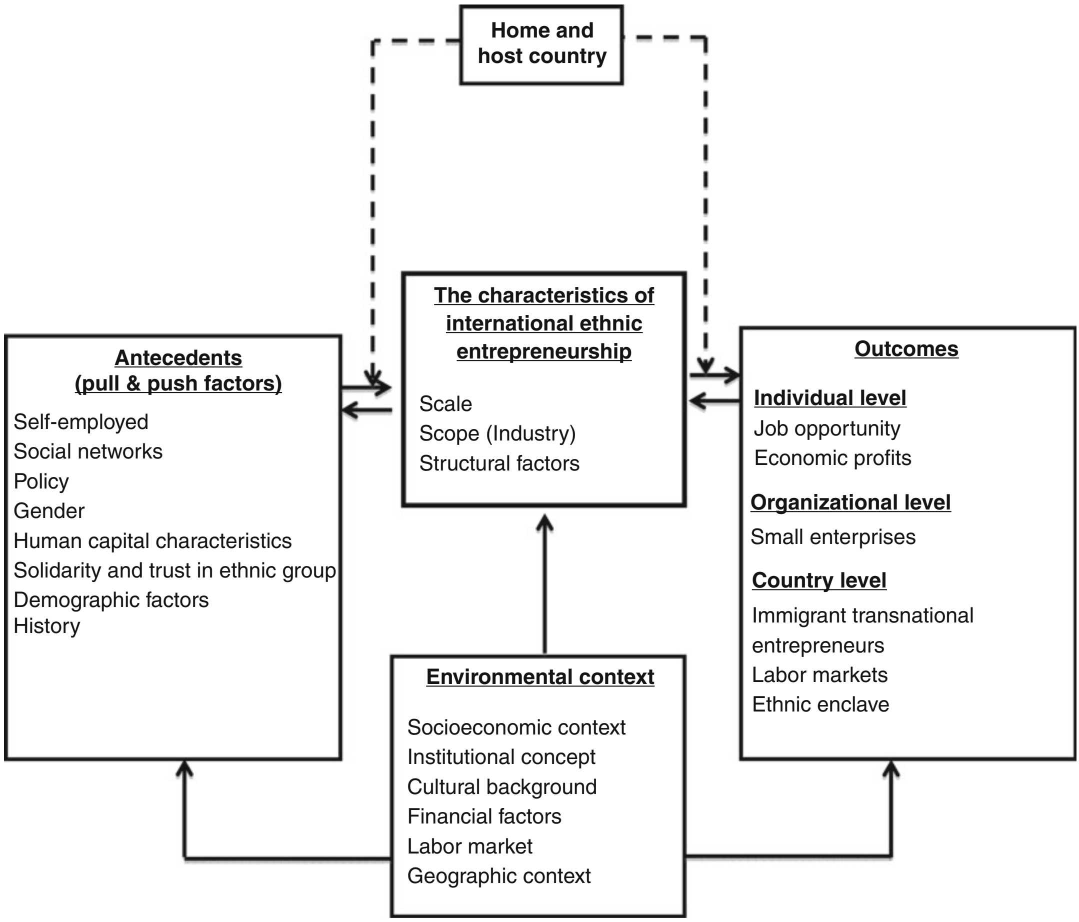
Eraydin et al. 2010 highlight the role of diversity in stimulating innovation. They quote Fainstein (2005), who declares that "forms of social, cultural, ethnic and spatial diversity attract multiple forms of human capital, and undoubtedly encourage cultural and artistic creativity, and technological and scientific innovation."

Contingency Factors

Ibrahim and Galt (2011) quote Evans and Jovannic (1989), who note that there is a link between the financial situation and entrepreneurship for some groups where initial endowments are restricted or where access to funds is difficult and there is likely to be a lower level of entrepreneurial activity and vice versa.

On the other hand, Ibrahim and Galt (2011) highlight the role of institutional arrangements proposed by the institutional economists (North 1990; Williamson 1975, 1985) in reducing transactions costs. These costs may be classified under three headings: search and information costs, bargaining and decision costs, and policing and enforcement costs (Dahlman 1979).

Concerning the relationship between the culture and entrepreneurship, it has been argued that some ethnic groups are endowed with social institutions and cultural norms that foster entrepreneurial talent



Diversity and Entrepreneurship, Fig. 1 Characteristics of international ethnic entrepreneurship (Ilhan et al. 2011)

(Davidsson 1995; Wilson and Portes 1980) (in Ibrahim and Galt 2011). Tight social networks provide flexible and efficient possibilities for the recruitment of personnel, acquisition of capital, and exchange of information based on mutual trust among the members of the network (Werbner 1990).

Furthermore, Eraydin et al. (2005) distinguish between types of social capital. The first, called *bonding capital*, is created via the strong social ties that exist between individuals, family members, close friends, and members of certain ethnic groups. The second is *bridging capital*, which exists between heterogeneous individuals such as friends of friends. A third type is *linking capital*, characterized by connections between individuals, established professional and administrative structures, and local communities (Foord and Ginsburg 2004).

According to Davidson and Honig (2003) (in Ibrahim and Galt 2011), factors in the exogenous environment in which business is conducted, such as the fiscal environment, labor market regulations, administrative complexities, intellectual property rights, and bankruptcy law, will also determine the specific response of ethnic entrepreneurial to establishing a business. Another factor that influences ethnic entrepreneurial decisions in a host country is the propensity for entrepreneurship in the country from which they or their families emanate. The historic differences between countries in the rate of entrepreneurship will influence the likelihood of individuals becoming entrepreneurs (Sternberg and Wennekers 2005; Wennekers, Uhlaner, and Thurik 2002) (in Ibrahim and Galt 2011).

Conclusion and Future Directions

Diversity is discussed in different literature: economy, management, sociology, anthropology, and so forth. Most authors focus their research on the relationship between culture and/or ethnicity and entrepreneurship, even though diversity involves other factors such as gender, age, and disability. This discussion highlights the fact that the culture of immigrants as much their ethnicity can affect, positively or negatively, self-employment. Many factors lead ethnic people to entrepreneurship: the existence of ethnic and social networks, labor and capital conditions, gender and age, racial background, and contingency factors such as institutional environment, geographic context, and so on. The model of Ilhan et al. (2011) (Fig. 1) summarizes the characteristics of entrepreneurship, taking into account all contingency factors. In this figure, the authors suggest that the environmental context, such as socioeconomic context, institutional concept, cultural background, financial factors, labor market, and geographic context, influence the outcomes on an individual level, organizational level, and country level. The environmental context elements are directly linked to the pull and push factors, such as social network, gender, and demographic factors. On the other hand, pull and push factors may influence the characteristics of international ethnic entrepreneurship, while the scale, the scope of the industry, and the structural factors may influence the outcomes and the pull and push factors.

Gender studies deserve further study because, in certain cultures or ethnic groups, women turn to entrepreneurship in order to be independent and/or to make a living for their family. Furthermore, exploring diversity from the perspective of economic competitiveness could be an interesting complement to studies of immigration and entrepreneurship.

Intuition and Creative Problem Solving

The ability to solve problems creatively is an essential element of success for individuals and organizations (Scott et al. 2004). As such, a thorough understanding of this process would be immensely beneficial, and is of paramount importance for enhancing performance on creative tasks. However, creative problem solving is a complex phenomenon that is influenced by numerous contextual factors and individual differences. Thus, deciphering the key influences on this process remains a core concern of creativity researchers, who have identified many factors that exert such an impact. Among these myriad elements, intuition appears to be especially important (Bowers 1987).

Scholars have defined intuition in numerous ways. However, there are several common elements across these definitions. In examination of these similarities, Eubanks, Murphy, and Mumford (2010) define intuition as a process that involves the development of an unconscious pattern that guides performance, problem solving, and decision making on complex tasks. In accord with this definition, there are three key characteristics of intuition:

1. Intuition involves the use of minimal information to identify patterns.
2. Intuition may occur through unconscious processes.
3. Intuition can influence performance on complex tasks.

In sum, intuition involves the unconscious manipulation of information as part of the problem-solving process. In order to understand how this may impact creative performance in particular, it is vital to examine the theoretical background of this and related constructs, as well as empirical research on this topic.

Overview and Theoretical Background

Baylor (2001) notes that definitions of intuition involving subconscious pattern formation and recognition must at some level involve implicit or tacit knowledge. Such knowledge is typically acquired unconsciously as a result of experience, and can be beneficial in complex problem-solving tasks, in part by giving rise to intuition (Reber 1989). Such an approach to problem solving is essential in the realm of creative performance, where problems are often ill defined, and connections between various elements may be ambiguous (Mumford and Gustafson 1988).

A related principle that is similarly valuable for creative problem solving is expertise. Indeed, intuition may in part be developed as a function of expertise (Baylor 2001). Similar to the way that intuition allows subconscious patterns to influence performance, expert performance is largely driven by unconscious recognition of patterns rather than conscious decision making (Shanteau 1992). Indeed, expert performance often relies on making quick judgments without time for reflection (Simon 1990; Shanteau 1992). Such performance develops over a long period of continued practice, through which an individual becomes increasingly familiar with his or her focal domain (Ericsson and Charness 1994). Cognitive theory on working memory suggests that as individuals gain expertise in a domain, they develop schema that enhance their ability to hold multiple elements of a problem in working memory (Baddeley 2007). Since the ability to make connections and determine patterns among information is reliant on what a person can maintain in working memory (Baddeley 2007), expertise may serve to facilitate intuition by directly enhancing this resource.

Furthermore, as an individual develops expertise, he or she forms a mental model of the domain, which serves to drive future decision making (Hill and Levenhagen 1995). In line with research on intuition, expert performance often relies on proceduralization, through which unconscious connections among prior experiences and ideas drive work-related behavior (Shanteau 1992). Thus, expertise often leads to increased subconscious processing of information and, therefore, more decisions that are driven by intuitive judgments.

Examining the influence of expertise can provide some possible explanations for the development of intuition. However, it must be remembered that while expertise and intuition are related constructs, they are not synonymous; intuition is capable of influencing performance beyond the effect exerted by expertise alone (Eubanks et al. 2010). Therefore, in order to more fully understand how intuition can impact creativity, it is necessary to examine some specific mechanisms by which intuitive judgments may occur.

In a synthesis of the extant literature, Eubanks and colleagues (2010) identify three competing interpretations of mechanisms by which intuition may impact creative problem solving. First, intuition may influence problem solving by triggering unconscious associations between contextual cues and salient affective experiences (Simonton 1980). According to this view, intuition results when aspects of the problem at hand trigger networks of associations related to affectively laden prior experiences. This is thought to induce the emergence of unconscious patterns, which in turn inform decisions.

In contrast, Johnson-Laird (1983) suggests that mental models form the basis for intuitive judgments. Such an approach posits that when an established mental model is activated and applied to a situation, it can lead to the individual making decisions about elements of the present situation that are consistent with the established mental model. This effect mirrors cognitive literature on satisficing, in which the activation of established heuristics can lead individuals to make snap decisions, based on the manner in which previously synthesized patterns of information can be applied to a current problem (Simon 1990).

Finally, Gresov (1989) suggests a fit appraisal-based approach to intuition. According to this perspective, when an individual's established mental model fits the current situation well, he or she subconsciously identifies similarities between the model and elements of the situation. These similarities then give rise to the patterns of associations involved in intuitive problem solving. It is worth noting that these theoretical approaches have not been thoroughly evaluated with regard to their influence on intuition and problem solving. However, these approaches may serve as jumping-off points for interventions to enhance intuition and improve problem solving, such as training programs. Such programs are discussed in more detail in a subsequent section. Before discussing such interventions to enhance intuitive problem solving, it is necessary to understand how intuition can be assessed at the individual level.

Measurement of Intuition

Research on intuition has demonstrated that it exists in part as a function of individual differences. That is, the ability and desire to act on intuition as a mechanism for problem solving varies among individuals. Although training and expertise within a domain may influence how intuitive a given individual may be (e.g., Baylor 2001), people do in fact have a baseline level of intuition that impacts performance. For instance, research by Bowers and colleagues (e.g., Bowers 1987) found that individuals were able to develop solutions to problems for which insufficient information was available. Specifically, participants were able to identify connections among elements within the problem and develop valid predictions about the solution before being presented with sufficient information to identify the correct solution. Furthermore, individuals differed not only in their ability to make intuitive judgments, but also in their willingness to propose solutions that were based on such intuitions. Additionally, Eubanks and colleagues (2010) note that such judgments can be useful tools in the process of creative problem solving.

In light of such individual differences, the measurement of intuition at the individual level becomes an important issue. Westcott (e.g., Westcott 1961; Westcott 1966) developed such an instrument to assess individual intuition. This instrument involved presenting individuals with 20 analogical problems to solve and allowing them the opportunity to request additional clues if they felt it necessary. Participants were found to differ both in the number of problems they solved correctly and also in the number of clues requested and their confidence in their proposed solutions. Westcott and colleagues identified intuitive individuals as those who correctly solved the greatest number of problems with the fewest clues.

This measure has demonstrated reasonable test-retest reliability, as well as construct validity (in terms of relationship with cognitive ability measures). However, this instrument is not without criticism, particularly with regard to its domain relevance. That is, critics suggest that the use of analogical problems has limited real-world applicability, and that there is a lack of evidence that this test is predictive of creative problem-solving performance (for further discussion, see Eubanks et al. 2010). More recently, Eubanks and colleagues (2010) devised a problem-solving task that assessed intuition in a creative domain. In their study, individual intuition was found to be a positive predictor of creative performance, particularly in terms of the quality and elegance of participants' solutions. It was suggested that solution elegance in particular may benefit from intuitive problem solving; elegance is an assessment of how well the components of a solution fit together and flow (Besemer and O'Quin 1999), and thus, highly intuitive people are more likely to produce such solutions due to their predisposition to unconsciously attend to patterns and themes.

Influences on Intuitive Performance

Numerous factors may influence the impact of intuition on creative problem-solving performance. In particular, individuals' level of positive affect is thought to be a key predictor of problem-solving success, and a major potential influence on intuitive performance. Research has demonstrated that positive affect predicts creative performance in particular, and that such effects are due to changes in thought processes, and not simply an increase in individuals' motivation (e.g., Isen 1993; Estrada et al. 1994). For example, a study of doctors found that inducing positive affect led to earlier correct judgments about patients' diseases (Estrada et al. 1994). Furthermore, relative to doctors who did not receive this affect manipulation, those who did integrated a larger number of sources and were less prone to making errors in their diagnoses.

Particularly relevant to the present discussion, research suggests that positive affect can influence problem-solving performance by inducing intuitive behavior (Eubanks et al. 2010). When positive affect is high, people are better able to generate patterns in information, incorporate a greater variety of information into such patterns, and identify similarities and differences within such patterns (Isen and Daubman 1984; Kahn and Isen 1993). Recent research has supported the role of positive affect as a moderator of the intuition-creative performance relationship. Specifically, Eubanks and colleagues (2010) found that inducing positive affect was associated with higher quality solutions for individuals low on intuition. However, inducing positive affect was also associated with a decrease in the quality of solutions proposed by highly intuitive individuals. It is possible that such a decrease is a result of decreased critical assessment due to participants' increased positive affect (Eubanks et al. 2010). A similar trend was observed for the originality of solutions proposed by these individuals. These findings suggest that while positive affect may enhance creative performance when individuals are not inherently intuitive, affect manipulations also have the potential to impair creative performance in certain circumstances. As such, it is important to consider additional factors that may influence the relationship of intuition with creative performance. In particular, training individuals to successfully cultivate and harness intuitive judgments may be especially beneficial.

Although intuition exists in part as a relatively stable individual characteristic, research on the relationship between expertise and intuition suggests that training may serve to enhance intuitive performance (Ericsson and Charness 1994; Baylor 2001). Cognitive theory suggests that the development of expertise (such as through a training regimen) results in the proceduralization of declarative knowledge (e.g., Berry and Broadbent 1984). Such a process is associated with the development of tacit knowledge, which was previously stated to be associated with the development and activation of intuition (Reber 1989).

It is thought that individuals trained to both recognize and apply intuitive judgments to the problem-solving process will perform better on creative problem-solving tasks. In particular, training may influence the relationship between intuitive understanding of a problem and subsequent creative performance. For instance, providing training on relaxation strategies is thought to enhance the effects of intuition of creative performance (e.g. Markley 1988).

Although it can be argued that training can influence the relationship between intuition and creative performance, it is noteworthy that approaches to intuition-based training programs may vary, depending on the perspective on intuition that one takes. That is, each of the three perspectives on intuition discussed previously likely would point to very different training programs. For instance, the associational approach to intuition (Simonton 1980) would recommend training programs that emphasize strategies to build and strengthen the associational networks that are thought to provide the underpinnings of intuition. Such an approach would likely promote exploration of one's environment and salient experiences, in order to develop more material to drive future intuitive judgments. In contrast, a mental model–based approach (Johnson-Laird 1983) would likely focus on exercises to enhance the recognition and activation of patterns of information. Such a recommendation is consistent with literature in the field of expert performance (e.g., Shiffrin and Schneider 1977), which suggests that highly trained experts rely heavily on automatized processes and previously synthesized information to make judgments. Finally, the fit appraisal approach to intuition (Gresov 1989) would likely involve providing trainees with opportunities to practice appraising situations in order to identify elements that are congruent with or dissimilar to established mental models. Further review and commentary on the characteristics of successful creative performance training programs may be found in Scott, Leritz, and Mumford (2004).

In order to further examine the effects of training on intuition and creative problem solving, Eubanks and colleagues (2010) developed a self-paced training program that provided training based on one of the three approaches to intuitive problem solving described previously. A fourth experimental condition received no such training and served as a control group. Findings in this study demonstrate the interconnectedness of intuition, training, and positive affect. For three dimensions of creative performance (quality, originality, and elegance; see Besemer and O'Quin 1999), training resulted in greater performance for individuals with neutral affect, relative to untrained individuals. However, individuals who experienced induced positive affect and did not receive training outperformed individuals who received both a training program and the affect induction. It is suggested that training programs may require individuals to switch from their typical preferred problem-solving strategies, whereas positive affect can enhance the efficacy of existing strategies, resulting in greater performance increases (Eubanks et al. 2010).

It is further noteworthy that, although all three training approaches demonstrated increased creative performance for individuals with neutral affect, an approach centered on strengthening individuals' mental models of the design space demonstrated reduced gains in terms of solution originality, relative to other training programs. It may be the case that reliance on existing connections among constructs and ideas (in the form of established mental models) may result in the development of solutions that are less novel than those developed from approaches emphasizing the development and evaluation of new patterns and associations.

Conclusion and Future Directions

Current findings demonstrate that intuition can be measured as an individual difference (e.g., Westcott 1966), and that individual variability in intuition can predict creative performance (Eubanks et al. 2010). Furthermore, also at the individual level, positive affect has been found to impact the effects of intuition on creative problem solving, particularly with regard to the quality of solutions devised (Eubanks et al. 2010).

Such empirical studies are a relatively recent addition to the body of literature on intuition and creative problem solving, and continued scholarly pursuits in this field will likely yield further gains. Specifically, recent work suggests the need to further examine the contexts in which affect most strongly impacts the intuition-creative performance relationship. Such research demonstrates that positive affect may in effect substitute for intuition in the creative problem-solving process. This also points to the importance of developing interventions to capitalize on this relationship. For instance, it would be fruitful for studies to examine when it may be most effective to provide affect-enhancing cues, and when it may be more valuable to provide potentially drier, but perhaps more informative directions.

Researchers also need to further investigate the conditions under which training may best enhance the effect of intuition on creative performance. Recent empirical research has provided preliminary evidence for such effects, but the conditions under which potential gains are maximized needs to be studied in more detail. Furthermore, additional moderators of this relationship (such as positive affect) should be tested more fully.

From a theoretical perspective, scholars in this area need to further advance their understanding of the factors that give rise to intuitive behavior in the realm of creative problem solving. Among the perspectives described in the extant literature, those that have been examined empirically seem to be similarly effective in many circumstances. This points to the likelihood that these apparently varied approaches may operate on similar theoretical underpinnings. Further studies to identify what these commonalities may be, and how they operate, could provide a better understanding of the phenomenon of intuition.

Finally, this body of literature has implications for the broader study of creative problem solving. In particular, research on intuition in problem solving (Eubanks et al. 2010) shows that intuition likely does not have a uniform, positive impact on all aspects of creative solutions. That is, highly intuitive individuals who draw heavily on prior experiences may not produce more original solutions than less intuitive people. Instead, solutions devised by these individuals are likely to excel on other dimensions of creative performance, specifically solution quality and elegance. This differential impact not only implies that outcomes of intuitive problem solving must be examined in terms of multiple constructs, but also underscores the importance of evaluating creative performance as a multifaceted construct (Besemer and O'Quin 1999). Thus, further study of intuition in creative problem solving has the potential to enhance our understanding of both intuition as a construct, and also of creative performance as a complex outcome.

Introduction

The objective of this text is not to present an exhaustive analysis of the economic theories of the entrepreneur but by revisiting the works of a few key economists, to develop a reflection on the evolution of the role of the entrepreneur in today's capitalist society. We should underline an apparent contradiction between two phenomena: the growing number of scholars of entrepreneurship (especially from the beginning of the 1980s) (Landström and Lohrke 2010; Boutillier and Uzunidis 1995) and the greater importance of large enterprises in today's capitalism, despite numerous new business start-ups (Microsoft, Apple, Google, Facebook, etc.). Even if it appears to be the result of the "destructive creation" of Schumpeter (1942; Boutillier and Uzunidis 1995), which is the process of the continuous technological and organizational change of capitalism, the recent progress in new technologies of information and communications offers new opportunities of profit and investment for entrepreneurs. However, from the beginning of the 1980s, economists' interest in entrepreneurship can be explained by the development of self-employment and the increase in the number of small businesses. Indeed, governments have sought an answer to employment problems by promoting the creation of new businesses. Conversely to this, subsequent to the period of economic growth from 1945 to 1975 in industrialized countries, since the end of the 1970s, the increase in salaried employment has slowed down.

We highlight that this economic evolution is taking place in a new historical context characterized by the rise of financial markets. Entrepreneurship has emerged as a specific field of research in economics since the beginning of the 1980s. This period was characterized by two linked phenomena: (1) the end of the economic growth period (1945–1975) and (2) the failure of Keynesian policy. This new economic evolution would be based on a radical economic and political change. Thus, the challenge was to find a new economics dynamic based on a new institutional structure, in other words, a new institutional structure to promote free markets and entrepreneurship (private initiative).

Between the end of the 1950s and the end the 1970s, the entrepreneur, as an economic instrument of change, disappeared from economic theory. Entrepreneur has been replaced by the firm. Baumol (1968) pointed out this weakness of economic theory: "the theoretical firm is entrepreneurless – the Prince of Denmark has been expunged from the discussion of Hamlet" (Audretsch et al. 2011, p. 166). The entrepreneur does not exist in the neoclassical model, even if he is a central figure of capitalism. How can you explain this situation? Can it be explained by the development of managerial capitalism? Certainly, but the answer can be found not only in economic facts but also in economic theory. Two main elements can be suggested: (1) since the mid-twentieth century, economics as a science has become increasingly formalized and mathematically oriented. "An approach that made it difficult to include the entrepreneur in the models of economics" (Landström and Lohrke 2010, p. 25). (2) The neoclassical theory with Walras' model has reduced the entrepreneur to a decision-maker. Three economists founded the theory of the entrepreneur: Richard Cantillon, Jean-Baptiste Say, and Joseph A. Schumpeter. They brought to bear three basic elements: uncertainty, risk, and innovation. Paradoxically, profit does not take a lot of place in the economic theory of the entrepreneur. To be an entrepreneur seems to be a game or in other words a challenge to change economic routines.

Entrepreneurs and Key Economists

Historical Contexts

Nevertheless, the entrepreneur, as an economic concept, appeared at the beginning of the eighteenth century with Richard Cantillon. For economists, the entrepreneur plays an important role in capitalism because he (or she) is a source of innovation (technical or social). Three historical economists founded the theory of entrepreneurship: Richard Cantillon (approx 1680–1734) in the eighteenth century, Jean-Baptiste Say (1767–1832) in the nineteenth century, and Joseph A. Schumpeter (1883–1950) in the twentieth century. All three brought the same determining elements: uncertainty, risk, and innovation. To summarize, the entrepreneur, as an economic function, embodied the continuous economic evolution of capitalism.

The Classical Age: Beginning of the Industrial Revolution

Since the early contributions in the eighteenth century, the entrepreneur has personified the uncertainty of the free market. Cantillon created his theory during the first industrial revolution, at the beginning of the eighteenth century, during a period when governments had an important economic influence. The objective of mercantilist policy was to promote the creation of big public enterprises and to limit economic dependence on other countries. War was a tool for governments to collect new wealth that they could not get though international trade or by their own economic development. According to R. Cantillon, the fundamental role of the entrepreneur is to make decisions in an uncertain economic context. In the *Essay on the Nature of Commerce in General* (published in 1755), the entrepreneur is described as a risk-taker who bears uncertainty. The entrepreneur takes risks because he buys a product with a definite price, but he sells the same product for another price which can be lower or higher. Cantillon does not offer in this text a precise definition of uncertainty. Cantillon, basically defines uncertainty as the inability to predict a future state or condition.

The Maturity of the First Industrial Revolution

J.-B. Say is, like Cantillon, a liberal economist. In his *Traité d'Economie Politique* ("Handbook of Political Economy" published in 1803), Say presents a theoretical model which is based on the free market, the basic engine of the economic process. The well-known Say's law illustrates this conception of the economic process. In this framework, the fundamental role of the entrepreneur is to innovate. The entrepreneur is a middleman between the scientist who produces knowledge and the worker who uses it to develop new industrial activities. Thus, Say emphasizes that the role or the entrepreneur consists of combining the factors of production into an organization. The entrepreneur has a coordinating role in production and distribution. But J.-B. Say does not show the links between his economic law and the place and the role of the entrepreneur in this economic context. Thus, if the goal of Say was to personify the invisible hand of Adam Smith, the result was very disappointing.

The Beginning of the Managerial Capitalism

J. A. Schumpeter, in *The Theory of Economic Development* (published in 1911), underlines that the entrepreneur is the economic individual who realizes new "productive combinations." Schumpeter provides an exhaustive list of typical opportunities for entrepreneurs who recognize and exploit them (Bonnet et al. 2010, p. 56):

1. The introduction of a new good – that is one with which consumers are not yet familiar – or of a new quality of good.
2. The introduction of a new method of production, that is one not yet tested by experience in the branch of manufacture concerned, which need by no means be founded upon a discovery scientifically new, and can also exist in a new way of handling a commodity commercially.
3. The opening of a new market, that is, a market into which the particular branch of manufacture of the country in question has not previously entered, whether or not this market existed before.
4. The conquest of a new source of supply of raw material or half-manufactured goods, again irrespective of whether this source already exists or whether it has first to be created.
5. The carrying out of the new organization of any industry, like the creation of a monopoly position (for example though trustification, or the breaking up of a monopoly position.

To summarize, Schumpeter provides five sources of change and profit. Schumpeter underlines that the entrepreneur is embedded in society. He is not atomistic, isolated, and immersed in a process quite different from the other social phenomena. Schumpeter develops his theory of the entrepreneur on the critical analysis of Walras. The Walras' model is static (competitive equilibrium context). However, two Walras' hypotheses have determining implications for the behavior of entrepreneurs, the hypothesis of market atomicity and the hypothesis of perfect information:

1. Entrepreneurs have equal access to the same risky ideas or technology and receive all the profit from risk-taking.

2. Entrepreneurs have access to the same information. They do not have a specific strategy in the competitive process. Entrepreneurs are always and everywhere maximizers.

The Scientific Project of Schumpeter

The scientific project of Schumpeter is to create a new economic theory because the Walras' model cannot explain the movement of capitalism (crisis, recession, growth, and technological change). In Schumpeter's theory, the entrepreneur plays an important role as an engine of change. The Schumpeterian entrepreneur is not rational (according Walras). If entrepreneur's objective is profit, it is also to call into question the organizational and productive routines.

But Schumpeter has been influenced by another famous neoclassical economist, Carl Menger (1840–1921). Menger's theory is fundamentally different from that of Walras' theory as a means of understanding entrepreneurial behavior. For Menger, individuals are heterogeneous, and they do not make decisions consequent on behavior of absolute maximization, but relatively. In other words, two economic individuals equipped with the same resources may behave in very different ways (contrary to Walras' theory). In Menger's model, uncertainty plays an important role, in contrast to Walras. The influence of Menger on Schumpeter's thinking was very important, even if this subject is not often developed by economists. Menger was a marginalist economist like Walras, but he drafted a theory which is the opposite of the economic rationality of Walras. According to Walras, economic rationality is based on a strict calculation between resources (capital or work) and a gain (profit or salary). Each economic group is homogeneous (capitalists, entrepreneurs, workers, or consumers). Menger's approach emphasizes the subjectivity of economic values. Menger's entrepreneur does not exist in a context of certainty (as Walras says). In an uncertain context, the entrepreneur has to find information and knowledge to build his own strategy. Focusing on the uncertainty angle, Menger picks up a theme introduced by Cantillon, who is often considered as the forerunner of Austrian thought. In Menger's model, uncertainty plays an important role, the opposite of Walras'.

The Schumpeterian concept of "creative destruction" summarizes the three elements which founded the economic theory of entrepreneurship: "capitalism (. . .) is by nature a form or method of economic change and not only never is, but never can be, stationary" (Boutillier and Uzunidis 1995, pp. 34–37). Schumpeter says that "creative destruction" is the "essence of capitalism." Thus, if the entrepreneur is the engine of change, then Cantillon, Say, and Schumpeter were themselves an engine of change of economic theory: Cantillon's theory criticized the Mercantilist theory and the high power of the state. Say's theory questioned the Smithian economic model and the theory of the "invisible hand." Schumpeter debates the Walrasian theory based on perfect competitive market structures. In addition, Cantillon, Say, and Schumpeter shaped a new economic paradigm. Beyond this proposition, another common characteristic links these three theories: the entrepreneur does not represent a person but a process or a function, not an employment category nor a start-up enterprise. In this sense, the entrepreneur is a kind of ideal type (according to Max Weber's definition). The entrepreneur personifies the evolution of capitalism at three different stages of its history: at the beginning of the eighteenth century with Cantillon (i.e., at the beginning of the first industrial revolution), at the beginning of the nineteenth century for Say (i.e., at a mature stage of industrial capitalism), and Schumpeter during the emergency of managerial capitalism. In other words, the historical context underlies economic theory.

Schumpeter Between Marx and Walras

Schumpeter created the concept of the entrepreneur to improve Walrasian theory, but in so doing, he follows Marx on the subject of the end of capitalism. According to Marx, capitalism would collapse because the system was programmed to fail. On the other hand, Schumpeter also feels that capitalism should collapse despite its outstanding and sustained success. But, they think in common that small enterprises will disappear. In the future, the economic system will be only composed of large firms that will plan the world economy. According to Schumpeter, the entrepreneur will disappear in this new scheme because the mechanism of innovation will be based not on an individual economic actor (the entrepreneur) but on an organization (the big enterprise): "Economic progress tends to become depersonalized and automatized. Bureau and committee work tend to replace individual action" (Schumpeter 1942, p. 133). Like Marx at the middle of the nineteenth century, Schumpeter was not the only economist who developed this idea. Alfred Marshall did so too, and a few years later, in the 1930s, Ronald Coase explained in a well-known article "The Nature of the Firm" (1937) the evolution of the market between large and small enterprises. He describes a dialectical process where large and small firms play a defined role according to the economic context (growth or recession) and the intensity of the uncertainty.

The End of the Entrepreneur: The End of the Capitalism?

Does the Entrepreneur Exist in Managerial Capitalism?

The main eccentric aspect of Schumpeter's analysis was the link between the extinction of the entrepreneur and the end of capitalism. It seems that he was influenced by the analysis of Karl Marx about the end of capitalism and the transition toward socialism and afterwards toward communism. The entrepreneur who was the central figure of capitalism disappears. For Schumpeter, like Marx, it is not a proletarian revolution which will kill capitalism. Capitalism will be destroyed by its own forces: the free market and competition. The managerial enterprise takes the place of the entrepreneur as an economic performer. Nonetheless, the "enterprise" takes the place of the "entrepreneur." Thus, after the Second World War, economists forgot completely the entrepreneur and focused their attention on the firm. But, according to E. Penrose (1959), the term "entrepreneur" can be used to refer to individuals or groups. So the concept of "entrepreneurial services" which are "those contributions to the operations of a firm which relate to the introduction and acceptance on behalf of the firm of new ideas, particularly with respect to products, location, and significant changes in technology, to the acquisition of new managerial personnel, to fundamental changes in administrative organization of the firm, to the raising of capital, and to making of plans for expansion, including the choice of method of expansion" (Penrose 1959, p. 31 ref). Before Kirzner, Penrose links the entrepreneur to the decision process based on the discovery of opportunities: "the decision to search for opportunities is an enterprising decision requiring entrepreneurial intuition and imagination and must precede the 'economic' decision to go ahead with the examination of opportunities for expansion" (Penrose 1959, p. 34, ref). In this way, the entrepreneur exists in a managerial economy. So in fact, the fundamental question is not the end of the entrepreneur and capitalism but the evolution of capitalism (accumulation and concentration of capital) along with the evolution of the role of the entrepreneur.

Uncertainty, Market, and Entrepreneur

Nevertheless, two contemporary economists, Franck Knight (1885–1972) and Israel Kirzner (1930–) have developed a theory of the entrepreneur exclusively based on uncertainty. So they take their place in the analytical field opened by Cantillon 200 years earlier. Frank Knight, in *Uncertainty and risk* (published in 1921), underlined the existence of a direct relation between the entrepreneur, uncertainty, profit, and risk. Knight defines uncertainty is terms of the entrepreneur's inability to accurately predict a future situation. Knight makes a key distinction between risk and uncertainty. According to Knight, the term risk properly used refers to situations in which the possibility of these outcomes can be expressed in terms of mathematical probabilities before a decision is made. Thus, under conditions of risk, the decision-maker is able to insure against possible negative outcomes. Within Knight's context, uncertainty represents "defects of managerial knowledge," and it is these defects that account for profit and loss.

Under conditions of uncertainty, decision-makers are not able to insure against possible negative outcomes because not only are they unable to predict the probability that any specific outcome will occur, but they are unable to meaningfully foresee the true range of possible outcomes. But like Schumpeter, according to Knight, the entrepreneur represents an economic function, not a person. Knight things in the context of managerial capitalism based on a collective management between shareholders and managers.

According to Israel Kirzner, the entrepreneur is not a hero, or in other words, anybody can be an entrepreneur, because the capitalist economy gives a large range of opportunities of profit. In *Discovery, Capitalism, and Distributive Justice* (published in 1969), Kirzner develops the analysis of the entrepreneur in two ways. The first follows Menger's theory. Even if the entrepreneurial theory has been influenced the other economists, mainly F. von Hayek, according to Kirzner, the role of the entrepreneur is to coordinate information as part of the process of division of knowledge. Like Menger, Kirzner does not consider the entrepreneur as a rational economic player who makes decisions in a certain context. The Menger entrepreneur exists in an uncertainty context. But, the main teaching of Menger's theory is the analysis of the "entrepreneurial alertness." In Kirzner's theory, profit opportunities result from prices, quantities, and qualities that diverge from their equilibrium value. Some individuals tend to notice, or be alert to, these opportunities, and their actions bring about changes in prices, quantities, and qualities. The entrepreneur is alert to a new product or a superior production process and steps into this market gap before others (Foss and Klein 2010, p. 105). The entrepreneur of Kirzner is a discoverer, not an innovator. Entrepreneur discovers new resources uses, new products, new markets, and new possibilities for profitable trade.

As stated above, the Kirznerian entrepreneur exists in an uncertainty context. One of the main functions of Kirznerian entrepreneur is to discover new knowledge about which products, processes, new organizational forms, etc. are needed. Thus, Kirzner builds a theoretical link between Cantillon's, Knight's, and Schumpeter's approach. This statement is confirmed by the role played by Kirzner's entrepreneur in the process of innovation. Even if Kirzner talks about "discovery" and not "innovation" like Schumpeter, his entrepreneur consists not of a category of employment or an enterprise but a "pure entrepreneur." In other words, the Kirznerian entrepreneur is an economic function or a kind of metaphor. He embodies the economic evolution of capitalism. For example, Kirzner argues that the entrepreneur is a "nonowner." As Schumpeter underlines, nobody can be an entrepreneur for all his life. The entrepreneur is an entrepreneur only when he creates innovation, so usually only for a short period of time.

The Entrepreneurial Society

According to David B. Audretsch (2007), "the entrepreneurial society had replaced the managed economy" (2007, p. 19). The "managed economy" was based on large firms, or in other words: conformity, monotony, rigidity, and homogeneity. The entrepreneurial society is based on entirely different values: nonconformity, autonomy, creativity, and self-reliance. The entrepreneurial society offers a large range of new opportunities. Workers can rapidly change jobs. Audretsch illustrates his book, *The Entrepreneurial Society*, with different cultural references from the 1960s: Bob Dylan, Janis Joplin, or Jack Kerouac who represented during this decade young people who wanted to change the world. These artists lived in the managed economy, an economy based on mass production and Taylorism, with no opportunity to create. The crisis of the managed economy gives new opportunities in the entrepreneurial field. A new division of labor will develop between small and large firms, reinforcing the notion that mass scale production is not the only criterion of the production organization.

Today, in spite of the development of managerial capitalism, the entrepreneur always embodies capitalism. Entrepreneur personifies his dynamic of change. In this intellectual context, the entrepreneur is not an individual but an economic function.

Entrepreneur and Economists, Table 1 The theory of the entrepreneur (synthesis)

Authors	The entrepreneur is	Theoretical criticism	Historical context
Richard Cantillon 1680–1734	A nonfixed income earner	Against mercantilism and the economic role of the state	Beginning of the first industrial revolution
Jean-Baptiste Say 1767–1832	The matchmaker between the scientist who produces knowledge and the worker who uses this knowledge in an industrial process	To personify the "invisible hand" of Smith	Maturity of the first industrial revolution
Karl Marx 1818–1883	The behavior of the entrepreneur (or capitalist) takes place in a particular economic system – capitalism	To criticize classical theory	
	The contradiction of capitalism		
Léon Walras 1834–1910	The role of the entrepreneur is to maximize his profit in a context of pure competition	To develop a new theory based on classical theory	Beginning of managerial capitalism
	Economic rationality of the entrepreneur		
Carl Menger 1840–1921	The entrepreneur has no place in a context of certainty. He (or she) has to find information and knowledge to build his (or her) strategy.		
Joseph A. Schumpeter 1883–1950	Is an economic function which realizes new combinations of factors of production	To develop Walras' theory of the entrepreneur and Marx's theory about capitalism	
Franck Knight 1885–1972	The entrepreneur faces the market uncertainty that cannot be probabilized	To develop the neoclassical theory of the firm	Maturity of managerial capitalism (fordist firm)
Ronald Coase 1910–	What are the opportunities for creation of enterprises according a dialectical relation between the enterprise and the market?		Maturity of managerial capitalism (network firm)
Edith Penrose 1914–1996	Entrepreneurial services. The entrepreneur can exist in a big enterprise.		
William Baumol 1922	Entrepreneurial activity is crucial for radical innovations and growth		
Mark Casson 1945	Entrepreneurs specialize in taking judgmental decisions about the coordination of scarce resources		
David Audretsch 1954	Creativity of the Entrepreneurial Society		

Conclusion and Future Directions

In economic reality, it is easy to identify entrepreneurs: Rockefeller, Carnegie, Renault, Tata, Gates, or Zuckerberg. But for economists, it is not an easy task. If they are certain that the entrepreneur is the engine of capitalism, they have, in contrast, great difficulty in finding entrepreneurs in economic reality. Since Cantillon, the pioneer of the theory of the entrepreneur, the entrepreneur is a metaphor to explain the capitalist evolution. If the entrepreneur can be identified as an individual, on the other hand, he takes his place in a social context which defines economic and social functions. So, the entrepreneurial function introduces economic and technical change, but it also contributes to the reproduction of a socioeconomic system based on competition and individual property.

So, in this context, we can understand why the entrepreneur exists in managerial capitalism. Entrepreneur, exists under different aspects in large and small enterprises. The entrepreneurial function explains the introduction of technical change in preindustrial society but also the development of new activities at the end of the twentieth century. However, in preindustrial economics, just as in managerial capitalism, the entrepreneur has an important task: to create jobs and first of all his (or her) own job. In an economy based on market mechanism that is the fundamental survival condition (Table 1).

Summary

At the end of the nineteenth century, the social question became paramount for many thinkers (Saint-Simon, Fourier, Owen, Buchez, Godin, and Proudhon) who advocated a new society in which fairness and social justice are the pillars. They imagined a society based on small entities of production and consumption using the principle of cooperation between the parties on an equal basis. Some of them, such as Fourier, Owen, and Godin, seek to put their ideas into practice. While none of these thinkers had a defined theory of the entrepreneur (the latter being associated with the capitalist owner), all took the company as a privileged social exchange.

Economic Concepts and Entrepreneurial Utopia

Entrepreneur

According to the dictionary "Petit Robert," the definition of the entrepreneur is "one who undertakes something," "a person who is responsible for the performance of work," or "any person who sets up various factors of production (natural agents, labor, capital) to sell products and services," or "anyone who runs a business on his own behalf and that organizes the various factors of production (natural agents, labor, capital) to sell products or services."

According to the Universal Dictionary of Trade published in 1723, "the contractor" is one who undertakes a work, while during the Middle Ages, "to be an entrepreneur" simply means one who undertakes a task. The definition of entrepreneur has changed its meaning by the sixteenth and seventeenth centuries leading to the definition of Diderot and Alembert, which defines the entrepreneur as "Whoever is in charge of a book"; that definition has changed a little from the one cited above.

It was not until the early eighteenth century that the concept of entrepreneur became a theoretical concept, when the economy became a field of independent thinking and a scientific discipline in its own right.

The first theory of the entrepreneur was developed by Cantillon (1680–1734) who in 1755 published an *Essai sur la nature du commerce en général*. If the word entrepreneur was already used in everyday language, Cantillon gives a rigorous economic meaning. The entrepreneurship is an active process of coordination of production and exchange, channeling goods from production to the final consumers through the exchange markets.

Cantillon defined the entrepreneur as the person buying the factors of production and/or goods at a certain price to sell at an uncertain price. The entrepreneur is seen as a risk taker. Other scholars also place the entrepreneur at the heart of the economic debate.

J-B. Say (1767–1832) follows the work of Cantillon by defining the "business of the entrepreneur." He carefully defines the different levels of intervention in the business and the qualities that must be provided as follows: First, the entrepreneur is the main agent of production. His work is productive as well as that of the worker or the scientist. Second, the entrepreneur must have an "ability to judge," that is to say, the entrepreneur must determine the needs and especially the means of satisfying them. Finally, the entrepreneur shall not rely on the routine and constantly innovate. The entrepreneur is thus placed by J-B. Say in an intermediary place between the scientist, who produced the knowledge, and the worker, who applies that science to industry.

Schumpeter (1883–1950) defines, in turn, a heroic entrepreneur who places his approach at the heart of innovation. He creates a new product not known to the consumer and introduces a new method of production.

The nineteenth century was marked by economic turmoil, social and technological disasters: development of industry and wage labor on a large scale. The working conditions were extremely hard for workers. In these conditions, the social question becomes paramount. A number of thinkers, such as Saint-Simon, Fourier, Owen, Buchez, Godin, and Proudhon, advocated a new society based on small entities of production and consumption under the principles of cooperation between the parties on an equal basis.

While these thinkers are not carefully defined so the economic concept of entrepreneur, all seek to apply their ideas then qualified of "dream economy" or "utopias," the company is, therefore, their instrument of choice.

Utopia

The word utopia, which originates from the title of the famous book by Sir Thomas More's *Utopia* (1516), refers to both a literary genre, a kind of political fiction that attempts, often in a cumbersome and sometimes brutal way, to achieve a form of social organization which is supposed to embody an ideal deemed absolutely good. Since 1516, the term has been used to refer to an ideal or impossible society.

The number of recognized utopias is considerable. However, some recurring themes and structures characterized utopia. Most utopias were born in the heart of the nineteenth century. They were based on egalitarianism and refuted private property. The repeated plea for collective ownership constituted a criticism of societies where private ownership of land or capital was the dominant social institution, and appeared as the primary cause of the ills of these societies. The perception of injustice and human misery lead the authors to imagine a form of organization that could eliminate the causes of these evils.

Many considered that social problems were the product of bad institutions, which distort or thwart the natural tendencies of men. The remedy most often suggested was the brainchild of more liberal and humane institutions capable of encouraging the development and improvement of the individual and the establishment of an education system that could foster the development of the individual. The Utopians preferred to experiment with the economic and social development of a complex economic theory. They generally started with a local action as an example.

The main interest of utopian thinking was to embrace not only the political but also social and economic private life (marriage, education of children, etc.). The formal presentation of a utopia involved the detailed description of an ideal or dreamed world. Utopianism is a way of thinking about the best or happier form of society without concession or compromise with existing institutions.

The Concept of the Entrepreneur in Nineteenth Century Utopians

Claude Henri de Rouvroy, Count of Saint-Simon (1760–1825)

Against the aristocracy, Saint-Simon opposed the new owners who were the purchasers of national property. In the review *L'Industrie (1816–1818)*, the author outlines the main principles of the philosophy on which it is based. Industry is work of any kind, guided by human intelligence, whether manual or intellectual, agricultural, industrial, or commercial. For him, the term "industry" has the same meaning as the term "producer." The farmer is a producer who works to be protected against the owner of private means. It is on the basis of these producers that Saint-Simon wants to rebuild a new society, against those who have no work, either the owners or operators of nonliving shareholders a dividend. Producers are, therefore, opposed to idleness.

In his text *Parabole (1819)*, the author emphasizes the uselessness to the nation, of all those who do (the "Hornets") not produce: of the Court and Princes of the Church, the officers, and the judges. However, he considers the most modest workers, in field or workshop as essential to the nation. Among the industrious, the share of the proletariat is important. Saint-Simon, therefore, wants to increase the number of proletarians capable of managing the business through education. At the top of the industry are the bankers who organize the economy through the issuance of credit. Thus, the author advocates a socialist, technocratic, and planned economy.

Charles Fourier (1772–1837)

Fourier (1829) criticizes industrial anarchy due to the fragmentation of ownership and commercial parasitism – sources of all the disorders of civilization. The first evil of the capitalist production system is poverty which "seems proportional to progress," and whose cause is the waste that involves the absurdity of mass circuits of production and consumption.

Fourier criticizes agriculture in its civilized form, based, according to him, on the two contradictory vices of fragmentation and concentration. If work in the fields in this form is disgusting, then the division of tasks and long hours of hard work make working in factories even more repugnant. The competition in this sector has the corollary that piecemeal work, compounded by the machinery, degrades the workers physically and mentally. The central question Fourier intends to answer, then, is – How to make work fun? For Fourier the only way to do this is to ensure that work becomes for man the fruit of his own passion and his own desire.

The whole theory of Fourier is based on the premise that the key to the problem of the social question comes down to knowing the ordering willed by God. This key is then nothing other than the "attraction," which, in the same way, enables the world and social order. For all human societies, the engine more than anything is *the passion* – "the passionate attraction." By analogy with the global world organized according to Newton's law, Fourier proposes an "industry association" based on "passionate attraction." It is no longer about creating, as in military, hierarchical organizations and authoritarian discipline, but to develop mechanisms that encourage individuals to work for the collective interest. Fourier escapes the liberal impasse which prohibited the development of businesses beyond the capabilities of monitoring bosses. He also avoids the paternalism of the philanthropists. In a logic that is hierarchical and vertical, Fourier proposes a new model of social relations based on careful management of the passions. Fourier's thought rests on two assumptions: attraction and association. The free play of passions must allow "universal harmony." To achieve this, he imagines a unique model of social organization: the phalanx. In "harmony," property is merely the participation in the entire property of the phalanx, without the absolute power of management. Far from being the mere fantasy of a utopian, the phalanstery influenced the thought of many manufacturers throughout the nineteenth century.

Jean-Baptiste Godin (1817–1888)

Locksmith's apprentice at the age of 11, Godin had an early awareness of the alienated character of the working class, through meetings and lectures. In 1837, he developed the idea of replacing the sheet metal by melting in the manufacture of stoves and furnaces, which earned him an immediate success. In 1881, his workforce totaled 1,337 employees and manufactures and the famous stoves has become a world leader in its field. To improve the working conditions and lives of his workers, in 1859 Godin built a social housing complex near the factory, the Familistery of Guise in France in 1859. Godin quickly took into account the aspirations of workers and immediate benefits of the work involved to better distribute wealth and ensure social protection. Pursuing the goal of gradually increasing the property of the company in the hands of its staff, he created in 1881, "the working capital association" that resulted in common ownership and profit sharing, as well as easier access to higher responsibilities and the distribution of wealth. It was put in place alongside pension and welfare, a welfare system managed by Mutual employees (health insurance made compulsory from 1861). It provided free medication and visits (1870). In addition, he invented the Republican promotion of Merit. While Godin was generous, he was by no means egalitarian. Participation went even further: It was not only aimed at limited results but also extended to the management of the company. In 1880, the company took the statutes of a working cooperative and kept its production going until 1968.

Robert Owen (1771–1858)

In 1800, Owen became the owner of the Scottish shadowing in England that tried to transform the factory model. Its design was the result of a moral protest against the damage caused on the social fabric by industrial progress and greed. He maintained that man is the product of its socio-economic and cultural environment. It is, therefore, sufficient to control education, production, and trade to restore collective solidarity. By acting on what he calls "external circumstances" (standard of living, morality, place of residence) that can transform the most radically human behavior. Owen's first practical social change at the microeconomic level involved experimenting with a new work environment based on education. Inside the factory, to respect the dignity of workers, he established a plan for economic and social reorganization based in particular on a reduction of working time (10 h instead of 15), the establishment of kindergartens (which would not be exploited in factories), the opening of evening classes for workers, etc. Owen implemented a program of modernization of machines and a system of preventive maintenance to reduce the costs of their dysfunction. He advocated a policy of high wages. On this point, his vision prefigures that of Henry Ford. Anticipating the socialists of the nineteenth century, Owen (1847) believed that "the natural standard of value is, in principle, human labor, or a combination of manual and mental energies of man when they come into action." But he does not ignore the importance of profitability for the company and the significant benefits that it could gain from the well-being of its workers. It is in this sense that this Scottish entrepreneur can be called modern.

Philippe Buchez (1796–1865)

Buchez is often considered one of the first theorist's worker associations. Thinker wants to practice Christianity and spread democracy in all spheres of economic life. He wants to "establish a republic in the workshop." Religious inspiration is also clear in the preamble to the statutes of the cooperative, the Association of Christian jewelry in gold, which he founded in 1834 and which he defines as "a simple application of moral principles taught by Christianity." To propagate his ideas to the working class, he published small workers' newspapers, such as *L'Européen* and *L'Atelier*. Founded in 1840, the workshop aimed to prepare the complete emancipation of the working classes. The reciprocity of his teaching is the way in which he approached this goal. Buchez not only dreamed of an ideal society but wanted to develop local initiatives for elite workers. His profession as a hygienist led him to combine theory with practice, but he first started listening to the workers.

His approach is essentially based on two dimensions: the condemnation of competition and a critical analysis of society. The criterion of private property, Buchez divided society into two classes: the entrepreneurs whom he sees as parasites, unnecessary intermediaries and workers, victims of the capitalist sampling. To help workers regain some dignity in work, Buchez calls for the elimination of the first class. To achieve this, he offers the solution of the labor organization of production. Based on the sharing of work tools, the association must avoid the hoarding of profits or surplus by the contractor, and allow for sharing between the workers. A fifth of those profits must, however, be set aside to build social and inalienable capital in order to avoid the situation whereby those who are established exploit the newcomers. Buchez defines in detail the status and functioning of workers' associations. He attempts, in particular, to determine the conditions of the supply of capital that prevent ownership of decision-making power by a minority. The cooperative principles defined by Buchez strongly inspired the International Cooperative Alliance (1895) and were reflected in the 1947 Act "on the status of cooperation."

Pierre-Joseph Proudhon (1809–1865)

Not believing in the power of a violent revolution, Proudhon recommended social reform within the capitalist system. This anti-society must apply the principles of association, mutually. The revolution of 1848 created an explosion of workers' associations. For Proudhon, the revolutionary act is in the will of workers to organize on their own. He deplored interference by the state and its authority in the management of these associations. The authoritarian state was incompatible with free management. Proudhon rejected all social organization imposed from the summit.

The position taken by Proudhon in respect of the property is another key element of his thought. This seems to be finalized after his first paper on the property, entitled *Qu'est-ce que la propriété?* (1840), in which he replied: "Property is theft." Yet the intention is not to deny property but to restore it on new foundations. Thus, Proudhon condemns private property. Private property to a certain extent is contrary to justice; it is the property that "receives different names according to the things that happen: rent, interest, profit, gain" and is based on "the amount of abuse," as he stated in 1841 in his letter to Blanqui. This "right to bargain" in a way is on the activities of workers and effortlessly from the owner. While acknowledging that the property is not reprehensible in itself, as a result of the work and savings and as an expression of freedom, Proudhon, nevertheless, holds that it steals the fruits of labor, the only productive element. Therefore, capitalist must give workers what is theirs: the key to the social problem, then, is to return to the worker the full product of his labor.

Proudhon is well in line with those who only work, defined as the intelligent action of man over matter, as the sole producer of wealth.

Rebuilding society from the bottom-up, that is to say, productive activities, Proudhon wants to work to be the source of personal autonomy. The worker, becoming once again master of his actions and decisions must recognize himself in a job that, in turn, has found its full meaning. Against the fragmentation of tasks, Proudhon proposes to go the worker with an entire series. The frustration of workers formerly confined to a single action disappears with job enrichment. Once the work is reinstated, the de-alienation of workers is accomplished in the work itself.

As far as the "right to bargain" is concerned, he draws constructive solution. Of course, the capitalist entrepreneur returns the worker a counterpart for his labor, but he keeps for himself the value of the extra work done in a collective manner. Proudhon, like Smith, thinks that the division of labor leads to increased productivity and denounces the capitalist ownership of the collective force. For Proudhon, the capitalist entrepreneurs "steal" the extra value engendered by the collective strength from the individual strength. The only solution that allows the worker to recover what the capitalist owner charged is through the formation of workers' associations. But the association is not a virtue in itself and must be dominated by law and justice, based on reciprocity, "the social contract, both political and economic, which embraces the individual, family, and the city."

The reciprocity is a justice formula that members of society, regardless of which rank they are, guarantee service for service, credit for credit, and property for property. Proudhon does not want to replace all private property with collective property, because this also contradicts the law. The social system that must succeed private property is possession. Opposed to the right to use and abuse that characterizes property, Proudhon highlights the benefits of a property under the control of the society. If for Proudhon's thought property is theft, the possession is, however, considered a prerequisite for the maintenance and development of a free and creative labor. For the same reasons, Proudhon wants to maintain a market economy: competition has an incentive; it is "the expression of social spontaneity," the guarantee of "freedom" associations.

Proudhon anticipates the slogan of the First International, which states that emancipation "will be the work of the workers themselves," which was proposed by subsequent Marxists. He is also the first to lay the foundation for the utopia of workers as self-producers.

Conclusion and Future Directions

A review of several utopias written or practiced in the field of entrepreneurship carries many lessons. For the utopian thinkers, their obvious interest is the fact that they were not only intellectual adventures and imaginary experiments, sometimes sustainable and economically efficient (in the case of Godin's company). They were not conducted systematically to overthrow the established order, but rather to transform it. These thinkers did not write the theory of the entrepreneur. However, the company has the appropriate level for them to transform society. Reform or modernization of its social relations calls for changes to all other levels of society, because it is an essential place of socialization. The social importance and richness of utopias studied here matter less for their achievements as multiple effects they were the crucible. Is it not in this sense that we should recognize them for being an inspiration and energy in the invention of other more equitable and humane business models?

The study of the etymology of words is a fruitful way to understand the history of social practices, as a reflection of social behavior. Words stem from social practices that change in dynamic interactive processes. Our objective is to present some examples of the etymology of the word "entrepreneur" in French and English. Since a long time ago, French and English people use the same word: "entrepreneur." The historical roots of the word "entrepreneur" as well as of the verb *entreprendre* go back to the war vocabulary.

Surrounding a town is indeed compared to an entrepreneurial activity since it is an act that combines strategy, organization, and risk. More recently, the words "entrepreneur" and *entreprendre* have worn an economic meaning. Thus, the entrepreneur is a person who concludes a contract with a government or a public authority as a goods supplier or to undertake – for its account – infrastructural investments (such as building roads or buildings). This illustrates a contractual relationship between the entrepreneur and the State or with another entrepreneur, and which supposes a kind of "trust" between the different parts of the contract. In such kind of contracts, the entrepreneur takes (economic or financial) risks, though. This explains that in the economic as well as in the war vocabulary, the entrepreneur is apprehended in the sense if "risk taker." According to the famous definition of Jeremy Bentham, the "entrepreneur" is also apprehended in the sense of a "project maker" in both economic and war vocabulary. In a different way of thinking, being an entrepreneur is also a mean to be at a higher level of the social ladder or hierarchy.

First, we will present the etymology of the word "entrepreneur" in both French and English languages. The aim from this presentation is to emphasize the complex relationship between risk and social dynamics related to this concept. Second, we will extend our etymological analysis of the word "entrepreneur" in other different languages, for instance, Arabic, Chinese, Japanese, and Russian. Through these examples, we confirm that the meaning of the word "entrepreneur" around the world is always related to the diptych "risk" and "trust."

The European Roots of the Word "Entrepreneur"

French and English people use the same word to name the "entrepreneur." In French, the word "entrepreneur" stems from the Latin word *inter prehendere*, which corresponds to the verb *entreprendre* in French and means "to grab" or "to take control." During the Middle Age, the verb *entreprendre* in France used to mean "to cover" while the word "entrepreneur" means "to attack." The entrepreneur used to mean an attacker in popular French language. However, at the beginning of the fifteenth century, the verb *entreprendre* means "to come to grips with" and later "to take risk" or "to challenge."

The primary sense of the word "enterprise" in French comes from war language, though. In fact, since military people need to handle complex technologies and equipment (Vérin 1982), an organization –thus a strategic process – to "make war" is required: that used to be called "enterprise." The economist and military engineer, Vauban (1633–1707), describes besieging a town as an enterprise. It is based on a complex organization, the objective of which is to conquest a town all by minimizing the loss of human lives (Vauban, 1707). Besides, during the siege of the town, there was the important concern of supplying the army with food.

Since the sixteenth century, the word entrepreneur in the French language has attributed a different meaning, that is, of a person who constructs a building or supplies goods for the account of a public authority, for instance, the government (Vérin 1982; Explorations in Entrepreneurial History 1960). This transaction is translated by a contract between the two parts (the entrepreneur and the public authority). According to this procedure, the entrepreneur earns a fixed sum predefined in the contract; taking thus a financial risk. The French economist Richard Cantillon defines the entrepreneur as a person who buys goods at a certain price and sells them at an unknown price. Hence, we reach a basic and universal definition of the word entrepreneur which corresponds indeed to the definitions given by other languages. In the

Dictionnaire Universel du Commerce (Savary des Bruslons 1723), the entrepreneur is simply defined as a person who undertakes a work. In the *Encyclopédie* of Diderot and d'Alembert (1751–1772), the entrepreneur is also defined as a person who undertakes a work. But this encyclopedia gives more detailed definitions by separating the fields of the work, such as the "manufacturing entrepreneur" (*entrepreneur de manufactures* in French) or "building entrepreneur" (*entrepreneur de bâtiments* in French).

In the English language, the word "entrepreneur" is frequently used as well as the words "undertaker" and "adventurer" or "merchant adventurers." In the *Johnson's Dictionary* (1755), the word "adventurer" is defined as a person who hazards, who takes any chance, or who wants to control his destiny. In the English language, the word "entrepreneur" (*The Oxford English Dictionary*, Weiner E.S.C., Simpson J.A., 1991) was also used during the fifteenth century according to the simple definition: "a person who undertakes." During the nineteenth century, the word "entrepreneur" is used as "one who undertakes an enterprise" or "one who owns and manages a business," or "a person who takes risk of profit or loss." The word "undertaker" is not used as a maker of business, but like a manager. For example, Adam Smith talks about an "undertaker of a great enterprise" in his famous book: *The Wealth of Nations* (1776).

To summarize, the entrepreneur, in French and in English languages, is a person who wants to control his life and to get rich. The entrepreneur is usually a bourgeois, rarely a noble. So, through doing business, a bourgeois can become an influent person, as we notice the social phenomenon in Shakespeare's (*The Merchant of Venice*) or Molière's (*Le Bourgeois gentilhomme*) works. This same phenomenon is partially noticed in the Arabian literature where the merchant could also be positively appreciated.

So, to become an entrepreneur is a way of social rise. For example, during the Roman Empire, slaves could manage a property (or a trade enterprise) for their master. If the slave-manager gets very rich, he can have his emancipation. But he could not forward his fortune to his children by inheritance (Andreau 1999).

Entrepreneur, Profit, Trust, Chance, and Risk: A Universal Way of Thinking?

In Greek modern language, for example, the meaning is similar as in French or English languages. The word *epixeimatias* in modern Greek language comes from *epixeiro* which means "to come to grips with." Thus, the entrepreneur is a person who has got an active behavior, who acts, but all by insinuating a notion of "trust."

In Arabic language, the etymology of the word "entrepreneur" is the same as in French. In literary Arabic, the entrepreneur is a *moukawel*. In other words, he is a creator of an enterprise or a maker of projects. The verb *kawala, youkawilou, moukawalatan* means to negotiate, to discuss a business, but also to give a work to someone (e.g., via subcontracting) (Vérin 1982). In the Arabian literature, the merchant has a good image as long as he does not intend to steal other people. This aspect of the Arabian literature is very important. Since the seventh century, Arabian economists (Averroès 1126–1198, Ibn Khaldoom 1332–1406) (Verrier 2009) have built an important economic work based on Aristotle's principles (the chrematistic). If most of these economists are liberal, they think that the free market is not only a mean to buy goods, but a mean for speculation, though. Thus, in this context, the entrepreneur plays an important role. We can also underline that the prophet Mahomet was a businessman, before to be declared as a prophet. He worked in the enterprise of his wife... In the Arabian literature, both Sinbad the sailor and Aladdin were also merchants...

In Chinese language (Chan 2010), the word "entrepreneur" is composed by three ideograms: the first one is *qi* which means in ancient Chinese "hope." The second is *ye*, which means "business" or "career." Together, *qi* and *ye* mean "enterprise." The third ideogram is *jia* which means "house" in ancient Chinese. Later, *jia* has been used as "master." So, in China, as in Europe, becoming an entrepreneur can be an opportunity to become a rich and influent man. The emergence of this expression dates to eighteenth to nineteenth century, with the development of trade exchanges with European merchants (and also during the Opium Wars).

In Japanese language, we have a static definition of the entrepreneur. The word "entrepreneur" is a *kigyou ka* in the Japanese language. *Kigyou* is an "enterprise." *Ka* means "house." But, *kigyou ka* in Japanese language has got two different meanings: "business" and "enterprise."

In Russian language, the "enterprise" is a *predpriatie*. The "entrepreneur is a *predprenimalted*. The verb is *predprinimat* (Барышников, 1994). The word *predpriat/predprinimat* is a translation form German language which means to begin to do something including the idea of responsibility. In Russia, during the seventeenth to eighteenth century, we can distinguish three types of "entrepreneurs" according to their sector of activity (Галаган, 1997). In the agricultural sector, the word employed is *koulak*, which could be translated to "punch." The *koulak* are the richest farmers of Russian villages. For trade activities, there is a large range of words: *kupets*, *torgovets*, *kommersant*, *spekuliant*, and *kantar*. *Kupets* comes from the verb *kupat/pokupat* which means to buy. *Torgovets* comes from Latin language *tirgus* or *turgus* which means "place" and "market." *Kommersant* comes from the French word *commerçant*. *Spekuliant* comes from the verb to speculate. *Kantor* comes from *comptoir* in French language or *kontor* in German language. For the industrial sector are used the words *predprenimatel*, *fabrikant*, and *manufakturshik*. The word *predprinimatel* means "entrepreneur." *Fabrikant* comes from the French word *fabrique* (in English "factory"). *Manufakturshik* comes from "manufacture." These three words include the fact to employ workers for a job and also the notion of property. From the eighteenth century (with Peter the Great and Catherine II), the entrepreneurial activity becomes easier (see for example, Барышников, 1994 and Кузьмичев, Шапкин, 1995). During the socialist period, the word "*predprenimaltelstvo* is mentioned as a forbidden activity. The only word that Lenin kept is "cooperative." Today, *preprenimatel*, *kommersant*, and *kantor* are used, but *kantor* has got now a popular meaning. The entrepreneur as a *predprenimatel* defines a legal statute. The English words "businessman" and "business" are widely used, especially for successful enterprises. Today, these words are universal in every language.

Conclusion and Future Directions

The etymology of the word "entrepreneur" is very rewarding. This brief etymological study shows that the entrepreneur is a social actor who has got an important role to play. By his capacity to invent, he has got the power to change his economic environment. But, the etymological study shows also the rise of an individualist behavior. To become an entrepreneur is a way of self-enrichment.

In France or in England, the entrepreneur as a social actor appears within the sixteenth to seventeenth century, with the emergence of individualism and the economic and geographical expansion of Europe, which became the first economic power at that time. Thus, European economic models have speeded toward other countries. Yet, a deeper research is needed in order to study more in detail the etymology of the word entrepreneur and its influence on our today's vocabulary.

Acknowledgments Authors want to express their sincere thanks to Guillem Achermann, Zeting Liu, and Nejla Yacoub for their precious help in the preparation of this work.

Synonyms

Innovative entrepreneur; Innovative entrepreneurship; Innovator

Introduction

In the current so-called knowledge economy, innovation is considered as the engine of economic growth (Romer 1990; Aghion and Howitt 1998; Audretsch 2006). During the second part of the twentieth century, the big firm was considered as being at the origin of innovation (thanks to its ability to gather large amounts of resources). However, since the 1980s, the entrepreneur has made his/her comeback on the forefront on the economic and political scene. What is the exact role of the entrepreneur, and how does he/she succeed in the innovation process, which still – and perhaps, because of its rapid pace, more than ever – requires the gathering of large amounts of money, competencies, and information? To answer this question, the work of several economists is studied, mainly J. A. Schumpeter is one (1883–1950), who can be considered as a precursor in the analysis of entrepreneurship linked to the innovation process.

The entrepreneur is the one who disturbs the neoclassical equilibrium by executing new combinations in the means of production (Schumpeter 1911/2006), who puts the economy on the path of motion and development (Schumpeter 1939), but he/she is also the one who, by his/her extinction, accounts for the self-destruction of capitalism (Schumpeter 1942/1976). The entrepreneur, the first hero of economists according to Schumpeter, is incontestably Schumpeter's own hero. But the hero is an elusive one: being an entrepreneur is not a profession but a function according to Schumpeter, and thus entrepreneurs have a butterfly-like existence.

What is the origin of the entrepreneur's function? Is entrepreneurship a natural gift, as J. A. Schumpeter seems to believe? Why does the entrepreneur's function disappear and is not a long-lasting one? It is important to develop an approach combining economics and sociology in order to go deeper into the analysis of the social origin of the entrepreneur's function, studying the construction of his/her "resource potential," that is, the set of knowledge, relations, and financial resources gathered together by the entrepreneur in his/her environment. This resource potential is not stable and may be increased or reduced in different economic, political, and social contexts. However, this entry does not try to define the exact ingredients of a "good" public policy for entrepreneurship. As a matter of fact, since J.M. Keynes on the one hand and also the work of the economists of the public choice school, economists have learnt that the impacts of public policies are not always the expected results (Keynes 1933; Buchanan and Tullock 1962). This entry aims to insist on the entrepreneur's socioeconomic background. Notwithstanding his/her own qualities (smartness, ability to judge), the entrepreneur is here considered as a social actor, influenced by the social, economic, and political context. The analysis in terms of "resource potential" aims at going deeper in the explanation of what turns the potential entrepreneur into the real one.

The first part of this entry comes back to socioeconomic and historical analysis of the entrepreneur's function, showing that this character is concurrently the driving force of capitalism, as well as the reason for the evolutionist character and the questionable self-destruction of this economic system. The second part points out the origins of the entrepreneur's function and develops an analysis of the resource potential in relation to a network approach, which is fed but also differentiated from current – or more ancient – approaches in terms of social capital. The proposed formalization in terms of "organic square of entrepreneurship" is thus an attempt to explain the temporary character of the entrepreneur's function. It also supports the thesis according to which today's entrepreneur can be sketched as a socialized entrepreneur (a network-based entrepreneur) at the interplay between the strategies of states and big firms.

Business Creation and the Dynamics of Capitalism

J. A. Schumpeter (1883–1950) is not the first economist to draw attention to the entrepreneur. Richard Cantillon (1680–1733), Jean-Baptiste Say (1767–1832), Karl Marx (1818–1883), or Alfred Marshall (1842–1924) made important contributions to the economic analysis of this character (Boutillier and Uzunidis 1995, 1999, 2006). However, J. A. Schumpeter's approach is original in that he/she formalized the entrepreneur's function in relation to the dynamics of capitalism (Uzunidis 2004, 2006a).

The Entrepreneur: The Driving Force of Capitalism?

First of all, the entrepreneur, as viewed by J. A. Schumpeter (1911/2006), is the one who questions the economic *status quo* prevailing in the neoclassical vision. As a matter of fact, for neoclassical economists, and especially their leader Léon Walras (1834–1910), the basic model is the one of pure and perfect competition. Competition is the only way the market can operate. In this context, there exist neither big firms nor small firms, but only firms of similar size (assumption of market atomicity). Firms are and will remain firms of similar size, which accounts for the absence of technical progress. The economy duplicates itself indefinitely. For L. Walras, the industrial entrepreneur "buys textiles and raw materials, rents factories, workshops, machinery and tools, hires spinners, blacksmiths and mechanics" (Walras 1874/1988, p. 287). The Walrasian entrepreneur does not innovate. He buys or rents services or raw materials or other input required by production. He selects according to the price of production factors (interest rate for capital, wage rate for labor).

The Schumpeterian entrepreneur questions the economic status quo because he/she is the economic agent that makes new combinations of production factors, corresponding to as many investment opportunities. He is the driving force of the capitalist economy. He embodies the dynamics of capitalist change as well as industrial and technological progress. There are five such combinations:

- The introduction of a new good – that is, one with which consumers are not yet familiar – or of a new quality of a good
- The introduction of a new method of production, that is, one not yet tested by experience in the branch of the manufacture concerned, which need by no means be founded upon

a discovery scientifically new, and can also exist in a new way of handling a commodity commercially

- The opening of a new market, that is, a market into which the particular branch of manufacture of the country in question has not previously entered, whether or not this market has existed before
- The conquest of a new source of supply of raw materials or half-manufactured goods, again irrespective of whether this source already exists or whether it has first to be created
- The carrying out of the new organization of any industry, like the creation of a monopoly position (e.g., through trustification) or the breaking up of a monopoly position (Schumpeter 1911/2006, p. 66)

According to Schumpeter, to be an entrepreneur is neither a profession nor a long-lasting state. On the contrary, to be an entrepreneur is a "function." This is the second characteristic of the Schumpeterian entrepreneur: "the entrepreneur's function is to combine the productive factors, to bring them together" (Schumpeter 1911/2006, p. 76). The entrepreneur is then very different from the common vision of the manager who manages the day-to-day production: "everyone is an entrepreneur only when he/she actually 'carries out new combinations', and loses that character as soon as he/she has built up his/her business, when he/she settles down to running it as other people run their businesses" (Schumpeter 1911/2006, p. 78). To be an entrepreneur does not mean automatically to have a long-lasting relation with an individual concern, as stressed by J.-B. Say or A. Marshall in their own words.

For J.-B. Say, (Say 1828/1996), the entrepreneur stands between the executing work of the worker and the research work of the scientist ("L'entrepreneur met à profit les facultés les plus élevées et les plus humbles de l'humanité. Il reçoit les directions du savant et les transmet à l'ouvrier," J.-B. Say, *Cours*, Atenéo, 1843, Chap. VI, p.96). As a result, there is a distinction between three kinds of industrial operations: the research by the scientist, the application by the entrepreneur, and the execution by the worker. However, according to Say, the entrepreneur may at the same time lead research, apply the results to industry, and by himself/herself manufacture what will be sold. In his/her *Principles of Political Economy*, Alfred Marshall (1842–1924) defines the entrepreneur as putting forward his/her managerial skills, his/her faculty to know how to organize the work of an important number of people. His function is to manage the production in a way that a given effort may have the most important effect to satisfy human needs (Marshall 1906).

The entrepreneur can then have various profiles: he/she can either be independent or an employee of a public company, or he/she can also have no durable relation with an individual business. As a result, J. A. Schumpeter has a particular view of the connection between entrepreneur, risk, and profit. One of the meanings of the verb "to risk" being "to attempt," to "undertake," entrepreneur and risk are directly linked, as shown by the history of the economic thought referring to the entrepreneur (Boutillier and Uzunidis 1995, 1999; Blaug 1998; Laperche 2003). The first main issues refer to the nature of the entrepreneur's remuneration. Then, as the dissociation between the entrepreneur and the capitalist becomes clearer, economists will be interested in the entrepreneur's function and the associated risks.

In the classical economic thinking, and particularly in Adam Smith's works (1723–1790), the economic agents that are the entrepreneur and the capitalist are often confused, as well as the financial risk and the undertaking risk. Before Adam Smith, Richard Cantillon, (see Cantillon 1997) who is, according to Schumpeter (1954/1983, t. II, p.242), the first economist to use the term "entrepreneur," the entrepreneur's remuneration is a fair remuneration of the incurred risk. According to him, entrepreneurs (the term is used, taking account of the period, to qualify merchants) are "people with uncertain revenues" because their revenues depend on the risk they take in a context of uncertainty. Their function consists in acquiring means of production at certain prices with the purpose to sell at uncertain prices. For Schumpeter, the entrepreneur's role does not only consist in taking economic risks. The terms "entrepreneur" and "capitalist" are not synonymous. The ordinary shareholder is not always an entrepreneur. The capitalist is only an owner of money, debts, or goods.

J.-B. Say, in the context of industrialization, and Schumpeter, when the movement of capital concentration gains ground, give substance to the notion of risk as they particularly focus on the entrepreneur's function. For these two authors, even if they express it differently, the undertaking risk is the risk linked to innovation. This point of view was also the one of Ricardo and Marx, who considered that industrial gains were composed, for a part, of the remuneration they receive, for a time, from the first introduction, in the economic process, of an original improvement, for example, a new machine. They have thus discovered, according to Schumpeter, a special case of the most typical gain of the entrepreneur, Schumpeter (1954/1983, t.II, pp. 361–362). However, while J.-B. Say and A. Marshall – who also draw attention to the organizational and productive function of the entrepreneur – tried to justify the profits of the entrepreneur, Schumpeter asserts that profit is not the entrepreneur's first motivation. His behavior is similar to the one of a gambler. The entrepreneur is prompted by a desire for power. The joy to win and to create prevails in the intrinsic lure of gain. Profit crowns the success of the "new combinations." This is the expression of the value of the entrepreneur's contribution to production in the same way as the wage is the reflection of the worker's production.

Finally, apart from these psychological characteristics of the entrepreneur, Schumpeter insists a lot on the capacity of this entrepreneur to overcome the banker's resistance, the latter feeling an aversion for risk linked to innovation. According to Schumpeter, the existence of the entrepreneur is not sufficient to put the economy on the path of evolution. The potential entrepreneur needs access to money, that is, the admission ticket to participate in the game: "The requisite funds – his/her admission ticket to the social store of means of production – he/she borrows from a bank" (Schumpeter 1939, Vol.1, p.131; see also Ulgen 1996). In *Capitalism, Socialism and Democracy*, Schumpeter will explain that credit is at the origin of development, saying that it is the source from which one can draw to finance the execution of new combinations.

Entrepreneur, Innovation, and Progress

In *Business Cycles* (1939), J. A. Schumpeter analyzes the cyclical process of evolution of the economy. This one stems from the business spirit, the entrepreneur's activity, and the introduction of radical innovations.

Innovation, in the broad sense of the word, is, for Schumpeter, the only origin of competitiveness, the determining element of accumulation. It is also at the origin of disequilibrium and imperfections. Schumpeter extends the marginalist theory (but then questions it) and cleverly explains, thanks to the concept of innovation, the emergence of profit differentials at a given time in a given economy driven by pure and perfect competition as well as the evolution of the economic activity.

Consequently, the role of innovation – and thus of the extraordinary person, the entrepreneur – is essential to the explanation of economic cycles (Uzunidis 1996, 2006b). According to Schumpeter, since only the most enterprising and venturesome people act, innovation appears in "swarms." These innovations induce a rise in the demand for capital goods, a decrease in production costs, and an increase in the number of goods supplied. The increased capacity on the supply side is associated to a boom in demand, stemming from the new consumption needs, the positive anticipations of economic agents, and the development of bank loans. The ensuing rise in profits puts the economy on an ascending trajectory. This stage of prosperity, after the stimulating effect of radical innovation, is prolonged by minor innovations. The boom, however, limits itself, as, paradoxically, innovation contributes to downsizing. Investment and excessive optimism during the years of strong growth may explain the cycle shift: losses, bankruptcies, and job-cuts, etc. The crisis will last as long as there exist production capacities in excess. When adjustment to the innovations is complete, deflation ends and the Walrasian equilibrium is restored. This thorough cleanup of the economy releases the business spirit so that a new innovation wave may occur. This refers to J. A. Schumpeter's "creative destruction" process which "is the essential fact about capitalism. It is what capitalism consists in and what every capitalist concern has got to live in" (Schumpeter 1942/1976, p. 83).

According to Schumpeter, but also to Marx, (see for ex. Marx (1976)) technical progress results in the increase in the production scale, the development of the limited company: the limited company supplies capitalism with the necessary capital for the development of the big industry. The entrepreneur disappears when the big firm emerges (resting on the partition of organizational work and production work, which is basic to automation), managed by a double-headed team, the managers, and the shareholders (partition between management and ownership of capital): "Technological progress is increasingly becoming the business of teams of trained specialists who turn out what is required and make it work in predictable ways" (Schumpeter 1942/1976, p. 132).

The entrepreneur, who was the driving force of capitalism in the heroic age, has been replaced by a team of specialists whose essential task is innovation. So, capitalism becomes impersonal, and the organization has replaced the individual. J. A. Schumpeter thus shares with K. Marx the concept of self-destruction of capitalism. In *Capitalism, Socialism and Democracy*, J. A. Schumpeter explains that capitalism has made technical progress its *raison d'être*: "capitalism, then, is by nature a form or method of economic change and not only never is but never can by stationary" (1942/1976, p. 82). Is not the entrepreneur the driving force of capitalism just because he/she innovates, thus continuously creating new investment opportunities?

K. Marx writes: "the actual barrier to capitalist production is capital itself" (p. 244, book III). "Capitalist production generates its own negation which conditions the transformations of nature. It is the negation of the negation" (p. 557, book I). J. A. Schumpeter writes: "that those factors make not only for the destruction of the capitalist but for the emergence of a socialist civilization. They all point in that direction. The capitalist process not only destroys its own institutional framework but it also creates the conditions for another" (Schumpeter 1942/1976, p. 162). K. Marx and J. A. Schumpeter share the idea of self-destruction of capitalism, that self-destruction being paradoxically caused by its success. For the latter, the development of shareholders will have destabilizing effects on the future of capitalism, thus joining A. Smith (Smith 1776/2002), for whom the development of joint-stock companies is incompatible with the development of business, as the private appropriation feeling is absent. It is dissolved in the multiple ownership of capital. For J. A. Schumpeter, the occurrence of collective private property destroys initiative and the will to enrich oneself which are the cornerstones of capitalism. The spirit of enterprise vanishes, and the firm is no longer a place of economic opportunities, nor a place of professional and personal fulfillment, all that being replaced by a bureaucratic organization. "The capitalist process, by substituting a mere parcel of shares for the walls of and the machines in a factory, takes the life out of the idea of property. It loosens the grip that once was so strong – the grip in the sense of the legal right and the actual ability to do as one pleases with one's own; the grip also in the sense that the holder of the title loses the will to fight, economically, physically, politically, for 'his/her' factory and his/her control over it, to die if necessary on its steps" (Schumpeter 1942/1976, p. 142).

Networks and the Socialized Entrepreneur

However, in this early twenty-first century, not only capitalism has not disappeared, but its power on the global society is reinforced. Big multinational firms, TNCs, dominate the world economy, while myriads of small firms are born, grow, and die on a regular basis, thus composing a kind of stock from which capitalism finds its means of development. "The age of the Entrepreneur is like Camelot: it is only here for a brief, shining moment each (roughly) half century," says in this vein, Ray Canterbury (2001, p. 423).

Therefore, the domination of big firms is not incompatible with the maintenance of large numbers of small firms. Quite the opposite! The strong economic growth that came after WWII had provided Western Europe and the United States with safe and stable markets. After the trauma of the 1929 crisis, which had paved the way for war and dictatorship, all-out state intervention had become necessary (support of supply and demand). The economic crisis starting in the 70s questions many certainties. The industries and activities on which economic growth was based have reached maturity. The information and communication technologies (ICTs) generated by military programs represent new investment opportunities. Therefore, it is necessary to release the capital which has been frozen by nationalizations. This is done by the financial revolution. The limited company has a free hand. It develops through venture capital and pension funds. This is the way "new capitalism" sees the light. The division of labor has become more complex within and between firms. Firms communicate in real time and all over the world on the Internet. Financial markets have expanded on a global scale. The gap between capital management and property has become wider. It matters little whether the ownership of capital is collective; what is important is the individual possession of the profits capital generates.

The economic history of the last 30 years confirms this observation: domination by big firms and survival of myriads of small companies. The theory of corporate governance (even if it reverses the balance of power between managers and shareholders) is based on that concept of bureaucracy and collective organization. However, how can one account for the economists' craze for the entrepreneur? Has the latter become the driving force of capitalism (again)? Is (entrepreneurial) capitalism the end result of human evolution, as F. Fukuyama says (1993)?

There are diverse reasons for the entrepreneur's comeback in the economic theory. Among the main ones (see Boutillier 2006):

1. *The slow-down in economic growth and the persistence of massive unemployment*. The formation of new firms is perceived as a way of creating wealth (and boosting technological innovation), but also of creating employment. The establishment of new firms is perceived by political leaders as a social integration facilitator.
2. *The decrease in government social spending, the privatization and deregulation of the economy*. Facilitating the formation of companies is less costly to public budget than granting unemployed people a substitute income.
3. *The occurrence of ICTs, all being new investment opportunities*. Small firms (often affiliated with big firms through financial relations) test those new fields.
4. *The development of financial flows (following the liberalization of the economic forces and markets)* offers new financial instruments which both feed and weaken the economic growth due to their high instability.

The big firms, which control global markets, are led by organizations, and not by one individual who can easily be identified: the entrepreneur and founder. The firm is led by managers on behalf of its shareholders (the owners of the firm), as John Kenneth Galbraith already explained in the late 1960s (Galbraith 1967). Apparently, the development of financial markets since the early 1980s has restored part of their lost power to the shareholders, as these now get rid of unsatisfactory managers. However, despite the questioning of the vertical integration of big firms in favor of a network structure (made possible by the development of ICTs), big firms are still the global market organizing entities. "Corporate power lies with management – a bureaucracy in control of its task and its compensation," writes J. K. Galbraith in his/her last book published in 2004 (Galbraith 2004, p. 31; see also the analysis of this debate in Laperche 2005; Laperche et al. 2005, 2006). Since the 1960s, he/she has not departed by a hair's breadth from his/her position. The development of corporate bureaucracy has not resulted in the disappearance of capitalism, or the entrepreneur. The latter even receives assiduous care from the political leaders who have crowned him/her as a creator of innovation and employment, as well as the champion of social integration.

The following assumption may be proposed: the entrepreneur has not disappeared, but he/she is no longer a hero. Thus, he/she has become a socialized entrepreneur, an entrepreneur who is a player in the economy made up of (a) the planning decisions made by big firms which, even if networked, nevertheless are powerful bureaucracies, and (b) the states' policies which aim at reducing unemployment and boosting innovation in the developing knowledge economy. This is the new capitalism of the early twenty-first century!

Faced with the complexity of the today's economic activity, M. Castels (1996, 1997, 1998) went as far as to maintain, quite cleverly, that the fundamental unit of the economic system is no longer the entrepreneur itself, the family, the firm, or the state, but the network composed of different organizations. Regarding innovation, the division of labor and the very refined specialization of skills in the process of production remove any possibility of autarkical organization of the technological production. Partnerships between companies and between public and not-for-profit institutions, on the one hand, and companies on the other hand, and a whole panel of technical, financial, and commercial contributions, illustrate the theories of the classical economists (e.g., A. Smith and K. Marx). For them, as fast as the industry takes over the social production (and enlarges its market by appropriating the resources at the time), technical transformations can be witnessed, as well as core changes in the organization of the production and in the matter that the entrepreneur makes business. The entrepreneur is not a *deus ex machina* who puts the economy on the path of motion. The following part comes back to and explains the economic and social origins of the entrepreneur's function, thanks to a discussion of the profile of the entrepreneur considered as an economic player in the contemporary network-based economy.

The Entrepreneur's Resource Potential and Entrepreneurial Dynamics

The Resource Potential: The Origin of the Entrepreneur's Function

The concept of "resource potential" gives the possibility to assess the role played by the social origin, the educational background, the professional experience, and the financing sources of entrants (Boutillier and Uzunidis 2004; Boutillier et al. 2004).

Entrepreneur's "Resource Potential," Innovation and Networks, Table 1 The entrepreneur's resource potential: elements of definition

Resource potential	Main characteristics
Knowledge	Tacit knowledge obtained from the family
	Scientific and technical knowledge learned at school
	Knowledge obtained through relations
	Knowledge obtained through professional experience
Financial resources	Personal savings
	Love money: parents, friends, etc.
	Bank loan
	Financial aid from institutions (e.g., public aids)
	Seed money from another entrepreneur
Relations	Informal relations (family, friends, neighborhood, colleagues, etc.)
	Formal relations (State, banks, other enterprise, research institutes, etc.)

Source: Authors

Each individual owns a set of resources and uses his or her potential to improve their economic situation (to find a job with a good salary, to create an enterprise, to find another professional activity, etc.), and their choices also depend on their own resources. The resource potential is not a natural gift, but it is the product of a social process, of the opportunities and constraints implied by this process. What are the entrepreneurs' social origins? What did they study? Who were their parents? Were they entrepreneurs? Employees? Civil servants? What are their relations?

The resource potential can be analyzed in three parts: (1) knowledge (schooling, secondary education, higher education, further education, and professional experience, etc.); (2) financial resources (personal savings, bank loans, venture capital, and different forms of public support); (3) relations (family, personal, professional, institutional relations, etc.) (Table 1).

These three parts are interdependent. For example, the knowledge of an individual depends on his/her education and/or professional experience. And the family context (cf. Casson 1990) positively or negatively influences the educational choices. Many entrepreneurs were born to families of entrepreneurs. While studying, the individual meets new persons, who can become partners and bring knowledge, money, and relations. Making up a substantial address book is fundamental because it facilitates the search for money, markets and associates, etc.

Schumpeter considered that the entrepreneur's function was the result of a kind of not explained ability, and that his/her success was due to his/her competencies and also to a bit of luck: "in most cases the man who rises first *into* the business class and then *within* it is also an able businessman and he/she is likely to rise exactly as far as his/her ability goes – simply because in that schema rising to a position and doing well in it generally is not or was one and the same thing" (1942/1976, p. 74).

So, this approach goes deeper into the analysis of the origin of the entrepreneur's function, trying to add to the notion of "ability" a social dimension, notably when he/she spoke of the qualities of the entrepreneur and, first of all, his/her ability to convince the banker. Of course, according to him, the successful entrepreneur is the one who has the banker's support. This is perhaps part of his/her explanation of the entrepreneur's gift. Moreover, if Schumpeter focused in priority on the entrepreneur's ability to raise funds, this ability can be considered as part of a multidimensional ability in which knowledge and relations also have an important role to play. This approach of the resource potential is fed but also differentiated from the current (or more ancient) approaches in terms of social capital, as presented below.

The Theoretical Roots of the "Resource Potential": An Economic Approach to Social Capital

The concept of social capital officially appeared in human sciences at the beginning of the 1980s. P. Bourdieu (1980) is one of its main originators. His aim was to go deeper into the analysis of social relations. At the beginning of the 1960s, G. Becker (1975) defined the concept of "human capital," considering that all individuals own their knowledge and that they can take the decision to invest in their human capital to increase their merchant value on the labor market. With the concept of social capital, social relations become valuable resources (Boutillier 2005). The concept of social capital is the foundation of the concept of resource potential. However, in the economic and sociological literature, social capital is most often defined as a set of social relations. One may consider that social relations are only part of the resources that individuals can invest in to find a job, start a business, etc.

Capitalizing One's Own Knowledge

At the beginning of the 1960s, the concept of human capital became essential, in the theory as well as in economic facts. Enterprises and notably big ones needed more and more skilled employees due to the development of the service industry and the clearer separation between design and manufacturing, the affirmation of full employment, the development of the educational system, the continuous technical progress, and the resulting automation of industrial work.

This theoretical breakthrough was fundamentally initiated by G. Becker in the 1960s. A. Smith did precede him/her in this analysis, putting a lot of emphasis on the necessary development of education. But the true precursors of "human capital" are certainly T. W. Schulz (1959) and E. F. Denison (1962). The quality of human resources, the investment in education, the information of individuals, and knowledge are production factors. G. Becker's human capital is different from physical capital or financial capital because the knowledge and the know-how acquired by an individual during his/her training are embedded in him. The employer can take advantage of this knowledge if the employee keeps on working in his/her enterprise. Employers do not have a property right on their employees.

However, the human capital is a capital and, as such, the theory of capital can be applied to it, adapting it and putting forward some specific properties: human capital can be accumulated. All individuals may increase the number of years dedicated to its formation, normally through a quasi indefinite process. Marginal returns of investment in education are decreasing: along the life cycle, the accumulation of human capital follows a decreasing trend. As years go by, economic agents dedicate less time to training, all the more so as job perspectives become less numerous. The human capital return decreases with age: the integration of human capital in the individual limits his/her investment capacity. He is dependent on his/her physical and intellectual capacities. Moreover, an individual may accumulate human capital, without any positive result (added value on the labor market); human capital is both a private and a public good as an educated population is also more productive (cf. GDP growth, Lucas 1988).

The theory of human capital therefore presents similarities with the one of capital. The individual invests in himself, as the capitalist invests in his/her enterprise: the first one is incorporated in the individual, but the capital remains exterior to the entrepreneur who invests it. The law of decreasing marginal returns applies to human and physical capital alike.

Capitalizing One's Social Relations

Since the early 1990s, various works have been conducted by American sociologists (R. Putman, J. Coleman) in this direction. Social relations are considered a resource which can be capitalized by individuals. In order to improve their economic welfare, individuals use their social relations which are regarded as an individual and a collective good. According to those authors, the characteristics of social capital are similar to those of physical capital: decreasing returns, decreasing marginal productivity, etc.

P. Bourdieu (Bourdieu and Wacquant 1992) defined the concept of social capital in an analysis of social stratification. Differences in terms of revenues are not the only criterion of differentiation between social classes. For equal revenues, social behaviors and notably cultural ones can be very different. This social capital is a means to gain access to jobs, funding, etc., and the individuals belonging to dominant social classes are those who benefit from a wide network of social relations. P. Bourdieu defines social capital as the sum of actual or potential resources which are linked to the more or less institutionalized network of inter-acquaintance and inter-recognition relations possessed by an individual. Every individual is endowed with a social capital, but the latter is not a natural gift but the result of a strategy. Consciously or not, individuals invest to increase their social capital, this one depending on other forms of capital: economic capital, cultural, and symbolic one. A high economic or cultural capital facilitates the formation of a social capital. And a high social capital is also a means to increase the economic capital of individuals.

Long before P. Bourdieu, other sociologists drew attention to the potential wealth that constitutes a network of social relations. M. Weber (1905/1964) showed the link there was in the USA at the beginning of the twentieth century between the adherence to a religious community and success in business. In 1963, S. Macaulay (1963) published the result of a study conducted in the USA on transactions between firms, which are very often agreed without contracts or in inaccurate legal conditions. Entrepreneurs are often reluctant to formalities which may question trust. For American sociologists who studied the concept at the end of the 1980s, social capital can also be considered as a network of various relations, enabling the individual to improve his/her social insertion. Subtle links between social capital and human capital are also established.

The issue of social capital is only apparently simple (Gasse et al. 2004). It is, as a matter of fact, possible to find as many definitions as there are authors who draw attention to it. J. Coleman (1988, 1990) describes the social capital as a resource incorporated in interindividual relations. The resources drawn from social capital are privately appropriated and have certain similarities with externalities generated by the functioning of the market. Social capital is productive, just as human capital, and contributes to the increase of welfare. R. Putnam (2000) defines social capital as the network and reciprocal norms which are associated to it. Social capital has a given value for the individuals who are part of the network. R. Burt (1995) stressed the role of social networks in the evolution of carriers, studying the promotion of executives in a big technological firm.

International institutions, OECD and the World Bank, for example, were quickly convinced of the interest of social capital in order to improve public policies efficiency. OECD

(OCDE 2001) credits social capital with a major part in the increase of social welfare, considering three forms of capital linked by institutional arrangements: natural and product capital, human capital, and social capital. For the World Bank, social capital is also a means to fight against poverty in order to fill the gap created by the absence of institutions. Social capital is also a social support to informal economic relations, which depends on subtle relations of mutual trust and solidarity. In terms of public policies, the translation lies in the development of the associative sector (World Bank 2000).

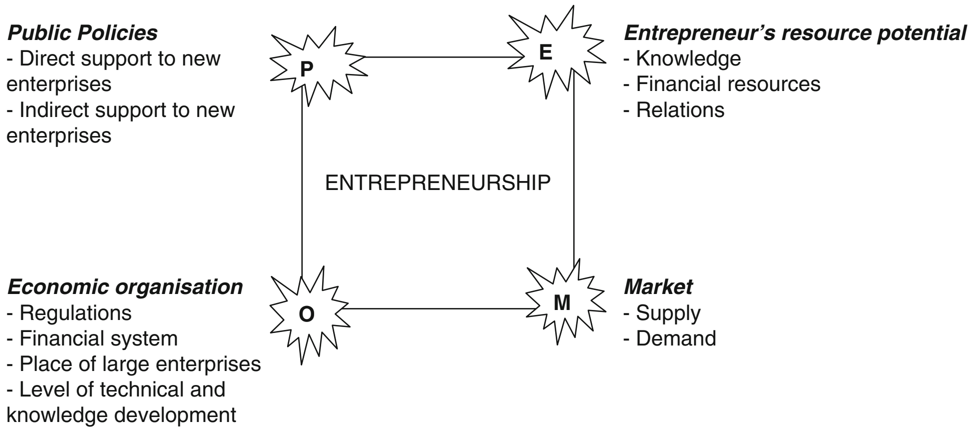
The concept of social capital also has certain similarities with the one of network, which was also introduced in social and human sciences in the 1990s. The image of the network as a sum of computer connections has lead many researchers to develop a metaphoric analysis (Castells 2001). Moreover, this kind of approach is interesting in that it takes account of the historical dimension. Merchant, political, and financial networks have always existed, but they have taken a new dimension with technical progress. This approach is not compatible with methodological individualism. The network is not seen as an appropriable good, capitalized by its members. The approach in terms of network is considered as a method to study the world's evolutions. The network is also used in different contexts, as, for example, the analysis of social cohesion, intermediary level between micro and macro. The accent is on the interpersonal links used to explain macro sociological phenomena (Granovetter 1973, 1985).

In a nutshell, those approaches in terms of human capital and social capital are interesting in that they question the pure rationality of individuals, putting them right in the middle of society (notably the role of family and state are clear) or in the "strategic group" (Porter 1982) they have chosen. In the management literature, the role of social relations and of networks is more and more used to explain the entrepreneurs' success (Sammut 1998; Davidsson and Honig 2003; Suire 2004; Marchesnay 2004; Chabaud and Ngijol 2005). But these approaches seem too simplistic because they remain largely focused on the individual, with very few references to the economic, social, and political context in which he/she acts. This analysis based on the "resource potential" can thus be considered as a further step in the social analysis of the requisites for an individual's success – more precisely the entrepreneur – or of the explanation of his/her failure.

The Organic Square of Entrepreneurship and the Network-Based Entrepreneur's Function

The resource potential is not a natural gift and is built by a conscious (or unconscious) strategy, linked to the economic, political, and social context in which the entrepreneur operates. Moreover, this potential is not stable. It can be increased, as explained by the above-mentioned American sociologist, but it can also decrease in some special cases or contexts. For example, a bankruptcy in Europe is very badly perceived and may be a case of drastic reduction in the resource potential; in another context, it may not change anything or even be regarded as an entrepreneurial attempt, which has to be followed by other attempts. In the same vein, public policies may help to increase an entrepreneur's resource potential or cause its decrease (support to business creation, taxes in connection with the creation of the enterprise, etc.). The economic network-based organization (regulations, financial system, locations of large enterprises, level of technical and knowledge development) and the market (supply and demand) may have the same positive and negative results on the resource potential of the entrepreneur and more globally on entrepreneurship. The formalization in the terms "organic square of entrepreneurship" is thus an attempt to explain why the entrepreneur's function is not a long-lasting and stable one. Being an entrepreneur is not a profession but a function which stops when the entrepreneur does not innovate anymore: the social, economic, and political context may cause the appearance or the disappearance of the entrepreneur.

First of all, the economic context is characterized by change. Change is created by the activity of entrepreneurs, and major change comes in a context of crisis. Change also creates new investment opportunities (creation of new needs thus causing an increase in demand, and so on).



Entrepreneur's "Resource Potential," Innovation and Networks, Fig. 1 The four extremities of the diagram represent the relationship between the Entrepreneur's resource potential (formed by its financial capital, cognitive and social), the market (inputs and outputs of the business), public policies to promote entrepreneurship and organization of the economic sector (regulation, barriers to entry, presence of large companies, etc.). These relationships define entrepreneurial capacity (entrepreneurship) in a given sector, a region or a country. (Source: Authors' own conceptualization)

The economic situation is thus fundamental to the emergence of the entrepreneurial function. Secondly, as mentioned earlier, even if the entrepreneur is a kind of *deus ex machina*, he/she also has some competencies, and notably the one to convince the banker and thus to raise funds. The financial resources are thus taken into account. More globally, the level of development of the financial system (and more precisely the banking system) is therefore very important to explain the entrepreneur's existence and success. Thirdly, institutional change (which characterizes the economic organization in the following scheme) is at the origin of the extinction or the revival of the entrepreneur's function. The aim here is to formalize the elements of the economic social and political context which may explain why the entrepreneur's function is not a stable one.

As a matter of fact, the entrepreneur's dynamism and qualities cannot explain per se the creation and success of small enterprises. This is the reason why a more systematic analysis of the key factors of entrepreneurship (or the network-based entrepreneur's function) – high tech or not – in today's economy may be proposed. Four major factors affect this: public policies, economic and social organization (the importance of large corporations, the nature of the financial system, and the level of development of knowledge), and the state of supply and demand which contribute to the building of the resource potential. The interdependence between these factors allows to analyze them through an "organic square of entrepreneurship" (Fig. 1).

The Organic Square of Entrepreneurship

What is the rationale of the "organic paradigm of entrepreneurship" and how to explain the choice of the incentive factors proposed here? To answer these questions, it is necessary to focus on the key factors of success of small businesses. S. Shane (2003), for example, makes a synthesis between the Schumpeterian entrepreneur (who is an innovator) and Kirzner's entrepreneur (who has to be well informed to catch the market opportunities) (Kirzner 1973, 1985). S. Shane defines the relevant environmental factors (institutional, political, and sociocultural) which may help the entrepreneur to innovate. However, he/she does not make reference to the entrepreneur's own resource potential. Many other studies conducted by specialists in management sciences have demonstrated that the creation and durability of small enterprises depend on the entrepreneur's ability to take into account the existing links between different internal factors (organization, financial resources, activity) and external ones (the different levels of the environment) (Sammut 1998; Marchesnay 2003). In this case, the approach is more centered on the individual. This analysis thus links the two approaches, focused on the entrepreneur and on the environmental factors.

This entrepreneurial "maturity" results firstly from the variety and abundance of the resource potential which they have built. The composition of this potential depends on external factors and on the entrant himself/herself. In particular, public support (direct or indirect) to the creation of new enterprises usually determines the financial resources entrepreneurs can have access to in order to set up or develop their business. The economic and social organization has several dimensions and different effects. The general level of development of knowledge influences the knowledge gathered by entrepreneurs (through their education and that of their staff through economic intelligence) and the technological level of their activity. The characteristics of the financial system (possibility or difficulty in being listed on the stock exchange, more or less "conservative" banks, and the access to venture capital) have an impact on the capacity of the individual to become an entrepreneur and on the development of new businesses. Market concentration and the place of large companies also influence the dynamism of entrepreneurial activities and the kind of activity they have. Finally, the overall economic situation determines the rhythm of new creations and also the types of activities conducted by such businesses (see Boutillier et al. 2004).

It is in this organic square of entrepreneurship that the entrepreneur's function lies. This is a temporary function because it stems from the gathering at one moment of some special conditions. According to the context, it is also possible to examine different types of entrepreneurs, which have different resource potentials – for example, high-tech entrepreneurs or low-tech ones for another part. This approach thus permits to go deeper into the analysis of the entrepreneur, no more as a disembodied agent but a social agent, in all its complexity.

Conclusion and Future Directions

To conclude, explaining the origin (resource potential) and the conditions of appearance of entrepreneurs (organic square of entrepreneurship or network-based entrepreneur's function) is all the more important as the entrepreneur has not disappeared, contrary to Schumpeter's prediction. He is on the contrary in the forefront of the economic scene. The entrepreneur is also in the heart of the political debate, his/her existence and durability (as an economic act and not as a function) being considered as the reason for economic growth. However, as explained above, the entrepreneur is no longer a hero. He has become a socialized entrepreneur, an entrepreneur who is a player in an economy made up of, on the one hand, the planning decisions made by big firms which, even if networked, nevertheless are powerful bureaucracies and, on the other hand, the state's policies to reduce unemployment and boost innovation and competitiveness.

The socialized entrepreneur in today's economy is an important force in the renewal of economic activity based on knowledge, information, finance, and industrial concentration. The innovative entrepreneur appears in innovation, knowledge, and finance-based networks built by large companies and specialized institutions. The debates on the networks focus as much on the flexibility, as on the increase in the firm's capacity to appropriate a large quantity of resources without investing in their formation. The large firm has turned into a center of formation and flexible coordination of partnerships but also of generating entrepreneurial opportunities. Coordination and innovation processes, both flexible and evolutionary, impose on the firm the pressing need to be provided with the different types of technological and intellectual means to acquire and combine uninterrupted flows of material and immaterial resources (see for ex. Howitt 1996). Complex networks associate large firms, start-ups, universities, public and private research, funding institutions, consultancy, and specialized business services, etc. dedicated to the innovation process. The importance taken by networks in economics reveals the necessity for collaboration, which is due to the complexity, the cost, and the risk of the innovation process. The growing burden on financial investment for the organization of productive activities implies cooperation between firms and institutions to facilitate continuous, "permanent" development of profitable new goods and services. It thus explains the renewal of the entrepreneur's function (notably spin-offs and outsourcing) as well as the invention of new organizational and interorganizational modes (alliances, partnerships, networks, clusters) (see Laperche et al. 2008).

The knowledge-based economy requires further research on the characteristics of the new entrepreneurs: the ability to adapt and the efficiency of the entrepreneur's capability depend on his/her cognitive categories, on the interpretation codes of the information itself, on the tacit skills and his/her procedures in solving the problems it encounters, and on his/her capacity to integrate innovation networks.

Schumpeter, focusing on the entrepreneur, considered as a *deus ex machina*, did not take enough account of the economic, political, and social context which may generate the entrepreneurial function. He did not see how far the entrepreneur was a social agent and even sometimes a political construction, sometimes aiming at repairing the system's failures and extending its life. Today, the approach developed here aims at better explaining it (when applied to the economic facts with socio-economic inquiries on entrepreneurial profiles), the innovative entrepreneur is replaced by a more pragmatic entrepreneur, whose main motivation lies in the acquisition of a revenue, which does not always mean his/her personal enrichment. Even if the conventional (in the sense of Galbraith) perception of the entrepreneur remains the one of a hero, the one who can easily, thanks to his/her natural gifts, become Rockefeller or Bill Gates, one may also consider how this myth is an "innocent fraud."

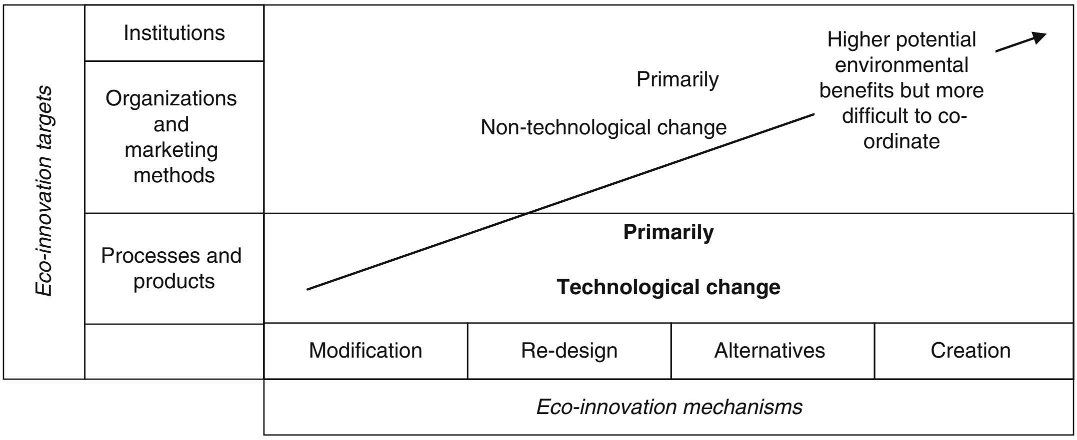
Capabilities to change firm's trajectory; Entrepreneurship and innovation; Innovation in green technology

The implementation of a sustainable mode of development has become a major aim of public policies in industrial countries, and the evolution of economic agents' behaviors (producers and consumers) is considered as the engine of this "new economy." Enterprises are thus induced to develop socially responsible behaviors, that is to say, to integrate social and environmental concerns into their business operations and in their interactions with their stakeholders on a voluntary basis. For firms, the entrepreneurial behavior that consists in the development of green innovation or eco-innovation resorts to this necessity to develop responsible behaviors. But the question for many firms (as well as for institutions and scholars) remains: how should the firm change its trajectory and thus develop an eco-innovation strategy?

Responsible Behavior and Entrepreneurial Behavior

If ethics was the first reason invoked by the tenants *of a social responsibility of enterprises*, the literatures on corporate social responsibility and on the objectives of the firm put forward two main reasons for developing responsible behaviors. The first one is related to the constraints that the external pressure from stakeholders such as employees, shareholders, customers, suppliers, the State, and the civil society puts on the firm. The second one is the opportunity for the firm adopting a responsible behavior to improve its economic results. Thus, developing a responsible behavior would be a "win-win" strategy first because it is more respectful toward the environment and the society and also because it is a profitable strategy. In order to improve its economic results in a global competition based on innovation as it is today, a firm needs to constantly develop and renew its products, processes, and organization. Innovation, whatever its forms, thus appears as the best solution to conciliate the idea of social responsibility with the necessity to make profits.

It is therefore possible to see a connection between responsible behavior and entrepreneurial behavior, for entrepreneurial behavior is also tightly linked to innovation, defined in the sense of Schumpeter. According to him, entrepreneurship is an economic function, which takes the form of a new product delivered through a new process, implementing a new organization, opening a new market... Entrepreneurial behavior, defined here by the innovation act, may be observed when an innovative firm is created as well as when an innovative project is implemented within an existing firm. From the enterprise point of view, the current equation of sustainable development therefore takes the following shape:



Entrepreneurial Behavior and Eco-Innovation, Fig. 1 Typology of eco-innovation (Source: OECD (2009))

"Corporate social responsibility + entrepreneurial behavior = eco-innovation."

But what does eco-innovation precisely mean?

A Definition of Eco-Innovation

"Green innovations," "eco-technologies," or "eco-innovations" have been so far mainly defined by political agendas; therefore, an economic definition that could be shared by scholars is still missing. In this entry, we retain the definition of eco-innovation provided by the OECD (2009), which adds two characteristics to the definition of innovation offered by the Oslo Manual: its explicit emphasis on the reduction of environmental impact and the fact that eco-innovation is not limited to products, processes, marketing, and organizational methods but also integrates innovation with social and institutional aspects.

This definition is therefore a broad one which includes products and processes forms of innovation. It also emphasizes the social and institutional changes involved in eco-innovation. The OECD (2009) offers a typology of eco-innovations based on targets, mechanisms, and impacts of eco-innovations (Fig. 1). Eco-innovation targets are products and processes, organizations and institutions. Four mechanisms – in other words the method by which change in the eco-innovation target takes place or is introduced – are identified: modification – small, progressive product and process adjustments; redesign – significant changes; alternatives – for example, introduction of goods and services that can fulfill the same functional needs and operate as substitutes for other products; and creation – design and introduction of entirely new products, processes, procedures, organizations, and institutions. The impacts define the effects of eco-innovation on the environment.

If social responsibility is not restricted to the development of technological innovation (new products and processes implemented on markets), it is one of the most visible ways to develop a responsible behavior. As a matter of fact, it is, for example, easier to communicate on a new ecological product or process than on, say, better working conditions which mostly concern the company's employees and not the consumers and potentially all the society. Green innovation or eco-innovation enhances the company image/reputation which may impact the profitability of the innovation process.

As also shown by the OECD (2009), firms thus largely focus on technological forms of eco-innovation, even if they also consider nontechnological changes, which may be organizational and institutional. The example of the automotive sector is interesting. While developing electric or hybrid cars, firms are more and more interested in offering a "service of travel," that is to say renting cars notably in urban areas. This is a good example as it implies to change the business model and thus the firm's organization as well as social norms and cultural values about using a car (which also resorts to institutional change).

Eco-innovation may be at the center of the new venture's business model, but it may be a new project in an existing firm. In the second case on which we focus here, the development of eco-innovation implies a change in the firm's trajectory. The issue of change at the firm level needs to be mobilized in order to understand the ability to change their technological trajectory in order to develop eco-innovation.

The Roles of Dynamic Capabilities in Trajectory Change

The evolutionary theory – particularly initiated by Nelson and Winter 1982 – tends to understand novelty and interpret change, by taking into account the environment and the history within which systems evolve. In those approaches, the evolution and objectives of firms are defined through the processes of learning and coordination, according to procedures of trial and error (search), which should lead to satisfactory results. The adoption of procedural rationality reflects the importance of uncertainty in which organizations operate and interact. According to the evolutionist approach, the evolution of the firm's trajectory depends on and results in a learning process that creates specific assets and new capabilities.

The learning process is a process by which repetition and experimentation lead to the fact that, over time, tasks are done in a better and faster manner and new opportunities in the procedures are constantly being tested. That process generates the production of cumulative knowledge materializing in organizational routines defined as models of interactions that are effective solutions to specific problems. They form an "organizational memory" embedded in the skills of workers and machinery. Those tacit routines are clusters of specific resources/assets and are not easily transferable. The firm operates along a path determined by the expertise accumulated through learning. Thus, specific assets determine the evolution or trajectory path of the firm. The path dependence precisely expresses that evolution of the firm, constrained by past investments. Even if accumulated skills can enhance the competitive advantage of the firm, they may also constitute a kind of trap, but the evolution of the firm is not necessarily gradual and does not exclude ruptures and bifurcations. The core or complementary assets present along the value chain can give the firm the possibility to change direction. The evolutionary theory of the firm can therefore help us comprehend the endogenous transformation of the firm over time.

The literature on innovation management (evolutionist theories and more globally resource-based theories) emphasizes the role of capabilities. The capabilities to develop and renew the specific resources and assets gathered into organizational routines are named "dynamic capabilities" by Teece et al. (1997). They refer to "the firm's ability to integrate, build and reconfigure internal and external competences to address rapidly changing environment" (Teece et al. (1997), p. 516). There are various kinds of dynamic as, for example, the dynamic capabilities to generate new ideas, to change the firm's projects, to develop new scientific and technical knowledge so as to change the knowledge base of the firm, to change the ways of launching new products, etc. All those dynamic capabilities are important in the trajectory change towards eco-innovation. However, the development of new scientific and technical knowledge aimed to change the knowledge base of the firm can be considered as a starting point.

According to us, the learning process and the building of immaterial specific assets gathering internal and external resources are achieved by and lead to the construction of what we call the firm's knowledge capital. "Knowledge capital" is defined as the set of information, knowledge, and know-how produced, acquired, combined, and systematized by the enterprise in order to create value. The building and the renewal of the knowledge capital appears as a tool to build new technological capabilities and thus to facilitate the change in the firm's trajectory. As a matter of fact, the knowledge capital of a firm refers to the way the enterprise acquires and collects information on markets, produces knowledge alone or/and in collaboration, transforms it into knowledge, routines, and know-how which are a source of specific advantages, and uses that knowledge and information in a process of value creation.

Technological capabilities and technological success are not considered today as the results of the firms' own resources but are the outcome of complex processes of collaboration and cooperation. Cooperation, collaboration, open innovation strategies, and scientific and technological networks are nowadays key words in the literature. The mutation of the firm's trajectory is expensive and risky. That is why, it reinforces the trend toward the collaborative creation of knowledge capital (or open innovation strategy), which is confirmed in the recent literature and involves various sectors, automotive to the pharmacy or even to chemistry, etc.

Firms collaborate with partners all along the supply chain: on basic research with universities and other research centers, on applied research and product development with other firms (suppliers, customers, start-ups, and sometimes competitors)... Collaboration is a way to reduce the cost (by sharing it) of development of new knowledge; it also gives the possibility to access to very specific knowledge. Collaboration has become a key word of innovation management and thus can be considered as a main feature of entrepreneurial behavior. And the role of collaboration is once more emphasized when one focuses on eco-innovation.

Collaboration as a Key Capability for Eco-Innovation

If we look more closely at the literature on eco-innovation, the role of capabilities and of collaboration is also put forward. To change the firm's trajectory toward eco-innovation, the creation of new dynamic capabilities is necessary. Lin et al. (2011) define green business innovation capabilities (GCICs) as "a green business innovation process wherein firms explicitly undertake capabilities to achieve higher green performance as well as commercial performance" (Lin et al. 2011, p. 1840). In their aim to evaluate GBICs at the firm level, they develop a framework made of 7 aspects – and 25 evaluation criteria – including the definition of a green technological innovation strategy, the attitudes of workers toward change in their work routines, the ability of the firm to formulate green innovative projects, the development and protection of green knowledge, the communication capability, the ability to work with external partners, and the management of business innovation. The development of new knowledge and the place of collaboration are clearly emphasized. Moreover, on the basis of a review of literature, Van Kleef and Roome (2007) compare the capabilities needed to develop innovation oriented toward competitiveness and those needed to develop innovation oriented toward sustainability. They show that these capabilities largely overlap, which is not surprising (as mentioned by the authors) as competitiveness is one part of the larger concept of sustainability. However, they put forward the importance given in the literature on green innovation to the communication and collaboration "with very diverse and culturally unfamiliar (and or local) networks of actors, on integrating their diverse perspective, criteria and information processing and decision styles" (Van Kleef and Roome 2007, p. 45).

From what precedes the development of collaboration reveals itself very important for different reasons:

- The sharing of knowledge and thus the risks and the cost of innovation in a context of economic uncertainty
- The necessity to comply with the different stakeholders' aims implied in eco-innovation strategies

To sum up, we can state that to be responsible, firms have to develop entrepreneurial behavior, that is to say, to innovate and more precisely to eco-innovate. Implementing eco-innovation often implies a change in the firm's trajectory, which can be achieved through the development of new dynamic capabilities. The constitution and renewal of the knowledge capital is the central tool for creating these capabilities. In this analysis, the ability to collaborate is emphasized for two reasons, one traditionally linked to the management of the innovation process (reduction of costs and risks, access to new knowledge) and one that is linked to the responsible behavior that characterizes eco-innovation (the various stakeholders implied in the eco-innovation process).

However, if we have here highlighted an important characteristic of entrepreneurial behavior in the context of eco-innovation, we should not forget that change is a difficult process. Can the eco-entrepreneur or the eco-enterprise succeed on its own?

The Costs of Change: How to Help Entrepreneurs to Eco-innovate?

Despite a growing awareness of the negative impacts of fossil fuel use and related technologies, attempts to shift toward cleaner substitutes are still proving difficult. On the one hand, that is because hydrocarbon technologies have benefited from advantages resulting from increasing returns to adoption and economies of scale that make them cheaper, performing, and user-friendly. On the other hand, green techs that fail to win early adoption success have been locked out from the market, unable to compete with the improved technology because of increasing returns. Moreover, in a context of crisis, the purchasing power of the population may decrease which do not stimulate the demand for new green products. Firms try by themselves through standards and marketing strategies to impose their products to "create" the demand and thus control the markets, but they do not make it all due to the cost, difficulties, and unproved profitability of eco-innovation (Laperche and Levratto 2012).

If we focus on the development of new scientific and technical resources and capabilities, the cost of change toward eco-innovation is also reinforced by the very important expenditures that are needed not only to develop product innovations but also to encompass new services and the activity's new organization. Despite the pooling of costs and risks and the acceleration of the innovation process enabled by collaborative research and development, the amounts of expenditures necessary to develop new products, processes, and services are still difficult to afford by the collaborating firms, especially in a context of economic recession.

Moreover, the shared costs implied by collaborative research do not exclude the existence of hidden costs that may increase the overall costs of change. Transaction costs (Williamson 1975) may be related to the finding to the appropriate partner (e.g., an academic laboratory working on the same subject), to the negotiation of the contract (sharing of knowledge and related intellectual property rights problems), and to the contract monitoring (risk of coopetition, intellectual property rights conflicts). These costs of change cannot be all overcome by the managerial capabilities of communication and diffusion of information. Institutional support is needed to reduce – if not overcome – this kind of costs. In France, for example, from the mid-2000s, in response to decisions made at European level in the Lisbon Strategy in 2000 and reaffirmed in 2008 to improve the competitiveness of enterprises, governments have become more involved in active support to the "technology transfer between public research and socioeconomic actors." Different devices, which are intended to support the constitution and promote the reorientation of knowledge capital in the future technologies have been introduced or improved: improvement of the Research Tax Credit (RTC), project financing via the ANR (National Research Agency), and European R&D programs as well as the French cluster policy named "Pôles de compétitivité" (2004).

Conclusion and Future Directions

Eco-innovation is now considered as a central element of industrial firms' strategies. To face the crisis and to position themselves on niches of the markets with high growth potential but also to satisfy the demand of various stakeholders, firms refocus their strategy and their organization toward the development of green products (goods and services) which imply organizational – but also many institutional – changes. At the firm's level and dealing with technological change, we have emphasized the role of the development of new dynamic capabilities. The capabilities to collaborate with various partners for the building and reorientation of the knowledge capital are central. As a matter of fact, in eco-innovation strategies, collaboration is a way to share the costs and risks of technological development and thus is a crucial vector of change of the firm's trajectory. It is also a way to comply with the aims and objectives of the various stakeholders implied in sustainable strategies of innovation. However, collaboration does not always reduce the cost of innovation since transaction costs may be the counterparts of the building of complex innovation networks. Institutional intervention (arrangements, laws, R&D and industrial programs, supply and demand incentives) is thus necessary to help firms overcome these hidden costs.

The Field and Practice of Entrepreneurship

As a subject of scientific and social inquiry, entrepreneurship studies cut across numerous disciplines: economics, behavioral and cognitive sciences, sociology, law, management, and organization sciences. Placed within a multidisciplinary canvas, recent academic research focuses on a wide array of determinants and predictors of economic performance, technological innovation, and human and social capital growth. Among numerous research foci, the question of sources of entrepreneurial capability and leadership is of paramount importance to both scholars and policy makers. It is particularly important to distinguish between individual creativity that characterizes inspirational entrepreneurs and the capabilities that result from collective action and organizational competences and know-how. Consequently, entrepreneurial capability can be defined as a distinct set of individual and organizational capabilities and skills as well as actions, practices, and routines that aim to explore, integrate, and exploit untapped business opportunities within an instituted market context. Placed within a broader canvas, entrepreneurial capability represents the multiple facets of individual and collective initiatives that encompass different forms of social and economic innovation and renewal strategies. Different forms of entrepreneurship (e.g., individual, corporate, social, and institutional) respond to a wide array of strategic, organizational, and environmental contingencies. While entrepreneurial capability is a necessary condition for creating economic wealth, entrepreneurial leadership constitutes an essential characteristic of the individuals who build and sustain human and social capital.

Theories of Entrepreneurship and Entrepreneurial Activity

Entrepreneurship has often been associated with individual and organizational creativity and viewed as a distinct ability to engage in new activities. Consequently, the questions of "who," "when," "how," and "for what purpose" should one engage in entrepreneurial activities addresses the need to identify the sources of opportunities, value identification, and wealth creation (Hitt et al. 2011; Ireland et al. 2003; Shane and Venkataraman 2000; Bamford 2005; Miles 2005). Building on a more expansive definition by Hitt et al. (2011, p. 59) that describes entrepreneurship as a "*context-specific social process through which individuals and teams create wealth by bringing together unique packages of resources to exploit marketplace opportunities*," we set out to demonstrate that the "resource–capability" frontier portrays a multidimensional relationship between individual and organizational capabilities on the one hand and the institutional context and market stimuli on the other (see section "Entrepreneurs as Creators and Innovation Leaders"). As such, entrepreneurial capabilities and market instituted contexts play a pivotal role in creating economic value and developing social capital.

Classical economics referred to two categories of economic agents: wage-earner workers and capital-provider owners. Cantillon (1755), Smith (1776), and Say (2005) were among the first to provide a detailed description of entrepreneurial dynamics by analyzing the production and exchange mechanisms in conjunction with the theory of labor division and behavior. Ricardo (1817) made a clear distinction between farmers and laborers and the entrepreneur, whom he regarded as a rent-seeking capitalist. Ricardo defined rent as "*the portion of the produce of the earth, which is paid to the landlord for the use of the original and indestructible powers of the soil. It is often, however, confounded with the interest and profit of capital*" (Chap. II). Ricardo emphasized the source of value: "*value, then, essentially differs from riches, for value depends not on abundance, but on the difficulty or facility of production,. . .by the invention of machinery, by improvements in skill, by a better division of labour, or by the discovery of new markets, where more advantageous exchanges may be made, a million of men may produce double, or treble the amount of riches, ...; for everything rises or falls in value, in proportion to the facility or difficulty of producing it, or, in other words, in proportion to the quantity of labour employed on its production*" (1817, Chap. XX). Mill (1885) made a correlation between risk and return and opined that those who seek an indemnity for risk are to be considered as entrepreneurs rather than capitalists. Knight (1921) noted that a Walrassian perfectly competitive equilibrium could not hold if one had to assume that "entrepreneurs are not willing to take risks when facing market uncertainty unless they can expect a sufficient reward."

The Austrian economic school provided an alternative explication, in line with the general equilibrium postulate and the evolutionary market perspective. Hayek (1945) emphasized the importance of information and knowledge in individual and social decision-making processes and pointed to the causal links between individuals' microdecisions and the broader social choices. Despite information biases, markets provide considerable benefits to entrepreneurs as they seek to decipher complex price, investment, and trade options. Entrepreneurs are prepared and willing to optimize their risk-bearing choices as long as they can exert full control over their economic options. Schumpeter (1934, 1949) addressed the market equilibrium conundrum by stating that, under the assumptions of "general market equilibrium" there would be no room for any reward, rent, or profit for the risk-taking entrepreneurs. He went on to criticize the neoclassical economic theory on the ground that innovation required market knowledge and organizational capacities that go beyond simple managerial functions and skills. Von Mises (1949) referred to the dynamic essence of entrepreneurhsip in capitalist economies, while Kirzner (1973) pointed to the unique ability of entrepreneurial minds that can spot weak market signals, thrive in fields of uncertainty, and take bold leaps of faith to create the future.

Among many critiques of classical economists, Veblen (1904) offered a alternative perspective of the true motivations of profit-seeking industry barons of the early twentieth century. He extolled the American businessmen and capitalists, scorned financial titans, and seemed comforted by the idea that engineers and productive machines would ultimately replace unethical capitalists who sought to retain the lion share of profits.

Neoclassical analysis, on the other hand, postulated that economic agents act rationnall as they seek to maximize their utiliy and markets would ultimately tend toward wage and profit equilibrium. According to neoclassical economic theory, in perfectly competitive markets, firms enter the market as price-takers and their economic profits will be zero. Arrow (1951, 1962) and Alchian (1950) went into considerable length to explain how individuals used market information to make optimal social choices. In a similar vein, Baumol (1968, 1990), Baumol et al. (2007) sought to demystify the mediating role of entrepreneurs by offering an explanation for the market-induced mechanisms that lead to innovation. Landes et al. (2012) provide a detailed account of the evolution of the firm and the prevalence of entrepreneurship as a guiding principle of the economics of innovation and growth. The market economy spawns the seeds of competition by rewarding entrepreneurial audacity even though at times entrepreneurs' bold initiatives may sound foolish, experimental, and prototypical. According to Penrose (1959), there is ample evidence to indicate that the growth of innovative firms stem from a concerted effort of a particular group of individuals with superior capabilities. The endogenous growth model, conceptualized and elaborated by Solow (1956) and Romer (1990), has shed further light on how the utilization of certain variables such as human capital, investment in R&D, and knowledge-intensive inputs can place the firm on a higher innovation and growth trajectory.

Entrepreneurial capability testifies to individual and organizational creativity and is closely associated with the ability to lead in an increasingly knowledge-driven economy. Whereas motivation, creative thinking, and skills foster good entrepreneurship, efficacious managerial practices, good judgment and vision are required for sustaining entrepreneurial success (Amabile 1998). The exercise of good judgment in making decisions is a critical feature of entrepreneurial function in an increasingly informational economy (Casson 1982, 2001). Entrepreneurs have the capacity to calculate financial risks, allocate resources to new ventures, and create new-to-the-market value. Whereas individuals and small firms may show a high degree of resiliency in the face of changing markets, large firms may fail as their past successes can actually become obstacles to new market challenges (Christensen 1997). By seizing and pursuing opportunities, entrepreneurs engage the society on a path to economic prosperity and social progress (Fukuyama 1996).

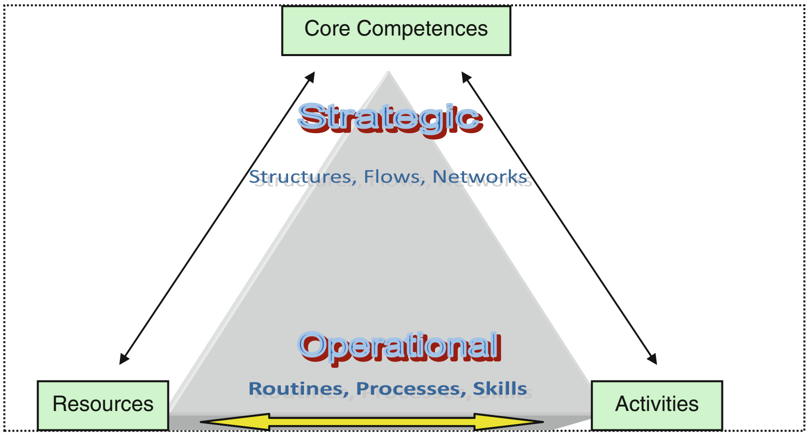
Opportunities, Resources, and Capabilities

Modern firms are characterized by a complex web of interactions among the various stakeholders whose decisions and actions shape the firm's innovation and renewal trajectory. Faced with unequal opportunities and steep competition costs, entrepreneurial firms seek to reconfigure their resources, reorchestrate their activities, and build new core competences throughout different growth stages. As complex organizations, modern firms seek to integrate and exploit new stocks of knowledge and acquire dynamic capacities in an effort to enhance their organizational and operational capabilities (Dooley and Van de Ven 1999). Dynamic capacity can be defined as an ability to integrate new competences and to reconfigure resources in response to changes in the business environment (Teece et al. 1997; Teece 2007; Helfat et al. 2007). Technological and organizational complements, such knowledge; individual and organizational skills; and the innovation structures, processes, and networks, constitute the main cornerstones of a firm's organizational capacities.

A significant research corpus has underscored the linkage between the firm's resource base, core competences and competitive advantage (Prahalad and Hammel 1990; Porter 1990; Barney 1991; Christensen 2001). The proponents of a resource-based perspective have brought to much scrutiny the nature of strategic resources that are used to create combinative and dynamic capabilities within an organization (Wernerfelt 1984; Kogut and Zander 1992; Teece and Pisano 1994; Augier and Teece 2006). The knowledge-based view of the firm (KBV) extends the resource-based view (RBV) by treating knowledge as a generic resource, and by emphasizing the importance of knowledge exploration, integration, and exploitation in building and sustaining organizational capacities. More specifically, the resource-based view treats knowledge as a generic resource (Brown and Duguid 1991; Grant 1996; Zack 2003). As such, knowledge may be categorized as "tacit," "explicit," "autonomous," and "systematic" (Teece 1998) or "core," "advanced," and "innovative" (Zack 1999). Whereas autonomous knowledge yields value without major modification of systems in which it has to be embedded, systematic knowledge requires modification to other subsystems (Teece 1998, p. 64). Unlike the codified form of knowledge, such as formulas and blueprints, tacit knowledge is difficult to articulate and transmit and may thus be subjected to errors of interpretation (Truch 2004; Greiner et al. 2007). By engaging in innovative ventures, entrepreneurs act as knowledge transformers and as agents of social innovation who instill creative thinking and disseminate knowledge skills. Corporations tend to use systematic knowledge and skills to acquire new market competences (Rogers 1983; von Hippel 1988). The competence-based view (CBV) of the firm places a particular emphasis on a broad array of individual and organizational skills as a foundation for knowledge creation and dissemination (Nonaka and Konno 1994; Nonaka and Takeuchi 1995).

Cohen and Levinthal (1990) have shed further light on the pivotal role of knowledge acquisition and assimilation as a mechanism for acquiring the capabilities that are needed to solve complex problems. In an effort to conceptualize the concept of absorptive capacity (ACAP), Zahra and George (2002) have identified two subsets by which firms acquire, assimilate, transform, and exploit knowledge. Knowledge "acquisition" refers to an externally generated knowledge, and knowledge "assimilation" points to the process of knowledge appropriation. Acquisition and assimilation activities enable a firm to achieve a potential capacity (PACAP), while transformation and exploitation tasks lead to a realized capacity (RACAP) (Zahra et George, pp. 190–91). The latter will improve a firm's feedback routines and augment organizational capabilities. Defined as a measure of organizational capability, absorptive capacity tends to increase with incremental use of information technology across the firm's boundary (Lane and Lubatkin 1998). It is noteworthy that changes in systematic knowledge imply technological discontinuities that lead to a different pattern of knowledge accumulation and utilization (Dosi et al. 2002). This is particularly the case of high-tech and information-driven industries such as biotechnologies (Mazzucato and Dosi 2006). According to Chandler (1977), roughly one half of the economic expansion during the 1840–1940 period resulted from improvements of organizational architecture rather than technological innovation.

Figure 1 illustrates the dynamic links between resources, activities, and core competences of the firm. Both strategic options and choices and operational architecture and activities need to be taken into account when assessing entrepreneurial capabilities. At the strategic level, structures, dynamic inter- and intra-firm flows, and network relationships need to assessed, designed, and



Entrepreneurial Capability and Leadership, Fig. 1 Building entrepreneurial capabilities (Source: S. Alijani)

implemented with a view on operational efficacy. Entrepreneurial capabilities have a direct bearing on the scale and scope of operations, the firm's organization, as well as its strategic positioning. Core competences can be sustained by reconfiguring the firm's resources and reorchestrating its activities.

In technologically advanced fields, firms carry out complex activities with a view on accelerating innovation and shifting their core activities toward knowledge-centric opportunities. Knowledge-intensive activities tend to focus primarily on building product and market innovation capabilities. The development of networks has spawned new knowledge-intensive collaborative modes and open innovation platforms among firms. By intensifying formal and informal relationships such as research partnerships and knowledge alliances and by setting up ambidextrous business units (Tushman and O'Reilly 1996), knowledge-intensive corporations tend to lower their transaction costs (Coase 1960, 1990; Williamson 1979). Williamson (1985) refers to the economic institutions of capitalism as increasingly complex organizations that must face comparative costs of planning, adapting, and monitoring task completion under alternative governance structures. Networks draw immense benefits from the pooling of research activities that facilitate cooperation across virtual business networks.

Central to the notion of entrepreneurial capability is the quintessential question of how institutional factors can affect entrepreneurial capabilities. North (1990) sheds further light on the formal and informal constraints and the impact of institutions on the firm's growth trajectory.

Entrepreneurs as Social Innovators

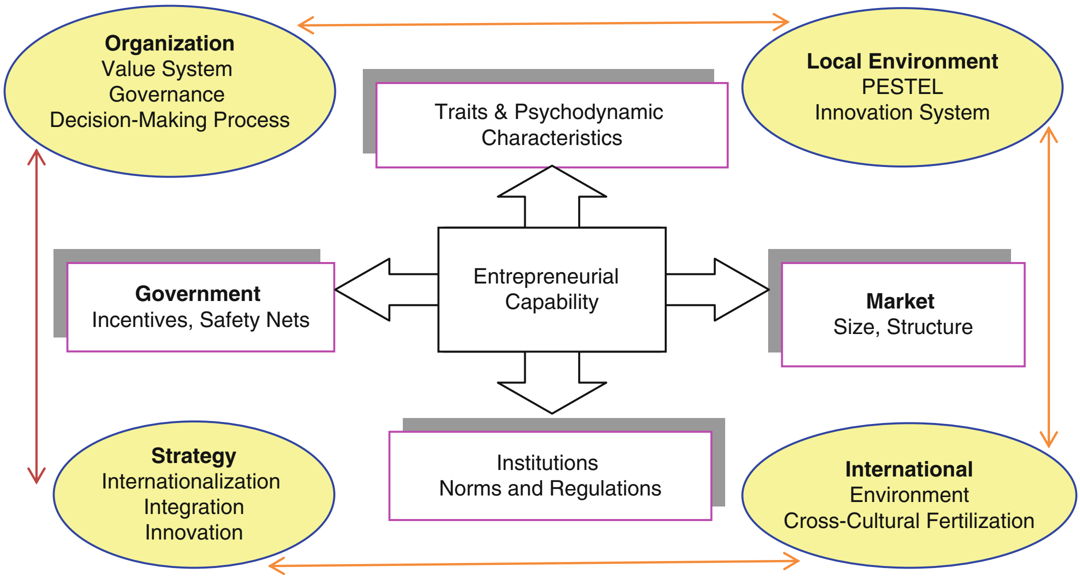
The entrepreneurial society is characterized by institutions, organizations, and individuals whose choices and collective action enable the society to effectively participate in creating and sharing value. The sheer generation of economic wealth may not be conducive to social justice. Yet, the absence of social and economic rights diminishes individual and social capacity to generate wealth. In Nicomachean Ethics Aristotle (2012) makes a clear reference to financial wealth where he avers "… wealth is evidently not the good we are seeking; for it is merely useful and for the sake of something else…" (1980, Book 1). The absence of political freedom leads to social and economic deprivations and shrinks the social space for free exchange of ideas and opportunities. While political deprivations bar citizens from making optimal social choices, justice and democracy provide the stimuli for cognizant and socially valuable initiatives. Sen (2009) endorses the idea of justice and considers that individual capability is directly linked to freedom "*…as it gives a central role to a person's actual ability to do the different things that she values doing*" (2009, p. 253). Consequently, the capability approach underscores the shift to opportunities and not the resources individuals and societies may possess. Sen's definition of capability and description of factors that lead to its deprivation are congruent with an entrepreneurial society that transforms economic wealth to social capability and blends individual capabilities to build social capital (Sen 2000, 2009).

Most studies point to key economic and social factors that affect such entrepreneurial and social capabilities. These studies emphasize the multiple links between capabilities and policies, in particular government support programs in favor of social justice, gender equality, education, and institutional building (OCED 2009). Good institutions instill the rule of law, institute and protect intellectual property rights, design effective social safety nets, and empower and engage a wide array of social and economic actors. While the local economy can provide a viable space for entrepreneurial initiatives, international markets can stimulate entrepreneurial momentum and spirit beyond national borders.

Cognitive Capabilities and Decision-Making Heuristics

Entrepreneurial capabilities may be viewed across different complementary dimensions that take into account a wide array of endogenous and exogenous factors such as entrepreneurial cognition, individual and social biases toward entrepreneurial and market initiatives. The cognitive dimension of entrepreneurial initiatives focuses on entrepreneurs' traits and value systems. Similarly, the decision-making heuristics demonstrates why an entrepreneur may feel confident and when he/she seeks new opportunities and goals for greater economic and social rewards (Shaver and Scott 1991; Bernardo and Welch 2001).

A significant research corpus has scrutinized the use of mental representations and shortcuts when making decisions (Simon 1957; Tversky and Khaneman 1974; Shanteau 1989; Gigerenzer and Todd 1999; Baron 1998). Individuals, communities, and societies show biases toward risk, success, failure, reward, status, sacrifice, tenacity, moral strength, discipline, and conflict. Cognitive biases may emanate from overconfidence and overoptimism (Cooper et al. 1988; Khaneman and Lovallo 1993; Bernardo and Welch 2001), control and planning fallacy (Keh et al. 2002), mood and affect infusion (Forgas 1995), overestimation (Russo and Schoemaker 1992; Busenitz and Barney 1997), and perceived self-efficacy (Chen et al. 1998; Shane 2003; Bandura 1997; Gist and Mitchell 1992). Overconfidence and overoptimism may be associated with the way entrepreneurs construe and interpret the temporal (when), social (for whom), and distal (where) dimensions of risk. Likewise, individual decisions may be associated with creative thinking and an intrinsic motivation to do something for its own sake because it is enjoyable (Deci and Ryan 1985), or a counterfactual thinking and assumption of how things may be done differently (Gaglio and Katz 2001), thus affecting the process of decision-making and decisions' outcomes. The perceived mismatch between optimal versus potential gains and losses are indicative of differences in individual traits and perceptions. Critics to the traits approach argue that time is a critical factor in evaluating risk and hence suggest a model that takes into account a wider risk horizon when measuring the outcomes (Das and Teng 1997). A near future approach to an expected outcome may be associated with new ventures with higher risks, whereas a distant approach may result in a lower-level risk perception (Dickson and Giglierano 1986). The proponents of intention-based theories focus on individuals' attitudes and behaviors in conjunction with the expected outcomes and goals. Tversky and Kahneman (1973) have categorized decision-making heuristics in terms of "availability," the ease with which an event can be imagined, "representativeness," how closely an object may resemble its parent population, and "anchoring" that suggests a comparison with some initial reference point. As an extension to their earlier "prospect theory," Tversky and Khaneman (1992) suggest using the cumulative prospect theory with a combinatory approach to low and high gains and/or losses. The critiques of such mathematical modeling argue that probability boundaries may be blurred by misperceptions, fallacies, and judgmental attitudes. Baron (2000) puts forward the idea



Entrepreneurial Capability and Leadership, Fig. 2 Multidirectional flows and effects of entrepreneurial capabilities (Source: S. Alijani)

according to which entrepreneurs frame decisions in terms of the gains they fail to make if they miss an opportunity rather than the losses incurred by seizing a new opportunity. The notion of framing refers to the way a decision's outcome is perceived by the entrepreneur and is closely associated with what can be viewed as a prospect for potential gains or losses. For instance, a risk-bearing entrepreneur is likely to think in terms of profits made or gains missed rather than losses incurred, whereas a risk-averse individual may think in terms of losses to be expected. Reasoned Action (Fishbein and Ajzen 1975) and Planned Behavior (Ajzen 1991) theories argue that personal beliefs are affected by other people's attitudes, especially by those whose views matter the most to the entrepreneur. Misperceptions and misinterpretations as well as social and economic fallacies lead to decision biases that affect entrepreneurs adversely. Krueger (2000) emphasizes the pivotal role of organizations in triggering entrepreneurial decisions and initiatives since organizations have the capacity to define norms and improve members' perceived self-efficacy.

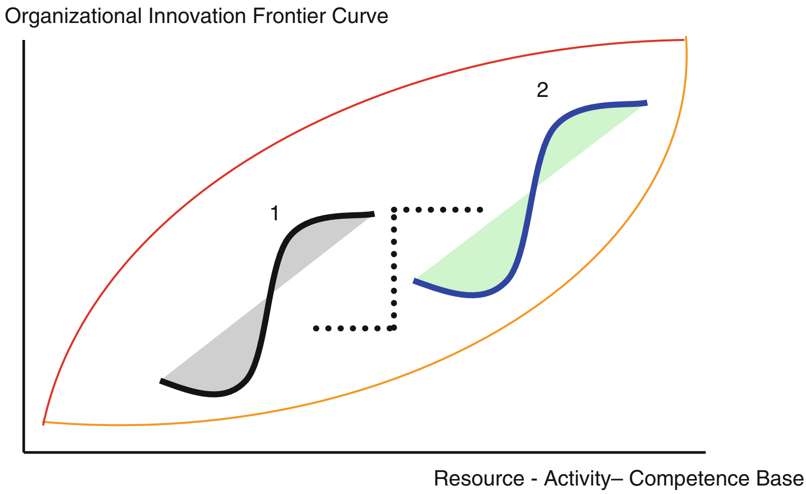
Faced with information asymmetry and uncertainty, entrepreneurs operate under conditions of bounded rationality every time they decide to create a new venture or move to a new market (Simon 1955, 1982). Since decisions can only be taken within the limits of one's cognitive capabilities – limitations of the human mind and the structure within which the mind operates – and since such decisions are subjected to a "time-space" constraint, entrepreneurs anticipate and respond to changes by considering different options, similar to what can be observed in efficient financial markets (McGrath 1999). In other words, entrepreneurs view new ventures as financial options whose success will depend on their distinct leadership qualities to face market contingencies. Figure 2 refers to a multidimensional model of entrepreneurial capability and points to four sets of determinants and factors that trigger entrepreneurial initiatives. Entrepreneurial capability may be observed to be associated with the psychodynamic characteristics of the individual, the firm's governance structure, market size and competitive structure as well as government support programs and institutional configurations, all of which determine strategic options and strategy-making modes (Mintzberg 1973, 1979). Factors such as exposure to international markets, integration and diversification intensity, government support programs (e.g., tax, investment, and export incentives), and property rights are among the factors that stimulate and bolster entrepreneurial initiatives and capabilities (Zahra and George 1991; Oviatt and McDougall 1999).

Entrepreneurs as Creators and Innovation Leaders

While creativity may be linked to one's emotions and psychodynamic characteristics, entrepreneurial capability is often associated with one's value system, leadership, and business ethics. Leardership measures the quality and extent of individual creativity as well as a distinct ability to engage in socially valuable and economically viable initiatives. The literature points to emotional intelligence as a criterion for leadership effectiveness (Antonakis et al. 2009; Goleman 1998; Mayer et al. 2008; Humphrey 2002; Walter et al. 2011). An emerging strand of research on neuroscience argues that leadership is shaped by one' coherence, a condition that can be attributed to coordinated brain activities measured by the degree of neural connectivity in the right frontal portions of the brain (Waldman et al. 2011; Camerer et al. 2005; Hines 1987).

Whatever the root causes of effective leadership – emotional intelligence, coherence, value systems, creativity, resilience, attention to minutiae, adaptation to change– effective leaders are likely to affect individual and collective perspectives by accelerating change and fostering innovation. This point can be further elucidated once placed within a historical perspective. For instance, the invention of the steam engine revolutionized the industry as it enabled entrepreneurs to use the new technology in their handcrafted activities and small fabrication industries. The second half of the nineteenth century heralded a heroic era of scientific entrepreneurship that was characterized by dazzling innovations in organizations and numerous industries. The transformation of the early steam engine and the emergence of a more robust combustion engine enabled engineers and entrepreneurs to turn their small-scale fabrication industries into mass production factories. The second half of the nineteenth and the early decades of the twentieth century were marked by a new breed of innovation-driven leaders who harvested the benefits of their investments in scientific and R&D activities. From early 1870s to late 1940s, a small number of local entrepreneurs succeeded in creating an impressive web of national and international ventures. The textile machine tool inventor, Eli Whitney, the pencil inventor and philosopher, Henry Thoreau, the prolific and multifaceted inventors of electricity and telephone, Thomas Edison and Graham Bell, the photography and computing machine visionaries, George Eastman, Herman Hollerith, and Thomas Watson are ranked among the most illustrious industry leaders and entrepreneurs who left an indelible imprint on the scientific and industrial foundation of their society. Thanks to their entrepreneurial initiatives and leadership qualities, market witnessed major technological breakthroughs and enjoyed numerous innovative products: photography (Kodak), computing and calculating machines (IBM), pharmacy and chemistry (DuPont), electricity and telephone (General Electric and Bell Laboratories), and automobile (General Motors and Ford corporation). Breakthrough embedded technologies gave birth to new ventures and entrepreneurial activities. The creation of Volta Laboratory by Alexander Graham Bell paved the way for a number of spin-offs in the telecommunication sector. Likewise, Henry Ford should be remembered as a visionary entrepreneur and industry leader who revolutionized the production organization by implementing new management practices and organizational innovation in the automobile industry. The advent of transformative technologies, such as semiconductors, microelectronics, and nanotechnologies in recent decades, has accelerated the pace of technological change. More importantly, knowledge-intensive firms have embraced the idea of acquiring new technologies and optimizing their value chains by sharing technical knowledge through open innovation platforms as a way to shorten the market-entry cycles (Chesbrough 2006, 2007).

Figure 3 illustrates the multiple linkages between a firm's "resource-activity" base and its "capability-competence" trajectory. The innovation-capability curve shows the incremental direction of growth resulting from the firm's continuous



Entrepreneurial Capability and Leadership, Fig. 3 Entrepreneurial capability trajectory (Source: S. Alijani)

effort to reconfigure its resources and reorchestrate its activities – in order to build new core competences. The "S"-shaped curve of innovation capability is indicative of the incremental nature of technology-competence diffusion dynamics, growing rapidly at initial stages and slowing down at later stages. The change can be measured through various organizational and financial indicators such as the revenues generated following the adoption of a new business model, the rate of return on assets resulting from new investments in R&D, or the productivity and profitability ratios resulting from new processes and implemented in the organization. Technical and organizational improvements will push the firm's innovation capability curve higher, thus creating feedback loops between individual and organizational capabilities.

The complementary nature of resources and the firms' dynamic capacities affects the pace and direction of the organizational innovation trajectory. Entrepreneurial creativity constitutes the cornerstone of organizational innovation and performance. Entrepreneurial efficacy requires leadership qualities, creativity, as well as a well-crafted global strategy.

Conclusion and Future Directions

Any attempt to assess entrepreneurial capabilities should begin by investigating the multidimensional flows and links resulting from individual, organizational, and market-constituted contexts. Such studies should provide a comparative framework for evaluating different forms of entrepreneurship. More importantly, future studies on entrepreneurial capabilities should encompass empirical and longitudinal research on market-instituted and organizational arrangements. The use of qualitative and quantitative data will allow to measure fully entrepreneurial performance and creativity across industries, cultures, and societies.

Opportunities: The Driver of Entrepreneurship?

Entrepreneurship is nurtured by a diversity of streams of thought, with different origins, and the approach of entrepreneurial opportunity aims to build a new inclusive paradigm, sometimes called *a general theory of entrepreneurship.* The entrepreneurial opportunity concept originates from Austrian Economics tradition (particularly Hayek, Kirzner, Schumpeter). Entrepreneurship is fundamentally a human activity, and the entrepreneurial opportunity paradigm focuses on the intentionality of human action and of entrepreneurial decision. Opportunity plays a fundamental role in allowing individuals to advance their goal pursuits. Shane and Venkataraman (2000) seminal paper lays the foundation for this renewal paradigm around the central notion of entrepreneurial opportunity.

Economists, psychologists, sociologists, and a range of more applied fields including strategic management and entrepreneurship are interested in this concept of entrepreneurial opportunity. While opportunity is an interdisciplinary topic which arises naturally wherever choices have to be made, thinking entrepreneurship in terms of opportunities – their discovery or creation, their evaluation, and their exploitation – is a challenge for scholars. In fact, important debates are crossing the field of entrepreneurial opportunities such as why, when, and how entrepreneurial opportunities come into existence, subjective or objective nature of entrepreneurial opportunities, reasons why some people discover and exploit opportunities and not others, modes of exploitation of entrepreneurial opportunities, etc.

But the common issue of the research on entrepreneurial opportunity is to highlight the process of change in a capitalist society and the driving force of entrepreneurship – in line with the Schumpeterian works – to understand how markets function and come into being, and, last but not least, to explain or predict empirical phenomena of entrepreneurship.

Notion of Entrepreneurial Opportunity

Entrepreneurship as Entrepreneurial Process

According to the entrepreneurial opportunity paradigm, the field of entrepreneurship concerns the study of *how, by whom, and with what effects opportunities to create future goods and services are discovered, evaluated, and exploited* (Shane and Venkataraman 2000). Here, entrepreneurship involves the nexus of two phenomena: the presence of lucrative opportunities and the presence of enterprising individuals (Venkataraman 1997). However, the only existence of opportunity is a necessary but no sufficient condition of entrepreneurial process. The entrepreneurial process rises in both the existence of opportunities and the ability of individuals to detect and appropriate these opportunities.

Entrepreneurial Opportunity

The definition of entrepreneurial opportunity is not totally stabilized. Some scholars refer to "those situations in which new goods, services, raw materials, and organizing methods can be introduced and sold at greater than their cost of production" (Casson 1982). Entrepreneurial opportunity leads to the discovery of new means-ends relationships through which new goods, services, raw materials, and organizing methods can be introduced in order to create economic value and move the economic system toward or away from equilibrium. So the development of an industry or the emergence of new organizations naturally leads to the creation of new opportunities. Other scholars consider that *"entrepreneurial opportunity consists of a set of ideas, beliefs and actions that enable the creation of future goods and services in the absence of current market for them"* (Sarasvathy et al. 2003). Anyway, entrepreneurial opportunities are mostly created by activities of human agents. Individuals may deliberately create opportunities, but often opportunities are the unintended outcomes of activities motivated by other objectives.

Individual-Opportunity Nexus

This framework of entrepreneurship is based on the nexus of the presence of lucrative opportunities and the presence of enterprising individuals (Venkataraman 1997). According to the individual-opportunity nexus (ION) approach, entrepreneurial opportunities emerge from market disequilibrium or, more specifically, from the differences people have in their expectations, beliefs, awareness, and/or knowledge about the relative value of resources. This approach considers that people have different beliefs because of a lucky hunch, superior intuition, private information, etc. Consequently, people make different conjectures about the price at which markets should clear, or about what possible new markets could be created in the future (Shane and Venkataraman 2000).

Key Issues Across Entrepreneurial Opportunity Field

Considering the three steps of entrepreneurial process, discovery or creation, evaluation, and exploitation of entrepreneurial opportunity, many questions remain. If Shane (2003) considers that entrepreneurial opportunity follows a linear process from discovery to exploitation, other scholars emphasize the overlap between discovery and exploitation. Others believe that opportunity does not preexist but is created along the way by interactions between acting individuals and their environment. This question echoes to the nature of entrepreneurial opportunity. Some researchers argue that the subjective or socially constructed nature of opportunities makes it impossible to separate opportunity from individuals. Others contend that opportunity is as an objective construct, visible to or created by the knowledgeable or attuned entrepreneur. Consequently public policy issues may be very different.

Origins of Entrepreneurial Opportunities

Where did these entrepreneurial opportunities come from? The question posed by Shane (2003) is why these situations emerge in which it is possible for a person to come up with a new means-ends framework for recombining resources? The literature offers traditionally two main different explanations for these situations, the Kirznerian perspective and the Schumpeterian perspective.

Firstly, according to Schumpeter view (1934), the existence of entrepreneurial opportunity is contingent on the introduction of new information – technological, political, social, or economical information. Entrepreneurs can use this information to understand how to recombine resources into more valuable forms. Consequently, Schumpeterian entrepreneur discovers and pursues opportunities that exist outside the economic sphere and that are not yet reflected by the price system (Schumpeterian entrepreneur).

Secondly, in Kirzner approach (1973), people use the information that they possess to form beliefs about the efficient use of resources.

The existence of opportunity is linked to a differential access to existing information. What is in balance here is not the existence of the opportunity but the individual capacity to capture it and to access it. Moreover, people make errors or omissions – at any time or in any place – and their decision-making framework is not always accurate. These errors generate disequilibrium and opportunities for other people that are able to identify them. So, Kirznerian entrepreneur discovers and pursues opportunities that exist within the economic sphere and that are reflected by the price system. These two types of opportunities have different effects on economic activity: Kirznerian opportunities reinforce established ways of doing things, whereas Schumpeterian opportunities disrupt the existing system (information asymmetry and business creation). Differences between Schumpeterian and Kirznerian approach of entrepreneurial opportunities may be summarized in this table.

	Schumpeterian opportunities	Kirznerian opportunities
Origins of entrepreneurial opportunities	Disequilibrating	Equilibrating
Role of information	Requires new information	Does not require new information
Innovative impacts of entrepreneurial opportunities	Very innovative, break away from existing knowledge	Less innovative, replicate existing organizational forms
Innovative intensity of entrepreneurial opportunities	Involves creation	Limited to discovery
Characteristics of entrepreneurial opportunities	Rare	Common

Adapted from Shane 2003, p. 21

More recently, according to the knowledge spillover theory of entrepreneurship, the divergence between individuals and hierarchies may also generate entrepreneurial opportunities. Divergence appears when new knowledge and ideas are created in one context but left not commercialized by the source of the idea. Namely, entrepreneurial opportunities are generated not just by investments in new knowledge and ideas but in the propensity for only a distinct subset of those opportunities to be fully pursued by incumbent firms. Indeed, a divergence process between an individual and its hierarchy may appear. This gap in the valuation of new ideas across economic agents, or between economic agents and decision-making hierarchies of incumbent enterprises, creates the entrepreneurial opportunity.

Opportunity Identification and Entrepreneurial Alterness

There is an unresolved debate between scholars to determinate whether entrepreneurs discover or create entrepreneurial opportunities. Sometimes entrepreneur create themselves the entrepreneurial opportunity and sometimes entrepreneur are engaged in a discovery process from pre-existing trend. In fact, many opportunities exploited by entrepreneurs may be not new objectively, and any theory of opportunity should distinguish between those opportunities that are new and those that are not. Opportunities may emerge as by-products of market competition, and agents may deliberately or unwittingly create opportunities.

All opportunities must not be obvious to everyone all of the time because information is not widely distributed across the population. This is partly due to the specialization of information in the society (Hayek 1945). Two broad categories of factors influence the probability that particular people will discover particular opportunities: firstly, the possession of prior information necessary to identify an opportunity, so-called information corridors, and, secondly, the cognitive properties necessary to value it.

How are opportunities identified or constructed? This central question concerns the opportunity identification and the so-called *entrepreneurial alterness*. According to increasing number of researcher, opportunity identification represents the most distinctive and fundamental entrepreneurial behavior (Gaglio and Katz 2001). Alterness concept was introduced by Kirzner (1973, 1997) in order to explain market dynamics and the role of entrepreneurial function from an individual receptivity to available opportunities.

Which Modes of Action Are Mobilized to Exploit Entrepreneurial Opportunities?

There is a disconnection between the discovery or creation and the exploitation of entrepreneurial opportunities. Exploitation of entrepreneurial opportunities, that is, the transformation of knowledge in economic value, can take many organizational forms. Entrepreneurship which implies exploiting new opportunities does not always require the creation of new organizations. The creation of new organization is only one of the modes of exploitation of entrepreneurial opportunities. Entrepreneurship can also occur within an existing organization by the means of corporate venturing (Corporate entrepreneurship) or spin-off (Spin-off). Moreover, opportunities can be sold to other individual or to existing organizations, by licensing, for instance. The organizational forms taken by the entrepreneurial opportunity (including the decision to create a new entity to operate an idea) depend on the characteristics of technological opportunities attached to them.

From Technological Opportunity to Entrepreneurship

Technological opportunity is one of the central notions of economic evolutionist theory. Technological opportunity concerns the appearance and the creation of new technological solutions that create new economic value. Technological opportunities arise from the evolution of scientific and technological knowledge or a change in the level and structure of demand. The development of new technologies generates entrepreneurial opportunities, but according to Shane (2001), "The probability that an invention will be commercialized through the creation of a new firm varies with the nature of the technological opportunity discovered."

Conclusions and Future Directions

The notion of entrepreneurial opportunities is a very pertinent analytical framework of entrepreneurship which aims to recognize the complexity of entrepreneurial process. Consequently, public policy issues may be questioned to favor entrepreneurship (Entrepreneurship policy).

Could we foster individual capacities to identify opportunities and make easier the access of information, or could public policy stimulate the economical and technological environment capacity of opportunities creation? How could we make easier the commercial exploitation of the gap between the individual perception of opportunity and the hierarchical one? Are changes in intellectual right property necessary (Intellectual Property and entrepreneurial strategies)? How to promote the creation of intrapreneurial opportunities in a firm?

However, to date, one of the weaknesses of this approach is probably the lack of empirical analysis of entrepreneurial opportunity. This leaves a number of conceptual debates unanswered and highlights insufficiently public policy issues.

Entrepreneurial Organizations

Thierry Burger-Helmchen
BETA- Bureau d'Economie Théorique et Appliquée, EM Strasbourg, Université de Strasbourg, Strasbourg, France

Synonyms

Entrepreneurial firms

Key Concepts and Definition of Terms

Entrepreneurial organizations are structures that promote the emergence and development of ideas from all members of the firm. To be functional, such an organization must have specific features that allow alternative views to emerge. An entrepreneurial organization combines several aspects of entrepreneurship and firm flexibility, namely, specific attention processes to make it possible for junior and senior managers to attract the attention of the decision makers, specific decision mechanisms (with adapted criteria, incentive, and remuneration schemes) that explain the acceptance of ideas, and a flexible, agile structure to allow the implementation. Entrepreneurial organizations differ from managerial organizations by their structures and characteristics; they have a specific innovation model, decision/financial model, selection process, human resource management and resources gathering, and utilization scheme.

The notion is related to corporate entrepreneurship, but it is distinct especially by the fact that corporate entrepreneurship is a management/cultural process that applies to existing firms to make them more dynamic (Stevenson and Jarillo 1990).

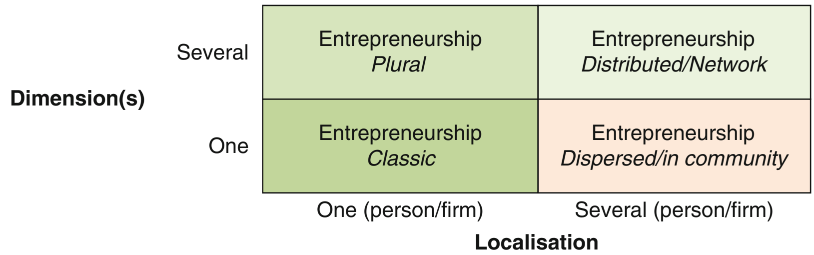
Theoretical Background and Open-Ended Issues

In the approach of Mintzberg et al. (2005), an entrepreneurial organization is centralized around a single leader who engages in considerable doing and dealing, as well as strategic visioning. Thereby, an entrepreneurial organization deals with the conceptualization of the business model and the way it is implemented. In a broader view, entrepreneurial organizations are not limited to a single entrepreneur in the firm.

Entrepreneurial organizations are strongly linked to the learning organization approach and knowledge-based approach of entrepreneurship. Entrepreneurial organizations can take different forms. Forms of entrepreneurship in the academic literature are numerous. As reported by Burger-Helmchen (2008a), one can find the following forms of entrepreneurship: academic entrepreneurship, diffused entrepreneurship, dispersed entrepreneurship, distributed entrepreneurship, disintegrated entrepreneurship, collaborative entrepreneurship, collective entrepreneurship, community-based entrepreneurship, corporate entrepreneurship, intrapreneurship, knowledge-based entrepreneurship, managerial entrepreneurship, modular entrepreneurship, network entrepreneurship, open entrepreneurship, plural entrepreneurship, and serial entrepreneurship.

Many of these notions overlap or are, simply speaking, synonyms; many of them could be pinpointed as entrepreneurial organizations with more than one entrepreneur. Figure 1 is a representation of the different forms of entrepreneurship

Entrepreneurial Organizations, Fig. 1 Various forms of entrepreneurial organizations



along two axes to distinguish them. The two axes represent (1) the localization of the entrepreneurial process or action and (2) the dimensions concerned by the entrepreneurial process.

The horizontal axis selects the location of the entrepreneurial process, by location we mean how many firms/persons are participating in the entrepreneurial process. Is it just one single entrepreneur, or are there several persons belonging to distinct firms? The vertical axis corresponds to the dimensions along which the entrepreneurial process takes effect. Does it modify the product, the business model, the organization, etc.? Are only one or several of these dimensions concerned? If we plot some of the entrepreneurial forms found in the literature on these axes, we obtain the distribution showed in Fig. 1.

The easiest situation corresponds to the case where there is one person performing an entrepreneurial act along one dimension. This case corresponds to the classic representation of entrepreneurship and of entrepreneurial organization. The Schumpeterian entrepreneur leading to the mark I innovation production corresponds to this point.

If we have several persons, possibly employed by several firms, we obtain a group of people involved in an entrepreneurial process. This corresponds to the notion of dispersed entrepreneurship or entrepreneurship in community. In an engineering approach, the tasks necessary to create a new product are split into different subtasks. Each group of engineers has to resolve the problem corresponding to a specific part, or subtask, of the project they are responsible for. More recently, this approach has been developed in organization studies together with the notions of communities (Cohendet and Llerena 2003). People can be working for different firms but be involved in the same community. Because different persons/firms are linked by the same practice, they can contribute to the creation of a new product, in this case the community is entrepreneurial. A current example of this form of entrepreneurship is the open-source community who creates new products by summing up the efforts of several persons dispersed around the world.

In this approach, there is only one dimension concerned, the product (or service) created by the entrepreneurial process. If several dimensions are concerned and different firms are involved, meaning that some firms are in charge of creating a new product or service, some other firms develop a new business model/market strategy, and/or some firms organize themselves in an entrepreneurial manner around those activities, we obtain a situation of distributed or network-based entrepreneurship.

Finally, the last field in Fig. 1 that we did not discuss yet is the plural entrepreneurship situation. Plural means that one single firm or person must not only create a new product or new services but also (if the product is really a novelty) find a new way of commercializing the product (a marketing/business model) and eventually develop an innovative organization of his or her activities. The more dimensions and localizations are concerned, the more entrepreneurial is the organization.

The success of a firm corresponds to the outcomes of entrepreneurial activities. Those activities must join into a coherent business strategy during the start-up phase. Therefore, this view is aligned with the concept of entrepreneurial strategy by Mintzberg et al. (2005). They define entrepreneurial strategy as

> . . .characterized by a visionary process: strategy exists first of all in the leader's mind as a long-term direction, a vision of the future and of the results of the organization. Such a strategic vision tends to be malleable, and due to this, entrepreneurial strategy often appears to be both deliberate and emergent, deliberate from the point of view of its global vision, and emergent in the way in which the details of the vision evolve.

Again, in entrepreneurial organizations, the entrepreneurial vision is not limited to the leaders' minds; thereby, those entrepreneurial organizations need a special attention and selection process (Ocasio and Joseph 2005).

Implementation for Theory, Policy, and Practice

The entrepreneurial mindset sees the environment and the stakeholders in a different way (Boisot and MacMillan 2004) and thereby influences the important resource allocation decision. The effectuation literature especially highlights this interpretation process and how it forges the entrepreneurial action within the organization (Sarasvathy 2004). The entrepreneurial logic influences behaviors, routine strategies, structure, and culture. In fact, the entrepreneurial mindset influences the firm in many domains, even if it is not noticeable at first sight. In the entrepreneurial organization, the concept of constant change is a dominant factor. Entrepreneurship creates new opportunities and promotes flexibility, creativity, and innovation.

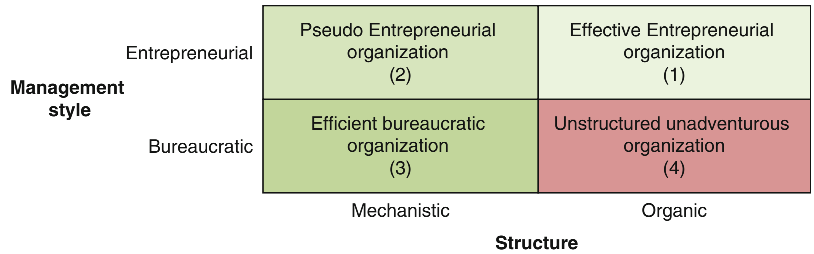
What Constitutes an Entrepreneurial Organization? A classification can be made based on the frequency of entrepreneurial acts and the degree of each entrepreneurial act (Morris et al. 2011). A firm can make a small number of really creative, innovative, highly differentiating acts or can make a large number of small, incremental advances and changes. Some researchers think that there is a link between the entrepreneurial intensity of an organization and several performance measures such as profitability, growth, sales, salaries, etc. (Morris et al. 2011). This could be particularly the case in turbulent changing environments. But it does not take into account the survival rate. Several approaches exist to differentiate the performance and environment that are more favorable for entrepreneurial organization or managerial organization, depending notably on the type of knowledge developed and the form of rivalry between firms. Empirical- and simulation-based approaches highlight the fact that entrepreneurial organizations are more efficient when uncertainty is high as in hypercompetitive environments (Burger-Helmchen 2008b).

Entrepreneurial Organizations Have Specific Architectures. The architecture of the entrepreneurial organization is important because it makes it possible to seize opportunities, to respond fast, and effectively to change. The setting up of architecture to exploit the distinctive characteristics of entrepreneurship are dynamic capabilities difficult to copy, mechanisms that build routines, culture to allow this to happen smoothly. The staff is not demotivated but motivated by the change and creativity of the other members of the organization. The value of an entrepreneurial architecture lies in its capacity to create organizational knowledge and routines, to respond flexibly to changing circumstances, and to achieve easy and open exchanges of information.

Entrepreneurial organizations exhibit more links to communities/networks (outside the firm) because the entrepreneurs are in the middle of a web of informal personal relationships rather than contractual formal relationships. At the basis, it is a learning organization. A learning organization has been defined as one that facilitates the learning of all its members and continuously transforms itself in response to the needs, wishes, and aspirations of people inside (and outside) it. Such an organization encourages systematic problem solving, encourages experimentation and new approaches, and allows more importance to be allocated to personal history. Therefore, entrepreneurial organizations are learning organizations.

An Entrepreneurial Organization Has Some Particularities of Size and Structure. Large organizations produce a bigger quantity of information that needs to be analyzed, shared, etc. It delays the decision making and kills creativity. To be entrepreneurial, a layer organization needs to organize into small groups or projects. But the decentralizing, delayering, outsourcing, and

Entrepreneurial Organizations, Fig. 2 Effective entrepreneurial organization



downscoping are not a guarantee that a firm becomes more entrepreneurial. Clearly, when the number of people reporting to the entrepreneur increases, the system becomes less effective.

Barriers to Entrepreneurial Organization. Many traditional management techniques are ineffective for such organizations but not always. As an entrepreneurial firm moves away from centralized, formal hierarchies to flatter structures with more horizontal communication, the need for management control diminishes. Several authors argue that the entrepreneurial behavior within the organization is positively correlated with performance when the structure is more organic (when authority is based upon expertise, not position) (Fig. 2).

The organization is more problematic when there is an incongruity between structure and style. This figure reports also what the authors call "cycling"; where firms change from one management style to another, a more bureaucratic style is needed (successful firms are in quadrants 1–3).

Conclusion and Future Directions

Entrepreneurial organization encourages the exchange and creation of knowledge to detect and exploit opportunities in a rhythm and way different from managerial organization. In particular, entrepreneurial organization encourages all the employees to propose new ideas. This implies that those firms have a specific type of attention. Subsequently, those entrepreneurial organizations have the flexibility to develop and exploit the proposed and accepted ideas. The number of actors that can propose ideas and the subjects of the ideas led several researchers to propose different forms of entrepreneurial organization. Depending on the structure and management style adopted, entrepreneurial organization can be more or less efficient than managerial organization.

Future research on entrepreneurial organization can benefit substantially from a richer conceptualization of the entrepreneur that is not limited to a certain position or title but recognizes the potential that entrepreneurial insight and creativity can be provided by all individuals in the organization. The necessity to be entrepreneurial along several dimensions requires a procedural approach to describe the evolution of the entrepreneurial activities. Previous work on that topic developed our knowledge of the common traits on the genesis and growth of the firms, for instance, they gave us a good understanding of the different phases of the development of firms (following a life cycle model), but by definition, this separation in phases (or steps) focuses on the important points in each phase, neglecting somehow the relationships between the different elements and their coevolution. The picture is then composed of the entrepreneur(s), the innovative products or services, the supporting activities, and the financial resources. The coevolution of all these elements in relation to entrepreneurship fosters the survival of the firm.

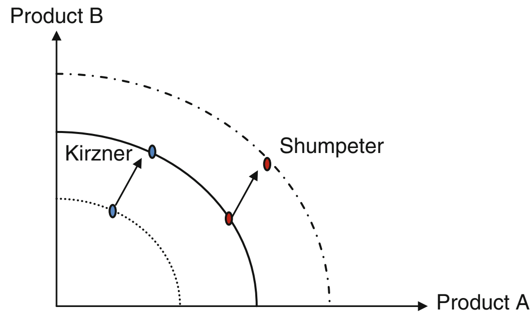
Introduction

The relationship between entrepreneurship and firms' growth, as well as economic growth more generally, has been the subject of a growing number of studies. This growing and renewed interest is due to several factors: first, the driving role played by entrepreneurship to promote economic development in Western countries, but also developing ones; second, a remarkable lack of studies on the causal relationship between entrepreneurship and economic growth; and third, new techniques have developed and individual data about entrepreneurs and entrepreneurship have been made available, permitting to test new hypotheses. Thus, added to the disparate definitions of entrepreneurship, studies that empirically measure that relationship are as rare in economics as in management.

Nevertheless, one main issue in economics has investigated the linkage between entrepreneurship, innovation, and growth at regional level (Audretsch and Kelibach 2007, 2008; Braunerhjelm et al. 2010). According to this approach, "entrepreneurs" and "capital entrepreneurship" are the missing links in the endogenous theory explaining business growth.



Entrepreneurship and Business Growth, Fig. 1 The Schumpeternian view vs. the Kirzernian view of entrepreneurship and the production possibility curve (Source: Hans Landström (2010), p. 15)

Definition

Entrepreneurship: Several definitions have succeeded each other since Cantillon's (1734). Since then, economists such as, Say (1857), Knight (1921), Schumpeter (1934), and Kirzner (1933) have been among the most influential contributors to the understanding of entrepreneurial behavior and its related processes. Even though, on the whole, their definitions differ from each other – in that they assimilate the notion of entrepreneurship to exchanges, risk, innovation, and business opportunities – they all complement one another. Indeed, Cantillon recognized that the shift between demand and supply in a market creates opportunities for buying cheaply and selling at a higher price; that sort of arbitrage would bring equilibrium to competitive markets. Based upon this approach, Kirzner states that the entrepreneurial function involves coordinating information, namely, identifying the gap between supply and demand, as well as acting as the broker between supply and demand, and making it possible to earn money from the difference. Finally, one more definition is worth mentioning: it is more contemporary with Scott Shane and Venkataraman (2000) and pertains to the same lineage as Cantillon's and Kirzner's, while stressing innovation more particularly; *"Entrepreneurship is 'an activity that involves the discovery, evaluation and exploitation of opportunities to introduce new goods and services, ways of organizing markets, processes, and raw materials through organizing efforts that previously had not existed."*

Entrepreneur: Traditional neoclassical economics has completely evacuated, from its analytical framework, the role of the entrepreneur in economic activity. Adam Smith made no distinction between a capitalist and an entrepreneur, whose role was reduced to acting as a coordinator between the various factors of production and capital owners. The idea that gives the contractor more than the role of a mere capitalist was born outside the neoclassical paradigm with such rare pioneers as Knight, Schumpeter, and Kirzner who deem that, "the entrepreneur is *someone who is alert to profitable opportunities for exchange. He or she is able to identify suppliers and customers and act as an intermediary*." Thus, the entrepreneur tries to discover profit opportunities and helps restore equilibrium on the market by acting on these opportunities (*entrepreneurial alertness*).

These definitions highlight the relationship between entrepreneurship and growth, where the entrepreneur is the main mechanism. That is, regarding the production possibility curve (see Fig. 1), Kirzner considers that the company is within the curve and reaches the edge of the production possibility curve by identifying gaps between supply and demand. However, Kirzner's entrepreneur does not create anything new. He is an intermediary who recognizes and exploits what already exists, but this action leads to better use of resources and therefore shifts the curve toward the edge of the production possibility curve.

Compared to Schumpeter's view, the entrepreneur creates something new rather than exploit existing resources. So, according to Schumpeter, the firm is on the edge of the curve. And the entrepreneur pushes the curve outwards by introducing innovations. Nevertheless, eventually, even though these two viewpoints look different on first reading, they are consistent and even complementary with each other, in that Schumpeter creates disequilibrium for further new possibilities and therefore growth. Besides, Kirzner acts on disequilibrium in the market for new growth.

Entrepreneurship as an Effective Mechanism to Explain Business Growth

The relationship between entrepreneurship and economic growth is far from established. However, it is recognized that Zoltan Acs and David Audretsch are two of the most prolific researchers in the field of small businesses and entrepreneurship, having contributed on the subjects of the evolution of small and medium enterprises (SMEs), entrepreneurial dynamics, innovation, and regional growth.

It is this approach that will be preferred here. These works, individually or in collaboration with David Audretsch and Zoltan Acs, consider that both incumbent firms and entrepreneurial activities are the main "missing links" in the literature to explain knowledge accumulation and its diffusion and conversion into economically relevant knowledge.

Braunerhjelm et al. (2010) suggest that the process of knowledge transformation resulting from fundamental research into economically exploitable knowledge is not a spontaneous and natural process. This approach complements the endogenous growth models that establish a direct link between investment in R&D (Research and Development) and economic growth – without demonstrating it, for all that. This entry is all the more relevant as empirical studies find no systematic correlation relations between R&D and GDP (Growth Domestic Product) growth in countries like Japan and Sweden, which have large stocks of R&D. This paradox suggests the lack of consideration for the mechanisms ruling the dissemination of knowledge spillovers. Within this analytic framework – and faced with the lack of an explanation regarding the dynamics of fundamental knowledge transfer to the economic sphere – that approach introduces entrepreneurship as the missing link in contemporary growth models. Thus, through his various business activities, from identifying opportunities, and from innovation to starting a business, the entrepreneur ensures the transformation of knowledge into economically useful and recoverable knowledge. Empirical studies show that there is regularity as to the relationship between entrepreneurship measured by starting a business (start-up) and economic growth, particularly through employment. The second innovative idea that has boosted the endogenous growth model is the introduction of entrepreneurship capital as a mechanism explaining variations in economic performance.

Capital Entrepreneurship

According to Audretsch (2007), the determinants of entrepreneurship are shaped by a number of forces and factors, including legal and institutional but social factors as well. The study of social capital and its impact on economic decision-making and actions stems back to classic literature in economics and sociology, in which social and relational structures influence market processes (Mark S. Granovetter 1985). In another relevant study explaining Silicon Valley's high economic performance, Saxenian (1990) suggested that the rich endowment of the city with what could be termed as "entrepreneurship capital" is the main factor to account for such performance.

> It is not simply the concentration of skilled labor, suppliers and information that distinguish the region. A variety of regional institutions – including Stanford University, several trade associations and local business organizations, as well as a myriad of specialized consulting, market research, public relations and venture capital firms – provide technical, financial, and networking services, which the region's enterprises often cannot afford individually…Equally important are the social relationships that develop with shared professional experiences and repeated interaction… These networks defy sectoral barriers: individuals move easily from semiconductor to disk drive firms or from computer to network makers. They move from established firms to startups (or vice versa) and even to market research or consulting firms, and from consulting firms back into startups. And they continue to meet at trade shows, industry conferences, as well as on the occasion of the scores of seminars, talks, and social activities organized by local business organizations and trade associations. In these forums, relationships are easily formed and maintained, technical and market information is exchanged, business contacts are established, and new enterprises are conceived…This decentralized and fluid environment also promotes the diffusion of intangible technological capabilities and understandings. (Saxenian 1990, pp. 96–97)

Thus, a region characterized by a rich endowment in entrepreneurship capital positively impacts the growth dynamics. Those contexts, based on a process of knowledge dissemination and spillovers, enhance individual propensity to create and innovate. And, inversely, regions with a weak entrepreneurship capital can inhibit starting up new firms.

Measuring the Relationship Between Entrepreneurship and Business Growth

It results from this framework that entrepreneurship capital is the fourth component inherent to economic development. So, just as physical capital, human capital, and knowledge, entrepreneurship capital is the fourth variable "input" of the conventional Cobb-Douglas production function. Empirical evidence supports these causal economic policies and suggests the development of entrepreneurial capital as a determinant of growth.

An Endogenous Growth Model with Entrepreneurship

Acs and Audretsch, as well as their collaborators, have widely contributed to the development of a growth model making it possible to measure the impact of entrepreneurship on growth. Their model (Audretsch and Kelibach 2008 et Braunerhjelm et al. 2010) suggests that not only is entrepreneurship induced by high investments in knowledge within regional contexts but regional growth also impacts entrepreneurship level of influence. Thus, an augmented production function that includes an explicit measure of regional entrepreneurship capital has been estimated. On this basis, it became possible to test the impact of entrepreneurship on economic growth on one hand and, on the other, the impact of knowledge investments and growth on entrepreneurship.

Two equations are specified simultaneously, taking into account the simultaneity bias:

$$Y_i = K_i^{\alpha} L_i^{\beta} R_i^{\gamma} E_i^{\delta} \tag{1}$$

$$E_i = f(y_i, x_i) \tag{2}$$

Where Y_i in Eq (1) is the economic performance of region i measured as GDP,
K_i is region I's endowment of entrepreneurship capital,
L_i is labor, R_i is regional R&D intensity, and E_i represents its endowment in entrepreneurship capital, while formally specifying that entrepreneurship contributes to the economic output of regions.

In Eq (2), y_i is a vector that measures region i's performance and xi is the vector of other variables influencing entrepreneurial activity in i. Two groups of factors shape the extent of entrepreneurship capital: (1) the generation of region-specific opportunities for entrepreneurial activity through knowledge and ideas and (2) a favorable general economic environment enhancing the creation of firms.

Variables Determining Entrepreneurship Capital

Two categories of variables determine entrepreneurship capital: factors stimulating entrepreneurial opportunities and factors influencing the economic context.

1. Factors Stimulating Entrepreneurial Opportunities

   Economic growth creates a growing market, which thereby generates greater exchange dynamics and therefore new business opportunities in Kirzner's sense. R&D intensity describes the potential of a region to create new knowledge, which in turn generates new opportunities to create knowledge-based firms, including through the mechanisms valorizing the development of fundamental research.

   According to the main assumption of the urban economic literature (Duranton and Puga 2004), the higher population density in cities eases local knowledge and informational exchange between individuals, leading to a better labor productivity. Therefore, these mechanisms induce faster diffusion and appropriation of entrepreneurial opportunities.

2. Factors influencing economic situations

   As suggested by many studies, the unemployment rate is linked to the entrepreneurial activity. However, the sign of that correlation has still not been established empirically so far. The same conclusion can be drawn concerning the impact of regional industrial diversity. No consensus on whether the firms benefit largely from a strong concentration of industry-specific knowledge (That is what, in the literature, is dubbed "Marshall-arrow-Romer" externalities) or from the variety of knowledge coming from different industry sources (Jacob's externalities). The impact of taxes on business start-ups is also being investigated. And again, in this case, the global impact of taxation is not systematically anticipated. Thus, local taxes can reduce the propensity to start up a new firm and hence the region's entrepreneurship capital. However, on the other hand, these taxes can help regions provide better business services and hence attract entrepreneurs.

Conclusion and Future Directions

Thanks to endogenous growth models, it has been possible to rehabilitate the role of entrepreneurship in economic growth, particularly through the concept of entrepreneurial capital. However, the concept of entrepreneurial capital is somehow a little too abstract and based on too aggregate parameters, like GDP or population density. Other parameters may need to be considered, further explaining young people's intentions to undertake. Support structures and outreach and training programs are all parameters that may influence individuals' predispositions to undertake, both in regional and national contexts.

Entrepreneurship and Financial Markets

Philippe Spieser
Groupe Escpeurope, Paris, France

Synonyms

Angel funding; Bootstrap transaction; Financial sponsor; Friends and family funding; Highly-Leveraged transaction (HLT); Seed funding; Seed money; Special Situation

"Entrepreneurship" and "financial markets" seem, at the first glance, to be somehow contradictory expressions. The entrepreneur, who is simply defined here, according to Lachman's (1999) definition as a person who uses a new combination of production factors, needs generally external sources of funds to set up and develop his company. Those financial means adopt many forms which cover different definitions and objectives. They show different profiles in terms of risk and return according to the financial business cycle which describes the revenues' in- and outflows as a function of time. But they have in common to be *private*, gathered precisely under the general term of *private equity* (here *PE*). This idea of privacy is far away from the concept of a financial market where securities are freely valued and traded. Nevertheless, PE financial flows and funds are not disconnected from the public financial markets' patterns, parameters, or vehicles. Different links, explicit or implicit, are to be discussed between PE and public markets.

Notions of "Private Equity" and "Private Equity Market" Refer Essentially to the Private Economic Sphere

Entrepreneur

Many definitions have been given for the notion of *entrepreneur* (see other contributions in this book). The most well-known theorist of this agent is the Austrian economist J. Schumpeter (1934). He stressed the role of innovation, such as new products and production methods, new markets, and forms of organization. Wealth is created when such innovation results in a new demand. From this viewpoint, one can define the entrepreneur as a person combining various input factors in an innovative manner to generate value to the customer with the hope that this value will exceed the cost of the input factors, thus generating superior returns that result in the creation of wealth. The entrepreneur needs money to start his activity and borrows this money from a *venture capitalist*. For the venture capitalist, the objective is the ability to achieve a significant capital gain resulting from the difference between the purchase and the selling price of the (private) shares. In order to start that new activity, which is by nature risky, the entrepreneur generally needs fresh money.

Private Equity

The expression "*private equity* (here:*PE*)" refers to specific actors, mechanisms, and money in relation with investment in private financial resources. The resources are made available for companies generally under the form of securities (equities) not involving any public offering and, consequently, not traded on a public stock exchange.

Private Equity Market

The private equity market consists of professionally managed equity investments in the unregistered securities of private (and sometimes also public) companies. Professional management is provided by specialized intermediaries (*limited partnership*, cf. *infra*), raising money from institutional investors and acquiring large ownership stakes. They take an active role in monitoring and advising the firms.

Private Equity Firms

It is a structure driven by an investment manager that invests in the private equity of operating companies in order to follow different objectives (like controlling or owning a substantial minority position) through a variety of financial means (like venture capital, leveraged buyout, growth capital) precisely in accordance with the specific investment strategies. A private equity firm will raise pools of capital or private equity funds that supply the equity contributions for these transactions; it will receive a periodic management fee as well as a share in the profits earned called *carried interest* from each private equity fund managed. Financially speaking, a PE firm looks to maximize the value of its investment, receiving a return on their investments through one of the following ways:

– An *initial public offering* ("IPO") – shares of the company are offered to the public, typically providing a partial immediate realization to the financial sponsor as well as a public market into which it can later sell additional shares.
– A *merging or acquisition process* – the company is sold for either cash or shares in another company.
– A *recapitalization* – cash is distributed to the shareholders (the *financial sponsor* and the private equity funds) either from cash flow generated by the company or through raising debt or other securities to fund the distribution.

The *private equity firms* can bear different names like *venture capital firms, angel investors, etc*. The different ways the PE financial resources are made available for companies have four names: *venture capital, leveraged buyouts, growth capital*, and *mezzanine capital*. This classification is not homogenous in the sense that it refers either to the steps of the firm's development or to the financial setup or objectives of the financing (cf. *infra*). The purposes of the working capital provided are different: to insure expansion, to launch new product development, or to finance restructuring of the company's operations, management, or ownership.

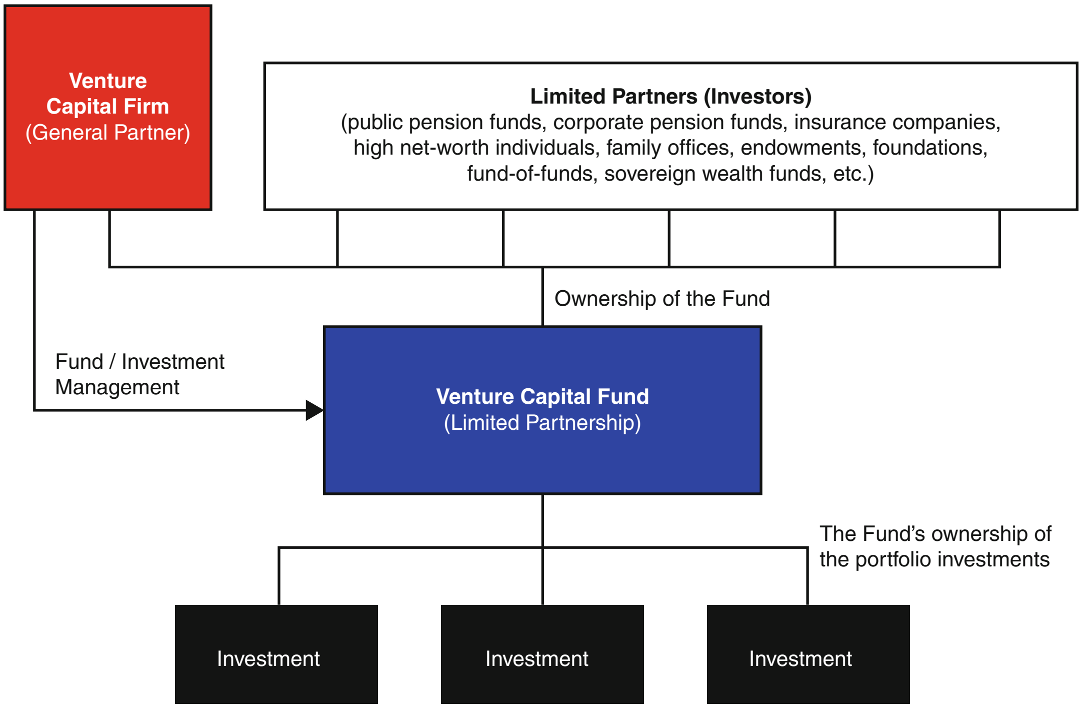
Private Equity Fund

A private equity fund is a structure raised and managed by managers of a PE firm (the *general partner*), building a collective investment structure designed to invest mainly in various equity securities according to one of the investment strategies defined by the PE firm. PE funds are legally *limited partnerships*, because they are granted through a limited partnership agreement, with a fixed term of (extendable) 10 years. Usually, a single private equity firm will manage a series of distinct private equity funds, attempting to raise a new fund every 3–5 years as the previous fund is fully invested. The general partner raises capital from institutional investors (pension plans, foundations, charities, etc.). The terms in the limited partnership agreement are the following:

Management fees – an annual payment made by the investors in the fund to the fund's manager to pay for the private equity firm's investment operations (1–2 % of the committed capital of the fund).

Carried interest (see above) – a share of the profits of the fund's investments (up to 20 %), paid to the private equity fund's management company as a performance incentive. The remaining 80 % of the profits are paid to the fund's investors.

Hurdle rate or *preferred return* – a minimum rate of return (generally 8–12 %), which must be achieved before the fund manager can receive any carried interest payments.



Entrepreneurship and Financial Markets, Fig. 1 Relations between VC firms, VC funds, and institutional investors (Source: H. Fantasia: the impact of the financial crisis in the French venture capital investment – report ESCP Europe and wikipedia)

PE funds are not intended to be transferred or traded but can be transferred to another investor, at the discretion and approval of the fund's manager.

One has nevertheless to point out that the world of PE remains specific in the world of "banking" or "market" finance; structures and people are not strictly confounded, mainly based on personal relations and confidence. The relations between PE firms, PE funds, and institutional investors are summed up in the following figure (Fig. 1).

Venture Capital

Venture capital (VC) refers to financial capital provided to firms at their early stage (start-up) when those firms are regarded as high-potential, high-risk, and promising-growth companies. The firms usually have a novel technology or business model in high technology industries, such as biotechnology, information technology, etc. So equity investments are made for the launch, early development, or expansion of a business. Venture capital is a subset of private equity; therefore, all venture capital is private equity, but not all private equity is venture capital.

Venture capital is often subdivided by the stage of development of the company, ranging from early-stage capital used for the launch of start-up companies to late-stage and growth capital; this last financial means is often used to fund expansion of existing business generating revenue but not yet profitable or generating cash flow to fund future growth.

The venture capitalists need to deliver high returns to compensate for the incurred risk he takes that makes venture funding an expensive capital source for companies. Venture capital is most suitable for businesses with large up-front capital requirements which cannot be financed by cheaper alternatives such as debt. In addition to angel investing and other seed-funding options, venture capital is attractive for new companies with limited operating history that are too small to raise capital in the public markets and have not reached the point where they are able to secure a bank loan or complete a debt offering. In exchange for the high risk that venture capitalists assume by investing in smaller and less mature companies, they usually get significant control over company decisions notwithstanding to a significant portion of the company's ownership.

Leveraged Buyout (LBO)

A leveraged buyout takes place when an investor buys a controlling interest in a company's core capital, a significant percentage of the purchase price being financed through borrowing. The assets of the acquired company are used as collateral for the borrowed capital. Since the cost of capital is cheaper than the cost of borrowing in a normal period of time, the operation is profitable, this mechanism being called *leverage effect* in the classical financial theory: the returns to the investor will be enhanced as long as the return on assets exceeds the cost of the debt.

Leveraged buyout uses a combination of various debt instruments supplied by banks and debt capital markets. Bonds or other papers issued for leveraged buyouts are commonly considered not to be first-category investment (*investment grades*) because of the significant risks involved. The companies involved in these transactions are generally mature and generate operating cash flows. In a typical leveraged buyout transaction, a private equity firm buys majority control of an existing or rather mature firm; this is distinct from a venture capital or growth capital investment, in which the investors invest in young or emerging companies and rarely obtain majority control.

Leveraged buyouts involve generally a financial sponsor without himself committing all the capital required for the acquisition; he will raise acquisition debt which is in line with the cash flows of the acquisition target to make interest and principal payments. A peculiar form is the leverage management buyout where the sponsor is constituted by the management of the company (*LMBO – leveraged management buyout*).

An LBO transaction's financial structure is particularly attractive to a fund's limited partners in the frame of private financial markets: it grants them the benefits of leverage but limits the degree of recourse of that leverage due to the fact that the borrower is not personally liable for the borrowed money.

Growth Capital

Growth capital refers to private equity investments (minority investments, in the general case) in relatively mature companies looking for capital to expand or restructure operations, enter new markets, or finance a major acquisition without a change of control of the business. So it intervenes after the venture capital operation.

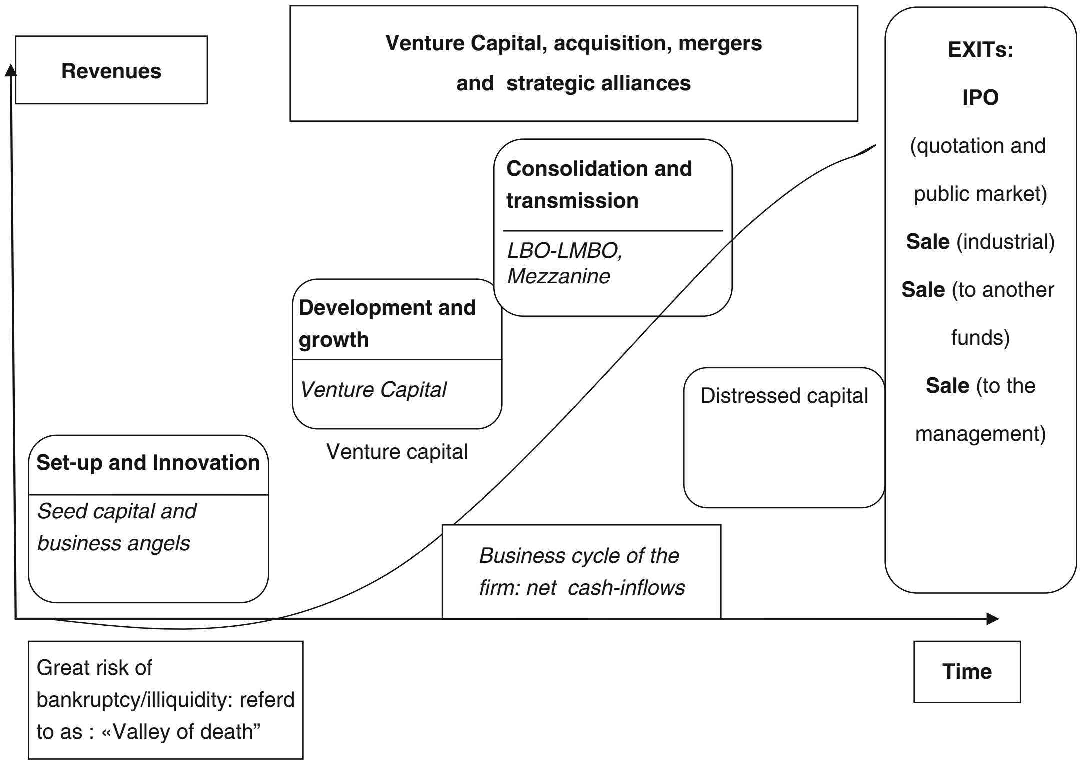
Mezzanine Capital

Mezzanine capital refers to *subordinated debt* or *preferred equity* securities (so financial means intermediary between equity and bonds) that is the most junior portion of a company's capital structure but senior to the company's common equity. This form of financing is often used by private equity investors to reduce the amount of equity capital required to finance a leveraged buyout or major expansion. Mezzanine capital, which is often used by smaller companies that are unable to access the high-yield market, allows such companies to borrow additional capital beyond the levels that traditional lenders are willing to provide through bank loans. In compensation for the increased risk, mezzanine debt holders require a higher return for their investment than secured or other more senior lenders.

Distressed Situations

Some PE funds choose to invest equity or debt securities of financially stressed companies, which is a strategy far from the investment in seed or venture capital. One can distinguish between "distressed-to-control" and "loan-to-own" strategies where the investor acquires debt securities in the hopes of emerging from a restructuring in control of the company's equity and "special situations" or "turnaround" strategies where an investor will provide debt and equity investments, often "rescue financing," to companies undergoing operational or financial challenges. The different terms and uses of financial PE sources of funds can be summed up here (Fig. 2).

The volume of VC has reached now a significant level. The Dow Jones VentureSource



Entrepreneurship and Financial Markets, Fig. 2 Sources of funds, business cycle, and "exit opportunities" (Source: Author and F. Prevost "Entrepreneur and private equity," RB editeurs, 2009)

indicates that venture capitalists from around the world invested $9.8 billion into 967 deals for companies based in the USA, Europe, Canada, Israel, Mainland China, and India during the first quarter of 2011. This represents a 20 % jump in investment but a 7 % decline in deal activity from the same period in 2010 when $8.2 billion was raised for 1,038 deals. VC investments in the USA accounted for two-thirds (66 %) of the total volume in the first quarter, with Europe (15 %) and China (14 %) next in line. The dominant sectors are in renewable energy, health care, and information technology.

But Actually, the Links with Public Financial Markets Are Constant and Unavoidable

Private equity and venture capital are closely linked to the financial markets via many channels, although they are logically and originally separated. Those links are put into light especially during crisis times. For example, the lower level of VC-raising capital in 2009–2010 are, according to the Europe PE and VC Association Research and in line with the overall constraints in public financial markets, *a liquidity shortage, a general uncertainty about the future*, and, lastly, *a difficult "exit solution"* – meaning, the choice of another investment opportunity after the PE and VC investment is over. The different channels are as follows.

1. The interest rate

   The first and probably the most important bridge between PE and the public financial market is *the interest rate*. It is simply the common benchmark for all types of investment opportunities. For all types on investors and according to the "CAPM" theory, (Capital asset pricing model, the dominant financial theory describing the relation between risky and unrisky asset returns) under some assumptions, the risk and the return of any risky asset are linked in a linear relation. In the risky assets, one must range of course all listed shares but also real estate, commodities, and PE investments. Since the risk is regarded as very high in this last opportunity, the expected return has to be very high too. This phenomenon explains why the internal rate of return in PE finance was and still is very high compared to the growth rate prevailing in the economies. In the same idea, the investment strategy of institutional investors is a global one, concerning all types of assets and (geographical or sectorial) markets, in the purpose of an optimal diversification. In the framework of the CAPM, if their attention is drawn to other assets showing less risk for the same return or higher return for the same risk, this will be made at the expense of VC. In other words, under a financial constraint, the risk/return relationship in the PE market is benchmarked by this same relation in public financial market, a phenomenon which is well illustrated during crisis when a "flight-to-quality" movement in favor of safe investments dried the PE activity.

The other links are as follows:

2. The existence of a "secondary market"

   The notion of "secondary market" refer to investments made in existing PE assets through the sale of PE fund interests (or portfolios of direct investments) in privately held companies to existing institutional investors like banks or insurance companies. If, by nature, the private equity asset class is illiquid and is designedly intended to be a long-term investment for buy-and-hold investors, this "secondary market" opens a liquidity window and simultaneously provides institutional investors with portfolio diversification along with, for example, geographical or sectorial diversification. Secondary investments also typically experience a different cash flow profile which is interesting to investors. The idea is that in private equity fund management, there is a J-curve effect due to the trend of PE funds to show negative returns in early years and investment gains in the outlying years as the portfolios of companies mature; this effect can be partly annulated by investing in new private equity funds. Often secondary investments are made through third-party fund vehicle which are structured similarly to *fund of funds*.

3. A growing tendency, for many PE vehicles, to be listed

   Many advantages have been underlined to justify this obvious trend followed by PE vehicles to get listed in markets. They can raise money more easily, which saves them to organize heavy and expensive road shows for fundraising. Most famous and wealthy funds are, to this respect, Kohlberg Kravis Roberts and Carlyle Group. This link is reinforced by the fact that important financial institutions like investment banks have directly created listed PE vehicles, for example, Goldman Sachs or Barclays. One can notice that the most quoted funds are Anglo-Saxon, because PE industry is more developed in the USA, Canada, and the UK than in the Europe. If they are listed, the performance of PE funds can then be directly compared to that of the common equity market, which is then a benchmark for investors.

4. The introduction to the market is the natural end of a PE investment

   The VC investment process goes naturally from a first step – identification of opportunities – to the last one – an "exit" solution (see above). There are five "exit" situations. The most logical one is an initial public offering, highly influenced by the financial market conditions: liquidity, market risk premium, and long-term private and public interest rate. This "exit" opportunity determines partly also the other four possibilities, namely, a sale of the shares to industrial investors, a buyback by the primary owners, a secondary buyout to another PE investor, and, last but not least, a write-off.

5. PE investments: a signal for markets

   The PE activity and VC investment take decisions about the sectors to invest in.

This drives the market's attention and indicates some trends for future IPO investments; it influences the public markets' investment decisions made by institutional investors as a whole.

Conclusion and Future Directions

PE and VC activities are by far not disconnected from public financial markets; they belong to the global investment policy (in terms of diversification, risk, return) of almost all categories of investors. Many observers underline the fact that new technology firms find more easily funds in the USA than in Europe, a phenomenon which partly could explain the dynamism of this sector in the American growth rate. The present gloomy situation of the financial markets (spring 2012), at least in the mature economies, makes the question of financing innovation and entrepreneurship more acute This challenge is to be related with the broader use of markets, instead of banks which are also shuttled by the needs of reinforcing their capital structure, in the financing of the economy in that part of the world. The future of PE is also partly determined by the perspectives in countries like China or India where the financial needs are important but where the political and economic systems are less adapted to an activity which is a symbol for capitalism.

Introduction

To define national culture, researchers and practitioners generally use national boundaries as a proxy for differentiating between distinct cultures and their respective cultural characteristics. Similarities in national cultures derive from common history, religion, geography, and language. Although there are differences within national borders, these differences are assumed to be of less significance than those found between nations. The concept of national culture refers to a set of values, beliefs, and attitudes shared by individuals of a human group, which in turn influences individuals' behavior and social relationships (Hofstede 1980, 2001). The interactive aggregate of common characteristics that influences a group's response to its environment is what distinguishes one group from another.

The main driving force of national culture is its values. Cultural values determine which behavior is appropriate, thus influencing an individual's choice. The result is persistent differences in human behavior in different countries. Consequently, when people establish organizations, the characteristics of these organizations reflect the people's cultural values. Against this backdrop, cultural factors exert an influence on entrepreneurship – a process that involves identifying an opportunity, developing a business concept, acquiring the necessary resources to implement the concept, and then managing the venture to reap benefits.

Numerous studies have linked national culture to the strategic decision-making process that occurs within entrepreneurial organizations, particularly the cultural dimensions that contribute to entrepreneurship. This endeavor has highlighted the importance of sociocultural variables in explaining variations in entrepreneurship and economic development. Research interest has focused on understanding the influence of national cultural values on the individual entrepreneur as well as the cultural variables in explaining variations in entrepreneurial motivation, orientation, and behavior across countries. If different cultures possess different attitudes toward entrepreneurship, then it follows that certain cultures engender more entrepreneurial behavior than others.

The issue of what cultural aspects impact entrepreneurial behavior is examined empirically most often on the basis of Hofstede's model (1980). Hofstede contends that a nation is a social system which has its own culture – legal, educational, and political systems, which serves as a vehicle for mental programming of the nation's members. Therefore, a nation possesses its own culture. Hofstede's (1980, 2001) study on national cultures within organizations not only analyzes national cultures but also demonstrates the effects of cultural differences inside organizations. His research is particularly useful to understand behaviors and attitudes at work, such as leadership, motivation, or the behavior and relationships between members and how these factors affect the level of entrepreneurship in any given society.

Hofstede's model of cultural dimensions serves as the basis for theoretical and empirical research over the past 30 years on how national culture influences business and management (Hofstede 1980, 1993, 2001). The first four dimensions of the model were initially detected through a comparison of the values of similar people (more than 100,000 employees and managers) in 64 national subsidiaries of the IBM Corporation (Hofstede 1980). People working for the same multinational, but in different countries, represent well-matched samples from the populations of their countries, similar in all respects except nationality. The following is a description of the four cultural dimensions represented in the model and their relationships with entrepreneurship.

Power Distance

Power distance describes the degree "to which less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally" (Hofstede 2001, p. 98). This dimension measures how far inequality is accepted by a culture.

Cultures with a high score in power distance show existential inequality between the superior and the subordinate. A high power distant organization will most likely use formal forms of address or those that reflect status differences. Such organizations centralize power in a few hands as much as possible. Inequality is an inherent feature of society, so it accepts and expects more powerful individuals to possess certain privileges. High power distance countries include China with a power distance index (PDI) of 90, Russia (PDI: 93), and Malaysia (PDI: 104) (Hofstede 2001).

In contrast, low power distance cultures accept that power be distributed equally. Equality is valued and those with more power or status should not act in ways that call attention to their advantages. Hierarchies are not as firmly established compared to high power distance cultures. Cultures with a low power distance index include Austria (PDI: 11), Norway (PDI: 31), and the United States (PDI: 40) (Hofstede 2001).

Mitchell et al. (2000) contend that high power distance has a negative effect on venture creation. Their argument is based on the fact that in such societies, individuals from the lower classes may consider firm creation to be restricted to the elites – individuals who have access to both the necessary resources and experience. Consequently, the majority of the population outside this small group of elites will fail to develop valid cognitive schemas either for evaluating environmental opportunities or for undertaking entrepreneurial ventures. Further, since entrepreneurs have high needs for achievement and independence, Hofstede (1980) found that power distance negatively correlated with a belief in the importance of independence.

Uncertainty Avoidance

Uncertainty avoidance refers to "the extent to which the members of a culture feel threatened by uncertain or unknown situations" (Hofstede 2001, p. 161). This dimension measures the extent to which members of a culture fear uncertain or unknown situations, reflecting the society's intolerance of ambiguity and uncertainty.

Strong uncertainty avoiding countries typically feel threatened by ambiguous situations and design ways to reduce their stress and fear of the unknown. The stress resulting from uncertainty leads to the need to adopt formal rules and to be less tolerant of people, groups, or ideas that diverge from already familiar models. Individuals fear failure in these societies, and consequently, their members avoid undertaking risks. Examples of countries with a relatively high uncertainty avoidance index (UAI) include Argentina (UAI: 86), Turkey (UAI: 85), and Italy (UAI: 75) (Hofstede 2001).

Low uncertainty avoidance societies fully accept uncertainty. Such countries exhibit a higher level of tolerance for change and ambiguity, and accept and often embrace the risks associated with an uncertain future. In societies with low uncertainty avoidance, organizational rules can be violated for pragmatic reasons. Conflicts and ambiguous situations constitute a natural part of life in an organization. The United States (UAI: 46), Malaysia (UAI: 36), and South Africa (UAI: 49) are examples of low uncertain avoidance societies (Hofstede 2001).

Low uncertainty avoidance cultures are interested in exploring new ways of doing things, although this necessarily implies some level of uncertainty. Individuals in these cultures are more ready to assume risks and exploit any opportunities they can identify in their environment, even in situations where information is limited (Busenitz and Lau 1996). All these behaviors create an atmosphere where the members of these cultures are inclined to manifest more entrepreneurial inclinations.

Individualism and Collectivism

This dimension of culture describes "the relationship between the individual and the collectivity which prevails in a given society" (Hofstede 2001, p. 209). The individualism-collectivism dimension shows whether the interests of an individual or a group are more important. According to this dimension, all cultures can be characterized by the strength of social forces, which bring individuals together to form social entities.

Individualism is the degree to which people in a country prefer to act as individuals rather than as members of groups. Individualistic societies are characterized by an emphasis on individual initiative, self-sufficiency and control, and the pursuit of individual goals that may or may not be consistent with in-group goals or achievement. In an individualistic environment, people are motivated by self-interest and achievement of personal goals. They are hesitant to contribute to collective action unless their own efforts are recognized, preferring instead to benefit from the efforts of others. Examples are the United States (IDV: 91), Canada (IDV: 80), and New Zealand (IDV: 79).

On the contrary, people in collectivistic societies are connected to each other through strong and cohesive groups that protect them during their lives. It is assumed that people are loyal to these groups. In collectivistic cultures, there is a communal-based regulation of society. People connect their identity with groups more than with other characteristics of personality. Collectivism involves the subordination of personal interests to the goals of the larger work group; an emphasis on sharing, cooperation, and group harmony; a concern with group welfare; and hostility toward out-group members. Collectivists believe that they are an indispensable part of the group and will readily contribute without concern for advantage being taken of them or for whether others are doing their part. They feel personally responsible for the group product and are oriented toward sharing group rewards. Countries with a relatively low index of individualism include China (IDV: 20), the Philippines (IDV: 32), and Indonesia (IDV: 14).

Recent research on entrepreneurship has mostly focused on the issue of the role of individualism and collectivism. Individualism-collectivism seems to be one of the more salient dimensions of culture insofar as entrepreneurship is concerned. It is suggested that of all the elements necessary for successful entrepreneurship, the independent entrepreneur is the most critical. Individual autonomy and a sense of ownership of innovation encourage the risk-taking and persistence required for entrepreneurship.

Therefore, in individualistic cultures, entrepreneurship is valued and encouraged by the society since the entrepreneurial individuals usually show high levels of personal confidence, initiative, and courage. For example, individualism is an intrinsic aspect of American culture, which helps to explain the relatively intensive amount of independent entrepreneurial activity in the United States.

In collectivist societies, both private property and the protection of individuals' ideas are limited. In these societies, in which collective economic activity predominates, there may be fewer opportunities for individuals to develop the capabilities and skills needed to create new firms. However, it should also be pointed out that in the context of Asian cultures that are more collective and relationship oriented than Western cultures, entrepreneurship may be more of a family or group emphasis than on individual endeavor.

Masculinity and Femininity

This dimension reflects a culture's dominant values with respect to achievement, recognition, competitiveness, and interpersonal relationships (Hofstede 2001). Masculinity-femininity shows to what extent a culture is dominated by such masculine values as orientation toward achievement and competition. The detection of self-assertiveness and other "masculine" values, such as independence and career, refer to masculinity, while discretion, tolerance, and solidarity describe feminine behavior. Hofstede (2001) describes a masculine culture as one in which "people live to work" (longer work hours and short vacations) and a feminine culture as one in which "people work to live" (longer vacations and flexible working hours).

Masculinity as one pole of this cultural dimension is highlighted in societies where the social gender roles are clear: men are supposed to be assertive, tough, and oriented toward material success. Masculine societies are aggressive, task and performance oriented, with many occupations typically considered gender specific. In a masculine society, challenge, advancement, and the accumulation of money are important. Countries with a relatively high MAS score are Japan (MAS: 95), Italy (MAS: 70), and Ireland (MAS: 68) (Hofstede 2001).

Femininity, on the other hand, characterizes societies in which the social gender roles overlap: both men and women are assumed to be modest, sensitive, and concerned about the quality of life. Feminine societies are characterized by an emphasis on relationships and social interactions. Economic growth may not necessarily be the primary concern of the society. In a feminine culture, a friendly atmosphere, job security, and cooperation are paramount. Such countries include Spain (MAS: 42), Thailand (MAS: 34), and Portugal (MAS: 31) (Hofstede 2001).

Masculinity of a society refers to assertiveness, competitiveness, and achievements. The Western concept of the entrepreneur follows the "hero" metaphor. It is argued that without the visionary leadership and persistence demonstrated by this individual, little will be accomplished. In masculine countries, individuals are taught to appreciate strong and independent heroes who personify superiority (Steensma et al. 2000). These cultures view failure as a sign of mediocrity, so the need for achievement intensifies. Conversely, individuals from feminine countries tend to be less aggressive and assertive as they are taught by their societies to seek mutual gain (Hofstede 2001). With these arguments, masculine cultures are associated with more entrepreneurial behavior – the higher the masculinity level in a particular area, the higher the level of entrepreneurial behavior.

Conclusion and Future Directions

Generally, cultural values identified with the classical Hofstede's 4-dimensional model and associated with entrepreneurship are high power distance, high individualism, low uncertainty avoidance, and high masculinity (McGrath et al. 1992; Swierczek and Quang 2004). Countries with these features are more entrepreneurial (entrepreneurship rates defined as the percentage of new business owners in a country). The classical model of the four cultural dimensions has been further developed for the last three decades. A fifth dimension, long-term orientation (LTO), was added in 1991 based on research by Michael Bond (Hofstede 2001) and modified later (Hofstede and Minkov 2010). Hofstede et al. (2010) then added a sixth dimension, indulgence versus restraint. There are also several other models of cultural dimensions that have been suggested in contemporary publications, e.g., Schwartz and Sagiv (1995), Trompenaars and Hampden-Turner (1998), and House (2002). However, within a global context of entrepreneurship, there are still contradictive findings published in the literature and a limited understanding of the extent of a particular culture's influence on entrepreneurship and entrepreneurial behavior. There is a need for further examination of the relationship between cultural characteristics and individual and organizational opportunity-seeking propensities and the peculiarities of venture-creation decisions across cultures.

Definition and Role of Entrepreneurship

Since the first definition of entrepreneurship by Cantillon in 1755, this concept has evolved and been defined differently by various scholars depending on their specific fields of studies: risk bearing, management, innovation, decision-making, profitability, opportunity seeking, and enterprising individuals. However, besides this heterogeneity in entrepreneurship definition, there is a wide consensus about entrepreneurship's importance in economic development. For example, the Schumpeterian approach states that entrepreneurship is a dynamic process of identifying economic opportunities and acting upon them by developing, producing, and selling goods and services. Kirzner approach stresses that entrepreneurship brings stability to the economic system.

Entrepreneurship becomes crucial, especially for small- and medium-sized enterprises (SMEs), because all governments worldwide recognize the importance of SMEs and their contribution to economic growth, social cohesion, employment, and local development.

Therefore, a serious attention has to be paid to entrepreneurship in SMEs, mainly in environments characterized by high uncertainty. In such context, agility becomes a strategic and organizational asset that managers have to develop, maintain, and enhance over time.

Entrepreneurship: Characteristics and Specificities

Definition

Entrepreneurship can be defined as a process by which an individual – for his own purpose or in an organization – pursues an opportunity under specific resources constraints (Stevenson and Jarillo 1990). In other words, it is the process by which an individual tests and investigates his ideas (Basso 2004; Bouchard 2009), whether in a new context, in case of a new business start-up or in an existing context, when a company already exists, also called "corporate entrepreneurship" (Shane and Venkataraman 2000).

Factors Encouraging Entrepreneurship

Several factors contribute to the development of entrepreneurship. Some authors propose models emphasizing individual, group, and\or environmental factors. Others defend models integrating organizational theory and strategic management.

As an example, Covin and Slevin (1991) studied the processes, practices, and activities of decision-making process that lead to the creation of new business. They were inspired by the works of Miller (1983) and highlighted entrepreneur's orientation toward risk taking, innovation, and proactivity. Lumpkin and Dess (1996) underline the role of competitive aggressiveness and autonomy in the entrepreneurship orientation. As such, Basso et al. (2009) think that competitive aggressiveness corresponds to proactivity and that autonomy is integrated into risk taking.

Schindehutte et al. (2000) underline the dynamic character of factors nurturing entrepreneurship. The dynamic interaction between managers' characteristics, employees, company, and external environment influences the entrepreneurship orientation. Other studies underscore the influence of national culture on the entrepreneurship orientation (Kreiser et al. 2010).

Different Facets of Entrepreneurship

Sharma and Chrisman (1999) explain that entrepreneurship can be studied according to several aspects. Indeed, Stevenson and Jarillo (1990) consider entrepreneurship from the point of view of entrepreneurial management. They define it according to six dimensions: strategic orientation, pursuit of opportunity, resource management, resource orientation, management structure, and reward philosophy. Brown et al. (2001) add two other dimensions to entrepreneurial management: growth orientation and entrepreneurial culture.

Entrepreneurship can also be considered from a strategic management view (Ferreira 2001). Entrepreneurial strategy depends essentially on the company life cycle, entrepreneur characteristics (abilities, values, belief system, and network), and external environment, but its influence is according to Ferreira of lesser impact. Holt et al. (2007) disagree with this conclusion and demonstrate that contextual and process variables influence entrepreneurial orientation more than individual characteristics.

Manimala et al. (2005) propose a model of organizational design for innovations. They stress on the importance of organization and its factors (training, time, available resources) but also underline the importance of entrepreneur's characteristics (knowledge, education) and management policy (rewards, motivation) to pursue an innovative project.

In their model "Corporate Entrepreneurship Strategy" (CES), Ireland et al. (2009) think that the individual entrepreneurial cognitions and external environment conditions can activate an entrepreneurial strategy. They support that this strategy is based on three elements: entrepreneurial strategic vision, pro-entrepreneurial organizational architecture, and entrepreneurial behavior and process.

Chang (1998) presents another model of entrepreneurship, in which he makes a distinction between intrapreneurship (within the organization) and exopreneurship (external to the organization).

Main Approaches of Entrepreneurship

Several studies about entrepreneurship are mainly interested in the results. This approach, called "causation," brings a particular attention about the purposes and objectives to achieve. It is to note here that an entrepreneur may follow several purposes (Markman and Baron 2003; Redien-Collot 2006).

However, Sarasvathy (2001) reveals that the entrepreneurship can also be studied through its processes and its effective modes of implementation. This approach, called "effectuation," is more interested by the deployment of entrepreneurial activities or to the available means to reach given results than by the end results. It is concerned by the individual ability to identify and manage contingencies in order to realize the expected results. So, it considers more risks and losses than return on investment.

Agility as an Entrepreneurial Objective in SMEs

A deeper knowledge of mechanisms and process leading to entrepreneurship is highly important in dynamic and uncertain environment, such as the one we are living in currently. According to Kuratko and Audretsch (2009:1), "*The twenty-first century business atmosphere can be characterized in terms of a new competitive landscape that encompasses increasing risk, decreased ability to forcast, fluid firm and industry boundaries, new structural forms, and an innovative mindset. [. . .] No organisation is immune to the immense pressure of these forces.*" In such context, agility can be a strategic and organizational asset, a sustainable competitive advantage, especially for SMEs which are more sensitive to environmental fluctuations.

Definition

Agility is a military concept derived from the field of aircraft combat (Richards 1996). Today, it is the capacity of a company to grow within a changing environment characterized by frequent variation in consumers' needs and requirements (Breu et al. 2001; Yusuf et al. 1999; Badot 1997).

Agility covers various areas such as the agility of competitors (Goldman et al. 1995), supply chain agility (Christopher 2000; Lin et al. 2006; Paché 2006), agility of business relationships (Preiss et al. 1996; Morgan 2004), agility of decision support systems (Huang 1999), and human resources agility (Forsythe 1997; Breu et al. 2001; Chonko and Jones 2005). Its attributes are different according to its field of practice.

Agility Attributes

Bessant et al. (2001, 1998), which have studied agility in English SMEs, stress the creation of strategic partnerships and networks in order to develop dynamic capabilities and a long-term agility. Coronado (2003) shows the importance of information systems in the agility of industrial SMEs, particularly within the production process.

Barzi (2011) defines the agility of the SMEs through four main dimensions: flexibility, reactivity, differentiation, and proximity. Their attributes are presented in the following chart (Table 1).

Entrepreneurship and Small Business Agility, Table 1 Attributes of SMEs agility

Dimensions of agility		Factors of agility	Attributes
Proximity (relationship, cultural, geographical, hierarchical)	**Flexibility**	*Human resources orientation*	Continuing training
			Versatile HR
			HR availability
			Staff participation
			Strong interpersonal relationship
			Good communication manager/staff
			Interenterprises teams
		Reasonable ambitions	Careful investment
			Firm reasonable size
			Flexible production
	Differentiation	*Customer orientation*	Good relationship – CRM
			Customer loyalty
			Excellent services
		Creativity orientation	New products
			Creation of needs
	Reactivity	*Commitment deadline*	Short production and delivery deadline
			Quick satisfaction of needs
		Easy making strategies	Nonformal choices
			Medium-term choices

Barzi (2011) emphasizes that proximity is the cornerstone of SMEs agility because it feeds the other dimensions. It strengthens customer and staff relationships by creating a new way of communication more appropriate for quick decision-making. All these four dimensions are in continuous interaction between each other that lead ultimately to a more progressive and incremental agility.

Therefore, the relationship between entrepreneurship and agility is very tight and complementary. On one side, entrepreneurship enhances agility because all the decisions and the actions taken by entrepreneurs should aim for the improvement of their company's agility to better meet the needs and the expectations of the market. On the other side, agility facilitates the decision-making of entrepreneurs and the implementation of their strategic choices. Entrepreneurs are better informed about the market and its opportunities and have deep knowledge about the resources to acquire and the skills to develop internally to meet these market's opportunities.

Conclusion and Future Directions

The dynamic forces that characterize today's environment call for a new organization and new management of SMEs. Entrepreneurs should change their way of thinking and the approach which they are dealing with environment to a better understanding of the market place. As an entrepreneurial objective, agility provides SMEs' managers the flexibility, the reactivity, the differentiation, and the proximity to compete effectively in hostile environment. It has to be an ongoing process, a continuous improvement program to meet the ever changing needs of today's customers.

Future studies will investigate possible differences related to agile attributes between companies of different sizes and sectors.

Social entrepreneurship; Social ventures; Society and entrepreneurship

Introduction

Over the first decade of the new millennium, academicians, professionals, and the media have attempted to make tangible the practice of entrepreneurs – and the notion of entrepreneurship – with a socially inclusive perspective via the specific terminology of "social entrepreneur (ship)" (for some representative reviews, see Alvord et al. 2004; Paredo and McLean 2006; Guzmán and Trujillo 2008; Matei and Sandu 2010; Granados et al. 2011; Desa 2012). The ensuing proposed variants of more precise definitions are innumerable. While this entry's purpose is on one hand to be synthetic and positive about the current body of knowledge of this important emerging discipline, on the other hand, it also wants to serve as a jumping board for further developments and critical inquiry and is necessarily interpretive, even normative at times. Thus, in order to render justice to the challenging complexities and multiple dimensions of this field of study as well as its praxis, this entry advocates an admittedly integrative and decidedly large definition for the analysis at hand:

Social entrepreneurship means creating public value with private means to reconcile the paradigmatic imperative with the pragmatic challenge of postcapitalist society.

While arguable quite a sweeping definition, it, however, does not matter-of-factly include several other, more remotely related notions, such as social corporate responsibility, intrapreneurship, or generic creativity (i.e., uncommercializable innovation at the level or art, culture, and craft). Social corporate responsibility typically remains a function of organizational managers, paid researchers, and largely ethical and moral, socially required standards. It does not seem to possess the qualities of sociocentric and capital-agnostic, genuinely generative human individuals or small groups, but merely frames the self-preservative contingent and systemic ambitions of firms (as a priori constructed and consequently volatile systems) vis-à-vis their environment: they want to be more sustainable situationally and relationally. On the other hand, intrapreneurship also, while it may very well express creative, innovative, and potentially socially beneficial intentions, remains confined to the profitability-centric organizational realm, resulting in protected, private, and proprietary intellectual property. And finally, if our goal is to collect and transmit epistemic and ontological knowledge about the branch of social entrepreneurship as a learnable, practicable, and impactful discipline for future generations, we cannot be satisfied with mere induction based on laudable, noble, yet singular events or actions. To become learnable by individuals and for those individuals to be developed, to be adopted and adapted, to become *praxis*, it needs to transcend the stage of perpetual *practice* (as in "practicing," trying, experimenting). While it may always retain some facet of *art*, it also needs to become *science*.

Entrepreneurship and Social Inclusion, Table 1 Type of goods

	Excludable	Nonexcludable
Rivalrous	Private goods: food, clothing, toys, furniture, cars	Common goods (common-pool resources): fish, hunting game, water, air
Nonrivalrous	Club goods: cable television	Public goods: national defense, free-to-air television

The "Social" Element of Value Creation in "Social Entrepreneurship"

Venturing by individuals or groups of individuals for the benefit of the public is neither a recent phenomenon nor is it a spectacularly novel idea. Already at the dawn of early, even primitive communities or social groups, producing for others in the community was necessary, acceptable, and right out desirable. Societies are constructed organisms, partly a consequence of evolutionary and behavioral processes to overcome the limitations of mere subsistence level survival and unsustainable self-preservation violence, partly a cognitive construct of leveraging individual idiosyncrasies, specialization, and exchange of the resulting excess production. But societies do not only have or need an economic dimension to sustain themselves materially. They also need a sociopolitical sphere to maintain them ethically, morally, and possibly spiritually. The latter inspires the norms of the first and the previous provides the resources to nurture and cultivate the second. More importantly and more precisely, the economic sphere is itself a multidimensional construct.

The Challenge of Social Economic Goods

In fact, economic goods are defined by the two dimensions: rivalry (not enough to go around for everyone's insatiable consumption) and excludability (while used by someone, it cannot be used (any longer) by others). The resulting famous construct is that of private goods such as typical normal or luxury goods, that is, objects of individual consumption (both rivalrous and excludable), public goods such as sunshine and air (neither rivalrous nor excludable), impure public goods such as information and infrastructure goods and utilities (rivalrous but not excludable), and common-pool resources or club goods such as intellectual property or natural resources upon discovery and appropriation (not rivalrous but excludable). Table 1 below illustrates that typology (Samuelson 1954).

While the paradigm of private goods is essentially captured by traditional so-called egocentric entrepreneurship, it is the remaining three quadrants that have always motivated the sociocentric social entrepreneur. Historically, these three paradigms suffered an inherent imbalance due to underproduction and overconsumption as well as incentives for social loafing and free riding, thus giving rise to market imperfections. This was antithetical and hard to reconcile with the basis of perfectly competitive markets under assumed conditions of full information, rationality, transitivity, self-interested benefit maximizing and positional optimizing, their converging forces toward equilibrium and Schumpeterian "creative destruction" resulting in the only viable alternative of monopolistic competition. Then, presently, these three nonprivate paradigms have reemerged with a vengeance as increasingly complex and complicating social systems demonstrate a consumptive insatiability of social goods. We increasingly demand the provision of precisely those nonrivalrous and nonexcludable public goods (e.g., information, air, and sunshine), nonrivalrous and excludable common-pool resources (energy and other natural resources), and, the most resource-hungry category of them all: rivalrous, nonexcludable impure public goods (transportation infrastructure, education, utilities, health care, security). And finally, for the future, the material criticality has dramatically surged as a consequence of the information technology advances of the past three decades. Making the transition from a predominantly transactional industrial economy that favored the acquisition of goods and services for immediate depreciative consumption, to a transformational "experience" economy promoted through intangibles and perceptions, pluralizing societies have seen their delicate interplay between consumptive and productive patterns shift, intensify and become complicated at an unprecedented velocity, resulting in prosumers and coproducers, unhinging the traditional notions of economic interactions: scarcity becomes abundance, effectives replaces efficiency, immediacy outdoes measured response, accessibility destroys control, purpose must precede objectives, context imports over content, and appreciation of intellectual capital eclipses depreciation of produced capital. Such paradigm shifts will require solutions above and beyond the current paradigm of the invisible hand, self-organizing markets, benign self-interest, and generally self-structuring organic systems. At different times and in different settings, these issues were being addressed with solutions of varied and questionable success, ranging from corruptively inefficient statism to inadequately effective community-based peer production; some were politically fragile models based on local taxation for the provision of municipal services, and then recently, more mission-centric nonprofit models to provide what would be considered "public goods" became popular. Enter "social entrepreneurship," the panacea destined to reconcile the competing objectives inherent in the pursuit of social value through economic means. Therein lies the positioning potential but also the positioning dilemma of the social entrepreneur.

The Role of the Social Entrepreneur in Responding to the Challenge of Social Economic Goods

It remains to operational the social aspect of social entrepreneurship on the three main constituents of a value-creating business model, purpose, process, and product, commonly referred to as strategy.

The Outrageous Purpose: Transformational Value Propositions Defined by Vision, Mission, and Leadership While some exaggerated claims of Google's Sergey Brin and Larry Page, for example, to want to dominate the world of knowledge or readying itself to challenge oppressive political systems, or Mark Zuckerberg's controversial market penetration attempts with Facebook in China may squeeze a muse or foster admiration, they are precisely the kind of sociocentric purpose that qualifies a social entrepreneur. While it is certainly not unwise to want to solve or mostly – at best "satisficingly" – resolve socioeconomic problems, or address social "bads," even contribute to lower socially controversial negative externalities or aspire to increase positive externalities, it remains that social entrepreneurship cannot be merely reactive in responding to perceived dissonance and discord between current state and desirable state. In doing so, they may and have, for that matter, often created additional problems: starting a stray pet care facility may lead to more stray pets if society now knows it can rely on someone else's conscience for stray pets. To qualify as a social entrepreneur, one must possess the attributes and capabilities to see society in a complete and complex context. That in turn requires vision, the ability to conceive a future so vivid and tangible, emphatically and passionately communicable and communicated to others that it will result in movement toward that future, typically referred to as leadership ability. But while conventional definitions of leadership are centered about the personality or the character of a particular person, the leadership necessary here is not based on such personality cult nor on demagogy or moral coercion. It is the "leadership from behind" or the leadership *effect* that defines the motion toward the vision. To become charisma independent in turn, this type of leadership effect supposes a mission so compelling that it in fact displaces the leader. Inasmuch, the social entrepreneur's social dimension is ultimately defined by a *transformational* ambition, far beyond the mere transactional ambition of the simple social problem solver. Transformational leadership as a defining component of the social entrepreneur thus requires him or her to also think as a social designer, a game changer, and critical dreamer: it will take not only the ability to propose value with a solution, but it will also require the attributes of courage and passion to architect entirely new contexts and think ontologically and normatively about the course of society. This is a tall order.

The Unconventional Process: Path and Progress in the Eye of Adversity

– *Managers make decisions – social entrepreneurs make choices*. While there is no point in glorifying the heroism, persistence, or crisis competencies usually attributed to entrepreneurs, it is important to point out that social entrepreneurs cannot be restricted to being resource minded, optimizing, or economizing risk minimizers. As such, managers typically identify if some dissonance can be addressed as part of the problem, part of the solution, or part of the landscape. Unlike the confines of the organization, however, society at large is forged by competing value systems, shared cultural interpretations, and historically shaped, inert rituals. Prospectors, those desiring change and competent to effect it have more in mind than solving or resolving problems at hand. In Ackoff's paradigm (Ackoff 1978), they are destined to "dissolve" such situations previously perceived as problematic by (1) moving the entire landscape or (2) becoming the landscape itself. Those are choices. Unlike decisions, choices are not limited by endless information collection, data analysis and evaluation, and risk assessment. While respecting available information, choices are also and more importantly action centric. Inasmuch, social entrepreneurs are qualified by their action bias and give true meaning to the synonym "action plan" for the term strategy.
– *Social entrepreneurship is a mindset, while traditional entrepreneurship is a phase in an entrepreneur's life*. Traditional entrepreneurs start with a project, aspire to operationalize it, eventually become managers, and lastly possibly insider shareholders in their own company. If they deviate, we may call them unsuccessful or label them "serial entrepreneurs." Social entrepreneurs are perpetual.

The Product: Social Value + Social Benefit = Social Impact

– *Traditional entrepreneurs build products and organizations – social entrepreneurs create movements and networks*. Resource-agnostic, action-biased, social value proposition-driven, sociocentric, transformational individuals or groups cannot afford to lose sight of the social context by even merely periodically focusing on some "internality," be it the tangible outcome of product or service or the organization of plans, humans, and capital to implement it. The outcome of social entrepreneurship can and should therefore be shifting perpetually as social positions do. The product is not specific tangibles, experiences, and transactions; the product is impact to society. Their product can only be more social entrepreneurship, more social innovation opportunities, and generating, developing, and educating more social value creation-minded individuals. By definition, their innovation is open, their intellectual capital is shared or at least made accessible, and their value is not determined by the hierarchy they built, but by the network they extended and the amount of connections they can nurture and cultivate. Maximizing social impacts is only possible by increasing the rate at which new social entrepreneurs are developed. Thus, social entrepreneurs do not build organization hierarchies; they perpetuate a "pyramid scheme."
– *Traditional entrepreneurs produce, consumers consume. Social entrepreneurs both coproduce and prosume*. Analogous to Peter Drucker's proposition in the Post-Capitalist Society (Drucker 1994), where today's knowledge society is by definition socialist since the knowledge workers not only are the productive resources, but they also own the productive resources through investments and pension funds mediated by the public financial markets, social entrepreneurship is truly social because not only are its intent and outcome social, but so are its vehicles and tools of production, represented by the social networks implicating the very receivers of the social benefits in the production of these very – indeed their own – benefits.

The "Entrepreneurial" Element of Value Creation in "Social Entrepreneurship"

Peter Drucker's notion of social entrepreneurship for a "not-for-profit twenty-first century" proves too restrictive today (Drucker 2006). Confining social entrepreneurship to not-for-profit may have resulted in its early demise. Fortunately, not for profit really never meant not for profit. And fortunately, the corporate paradigm does not always rest on greedy shareholders. In the following, we analyze how to reconcile the pragmatic social imperative with the impractical financial challenge of financial sustainability for social entrepreneurship.

Irrelevance of the for-Profit Versus Not-for-Profit Controversy for Social Entrepreneurship Models

The for-profit vs. not-for-profit controversy as to the appropriate model for financially sustaining social ventures is grounded in an ironic historical context. Some of the most famous social benefactors happened to be some of the richest of the original capitalist, industrialists, and elitists of the previous centuries. While their charities and philanthropy created some amazing social results, their ulterior motives are questionable at best. Maybe it was self-serving ways to cope with guilt, prevent social unrest, or genuine concern for the lower classes of society. But it was neither social, nor was it entrepreneurial.

Social Entrepreneurship Is Neither Defined Nor Does It Depend on Philanthropic Capital Charitable giving, philanthropy, and donations are indeed antithetical to social entrepreneurship. They create a dependency of the purpose of a social venture on the whimsical availability of excess wealth. The focus of the social entrepreneur thus shifts from the value proposition to resource acquisition. It shifts from motivating the network to meeting the conditions of the giver. The conflict is further compounded by a mostly opaque process of such giving, the ensuing control ambitions of the giver, and the potential for undue influence by the giver. Finally, even if one overcame the ambiguities associated with charitable capital, one is left with the sheer insurmountable problem of operationalizing such structures. That is, how does one turn these project-centric episodes as they are conceived by the giver into a sustainable venture, that is, a going concern as is needed by the social entrepreneur. And ultimately, basing social entrepreneurship off of such charitable structures precludes it from becoming a teachable discipline and learnable practice. It relegates social entrepreneurship to pure craft and unsystematic artistry. Inversely, many a venture has emerged, even excelled, and sometimes overwhelmed our wildest expectations: Google, eBay, the Chinese Baidu, then Yahoo, even Amazon, Facebook and YouTube, MySpace, to name only the most prominent of the day. And they did not rely on donations. In fact, they are all hard-core for-profit corporations (Jelen 2009). Yet, the tremendous amount of social value and social benefit, the social change, and the social transformations that resulted are beyond doubt, even if we yet have to find the right metrics to capture such value.

Social Entrepreneurship Cannot Be Selfish, But Does Not Need to Be Selfless While the Smithian notion of self-interest pronounces much smoother than it is practiced, it remains a central tent to this second part of the present analysis. While typical egocentric entrepreneurial capital of the traditional kind promises returns to selfish financial risk takers in a project, the capital needed for social ventures does not have to be of diametrically opposed quality as is presumably selfless capital of the charitable kind. If capital is committed in the Smithian spirit of self-interest, respectful of all other self-interest, and knowingly flows to ventures that have an explicit intent and impact of social spillover, positive externalities, and public benefits above and beyond the private returns, it should leave intact the social quality of the venture. Constraining social ventures to the not-for-profit version of corporate activity reduces the incentives for private patient capital to zero. But excluding social ventures from private patient capital is indeed perverting the spirit of social value creation. On the other hand, accommodating the definition of the social venture to naturally include private patient capital also allows us to remediate the opacity of philanthropy. If capitalists want to give, they will now do so as shareholders in audited public corporations or auditable private equity firms and closed corporations with established oversight processes. If we thus disassociate the outcomes from the early restrictive operational definition of the social enterprise, and consequently leverage proven postcapitalist frameworks of public equity ownership and patient capital – along with value-adding work-structuration models for private organizations, networks, or hybrids – we can define a substantially richer and more promising set of opportunities for more dynamic, more resilient, and more effective creation of collective benefits for the twenty-first century.

From Entrepreneurship to Social Entrepreneurship to Social Innovation to Open Innovation to Social Inclusion

Part of the human condition, its organic predisposition with cognition in particular, drives individuals and groups to be creative, innovative, generative, and productive regardless of the quality, quantity, and immediacy of incentives. The particular quality of entrepreneurs is that they transcend mere (organic) opportunism with intention and initiative for (constructed) opportunities. Thus, generally defined as a venturing process of value creation, entrepreneurship can apply equally to generate private and public wealth. Yet, entrepreneurship has long been too narrowly defined, taught, and normed as exclusively related to private wealth creation, whereas the public wealth value creation was the area of state. In the postcapitalist era where state welfare is restricted because of political sensitivities, but moreover because of material and resource constraints, there are growing needs for social services that the state can no longer satisfy. As a result, social exclusion is growing in many countries, and it raises the needs for inventive ways to respond to them not only through state "intervention" but also through the creative generation of new ideas and exploitation of such opportunities by private actors. Entrepreneurship has often been excessively depicted as an expression of liberalism with an emphasis on private property and one's liberty to exploit the fruits of one's work. This conception has restricted the social side of any venturing process. Inherently, all entrepreneurship is a socialization process through which the entrepreneur creates weak and strong ties to exploit an opportunity. Such networking might result in more structured and stable relationships. In that sense, entrepreneurship is a process of social inclusion for the entrepreneur himself but also for other individuals who might join him or her in the project. Thus, an originally restricted notion is resolving graciously into a greatly expanded model for social value-creative ventures: information-technological ingenuity as a factor of production of the new experience economy has displaced concerns for the "old" factors volunteer-type labor and charity-like capital. Thus became possible Yunus' microfinance model, Social Impact Bonds, Open Innovation originated in the favelas of Rio De Janeiro and Sao Paolo, and New Yorkers converting a defunct and decommissioned railway structure into a delightful urban green public space, the High Line.

Conclusion and Further Direction

At the outset, we adopted an inclusive definition for social entrepreneurship: creating public value with private means to reconcile the paradigmatic imperative with the pragmatic challenge of postcapitalist society. Inasmuch social entrepreneurship is distinct from governmental projects, for example, that devote public means for public value creation. It is also distinct from traditional private entrepreneurship. The latter is typically only motivated if there exists the possibility to appropriate private value in excess of positive externalities or spillover social value that cannot be captured by the entrepreneur. In retaining the public value purpose and goal of the one and the profoundly constructive, productive, cognitive, and generative nature of the human condition of the other, a social entrepreneur is consequently someone less concerned with the nobility of the support for their generative processes and more with the impact of their results in terms of social value creation; he or she will be generative of this social value through commercialized creativity; and he or she will leverage aspirational social innovation with market-economic rationality into a purposeful venture and an entire sustainable system, much beyond merely resolving public needs and social problems, but aspiring to produce collective wants, communal experiences, and common cultural value.

While our focus was to develop the still popular notion of social entrepreneurship as principally juxtaposed to traditionally understood entrepreneurship, it may soon be a futile attempt to draw such distinctions in the light of the obvious: our collective interests and aspirations are taking on a dimension of unprecedented proportions in our lives and entirely new resource constraints and scarcity concerns are forcing us to think more sociocentrically. We will have to learn new ways of how to leverage limited financial, material, and intellectual resources at unprecedented scale to initiate social, global, and substantial change. The ingenious proposition of entrepreneurship in general and social entrepreneurship as a business *model* and a business *mode* with its explicit sociocentric purpose executed via private means is to create value, to realize opportunities, and to design, initiate, and motivate contextual change *before* crisis. In crisis, we are all entrepreneurs. And in social crisis, many of us quickly discover their Good Samaritan side. But we do not need to strive for more good Samaritans, or better Samaritanship. While such responsiveness is certainly important and has its place in the socioeconomic compact, the true nature of entrepreneurs and entrepreneurship is not to be merely reactive, protective, or defensive. They are true prospectors in Myles and Snow's paradigm. Entrepreneurs are not limited by opportunities resulting from accidents or incidents. They are not confined to *opportunism*. Social entrepreneurs transcend the paradigm of recognizing and realizing opportunities but want to intentionally design, create, and construct *opportunities* in their own right.

Entrepreneurship Education: Issues and Challenges

Entrepreneurship and, thus, small- and middle-sized firms (SMEs) have had a growing interest for the past two decades, from the academic world as well as from public authorities. This interest is part of many economic changes. In particular, technological change and the increasing incidence of innovation in most developed countries have reduced the importance of the size of the companies in the industry and favored the development of entrepreneurial activities. In addition, globalization would have dragged the comparative advantages of North American and European countries toward knowledge-based activities, while the "knowledge-based economy" would be relatively more conducive to entrepreneurship and to SMEs.

At the European level, the Lisbon Agenda (2000) confirms the significance of innovation as a driver of change in the economic growth of tomorrow. In this perspective, entrepreneurship can be considered as one of the main levers to operate, especially since it is part of specific contemporary dynamics. First, researchers in economics highlight the involvement of a growing number of active SMEs in the innovation process, particularly in the case of clusters and competitiveness clusters. Moreover, the increase rate of unemployment during the 2000s, also fueled by economic and financial crisis that begun in 2007, led governments of many countries to ease the creation of business or to promote self-entrepreneurship, in order to induce agents to create their own jobs. In addition, developed economies coped with the aging of their populations, including company leaders, whose business will have to find a buyer who could well manage them. Furthermore, a transmission of small business on five results on a bankruptcy filing within 6 years in France or in Canada.

The issues in terms of ability to manage the creation, transition, and business development are primordial, both in their qualitative and quantitative dimension. It is in this context, conducive to new needs of knowledge, that emerge entrepreneurship teachings designed to inspire and enable individuals to start and to grow entrepreneurial ventures. They can be addressed in two steps. First, a historical approach will show how teachings in entrepreneurship have evolved in their implementation based on a double dynamic of empowerment and "complication" of training programs in entrepreneurship, which seems structured around the controversy over the ability to learn to undertake business or initiate the risk culture. Second, practical teaching methods of entrepreneurship will be analyzed, making sure to highlight the multifaceted reality of innovative approaches and actions through an international benchmark conducted by the PIMREP (ParisTech Innovation Management Research and Education Program) network (PIMREP 2010, 2011) (► Higher Education and Innovation).

The Story of a Controversy: Can We Train to Entrepreneurship?

Historically, Myle Maces has provided the first entrepreneurship courses in Harvard in 1947 (Katz 2003). However, the 1970s mark the true genesis of a plethora of actions that affects other schools: high schools, universities (schools of business and engineering), and centers of entrepreneurship (ibid.), both nationally and internationally, starting by Anglo-Saxon cultured countries. This expansion is fueled by accreditation bodies of academic programs that enhance the efforts to encourage entrepreneurship in the design of programs, from the mid-1990s (Adcroft et al. 2004). During this particularly prolific period, two significant trends have come together to shape entrepreneurship education as we know it nowadays. Firstly, it is a process of empowerment of entrepreneurship training programs: "entrepreneurship in universities has so far been developed as an add-on to business education, first as an elective course, then more courses, and finally as a concentration, major or program" (Vesper 1999). Secondly, teaching programs are subject to growing complexity, in terms of teaching through theoretical approaches and in terms of broadening perspectives. According to this interpretative framework, it is possible to distinguish several periods that stand out by their approach to entrepreneurship, which seem to be structured around the controversy over the faculty and the opportunity to learn to undertake business or to initiate the culture of risk.

"Entrepreneurs cannot be manufactured, only recognised"

In early youth of entrepreneurship education, it has been mainly treated around the issue of business creation. The teachings are based primarily on the testimony of successful business entrepreneurs (► Entrepreneur; Fiet 2000) with the aim to share meaningful experiences of business creation and to highlight the elements of success of these success stories. Learn from experiences through analogies, even though each business creation is – by definition – specific, may seem paradoxical. It is this gap that interferes in a series of skeptical researchers against such teaching practices and critical of the ability to train in entrepreneurship. Most of the arguments are based on the idea that the concept of entrepreneurship education refers both to the teaching of know-how that are objectifiable and to teaching of skills (▶ Entrepreneurial Capability and Leadership). They cover two levels of analysis. The first relates to the figure of the entrepreneur himself, which economic literature has long strived to shape: attracted by risk-taking and marked by the need for achievement, it stands out for others by his taste for independence and deviance to the familiar and established. In this context, Chaharbaghi and Willis (1998) argue that "entrepreneurs cannot be manufactured, only recognised." The second criticism concerns the deterministic and contingent dimensions of testimonies and more globally, of the overall teaching methods mobilized. Some authors suggest that entrepreneurship takes a pattern of behavior that is rooted within a specific context and is isolated within that context, whereas Adcroft, Willis, and Dhaliwal (2004) state that "the entrepreneur being in the right place at the right time may involve elements of judgement but also involves elements of serendipity." As a consequence, entrepreneurship has long been considered as non-teachable because it cannot result from an optimized and infinitely reproducible approach.

"Entrepreneurship is not an innate quality, but a discipline of mind and action"

It is interesting to note that these criticisms are the seeds of a radical change in approaches to the issue of entrepreneurship in the 2000s. Indeed, beyond several empirical studies validating the specific value of entrepreneurship training, it seems to be largely in response to the criticism that academics undertake to enrich the educational treatment of entrepreneurship. The latter is more complex and therefore wins the groundwork for a separate discipline: "entrepreneurship is not an innate quality, but a discipline of mind and action that can be the appanage of a great number of students if only we train them" (Santi 2006). In any case, entrepreneurial skills must allow students to face a new problem by drawing on a heritage of knowledge and by reconstructing from them the elements necessary for the exploration of new solutions, although they take place in a complex and dynamic environment. The process that initiates such a change of mind – which will be only slightly challenged later – goes through a drastic evolution in the way we apprehend entrepreneurship, at the crossroads of several factors. On the one hand, the shared sense that entrepreneurship education should be divided into two approaches, both through action on the individual behaviors of students to stimulate innovative initiative and autonomy necessary for its development, that through the transmission of theoretical (and methodological) corpus necessary to analyze the essential elements of trends extension or, conversely, discontinuous elements. On the other hand, a process of empowerment of training curricula for entrepreneurship is coupled with programs that are getting more and more complex, in terms of theorization and in terms of broadening perspectives.

Multiple Dynamics Overlapped and Fertilized Entrepreneurship Education

During the 2000s, trainings in entrepreneurship are subject to multiple dynamics that overlap and fertilize. The first of these consists in promote a balance between theoretical and practical lessons, which greatly contributed to the empowerment and to the recognition of the entrepreneurship education. The purpose of such theoretical approaches, known as theory-based education (Fiet 2000), was to build a consistent and structured framework to maximize the probability of success for entrepreneurs. Specifically, they mobilize concepts and theories that have a clear applied and explanatory nature, such as agency theory, resource theory, or the economics of transaction costs (ibid.). Beyond the theoretical knowledge deepening that mainly concerns business schools, entrepreneurship trainings drastically expand the range of topics covered, as the legal aspects (idea protection), technical aspects (new product development, technological innovation), organizational aspects, marketing aspects, and especially the financial aspects (▶ Business Project; ▶ Angel Investors; ▶ Business Incubator) and individual stimulation (negotiation, leadership). Also, the entrepreneurship courses have not kept out of the profound mutations of pedagogical logic, since treatment of these last two themes went hand in hand with the shift from a passive pedagogy, in which instruction is designed as an "information delivery," to an active approach in which the purpose is to make the learner an actor of learning, which is referred to as experiential learning. This type of teachings is based primarily on computer and behavioral simulations or on creativity techniques (mind mapping, divergent thinking, brainstorming, or lateral thinking).

So far, transformations of entrepreneurship education have been drawn in broad strokes. It should be noted that they vary in space, in addition to vary over time. Indeed, if Solomon, Duffy, and Tarabishy (2002) find that business plan, case studies, and traditional teachings were still dominant educational tools in entrepreneurship education in the early 2000s, there have been mutations since then, both in terms of depth, that enlargement of views, or in teaching approaches. In this landscape renewed, what are the novelties concerning entrepreneurship education? Does the generalization of these developments have given rise to a standardization process of training in entrepreneurship? Some of the answers and lines of thought based on an international benchmark on training in innovation management led by the ParisTech Innovation Management Education Research (PIMREP) can be provided.

How Far Have We Advanced on the Learning Curve for Teaching Entrepreneurship? Findings of an International Benchmark

The PIMREP network was set up at the end of 2008 and encompasses many French high schools which belong to the ParisTech network (http://www.paristech.fr/index.php/eng/). After a study in 2009 on training in innovation in ParisTech schools, the PIMREP conducted an international benchmark in 2010–2011 in the same field and that is useful here. The aim was to identify trends and foster experience sharing between the members of the network and faculties abroad. The scope of this benchmark has covered eight institutions, including business schools (HEC Montreal, NCCU), technological institutes/universities (TU Munich, ETH Zurich, KTH, KAIST), and comprehensive universities (NUS, Aalto University). This selection demonstrates a commitment to observe the most innovative teaching practices on innovation and entrepreneurship (▶ Creative Pedagogy) and also intends to embrace a broad spectrum of contexts and of cultures in order to measure their relative importance on teaching approaches adopted. Each of these institutions has been visited and has been subjected to a questionnaire structured around a specific grid analysis. From this one, several trends have been identified. Training in entrepreneurship requires diverse teaching models that range from the acquisition of academic knowledge to learning that recreate a context of thought and action that are close to real-life entrepreneurship situations. Given the traditions and contexts of each institution, the survey shows a wide variety of experiences following two separate models, but with similar lines of development, but above all, these experiences appear more and more territorially (▶ Territory and Entrepreneurship).

An Analytical Grid to Characterize Programs in Entrepreneurship

The PIMREP network designed a system of reference to characterize the programs under study, which is built around different "educating situations" in innovation and entrepreneurship programs: awareness raising (involving presentations, testimonies, and introductive conferences), development of students' capacity for initiative (challenges, i.e., individual experiences with little assistance in terms of methodology or theory), training in methods and theories (lessons, seminar), and training in contexts of innovation (implication in entrepreneurship contexts focused on the integration of theoretical and methodological tools through tutoring). The survey consisted in analyzing the schools' degree courses with the following grid: type of teaching situations offered, type of students involved, "weight" in terms of time allotted and credits, and distribution throughout the degree courses. It aimed, on the one hand, to identify trends and typical configurations and, on the other, to identify and describe particularly interesting cases.

The Architectural Side of the Entrepreneurship Education

The first observation is that all these schools implement each of the teaching situations identified. Depending on their dominant culture (school of engineering, school of commerce, etc.), and according to other contingency factors (size, composition of the labor pool), the emphasis is placed on some of these teaching situations and, beyond, focuses on the issue of the creation or on the issue of business resumption. In addition, if the trainings in entrepreneurship are always available at each stage of university studies degree, the most ambitious educational activities, also the most demanding educational resources, are mostly related to specific curricula, as MSc, MBA, or EMBA. In this context, the master program is often called as bank storage for teachings or for case study bound for degree programs and PhD. Another finding is the fact that teaching staff are not only strongly multidisciplinary but consist of a large proportion of entrepreneurs previously or concurrently to their teaching. This proportion varies from significant to exclusive (TU Munich) and goes hand in hand with a changing role of trainers, from the role of teacher, to that of tutor, and up to the role of coach. Some workshops are self-managed by students, teaching staff being there only to guide and to answer questions from students. Please also note this revolution resonates with the emergence and spread of project-based teaching models.

The Pedagogical Side of the Entrepreneurship Education

Project-based teachings, i.e., concrete scenarios, real or simulated, based on collaborative or individual learning, greatly resonate to teaching teams. Frequently, on the basis of an original business idea, a gradual approach requires students to identify the major trends of the environment, to prioritize those most likely to have an impact on the development of the idea, and, finally, to explore possible changes or variations. In addition, on many occasions, multidisciplinary approaches (► Interdisciplinarity and Innovation) and those claiming to "design thinking", combining empathy and iterative process, were mentioned. However, one important trend is to give a more and more concrete perspective to teachings, in particular through the submission of actual projects by industry that can give rise to an oral assessment with the presence of top managers, also through networking with entrepreneurs from all backgrounds, and through the access to venture capital – simulated or not – of the students projects (► Networking Entrepreneurship), which are now major areas of improvement for trainings in entrepreneurship. The corollary is that even if for some training in entrepreneurship, pedagogical considerations dominate, in a growing number of other cases, territorial considerations seem to prevail (bavarian silicon valley in Germany, silicon valley of user-driven innovation in Otaniemi, Finland, etc.), especially in the context of ► Clusters (► Innovative Milieux and Entrepreneurship (Volume Entrepreneurship)).

Conclusion and Future Directions

"Compared to many other disciplines, the discipline of entrepreneurship is in its infancy, with no standard framework or agreed upon best practices for entrepreneurial education" (Solomon 2007). This finding should be reconsidered in the light of the foregoing. Indeed, even if the learning curve for teaching entrepreneurship is still long, it seems clear that the practices of experiential learning are now well established, as well as the "learning by studying" of the early time has been replaced by the "learning by experiencing," the "learning by interacting," or the "learning by doing." New perspectives probably depends on a "territorialization" of the teachings marking a decompartmentalization of entrepreneurship training that yesterday freeing itself from the shackles of traditional disciplines, now probably tends to emancipate itself from the shackles of (higher) education. The challenge is now to articulate this education to all stakeholders that form the ecosystem of the entrepreneur (education and research institutions, national and local policymakers, entrepreneurs, private sector, etc.). Many approaches apprehend this issue, been called for by the United Nations, such as KIC (Knowledge and Innovation Communities) from the EIT (European Institute of Innovation and Technology), or the project PEEPS (Pôle de l'Entrepreneuriat Etudiant Paris Saclay – Paris student entrepreneurship center) carried by the PIMREP network.

Creativity, Entrepreneurship and the Creative Economy

Entrepreneurship is essentially a creative activity, even if creativity is not limited to the entrepreneurial creativity. Thus, creative economy shares some of the most significant properties of an entrepreneurial economy. Creative activities rely on innovations, vision, and talent of authors, creators, and performers. Development opportunities related to changes in cultural practices also require a high degree of alertness from creative economy stakeholders. Besides, creative economy must cope with high demand uncertainty. As entrepreneurial creativity, artistic and cultural creativity is an activity based on risk. Creative economy combines two types of entrepreneurs. A first type relies on the shifts that occurred in the cultural policies of cities and in the proximity dynamics of creative clusters. And the second type is linked to the economy of contribution and to its different application fields, especially digital economy and social economy.

What Is the Specific Nature of Entrepreneurship in the Creative Economy?

Creative Entrepreneurship

When people put in practice their creativity, ideas, and talent to build up a business or a self-employed business in the cultural and creative industries, they act as creative entrepreneurs. Creative entrepreneurs use their talent, creativity, and artistic knowledge as specialized assets in the creative economy (Howkins 2001). Like kirznerian entrepreneurs, they often have no productive or financial assets at first. They try to put in value their social capital and their artistic or creative ideas as a symbolic capital.

Besides, creative entrepreneurs must cope with the uncertainty of the demand for cultural and creative goods. From this standpoint, they look like a type of knightian entrepreneurs. They also run the risk to be imitated. The only way to protect their cultural and creative assets is to rely on property rights, if they can meet the cost and complexity of the intellectual property protection.

Part of entrepreneurs come from creative economy stakeholders, especially the "creative class" (Florida 2002) that grows with the development of "cognitive-cultural production systems" (Scott 2008). Another part consists of creative entrepreneurs-contributors coming from the digital economy, social networks, and social economy.

Creative Entrepreneurship in Creative Cities

Entrepreneurship in the creative economy is not only a process by which people use their cultural and creative talents to set up their own business. If the determining role of creativity and innovation appears in the definition of the creative entrepreneurs, it also introduces analysis on the functions of creative entrepreneurship in societal and cultural mediation. To be creative, an idea must be socially recognized. Creative entrepreneurs dispense a lot of efforts and ideas for the cultural and creative life of the city. And creative entrepreneurship is at the heart of the cultural metropolitan projects, as it has been shown in capital projects, such as New York, London, Paris, and Berlin, but also in the cultural projects of metropolitan-regional cities, such San Francisco, Los Angeles, Liverpool, Bilbao, Barcelona, Milan, etc.

Besides, process of artistic research and creation also benefits from the results of the prospective policy regarding the city and regional development, which is at the root of long-term planning strategies (Pratt 2004). Those strategies can stimulate the development of creative and cultural industries, in the broader perspective of a territorial design related to the cultural needs of cities

Thus, entrepreneurship depends on both the creative activities and territorial dynamics, not only because there are new talents, entrepreneurs, creative assets, and relevant public policies, but also because the city asserts itself through implementation of cultural and artistic projects, as a creative city. Therefore, it becomes a creativity platform, going beyond the definition of an *augmented city* born out of digital technology. The spatial concentration of creative industries carries with it important changes in terms of impact on clusters and entrepreneurship. It becomes a source of comparative advantages for the city.

Creative Entrepreneurs and Cultural Mediation

From this standpoint, creative entrepreneurs are also societal entrepreneurs. Thus, it seems possible to connect the nature of creative entrepreneurship with functional theories of the entrepreneur, in particular those of Leibenstein and Baumol, which partly follow the theoretical prospect opened by Schumpeter.

In Leibenstein's interpretation, the entrepreneur's behavior is guided by four principal objectives. Initially, the entrepreneur is an *intermarket operator*. Creative entrepreneurs often connect different cultural and creative activities to enlarge the wide range of their business or to improve their self-employment, such as in performing arts. They also show their ability to compensate for the cultural and creative market insufficiencies (*gap-filling*), such as in open-source software. Then, creative entrepreneurs act as *input-completers*. They try to join together the factors which become necessary to the realization of new cultural and creative activities or performances, such as in film and music. Lastly, they know how to create or develop *efficient organizations*, such as they do in the framework of cultural clusters or creative cities.

So, the influence of the entrepreneurship as a functional mediation in the cultural projects depends on the more or less ability of the creative entrepreneur to fulfill the functions of intermarket operator, gap-filling, input-completion, and efficient organization building. In addition, as Baumol has underlined, the repartition of entrepreneurial resources depends on the profit distribution between productive and unproductive activities, and this allocation is heavily influenced by the relative payoffs offered by the societies to such activities. From this standpoint, urban cultural policies offer heavy incentives to the artists, creators, and performers to retain the talented entrepreneurs.

Entrepreneurship and the Taxonomies of Creative Industries

Studies and reports on creative economy often put the stress on the numerous distinctions and taxonomies that endeavor to chisel out the limits and the respective scopes of cultural and creative industries (Table 1). But, in the major role played by creative entrepreneurship, there would indeed seem to be a characteristic common to both. By their very nature, these activities, from performing arts to fine art, digital arts, architecture, and design, assert themselves as entrepreneurship ecosystems. The dynamics of creation, specific to cultural and creative industries, demand that ideas, talents, competence, and expertise circulate and contribute to fluidifying and amplifying creativity and innovation, as complementary assets (Potts 2011). They also combine different kinds of exchange that can be market and nonmarket exchanges, as well as different kinds of relations, ranging from cooperation to competition.

Entrepreneurship and the Specific Economic Characteristics of Creative Industries

The cultural and creative industries refer to a wide range of activities which are concerned with the valorization of artistic ideas, innovative knowledge, creative process, and intellectual property rights. From an economic standpoint, Richard E. Caves identified seven properties that could highlight the specificities of cultural and creative industries and distinguish them from other economic and social activities (Caves 2000). Such properties need to be emphasized from entrepreneurship point of view:

- Creative entrepreneurs are risk takers, facing with the radical uncertainty about the demand, because of the unpredictable positive or negative reaction of the consumers/users for each new creative product.
- They also act as input-completers, coping with a wide variety of differentiated activities; each of them can lead to an infinite variety of products and uses. And they deal with the complexity of the creative products that use a wide range of skilled and specialized workforce, as in music, film, or multimedia.

- Creative entrepreneurs have to develop efficient organizations. On one side, creative projects in music, film, and performing arts often require a high degree of coordination for the relevant uses of skills, and time becomes a very scarce resource. On the other side, creative products must be protected, by relying on copyright protection for providing durable rents to authors, creators, performers, and other stakeholders.
- They must also deal with skill structure and behavior at work. Artistic or technical skills are vertically differentiated in the creative industries; there is a ranking of talents that results in strong financial implications on the individual earnings and on the costs of production. Besides, workers in creative industries much care about individual skills (artistic or technical skills), than in other activities, and they want to freely use their skills.

Creative entrepreneurs have to deal with another complex economic characteristic. Creative goods have a specific cost structure, with high costs of production and low marginal costs of reproduction (Hesmondhalgh 2007). Contents activities' organization must cope with the sunkenness of costs. And the pervasiveness of the fixed and sunk costs in some capital-intensive activities can appear as a barrier to entry and to mobility and a barrier to exit for the entrepreneurs in the creative industries, because of the uncertain profitability.

The Spatial Dynamics of Creative Industries

Description

Creative industries can be characterized as *territorialized industries*, as activities the territorial anchoring of which constitutes a structural characteristic, with a strong influence on the conditions of valorization of cultural goods, on the location of creative economy stakeholders and so, on the development of creative entrepreneurship. The mobility of cultural and creative goods often comes with the territorial concentration of production. The spatial dynamics of creative industries tends to favor the organization of development poles, in creative clusters or in creative cities, with their clearly defined specificities (Cooke and Lazzeretti 2007).

So, the development of cultural and creative industries is based on the exploitation of a built-up territorial advantage, the result of the joint influence of creativity and innovation among creative economy stakeholders, entrepreneurial visions, proximity dynamics, cultural practices, and public policies. Entrepreneurs try to transform localized creative assets in specialized resources. These localized assets can be constituted via expertise linked to a recognized artistic and cultural specialization. They can also be related to public policies favorable to cultural industries and opened to the requirements of the artists, creators, and performers. And they allow creative entrepreneurs to increase their *pool of knowledge* by exchanging ideas, competence, and techniques. The valorization of these specialized assets – available locally under very favorable conditions – constitutes strong incentives for entrepreneurship in the creative economy.

How Do Creative Entrepreneurs Contribute?

Creative Entrepreneurship and the Economy of Contribution

The economy of contribution has introduced a paradigm shift in the approach of entrepreneurship in the creative economy. The schumpeterian entrepreneur, both producer and innovator, now copes with the major influence of "users-contributors" and the open and collaborative innovation. The market economy highlights the producer's role, from the perspective of profit maximization, and the consumer's role from the perspective of utility function. The economy of contribution gives an alternative choice with the contributor's role that mixes entrepreneurship, freely chosen participation in the creative and cultural activities, interest for nonprofit organizations, and the creation of societal value. The contributor's intervention within the activity depends on an individual arbitrage that reflects a desire for personal involvement. It also depends on the trust he or she may have for the other participants, on the level of interaction triggered by the participation in a certain activity, on the satisfaction felt from relationships with the others, and from the activity in itself.

How do relations between the economy of contribution, entrepreneurship, and cultural and creative industries function? The economy of contribution makes it possible in particular to identify the sectoral trajectories of the digital economy and the third-party sector. Thus, digital art, open sources, electronic games, multimedia applications, or innovations linked to Web 2.0 platforms came about thanks to creative entrepreneurs-contributors in the digital economy. Likewise, the organization of an important number of artistic and cultural activities is handled in the context of the third sector in relation with social entrepreneurs and nonprofit organizations.

Digital Economy, Social Economy, and Entrepreneurs-Contributors

With regard to the first sectoral dynamics, the development of information processing and transmission has favored the emergence of a large group of applications and services, the users' appropriation of which has become a massive phenomenon. Usage and communities highlight the preeminence of new behaviors, especially that of entrepreneurs-contributors who devote themselves to sharing and appropriating knowledge, who offer their expertise or seek to acquire it. So, the economy of contribution here refers to a group of specific entrepreneurial practices that concern the freely involved contributors' participations in the activity. Entrepreneurs-contributors accept to cooperate and to share their knowledge. This phenomenon has a deep influence on the way creative and contributive entrepreneurship diffuses through various creative and cultural activities.

The second trajectory of the economy of contribution, which influences the diffusion of entrepreneurship in the creative industries, refers to the social economy. The third sector is by nature a contributive model, in which social entrepreneurs serve a role of entrepreneurs-contributors. Strong interactions between actors create considerable external effects in the cultural and creative activities of the social economy: network spillovers, skills enhancement, and societal spillovers.

The economy of creative contribution is thus set up with a principal factor – the contributors' competence, which is itself influenced by the structuring of other factors that refer to variable combinations between individual trajectories and social determinations: education, training, experience, availability, mobilization, altruism, or leadership. The interactions between creative entrepreneurs-contributors are based on relational technologies and social relationships. They also relied on availability and alertness of the communities associated with creative and cultural practices.

Creative Entrepreneurs and Public Policies

The development of creative economy stakeholders and networks of entrepreneurs-contributors is not only the result of a combination of creativity, innovations, and private investments. Agglomeration effects in creative economy also largely benefit from public policy (Throsby 2010). The participation of the creative activities in local development, in employment growth, in the qualification of the workforce, and in the development of an expertise in careers linked to the fields of creation and culture all go to constitute the counterparts of a territorial anchoring supported by private investment and public policies (Table 2). By assuring stability and growth in creative and cultural activities, public policy contributes to support the development of new entrepreneurial models to ensure creativity as a pervasive asset in local economy.

Entrepreneurship and Externalities in Creative Industries

Territorial integration in clusters or cities of creative process and the development of creative entrepreneurship through the creative economy stakeholders or the economy of contribution are supported by external economies linked to the dynamics of cultural and creative activities (Bathehlt et al. 2004). The most general typology of externalities shows various situations in which the action of an economic agent has a positive effect on another agent without one or the other wanting to lead this action for such a purpose. Regarding creative and cultural industries, externalities can concern purely artistic activities (fine arts, performing arts, etc.) as well as activities linked to digital products (software, games, digital applications).

Creative industries are based on the dynamics of proximity to guarantee the accumulation and the sharing of specialized knowledge in the creation process, thus generating *knowledge spillovers*. These spillovers happen when creative entrepreneurs benefit from new ideas, discoveries, and artistic innovation from other cultural actors. The transmission of creation process and artistic innovation turns out to be all the faster and more pervasive as the spatial concentration of actors working in the same activity or in complementary activities contributes to the multiplication of *network spillover* effects.

Likewise, *training spillovers* are the result of a collective process of skill enhancement, which take the form of specialized segments of the labor market, of a training and research system, and of a mix of private investment and public policies. This collective process seems to be profitable for all the actors linked to a profession or a group of professions, thanks to mobility inside the same creative industry, but also from one creative industry to another. As for the *artistic spillovers*, they constitute a very important element of the creation process in cultural industries. They contribute to improve the standard level in each creative industry, having thus an indirect influence in the professional practice of the other participants in the profession.

Entrepreneurship in Creative Economy, Table 2 Creative industries policy options

Policy level	Objective	Option
Micro	Analysis and mapping of the economic and social impact of the creative industries	Situational analysis of value-chain cycles, review of the (non) existing policies and the ecology peculiar to each industry
	Supporting creative SMEs	Creative SMEs development initiatives: financial and fiscal support, business skills training, tools for start-up businesses and market strategies
Meso	Comparative analysis of the relationship between the creative and the relative industries	Establish creative clusters and creative-industry infrastructures to motivate best practices, sharing of knowledge and absorb the informal sector
		Organize networking and sectoral associations: facilitate partnerships, joint-ventures involving different stakeholders including NGOs and academia
		Expand the use of ICTs and promote the use of other new technologies to benefit from new business models in all stages of the creative chain
		Identify crucial interfaces and intermediaries among all constituents
Macro	Establishment of an informed, evidence-based policy-making system	Set up a monitoring system and collect necessary information to identify the most appropriate models
		Distinguish the gap between national statistics and real market activities for a assessment tools
	Cross-departmental institutional mechanisms	Set up a multidisciplinary center or an interministerial task force to facilitate coordination among different departments, such as culture, trade, finance, tourism, labor, technology, education, and migration
	Socioeconomic development	Identify the uniqueness, strengths and weaknesses of local creative industries and opportunities for international trade
		Examine the limitations of existing copyright schemes and other intellectual property rights and implement an appropriate competition law
		Promote cultural diversity and social inclusion policies, particularly tailored for the youth and women
	Creation of national identities	Apply creative industries "branding" as a national strategy to promote image
Meta	Analysis of the long-term impact of creative industries	Analyze the changes in aesthetics, lifestyle, and commodification over a long period and their impact on national strategies

Source: UNCTAD, *Creative Economy, Report 2010*, p. 262

By valorizing interdependence relations inside the same creative industry and between different but hinged creative industries and by reinforcing fluidity and the pervasiveness of the circulation of ideas, of skills, of talents, and of cultural goods, dynamics of proximity in entrepreneurial clusters or in cultural-oriented cities serve to multiplying spillovers. Thus, externalities are at the roots of entrepreneurship ecosystems in the creative and cultural industries.

Conclusion and Future Directions

The entrepreneurship ecosystems, the dynamism and reactivity of cultural networks, the creativity of actors, and the capabilities related to the economy of contribution obviously constitute dominating factors in creation transmission. Private initiative is at the roots of entrepreneurship in the creative economy. But the valorization of localized creative assets also highlights the increasing role of public policy and the ability of the latter to promote new cultural projects and to extend positive externalities. It is likely that entrepreneurship, public investment, and proximity dynamics in the framework of the cultural clusters and cities projects will continue to converge to be the driving forces of the creative economy.

Synonyms

Entrepreneur; New business firm, creation

Introduction

The topic of entrepreneurship has been receiving much attention for decades in most developed countries, while investigations on this subject are scarce in developing countries. Indeed, until the late 1980s, entrepreneurship in developing countries has not interested researchers. However private sector as a development engine was born following economic liberalization required by international financial institutions to developing countries. For these financial institutions, notably the World Bank, private enterprise has been, for a long time, the missing link to socioeconomic development of these countries. Thus, the liberalization effected through structural adjustment programs of the early 1990s has seen the development of initiatives to promote the entrepreneurship in developing countries.

This entry tries to explore the fundamentals of entrepreneurship in developing countries and analyze the relationships among entrepreneurship, economic growth, and public policy in these countries.

The Entrepreneurship: An Overview of Concept

The entrepreneurship, despite the initial flurry of activity following Schumpeter’s contributions, was largely concerned over this period not with understanding the economic performance of countries but with understanding the process of entrepreneurship (Naudé 2010a). In fact, the author shows that entrepreneurship is the resource and process whereby individuals utilize opportunities in the market through the creation of new business firms. As a resource, entrepreneurship results in innovation, risk-taking, and arbitrage – the classic functions of the entrepreneur as identified by Joseph Schumpeter, Israel Kirzner, and others. Entrepreneurship is studied as the various activities undertaken by entrepreneurs throughout the life cycle of a firm, from conception to exit (Naudé 2010a).

Today, the bulk of the entrepreneurship literature is concerned with the individual choice to become an entrepreneur, the determinants hereof and personal characteristics, and the growth, success, failure, and exit of entrepreneurs from the market. As cited by Autio (2008, p. 2), Audretsch et al. (2007, pp. 1–2), stated "this literature has typically not considered the implications for the broader economic context. It so results a very little know about whether and how entrepreneurship either contributes or does not contribute to economic growth in developing countries".

Nowadays, many authors (see Baliamoune-Lutz 2009; Acs et al. 2008) have taken for granted that entrepreneurship is indispensable for economic development. In fact, they provided a number of references to substantiate this claim and wrote that the entrepreneurship clearly refers to the capacity for innovation, investment, and activist expansion in new markets, products, and techniques. For its part, Baliamoune-Lutz (2009, p. 3) notes that *entrepreneurship affects development through the process of innovation, investment, and market expansion*. In the same vein, Acs et al. (2008), p. 219 show that *entrepreneurship is considered to be an important mechanism for economic development through employment, innovation and welfare effects.*

Moreover, Acs and Szerb (2007), p. 112 recognize that *entrepreneurship can contribute to economic growth by serving as a mechanism that permeates the knowledge filter and provides the missing link to economic growth. It is a virtual consensus that entrepreneurship revolves around the recognition of opportunities along with the cognitive decision to commercialize those opportunities by starting a new firm* (Acs and Szerb 2007, p. 112). As well, the authors point out that entrepreneurship policy is different from traditional business policy that tried to constrain the corporation. In this regard, the authors expose the emerging of a new policy approach that focuses on enabling the creation and commercialization of knowledge. According to them, *the policy differs from small business policy that tried to confront the cost disadvantage of small firm due to scale economies. In contrast, entrepreneurship policy has a much broader focus* (Acs and Szerb 2007, p. 112).

A number of recent studies have focused on the role of institutional and policy reform on entrepreneurship (see, e.g., Djankov et al. 2008; Baliamoune-Lutz 2009). Institutional reform that affects taxes or liquidity constraints, for example, would have an impact on entrepreneurial activity (Djankov et al. 2008). Thus, *one channel through which institutional and policy reforms would affect growth could be through their interplay with entrepreneurial activities* (Baliamoune-Lutz 2009, p. 1). Iyigun and Rodrik (2005) assume that the impact of institutional reform depends on the level of entrepreneurial activity. More specifically, the authors show that institutional reform has negative growth effects when entrepreneurial activity is strong and positive effects when entrepreneurial activity is weak. This is because reforms could impose a cost on the existing entrepreneurs, while it may be neutral or even helpful to new ventures.

The Entrepreneurship in Developing Countries: Realities and Constraints

Entrepreneurial studies, especially neoliberal theories, are derived primarily from the general growth and economic and historical experiences of industrialization in developed countries. However, these theories are not necessarily transferable to developing countries, even in the context of globalization. Thus, entrepreneurship in developing countries is becoming increasingly a subject on which policies linger and to which they are paying attention. Desai (2009) exposes that much of the research on entrepreneurship in developing countries indirectly or directly categorizes activities. She states that several dichotomies commonly used to describe entrepreneurship in developing countries are worth discussing: formal/informal, legal/illegal, and necessity/opportunity (Desai 2009, p. 2). In fact, the author explains that in many developing countries, *there are few incentives for entrepreneurs to participate in the formal sector, particularly if they operate on a small scale* (p. 2). Immediately, the vast majority of entrepreneurs in developing countries are involved in micro- and small enterprises (MSE), often informal, contributing little to poverty alleviation and growth. Moreover, only a few new start-up firms survive for a long time; the majority fails within the first 2 years (Naudé 2010a). John Bennett's paper *Informal Firms in Developing Countries: Entrepreneurial Stepping Stone or Consolation Prize?* shows that the so-called informal sector is significant in most developing countries, noting that it may contribute up to 40% of a poor country's GDP. *As a result, the size of the informal labour force is important; it can reach more than 50% in some countries* (*cited by* Desai 2009, p. 2). Actually, *with developing countries, the choice of entrepreneurship and the returns on entrepreneurship have quite often been seen as dismal, with entrepreneurship (or self-employment) considered as being driven by necessity (for survival) and offering meagre returns* (Naudé 2010a, p. 8). In this view, the author exposes that often large informal sectors in developing countries are seen as symptomatic of this no-choice entrepreneurship and are seen as undesirable. Some even see the informal sector as a drag on economic development, lowering overall productivity, and competing with the formal sector (Naudé 2010a).

For its part, Desai (2009) demonstrates that the nature of informal entrepreneurship in developing countries generates illegal activities. She shows that "illegal" applies to the nature of the selected activity and depends on the explicit legal code and regulatory frameworks in the country. Nevertheless, legal entrepreneurship applies to activities that are permitted by law. Also, the author exposes that the dynamics of necessity/opportunity entrepreneurship are closely connected to formal/informal status. One reason for high rates of necessity entrepreneurship in developing countries is the size of the informal sector. Workers that become entrepreneurs to avoid unemployment will likely be starting low-skill, small-scale, subsistence activities (Desai 2009).

Many authors imply strong causality from entrepreneurship to economic growth in developing countries. In fact, some economists, such as Baumol, Lazonick, and Naudé, even report a negative relationship between entrepreneurial activity and economic growth in developing countries. According to Naudé (2010b, p. 5), *entrepreneurs in developing countries are neither irrelevant nor impotent*. The author claims that the relationship between entrepreneurs and development outcomes is complex, with entrepreneurship as much depending on economic development and growth and vice versa. So, *designing policies for development through the promotion of entrepreneurship in developing countries is complicated* (Naudé 2010b, p. 5). In this case, Baumol (1990, *cited by* Naudé 2010b) posits that governments cannot raise the supply or quantity of entrepreneurship but can merely influence the allocation of entrepreneurial ability. In this view, the author mentions that what the government should do is "get the institution's right," i.e., ensure the protection of property rights and a well-functioning legal system, and maintain macroeconomic and political stability and competitive tax rates (Naudé 2010b). In addition, Naudé (2010b) proves that general policies to facilitate the entry of entrepreneurs may disproportionately encourage entrepreneurs with low "entrepreneurial ability," leading banks to reduce their overall extension of credit. The apparent irrelevance and impotence of entrepreneurship is the danger that well-intentioned support policies for entrepreneurship may have unintended negative consequences. These include patronage, corruption and rent-seeking, and prolonging the life of inefficient and low-productivity firms (Naudé 2010b). Moreover, Schott and Jensen (2008), p. 195 argue that developing countries are prone to apply policies that *(1) are based on experiences in developed countries which have not proven to transfer fittingly to developing* *economies, (2) are only partly implemented and are not internally consistent as a result of a lack of resources to do so, and (3) are more beneficial on paper than on actual activity*. These measurements will generate a too low dynamic industrial in developing countries caused by a lack of depth of local and regional markets. In terms of productivity, the difficulty lies in the inadequacy and lack of training of individuals or the less integration of people trained in this entrepreneurial dynamism. Also, we must not omit the importance of entrepreneurial culture with these four dimensions: sociocultural, psychological, managerial, and economic policies. The reluctance of major developing countries to entrepreneurship could be explained by their lack of risk culture and deficiency in recognizing the sector. In this situation, there is a significant gap between the support needs of project and the means used by their country. The last brake facing entrepreneurs is about financing.

Indeed, the loan system in developing countries requires guarantees of a financial nature that it is difficult to mobilize. Consequently, entrepreneurs in developing countries face less efficient financial markets, more volatile macroeconomic conditions, and higher entry costs.

Conclusion and Future Directions

In sum, policies in developing countries that place too much stress on entrepreneurship as the key to economic development can undermine collective and cumulative processes of organizational learning required for innovation (Lazonick 2008, *cited by* Naudé 2010b). As a result, economic growth in developing countries slows down; high-ability entrepreneurs, with fewer incentives to innovate, will exit (Naudé 2010b). In this context, the keys to entrepreneurial development in developing countries seem to be the involvement of support structures in the political debate allowing greater involvement of the state in this process but also including spin-offs based on public-private partnership. The mechanism of entrepreneurship through spin-off was established as an objective of dynamism in economy, especially in industrial countries. Therefore, the use of this measure involves profound changes in the institutional structure of the global political and scientific community, thus allowing to reduce the problem of loose coupling between science and entrepreneurship activity. Consequently, a stronger coupling between science institutions and industrial practice would not only likely improve the quality of entrepreneurship research in developing countries but would also facilitate an economic development growth enacted by policy makers in developing countries.

Introduction

Globalization: An International Context for Complex Venturing

The globalization of the economy is not new, but it reaches an unprecedented level with the conjunction of multiple factors such as lower tax barriers for international trade, lower cost of transport system, and lower cost of communication through the Internet. Lower production costs are accompanied by the acceleration of international trade in the second half of the twentieth century.

Globalization can be considered as an opportunity for entrepreneurs, as it widens the perspectives for both supply and demand. On the supply side, entrepreneurial creativity is infused with a range of new ideas coming from other entrepreneurs across the world. Furthermore, it offers a worldwide platform for new partners and suppliers around the world, giving entrepreneurs a wider scope for adding value to their offer. On the demand side, responding to various market needs from different countries and cultures also enhances creativity and can lead to creating new products and markets. Thus, globalization increases the scope for detecting and exploiting market opportunities from around the globe.

However, globalization can also be a threat for entrepreneurs. It shifts competition at a higher level. Local markets are open to global competitors who can easily invade these markets with competitive products at a lower cost of production. If such market entrance might offer new products at lower prices for the customer, it can also contribute to the destruction of local producers who can hardly compete despite distinctive competencies.

In sum, internationalization is part of the business environment of every company. Even a small company operating on a local market only might have to face global competition depending on the market's scope and attractiveness. In that sense, every venturing is inclined to design a more complex strategy with an international insight, whether it concerns competition, suppliers, customers, or partners. Good or bad, globalization goes in hand with the internationalization of both large and small companies.

International Entrepreneurship or When Small Goes International

At first sight, it seems that large companies are more able to internationalize due to a sufficiently large domestic market and/or expertise in the strategy of internationalization. However, it's not only a matter of size. Young and small companies can equally be efficient in such processes. International entrepreneurship is the area which focuses on the internationalization of small and young companies. In that respect, we can distinguish different approaches to internationalization – stage or systemic relating to different profiles of companies: late developers and early developers.

Late developers are small companies, which internationalize after establishing a strong position in their domestic market. Usually, they are established SMEs which develop products and markets abroad progressively. This strategy is mainly incremental, also known as a stage approach. In that perspective, small firms will progressively develop organizational capabilities for internationalization such as the skills to plan the internationalization process in advance, to organize and develop in foreign markets, and to effectively monitor markets (OECD 2008). In order to analyze the process of internationalization of late SMEs and corporation, management science scholars initially concentrated on the process and organizational culture characteristic of small firms with a limited amount of capital and relatively few clients. Studies following this trajectory focused entirely on opportunities for and obstacles to internationalization. One such study described a highly rationalized progression involving four stages (Johanson and Wiedersheim-Paul 1975; Johanson and Vahlne 1977). From that perspective, internationalization is a major objective at the outset – which presupposes that the entrepreneur behind the company should have a broad vision of where he or she wants to take the firm, an advanced capacity to learn, a receptivity to new concepts and ideas, a high degree of diplomatic skills for the management of complex networks, and, since the time required to penetrate markets varies considerably, an ability to adapt to different cultural contexts. More recent studies have drawn attention to the fact that, for start-up companies, the process of internationalization does not follow such formalized schemas (Karlsen et al. 2003; Autio et al. 2000). If a stage approach seems particularly suited for small business internationalization, various scholars cited cases of born-global firms and small businesses experiencing rapid growth at the global level. Such counterintuitive cases have given rise to a new perspective in which SMEs are "born global" or "early developers." Such young and small companies, qualified as early developers, go international during the first years of their establishment. Such precocity is a new perspective on international entrepreneurship, and it is known as "Born Global strategies" (McDougall 1989; Oviatt and McDougall 1994, 2005; McDougall and Oviatt 1997). This approach provides an iterative and learning perspective on internationalization by focusing on the proactive role of the entrepreneur in a dynamic process of unique resource and competence building to conquer market opportunities abroad. This process is largely enabled by networks that constitute the most important source of change and opportunity (Ucbasaran et al. 2001) – especially weak-tie networks that challenge routines and established beliefs and stimulate creativity and innovation (Julien et al. 2004). Moen and Servais (2002) conclude that born-global firms reveal an important change in export behavior. In order to establish precocious export strategies, they identify and acquire competencies within their close and distant networks. In the same vein, Knight and Cavusgil (2004) demonstrate that born-global firms have a more sophisticated knowledge base than the late developers. They emphasize that born-global firms have a strong marketing orientation that is sustained by solid technological capabilities in their respective product and firm categories. Sharp data mining about markets, customers, and competitors guide their international operations. The born-global firms' networks help to update these precious data and, ultimately, support their marketing strategy (Rassmussen et al. 2001).

Whether entrepreneurs are early or late developers, globalization is revealing new entrepreneurial mindsets to think about the global and local strategies when small businesses go on international markets.

Global Mindset for Local Entrepreneurs

Large companies with established business models but sometimes declining ones usually strategize globally and operate locally. Strategic thinking is made at a global level before it is applied to operations at local levels. Such strategizing is relevant for large companies. Small companies with experimental business models strategize at a local level, but they can aim at global operation (outsourcing, partnership, etc.). For entrepreneurs, it has become apparent that decisions concerning internationalization and the successes and failures deriving from them depend less on specifically organizational characteristics (size, capital, resources) or on environmental factors and the context of domestic and international regulations in favor of internationalization and more on the profile, training, and international experience of the entrepreneur (Lloyd-Reason 2004). The character traits, experience, and motivation of the owner-manager determine the long-term success of start-up companies in terms of internationalization. Lloyd-Reason and Mughan (2002), and Manolova et al. (2002) highlight the degree to which the owner-manager must have mastered his or her skills before implementing monitoring and planning procedures prior to moving into international markets. The stance taken by Lu and Beamish (2001) is more radical: the internationalization process must emerge either when the company is founded or in its initial phases of development. Consequently, all training in the field of entrepreneurship (incubators, continuing education, initial training programs) should encourage the emergence of those skills and, equally, foster a desire on the part of students to seek out experiences or develop projects enabling them to develop such skills and identify the resources required for elaborating successful internationalization strategies.

Conclusion and Future Directions

Surprisingly, literature on entrepreneurship education and entrepreneurial support system does not yet focus on international entrepreneurship. Apparently, the paradigm of the born-global start-ups stresses business owners' genuine skills and the firms' spontaneous capabilities. Therefore, there is no comprehensive research concerning the different learning processes in the context of the internationalization of SMEs. Similarly, there is no mention of specific coaching and mentoring practice for entrepreneurs who are developing strategies of internationalization. Literature should explore the different issues concerning international entrepreneurship education and counseling in order to stimulate more experimentation within incubators and networks of entrepreneurs. From a social constructionist perspective, international entrepreneurship can thus be defined as "the creative enactment and envisioning of future scenarios and opportunities for service/product/organizational transformation that are socially constructed and realized through cross-border co-ordinations" (Fletcher 2004, p. 295). Such cross-border organizing takes place through the entrepreneurs' personal networks, but it can also be catalyzed through local business assistance organizations such as incubators and innovation centers (Bonnafous-boucher and Laviolette 2009).

Entrepreneur; Innovation; Public policy; Regulation

Economic policy refers to actions that governments take in the economic field. It covers the system for setting interest rates and government budgets as well as the labor market, the size of the public sector, and many other areas of government interest in the economy. There are different types of economic policy, for example, trade policy, redistribution of income, the regulatory environment, antitrust, industrial policy, and so on. Since antiquity, governments have played an important economic role, for economic, social, and political reasons. Public policy is linked with state power. For example, the main subject for the mercantilist economists in the seventeenth to eighteenth century was how to collect a large quantity of resources from other countries and to keep them within the borders of their own countries. Some years later, Adam Smith and other classical economists would discover the secret of wealth: labor power. The creation and the development of new business has for many years been, for governments, a means of attracting new revenues by taxation. Ever since the industrial revolution, the development of innovative enterprises has been an important factor in the competitiveness of the economy. So, the objective of governments is to collect resources to strengthen their political and economic power. Different tools are available to them to achieve this objective: by strong political and economic regulation (based on public property and planning) and by the definition of framework laws (ownership, market regulation). Between these two options, we have a wide range of actions, from socialist to liberal. The Keynesian option consists of introducing rationality into market mechanisms.

So today, even in the free market economy, public authorities have an important role to play to promote industrialization, entrepreneurship, and the development of knowledge in science and technology. Governments have to build the framework to sustain economic activity and the durability of their power. Since the end of the 1970s, in a new context of deregulation and privatization, the economic role of the state has changed. The state in developed countries is less of an entrepreneur but more and more a manager of economic development. The creation of enterprises is an important economic challenge, to promote innovation, to create new jobs, and to support economic growth in different territorial areas. More generally, we observe a convergence between the behavior of the state and that of firms. Both have an entrepreneurial character. They take decisions according to a rational calculation between costs and benefits, even if public policy is a response to market failure. In this entry, we will present some generalities about contemporary economic and political context to explain how the nature of public policy has changed since the beginning of the 1980s. Thus, we will review the main characteristics of public policy (short-term and structural policy). Today, public policy is one of four elements to support economic growth by entrepreneurship. To explain this process, we have developed the concept of the organic square of entrepreneurship, which will be presented in the last part of this entry. There exists no magic formula to develop entrepreneurship and innovative enterprises. The four elements of the organic square of entrepreneurship are public policy, entrepreneurs' resource potential (see the entry on this subject), economic organization, and market situation.

Historical Context and Evolution of Public Policy in Developed Countries

After the Second World War and Keynesian Policy

After the Second World War, economic growth was supported by a strong public policy in the economies of Western countries in Europe and in the United States. According to the theory of the welfare state, the state was an important actor in economic and social life: to promote or to develop education, health, and social justice and to build infrastructures (airports, roads, harbors, and so on). Numerous enterprises in strategic activities were public (energy, steel industry, water, telecommunication, and so on). For instance, according to Galbraith (1967), Williamson (1968), and Chandler (1977), it seemed inevitable that exploitation of economies of scale by large corporations would become the main engine of innovation and technical change. In this context, J. K. Galbraith (1967) argued about a convergence between American and Soviet systems. Even if the economy of the United States was based on private property (and the Soviet economy on state-owned property), in both economies, the role of the state was very important in promoting industrial activities. We know that Galbraith spoke principally about the military-industrial complex which had an important role in both countries during the Cold War. But since the end of the Cold War and the downfall of the Soviet Union (at the beginning of the 1990s), public priorities have changed.

During the 1950–1970s, the objective of governments was not to promote the creation of new firms, but to develop big public corporations to rebuild the economy after the Second World War. The product of this policy was the development of a new salaried society. Today, in developed countries, 80–90 % of the working population is salaried. In these conditions, the spirit of initiative, according to J. A. Schumpeter or M. Weber, has disappeared. The objective of the new public polices is to rekindle this spirit of initiative which was the engine of heroic capitalism (see the section on the ▶ Heroic Entrepreneur, Theories). But this does not mean the decline of large firms, and a return to the perfect competition model (infinite numbers of buyers and sellers), but a new context to promote entrepreneurship in order to create new firms and to promote innovation and change in current enterprises.

The Crisis of the 1970s: A New Definition of Public Policy (A New Place for Market Regulation)

The economic crisis of the 1970s was also the crisis of this public policy based on Keynesian principles. Liberal policy, which was ineffective during the 1950–1970s, was promoted as the new solution for economic growth. For example, according to W. Baumol (Baumol et al. 1982) and the theory of the contestable market, a perfectly contestable market has three main features. It is a market that has (1) no entry or exit barriers, (2) no concealed costs, and (3) access to the same level of technology. The objective of Baumol is to demonstrate the superiority of the market economy over the state economy. The objective is to develop competition and mechanisms of market equilibrium: in this context, to create conditions for the perfect competition of neoclassical theory. For liberal economists, this is the guarantee of low prices and economic prosperity. The main objective is to reduce inflation. The decrease of the economic role of the state promotes entrepreneurship. For example, the privatization of public enterprises and in general the deregulation measures have created new opportunities for investment by entrepreneurs in different industrial sectors and in service activities (distribution of electricity, water, telecommunication, transport, and so on). To sustain economic growth, governments reformed the financial system: numerous public banks were privatized, and the financial markets, virtually nonexistent during the 1950–1970 period, have taken an important new place in the economy of capitalist countries.

On the other hand, in this new context of competition, the principles of the welfare state are revisited. The objective is not yet to distribute public aid but to help to find a new job or to create a business. For example, to realize this objective, new educational programs are developed to update and develop new competencies and skills. To summarize, the objective of the state is to create a framework (regulations and laws) to foster economic initiative and competition. On the other hand, the development of financial markets (as a consequence of deregulation policy) gives new opportunities to public authorities to raise revenues. But the cost of this new freedom is very high. Since the beginning of the 1990s, economic growth has been less stable, and economic crises have become numerous in developed and also in developing countries.

The Means of Action for Public Policy

Since the 1950s, developed countries have put in place a set of public instruments to drive and to push economic growth. The national accounts give a set of indicators to determine the economic situation and to intercede if needs be. To realize its objectives of economic growth and innovative development, the state has developed different principal means of action (Barro 1990). We can distinguish two types of public policy: (1) short-term policy and (2) structural policy.

The Short-Term Policy

The objective of short-term policy is to manage urgent problems, by definition for a short-term period, for example, to create businesses to create jobs and to attract foreign firms to create jobs. The results of public measures in this case must be quick (less than 1 year). Public authorities target in this case (a) firms whose costs of production are very high (e.g., heavy industries) and (b) potential businesses in low added-value sectors based on a determinate trade. The main measures of a short-term policy are the following:

1. Financial incentives: grants to create new businesses and help for investment, recruitment, subsidized loans, and so on. These different types of aids can be attributed by central government or by local authorities.
2. Fiscal incentives: reduction of taxes on investment, tax exemption for importing different types of production machinery or raw materials.
3. Indirect incentives: subsidized real estate or buildings (e.g., in the business sector), means of communication, access to public markets, and so on.

Structural Policy

Structural policy consists of a set of industrial and innovative measures whose objective is to build or to develop the scientific and technological potential of the country, by definition in a long-term perspective:

1. To promote the creation of innovative enterprises
2. To develop new technologies and knowledge and to facilitate technology transfer from scientific centers to businesses (and specially to large firms)
3. To help cooperation between scientific centers and businesses to develop new technologies and knowledge with a high scientific content at global level

4. To develop means of technological and commercial intelligence to canalize the strategies of businesses (large and small)

The results are cumulative and (by definition) of long-term nature. The objective of public authorities is to support entrepreneurial strategies to create jobs and innovation.

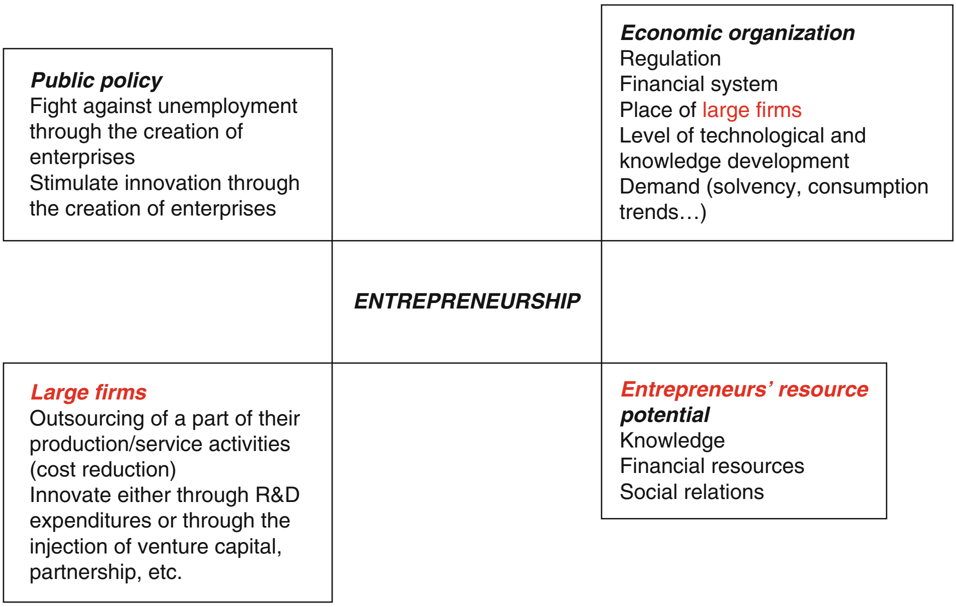
The main measures of structural policy for promoting investment are the following:

1. Massive public investments to develop means of communication and transport; education, research, financial support for innovation, health policy, and quality of life by the promotion of cultural activities
2. Introduction of means for financing research and innovative policy to develop relations between enterprises and scientific centers
3. Development of networks between firms (large and small) and scientific centers

In the event, we are confronted by two different types of strategy: the public strategy whose objective is to attract and to retain businesses, investments, and knowledge inside its borders and, on the other hand, the entrepreneurial strategy whose objective is to develop activities at the world level to capture new resources from different countries. So, in a world economy, the objective of public authorities is to capture resources to develop their scientific and technological potential. The indicators of countries' economic performance are based on national accounts (gross domestic product, balance of trade, and so on). Firms have their own strategy, and they (large groups) can declare their income in different countries where taxes may be lower. Such groups can develop a world strategy corresponding to their growth objectives. The main difficulty of public policy (but also the reason for the existence of public policy) is that the economic context (in today's terms, the capitalist society) is characterized by change. Change is created by the activity of entrepreneurs, and major change comes particularly in a context of crisis. Change also creates new investment opportunities (new needs causing an increase in demand, and so on). So, we are facing a paradox: the objective of public authorities is to promote economic change which is the main element of the economic competition between economies. But, on the other hand, public authorities intervene in the market to stabilize economic activity in period of crisis, for example. So if public policy has changed since the 1980s in an economic context marked by the liberal theory, we observe also that the state is also an important economic actor.

The Organic Square of Entrepreneurship and Public Policy

The organic square of entrepreneurship (OSE) is formed by four elements: (1) public policies, (2) entrepreneurs' resource potential, (3) economic organization, and (4) large firms. These four elements are linked by synergistic relations, but each element has the same importance. A ***public policy*** cannot by itself promote entrepreneurship and create innovative enterprises, but the role of the government is rather to create a business climate. For example, the composition of the ***resource potential of the entrepreneur*** depends not only on his own personal qualities but also on external and social factors. In particular, public support (to create jobs and to promote innovation) for the creation of new enterprises usually determines the financial resources entrepreneurs can access in order to set up or develop their business. The ***economic organization*** has several dimensions and different effects. The general level of growth in knowledge influences the knowledge gathered by entrepreneurs (through their education and that of their staff and through economic intelligence) and the technical level of their activity. A societal knowledge stock is composed of a set of knowledge stemming from activities by incumbents and start-ups, that is, knowledge refers not only to scientific discoveries but also to knowledge associated with novel ways of producing and distributing in traditional businesses, modifying business models, changing marketing strategies, and so on. In a context of economic deregulation, according to Coase (1937), ***large firms*** develop outsourcing for a part of their activities (industrial or services). For individuals, this strategy can be an opportunity to create a business.



Entrepreneurship Policies, Fig. 1 The organic square of entrepreneurship (OSE)

The characteristics of the financial system (possibilities or difficulties of being listed on the stock exchange, more or less conservative banks, and access to venture capital) have an impact on the capacity of the individual to become an entrepreneur and on the development of new businesses. Market concentration and the place of large companies also influence the dynamism of entrepreneurial activities. Finally, the overall economic situation determines the rhythm of new creation and also the types of activities conducted by such businesses (see Fig. 1).

State intervention explicitly promotes and guarantees the drawing up of coherent rules in order to organize public and private economic activity and, in our case, to facilitate innovation and business creation. Public policy directs and coordinates the different economic performers to create the organic square of entrepreneurship. State intervention can take different forms: financial assistance for activities which generate economic resources, creating devices that allow business creation, and the imposition of procedures for cooperation between public and private bodies with the objective of funding private investment projects likely to have wide-scale economic impact.

The creation of a pool of productive and financial resources (able to be appropriated at any time by companies and potential entrepreneurs) is considered to be the fundamental aspect of state intervention in innovation and entrepreneurship. Traditional scientific and technological policy has been replaced by one of research and innovation (structural policy). In order to be fruitful in terms of competitiveness, the state has to guarantee the efficiency of the procedures for transferring knowledge, technologies, and ideas between enterprises, entrepreneurs, public institutions, and other nongovernmental organizations (the "commercialization" of R&D, support for the creation of networks to boost innovation and competitiveness among firms, etc.) with regulations (protection of patent rights, antimonopoly measures, etc.), the tax system, the budget, etc., in order to favor the emergence of new innovative enterprises (short-term policy) (Laperche et al. 2008).

Conclusion and Future Directions

Historically, governments had played an important economic role in collecting resources to strengthen their power. Since the industrial revolution (and especially during the nineteenth century), public policies have become more sophisticated with the objective of changing and developing economic activity. Since the end of the Second World War, public policies have been developed to integrate a large range of activities (social, education, health, transport, energy, and economic regulation). The economic growth of the 1950–1970s was based mainly on large public companies and economies of scale. These companies and the public scientific system became the engine of economic growth. But the economic crisis of the 1970s was also the crisis of the Keynesian model. Public policies have since changed to promote entrepreneurship.

Today, it is clearly evident that economic growth is based on entrepreneurial activity. It is not an exogenous phenomenon. Entrepreneurial activity is influenced by a large range of elements: public policy (of course) but also the strategies of large companies and the economic framework (financial system, market situation, and so on). The role of the state is to canalize entrepreneurial activities which create innovation and jobs. The wealth of the state is based today on entrepreneurial dynamics and on financial markets. But this state wealth is also less stable. Since the beginning of the 1990s, economic crises have become more frequent and widespread. This instability can produce social unrest.

Entrepreneurship Policy

Patrice Noailles-Siméon

RRI – Marne-la-Vallée University, Seillans Investissement, MemoPage.com, Paris, France

Synonyms

Development policy; Innovation policy

Entrepreneurship thrived in Mesopotamia, long before there was any entrepreneurship policy. This is underlined by Baumol, Landes, and Mokyr (2010). Throughout history, entrepreneurs, who are not all innovators, have had many different embodiments, from the large landowners described by Cicero, through the Cistercians and lords in the Middle Ages, to inventors such as Gutenberg and Edison and businessmen such as Ford and Eiffel.

The term *entrepreneur policy* became a "politically correct" policy topic in the 1990s. Today it is a requirement in policy topics, at the center of a society's ability to progress. Entrepreneurship policies are diverse. Based on a broad definition of *entrepreneur*, entrepreneurship policies include intrapreneurship policy, a large part of small business policy, and innovation policy, in addition to parts of development policy and even employment and immigration policies. Finally, it may touch cultural policy or even social integration policy.

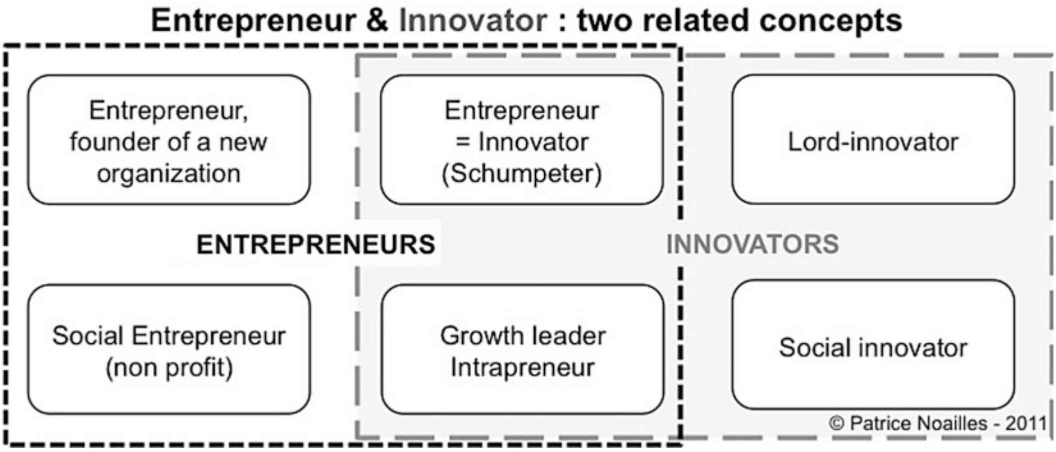
Definitions

Neither scholars nor policymakers have all the tools necessary to scientifically understand and govern entrepreneurship policies, which are still mainly pragmatic. However, it is possible to make clear some terms and debates.

Entrepreneurs

Theoretical and pragmatic approaches of entrepreneur are divided into – at least – four categories:

Entrepreneurship Policy, Table 1 Entrepreneur and innovator



1. *Entrepreneur as a "true" innovator*. This seems to be the definition of Shane and Venkataraman (2000) and was the definition of Schumpeter (1911–1982) as well as the OECD (2009).
2. *Entrepreneur as a creator of a new organization*. This included one-person companies, which can be part of an employment policy such as the "auto-entrepreneur" in France. This was the original meaning by Cantillon (1755), who required some risk in the activity of the entrepreneur.
3. *Entrepreneur as an intrapreneur or growth leader who develops businesses in existing companies*.
4. *Social entrepreneur, often called a nonprofit entrepreneur, who creates value for the society as a whole, mainly through the creation of an organization in a nonprofit environment*. This includes also a political changes in regulation, which may broadly affect business and the global capacity of value creation.

As shown in Table 1, "entrepreneur" is a concept similar to "innovator" but different. Entrepreneurs also may be copycats or simply business people in established activities.

Entrepreneurship Policy

Entrepreneurship policy enables entrepreneurs to start and develop new ventures. It aims to make it easier to create new enterprises and/or develop new products and services. National or global policies are the legal side and local policy is the societal side. It bears on low-technology economic activity as well as high-tech (although the latter is emphasized here). Overall, it encompasses a social dimension of risk acceptance, a view of life, and an ethic that allow individuals to become entrepreneurs. This seems to be the way in which the World Bank does business.

Entrepreneurship policy includes six main topics:

- Global economic and social environment (infrastructure, regulation stability, deregulation, free markets for finance, goods and labor).
- Creation process (1 day and no cost plus physical infrastructure, including "clusters" and start-up facilities).
- Development assistance (financing solutions (e.g., SBIC), market openness (e.g., SBA), R&D transfer).
- Entrepreneur concerns (management of risk, patents, tax incentives, insurance).
- Ethics and ideology (cultural and social norms, open city).
- Education and training programs.

Entrepreneurship policy belongs to the liberal side of economics, whereas innovation policy comes from a state-organized economy.

They have merged because entrepreneurship seems to be the best way to speed up innovation.

Entrepreneurship Policy Management: Decision Making, Governance, and Assessment

While entrepreneurship policies have progressively involved many different government sectors at several levels (national, regional, and local), there is no established organization for entrepreneurship policy, nor any established governance or official assessment!

Japan has a minister of state for innovation, not for entrepreneurship, but Japan is not more successful than other countries. The British government decided in 2007 that the prime minister would control innovation and entrepreneurship policy, however, Her Majesty's Treasury still manages a large part of it.

Entrepreneurship Policies

Entrepreneurship policies are not theoretical approaches; they are entirely pragmatic and efficiency driven. They began in United States in the 1930s, with the New Deal, and increased during the 1950s and after.

US entrepreneurship Policy: From SME to Innovation

US entrepreneurship policy, which originally was not known by this name, began as small and medium enterprises (SME) policy before dealing with research and innovation and then with jobs creation. Today, the Small Business Administration (SBA) and seven laws (SBA, Subchapter S, Business Angels, Small Business Investment Company (SBIC) and venture capital (VC) regulation, Small Business Innovation Research (SBIR), the Bayh-Dole Act, and patents) make up the current entrepreneurship system in the United States.

The SME policy of the United States was the model for numerous other countries: Taiwan (1954), The Netherlands (1954), Canada (1961), Australia (1973), the United Kingdom (1970), Ireland (1982), Finland (1993), and Spain (1996).

1932–1952: RFC and OSB for SME

The Reconstruction Finance Corporation (RFC) was founded in 1932 by President Herbert Hoover to finance all kinds of businesses and was integrated into the New Deal program by President Franklin D. Roosevelt.

The SWPC (Smaller War Plants Corporation) was created in 1942 to provide loans to private entrepreneurs and was dissolved at the end of the World War II; its activities were transferred to the RFC.

The Office of Small Business (OSB), part of the Department of Commerce, provided information to SMEs.

During the Korean War, the Small Defense Plants Administration (SDPA) was created to perform the same function as the SWPC. In 1952, it has been decided to shut down the RFC and President Dwight D. Eisenhower proposed the creation of a new agency combining the main functions of the RFC and OSB.

1953: SBA

The Small Business Administration (SBA) was created by the Small Business Act of 1953. Its function was to "aid, counsel, assist and protect, insofar as is possible, the interests of small business concerns." In addition, the SBA would ensure small businesses a "fair proportion" of government contracts and sales of surplus property. In 1954, the SBA began to make direct loans and to guarantee bank loans to SME.

In 2011, the SBA was a multifunction agency with a budget of US$ 500 million and eight major programs: Financial Assistance, Contract Opportunities, Disaster Assistance, Online Training, Counseling & Assistance, Special Audiences, Laws & Regulations and Compliance. New efforts for minorities and clean technology were implemented at the beginning of 2012.

1958: SBIC and Subchapter S

The Small Business Investment Company (SBIC) was established to finance privately owned venture capital investment firms with the help of the US government. These investment companies, dedicated to investing in start-ups and SMEs, can get a loan at low rate (1%) for double their capital. This allows leveraging of their efficiency, which is necessary to obtain fair profitability in the venture capital business.

The Subchapter S law was adopted in 1958 and reexamined several times since then. Through assessment reports and the study of Robert Gaston ("The informal supply of capital," 1988) this system has contributed to the emergence of one million business angels in the United States, investing from $30 to $100 billion annually.

1980–1982: SBIR-STTR, the Bayh-Dole Act, and Patents

To meet the industrial demand for US electronics at the end of the 1970s, the US Congress adopted three main laws regarding R&D and technology transfer. The idea was that America had to preserve its innovation capacity by better using its R&D capacity. Patents improvements and SBIR were adopted for better applied R&D, and the Bayh-Dole Act was enacted to accelerate – and even force – technology transfer.

The Small Business Innovation Research (SBIR) program is a partnership program between SME and federal research agencies. The STTR (Small Business Technology Transfer Program) takes a similar approach with SME and nonprofit US research institutions; this is clearly a mix with innovation policy.

Years 2010: Immigration – Towards a Startup Visa Act

The Kauffmann analysis determined than immigrants found companies at greater rates than native-born Americans do, and they are disproportionately more successful in starting high-growth and high-tech firms. This lead two senators to propose a new law granting green cards to foreign entrepreneurs and even to all STEM (science, technology, engineering, mathematics) graduates. This is also a mix with innovation policy.

2011: Patent Law

On September 16, 2011, the US Congress passed the America Invents Act, a new patent law following decades of debates and three "patent reform acts" of 2005, 2007, and 2009. This act modifies the US patent system from a "first to invent" to a "first to file" system, eliminates interference proceedings, and expands post-grant opposition. This act also defines the new organization for the US Patent and Trademark Office (PTO).

1945–1970: The Growth of Venture Capital – From VC Funds and Angel Investors to Crowd Funding

The modern form of venture capital began with the ARDC (American Research and Development Corporation) and a French-American Harvard professor, Georges Doriot, just after World War II. The legal status took time, however, and came along with private equity funds in the 1960s. In a strict sense, this is not a national policy, but in a market approach, venture capital funds and business angels (see below) are natural parts of a National Innovation System (NIS). Due to the necessity for due diligences and management fees, theses funds can only invest in developing projects, in an amount of more than US$ 1 or 2 million.

For seed capital and early-stage development, angel investors are able to invest any small amount without management costs and due diligence. They have the capacity to evaluate from either a specialist point of view or a proximity evaluation. According to professional associations and the Small Business Administration, the number of US angels investors is estimated to be around 300,000 per year. Angel investors are often retired entrepreneurs or executives who are investing not only for monetary return but also to help other entrepreneurs and to become a real partner.

In 2011, we saw the first beginnings of crowd funding on the Internet, allowing angel investors to invest small amounts (some thousands of US$) in a venture together with many others. Today, this activity is not clearly regulated. Crowd funding, which began in the independent music industry, could be considered as a kind of microfinance. Regulation has to be deepened in the United States as well as in Europe because this is a kind of public offering. On April 5, 2012, the Jumpstart Our Business Startups Act (JOBS Act) was signed by the President of United States. It intended to encourage funding of small businesses by easing various securities regulations.

Entrepreneurship Policies for Developing Countries (OECD-ONU-WEF-UNCTD/United Nations Conference on Trade and Development)

For many development organizations experience has shown that the most efficient approach to reducing poverty in low-income countries is the development of productive capacities, i.e., “productive resources, entrepreneurial capabilities and production linkages which together determine the capacity of a country to produce goods and services and enable it to grow and develop” (UNCTD).

On this basis, all international organizations now urge to development of entrepreneurship policies.

Europe: Science and Innovation

In Europe, there used to be conflicts between two kinds of policies: the centralized approach of innovation policy and the market approach; in other words, between liberal and not.

As the debate on innovation and entrepreneurship policies took place at the beginning of 2000 and ended with the Lisbon Agreement, it was only possible to build a general agreement, except on the global R&D expenditure, with a target of 3%. Entrepreneurship and transfer of technology policies were ignored, as there were wide differences among countries. The differences were also large in education systems. Each country is supposed to organize its own policy.

France, from “State Innovation” to Entrepreneurship

General de Gaulle looked for new ways of obtaining power and, after him, Georges Pompidou sought economic development. France had a state innovation policy during the 1960s and 1970s, with large national programs such as Ariane (rocket), Airbus (planes), TGV (train), Minitel (IT), nuclear plants (energy), and even computer chips (ST Microelectronics). Other programs for machine tools and computers were less successful. However, at the same time, the first company in the world to manufacture a microcomputer for business, named Micral, was created in 1972 by M. Truong in France, and as Apple was founded in 1977! However, Truong worked alone and didn’t find financing. After selling 100,000 professional microcomputers between 1972 and 1977, he sold Micral to a large company (Bull), which did not understand the product.

Innovation policy without entrepreneurship policy is a centralized model can be found in many countries, with still less success than in France. France has also tried some kinds of clusters, with the “technopoles” in the 1980s and now the “pôles de développement.” Results have been limited, according to a study by the French Parliament.

Three Global Entrepreneur Policy Models

There are three main kinds of combined entrepreneurship policies:

– Development policy; SBA is the base of this policy
– Innovation policy
– Employment policy, which came later, in the 1980s, with research financing and adapting the rules to create a society, and even one-person company.

For innovation, there are two major directions in addition to research financing:

– The Anglo-Saxon model, mainly based on market-driven innovation. This model seems to be efficient for breakthrough innovations.
– The Continental Europe model, relying mainly on big firms or the state to manage innovation system. This model works well for incremental innovation and for diffusion.

Theoretical Debates

Historical Evolution

There have been three major trends in the theoretical debates since the 1930s and a fourth trend is developing.

The Pure Pragmatic Way (Since the 1930s)

The work of the US Congress (and of politicians and their advisors) shows us the importance of being pragmatic in political decisions, since they have established the basis of entrepreneurship policy without even having the intellectual tools to build it!

There is still a pragmatic way that consists of treating each problem as it comes: "proof of concept center," "incubators," "accelerators," "death valley," "innovation death spiral," "prototype centers," and so on. Each problem has a limited solution. The ultimate problem is to organize and rationalize them all.

The Entrepreneur Theoretical Way (Starting in the 1960s, Emerging in the 2000)

From the 1960s, entrepreneurship began to be the subject of research, reports, and debates by scholars and in think tanks. These first steps were mixed with questions on innovation, as an entrepreneur was often seen as an innovator.

The scholarly debates on entrepreneurs actually began in the 1990s, and Venkataraman drew a picture for future academic work in 2000(Shane and Venkataraman 2000), but only for entrepreneurship, not for entrepreneurship policy.

The Global Economic Approach (in the 2000s)

Scholars and policy makers need global analysis and not only pragmatic and incomplete approaches. By this time, they had a global economic approach, but it was still not completely academic. In this context, there are two main kinds of debates: the *existence* and the *efficiency* of entrepreneurship policy (see below);

But there is a another economic question, which is the quality of entrepreneur. In classical economics, we see only three actors: the market, the consumers (mass), and the producers (companies). We never speak about individuals. There is no room for entrepreneurs. The question today could be "what is the place of entrepreneurs in economics."

An Emerging Question: The Role of Culture (for the 2010s)

Behind this question regarding the entrepreneur in economics, we find a more general debate in sociology and economics about the individual in these two sciences. The debates are between social sciences, from sociology to economics, and individuals. We also find the question of the relationship between sociology and psychology, between economics and management.

These debates have a common point: the importance of culture that regulates the individual behavior in the society.

Why Does Society Need Entrepreneurship Policy?

Remember that, until 1980, the academically correct approach to development or employment in the twentieth century was based on the idea that large firms were the major sources of economic growth and employment. Neither entrepreneurship, nor innovation, was a subject for economic study.

Nevertheless, during the 20 last years of the twentieth century, scholars and policy makers pointed out two key facts (Birch, Thurik, Audretsch et al. (2007) from 1979 to 2011):

– The major role of new firms is job creation, accounting for more than 80 % of job creation in the United States;
– The role of new enterprises is the innovation process and growth (Block and Keller 2008).

As a result, after being ignored in previous theories, the entrepreneur and the start-up became central in economic development.

At the same time, the theory of the contestable markets was developed (Baumol 1982) and gave a theoretical entrance for the new policy approach, which became a clear shift from the managed to the entrepreneurial economy. As a result, the premise of entrepreneurship policy is market failure together with the idea that when markets are efficient, innovation will destroy the equilibrium (Venkataraman 1997).

In a period of globalization, innovation is the only way to renew the competitive advantage of developed countries; and entrepreneurship is the most efficient way to foster innovation. Thus, much should be done to make the entry of actors of innovation easier. New policy must also deregulate, privatize, and enable knowledge uses through R&D transfer.

Systemic or Individualist Approach: Entrepreneur or Company?

Among policy-makers and politicians, efficiency is often the ultimate goal, without trying to find the theoretical explanation. For this reason, these people apparently speak indifferently of an "entrepreneur's ecosystem" as well as an "innovation system" or "systemic policy" or even of "rainforest" (Hwang and Horowitt 2012).

Nevertheless, there is a dispute over the theoretical bases of these policies:

– On one side, economists are at least quantitativist and work on the factors of entrepreneurship, trying to modulate policy measures according to efficiency. They gladly speak about marginal efficiency of the lower rate of corporation tax, while they speak much less of ethics and ideology. They speak about economic system and structure.
– On the other side, some economists are speaking about entrepreneurs and their way of life. In this approach, there is a diminishing interest in the infrastructure concepts as the National Innovation System or clusters as the key object of the politics. These "old" concepts are shifting from operating concepts to description concepts. And the key concept of entrepreneurship policy begins to be the entrepreneurs, their ethic, and their risk management or values, all that we can consider as an ecosystem.

Debates on Efficiency of Tools for Innovation-Entrepreneurship Policy

Management of the Knowledge Spillover? Localization, Proximity, and Quality Effect

The Knowledge Spillover Theory of Entrepreneurship tends to localize start-up close to the actual source of knowledge. The question still exist of how it works: in the 1970s there were many people around the Xerox-PARC and only one company named Apple! Clearly, there is no matter of quantity. If knowledge input increases by 100 %, you can't be sure of a similarly increase of innovation nor entrepreneurship. There is a quality effect, as with artistic creation, and a proximity effect, which nobody understands nor controls.

It is clear that there is no relationship between entrepreneurship measured by the number of new companies/inhabitants and the quality of innovation in the same area. The statistics in France and the United States are consistent on this point.

Local or Global? Efficiency of Clusters Policies

In the 1990s, policymakers and scholars became convinced that the local level is the key for entrepreneurship. In the mid-1990s, clusters were the alpha and omega of innovation policy seen by OECD. However, reports from international institutions were skeptical of the efficiency of the clusters in Japan or in France during the first decade of the twenty-first century. The OECD cluster policy of the 1990s has been progressively replaced by "fostering innovation" and is moving toward a global concept of enabling entrepreneurial acts.

Organized "top-down" clusters are not the best, whereas spontaneous clusters that are "bottom-up, such as Boston or Silicon Valley, are the most effective. If clusters are no longer *the* way to entrepreneurship, the "local" is still a key approach. The right concept of local seems to be "territory" that is still a fuzzy concept, meaning an area where people have a common view on life, a kind of ideology, and a proximity, allowing the building of a community spirit.

At the moment, there is still not established opinion and the local concern of entrepreneurship policies, except that there is a heavy local trend in entrepreneurship policies.

The Emergence of the "Entrepreneurship Culture" Concept

Entrepreneurship culture is a concept that comes from management. The subjects were "top-down innovation" or "firm culture," and consultants still use these concepts.

As there are many emerging concepts and probably no accepted model, everybody must stay aware of. After "fostering innovation," we'll discuss "innovation or entrepreneurship culture". But look out, you need both structures and mind!

Entrepreneurship Policy, Table 2 TEA index (%) in innovation-driven economies (Source: GEM Report 2011)

Country	TEA index
Australia	10.5
Belgium	5.7
Denmark	4.6
France	5.7
Germany	5.6
South Korea	7.8
Sweden	5.8
United Kingdom	7.3
USA	12.3

Entrepreneurship Policy, Table 3 Top ten and bottom ten of starting a business ranking in Doing Business 2011 report (Source: Doing Business Report – 2011)

Easiest	Rank	Most difficult	Rank
New Zealand	1	Iraq	174
Australia	2	Djibouti	175
Canada	3	Congo Rep.	176
Singapore	4	Sao Tomé and Principe	177
Macedonia	5	Haiti	178
Hong Kong	6	Equatorial Guinea	179
Belarus	7	Eritrea	180
Georgia	8	Guinea	181
USA	9	Chad	182
Rwanda	10	Guinea-Bissau	183

The Emergence of Measuring Entrepreneurship

After more than 10 years of controversial debates between scholars and policy makers, three series of indicators are under development in the world.

The TEA Index by GEM

Global Entrepreneurship Monitor (GEM), a worldwide organization whose guiding purpose is to measure individual involvement in venture creation, is developing a number of indicators that are progressively extended worldwide. The major index is TEA (Total Early-Stage Entrepreneurship Activity – see Table 2): the prevalence rate of individuals in the working-age population who are actively involved in business start-ups, either in the phase preceding the birth of the firm (nascent entrepreneurs), or the phase spanning 3½ years after the birth of the firm (owner-managers of new firms).

Doing Business

"Doing Business" is an annual report by the WEF (World Economic Forum) and the World Bank that provides open data on the way of doing business in each country. "Starting a business" includes four criteria: procedures (number), cost (% of income per capita), time (days), and paid-in minimum capital (% of income per capita). Table 3 shows the best and worst rankings.

Entrepreneurship Policy, Table 4 Topic categories for entrepreneurship indicators (Source: OECD-EIP report for 2009)

Indicators for determinants	Indicators for entrepreneurial performance	Indicators for impact
Regulatory framework	Firm-based indicators	Job creation
R&D and technology	Employment-based indicators	Economic growth
Entrepreneurial capabilities	Other indicators of entrepreneurial performance	Poverty reduction
Culture		
Access to finance		
Market conditions		

This assessment is far from accurate regarding the entrepreneurship policies in most developed and even developing countries, however, in 2011, it is the only available worldwide assessment.

Eurostat-OECD

In 2006, the OECD launched the EIP (Entrepreneurship Indicators Program) to build internationally comparable statistics on entrepreneurship and its determinants. In 2007, Eurostat jointed the project. The first reports were edited in 2008 and 2009, but there are not yet any worldwide statistics. OECD has made the choice to follow three series of indicators, as detailed in Table 4:

determinants of entrepreneurship, entrepreneurial performance, and impact.

Policies Assessment

As there is still no established measurement system, there is no possibility of global assessment or rating.

Several parliaments have made punctual assessments: the US Congress has realized assessments of the US policies, from SBA to SBIR. French Parliament made the assessment of "pôles de développement" or clusters in 2009.

Conclusions and Future Directions

There are two major conclusions and future directions for policy makers and scholars.

Some Rules of Thumb for Policymakers

As a general conclusion of this short review, it seems that almost all the financial and physical tools are useful and often necessary, but they don't give any guarantee of success if there is no cultural and societal policy.

At the end, in this matter of "entrepreneurship policy," which is still a new subject of scholarly studies, there is no established academic opinion regarding the way to success. Far from theoretical debates, policymakers need only some golden tenets to avoid major failures. According to the opinions expressed in publications edited by GEM, Kauffmann Foundation (Lerner 2009), Babson College, the World Bank UNACTD (UNCTAD Secretariat 2011), and others (Porter 2003), there are six golden tenets:

1. *Think people, not just structures*: there is no mechanical system producing entrepreneurs, but an ecosystem enabling people to become entrepreneurs. Think global entrepreneur ecosystem, not only environment;
2. *Think worldwide and local*; not too big and not too small. Entrepreneurship needs global connections but entrepreneurs live locally.
3. *Be politic and watchful*: give orientations and means; don't drive by yourself; take care that public initiatives need long time. Don't look for immediate effect. Implement a careful evaluation system (quality and quantity).
4. *Be yourself and be cautious*: success is never only a matter of copying. Correct choice of entrepreneurship policy instruments is determined by context. Use international standards to finance entrepreneurship and innovation, respect market opinion and use the well-tested tools from start-up funds to proof the central concept.
5. *Don't forget knowledge*, from education to R&D.
6. "*The entrepreneurial spirit*" *is the only way to drive the new economy*. Take care of establishment. You need many stakeholders to support entrepreneurs.

New Economics

Entrepreneur may find that entrepreneurship is not a current concept in economics. Entrepreneurship policy was founded to meet unsolvable problems in the 1930s. Because of its success, it was developed further in the 1950s. Today, management academics try to elaborate the conceptual analysis of entrepreneur and of entrepreneurship policy.

Apart from armies and some Indian companies or postal services in Europe, the big companies began to develop during the nineteenth century, with the steam engine, railways, chemical products, telephone, and even electric equipment. At the beginning of the twentieth century, these companies seemed to be the center of economic life. Even Schumpeter thought this way in the 1930s and 1940s.

The rise of big business seemed to confirm these global economic approaches, whether liberal or Marxist. Market, materialist, and centralized economies knew only structures and mass, not individuals. But the years 1950–1980 brought a new idea, which is the comeback of the entrepreneur as the main economic agent for creating jobs, developing business, and innovating.

This may be a major turnaround in economics. As sociology will take into account psychological questions, perhaps economics will have to join management; and the link between management and economics could be the entrepreneur. In fact, for policy makers, entrepreneurship policy is already the link between economic policy and the regulation of business.

Introduction

The entrepreneurship literature have long been interested in the question: What are the determinants of entrepreneurship? Literature analyzing this question has – in the early researches – examined the impact of personality trait on the creation of a new venture. Then, from the 1980s, it has been recognized that the external environment plays also a crucial role in the process of new-firm foundation by researchers adopting a more holistic approach to study the entrepreneurship by taking into account both individual and environmental determinants.

Thus, individual factors are opposed to environmental factors. Individual factors are linked to the individual himself while environmental factors are related to the context in which the entrepreneur is situated. They refer to political, economic, social, and cultural elements that promote the foundation and the development of new ventures.

This entry contributes to review the literature which explored the effects of environmental factors on entrepreneurship activities.

Many authors have identified the environmental determinants of entrepreneurial behaviors of individuals. The most studied factors in the entrepreneurship literature are entrepreneur's family and friends, universities, work experience, territory, and national culture. It has been demonstrated that these factors have a considerable impact on entrepreneurship.

Entrepreneur's Family and Friends

Entrepreneur's family and friends play a crucial role in the decision to create a new venture. Muhanna (2007) notes that individuals whose relatives and friends are entrepreneurs are more likely to be entrepreneurs. He explains that growing in a social circle with many entrepreneurs allows individuals to consider them as examples of success. Thus, the entrepreneurial process is perceived as a recognized and valued behavior. They can also benefit from the experiences and advices of these people throughout the process of creation of their companies. Furthermore, the role of the family and friends can be manifested by forming entrepreneurial teams. Several entrepreneurs found their businesses with their colleagues at the university or at work to benefit from complementary skills and sources of funding.

In addition to these roles, Verstraete and Saporta (2006) stressed the importance of the family as a source of funding. In fact, financial resources are indispensable for the potential entrepreneur to start his new venture.

Education

Additional studies found that entrepreneurial intentions and actions are significantly associated with education. Aurifeille and Hernandez (1991) note that individuals with higher education level are more likely to become entrepreneurs. They argue that schools and universities are an important source of knowledge spillovers and they give people skills and abilities in a particular domain encouraging them to create new ventures.

An important number of researches have examined the impact of different entrepreneurship programs (entrepreneurship awareness, support, etc.) on the foundation of enterprises. Peterman (2000) indicates that entrepreneurship education intensifies perceived feasibility of starting a business and increases interest in entrepreneurial careers. It appears at a specific time in students' lives playing a crucial role in their career choices.

Prior Experience

One other important determinant studied in many researches is the prior experience of the entrepreneur. Ardichivili et al. (2003) describe the importance of prior experience in the development of market knowledge and in the recognition of successful opportunities. They demonstrate that most business ideas stemmed from prior experience. Generally, entrepreneurs create their businesses after having worked in the same activity of the new company and where they have acquired their skills and their experiences with the product or the technology used. The work offers also to the employee the opportunity to develop relations with the employer and experienced colleagues. These relations are important because they favor learning and develop different cross-curricular skills. Hsu (2007) takes into account the importance of prior venture founding experience in the development of negotiating abilities and network contacts which are very necessary to the firm's success (e.g., contacts with suppliers and customers). Consequently, the entrepreneur has a positive perception of his self-efficacy or self-confidence to succeed the creation of his enterprise.

Territory

Another prominent area of research has examined the impact of a favorable territory on the creation and development of successful enterprises. The board conclusion of this literature is that this type of territory offers a favorable business climate composed of a developed infrastructure and many institutions such as incubators, technology parks, and state-driven laws (Fayolle 2003). Territories may have many characteristics that attract potential entrepreneurs and encourage them to create their businesses. These characteristics can be an infrastructure suitable for the emergence of entrepreneurship, the agglomeration and urbanization benefits in a given environment – urban location and the existence of several enterprises in an industry have an influence on the creation of new ventures – and the presence of different institutions (financial institutions, institutions of support, etc.). The technology park is a relevant example of a territory composed of enterprises, universities, and structures of support. The purpose is to promote the creation and the development of new and innovative firms.

Thus, all these characteristics are particularly impactful on entrepreneurial activities because they facilitate and accelerate the foundation of new ventures. Consequently, they increase the overall likelihood of innovation and entrepreneurial success.

Many researches in the entrepreneurship literature find some evidence that family and friends, education, prior experience, and territory are important in determining entrepreneurship. Fayolle (2003) has studied all this determinants. He defined them as social and cultural factors. They relate to the different places known and frequented by individuals. Additionally, he was interested in contextual and economic factors.

Contextual Factors

Contextual factors are factors that generate a discontinuity in the personal or professional trajectory of an individual driving him to the entrepreneurship without a prior intention to create a business. They may be positive ("pull factors") or negative ("push factors") (Shapero 1975). "Pull factors" may be a meeting with a potential client or partner, recognition of an opportunity, etc. However, negative factors can be unemployment, layoff, unsatisfactory work conditions, etc.

Economic Factors

Economic factors relate to the availability of the required human, technical, financial, and informational resources which are very important to start a new business. In other words, the difficulties of access to these resources can be a serious obstacle to the creation of new ventures.

National Culture

Several researchers noted that the creation of new venture is also function of national culture. Audet et al. (2004) argue that the emergence of entrepreneurs cannot be realized without the cultural influence of their environment. According to these authors, the concept of culture is associated with "the existence of models of entrepreneurs in the social environment," "the social attitude towards failure," "the social status of the entrepreneur and the entrepreneurship as a career choice," "the media treatment of the entrepreneur," and "the perception of the presence of business opportunities." If the image of entrepreneurship as a career alternative is positive, it may be a factor which encourages a large number of individuals to the creation of new ventures. If it is negative, it may discourage many entrepreneurial activities.

A large empirical literature has tested the role of environmental factors influencing entrepreneurship. Typical explanatory determinants contain education, capital assets, previous professional experience, and professional status of the parents (Freytag and Thurik 2007). Furthermore, in his empirical study conducted on 65 entrepreneurs in South Africa, Muhanna (2007) demonstrates that education, previous experience, and social network in addition to other individual determinants such as self-confidence and risk tolerance are important for the choice to become an entrepreneur. It should be noted that most of the researchers have studied the impact of each determinant cited in this entry alone and only some researchers have examined the influence of all of these factors on entrepreneurial activities.

Conclusion and Future Directions

In conclusion, this entry sought to contribute a greater understanding of the environmental factors that encourage individuals to create new ventures. The study was focused on the most studied determinants in the entrepreneurship literature. These determinants are often examined separately by a great number of researchers in the field.

Attention was paid on the role of family, education, prior experience, territory, and national culture on the foundation of new enterprises.

As a recommendation, it is very necessary that public policies do not lose sight about the importance of these determinants. For example, providing a favorable business climate by developing the infrastructure and the multiplication of institutions supporting entrepreneurs (like incubators, technology parks, financial institutions) could be a key factor to encourage individuals to the entrepreneurship.

Furthermore, it would be necessary to many governments to better adapt their education system to the preparation to entrepreneurial activities. In order to achieve this objective, entrepreneurial education should include courses based on reality and practical cases. That will allow students to develop their entrepreneurial abilities and to have the motivation to create new businesses.

The image of entrepreneurship as a career alternative should be also improved and valued by media by providing proximity between individuals and successful entrepreneurs.

Such recommendations could be impactful on the promotion of entrepreneurship which is seen as a source of wealth, new jobs, and economic development for any nation.

The Conceptual Sociotechnical, Socioeconomic, and Sociopolitical Context for the Epidemiology of Innovation

With the onset of organized human activity going back thousands of years, and surely since the industrial revolution, science, technology, innovation, and entrepreneurship have evolved to be major determinants of the way humans live. In the Western world, science, technology, and economy are interrelated and have allowed for both the growth of the economy and the emergence of national and supranational structures and so-called globalization. Due to this common perception, the last decades are characterized by a steadily rising interest of scholars for the many interactions between science, technology, and socioeconomic development and its sociopolitical implications. There is an extensive debate concerning the influence, evaluation, role, connections, and transfer of science and especially technology upon, within, and between societies and in particular within and across sectors of economic activity and geographic regions. The same reasoning may apply to business, industries, sectors, and clusters at the macro-, meso-, and micro-levels.

The recent economic downturn has highlighted the dynamic interplay between economic forces and general health and well-being of consumers and businesses. Examples in the popular media describe situations in which job loss or other unexpected events (e.g., the onset of a chronic condition or an increase in variable rate debt service payments) can cause many households to become insolvent, and ultimately to file for bankruptcy. Similarly, in the housing market, foreclosures within a community depress property values for other homeowners and business owners within that community, making it more difficult for them to sell or refinance their assets. This leads to a type of "social contagion," where a single event or a series of events can lead to deleterious consequences for an entire community. Traditional economic and financial theories have failed to adequately incorporate these sociocultural, institutional, and other evolutionary forces into their empirical and theoretical frameworks.

One field of study that has incorporated a comprehensive approach to human decision making and policy design is public health, and its empirical subfield of epidemiology. Public health not only recognizes that the outcomes of effective decision making are multifaceted (and explicitly incorporates this fact into its theoretical and empirical models) but also recognizes that those outcomes are driven by (and collectively drive) social norms, institutions, and public policies. In short, public health adopts ecological and evolutionary principles as core tenets.

In this broader context, the theoretical concept of innovation, based on the ideas of Joseph Schumpeter, has evolved and been used in the study of many aspects of those interactions. Innovation has been studied in a variety of contexts (e.g., technology, manufacture, commerce, and social systems) and has been proven a useful tool for both situation analysis and policy making in a sectoral, regional, national, and supranational perspective. Although further interdisciplinary research of such a complex social phenomenon is needed, certain conclusions can already be drawn on the role of innovation. It is widely accepted that innovation enriches economic evolution by increasing its substrate, namely, the technologies that are used.

Since the emergence of the so-called endogenous theory of growth, the research interest has been focused on the micro-level and takes into account the fact that innovation does not occur in isolation but depends on a "selection" environment. This is highlighted by its tendency to cluster in sectors, causing structural, organizational, and institutional changes.

Taking into account that nations, regions, and sectors as well as firms and universities are open, esoteric, heterogeneous systems, it seems reasonable to assume that the ability of such a system to produce or adopt innovation plays an important role to their economic performance. Indeed, the way these systems learn, accumulate, convert, and transfer innovation concepts and practices, that is, the diffusion of innovation, is a condition sine qua non for economic performance and development. The study of innovation diffusion has therefore fairly attracted the research interest of many scholars and has led to the development of many relevant theories and empirical models.

Definition of Terms: Epidemiology, Innovation, and Interrelations Thereof

Epidemiology

Epidemiology is "the study of the distribution and determinants of health-related states or events in specified populations, and the application of this study to the prevention and control of health problems" (Last JM. A dictionary of epidemiology, 4th ed., Oxford University Press, 2001).

Being a fundamental science of public health, epidemiology uses quantitative methods and has made major contributions to improving population health.

Traditionally considered a biomedical science, epidemiology is in reality an interdisciplinary science with contribution to other scientific fields, among others, in biostatistics, social and behavioral sciences, demography, and geography. This evolving conception of epidemiology as a liberal art has also found applications in emerging fields of studies (N Engl J Med 1987; 316:309–14). In the field of computer science, the use of biological analogies has led to the development of various theoretical models for the prediction of the rate and extent of propagation of a computer virus infection (Journal of Computer Science 1 (1): 31–34, 2005). Furthermore, the use of epidemiological investigations and interventions has been increasingly focusing on social networks leading to a better understanding of the processes that determine how networks form and how they operate with respect to the spread of behaviors that affect public health (Norsk Epidemiologi 2009; 19(1): 5–16).

The origins of epidemiology can be traced in Hippocrates and his alleges about the impact of environmental factors on the occurrence of disease. In the years of Renaissance, which reintroduced classical Greek texts in combination with the development of commerce and the exploration of the new world, an underlying belief of a relationship between physical phenomena and mathematical axioms was common among scholars and university professors. This trend to quantify phenomena signifies the birth of modern epidemiology as well as the birth of social sciences.

It is in this same spirit that Descartes' conception that organisms in general and the human beings in particular (possibly even the human mind) are no other than special-purpose machines started to dominate the Western world (ref). At approximately the same time and place, the sociopolitical conditions, referring mainly to merchant, had as a consequence the establishment by the revolutionary French Academy of Sciences, with Laplace as chairman, of the International System of Measures and Weights (ref). This trend to mechanize and measure almost everything was the matrix out of which resulted the possibility to quantify and represent everything that happens in the human body in state of health or disease. In the late seventeenth century, William Petty published his pioneering work "Political Arithmetick," promoting the assumption that society could, in a clear analogy to an organism, be studied with the use of mathematics. The term "epidemiology" was coined in 1802 with the publication of *Epidemiologia Espanola* by Don Joaquin Villalba.

Despite diverging paths between epidemiology and the social sciences, they both rely to a great extent on each other through a diffusion of methods and ideas mainly due to the same substrate of their research, namely, groups of entities. In the second half of the twentieth century and the emergence of social constructivism, social sciences begin to use theoretical tools from epidemiology in an attempt to quantify their research and gain scientific merit. On the other hand, epidemiologists try to track origins and patterns of contagion to social behaviors. This new mutual grafting is signified by the emergence of new scientific journals such as the *Journal of Health and Social Behavior* and *Social Science and Medicine*.

Having already stated that research in dynamics of innovation diffusion has revealed patterns resembling the spread of a disease over a human or animal population, it is reasonable to investigate whether the diffusion pattern of innovation can be studied using principles derived from epidemiology.

Innovation

Although a theoretical link between innovation and economic growth is almost self-evident, it was not until after World War II (Bush 1945) and the work of Solow that innovation took a central place in formal economic models. Innovations provide the necessary substrate for business opportunities and future innovations as well, thus allowing for sustainable economic growth. Those premises, which rely to a major extent on the work of Joseph Schumpeter, were further elaborated by economists who used mathematical tools and implemented those ideas to new dominant economic models. Therefore, during the last decades, innovation has been intelligibly recognized by several nations as a major determinant of economic growth.

The importance of innovation for long-term economic growth is almost self-evident. The significance of innovation for economic performance was impressively illustrated by research work of Professor M. Abramowitz. The core of his argument was that increase in the output of the economy results either from increase of inputs that go into the productive process or by increase in productivity, that is, increase in output per unit of input or output per worker. Abramowitz measured the growth of both input (of capital and labor) and output of the American economy between 1870 and 1950 and discovered, surprisingly, that the measured growth of input accounted only for about 15 % of the measured growth of output. Therefore, the residual 85 % should be attributed to other factors that could stimulate growth, namely, technological innovation. According to many economists, productivity, income distribution, and unemployment are the variables most commonly used as indicators of national economic performance. Productivity lies in the core of every measurement that tries to evaluate economic growth and is largely dependent on investment in capital formation, in people, and in technical progress. A second level of agreement between economists is that of all these variables, technological innovation is the most significant and is considered to play a substantial role for long-term growth of productivity. Indeed, innovation is one of the very few concepts that economists diachronically and persistently recognize its significance. However, it was not until the late nineteenth and early twentieth centuries that innovation was placed central to the theories of economic growth by Marx and Schumpeter, respectively.

Karl Marx and Joseph Schumpeter adopted a similar approach which relied on the assumption that technological competition is the main form of competition between firms in the capitalistic environment and that innovations set up the stage for business opportunities and future innovations as well, thus allowing for sustainable economic growth. Their ideas were further elaborated by economists who used mathematical tools and implemented those ideas to new economic models such as the “new growth theory” or the “endogenous growth theory.”

The theoretical concept of innovation has been elaborated by researchers especially during the last decades of the twentieth century and many of its characteristics, categories, and types have been elucidated. Although the boundaries between different types or ways of innovation are often fuzzy, the relevant research has highlighted four major areas in which innovation takes place. Analytically, the term “innovation” refers to either the capability to introduce or improve products or processes or the capability to define or redefine the positioning of the firm or products or the dominant paradigm of a firm. Since Solow introduced innovation in formal economic growth theory, a constellation of models has been proposed to conceptualize innovation and its relationship with growth. Among the most sophisticated and influential approaches are those highlighting the role of knowledge in the process of innovation. Indeed, change and learning are two sides of the same coin. This means that innovation entails knowledge either (and mainly) as a precondition or as the cause of new problems, theoretical or practical, which demand new skills and knowledge in order to be solved.

During the last several decades, a vast amount of literature has shed light on the relationship between knowledge and innovation. It is almost incontrovertible that a process of continuous learning plays a most important role in the economic performance of firms and nations mainly through its impact on innovation. These led to the recognition of knowledge-based innovation as a premise for infinite economic growth and to the concepts of knowledge-based economy and learning economy. In the new global economy, the economic performance of firms and nations relies mostly on their learning and adopting abilities, since the latter lead in turn to technological capability. This can be conceptualized as the knowledge and skills necessary to choose, install, and operate new technologies and furthermore to improve and develop them. In other words, learning is in the core of what is called innovation diffusion.

Innovation is a complex, nonlinear phenomenon and in order to study it, all factors should be taken into consideration that influence it and enhance its diffusion in a certain environment. Indeed, the interactions with the factors of the "selection" environment are a dynamic phenomenon, where the impact of every factor on the economic performance of a certain actor (e.g., a firm) is almost unpredictable and therefore difficult to measure. However, multifactor performance indicators, focusing on the knowledge dynamic of the firm under evaluation, are the core of almost every attempt to determine their innovative status. Those approaches take into account the importance of information, skills, and know-how to economic success with an emphasis on knowledge varieties, growth, and diffusion as reflected in innovations related to organization management, marketing, and industry environment and human resources.

The current era is marked by significant changes in the global socioeconomic environment, propelled to a great degree by the exploitation of advances in science and technology. Perhaps the most striking example is the generation and organization of the Internet, which has led to the rearrangement of the global environment. One of the major aspects of these changes is the so-called globalization, indicated by the birth of supranational structures such as the European Union and the establishment of highly complicated networks between nations, organizations, and human agents which unify and transform almost every aspect of social life including economical models, procedures, and interactions. On the other hand, regional, national, and supernatural characteristics seem to affect dramatically the different innovation systems in the contemporary economy. It is otherwise difficult to explain the increasing positive analogy between knowledge-intensive economic activity and spatial clustering. In this constantly changing environment, the reevaluation of certain premises concerning traditional core performance areas especially in economy is almost imperative, since economic growth plays a substantial role in nations' and peoples' welfare. It is within this wider context that new notions such as the knowledge-based economy or the learning economy have emerged, while others such as the theoretical concept of innovation and more specifically the diffusion of innovation are now central in almost every theoretical approach of economic growth.

Although Schumpeter referred to innovation and recognized characteristics of the latter such as the tendency to "cluster" in certain contexts, he did not move his analysis any further concerning the origins or the management of innovation. Over the last few decades, a wave of research on innovation has swept the debate about theories of the growth of firms. The results of such an enormous literature cannot be easily summarized. Nevertheless, the point that almost every study highlights is that radical and mainly incremental innovations, firm-specific technological knowledge accumulation, networking relationships, interaction with users, and integration of R&D activities, all play substantial role through a process of continuous interactive learning to the growth of firms. Again learning and knowledge, scientific or technological, tacit or codified, plays a central role to the economic performance. By 1996, the OECD report for knowledge-based economy recognized knowledge and knowledge networks as a premise for infinite economic growth through their impact on innovation.

Aspects of the role of learning or knowledge have been extensively developed by many economists. Although innovation and learning are not interchangeable notions, research has shown that learning, at least in the form of learning orientation of a firm, constitutes a major input in a process where innovativeness can be viewed as the output. In the constantly changing environment, firms have to respond to many challenges. Sustainable competitiveness relies foremost on the ability of economic actors to adapt to the emerging and rapidly changing techno-economic environment. As mentioned elsewhere, this ability is mostly illustrated and embodied in the ability of nations, regions, and sectors to be innovative. Innovation in turn, either in the

Science, Technology, and Innovation (STI) mode or the Doing, Using, and Interacting (DUI) mode, relies on learning and adopting. The context of the learning or the knowledge-based economy not only reflects the increasing volatility of the products and the profound changes in the ways of production but also entails a normative dimension in the sense that facilitates us to adapt to the new socioeconomic environment and to develop suitable policy tools. Indeed, in the new global economy, the economic performance of firms depends on their learning and adopting abilities, since the latter result in technological capability, that is, knowledge and skills necessary to choose, install, and operate new technologies and furthermore to improve and develop them.

A wide body of literature conceptualizes firm-level technological progress, which leads to sustainable competitiveness, as a learning process and in particular higher order technological learning (Carayannis 2000). In that sense, innovation is a key to economic vitality and a crucial factor which affects the learning ability of firms to take advantage of and to create new business opportunities. The radical influence of the works of Romer and Lucas on the neoclassical theory of economic growth resulted in the redirection of emphasis on the human capital as a major determinant of technological progress and, in turn, of long-term economic growth. Lucas expressed it more explicitly arguing that the main propellant of growth is the accumulation of human capital in the form of knowledge either codified or, to a perhaps greater extent, tacit.

Since innovation is regarded as a nonlinear, evolutionary, and interactive process between the firms and their selective environment, it is almost self-evident that in trying to conceptualize it, any factor should be taken into account that plays a role in that concept. The term "innovativeness" entails two different dimensions, namely, "innovation performance" and "innovation capabilities." The concept of "innovation performance" refers to the current innovation activity as measured empirically. On the other hand, the theory that underlies the term "innovative capabilities" is mainly conceptual. It is future oriented and focuses on abilities to innovate that may not be currently realized. Therefore, it is not directly observable and it is hard to measure. As economic thinkers have long started considering knowledge as a major determinant of innovative capabilities and therefore economic growth, intangible inputs of information, skills, and competence in the form of learning through experience, interaction, and networks play a significant role in competitive advantage along with traditional, codified, formally produced scientific knowledge and the conventional tangible economic inputs of growth such as land, labor, and capital. The ability of a firm to learn and adopt, in other words, the diffusion of innovation within a certain environment plays a significant role in the economic performance of firms. The ways innovation diffuse between firms of the same cluster or the same sector should be taken into consideration in any attempt to evaluate the innovation profile of the latter.

Beyond the level of the firms, the importance of the diffusion of an innovation may well precede the innovation per se if taken into account that it is a sine qua non for the multiplicative influence of the latter. Indeed the adoption of new ideas and practices, that is, innovations, from firms leads to a second-order spread to other firms. This is a precondition for the adoption of a certain innovation from a certain number of firms that constitute the critical mass for its establishment. It is for the above reasons that the study of dynamics of innovation diffusion between firms and sectors has attracted the research interest of many scholars who seek to identify which policy measures should be adopted in order to achieve competitiveness and better economic performance.

Diffusion of Innovations

In Latin, the word "diffundere" means "to spread out." Essentially being one of the several transport phenomena that occur in nature the notion of diffusion has been extensively researched and used apart from the physical sciences from the social sciences as well, with anthropology being one of the first scientific fields shedding light on the characteristics of this phenomenon. In his influential paper, Kroeber notes that this certain pattern of diffusion which he calls stimulus or idea diffusion "occurs in situations where a system or pattern as such encounters no resistance to its spread, but there are difficulties in regard to the transmission of the concrete content of the system. In this case it is the idea of the complex or system which is accepted, but it remains for the receiving culture to develop a new content."

After World War II, the accumulated body of research in the field of diffusion started having application in market research. The ongoing industrialization and competition for market share highlighted the importance of notions such as the diffusion which in turn led to the increased finance and research interest from the academic community. In recent decades, the concept of innovation is considered a core topic of research in many heterogeneous scientific fields, ranging from anthropology to politics and from education to marketing.

In the field of innovation, the relevant research is based on Rogers' fundamental theory of innovation diffusion (Rogers 1962). According to him, innovation is "an idea, practice or object that is perceived as new by an individual or other unit of adoption," whereas diffusion is "the process by which an innovation is communicated through certain channels over time among the members of a social system." Going further, Rogers (1962) discusses five factors that impact the rate of adoption: (1) relative advantage, (2) compatibility, (3) complexity, (4) trial-ability, and (5) observability.

In this seminal work, Rogers (1962) argues that diffusion is a generic process not depending on the type of innovation or other spatiotemporal characteristics, displaying the same regularities across many typological boundaries. Further research has highlighted certain characteristics of these patterns of diffusion aiming at the design of relevant models of the spread of an innovation mainly in marketing.

Most relevant research has tried to represent the several reactions of the diffusion process with mathematical equations presenting a formalistic approach to the study of this phenomenon. Gatignon and Robertson (1986) differentiate between theoretical (descriptive), normative, and empirical models. It is worth noticing that research in dynamics of innovation diffusion in the field of marketing has mainly focused on the temporal pattern of this diffusion as an innovation spreads over a population following a pattern that resembles the spread of a disease over a human or animal population. It is thus only fair to investigate whether the diffusion pattern of innovation and the diffusion pattern of diseases share similarities and obey the same general rules.

Epidemiology in the Study of Innovation Diffusion

The current era is characterized by the emergence of new fields of study that transverse the traditional boundaries between scientific fields. The new evolving concepts of globalization and the emergence of the new vast markets of East Asia pose great challenges to the political and economic field. Researchers from different disciplines are trying to explain and interpret the different phenomena using not merely traditional theoretical tools from their tract but also enriching their armamentarium from ideas and methods from other disciplines. For traditional industrial powers such as the USA and the EU, the massive transfer of manufacturing to East Asia has highlighted the need for a paradigm shift in the economy. Innovation plays a more important role than ever since these regions have to innovate since they cannot rely on manufacturing anymore. An important and well-studied aspect of the innovation concept is the diffusion of the latter. The significance of diffusion relies on its multiplicative effect which is often many times more important than the innovation per se. As already mentioned elsewhere, diffusion of innovation has been extensively studied and many fruitful conclusions have been drawn. However, there are many aspects of this phenomenon that need an alternative approach for their research. Epidemiology has gained popularity in the last decades as it represents a "generic" science, offering methods of study that can be applied to many different scientific fields. In the last years, epidemiological tools and methods have already been incorporated into economic-related fields of study such as epidemiology economics and pharma-economics. Taking into account the similarities between diffusion of innovations and diffusion (in terms of contagion) of diseases in a certain "selection" environment, it can be argued that epidemiology can be used in the study of innovation diffusion among economic entities. However, it should refer to potential limitations of an attempt mainly due to prevailing differences between spread of diseases and diffusion of innovation such as the fact that adoption of innovation is a conscious act that usually offers an advantage to the adopter who, in contrast to a host infected from a disease, does not activate his immune system in order to eliminate the offending agent.

In medicine, the dynamics of disease transmission, that is, contagion, is based on a schema consisting of a source or reservoir of infection, a transmission mode, and a susceptible host. In this model, the source of infection is defined as the person, animal, object, or substance from which an infectious agent passes or is disseminated to the host (immediate source). The reservoir is the natural habitat of the infectious agent. A carrier is an infected person or animal that harbors a specific infectious agent in the absence of discernible (visible) clinical disease. A carrier serves as a potential source of infection to others. The transmission can be direct or indirect. The susceptible host provides a portal of entry and those environmental circumstances where the infectious agent can replicate, exit the organism and again, directly or indirectly, affect others. A schematic representation of the above-mentioned characteristics would then look like the following:

Host---exposed host---infected host---cured host.

In such an attempt, the first step is to define the economic entity being referred to, that is, the host. Although in a networked economy different economic levels (firm, sector, cluster) are connected with each other, we need to identify the basic entity that will later serve as the host of the contagious agent.

In this view, the most appropriate analogy is between a human organism living in a certain environment and a company active in a networked cluster. Indeed, if it is taken into account that human beings are similar to their basic functions, choosing the level of company as analogue to the human level eliminates potential confounding factors that would be implicated if economic entities of different scales are chosen such as a company, a cluster, a sector, or a market economy. The sample of a possible epidemiological study referring to business entities should be kept as homogenous as possible since that would allow for the extrapolation and generalization of the relevant results.

Special Case-in-Point: The Academic Firm

The "academic firm" represents a type of firm (firm-based organization) that focuses on encouraging, supporting, and advancing knowledge production (research, research and experimental development, R&D) and knowledge application (innovation) within the context of the Quadruple Innovation Helix (Government, University, Industry and Civil Society) (Carayannis and Campbell 2009). The academic firm is also inclined to generate profit (revenues), but follows here more the logic of a "sustainability" in balance with knowledge production and the principles of knowledge production. The contrary concept to the academic firm would be the "commercial firm," which is primarily being motivated and driven out of an interest of maximizing profit (revenues). Between these two conceptual poles of understanding, there are various possibilities of a gradual or also unconventional (radical) combination of principles for the empirical organization of a concrete firm, its organizational manifestation. The shortcut for a definition therefore is: "The Commercial Firm concentrates on maximizing or optimizing profit, whereas the Academic Firm focuses on maximizing or optimizing knowledge and innovation" (Carayannis and Campbell 2012, p. 27).

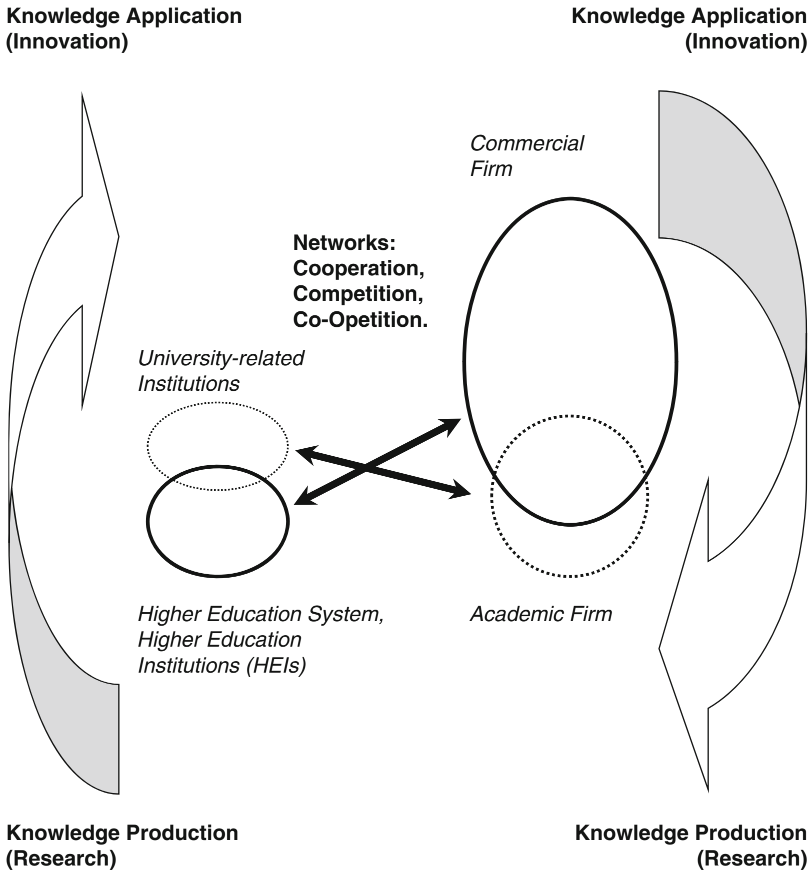
Knowledge and innovation are crucial key drivers for the academic firm. Academic firms can follow the logic of linear innovation, but also the logic of nonlinear innovation. The model of linear innovation often is being assigned to Vannevar Bush (1945). This model assumes a sequential "first-then" relationship, where there is first basic research at universities that gradually diffuses out into society and economy, and where firms then translate the lines of basic research into application and economic as well as commercial uses and profits. But nonlinear innovation favors a different approach. Nonlinear innovation is interested in a more direct and parallel coupling of knowledge production and knowledge application, where there are mutual interferences and parallel as well as parallelized interactions between basic research and knowledge application. The organization of nonlinear innovation encourages creative organizational designs (Campbell and Carayannis 2012). In context of firm-based organizations, also for the academic firm, the processing and advancement of nonlinear innovation may imply the following: (1) firms (academic firms) engage simultaneously in different technology life cycles at different levels of technology maturity; (2) firms (academic firms) accept to a certain extent, even encourage, cross-employment of their employees with other institutions, for example, academic institutions, such as universities or other higher education institutions. Cross-employment, as a concept, identifies forms and varieties of multi-employment, where an individual person is being simultaneously employed by more than one organization (by at least two organizations): Should those organizations also root in different sectors, then cross-employment displays characteristics of a trans-sectoral network-building (Campbell 2011).

Academic firms express a particular interest to network with universities, other higher education institutions, university-related institutions, and all forms and manifestations of organizations that conduct an academically based type of research or basic research. Academic firms explore also possibilities, options, and opportunities of networking with other firms (academic firms, but also commercial firms). There always remains the challenge, how to balance and how to refer to each other (out of the perspective of the firms) with regard to cooperation and competition. Furthermore, networks can integrate aspects of cooperation and competition. The organizational design of patterns of cooperation and competition allows creativity, and can also be captured and described by the notion and concept of "Co-Opetition" (Brandenburger and Nalebuff 1997) (see Fig. 1).

Knowledge production in context of universities and the higher education system has been explained on the basis of the models of "Mode 1" and "Mode 2" of knowledge production. Mode 1 emphasizes a traditional understanding and refers to university basic research, with no particular interest in knowledge application, and being organized in context of academic disciplines. Here, the established peers of the academic disciplines define and decide on quality (acceptance and rejection of work). Mode 2 already expresses a greater interest in knowledge application and is characterized by the following principles: "knowledge produced in the context of application"; "transdisciplinarity"; "heterogeneity and organizational diversity"; "social accountability and reflexivity"; and finally "quality control" (Gibbons et al. 1994, pp. 3–8, 167; see furthermore Nowotny et al. 2001, 2003 and 2006).

"Mode 3" universities or higher education institutions are inclined to seek and to explore creative, novel, and innovative combinations of Mode 1 and Mode 2. One key interest of Mode 3 is "basic research in the context of application" (Campbell and Carayannis 2013, p. 34). Mode 2 as well as Mode 3 universities clearly meet and fulfill some of the characteristics of the "entrepreneurial university." However, it is important to realize that a Mode 3 university is more than an entrepreneurial university, in the sense that Mode 3 universities are still interested in focusing on and in conducting basic research. But the Mode 3 university does not assume an intrinsic contradiction between basic research and innovation (knowledge application): in fact, quite contrarily, the Mode 3 university sees benefits and opportunities in a parallel (nonlinear) approach to knowledge production and knowledge application, to forms of combinations between basic research and innovation.

Epidemiology of Innovation: Concepts and Constructs, Fig. 1 Knowledge production, linear and nonlinear innovation interaction between academic firms, commercial firms, and universities (higher education institutions) (Source: Authors' own conceptualization based on Carayannis and Campbell (2009, p. 211; 2012, p. 25) and on Campbell and Carayannis (2013, p. 29))



Mode 3 universities (higher education institutions) have the opportunity of offering and developing "Creative Knowledge Environments" (on creative knowledge environments, see Hemlin et al. 2004).

Mode 2 and Mode 3 higher education institutions are the perfect organizational vis-à-vis of academic firms to engage in trans-sectoral networks and to perform good knowledge production. Here, a creative and innovative hybrid overlapping in regular frequency occurs or should possibly occur. This represents a coming-together and networking on equal and fair grounds. Not the universities (higher education institutions) should adapt one-sidedly to firms and their economic needs, but both sides should learn mutually from each other to the benefit of all involved parties, actors, and institutions. The assertion is: "While the entrepreneurial (Mode 2) university represents a partial extension of business elements to the world of academia, the academic firm could serve as an example for an extension of the world of academia to the world of business. Academic firms are knowledge-oriented, interested in engaging in networks with universities (the higher education sector), encourage 'academic culture and values' to motivate their employees, allow forms of academic work (such as academic-style publishing), and support continuing education and life-long learning of and for their employees (flexible time schemes, honoring life-long learning and continued continuing education with internal career promotion)" (Carayannis and Campbell 2012, p. 27).

Conclusion and Future Directions

Epidemiological tools and methods have already been incorporated in economic and economically related fields of study such as epidemiology economics and pharma-economics. It is therefore fair to argue that these methods could also be applied to other economic issues such as the study of the diffusion of innovation. The recent global economic developments have revealed the existence of clear analogies between medicine and economic science underlined by the usage of relevant expressions in scientific papers (e.g., economic recovery, economic health, financial health). It is often written that the economic crisis manifests itself like a "financial disease" and spreads throughout the financial markets. Traditional empirical and theoretical frameworks have failed to incorporate the effects of these types of "social contagion" in their predictive models. It is therefore of crucial importance to explore if these analogies between medical and economic terms could be used as the basis for a new conceptual framework that links these metaphors to economic science concepts and to innovation in more particular. Development of relevant models could theoretically lead through the real-time identification of early signs and symptoms to the adoption of appropriate measures and control of possible contagion.

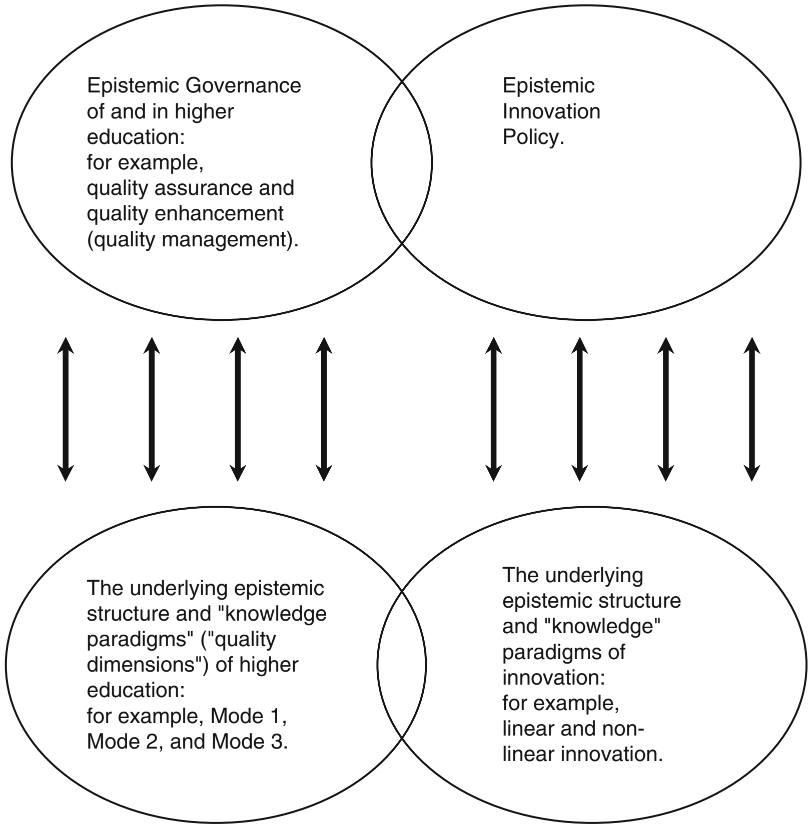
The Conceptual Definition of Epistemic Governance and of Epistemic Innovation Policy

The concept of epistemic governance is based on the understanding that the underlying epistemic structure, the underlying epistemic base, and the underlying epistemic paradigms of those organizations, institutions, or systems (sectors) are being addressed, which should be governed. In context of higher education, governance can refer not only to internal governance within a university (higher education institution) or within the higher education system but also to external governance, for example, governance measures of a government for universities. A more detailed definition of epistemic governance would stress as follows: "'Epistemic' governance of and in higher education therefore requires that the underlying epistemic structure of higher education and, more particularly, also the underlying paradigms of the produced knowledge are being addressed. Epistemic governance refers directly to the underlying 'knowledge paradigms' of higher education that carry and drive higher education" (Campbell and Carayannis 2013, p. 27). Here, in this definition, the focus is placed on "epistemic" in the context of "epistemic governance." Consequently, one important implication therefore is "good, sustainable and effective (external and/or internal) governance of organizations, institutions or systems (sectors) is in the long run only possible, when the underlying epistemic structure, the underlying epistemic base or the underlying epistemic paradigms" are indicated (Campbell and Carayannis 2013, p. 27). The epistemic structure reveals also what the self-rationale of an organization or a system is. Alternative definitions of epistemic governance may lean more toward the aspect of governance within the context of epistemic governance: "In this context the conceptual framework of 'epistemic governance' aims to address the power relations in the modes of creating, structuring, and coordinating knowledge on socio-ecological issues. . . . Finally, the production and use of knowledge is seen to be linked to questions of relational, structural, and soft power, and to the relationship between science and policy" (Vadrot 2011, p. 50).

Is it possible that there is an organization, institution, or system without an underlying epistemic structure? This may (or may not) be true for some organizations or institutions; however, for a whole system or sector, this appears to be unlikely and improbable. Particularly in the case of universities, higher education institutions, and higher education systems, it is evident that these rely, operate, and behave on the basis of an underlying epistemic structure. "Knowledge paradigms" refer to the conceptual understanding of knowledge production (research) and knowledge application (innovation) in the higher education system (universities) or the economy (firms). For describing and explaining how knowledge production is functioning within the higher education sector or a university-type system, the concepts of "Mode 1" and "Mode 2" of knowledge production were introduced more recently (Gibbons et al. 1994; see also Nowotny et al. 2001, 2003, 2006). University research in a traditional understanding of Mode 1 concentrates on basic research, mostly organized within the matrix of academic disciplines, and not formulating a particular interest for the practical use of knowledge and innovation. Mode 1 is being challenged by Mode 2. Mode 2 expresses a greater interest for knowledge application and a knowledge-based problem-solving by referring to the following principles: "knowledge produced in the context of application," "transdisciplinarity," "heterogeneity and organizational diversity," "social accountability and reflexivity," and "quality control" (Gibbons et al. 1994, pp. 3–8, 167). Success and quality are being approached and defined differently in the analytical architecture of Mode 1 and the Mode 2. For Mode 1, the answer is "academic excellence, which is a comprehensive explanation of the world (and of society) on the basis of 'basic principles' or 'first principles', as is being judged by knowledge producer communities (academic communities structured according to a disciplinary framed peer review system)." For Mode 2, success and quality are a "problem-solving, which is a useful (efficient, effective) problem-solving for the world (and for society), as is being judged by knowledge producer and knowledge user communities" (Campbell and Carayannis 2013, p. 32). Mode 3 knowledge production represents the conceptual and organizational attempt of trying to combine Mode 1 with Mode 2 (Carayannis and Campbell 2006, 2009, 2012). A Mode 3 university, higher education institution or higher education system, is a type of organization or system that explores ways and approaches of not only integrating different principles of knowledge production and knowledge application (such as Mode 1 and Mode 2), thus promoting diversity and heterogeneity, but also creating creative and innovative organizational contexts for research, teaching (education), and innovation. Therefore, Mode 1, Mode 2, and Mode 3 qualify as examples for "knowledge paradigms" in higher education.

Quality management (QM) within universities or other higher education institutions refers to quality assurance but increasingly also to quality enhancement. Advances in the quality of a university and support of university development represent objectives of quality management. Therefore, also quality management should be designed, implemented, processed, and developed in accordance with the principles of epistemic governance: “This emphasizes our understanding that all forms of comprehensive and sustainable quality management in higher education must also refer to the underlying epistemic structure of higher education (at least implicitly)” (Campbell and Carayannis 2013, p. 27). For example, it makes a difference, whether a university or university unit operates according to Mode 1 or Mode 2 or a combination of both in Mode 3. This must be reflected by the specifically applied approaches in governance and quality management. For that purpose, it appears also to be necessary to connect and to link the underlying epistemic structure and the knowledge paradigms to concrete “quality dimensions” so that governance and quality management can refer to knowledge paradigms as well as quality dimensions. Possible quality dimensions are quality, efficiency, relevance, viability (sustainability), and effectiveness (Campbell 2003, p. 111; Campbell and Carayannis 2013, p. 52). When knowledge paradigms are being translated into quality dimensions, this may make it then for governance and quality management easier to address epistemic issues in relation not only to knowledge production but also to knowledge application. According to Ferlie et al. (2008, 2009), there exist currently two main narratives of and for governance in higher education: New Public Management (NPM) governance and network governance. While NPM already appears to be more conventionally established, network governance represents a more radical frontier for contemporary governance, with not so clear implications, fostering perhaps a demand for creating also new types of organizational manifestation in higher education. “Cross-employment” (Campbell 2011; Campbell and Carayannis 2013) may serve here as one possible example, where one and the same person is being simultaneously employed by more than one organization (by at least two organizations), either within higher education or trans-sectorally connecting higher education with organizations outside of higher education. Cross-employment qualifies as a form of multi-employment.

Ramifications of epistemic governance should also be thought of in a wider context. Principles of epistemic governance apply to innovation and innovation policy as well and the concept of “epistemic innovation policy.” Innovation policy should address the underlying epistemic structure and knowledge paradigms of the innovation and type of innovation to be governed. Two examples for knowledge paradigms in context of innovation are linear innovation and nonlinear innovation. The more traditional model of linear innovation is being frequently referred to the concepts of Vannevar Bush (1945). The core understanding here is as follows: the linear model of innovation underscores that first there is basic research in a university context. Gradually and step-by-step, this university research diffuses out into society and the economy. Firms and the economy as a whole pick up these lines of university research and develop them further into knowledge application and innovation, with the goal and interest of creating economic and commercial success and success stories in markets outside of higher education. Within the model of linear innovation, there operates a sequential first-then relationship between basic research (knowledge production) and innovation (knowledge application). Nonlinear innovation follows a different logic (Campbell and Carayannis 2012). The model of nonlinear innovation expresses an interest in drawing more direct connections between knowledge production and knowledge application. Here, basic research and innovation are being coupled together not in a first-then but within the structural design of an “as well as” and “parallel” (parallelized) relationship (Campbell and Carayannis 2012). Networks for nonlinear innovation operate differently than networks of linear innovation but may overlap substantially. Examples for nonlinear innovation are either firms or other types of organizations operating across a variety or ensemble of technology life cycles with differing degrees of technology maturity on the one hand or specific constellations of cross-employment on the other hand, where persons work (at the same time) concurrently at organizations, where in one case the organization (organizational unit) focuses on knowledge production but in the other case on knowledge application. Nonlinear innovation also cross-connects to Mode 3 knowledge production. One key interest of Mode 3 is to



Epistemic Governance and Epistemic Innovation Policy, Fig. 1 Epistemic governance of and in higher education, and epistemic innovation policy (Source: Authors' own conceptualization based on Campbell and Carayannis (2013, p. 28))

encourage and to promote "basic research in the context of application" (Campbell and Carayannis 2013, p. 34). Furthermore, also Mode 2 appears to be compatible with a more nonlinear logic of innovation (see Fig. 1).

Conclusion and Future Directions

Epistemic governance and epistemic innovation policy formulate a critique against too-narrowly defined approaches to governance, where governance follows one-sidedly bureaucratic or technocratic considerations. Instead, epistemic governance (also quality management and quality enhancement) and epistemic innovation policy should be regarded as a plea for a more comprehensive understanding, where the explicit-making comprehension and reflection of knowledge, knowledge production, and knowledge application are keys for a successful governing and governance. In that respect, epistemic governance speaks and argues also in favor for the practical feasibility of a "Philosophy of Governance." Epistemic governance, as a concept and as a practice, qualifies as a novel form of governance, representing a new and innovative frontier and frontier line of and for governance, with a hybrid overlapping to other concepts and measures such as network governance, cross-employment, and epistemic innovation policy. There is also a governance of innovation and innovation policy, so the cross-connections between epistemic governance and epistemic innovation policy demand further elaboration and a more advanced fine-tuning for practical purposes. In conceptual terms, epistemic governance and epistemic innovation policy still require to be broadened and expanded. For example, also universities of the arts are being regarded as institutions that contribute considerably to national and multilevel innovation systems (Carayannis and Campbell 2012, pp. 14–17). From that universities-of-arts-based input, important interdisciplinary and transdisciplinary impulses ought to be expected. The specific and potential roles of arts universities and artistic research, also in connection to their governance and epistemic governance, are to be further developed. The same applies to cross-connections between artistic research, artistic innovation, and epistemic innovation policy.

Experiential Learning and Creativity in Entrepreneurship, Fig. 1 Components of creativity (Amabile 1983)

Definition

Entrepreneurial creativity can be defined as the social and cognitive processes through which entrepreneurs develop novel and useful ideas that transform and create new markets (Gemmell et al. 2011). Innovative entrepreneurs form new businesses by applying creative ideas to produce unique and transformative new products and services. Experiential learning theory (ELT), described by David Kolb as the "dynamic view of learning based on a learning cycle driven by the resolution of the dual dialectics of action/reflection and experience/abstraction" (Kolb 1984), has dramatically expanded researchers' understanding of how entrepreneurs use creativity to solve customer problems and produce innovative new products and services.

Theoretical Background

The Kolb experiential learning theory (Kolb 1984) has been a useful tool for addressing the real-world challenges of entrepreneurial creativity and innovation. The core principles of experiential learning permeate other similar theories of learning, demonstrating the vast impact of experiential learning on learning and creativity scholars. There are many theories of creativity; however, Teresa Amabile's Componential Framework (Amabile 1983) and the classical Wallas' stages of creativity (Wallas 1926) have proven most highly impactful to management studies.

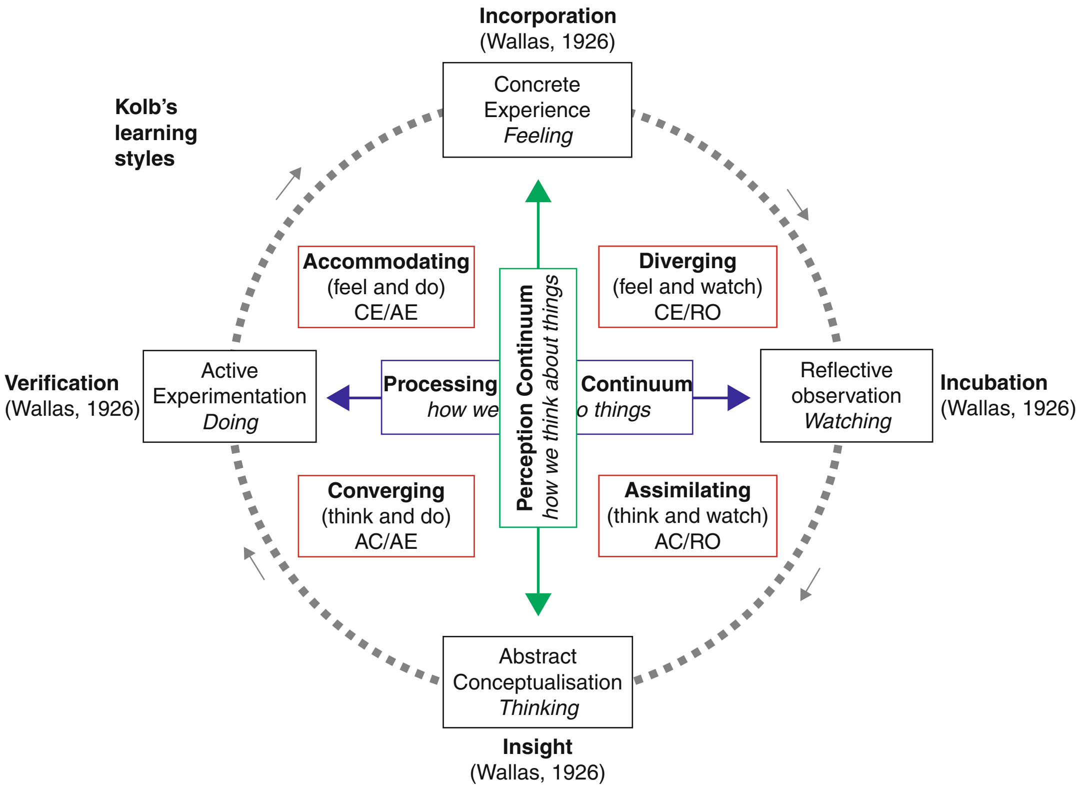
Learners have a preference for certain learning modes of grasping and transforming experience into understanding which are defined as the individual's "learning style." Learning style can be correlated to career choices, i.e., learners with a diverging style are often interested in the arts while convergent learners tend to be specialists in technical fields. Assimilative learners are usually interested in theory and abstract problem solving while accommodative learners gravitate toward action-oriented careers such as marketing and sales. Learners may also have a balanced or flexible style that allows them to adapt their learning on a situational basis.

Amabile's theory of creativity involves three components – domain knowledge, creativity skills, and motivation (summarized in Fig. 1 below).

Successful entrepreneurs learn two forms of knowledge: (1) domain knowledge related to a particular market or technology and (2) knowledge of how to be an entrepreneur ("entrepreneuring") (Minniti and Bygrave 2001). Entrepreneurs require a base of domain knowledge in order to perform creative transformational processes; however, base knowledge is a "double-edged sword" and can lead to entrenchment and inflexibility (Dane 2010). Recent research has shown that entrepreneurs tend to innovate within a relatively narrow space, demonstrating the extraordinary role of domain knowledge within the practice of innovation (Gemmell et al. 2011).

Knowledge is essential to entrepreneurial opportunity recognition, and asymmetries in both knowledge and learning style likely account for why entrepreneurs in the same environment do not all recognize the same opportunities (Shane 2000; Corbett 2007).

Amabile's second component, creativity skills, refers to cognitive style, heuristics, and creativity techniques. Cognitive styles are closely related to Kolb's learning styles and consist of an individual's preferred approaches to solving problems. Heuristics are algorithms or shortcuts for problem solving, and creativity skills are transformational techniques and processes utilized to facilitate development of novel ideas.

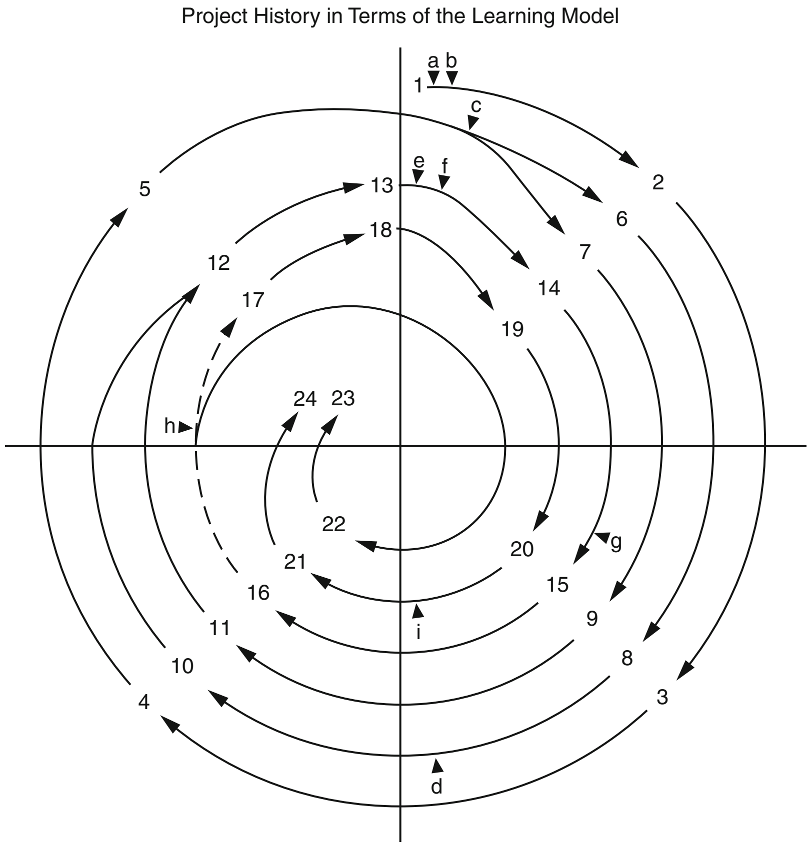


Experiential Learning and Creativity in Entrepreneurship, Fig. 2 Cycle of learning and creativity (Gemmell et al. 2011)

Intrinsically motivated individuals are compelled to creative action based on a sense of doing something important mostly for the joy of doing it (Amabile 1983). On the other hand, extrinsic motivation is derived from external pressures to perform, some of which might be perceived as useless or arbitrary. Entrepreneurs perform best under conditions of "synergistic motivation," i.e., a blend of intrinsic and extrinsic factors depending upon the stage of creative production (Amabile 1996). Intrinsic motivation matches well with relatively divergent stages of innovation while extrinsic pressure is often needed for relatively convergent stages such as production of documentation or a prototype.

Wallas' classical stages of creativity, as expanded upon by Csikszentmihalyi (1996), are merged with Kolb's experiential learning theory in Fig. 2 below to form an insightful "cycle of learning and creativity." Creative entrepreneurs typically engage problems through a direct concrete experience which triggers a variety of ideas and potential solutions. Following periods of reflection and subconscious incubation, entrepreneurs often have a flash of insight commonly referred to as an "aha" moment. The entrepreneur experiments with this trial idea resulting in additional experiences and refinement of the creative idea through cycles of learning.

The Kolb Learning Style Inventory is an individual assessment tool – as a result, the theory could be viewed as primarily an individual level model of learning. However, studies of innovation, problem solving, team learning, and organization learning have demonstrated the broad utility of Kolb's experiential learning theory across multiple domains and levels. Furthermore, the basic concepts in experiential learning theory have influenced other learning theories, some of which have endeavored to address the enormous



Experiential Learning and Creativity in Entrepreneurship, Fig. 3 Tracking R&D project in experiential learning space (Carlsson et al. 1976)

challenges of developing a comprehensive model.

Carlsson et al. (1976) used Kolb's experiential learning theory to study the processes of team innovation within an R&D setting. The research team studied biweekly reports written by members of the corporate R&D teams in order to map activities into the Kolb experiential learning space. The researchers found that activities followed the clockwise sequence of stages according to Kolb's experiential learning theory with minimal deviation (see Fig. 3 below). When steps were skipped or taken out of sequence, the impact on the project (delays, impasses, team conflicts) was generally quite evident. The mapping was an easy and effective method of tracking projects and assessing both the status and strengths/weaknesses of each project.

Managers would generally "look ahead" one or two stages in order to anticipate upcoming challenges. Managers were also able to address issues of entrenchment by becoming more directly involved when a team became "stuck" at a particular stage. The researchers found that project teamwork could be improved by allocating work by matching learning style of the individual with the learning stage orientation of the particular task (see Fig. 4 below).

Effective managers led the team around the model and resisted the temptation to jump across stages to accelerate projects. Interventional techniques were developed based upon the stage of the project (see Fig. 5 below). For example, teams struggling in the divergence stage were assisted with ideational techniques whereas issues with convergence could be addressed through analytical methods such as decision trees and mathematical modeling.

Contrary to the popular image of the entrepreneur as a loner, studies now show that most start-up firms would not even launch, much less succeed, without the collaborative efforts of

Experiential Learning and Creativity in Entrepreneurship, Fig. 6 Matching team members to project stages (Kolb and Kolb 2005)

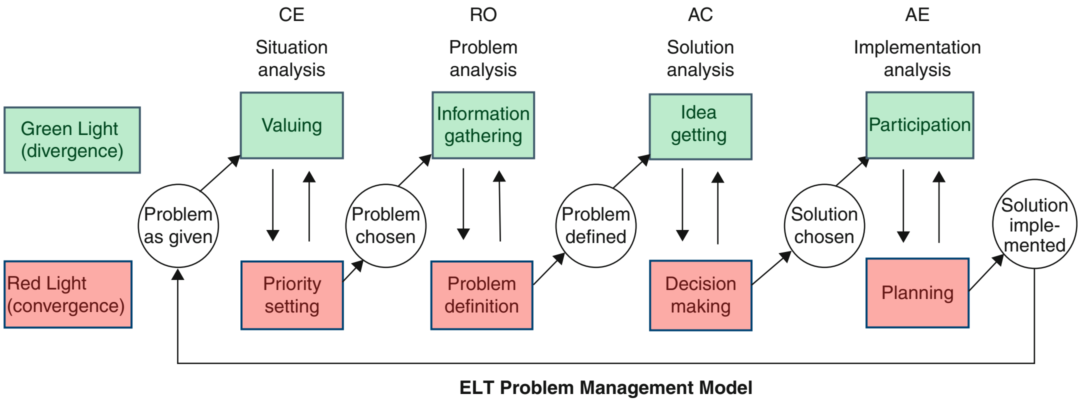
a partner and/or entrepreneurial team (Gemmell et al. 2011). The Kolb experiential learning theory has also been used effectively to examine the dynamics of team level learning and creativity. This application of experiential learning is a natural extension of Kurt Lewin's (1948) early concepts of learning space or conversational space for teams to reflect on shared experience.

Kayes and Kolb utilized Mills' team development theory (1967) to describe a five-stage progression toward increasingly more sophisticated goals and purpose: immediate gratification, sustained gratification through greater learning efforts, identification and pursuit of a collective goal, self-determination through conscious directed effort to achieve collective goals, and growth to achieve multiple increasingly complex goals requiring higher levels of innovation. The emergence of shared purpose is the defining moment when the team begins to operate as more than a collection of individuals, i.e., as a learning unit.

Team size is a balance between sufficient size to be effective without being too large to function and communicate and coordinate activities. Teams with similar superficial traits are attracted to each other and have an immediate sense of comfort (homophily); however, most researchers associate diversity with greater prospects for innovation (Ruef et al. 2003). Trust and a sense of safety (when expressing ideas to the group) are also important to team performance (Kayes et al. 2005).

Teams composed of individuals with learning style preferences covering the complete learning cycle will more easily function through the complete learning role taxonomy. However, a balanced team can be difficult to attain, especially since individuals are often attracted to certain career fields based upon their learning style (Kolb and Kolb 2005). It is desirable, although often difficult, to allocate teamwork by matching each project stage with someone whose style matches the demands of that stage (see Fig. 6 below).

Entrepreneurial teams struggle to align limited resources to either exploit known markets or explore new possibilities, knowing they lack the



Experiential Learning and Creativity in Entrepreneurship, Fig. 7 Experiential learning model of creative problem solving (Kolb 1982)

resources to do both and realizing that exploration could offer higher growth but exploitation lower risk (March 1991). Top management team (TMT) composition in a start-up firm influences the firm's preference for exploitative or exploratory strategies (Beckman 2006). Founding teams with a diverse work history (coming from different companies) are more likely to pursue an exploratory strategy because they bring different ideas and network ties into the firm. Conversely, teams composed of individuals who have all worked together previously are more likely to pursue an exploitative strategy by virtue of bringing mature exploitative routines and procedures from their previous company.

Kolb's experiential learning theory is also useful as a creative problem-solving framework to examine how entrepreneurs develop practical innovative solutions for the marketplace (Kolb 1982). Creative problem solving can be analyzed as moving through four stages, each of which is anchored in one of the four stages of experiential learning (see Fig. 7 below). Each stage alternates between a more exploratory "open" divergent cognitive process (green light) and an exploitative "closed" convergent process (red light).

The case study of entrepreneurial creativity shown in Table 1 below (Gemmell et al. 2011) shows the development of an idea from inception to product launch and offers some interesting extensions to the Kolb experiential learning theory. The case study clearly demonstrates innovation through iterative, action-oriented meta-cognitive learning by the entrepreneur. The entrepreneur in this case study consciously wrote problems and thoughts in a notebook, periodically recopying these notes to keep the problem fresh in his subconscious mind. After several months of mostly subconscious reflection, the entrepreneur experienced an epiphany (the "aha" moment) in which he realized that a troublesome product "defect" could actually be used as a creative solution to his customer's problem. Following this moment of insight, the entrepreneur skillfully used both intra-firm and strong extra-firm social contacts to further develop and refine the problem solution.

The entrepreneur also used social networks to essentially institutionalize his solution by sharing the idea with key management team members and with his board of directors to get their buy-in. This process of developing and maintaining shared vision is crucial to socialization and institutionalization of new learning (Pearce and Ensley 2004). Failure to perform this socialization process can result in dysfunctional organizational dynamics such as "not invented here." Sharing the idea with the board of directors helps to maintain an organizational culture of psychological safety since board approval means broader distribution of risk or effectively less concentration of risk on the shoulders of the CEO and management team.

Experiential Learning and Creativity in Entrepreneurship, Table 1 Case study of entrepreneurial creative idea development (Gemmell et al. 2011)

Kolb ELT map	Stage of entrepreneurial ideation
	**1. Problem Engagement (Individual)**: "I tend to write things down because it just kept it top of mind for me. I've got a note in a notebook somewhere where I wrote a note that says we need to have something we can sell directly to independent contractors, and that was the beginning of the thought.. It was enough of a reminder,"
	**2. Incubation (4–5 Months, Individual)**: "It just kept getting moved from one to-do list to the next one to the next one, and some background process in my brain was running around. I was talking to people about it. Customers, constantly talking to people about it."
	**3. Insight (Individual)**: "when I write things down like that. I have . . . these flashes. One day – it occurred to me that our technology was one weeks' worth of effort away from being able to do something that nobody else could do. So that's when it tripped over."
	**4. Social Experiment (Inner Group)**: "Great idea. We can make that work. We'll go off and get that done. . . the board was just like, "How is this going to make us more money?" So when I explained it to them, they were all excited."
	**5. Social Experiment (Close Outer Group)**: "And then in a 48-h period, I managed to scare up the two companies I wanted to partner with, get them both on the phone. I knew them, all the players there. I laid it all out and they agreed immediately."
	**6. Social Experiment (Close Outer Group)**: "She has this idea that instead of using VARs, why don't you talk to these companies that provide service? Without her and the guy from the employee outsourcing company - and the interesting thing about that is those relationships. . . are years old. . . the constant nurturing of these relationships is an important part of getting things done these days."
	**7. Social Experiment (Outer Group)**: "I talked to two or three of the value added resellers that thought they might be able to help out. . .But they didn't have any positive ideas. The interesting thing about that talking to that group was it was a roadblock conversation. "Hey, I've got this idea." Yeah, but."
	**8. Active Experiment**: "We've put up a webpage to take reservations for it just to see what kind of traction it would get in the industry. We're going to let the registration page run for five or six weeks. Then take stock of how many people are actually signing up for it and whether or not it's worthwhile in putting in the final touches."

Conclusions and Future Directions

Experiential learning theory provides a useful framework for better understanding the links between learning, entrepreneurial creativity, and innovation. Successful entrepreneurs take action to iteratively experiment, learn, and develop creative ideas.

There is growing recognition within the entrepreneurship research community of the significant and underserved role of social interactions and collaborative creativity and learning within the process of innovative new business formation. Recent data suggests the traditional assumption that simple theories of homophily and diversity do not fully explain the intricate workings of an effective entrepreneurial team or partnership.

In particular, there are open questions about the composition of an ideal partnership or team – what sort of mix of learning styles and learning flexibility (Sharma and Kolb 2009) produces the best results for an innovative start-up firm? How does this composition influence decision-making processes related to innovation?

Research has shown that entrepreneurial innovation requires a mix of both divergent exploration and convergent exploitation. Are certain teams, by virtue of their learning traits, more predisposed to innovate through exploration of new markets while others excel at innovative exploitation of well-understood markets? Is there a team learning trait composition that yields the ideal mix of both exploration and exploration (commonly referred to as ambidexterity)?

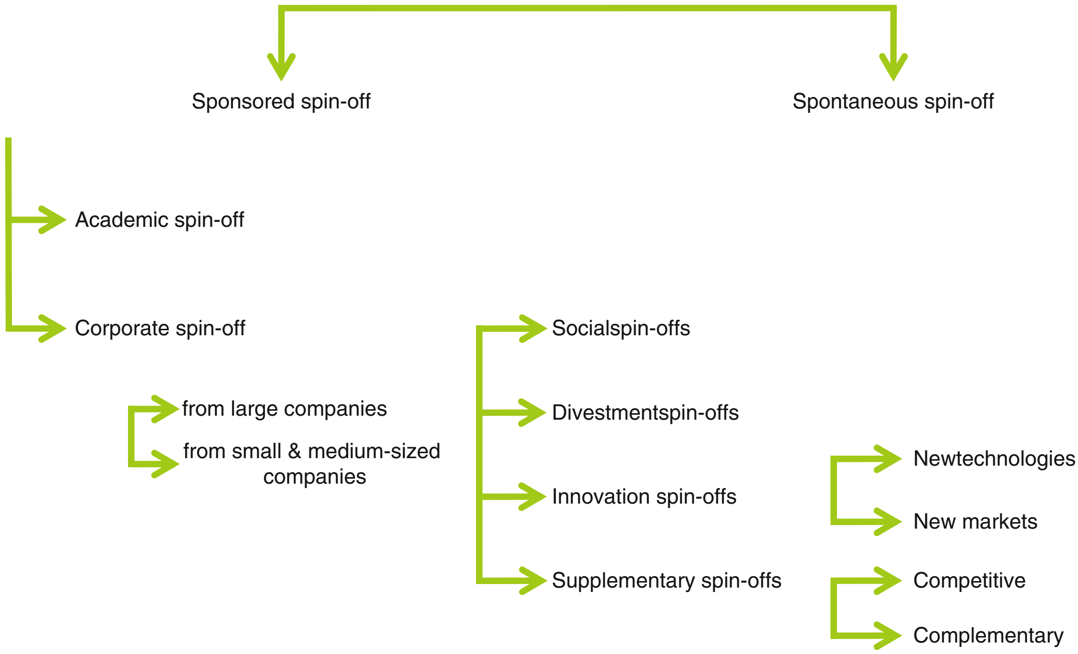
A Promising Form of Entrepreneurship

Citizens, firms, and territories continuously focus on entrepreneurship. The fact that some countries have a low entrepreneurial capacity may be deplored, and it results in two phenomena: on the one hand, the small number of business start-ups and, on the other, the difficult emergence of growth potential businesses, or of middle-sized businesses, as opposed to very small businesses.

In the wide research field of entrepreneurship, extrapreneurship is relatively little explored. Yet it covers various situations which may inspire public or business policies by shedding a new light on them. Extrapreneurship indeed relies on exploiting opportunities and assets coming from an existing company. It enables experienced entrepreneurs to develop new technologies and explore new markets, thus creating value and growth potential businesses.

Studying extrapreneurship leads us to focus on the strategic choices of firms and on their boundaries. According to the resource-based view, spinning-off may be considered as a phenomenon which can generate business opportunities promoted by the relationships set between parent companies and spin-offs.



Extrapreneurship, Fig. 1 Spin-off typology

Spinning-Off: A Multiform Phenomenon Relying on Corporate or Public Research

A spin-off is a firm formed by one or several employees coming from the same parent organization. This creation formally or informally relies on the assets of this organization, be they tangible or intangible. Spinning-off is therefore different from creating a company ex nihilo. In extrapreneurship, the emergence of the new company is accomplished by breaking off with the organizational or institutional structure of the parent firm (i.e., by creating a new legal entity or setting up a new type of organization). The starting point of spinning-off is the discrepancy between the parent and the spun-off company: be it the desire for independence of an employee, diverging views on the opportunity to get involved in an innovating project, a divestment of the parent company, or the strategic intention not to pursue the promotion of an ongoing research. Extrapreneurship makes possible to exploit opportunities, assets, or skills which were born in the parent company.

This phenomenon takes various forms, and its typology is presented in Fig. 1.

This typology is based on several criteria:

– The spontaneous aspect of the creation or, on the contrary, the impulse or support given by the parent organization.
– The type of parent organization: public research or corporation. The latter being called corporate spin-off.
– The diverging point from which the spin-off is created and the latter's orientation: divestment or reorganization, grasping technological or market opportunities, reorganizing the value chain by outsourcing. This aspect refers to the degree of maturity of the activity that is spun off: mature activity from the parent company or, on the contrary, new or embryonic activity. Thus, some authors distinguish between opportunity spin-off and divestment spin-off.
– As regards the particular but widely spread case of supplementary spin-off which is a type of outsourcing, the typology can determine the degree of competition existing between the parent company and the spin-off, whether the latter becomes a competitor of its parent company or not.

Spontaneous Spin-Off

This type of extrapreneurship corresponds to the spontaneous departure of an employee who decides to create his/her own company, without having been incited to do so or backed by the parent company. The activity of the spin-off can be created with or without any connection with the parent company. Spontaneous extrapreneurship is a manifestation of the labor mobility, which allows knowledge to circulate and contributes to keeping up the vitality of labor pools. It can explain the existence of spontaneous clusters (Merlant 1984).

Social Spin-Off

Social spin-off is a practice which large companies may be compelled to in times of reorganization or which they set up more permanently so as to promote the mobility of their employees. Thus, they help weave a web of companies around their original site and compensate for the job losses that such a reorganization may cause. In such a case, social spin-off promotes the emergence of entrepreneurial initiatives based on the individual projects of employees which may have no actual connection with the activities of the parent company or its markets. The large company's involvement consists in supporting the project variously, including by providing financial support. This type of extrapreneurship is in line with the employment policy of parent companies and also with their image policy and relational strategy. It results from their social liability.

Academic Spin-Off

In this case, a researcher or a team of researchers decide to leave their original laboratory to promote a result of their research (Pirnay et al. 2003). This type of extrapreneurship has been widely developed for several years in North America, where some universities are well known for technology transfer. The creation of a company from public research requires a set of determining conditions. Universities and public research need to have a technology transfer policy and an expertise on the transfer of intellectual property to the spin-offs; they need to inform and train researchers about entrepreneurship and to define specific status for researchers becoming entrepreneurs; they have to welcome young entrepreneurs with incubators. And last but not least, there must be an appropriate financial environment with special connections with business-angel and venture-capital networks.

Technological Extrapreneurship and Corporate Venturing

Technological extrapreneurship consists in creating a spin-off by relying on a technology which has been initially developed in the parent company. Such a creation can be explained by the strategic and financial arbitrations of the parent company. Connections between the latter and the start-up may consist in a technological cooperation, in cofinancing the innovation or becoming a stockholder of the start-up and sharing intellectual property with it. Technological spin-off comes within the frame of innovation management and corporate venturing. The latter practice allows an existing company to explore new business opportunities with a limited investment, by resorting to the skills and the agility belonging to an entrepreneurially managed small firm, and finally by sharing risks with it.

In some industries requiring highly specialized knowledge, like biotechnologies, creating a company is always achieved by founders coming from public or corporate research or industrial research. Spinning-off is then the only way to create new companies.

In 1988, Marc Lassus and four engineers left the Thomson group and founded Gemplus since the group chose not to get involved in the development of microchips. As phone cards were spreading, France Telecom became the first customer of the young company. In the 1990s, Gemplus was part of the mobile phone market explosion and became the SIM cards world leader. In 2006, after merging with Axalto, Gemplus, now Gemalto, became the microchips world leader and was present on three main markets: mobile phones, financial transactions, and identity safety. In the close field of semiconductor devices, Thomson spurred the creation of STMicroelectronic as well as many other companies created in the 1980s.

Supplementary Spin-Off

Supplementary spin-off consists in outsourcing an activity which was previously led by the parent company. The company thus created becomes a supplier or retailer of the parent company, on a temporary or permanent basis, which may lead it to try to address other customers. Supplementary spin-off requires to move one or several employees of the parent company and may be followed by the transfer of industrial or commercial assets. The parent company becomes an outsourcing company, according to the logic of transactional firm defined by Fréry (1996). The spin-off results from the optimization of the value chain by the parent company which grants resources more efficiently, variabilizes fixed costs, and looks for flexibility and for the advantages of specialization.

Divestment Spin-Off

This type of spin-off comes within the field of portfolio management by the parent company which makes the decision to withdraw from some of its activities in order to use its resources for other activities. Thus, spin-off results from diversifying and refocusing choices which may lead to reconfiguring the parent firm's perimeter. This reconfiguration may follow an industrial or a pure financial logic.

A research (Wallin and Dahlstrand 2006) conducted on 101 companies which entered Stockholm stock exchange between 1992 and 1996 showed that 28 % of them were spin-offs and 11 % were sponsored spin-offs. In this study, spin-offs are defined as companies whose capital is held by a large company before entering the stock market, the latter keeping a share in sponsored spin-offs after their entrance. Wallin and Dahlstrand highlight the fact that these companies have three specificities distinguishing them from other quoted companies: they are larger at the time of their creation, their workforce grows faster in the years after they enter the stock market, and, finally, they are more widespread in high- and medium-technology industries.

Opportunity and Divergence: Spin-Off Seen Through the Resource-Based View

Extrapreneurship belongs to the field of entrepreneurship and may be distinguished from creating a company ex nihilo. It can have an impact on the creation of companies with value and growth potential. Notions of divergence and opportunity are essential to understand the spin-off phenomenon. They allow to review it through the resource-based theory.

Spinning-Off and Accessing Business Opportunities

The example of the founder of Gemplus gives a good illustration of the assets an extrapreneur may have: he knew the market, had developed technological and management abilities and management abilities, and acquired international experience within the parent company, which turned out to be particularly favorable conditions to create a high growth potential business (Daviet 2000). His evolution within the Thomson group enabled him to identify and measure the technological and commercial opportunities related to microchip development. Fayolle (2001) mentions the notion of "launch window" which makes perfect sense when used in the context of extrapreneurship. Verstraete and Fayolle (2005) defined the paradigm of business opportunities as a "social construction arising from interactions and confrontations between the people undertaking the entrepreneurial project and the context of their evolution." Many researchers underlined the difference between the achievements of companies created ex nihilo and those of spin-offs. This gap can mainly be explained by the founders' acquired experience and their better access to opportunities.

Paillot (2003) studies entrepreneurial socialization and defines it as the historical process of learning, integrating, and finding one's social place. Deciding to spin-off becomes part of a career course and constitutes an alternative (Fayolle 2001). Minniti and Bygrave (2000) highlighted a decisive factor related to such a decision: the difference between value being an entrepreneur and an employee.

Thus, drastically restructuring a company may trigger innovating entrepreneurial opportunities, as Buenstorf and Fornahl (2009) showed in a case study about the Intershop German company, created in 1992, introduced to the Neuer Market and to NASDAQ in 1998 and considered as the finest example of new economy. This company, which developed tools for Internet software and online business, used to have 1,218 employees in 2000 at the top of its development, but it considerably reduced its size after the Internet bubble burst (about 200 employees in 2007). Yet, in just a few years, about 40 companies, mostly working in the same field and located in the same area, were created as a result. Creating these companies, also called necessity spin-offs by Buenstorf and Fornahl, had a double impact. It first allowed to save employment in the regional area by compensating for the job cuts of Intershop. Then it allowed to create a software cluster, which was spurred by the parent company. Therefore, the company had a temporary success within its boundaries but a long-lasting effect on regional development.

Divergence: Spin-Offs' Starting Point

Extrapreneurship always has its origin in a kind of break or divergence within the parent firm. This is obvious in social spin-off, but it also exists in supplementary and technological spin-off. It may be linked to job cuts, to a different choice of investment which may lead to giving up an activity or a development, to a decision to exploit technological or market opportunities through a small company, or to the management of a business portfolio.

These divergences may lead the parent company to reconfigure its organization, change its boundaries, and, depending on each case, develop new activities or reconfigure mature ones.

Audretsch underlined the importance of such a break in the emergence of the new company since, as he noticed, each individual grants different potential to a single idea:

> Because of the fundamental characteristics inherent to new ideas, what an agent considers as a potentially valuable idea can be considered otherwise by the people who make decisions in his firm, (especially) if the new knowledge does not fit with the core competences of the firm, or if it is not in line with its technological course. (This) divergence (. . .) submits individual workers (or teams), who make intellectual contributions, to a fundamental choice: they can either ignore their idea and reorient their activities to be in line with the organization, or try and appropriate the value of this new idea in the organizational context of a new firm. (Audretsch et al. 2006)

Strategy of the Parent Company and Resource-Based View

Some researchers on entrepreneurship emphasize the role of the context and define it as a spurring, facilitating, or stimulating element in the creation of a new firm. As far as extrapreneurship is concerned, these contextual elements are obviously present, but there is another specific factor related to the conditions of incubation of the new venture within the organizational matrix of the parent company.

While there may be cases of spontaneous spin-offs, which are not backed and are ignored by the parent company, academic literature most frequently deals with initiated cases, which are supported or at least allowed by the parent company (Parhankangas and Arenius 2003). This leads us to question or review extrapreneurship from the point of view of the strategic choices of companies and of the evolution of their boundaries.

These choices may be interpreted according to the resource-based view which highlights the way a company articulates its resources in order to get competitive advantage and to position itself on the value chain. According to this theory, the parent firm reviews its business perimeter and makes development, divestment, or diversification choices by optimizing the connection between its inner and outer resources, be they material, immaterial, or financial. The resource-based view is useful in that it helps understand the direction and results of the diversifying movements of the parent firm. As such, it highlights the factors leading to the decision to spin-off. This theory shows that extrapreneurship helps reduce the resources of the parent company and its business portfolio when it considers that its externalized resources are too far or that they are not part of its core resources (Richardson 1972). However, building partnership or financial connections with the spin-off allows the parent firm to have a subsequent access to externalized resources or even to the results they generate.

The issue of firm boundaries in the spin-off process was dealt with by the theory of transaction costs. As far as supplementary spin-off is concerned, Johnsson and Hâgg (1987) consider that extrapreneurship corresponds to an intermediary situation between market and hierarchy since the two firms are interdependent.

Characteristics of Female Entrepreneurship

Female entrepreneurs are the women founding, building, owning, and driving new companies in emerging and established industries. What is understood as entrepreneurship can range from being self-employed and, for instance, running a small catering service from home to owning a business venture worth millions of US dollars. Starting from Schumpeter's original portrayal, entrepreneurs are often seen as charismatic individuals who use inventions, resources, and creativity to push for commercial success of innovation. The classical theoretical view presents entrepreneurship as gender neutral. Research on the secret of entrepreneurial success highlights the personal characteristics of the individual. Scholars use descriptors such as inventive, energetic, risk taking, aggressive, dynamic, self-motivating, and tolerant of ambiguity. These "entrepreneurial traits" are clearly male attributes. Prior to 1980, entrepreneurial activity in most developed countries was dominated by men. Not surprisingly, research investigated men and their motives, behaviors, and characteristics. The phase of treating entrepreneurial behavior as gender neutral as well as without any other crucial distinctions across populations lasted until the 1990s. Since then, the research focus has shifted. The number and importance of female entrepreneurs grew, and now female enterprises contribute considerably to economic development all over the world. Thus, it is no longer appropriate to neglect the specific motives and performance of female entrepreneurs. Though still limited and fragmented, a specialized literature on women entrepreneurship is evolving and growing (Brush et al. 2006; Carrier et al. 2008; Klapper and Parker 2011; Patterson and Mavin 2009).

More insights into female entrepreneurship derived from a large body of research that compared the experience and human capital of male and female entrepreneurs. At the same time, research began to focus on environmental (available financial and other resources) and societal factors (networks, social capital) in order to explain the "gender gap" in entrepreneurship. More recent research challenges the concept of gender neutrality (with masculine undertones). Most studies seem to reject the notion that gender-related discrimination in laws and regulation should be the major reason for the disproportionate participation of females in start-up businesses. Some go so far as to place gender at the center of understanding the essence of entrepreneurial activities (Lewis 2006; Wagner 2007). Are female and male entrepreneurs really so different? If so, what are the main differentiating factors?

Numbers: The Status Quo

The ratio of female to male entrepreneurs is different across regions and countries. In many parts of the world, male entrepreneurs outnumber females by far. While there has been a great increase in the number of female entrepreneurs, research shows that participation is still low. For instance, female entrepreneurs make up 37.7 % of all entrepreneurs in New Zealand in 2010. And in the USA, according to their 2002 census, just over one quarter of all US firms in 2002 were owned by females. The trend in the USA for female new ventures is positive with a yearly increase of 20 % which amounts to doubling the overall growth rate. In Europe, female entrepreneurs also own and run just a minority of businesses. In the EU, female self-employment ranges from just over 20 % to 40 % depending on the country. Many European women report that they start businesses to avoid under- or unemployment. For much more women than men in the developed world, self-employment is a part-time activity. In the transitional economies of Eastern Europe and Central Asia, it varies from over 40 % (Latvia and Hungary) to just over 8 % (Tajikistan).

Research on female entrepreneurship in Latin America and the Caribbean found very high rates of female entrepreneurship in the poorest countries of the region. For instance, over 35 % of business owners in Peru are female. However, only 13 % of women entrepreneurs in the region indicated that they expected their firm to grow over the following 5 years. In many cases, opportunities and incentives are unfavorable for women to begin businesses, even when they have the abilities and knowledge.

The analysis of entrepreneurship focuses on the formal private sector; however, the "informal" sector plays an important role in many countries and particularly in developing ones (e.g., 70 % of official GDP in Nigeria). If female entrepreneurship is much more widely spread in this "shadow economy," such neglect may lead to a considerable omission.

Performance: The Status Quo

In terms of standard measures of performance like earnings, profits, return on capital, growth rates, etc., male entrepreneurs tend to outperform their female competitors. There is general agreement in the literature that female entrepreneurs tend to earn less income and that their businesses grow at a lower rate than those owned by male entrepreneurs, with no difference between developing or developed countries. Overall women's businesses tend to be smaller, utilizing less capital and finance from banks and other lenders than men's. This is due to women entrepreneurs concentrating in (sales, retail, and services) industries with lower capital intensities and lower average return on capital and is not due to their lower business effectiveness or capabilities. Even when studies find that female owners earn similar rates of return on assets as male owners, lower investment at the start leads to comparatively lower absolute income and profits for female entrepreneurs. Moreover, women's businesses tend to generate lower sales turnover than men's and therefore are less profitable than those of men, even in same industry comparisons.

How can these gender differences be explained?

Motivation and Characteristics of Female Entrepreneurs

Major reasons to pursue an entrepreneurial way of life, namely, to solve work issues, are shared among both genders; such is the desire to avoid low-paid occupations, to escape supervision, and to gain the opportunity and flexibility to coordinate family life and other social responsibilities with gaining income. The common ground for these motivations has been increasing in recent times with a trend toward more shared child-rearing practices and more joint responsibility for family life in modern societies. The increase in educational qualifications, professional skills, and labor force participation of women in general has promoted a reevaluation of the traditional distribution of family roles. However, while some women enter professional self-employment for similar reasons of career advancement as men, another group enters nonprofessional self-employment primarily to juggle family commitment and work hours. A 2005 Eurostat survey of entrepreneurs in 15 EU countries finds that much more women than men cite the ability to combine family life and childcare responsibilities with work as a motivation to start up their own business. Time-budget studies in developed countries show that women do work fewer hours in business and do more childcare and housework than men. In general, many women perceive their social and child-nurturing obligations as very important, so it is not a surprise that female entrepreneurs strongly identify flexible work hours as their most important incentive toward independent businesses. This is in contrast to male entrepreneurs who identify self-determination and the sense of success and achievement as their main drivers to enter entrepreneurship. Some studies suggest that women are less motivated by growth and profit than men and more by intrinsic goals such as personal fulfillment, flexibility, and autonomy. However, in the light of the aforementioned family obligations, at least the latter two goals can be interpreted as extrinsic motivation rather than intrinsic.

There is evidence showing a number of professional women shunning their corporate careers in favor of entrepreneurship. The "glass ceiling," flexibility, independence, control, and family are the most commonly cited reasons for why women become entrepreneurs.

A recent Dutch study finds that on average, women invest less time in business than men (Verheul et al. 2009). This can be attributed to both a lower preference for work time (driven by risk aversion and availability of other income) and a lower productivity per hour worked (due to lower endowments of human, social, and financial capital). Many young, well-educated, and financially well-off women choose part-time entrepreneurship today as the preferred option to pursue a career and professional development combined with family life while having young children. Sometimes, these women are referred to as "mumpreneurs." The necessity of earning a living is not the major issue here, but it is in most cases rather a lifestyle choice. Recent studies confirm this trend of increasing rates of married women with children in part-time entrepreneurship in their attempt to combine self-development and family life as a form of postfeminist entrepreneurship. The situation of part-time work might explain the lower success or performance rate of female entrepreneurial ventures than average compared with their male counterparts.

On the other hand, a number of studies point to job transition or reentry into the workforce following a layoff or voluntary leave as a major motivation for self-employment. The 2005 Eurostat Business Success Survey conducted in 15 EU countries finds that a much larger proportion of female than male respondents answer "to avoid unemployment" when describing their motivation for starting their own business. This supports the hypothesis that women more than men are pushed into entrepreneurial activities by changing economic environments and resulting lack of household income.

Research into the psychological characteristics of female entrepreneurs has led to a classification into three motivational types: the need achiever entrepreneur, the pragmatic entrepreneur, and the managerial entrepreneur. Need achievers have a high need for achievement, the managerial entrepreneurs have high self-attributed need for power and influence scores, and the pragmatic entrepreneurs are moderate on both motivations of achievement and power. Perhaps, the female situation differs from male characteristics within this framework because women seem to be less power hungry than men. Some Canadian studies suggest that running a small and stable business is the preferred modest practice among female entrepreneurs but not among male ones. Although, there is major support for a gendered somewhat general concept of entrepreneurship, recent empirical research sheds light on a wide range of perceptions and a variety of distinctions among female entrepreneurs.

Some studies argue that men and women perceive risk differently (Wagner 2007). However, evidence that female entrepreneurs have in general less appetite for risk taking compared with male entrepreneurs is inconclusive and sparse.

Preferred Industries and Environmental and Societal Factors

Female and male entrepreneurs start and run business in different industries, develop different products, and also have different goals. International studies in gendered entrepreneurship which concentrate more on environmental (macro) factors than on individual (micro) motivation stress that the chosen sector of activity is important in explaining differences in male and female entrepreneurship. Canadian studies find that "type of business" is a significant factor explaining gender differences among nascent entrepreneurs (Menzies et al. 2006; Pare and Therasme 2010). Moreover, women tend to be less likely to operate in high technology sectors, and they are much more predominant in the service sector (Verheul et al. 2006; Pare and Therasme 2010). In the USA, 69 % of women-owned firms were in the service sector. Other studies find that female entrepreneurs tend to concentrate on consumer-oriented sectors (Allen et al. 2008). However, there is also apparently a recent tendency for female entrepreneurs to move away from traditional female industries into male industries like manufacturing. Nonetheless, the overall situation appears to be that woman entrepreneurs still favor the service sector and in particular industries which do not require a high start-up capital. Therefore, female entrepreneurs are highly represented in areas such as sales, retail, and specialized care and catering services. This female industry concentration may explain the aforementioned gendered characteristics of smaller scale, more intense competition, and lower average returns.

Both male and female entrepreneurs choose normally industries and businesses for start-ups that are related to areas of former employment. Drawing on previous work, experience reduces the risk of failure and in most cases provides entrepreneurs with access to valuable networks. This practice, of course, reinforces the status quo concerning the choice of industries. For example, historically, there has been a concentration of females in clerical and administration jobs which normally require less-advanced qualifications but also restricted their potential income. Fewer women than men study business and technical subjects. Moreover, men are more likely than women to have had valuable previous work and business experience in industry and in managerial roles. It might explain why female entrepreneurs selected traditional "female" industries in the past and are still choosing them today, although other sectors might be more profitable and promising higher growth rates. The question, "What are the main reasons for these choices: societal pressure or traditional untested gender perceptions and roles?" remains unanswered. Research suggests that women are sometimes more influenced by external factors like family or community opinions than men. Societal norms vary around the globe and so can the geographical variances of female entrepreneurship and the difference in practices and performances.

Finance and Other Barriers/Problems for Female Entrepreneurs

Some studies focus on particular barriers faced by female entrepreneurs. Early research reports major obstacles for female entrepreneurs as problems with finance and credit and property regulations as well as lack of business and financial training. Today, these barriers seem to be more pronounced in developing countries in Africa and Asia and transition economies than in developed countries. Studies about women in these areas report more systematic difficulties with accessing finance than those conducted in North and South America and Europe. However, access to sufficient start-up capital for new ventures in the poorer regions of the world might not be entirely a gender issue; the reason for the capital shortage might be also a general deficiency in supply.

Lack of education, lack of business experience, and lower financial literacy leading to weaker loan applications and weaker credit rating scores are the proposed factors to the diminished equal opportunities of female entrepreneurs in the literature. Moreover, most firms led by women operate in the service sector. Since service sector firms are often very small, require little start-up funding, and tend to operate in volatile markets, all these factors may explain the reluctance of financial institutions to lend money. Evidence suggests that discrimination against women has diminished over the last 10 years and in many cases completely disappeared. However, females who perceive prejudice regardless if it is true or not will experience intrinsic limitations and may be less likely to ask for outside financing. This in turn will have an impact on the future growth of their businesses. Perceived discrimination can thus become a self-fulfilling prophesy. Another interesting obstacle has been identified as the physical appearance of the borrower, the less attractive and beautiful a female loan applicant is, the less likely she is going to get a loan approved.

The legal environment can also function as a barrier toward female entrepreneurship. If the legal framework discriminates against women as to freedom of ownership rights or asset transfers and adverse marital rules, this all can become a serious impediment toward doing business successfully. Even if the law explicitly does not require the husband's or father's signature to receive a loan for a female entrepreneur, in some countries, implicit social norms and differential treatment under the law can have similar deterring effects.

Overall, women seem to require much less funding and in particular lower loans to start up their businesses. While it is not clear if this is a result of institutional barriers concerning access to finance for females or due to gender differences in motivation, it definitely influences their choice of industry.

Policy Implications

In general, the literature suggests that improvements in the business environment can help promote high growth of female entrepreneurship. Women may have relatively less physical and "reputational" collateral than men, which might consecutively limit their access to finance. Therefore, public policies that circumvent the requirement of collateral and create alternatives to secure a loan can promote low-interest loans and small grants to females wishing to start up a business and might thus bridge the gap between genders. Assistance in terms of training programs in business skills and financial literacy and effective consulting services might also help aspiring female entrepreneurs. Interestingly, however, research into existing support programs indicates that there is no real gender difference. Male and female entrepreneurs seem to be virtually identical in terms of their needs for assistance. Females do not appear to need more assistance than males nor do they appear to require different types of assistance. The virtually identical ratings of service value among males and females also indicate that both genders are equally satisfied with the assistance received.

The strengthening of a legal framework unbiased toward gender and thus allowing females to operate under the same conditions as males would go a long way toward progress of female entrepreneurs in some countries.

There are of course also societal measures conducive to possibly improve the future development of female entrepreneurs. Some of these more general recommendations call for women to be encouraged to study fields other than liberal arts. Women need access to seminars on finance, management, marketing, etc. And finally, it is recommended that women seek assistance from experts, colleagues, and friends to establish formal and informal networks. Experienced female business owners emphasize that in order to further develop women's role in business, stereotypes concerning women as entrepreneurs need to be eliminated through public awareness workshops and more visible role models and that mentors for younger women are needed.

A Role Model from the Past

While Coco Chanel was arguably the most famous French self-made woman of the twentieth century, "Veuve" Barbe-Nicole Clicquot was certainly the most impressive female French entrepreneur of the nineteenth century (Mazzeo 2008). Widowed in her late twenties, in the middle of the Napoleonic Wars, without formal training and no experience, she had to take over a small struggling family vineyard from her husband and turned it into probably the most important champagne house of the nineteenth century. Madame Clicquot led the wine brokerage through several failed attempts to expand sales of her champagne to Britain and other parts of Europe and created an amazing vintage in 1811. Not only did she manage to protect this treasure in her cellars from looting by Russian occupying troops in her hometown Reims, but she also used the chance to introduce Russian officers to her sweeter, fortified champagne. As soon as the opportunity arose to export French wine to Russia in 1815, she seized it and shipped and sold her magic 1811 vintage ahead of all other competing vineyards with great success in St. Petersburg and Moscow. Because of this success, she is credited today for "internationalizing the champagne market" and "establishing brand identification." Moreover, Madame Clicquot invented and developed a process called in French *remuage sur pupitre* which is an efficient system of clearing champagne of the yeasty debris trapped in the bottle after secondary fermentation to create the bubbles. Even today, this procedure is indispensable to reduce wasting wine and does significantly increase the output of wine in numbers of bottles. Keeping it an industrial secret, this method helped her in gaining competitive advantage over her competitors for 20 years.

An Exemplary Case in the Present

In some instances, female founders of companies employ exclusively women to gain competitive advantage. The Japanese company Digimom presents an example for this. The motivation for such a practice was to tap into the underutilized female workforce in Japan. As the authors researching Digimom point out, one of the four most important success factors for the company is the right choice of industry (Futagami and Helms 2009), which is linked to an exclusively female workforce. The advantage is that Digimom's provision of IT services allows for flexible work from home. Such an option is much harder to offer in sectors other than the computer service industry.

Conclusion and Future Directions

It is interesting to note that women entrepreneurship is not a recent phenomenon, let us say, of the last century. In fact, the "champagner" story indicates that successful businesswomen can be found throughout history. The beginning of mainstream research into start-up ventures, clearly, centered on the entrepreneurial (in particular male) behavior traits. It was sought to understand what kind of prerequisites and characteristics the individuals had to have for entrepreneurial high achievement. Thus, classical entrepreneurial research produced evidence that featured decisiveness, aggressiveness, business acumen, and risk-taking behavior. The success in business, of course, was "male" and measured mainly through quantitative outputs and "hard" facts. During the last 20 years, research on female entrepreneurship developed, which questioned the necessity of male attributes for the female entrepreneur; thus, this new research branch moved away from the mainstream model of entrepreneurs to explore entrepreneurship with a gendered focus. It seems now widely accepted that female entrepreneurs are often different from their male counterparts. Women choose different industries and products than men and, in many cases, have different motivations and goals. Discrimination and differences in social roles might not be the only factors influencing these choices; females might have also a different attitude toward resources and the sustainable use of them. Current research into gendered entrepreneurship in developing economies, in particular, pertains to microfinance/microenterprise development and supports this notion.

What Should Be the Target of Future Research?

The developing field of gendered entrepreneurship needs a stronger theoretical base in order to mature. Integrative theoretical frameworks would provide better a base for scientific discussions. Currently, there is plenty of interesting empirical work, case studies, and other qualitative enquiries, such as narrative and interpretivist studies, being done, which increases our understanding of the issues and motivations of female entrepreneurs. However, a useful theoretical structure to integrate what we know so far is missing.

On the other hand, entrepreneurship scholars could explore more opportunities for interdisciplinarity in their work. Much is to be gained from inputs from other academic fields such as social sciences, gender and diversity, psychology, management, leadership, international business, international strategy, and so forth. Thus, multidisciplinary collaboration on female entrepreneurship should be pursued more often.

As the field matures, we might move away from looking mainly at negative aspects, the disadvantages, and barriers to female entrepreneurs in comparison to their male counterparts. It might pay to concentrate on the strong positive features of women entrepreneurs for future research.

In conclusion, future research should focus on the internationalization of female entrepreneurship, especially beyond the mainstream Anglo-Saxon context. The time is ripe for abandoning the rather ethnocentric stance that industrialized countries provide all the answers to successful (female) entrepreneurship. In order to achieve more sustainability and real action to tackle global poverty, research into female ethnic entrepreneurship might provide solutions. Many women entrepreneurs in developing economies are able to create successful ventures, albeit sometimes very modest ones, with little start-up capital and outside official financing. This fact should actually be celebrated as strength. Female entrepreneurs are obviously innovative and resourceful. And as resources diminish globally, the female entrepreneurial model might become extremely valuable in future.

Entrepreneurship and Finance

The entrepreneurship and the finance were considered for a long time as two different fields of research. The entrepreneurship is usually defined as the action of undertaking economic activities, through a specific organization, which aims at the creation of market value and which can also concern process of innovation as it involves, in a dynamic setting, creating/discovering new opportunities. The finance deals with matters related to raise monetary funds or capital through the issuance and sale of debt and/or equity. It is concerned with resource allocation as well as resource management, acquisition, and investment.

In a monetary economy, the entrepreneurship and the finance are two connected phenomena. Any entrepreneurship activity requires some financing because the processes of production, investment, and marketing need various sources of financing. The realization of entrepreneurs' projects and particularly the implementation of innovative plans are dependent on conditions of their financing.

Theoretical Grounds

As Joseph Alois Schumpeter stated in *The Theory of Economic Development* (1934/1961), the money markets are the headquarters of the capitalist system such that the money (the finance) is the entrance ticket into the market. In *Business Cycles* (1939), Schumpeter also stressed that economic action cannot be explained without taking account of money. Therefore, the financial constraint (i.e., conditions of obtaining adequate access to capital) is one of the major obstacles to starting and/or growing a business. Then there is a relationship between the financial market development and the entrepreneurship, and the financial disturbances appear to have a substantial negative effect on investors' willingness to finance innovative entrepreneurship (Lerner 2010).

Various ways of entrepreneurship financing can be analyzed according to the level of development of monetary and financial markets, such as the financial bootstrapping, the venture capital funding (risk capital), business angels, and bank credit and other financial-innovations-led loanable funds affecting the realization and the effectiveness of the business plan. The economic evolution depends on entrepreneurs' behavior, and the entrepreneurs' activity depends on the conditions of the financing of their expectations.

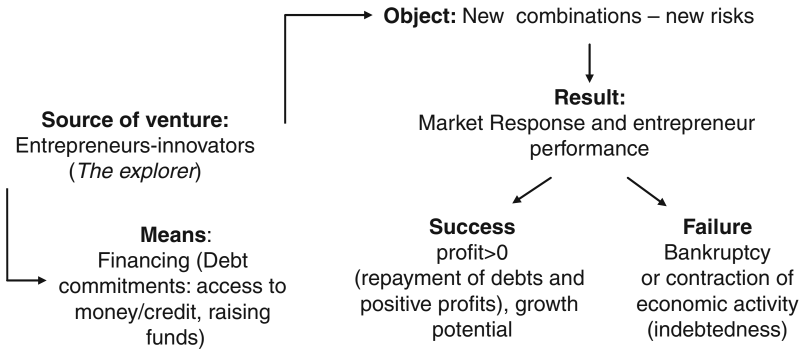
Schumpeter stresses that "*Economic action cannot (. . .) be explained without taking account of money*" (1939, p. 548). The monetary system's *modus operandi* is the first step of all economic propositions. Hence, the definition of the capitalist economy is a monetary one: "*capitalism is that form of private property economy in which innovations are carried out by means of borrowed money, which in general (. . .) implies credit creation*" (Schumpeter 1939, p. 223).

Hence, there is a very close interdependence between money/financial markets and economic evolution. Money markets are the *headquarters of the capitalist system* (Schumpeter 1934/1961, p. 126), where the settlement of plans for further development is decided. All kinds of economic projects are first brought into relation with one another and contend for their realization in it.

The entrepreneur-innovator, the *explorer*, cannot dispense with money. Dynamics enter the picture with the innovation decisions of entrepreneurs. To innovate means to change deeply the economic status quo (*the setting up of a new production function*, Schumpeter 1939, p. 87). The leading figure of the innovation is the entrepreneur who tries to design and execute new combinations. Innovation is the driving force of accumulation. But the sole presence of entrepreneurs is not sufficient to guarantee the system's evolution. In order to innovate by founding a new firm, constructing a new plant, and ordering new equipment from existing firms, entrepreneurs need means of financing.

In this respect, access to money is the power to command and to determine the level of economic activity, that is, the access to credit money. Credit money is the variable which authorizes an economic separation between entrepreneurs-innovators and other agents. The financing of enterprise has been assigned logical priority in the process of economic development since "this is the only case in which lending and the ad hoc creation of means of payment are crucial elements of an economic process the model of which would be logically incomplete without them" (Schumpeter 1939, p. 114). The innovator must have monetary funds before starting his dynamic activity (Fig. 1):

As stated in Ülgen (2003), Schumpeter (1939) maintained that the requisite fund is the entrance



Financing Entrepreneurship, Fig. 1 Entrepreneurship as a real and monetary change process

ticket to the social store of means of production. This fund is borrowed from a bank. Schumpeter (1934/1961) also emphasized that the individual can only become an entrepreneur by previously becoming a debtor. What he first wants is credit. Before he acquires commodities, he needs purchasing power. He is the typical debtor in capitalist society, "no one else is a debtor by the nature of his economic function" (Schumpeter 1934/1961, p. 103).

In the process of innovation, the rise of monetary needs and the rise of risk may dissuade some firms from engaging in innovative activities. The high costs of R&D imply some advantages for leader and R&D firms. Then the fate of new combinations is decided on money markets through daily price struggles between entrepreneurs and bankers/financial resource providers.

Entrepreneur and the Finance

Entrepreneurship

Entrepreneurship can be defined as an act of undertaking private/individual expectations-based projects. So the entrepreneur is a risk-taker who undertakes innovations with necessary finance and business acumen in an effort to transform things into economic values, which should be able to give further gains. This may result in new organizations or may be part of revitalizing existent organizations in response to a new opportunity. The most obvious form of entrepreneurship is that of starting new businesses (a start-up company). Entrepreneurship can also describe activities within a firm or organization including corporate venturing.

Usually, a more or less part of working people may have engaged in self-employment for several years depending on economic and cultural characteristics and habits of the country where they live. Participating in a new business creation seems to be a major driver of economic growth in advanced economies.

Many definitions for the notion of entrepreneur are available in economic literature. The most well-known scholar in this area is Schumpeter who stressed the role of innovations (new products, new production methods, new markets, new forms of organization, etc.). From this viewpoint, the entrepreneur can be identified as a person combining various production factors in an innovative way to generate value to the customer with the expectation that this value will exceed the cost of production, thus generating superior returns that result in the creation of profits. The entrepreneur needs monetary funds to start his activity or to expand an existing firm. She/he must borrow those funds from banks and/or from other financial investors who are called the lenders. For the lender, the objective is the ability to achieve capital gains.

Entrepreneurial activities can be of various kinds depending on the type of organization and creativity involved. Also various types of organizations exist to support entrepreneurs' financial needs as venture capital, angels, banks, business incubators, etc.

Internal Versus External Financing

In the financing process of entrepreneurial activities, different means and practices can be observed. While liquidity constraints in entrepreneurship present a persistent puzzle for enterprises and for theorists, the relevant way of financing a given project depends on the nature of the project itself as well as on the type and characteristics of the entrepreneur to be financed. Therefore, some stages of financing have to be noted in order to identify the nature of the project and the borrower. At the first stage, the issue is related to the starting of a new activity. Seed capital, personal resources, friends, family members, business angels, and small business investment companies (e.g., small industries development banks in developing countries) may intervene at this stage to provide the bulk of the funding. At the second stage, the financing through public equity and venture capital can be observed as the main financing tools. More developed enterprises can attract external financing for early-stage investments and then for later-stage investments. The third stage (later-stage) includes acquisition/buyout practices and also participation of venture capital companies. The presence of bank credit, especially in local financing (small firms, working continuously with the help of local banks) and in the financing of large firms, is also a common way of sustaining firms' economic activities. For successful entrepreneurs, the access to public markets through public offerings constitutes also a source of funding of new projects.

Internal Financing

The internal financing possibilities depend before all on the individual wealth of would-be entrepreneurs to cover required capital as regards the financing needs of a start-up company to invest in new projects as well as operating capital needs to finance everyday expenses. Entrepreneurs can tap friends and families to finance their businesses but they can also utilize credit cards to bootstrap their new venture.

A specific type of internal financing is the *sweat equity*. That refers to a partner's contribution to a project in the form of effort. Another type is the *financial equity* which is a contribution in the form of capital. Those forms are related to a partnership such that some parties may contribute to the firm through capital and others through sweat equity. For example, in a start-up company formed as a corporation, workers may receive stock or stock options and become part-owners of the firm. In return they can accept low wages below what they would demand in another context.

Financial bootstrapping is another way of dealing internally with the financing issue. That covers different methods for avoiding the use of external financial resources from banks and/or market investors. That is a collection of methods and ways of financing aiming to minimize the amount of outside debt and equity financing from banks and financial investors. The use of private credit card debt is the most known form of bootstrapping (see Rani and Rao 2008 for the Indian case), but a wide variety of ways can be imagined for entrepreneurs. While bootstrapping involves a risk for the founders, the absence of any other party gives the entrepreneurs more freedom to develop the company.

However, internal financing is not enough to realize all entrepreneurial activities. In many cases, internal resources are not sufficient to finance expected projects. Bringing in external financial institutions and investors can be beneficial not only for the collection of required capital but also for the acquisition of more professional knowledge, skill, and experience. Investors and banks are specialized in the analysis, accompaniment, and monitoring of productive activities. Outside lenders can provide financial oversight, accountability for carrying out tasks, valuable contact networks and experience to the project. They can remove financial obstacles by sustaining innovative and risky productive projects, but they can also erect financial barriers, and technical and strategic hurdles when they expect that new options are not able to generate higher profits through quick returns on investments (Ülgen 2007).

External Financing

The external financing of entrepreneurship can be allowed through different ways. The access of firms to different external financing obviously depends on the characteristics of firms and projects.

The bank credit is usually the dominant practice in firms financing in a market economy because banks control the major part of monetary and financial markets but also they are the headquarters of the capitalist economy as they can grant credit through credit money creation in response to entrepreneurs' needs of funding expansion strategies. Large firms which can easily access financial markets through equity financing must be accompanied by bank syndication credits to allow huge amounts of new capital required in acquisition operations.

Several types of conventional bank loans exist:

- Character loans are used when the entrepreneur does not have the assets to support a loan. The entrepreneur may need a loan based on her/his own personal financial position. This usually implies engaging personal assets of the entrepreneur.
- Installment loans: Available short-term funds are frequently used to cover working capital needs and help to have a track record of sales and profits.
- Straight commercial loans are used for seasonal businesses and to building up inventory. These funds are advanced to firms for 1–3 months.
- Long-term loans are frequently allowed for strong and mature companies. They can be available for up to 10 years.
- Lines of credit: For a given amount of credit allowed by banks to firms following the potential fund expected to be withdrawn by firms, firms pay interest on the portion that they use and they pay commitment fees up front to ensure that the rest of the fund will be available at their disposal.

Cosh et al. (2009), investigating the internal versus external financing decisions among several UK firms, identify factors leading firms to seek external finance. The evidence seems to point out that firms with higher capital expenditures and profits and firms with stronger growth objectives are much more likely to seek external finance. It also appears that the most important factors with regard to obtaining the desired level of bank finance is a firm's assets. Smaller firms without significant assets have difficulty obtaining bank finance and they try to obtain finance from private individuals. For instance, young innovative firms without enough assets or profits seek capital from venture capital funds.

Angel investor (synonyms: business angel, informal investor) is an individual who provides capital for a young start-up business, usually in exchange for convertible debt or ownership equity. As start-up companies projects are new ventures in an unknown future, some angel investors organize themselves into angel networks to share research and pool their investment capital in order to reduce risks. Angel capital fills the gap in start-up financing between friends and family who provide seed funding, and venture capital. It is usually difficult to raise huge amounts of money from friends and family. Also venture capital funds are not usually willing to fund low-investment projects. Angel investment plays then the role of financing for start-ups which cannot be financed through bootstrap finance or venture capital and bears extremely high risk in innovative projects. Because a large percentage of angel investments are lost completely when early-stage companies fail, professional angel investors seek investments with high returns (potential to return at least 10 or more times their original investment within 5 years).

In addition to angel investors and seed funding practices, *venture capital* is used by new young firms with limited experience that are not large enough to raise capital on financial markets and not considered to be able to secure a bank credit. A venture capitalist is a person or investment firm that makes venture investments, and these venture capitalists are expected to bring managerial and technical expertise as well as capital to new innovative projects. Venture capital is provided to early-stage, high-potential but high-risk start-up companies. The venture capital fund makes money by owning equity in the companies that it funds. These companies usually have a new business model in high-technology sectors (such as biotechnology, IT, etc.). The venture capital is a growth funding round investment as it occurs frequently after the initial seed funding of innovative entrepreneurship. Venture capital is a type of private equity. In exchange for the high risk that they assume by investing in smaller and new companies, venture capitalist usually gets significant control over firms' decisions and a significant portion of firms' ownership. Therefore, a core skill within venture capital is the ability to identify new technologies that have the potential to generate high commercial returns at an early stage by playing also a role in managing young enterprises at an early stage.

Informational Asymmetries and Uncertainty in the Innovation Process

Different ways of financing presented above underline some issues in the financing of innovative activities that new, nascent or young, and small entrepreneurs may be faced with. In this respect, two major issues can be presented following Mahagaonkar (2010).

The first one is well studied in the economic theory in more general terms through the analysis of imperfect markets and information asymmetries (Leland and Pyle 1977). These asymmetries are between banks/financial investors and entrepreneurs who need funds to realize new plans. Asymmetries arise when the firm has better information about the characteristics of its investment (degree of the risk, relevance of expected returns, etc.) than do capital providers. When economic agents involved in economic transactions act with less than perfect information and cannot foresee all the future possibilities and cannot monitor others' decisions and behavior, their rationality is limited (bounded rationality).

In this regard, the relation between a fund provider, the bank or a financial investor, and an entrepreneur who asks for the financing of her/his new project is an agency relation. That is a mandating or delegated relation between two or more agents in which the lender, called the principal, delegates a decision power to the borrower, called the agent. This later has to accomplish a task, undertaking a specific activity, on behalf of the lender as the lender grant money to the entrepreneur. The final profit of the lender depends on the action or decision of the borrower. In such an environment where the bounded rationality holds, the problem arises because all relevant and required information is impossible or costly to acquire and to process. That can provoke agency costs involved in monitoring the behavior of the borrower. These costs are mainly due to the existence of opportunistic behavior as the moral hazard and the adverse-selection.

The case of *moral hazard* is a problem of imperfect information or a form of ex post opportunism. The lender cannot observe the effective action of the borrower or she/he cannot know if this action is appropriate or not regarding the circumstances. Then, the contract between these two parties is imperfect and may generate additional costs for the lender. Moral hazard in innovation investing arises also because of the separation of ownership and management in modern firms. When the objectives of the parties are in conflict, investment strategies cannot be share-value maximizing. Such an ambiguity in the firm's decision and strategies can lead to an unwillingness of finance providers to fund entrepreneurs (Rampini 2004).

The *adverse-selection* is a problem of incomplete information or a form of ex ante opportunism in which one party (e.g., the borrower) does not reveal her/his private information on her/his intrinsic characteristics (quality, ability, etc.) or on the project that s/he wants to fund through credit at the time of negotiation. This reduces the benefits of the other party (the lender) who must suffer additional contractual costs. When there are several types of agents in the market, the quality-individuals must send some informative signals in order to show their true quality and allow the buyers to purchase their products or services. On the contrary, the market adverse-selects and the quality-individuals exit the market lenders trying to charge higher returns or interest rates according to higher risks they perceive. It is likely that information asymmetries are higher for nascent entrepreneurs who do not have any established track record. The case of start-ups and young innovative firms obviously belongs to this category of issue and constitutes financial barriers to entrepreneurship. Then, the risk-premium for innovative projects will be higher than that for ordinary investment because investors have more difficulty to distinguish between good and bad projects. The lack of experience and historical record, but also the little size and low guarantees that new or young firms can offer to banks and financiers make that the funding of new activities or projects suffers problems of adverse-selection.

The second factor is the fundamental uncertainty inherent in entrepreneurial innovations. New products, processes, organizations, etc., are intrinsically uncertain in their potential economic value. Therefore the entrepreneurship, which can be defined as the process of undertaking new and risky activities, may become discouraged because of difficulties of obtaining required financing related to uncertainty. This problem exists for all firms per se. But in the case of innovative activities, potential investors are more careful and may require further collateral to cover their commitments (Ülgen 2007).

Public Support for Innovation-Based Entrepreneurship Financing

In view of various financial hurdles impeding entrepreneurial innovations, there is increasing public support for the entrepreneurship financing. International and intergovernmental institutions, such as the OECD, implement different policy measures to simplify and streamline procedures in the existing support programs to make information and rules more accessible with respect to enterprise access to funding. These programs aim to frame and implement new ways to improve the role of banks and financial institutions for local entrepreneurship development, to strengthen the existing schemes of venture capital in favor of new and growing small and medium businesses (SMEs), to boost the number of business angels, and to seek their involvement as counselors to young enterprises.

In this aim, the *Competitiveness and Innovation Framework Programme 2007–2013* (CIP), which is a part of the *Entrepreneurship and Innovation Programme* of the European Union, allocates over 1.1 billion euro to enable financial institutions to provide about 30 billion euro of new finance for up to 400, 000 SMEs in Europe. This allocation addresses SMEs' needs for financing at various stages of development through the European Investment Fund and selected financial institutions. For venture capital, the program finances early and expansion stage of specialized sectors (e.g., eco-innovation). The program also provides financial guarantees by establishing risk-sharing arrangements with financial institutions that fund directly SMEs. Five hundred and fifty million euros constitute the *High Growth and Innovative SME Facility* (GIF1 and GIF2, seed and start-up investments and expansion stage), while 506 million is allocated to SME Guarantee Facility (SMEG). The latter provides guarantees to lead banks and other financial intermediaries to make more debt finance available to SMEs by reducing their exposure to risk, as an important part of the SMEs' difficulties in accessing finance is due to the perceived higher risk or to the lack of required collateral (see information on asymmetries, lack of capital, etc. above). SMEG provides loan guarantees for microcredit to microenterprises up to 9 employees; equity guarantees for seed capital, mezzanine financing, and risk-capital operations to support businesses up to 249 employees; and securitization structures to assist financial intermediaries in mobilizing debt finance for SMEs.

Obviously, the financing conditions of the entrepreneurship in an economy are related to the structure of the financial markets and banking system development. When markets and banks are usually intervening in new activities and projects, the formation of a technical and financial know-how can facilitate the funding of entrepreneurs' venture. But the evolution of financial markets can also harm the financing conditions of the enterprises when the monetary and financial system becomes more oriented through short-term speculative investments and less involved in the financing of productive activities.

Financial Development and Entrepreneurial Dynamics

Links Between Finance, Growth, and Innovations

The creative destruction process occurs also in the field of finance as new ways of financing and speculating may come into the picture when banks are considered not only as intermediaries between entrepreneurs and capitalists but also as innovators on money markets.

Schumpeter argued that the services provided by financial intermediaries (mobilizing savings, evaluating projects, managing risks, facilitating transactions) are essential for technological innovation and economic development as a monetary complement of the growth process. Recent works on the link between financial intermediaries and economic development show a renewal of interest for this Schumpeterian vision. King and Levine (1993) stated that Schumpeter might have been right about the importance of finance for economic development as financial services would stimulate economic growth by increasing the rate of capital accumulation and by improving the allocation efficiency of markets. King and Levine argue that the financial system can promote economic growth: "The link between growth and financial development is not just a contemporaneous association. Finance does not only follow growth; finance seems importantly to lead economic growth" (1993, p. 730).

Also Bencivenga and Smith (1991) model the effect that intermediaries can have on an economy's growth rate by encouraging a switch in savings from unproductive liquid assets to productive illiquid ones. If agents face some probability that investments will have to be liquidated at an inopportune time, they must self-insure against random liquidity needs and they invest in unproductive liquid assets. Because of long delays between investment expenditures and receipts of profits from capital, capital investors may face unpredictable liquidity needs, leading to delays in further investment or to liquidation of investment already undertaken.

Financial intermediation can promote growth because it allows a higher rate of return to be earned on capital, and growth in turn provides the means to implement costly financial structures. Saint-Paul (1992) emphasizes the role of financial markets in channeling savings toward investment and the fact that financial intermediaries are able to solve informational problems that would otherwise lead to inefficient outcomes. The best management of risk reduction and the liquidity services of financial intermediaries lead the economy to orient savings to long-term financial investment. Financial intermediaries tend to alter the composition of savings in a way that is favorable to capital accumulation because the banks are assumed to permit risk-averse savers to hold bank deposits rather than liquid unproductive assets. Therefore, funds that banks obtain on markets become available for investment in productive capital. Financial institutions play then a crucial role in the microeconomic resources allocation process thereby affecting the economic performance of firms. This is true when we take into account technological innovations because of the fact that technological change means new uncertainty.

Financial Development

These results underline the importance of the development of financial markets in the growth process. Kerr and Nanda (2009) present a comprehensive analysis on the links between the role entrepreneurship plays in the economic growth of a country through its financial market development. The financial development (*financial deepening*) is usually defined through the *breadth* (broad markets with wide transactions, numerous actors), the *depth* (deep markets with wide range of products), and the *liquidity* (liquid markets without restriction on financial transactions) of financial markets. It is assumed to spur growth through either a supply-push (increasing and improving availability of finance for the real economy) or a demand-pull process (demand for new financial products). The financial development is usually related to the liberalization process.

Following the way paved by Goldsmith, McKinnon, and Shaw in the 1960s/1970s, numerous works (see Levine (2005) for a literature review) assert that liberalized finance would improve the competitive incentives leading to innovations and then allowing banks to provide more efficient financial services (e.g., risk management, information acquisition, and monitoring). It is also assumed that the more competition and opened markets would foster growth and improve economic stability, at least at the long run. In this vein, deregulation policies have been implemented since the late 1970s, which provoked expansion of financial markets and modification of financing practices. With the extent of structural changes in financial markets, regulatory and technological barriers among different types of intermediaries have tumbled, while new financial instruments and usages have proliferated. Such an improved financial environment would support the Schumpeterian vision of creative destruction process by which innovations replace old methods and goods with better process, commodities, and services. As a result, financial intermediaries would make possible technological innovation and economic development.

Banks' innovations change the economic conditions as much as the entrepreneurial innovations. They affect the functioning of economic engine because they modify the monetary and financial conditions on which the whole economic structure is founded. Most of the recent monetary and financial innovations seem to increase the elasticity of finance. However, in view of the current financial disequilibria faced by numerous economies in the world, such financial innovation dynamics present a real challenge as regards the systemic stability.

New Financial Environment and Market Dynamics

Innovative dynamics of financial markets enlarge the operations of securitization that allow lenders and borrowers to match different types of availabilities with different types of needs to finance various economic activities. At the same time, growing interdependencies among financial institutions but also among individual lenders and borrowers generate high sensitivity of finance-related real activities as regards the sudden reversal of market expectations and opinions about the soundness of previous positions. The boundaries between the assumed positive outcome of financial innovations for the economic development (creative destruction) and their instability-generating sensitivity to ex post-observed disequilibria are very ambiguous and do not seem to be "panic-proof." Accumulated fragilities may come from unfettered and ill-framed financial liberalization that leads financial institutions to implement innovations which reveal to be detrimental to the sustainability of debt-financing economic development. Therefore, the financial development casts doubt on the creative nature of innovations and implies new macro-prudential regulatory rules in order to direct financial markets' innovative dynamics toward more productive economic activities beyond the short-sighted speculative transactions.

Impacts of Financial Turmoil on Entrepreneurship Financing

The ongoing economic crisis, officially announced at the end of 2007, seems to be continuous in spite of prompt and massive interventions of monetary and public authorities all around the world. Governments stepped in with several hundred billion dollars bail-out plans in hopes of saving financial system on the edge of global disaster and of riding out recession. Consequences of such a turmoil are more than anecdotal and point to the crucial importance of financing conditions on the entrepreneurship dynamics of economic expansion. As stated by Lerner (2010), in USA, venture capital investment dropped 30% in the fourth quarter of 2008 to its lowest level since 2005. Also, start-ups lay off full-time employees and cut projects in the hope of reducing their costs and exposure to the effects of the crisis, while investors and banks are retreating from new commitments and investing into the existing portfolio companies rather than in new generation start-ups. Some investors can also renege on previous commitments what stops suddenly the funding of young enterprises, leading them frequently to file for bankruptcy.

Innovation projects are risky, unpredictable, multistage, and usually long-term. They tend to be idiosyncratic and difficult to compare with other projects which could give investors some benchmarks to evaluate the return potential of projects. Therefore, during periods of crisis, these characteristics make difficulties worse for the financial support of innovative entrepreneurs. Entrepreneurial innovations are a part of the long-run growth process as they can drive booms, and downturns and changes in the conditions of their financing determine the effective path of economic development.

Conclusion and Future Directions

In an entrepreneurial market economy, every economic activity needs specific financing in order to be effectively realized. Entrepreneurship and financing mechanisms/tools are two related parts of the economy. The entrepreneur needs finance to fund her/his plans and innovation projects (founded on private expectations aiming at obtaining positive and high profits), and the financial funds and banks (money funders) have to find entrepreneurs to whom they could grant credit in order to realize profits from their own activities. In such an economy, economic development mainly comes from innovative projects which allow people to produce more and better products (goods and services). Innovations are related to industrial novelties as well as to new financial techniques, products, and processes.

Different situations can exist depending on the characteristics of entrepreneurs and specificities of projects to be financed as there may be different ways of financing and various financial institutions and techniques. New, young, and small enterprises, locomotives of change in immature and unconcentrated sectors, have specific needs of financing that large and mature firms, major sources of change in concentrated and worldwide global sectors, do not have (CPI). These latter's need of financing is usually satisfied on financial markets and by bank consortiums.

That is why it seems that finance and entrepreneurship, or in more specific terms, financing entrepreneurship is a research (and also economic policy) area where the issues are many and related to the functioning of a capitalist economy. In the capitalist economy, entrepreneurs are the real sources of economic dynamics, while banks and financial institutions and resources are the monetary dynamics of economic change. Changes in the conditions of financing of entrepreneurship affect, therefore, the path of economic development.

Hence, searching for relevant economic policies aiming at creating and implementing incentives to innovate in entrepreneurship and in financing mechanisms of productive activities through a consistent macroeconomic framework able to reinforce the systemic stability against financial markets disequilibria is one of the major issues that analysts and policy makers have to deal with. The economic action cannot be understood without taking account of monetary and financial conditions under which the entrepreneurship can or not be fully conceived as a source of continuous positive economic evolution.

Corporate finance; Entrepreneurial finance; Innovation policy

Introduction

Innovation is the creation of better or more effective products, processes, and services and often associated with technological activities. At the level of firms (or other organizations) innovation activities are highly uncertain and require the commitment of resources. *Incentives* to invest and the *ability* to commit (or raise) the necessary funds are central.

Incentives to Finance Innovation

The *limited appropriability* of the returns of innovation activities implies that private returns often fall short of the social returns to innovation. This leads to a potential underinvestment in innovation. This problem is independent of the firm's actual financing capacity. It originates in the limited salability of new ideas. Since knowledge can remain in circulation no matter how many people use it, it tends to produce high social returns. In turn, the private returns of an innovation often fall short because of the difficulty to enforce any payment once the new knowledge has been disclosed. As a consequence, innovative firms face the dilemma that they might be unable to communicate the value of a new idea to a potential buyer without disclosing the idea itself, which in turn implies that a potential buyer may no longer be willing to pay for it (Arrow 1962).

In practice, innovative firms try to limit the problem of lacking appropriability by deliberately managing their knowledge flows. Geroski (1995) lists a number of strategic options for individual enterprises, among them intellectual property rights, secrecy, lead-time, and embodied knowledge ("sell products, not ideas"). Depending on the particular technology and market characteristics, some strategies will be more effective than others, but overall, an innovative firm cannot expect to fully prevent the unpaid diffusion of new knowledge, and the more distant the research is to the market, the more difficult it becomes, to fully appropriate the returns. As a consequence, the private incentives to finance innovation tend to be lower than what would be desirable for the society at large. Thus, limited appropriability is a primary rationale to government policies in the pre-competitive research.

Financing Gaps

Imperfections in capital markets are a second cause of underinvestment in innovation. In the hypothetical state of perfect capital markets, all projects are funded according to their own merit, and firm-specific financial factors, such as its equity ratio or the availability of collateral, can have an impact only on the terms of the contract but not the financing decision itself. Riskier projects simply call for higher rates of interest. In practice, however, interest rates are rarely used to discriminate between projects, and firms without sufficient collateral face credit constraints.

The financing constraints result from asymmetric information in the financial market. In particular, there are two problems of asymmetric information between the entrepreneur and the investor. *Adverse selection* is the problem of identifying the true quality of a project. If the entrepreneur cannot provide a credible commitment, the investor denies credit rather than raising the interest rate. The reason is that the latter would attract the riskier projects. In the case of *moral hazard*, entrepreneurs may alter their behavior at the cost of the investor after the funding decision. For example, they may reduce effort, or become less prudent to avoid the risk of a default. Investors can mitigate information asymmetries by means of expensive screening and continuous monitoring. But when the implied costs are too high, they must deny financing even though the project may again have been desirable for the society at large. The problem of asymmetric information is especially high for new technology-based firms that require large sums of money in order to make their innovation projects market-ready.

The Financing of Innovation and the Valley of Death

Many innovation projects are abandoned before the idea is developed into a marketable product. This failure is sometimes called the "valley of death" (Osawa and Miyazaki 2006) and is generally observed for large firms but presents a much larger problem for technology-based entrepreneurial firms. Large established enterprises are able to set up a portfolio of innovation projects, but more importantly they are able to finance their innovation projects with their cash-flow. Pecking order theory (Myers and Majluf 1984) predicts that taxes and asymmetric information lead to a pecking order of financing of investment and innovation projects. Own cash-flow is preferred to debt finance and debt finance in turn to equity finance. Transaction cost theory links the investment project with the form of finance and predicts that projects that are riskier and specific to the firm should be financed by own cash-flow or equity (Williamson 1987), and only low-risk projects should be financed by bank credit. These theories predict that the financing constraints of technology-oriented entrepreneurial firms are related primarily to an equity gap, as those firms have neither a large cash-flow nor enough collateral to be attractive for bank finance. Moreover, the access to the capital market (equity and bonds) is generally restricted to large and established firms (Hall 2009). Thus, the disadvantage of being small and new weighs even more in the case of financing *innovation* (Carpenter and Petersen 2002).

New Technology-Based Firms (NTBFs)

In response to this, financial institutions have evolved in order to deal with problems of asymmetric information. Specialized financial intermediaries and specialized financial instruments have developed that allow to provide the required finance to new technology firms.

By the complex nature of most innovation projects, screening and monitoring is very costly and requires expensive expert knowledge, while entrepreneurs are more reluctant to disclose information due to its fear of imitators.

To summarize, internal sources from own cash-flow are the dominant source of financing innovation for most established businesses. But the importance of external sources rises significantly for new technology-based firms (NTBFs) with high growth opportunities. Over time, also these innovative firms can reduce the financing constraints by building-up steadier and stronger cash-flows and reputation. Consequently, there is a "financing gap" that affects only a limited number of firms, but precisely those with the highest potential to foster radical innovations (Peneder 2012).

Business Angels and Venture Capital

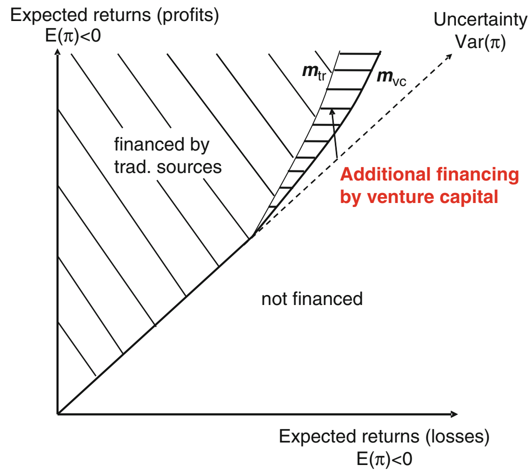
Among the specialized institutions that finance new technology-based firms (NTBFs) are business angels or venture capital firms and corporate venture capital (Gompers and Lerner 1999). Since these are discussed at more detail in separate entries the focus of this section will be on their joint characteristics with respect to the financing of NTBFs.

Business angels and venture capital associate with three economic functions that render them particularly important for innovation: First of all, as active investors and in addition to capital they contribute managerial experience, access to informal networks and professional business models, which is quite different from other financing sources and establishes a genuine *value adding function*. Second, both also serve a specific *selection function*, which involves the allocation of financial resources to the most profitable uses under conditions of high uncertainty and asymmetric information and which is characteristic of innovation projects. Finally and foremost, when bridging the aforementioned financing gaps and providing funds to businesses which otherwise would not have access to sufficient financing through traditional sources of capital, they serve a specific *financing function*.

They achieve these functions by virtue of their specialized business model, which encompasses a careful screening and subsequent monitoring of projects as well as the active participation in the development of a company, all of which mitigate the problems of asymmetric information. For the purpose of NTBFs, two characteristics are particularly notable. First, the investments are of limited duration. Second, dividends are not expected during the investment period, since investors aim to earn their profit on rising company values. Consequently, current cash-flow can be reinvested in the further build-up and expansion of the business.

Figure 1 provides a stylized presentation of the specific financing function. The diagram is plotted on two independent axes: the expected profits E(π) and the degree of uncertainty Var(π). The figure describes the expected profits and accompanying uncertainty of the project's success in the form of its variance. By means of bisecting all angles, the independent dimension Var(π) is drawn along a 45° degree diagonal line. The vertical axis depicts financing projects with a positive value of expected profits, and the horizontal axis depicts projects with expected losses.

In the ideal case of perfect markets without information problems, the amount of financially feasible projects for risk-neutral capital investors is determined through the expected profits and therefore, independent of the extent of uncertainty. All projects above the diagonal line will be financed, all others will not receive financing because their expected returns are equal to or less than zero. In imperfect markets with asymmetric



Financing Innovation, Fig. 1 Business angels and venture capital (Source: Peneder 2010)

information, additional costs *m* are generated through the need for more elaborate selection and monitoring processes in order to mitigate problems of adverse selection and moral hazard. The boundary of financially feasible projects moves upward and away from the diagonal by the distance *m*. The *financing gap* arises, as certain projects are no longer considered financially feasible due to increased monitoring, advising, and control costs. Given such a situation, business angels or venture capital funds take advantage of their role as specialized finance intermediaries. As a result of their diligent project screening and monitoring, as well as their accompanying advisory services, they shift the boundary of financially feasible projects outward.

Due to specialization advantages, the marginal costs of overcoming problems of asymmetric information are lower for projects financed by business angels or venture capital (m_{VC}) than for those using traditional financing instruments (m_{tr}). The additional costs for screening, monitoring, and advising m_{VC} are the price to be paid for overcoming principal-agent problems and thus, securing financing for projects with a high degree of uncertainty and informational asymmetries. In short, business angels and venture capital enable the pursuit of new financing opportunities and increase the number of feasible projects, thereby reducing the financing gap.

Policy

External effects (spillovers) and asymmetric information constitute two standard cases of market failure. But it is important to understand that market failures do not automatically call for policy intervention. The cost and the unintended consequences of policy actions need also be taken into account. Besides that, both *rationales* are quite distinct and relate to different policy targets and consequently different instruments (Peneder 2008).

Regarding the first rationale of distorted incentives to pursue innovative activities, policy *aims* to change the relative cost or returns of innovation. Regarding the second rationale of financing constraints, policy aims to bridge the gap in access to external funds. But the distinction between the two rationales is also important in setting the appropriate policy *targets*. Regarding the first rationale, public support is awarded primarily on the merits of a particular project or technology and not of the firm. In contrast, the second rationale of lacking access to financing calls for policies that specifically target a certain type of enterprises, such as the NTBFs. Finally, the two rationales call for different policy *instruments*. When compensating for positive spillovers and thereby raising the incentives to invest according to the first rationale, the menu of policies used by different countries to different degrees is typically comprised of *fiscal incentives* (i.e., tax credits and allowances, or rebates on wage taxes and social security contributions of R&D related personnel), the funding of pre-competitive (basic) research and the use of *direct funding* instruments, such as grants or soft loans. In contrast, typical policies that address the lack of access to external sources of finance according to the second rationale are soft loans, public guarantees, and/or public equity schemes.

The support schemes need much care in design to avoid the crowding out of private investors, such as business angels and venture capital. Otherwise policy does not only waste public resources, but can also inhibit the development of a mature and self-supporting ecology of private investors. Thus, public support should, therefore, focus on the most persistent gaps in early stage investments, particularly in the seed phase, when private investors are especially reluctant to enter. The use of soft loans needs to be made complementary to the private market. Public support should concentrate on the support of pre-competitive research and not aim at selecting single firms. Public guarantee instruments need to be applied with caution, since they may cause their own moral hazard with respect to the entrepreneur's risk behavior. Beneficiaries, therefore, should always have to carry part of the risk and pay an appropriate risk premium.

Conclusions and Future Directions

To support effective and evidence-based policies directed at the financing of innovation, much more research is needed in future on the impacts of the various instruments. While program evaluations are often called for, few of them have the opportunity to apply rigorous tests proposed in the literature on program evaluation. This is often related to the lack of access to individual firm data and counterfactual observations of enterprises not supported by the particular schemes and to the incomplete knowledge about the systemic aspects of financing innovation within specific institutional settings.

Insolvency as a Crucial Economic Phenomenon

Research on entrepreneurship use to insist upon business creation, firm growth, and market expansion which are then the shining side of economic activity (see the entry "▶ Entrepreneurship Policies"). However, a dark side of entrepreneurial ventures exists as risk becomes effective and causes the failure of the firm. Exit is generally considered a sign of failure of the firm, a consequence of poor performance: firms that underperform as they compete in the market will, sooner or later, exit the market. This process is worth knowing better at least for two main reasons. Firstly, the Schumpeterian concept of creative destruction which describes the process of transformation that accompanies radical innovation supposes the replacement of established companies by new entrants involves by the fact the exit of a certain amount of existing firms. Besides this renewal of productive system it ensures, exit can also have a positive value since individuals who have closed down the company they owned or managed in the previous year are more likely to engage successfully in a future entrepreneurial activity. Secondly, despite the efforts and measures adopted by the states, the rate of exit of new entrants barely decreases below 50 % before their fifth birthday, and the global rate of corporate bankruptcy demonstrates a rare stickiness except when the law changes. It is then essential to determine a pattern of failure and exit in accordance with these theoretical and factual dimensions.

The problems most scholars and practitioners face whenever it is a question to define, understand, or prevent firm failure start with the definition of insolvency and the differentiation with bankruptcy. However, the definition of a border line which separates going concerns from defaulting company is not the final purpose of research dealing with insolvency. Instead, an abundant literature is devoted to the identification of determinants of default or failure, thanks to the identification of discriminant functions that are able to discriminate between healthy companies and firms that are likely to fail in a near future.

Most of this research aims to identify the items of the balance sheet or the profit and loss account that are able to reflect the distress of the firm. However, focusing on the predictive signal of insolvency, this literature mainly deals with the symptoms of default and not with the causes. That is why a growing number of works goes one step beyond the question of expectation to study the causes of exit in order to prevent failure. The remaining portion of this entry is organized as follows. Section "Defining Business Failure" considers the variety of definitions of insolvency and puts some order in differentiating default, insolvency, and bankruptcy; Section "A Large Variety of Causes of Insolvency" presents the literature dealing with the prediction of insolvency looking at its more visible manifestations, whereas Section "Forecasting and Estimation of the Probability of Failure" insists upon the efficient causes or primary sources of failure which have more to do with the productive combination and the market positioning of the company than with the financial and accounting ratios.

Defining Business Failure

The attribution of success and/or failure to small firms is complex, dynamic, and problematic. Despite an abundant literature devoted to firm default, it still does not exist as unique and broadly accepted. Broadly speaking, insolvency is defined as an incapacity to pay debts upon the date when they become due in the ordinary course of business. This definition permits to make a distinction between healthy companies as they respect their contractual commitments and distresses companies which are just about to file for a petition. Such a definition has however a drawback. It tends indeed to create a confusion between insolvency and default mainly seen as the nonrepayment of a debt by the literature devoted to the functioning of credit market. The word "insolvency" refers then primarily to a corporate reality which is not so simple to define as far as one is concerned in differentiating defaulting firms from going concerns.

However, establishing a clear dividing line between the two previous kinds of companies is a key challenge in the proposal of a typology of companies according to their degree of robustness. It is all the more important that such a distinction is mandatory for bank in accordance with Basle 2, and coming Basel 3, principles and that an increasing number of research aims to propose an empirical analysis of distressed firms. To cope with these goals, two polar definitions of insolvency are currently used in economics; the first one is economic whereas the second one refers to judicial rules.

The Economic Conception of Insolvency

According to the advocates of the economic conception, insolvency is defined as a set of situations of failure such as the nonrepayment of a debt, the inability to pay dividends to the shareholders, the financial distress, etc. which can lead, or not, to the beginning of a judicial proceeding. In such an approach, the suspension of a company is then conceived like the result of a progressive process. It is characterized by the fact that, during all this process, the company is unable to fulfill in a regular way the commitment toward its various partners. Indeed, the problems which a company can encounter must be analyzed as a continuous and cumulative process: The failure starts with small difficulties which are gradually transformed into more serious problems. Some works, following Beaver (1966), thus tried to propose models in which the nonpayment is used like the signal of the failure of the company. Because of the low level of correct classification provided by this fuzzy definition, the term "default" is no longer used to empirically illustrate the concept of failure.

In order to escape the blind alley resulting from the strict assimilation between insolvency and default, some authors have considered other events. A company is then considered as insolvent if it is no longer able to meet its economic, financial, and social objectives on a regular basis. Some go even further by considering that firms enter in periods of decline when they fail to anticipate, recognize, neutralize, or adapt to external and internal pressures that threaten their long-term survival. The separation between the failing companies and the others based on different performance criteria is proposed by Platt and Platt (2002). They draw a line between going concerns and distressed firms having experienced either several years of losses or decreases in the distribution of dividends or a major restructuring. Beaver (1966) is representative of this approach and defines the failure as the result of the inability of a company to meet its commitments once they have reached maturity. The results are quite poor however and become even worse when the purpose is to discriminate between profitable firms and nonprofitable ones because no function properly separates the two classes. More recently, this approach has also been adopted by Bose and Pal (2006) who obtained prediction rates ranging between 65 % and 75 % in their attempt to separate companies a priori considered as financially healthy from those which are not.

The problems encountered in testing the different border lines between viable firms and those that are going to fail come from the fact that the separation between these two situations is both porous and blurred. That is why numerous studies agree that the cessation of payments is the final step of a process, sometimes called "a spiral of failure," from which a firm can escape, thanks to the adoption of corrective and preventive measures consisting in a modification of its operating cycle.

The Managerial Perspective

The second set of papers considers failure from a legal point of view. It is then defined on the basis of judicial criteria introduced in the insolvency law enacted in a given country at a given period. Most legal rules considered a firm as bankrupt when the judge decides it is not able to make its repayments when the claims fall due (Cabrillo and Depoorter (1999)). Insolvent companies always conform to this mix of legal and accounting logic. At each stage of the judicial process, accounting considerations are introduced to strengthen the rationality of the decision made by the judges. Indeed, the proceeding always begins with a cessation of payments and ends up with a liquidation or continuation plans. To fix a point of time to signal the transition from a reliable and sound company to a failing one, many scholars consider that the failure occurs from the moment a company presents to the courts the legal documents required for its liquidation or reorganization. The failure is then assimilated to the entry in the insolvency proceedings.

Although the meaning and nature of the proceeding may differ, the arrival in a commercial court which registers the cessation of payments gives a simple criterion to "objectively" separate two classes of firms: those that are governed in accordance with the rules of collective proceedings and those which are still operating in an economic world dominated by the respect of contractual commitments. As in the previous set of papers, the robustness of this conception rests upon the binary choice provided by the judicial perspective: Either the company is sound or it is insolvent. The judicial definition of insolvency has given rise to much research of which this entry provide only a brief glance.

Proposing an empirical analysis to check out the differences between legally insolvent firms and those only reporting financial difficulties, Agarwal et al. (2001) determine a performing function whose exact classification rates are above 93 % for both groups. It appears that models relying on a legal definition and separation of businesses into two classes lead to more reliable results than the ones based upon financial performance levels. Different reasons explain this superiority. Firstly, the differences between failing and viable firms are clearer as one is closer to the cessation of payments. Secondly, the transition between an economic order, dominated by commitments and contracts on one hand, and a judicial universe in which pure market logic is supplanted by a legal order on the other is clearer than an assessment based on corporate performance. Therefore, in the legal order, the sequence is structured by a threefold stage. Firstly, it consists in the statement of cessation of payment. Secondly, it is followed by an arbitrage between direct liquidation and rescue which depends on the particular situation of the insolvent firm and the context in which the decision is made. Thirdly, the validity of this decision is known later if the rescued firm effectively survives.

A Large Variety of Causes of Insolvency

Various studies have endeavored to identify the causes of corporate bankruptcy which can be as numerous and complex than factors leading growth (Entry "▶ Entrepreneurship and Business Growth" in this opus). They succeed in identifying the profile of a vulnerable enterprise whose probability to go bankrupt is higher than the "normal" risk of failure. Everybody agrees that weak firms are naturally predisposed to go bust. The stake is then to isolate some ratios or indicators that give an accurate representation of the firm fragility. Different families of causes of insolvency may be then compounded according to the facet of the company they concern. An exhaustive presentation is available in Caves (1998) which provides a review of prior literature.

Size, Age, and Activity

The analysis of the possible causes of insolvency began with the introduction of firm size, following the Gibrat's law often considered in models of firm growth. Most of the researchers agree upon the fact that the smaller the firm size, the greater the chance for the firm to go bankrupt, and, as a complementary rule, one may consider that the probability of a firm to go bust decreases with its size. The same relationship prevails with age as the smaller firms are the more likely to be the younger too. Most of the time, these structural variables capture information contained in firms' specific characteristics. Young failures can be attributable to inadequate resources and capabilities (relative to initial endowments). Older failures should be attributable to a mismatch between resources and capabilities and the demands of the competitive environment. These internal processes will manifest themselves in vulnerable business models which fail to generate positive cash flow. The strength of the relationship varies with the context and, mainly, with the business climate in the industry. A nonnegligible part of research proposes then models in which mortality dynamics depends on age, size, and population density mechanisms.

However, considering these structural variables as appropriate proxy to determine the probability of bankruptcy cannot satisfy those who want to determine which firms are the more likely to default in order to use this information to make a right decision such as financing or to advise managers. Progressively, other elements more narrowly dependent on the specific characteristics of the firms have been introduced. The inspiration directly flows from the resource-based view which has principally been employed in the study of above-normal performance but is also instructive in the context of below-normal performance.

Financial Causes

In contradiction with the Modigliani-Miller theorem which states that, under specific assumptions, the value of a firm is unaffected by how that firm is financed, a large number of works shed some light on the role plays by the financial structure in the vulnerability of the firm (an analysis of the crucial role played by finance and financing institution is available in the entry "▶ Entrepreneurship Financing"). One may consider that the interest coverage and market value of equity/total liabilities are negatively correlated with the odds of corporate bankruptcy. In the same vein, the likelihood of going bankrupt increases with the leverage level and capital intensity but decreases with the liquidity level and growth prospect of a firm. Some are also interested in the expectations and appetite of shareholders as the smaller the stock return, the greater the chance for the firm to go bankrupt. Following the pecking order theory, one can support the idea that companies prioritize their sources of financing (from internal financing to equity) according to which the principle of least effort, or of least resistance, preferring to raise equity as a financing means of last resort. Hence, internal funds are used first, and when they are depleted, debt is issued. When it is not sensible to issue any more debt, equity is issued (Myers and Majluf (1984)). The ability of the firm to finance its investments by itself appears as a crucial factor for its stability. Thus, a high initial level of financial resources (equity and long-term debt) can protect the firm from a risk of failure.

Sales and Market Position

Other explaining variables have to do with the business and the market position of the company. The firms able to sell their products are less likely subject to a cessation of payments. The higher importance of the capacity to create a good customer relationship is pointed out by Shumway (2001) who finds that market variables are more useful than financial ratios in predicting bankruptcy.

Corporate Governance and Shareholders

Becchetti and Sierra (2003) include a group membership dummy ill a prediction model estimated on a large sample of Italian manufacturing firms and find a negative relationship between probability of failure and business group membership between 1992 and 1997. This evidence can be enlarged. On average, firms integrated in large corporate groups are more likely to be supported by the parent company and thus less likely to be insolvent. More recently, a report Levratto et al. (2011) argued that the odds of going bankrupt increases with the level of restrictions imposed on corporate internal control.

All these different causes do not intervene independently in the process of failure but combine each other. The decline of a company begins most of the time by mismanagement and unmarketable products which may cause a decline in sales over several years (and a correlative decrease in earnings if nothing is done to improve the market position). In the worst case, the falloff in turnover results in a decrease in profitability, followed by a deterioration of operating conditions which are at the origin of a solvency crisis. At this stage of the vicious circle, the company's managers have a strong incentive to accept less favorable market conditions (rebates or longer terms of payment, etc.) in the hope of restoring sales and profitability. Such a reaction can however be counterproductive as it can cause an increase in trade debts and inventories, especially in the manufacturing industry. As a consequence, the company may be short of cash and, therefore, may face a liquidity crisis which could lead lenders to practice credit rationing and increase interest rates since the simultaneous increase of indebtedness and decrease in self-financing deteriorates the probability of repayment of such a debtor. Subject to a shortage of financial resources, to a decrease in the EBIT aggravated by an inability to repay the claims once they fall due, the company may decide to file a petition for bankruptcy before the creditors decide to present one to the commercial court. Once one of these two possible events happens, the insolvency turns into bankruptcy.

Forecasting and Estimation of the Probability of Failure

Understanding and predicting company default has been an area of extensive research for at least 40 years. The literature exploring corporate failure started with the simple univariate discriminant analysis approach, pioneered by Beaver (1966). His univariate analysis of a number of bankruptcy predictors states that a number of indicators could discriminate between matched samples of failed and nonfailed firms for as long as 5 years prior to failure. Models of that kind are appealing in their simplicity, but their main disadvantage lies in their inability to account for the coexisting effects of many different indicators of default. They have been rapidly outperformed by the use of multivariate analysis, whose the Z-Score model proposed by Altman (1968) is still considered as a key reference in the literature. Its performance rests upon the innovative use of multiple discriminant analysis in the field of economics and finance. Multiple discriminant analysis is a statistical technique used to classify an observation into one of several a priori groupings dependent upon the observation's individual characteristics. It is used primarily to classify and/or make predictions in problems where the dependent variable appears in qualitative form, for example, bankrupt or nonbankrupt. From this venerable model, an unmeasurable number of variants have been tested. Either the number of indicators compounding the final score was changed to improve the fitness of the index or the formula was adapt to fit better with peculiar situation such as specific activities (services, start-ups, etc.) or markets (emerging, blue ships, etc.). Another generation of risk index models introduces the concept of indexing the individual failure-predicting indicators; however, their approach shares the same weaknesses of univariate analysis and provides largely arbitrary risk metrics.

The most visible progress results from the introduction of nondeterministic and nonparametric methods in the estimation of the probability of failure. They mainly consist in adopting artificial neural networks, computational structure modeled loosely on biological processes, to the bankruptcy prediction. One of the first studies to apply neural networks to the bankruptcy prediction problem was the work by Odom and Sharda (see Zhang et al. (1999) for a survey on this method). Despite their growing success, neural networks are still criticized due to the lack of transparency concerning the estimation process: They are even suspected to be "black boxes" that is a real weakness, whereas accuracy and information disclosure are required from banks in determining the exposure at risk. That is why the judgment is still balanced. On one hand, neural networks, when they are effectively implemented and validated, show potential for forecasting and prediction. But, on the other hand, a significant portion of the neural networks research in forecasting and prediction still lacks validity.

Currently, several of the major commercial loan default prediction products are based on neural networks. For example, Moody's Public Firm Risk Model (Online: www.moodysqra.com) is based on neural networks as the main technology. Many banks have also developed and are using proprietary neural network default prediction models. Nowadays, there is a wide range of default prediction models, that is, models that assign a probability of failure or a credit score to firms over a given time horizon. The literature on this topic has developed especially in connection with Basel II, which allows banks to set up an internal rating system, that is, a system to assign ratings to the obligors and to quantify the associate probabilities of default.

The requirement of the microregulation of the banking system and the increasing need of more accurate expectations on the exposure at loss of financial institutions are probably going to push up research on firm insolvency. A better knowledge of the causes of firms' failure is not only wished for an improvement of financial sphere functioning. It can also deserve firms' interests and companies' advisors to implement better practices of growth (the entry "► Accompaniment of Business Creation" gives an idea of the role of external supports as a reason of success). From an academic point of view, one may consider that the existence of firm-specific failure determinants offers support to the resource-based theory of the firm and contributes a more fine-grained perspective to the study of organizational ecology.

Conclusion and Future Directions

Over the past 35 years, corporate insolvency has been at the origin of a broad and in depth literature aiming at embracing legal and industrial features. Seen as a promising way to have at disposal prediction models possibly used by banks, firm exit has increasingly become a fashionable topic. The increasing number of works is especially visible in two fields. An empirical analysis of firm exit or default determinants which tends to provide a better knowledge of explanatory variables on one hand and a methodological perspective on the other, mainly consists in testing new techniques. In these two fields, the progress is really perceptible. The main problem remains that default, exit, and insolvency are ex post phenomenon and that their occurrence is highly sensitive to the context. To depart from the determinist view which characterizes parametric models, scholars tend to prefer nondeterministic ones. However, they tend to hide the reason why firms fail. In the future, one can expect that semiparametric models will be preferred, even if that requires intensive tests to improve their reliability as prediction tools. It is the price to pay to get a comprehensive model of exit.

Fostering Creativity Through Science Education

Mavis Haigh
Faculty of Education, The University of Auckland, Auckland, New Zealand

Synonyms

Innovation in practical work in science education; Open-ended investigative practical work in science education

Key Concepts

This entry focuses on the premise that creativity can be fostered through science education. There are two contrasting views of the nature of creativity – the first is the extraordinary, or high, creativity displayed by geniuses, and the second is the more everyday creativity, sometimes called possibility thinking, that occurs as an individual makes inventive decisions when faced with novel and/or demanding contexts. Craft (2001) used the notions of “big C creativity” (BCC) and “little c creativity” (LCC) to frame these two views of creativity within education. The concept "creativity" applies both when ideas and artifacts are produced for the first time in human history and when the ideas are new simply to the person who generated them. Both LCC and BCC require imagination, flexible thinking, and originality. It is generally LCC that we can foster through science education, though students involved in research projects may arguably be involved with aspects of BCC such as novelty and peer validation (Feldman et al. 1994).

Creativity is recognized as domain specific or dependent, which suggests that there is a particular kind of creativity associated with divergent thought when considering science ideas. It can be argued that hypothesizing, designing experiments, and problem solving all require a particular kind of creativity peculiar to science, as does the technical innovation that is often required as part of experimental design. However, scientific creativity is a subtle concept that is hard to pin down and is often used in different ways. Kind and Kind (2007) provide an analysis of teaching creatively, creativity's link with inquiry teaching, and creativity as an aspect of the nature of science.

Hu and Adey (cited in Lin et al. 2003) proposed a definition for scientific creativity when they developed a test for scientific creativity for secondary school level science. Their definition included three dimensions: process, trait, and product, and seven core elements: unusual use, problem finding, product improvement, creative imagination, problem solving, science experiment, and product design. They, and their team of researchers, have used this framework to compare the scientific creativity of students who have undergone the Cognitive Acceleration through Science Education (CASE) program with those who have not (Lin et al. 2003). The CASE program did appear to promote scientific creativity in secondary school students though the effects on different aspects of creativity varied, with items testing science experiment and product design having large effects and creative imagination having a smaller, but still statistically significant effect. The effect of CASE on creativity was shown to be often delayed until one or more years after the end of the intervention program. The research team argued that "the CASE programme improves students' cognitive processing, and only when this has been achieved can it be applied to problems requiring creative thinking."

The Place of Creativity in the Science Curriculum

Across the world, science education is increasingly being required through its curriculum documents to address the nature of science and its social practices as well as the content of science. This requirement is supported by the argument that "in a society where science increasingly permeates the daily discourse, some understanding of its underlying epistemic values, methods, and institutional practices is essential if the citizen is to engage with the issues confronting contemporary society" (Osborne et al. 2003). After carrying out a careful Delphi study with representatives of groups involved in science and science education around what ideas about science should be taught in school science, Osborne et al. listed nine key aspects of the nature of science that were considered as essential in school science curricula. One of these was an understanding that science is a creative endeavor. If creativity is fundamental to science, it arguably should also be a prominent feature of science education.

However, it is not sufficient to simply tell students about the creativity inherent in the scientific endeavor, though an appreciation of the role of human engagement and creativity in the development of scientific ideas might be addressed through carefully crafted historical study (Kind and Kind 2007). Instead, students need to be encouraged to do science in ways that foster creativity. Ways of fostering creativity in science education include making models to explain ideas and visualizing processes in an attempt to explain phenomena. Developing students' futures thinking within science education is another approach likely to foster creativity given that imaginative creativity is a significant feature of futures education. A study of socio-scientific issues within futures education approaches calls for student understanding of current situations to inform, imagine (create), and evaluate possible and preferable futures (Jones et al. 2011).

Encouraging questioning and problem-posing, formulating hypotheses and predictions, and designing and carrying out investigations to test these also offer students ways of authentically experiencing the creative aspects of the development of science ideas. Students also need experience in interpreting data and in making decisions about the status of evidence and the validity of inferences. Experience in defending their interpretations, especially should others offer conflicting interpretations, is also necessary. Notions of collaborative creativity can be fostered through deliberately encouraging students to work cooperatively, thus permitting a glimpse of the common effort involved in much scientific work (Osborne et al. 2003).

Student engagement in scientific inquiry holds the potential for fostering students' understanding about the nature of the scientific endeavor, including the role of creativity in the development of ideas in science. Many curricula emphasize the centrality of inquiry (sometimes framed as investigation) to school science. However, science education researchers hold variable views regarding the possibility and actuality of inquiry approaches in school science classrooms for providing a context for students to experience authentic scientific inquiry (e.g., Abd-El-Khalick et al. 2004; Kind and Kind 2007). It has been argued that there is a difference between the ideals of inquiry science in schools and its reality in practice. In part, this may be the result of teachers' differing perspectives of the nature of science. In part, it may be because teachers continue to tightly frame student investigations. If school inquiry science is to become more authentic, then it is likely to require teachers to reconsider their roles and the classroom activities they plan and for students to accept changes in teacher-student engagement and learning environments (Haigh 2010).

It is recognized that the processes of scientific inquiry require a sound understanding of context and concepts inherent in the investigation, a particular challenge to student novices and teachers alike. Minimal guidance by the teacher is unlikely to result in anything but frustration for the students. Teachers wishing to support their students' inquiry approaches are likely to have to address their students' lack of scientific knowledge by providing information as it is required, or at least direct the students to where the information may be found (Haigh 2010). Given that scientific creativity and rationality are likely to work together, it is also to be expected that teachers will need to directly teach rational processes such as careful empirical testing (Kind and Kind 2007).

The Potential of the Practice of Investigation in the Science Classroom

Although science educators continue to critique the notion that inquiry science in school can truly reflect the work of scientists, there is some research supporting engaging in investigative practical work as a means of fostering scientific creativity in secondary school students. Haigh (2010) carried out a 4-year empirical project where teachers facilitated their students in open investigative practical work in biology. This New Zealand research sought to find out how student's abilities at carrying out open investigative work can be enhanced, how teachers can be supported in this work, what the perceived benefits from such an introduction are, and what the perceived constraints might be.

The study was conducted in three phases, with phases 1 and 2 taking place in a large urban secondary school and phase 3 involving senior biology teachers and their students in 22 other secondary schools across New Zealand. In total, 27 teachers and approximately 500 students were involved in the study. The students encountered a number of partially open biology problems. The problems that the students were working with were deemed partially open as the teacher had set the context of the problem and focused the student thinking through directed questioning about the problem. The tasks were authentic and relevant to the students' school or home environments. They were linked to aspects of the New Zealand senior biology curriculum such as eutrophication, osmosis, transpiration, photosynthesis, and enzyme activity. The students were required to make decisions about the inquiry design, generate data, and draw conclusions after considering the status of their gathered evidence. Frequently, the process involved redesign and the generation of new data. When designing the investigation, they worked as individuals at first and then joined in groups where they were required to defend their approach to the problem and move to a group decision. As a group, the students had to work collaboratively to complete the investigation and generate findings. The group then had to argue for the reliability and consequence of their findings and prepare a report for a nominated audience such as a school newspaper or scientific journal. The processes followed by these students incorporated the essential features of the domain for inquiry-based science instruction that have been outlined by Minner et al. (2010).

Findings from this study indicated that both teachers and students identified that carrying out practical investigations provided opportunities for the students to think scientifically creatively, albeit largely within the LCC framework. The students were challenged to question initial assumptions: their own or those provided by teacher or text. Having to work through a number of what, how, how many, when, where, and why questions encouraged students' possibility thinking. Some students did things differently, that is, they took a distinctly different approach to solving the problem. Some had done things better, that is, they made changes to a previously used procedure in ways that improved the reliability and validity of their findings. The teachers reported that as the students worked with a number of similar investigations in different contexts, they became more innovative in what they planned and demonstrated an increasing flexibility of thinking. In addition, the students indicated that engaging in open investigative practical work brought with it a greater understanding of the creative and sometimes uncertain nature of science investigation; they had broadened their understanding of the importance of the collaborative nature of the scientific endeavor and the tentative nature of scientific knowledge.

However, Haigh's project also highlighted that aspects of teacher engagement may need to be altered if the potential of investigative practical work to foster and enhance creativity is to be realized; these are the dynamics of the classroom and the nature of teacher-student and student-student interaction. Specific activities and teaching strategies were also identified as enhancing the potential for students to creatively engage with the investigation. A classroom that encourages creativity embraces coconstruction of knowledge. The classroom will be learner-oriented. Students' existing knowledge will be recognized, and they will be supported to restructure these understandings where necessary. Students will be given opportunities to learn from others, the teacher, or each other through collaborative activities. Teachers will deliberately scaffold their students' investigative attempts. Haigh (2010) details a number of strategies suggested by the teachers and students in her study that enhance student engagement, critical thinking, and creativity during investigative practical work. The strategies support the students' shifts from following "recipe"-type practical work into more open practical work where students are required to pose and test possibilities. A teacher might help the students to analyze "recipe"-style investigations to determine why the author had chosen that particular approach, the students might plan an investigation and then critically compare their plans to one provided by the teacher or text, students will be expected to critically evaluate their own work on completion of the investigation, teachers will emphasize the value of cooperative working practices, teachers will help students to seek links between prior knowledge and the investigative situation, and the teachers will actively cue the students as they work through the various stages of an investigation.

A United Kingdom-based study around a collaborative curriculum development project also highlights the necessity for pedagogy to change if science education is to foster creativity. Teachers will need to teach creatively. A focus on the need for these changes should begin in teacher education programs if they are to have any impact on teachers' work and continue into ongoing professional dialogue. Braund and Campbell's (2010) study involved student teacher and teacher-mentor pairs devising, teaching, and evaluating novel lessons and approaches around teaching about ideas and evidence in science. A significant outcome of the study "was the perception of teaching shifting from delivery of standard lessons in prescribed ways to endeavours demanding creativity and decision making" (p. 203). However, when the student teachers began teaching as newly qualified teachers, the context of the school limited their ability to act as agents able to make a difference to the way the school at large taught science, leaving much of the teaching still largely the delivery of standard lessons in prescribed ways.

Conclusions and Future Directions

Providing opportunities for student to carry out investigative practical work in science has the potential for enhancing their creativity and their understanding of science as a creative endeavor. Collaborative investigative practical work provides many opportunities for social possibility-thinking and decision-making, at least at the LCC level. It may also, in part, meet Feldman, Czikszentmihalyi, and Gardner's (1994) three-part system of high creativity where individuals develop ideas that are validated by experts. With support, teachers can establish a classroom culture that supports students as they engage in logical and creative construction of scientific knowledge. However, there are questions around this aspect of science education that require further exploration. Some possible inquiries are as follows: Is there a tension between teaching for creativity and teaching for conceptual understanding in science? How might science teachers be better supported to teach creatively to enhance students' creativity? How can the tensions between open approaches to practical work in school science and the drive for accountability in education, often through rigid assessment, be addressed?

Four Ps in Organizational Creativity

Russell Schneck
WorkingLessons, Red Hook, NY, USA

Synonyms

Four Ps of creativity

Key Concepts and Definitions

Organizational creativity refers to the people and process capabilities, and the conditions that develop and support these capabilities, in order for an organization to consistently produce innovative products, methods, business models, and experiences to meet the needs of its customers, employees, and stakeholders.

This conceptual view begins with the four Ps (Rhodes 1961) by considering creative product as the outcome of the interaction of person and process, operating within an organizational climate (press). These dimensions are defined:

Product – The communication of a novel and useful idea, concept, or theory

Person – Cognitive abilities, personality traits, and biographical experiences

Process – The methodology that produces a creative product

Press – The relationship of the creative person to the environment they are creating within

Within the context of organizational creativity, two additional dimensions need to be considered in combination with the four Ps. Teams are included to reflect that organizational creativity is often a collaborative effort. The influence of leadership must also be recognized since the successful application of the other capabilities and practices are directly dependent on this foundation.

Theoretical Background

Product

Theorists have highlighted that the study of creativity needs to begin with creative product since creativity is demonstrated by the existence of a creative product (MacKinnon 1978; Rhodes 1961; Rogers 1961). Rhodes (1961) specifically states: "Objective investigation into the nature of the creative process can only proceed in one direction, i.e., from product to person and thence to process and press" (p. 309).

Innovation is a creative product. More specifically, it is a creative product that reaches implementation (Kaufman 1993 cited in Vehar 2008). Innovation is the result of creativity, and this understanding means that it is necessary for organizations to develop and support creative capabilities in order for innovation to consistently occur.

Person

Much of the understanding of the creative person can be attributed to the impetus provided by Guilford and his presidential address to the American Psychological Association (Guilford 1950). Guilford's own work advanced the understanding of the cognitive abilities associated with creativity and established the importance of divergent and convergent thinking. Cognitive abilities are only part of the story. Beyond cognitive abilities, creativity can be attributed to personality traits and biographical experiences (Davis 2004).

Creativity is commonly equated to imagination, and this undeniably is an important characteristic, but it is a limited perspective. The topic of the creative person is complex, and it is well-researched area, with extensive information available. For example, Davis (2004) describes a meta-analysis of over 200 adjectives and descriptions from 50 sources to arrive at 16 categories of recurrent traits in creative people.

Guilford (1950) offers a conception that brings attention to a particularly important trait: "Creative productivity in everyday life is undoubtedly dependent upon primary traits other than abilities. Motivational factors (interests and attitudes) as well as temperament factors must be significant contributors" (p. 454). Continuing on the importance of motivation, Amabile (1987) offers insight into the importance of motivation, particularly intrinsic motivation: "There is abundant evidence that people will be most creative when they are primarily intrinsically motivated, rather than extrinsically motivated by expected evaluation, surveillance, competition with peers, dictates from superiors, or the promise of rewards" (p. 39).

Amabile's Components of Creative Performance (1983) informs the conception of the attributes necessary to consider in the creative person dimension with creativity-related skills, domain-related skills, as well as task motivation.

Process

Process can be the specific cognitive and affective abilities that are applied as well as a framework that defines the steps or phases that are common to creative problem-solving. The importance of innovation to organizational creativity, and the requirement of a creative concept to be taken to fruition for there to be innovation, demonstrates that process must advance creativity through implementation or commercialization.

Discussion of process can focus on defined methodologies such as creative problem-solving (CPS) (Osborn 1953) or synectics (Gordon 1961). Mumford et al. (1991) review well over a dozen processes beginning with the pioneering efforts of Dewey (1910) and Wallas (1926) to recognize a progression showing a continuous increase in understanding of the mechanisms that produce idea generation. The specific conclusions relating to this are articulated in this way:

> Researchers have also begun to display greater sensitivity to the dynamic, perhaps cyclical nature of process application, the goal-oriented nature of creative problem solving efforts, the significance of real world constraints, and the impact of motivational, developmental, and personality attributes which can condition the efficiency of process application. (p. 99)

In practice problem-solving is often conceptualized as descriptive expression of steps or phases. While there is no universally accepted approach, generically the process has four basic phases (Beecroft et al. 2003; Puccio 2002):

- Clarification
  - Define and clarify the opportunity or challenge
- Ideation
  - Generate ideas
  - Evaluate and select an idea(s)
- Development
  - Transform ideas into solutions
  - Test, refine, strengthen solution
- Implementation and Maintenance
  - Implement solutions
  - Evaluate solution over time

Teaching and training that supports the development or improvement of creativity and problem-solving abilities most often addresses process. The work of Scott et al. (2004) was a meta-analysis of 70 studies of creativity training program evaluations that concluded "that more successful programs were likely to focus on development of cognitive skills and the heuristics involved in skill application, using realistic exercises appropriate to the domain at hand" (p. 361).

This research brings the focus to an understanding that creative problem-solving is about having an awareness of the unique mental function required for the task at hand. This understanding is conceptualized by *The Thinking Skills Model* (Puccio et al. 2011) which articulates specific cognitive and affective abilities associated with each process step. With its focus on cognitive and affective abilities, The Thinking Skills Model connects the discussion of process to the creative person. The discussion of process also leads directly to the topic of teams, and their relationship to the four Ps, since a characteristic of effective teams is a commitment to a common approach, a process, of working together (Katzenbach and Smith 1993).

Press

The interaction of person, process, and teams that is required to generate creative products does not occur in a vacuum. The practice of organizational creativity must contend with a multitude of forces internal and external to the organization that influence the needs, requirements, and effectiveness of the effort. These forces, pressures, are the press.

Discussion of press includes a macro view of the dynamic operating environment, external forces that organizations cannot control but must respond to, and progresses to internal considerations that can be managed in a deliberate manner that will help develop and support organizational creativity.

The Dynamic Operating Environment. There are external pressures on an organization that are beyond the control of the organization. These include customer expectations, shareholder requirements, technology advances, competitive factors, economic conditions, legal and regulatory considerations, and globalization. This dynamic operating environment establishes the need for consistent and sustainable innovation simply to keep pace with the change made necessary by outside forces. But how an organization responds to these pressures also establishes the conditions that will support or detract from creative efforts.

Climate. The creative climate can vary among work teams even within the same organization. However, the more consistent the creative climate is throughout an organization, the more consistent and sustainable the creative contribution will be throughout the organization.

Ekvall (1996) defines creative climate to describe how behaviors and attitudes work to shape the creative output in an organization. Ten factors are identified which collectively describe the creative climate of the organization. These factors are (a) challenge, (b) freedom, (c) idea support, (d) trust/openness, (d) dynamism/liveliness, (e) playfulness/humor, (d) debates, (e) conflicts, (f) risk taking, and (g) idea time.

A discussion of press leads directly to the importance of leadership. Leadership that does not deliberately work to encourage organizational creativity by development and support of the four Ps can be an adverse part of the press that needs to be overcome. However, effective leadership is instrumental in creating the conditions that will develop and support organizational creativity, and this begins with recognition of the importance of each of the four Ps as well as teams.

Beyond the Four Ps

It is only by looking at the four Ps in combination with teams and leadership that a complete picture of product, person, process, and press in the context of organizational creativity is formed. The four Ps can be seen as the foundation of organizational creativity, but the additional considerations of teams and leadership are integral to the practice of organizational creativity and influence the dimensions of the four Ps as significantly as each of the four Ps influence and interact with each other.

Teams

Within organizations, creative products are often the result of collaborative efforts with multiple individuals making a contribution. A team is more than the sum of its parts. Teams need to be recognized as more complex entities than a collection of individuals. Interpersonal dynamics ensure that this will be the case. Teams are defined by a collective work product (Katzenbach and Smith 1993). This directly relates the function and importance of teams to the purpose of organizational creativity to produce creative product.

Amabile (1998) makes it clear, "If you want to build teams that come up with creative ideas, you must pay careful attention to the design of such teams" (p. 82). Effective teams are mutually supportive groups with a diversity of expertise, experiences, and thinking styles. Members of effective creative teams share and contribute to excitement about their objective, have a willingness to help teammates overcome challenges and setbacks, and appreciate the unique knowledge and perspective the other team members have to offer. "These factors enhance not only intrinsic motivation but also expertise and creative-thinking skills" (p. 82).

The conditions that promote team effectiveness extend beyond the composition of the group and require attention to the collective experience of the group. Tuckman's model for team development (Tuckman and Jensen 1977) highlights that teams will not be fully operational at inception and must be given the opportunity to evolve. The model presents five stages that teams progress through as they develop the ability to successfully work together.

1. Form: The team is brought together and learns about each other and about the opportunity and challenges it faces.
2. Storm: Personal conflicts are exposed. Team members confront each other's ideas and perspectives. Different ideas compete for consideration. Not every team gets through storming.
3. Norm: Team members often work through this stage by agreeing on rules, values, professional behavior, shared methods, and tools.
4. Perform: Teams are able to function as a unit as they find ways to get the job done efficiently and effectively without inappropriate conflict or the need for external supervision.
5. Adjourn: The required task is complete the task and the team is disbanded.

Leadership

The effective application of organizational creativity requires a foundation of leadership. The dynamic operating environment establishes the need for consistent and sustainable innovation. The executive leadership of an organization determines the approach the organization uses and, in thought, words, and deeds, sets the tone for how the organization responds to these pressures.

Leadership is a topic that is broad in scope. Particularly relevant to this discussion are mental models and the role that leadership plays in establishing and reinforcing the dominant mental models (Schwenk 1989) that define the beliefs and attitudes that govern perceptions, reasoning, and behavior in an organization. Senge (2006) defines mental models as:

> Deeply ingrained assumptions, generalizations, or images that influence how we understand the world and how we take action. Very often we are not consciously aware of our mental models or the effects they have on our behavior. (p. 8)

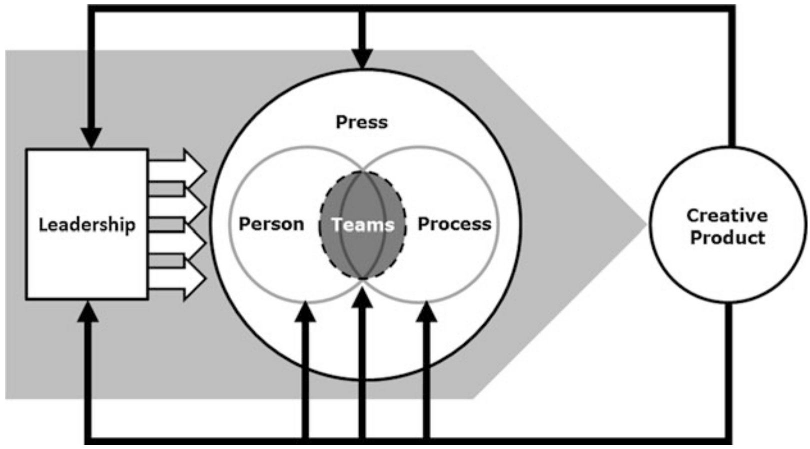
Caughron et al. (2009) extend the concept to organizations by conceptualizing dominant mental models "as a form of shared mental model that extends beyond the group level into broader social contexts such as organizations" (p. 11). Dominant mental models often reflect the influence of individuals in positions of authority (Schwenk 1989).

Organizational creativity will flourish when leadership supports and applies a dominant mental model that recognizes and promotes the value of creativity and the conditions that are conducive to creative performance.

With a foundation of leadership, it becomes possible to establish a supportive climate. Research supports the connection between leadership and climate. Ekvall (1999) provides a particularly compelling statistic; leadership behavior accounted for a range of 30–60% of the reported variances in his research of creative climate. Conditions that support organizational creativity cannot be sustained without leadership that brings intention and attention to the task of establishing and maintaining a creative climate.

By establishing a creative climate, the conditions exist for individuals, teams, and processes to develop in a way that will produce creative products. Since the work of Ekvall (1996) and Amabile et al. (1996) substantiate that climate, including perceived climate, influences creativity and innovation, it is reasonable to conclude that climate is also exerting influence on person, process, and teams, since it is the interactions of these dimensions within the climate that produces the creative product.

Figure 1 presents a view of organizational creativity with a foundation of the four Ps. Support and development of the organizational competencies required to achieve effective and sustainable creative performance begins with leadership. The arrows extending out from the leadership box reflect the influence of leadership on press, person, teams, and process. The model shows the interaction of person, teams, and process, operating within the influence of press to produce an outcome of a creative product. The arrows from product back to the other dimensions indicate that the assessment of product begins a feedback cycle leading to continuous learning and improvement. Ekvall (1996) recognizes that outcomes influences climate and resources which is a description of this feedback.



Four Ps in Organizational Creativity, Fig. 1 The four Ps in organizational creativity ©2012 Russell Schneck

Conclusion and Future Directions

Examination of the four Ps in organizational creativity has implications for leadership, organizational development, as well suggesting directions for creativity research.

Support and development of the four Ps is instrumental to organizational creativity. And while it may seem simplistic, the opposite corollary is also true; factors specific to organizational creativity that inhibit its practice can be viewed in terms of a failure to develop and support the conditions that contribute to organizational creativity. The implications for leadership and organizational development are clear.

Individuals must be provided appropriate training and support to develop domain-related expertise as well as creative problem-solving abilities. Process must provide a commonly understood framework that facilitates the type of outcomes that are expected and required. Teams must be created with attention to diversity of skills and perspectives. They must be given adequate opportunity to develop in order to perform effectively. There must be deliberate attention to establish and maintain a climate supportive of creativity. This needs to be actively monitored with interventions for improvement as needed. Leadership must support development of each of these components and consistently demonstrate a commitment to organizational creativity to ensure that the importance organizational creativity remains a dominant mental model. Evaluation of creative product provides the feedback that is necessary to support the ongoing development of organizational creativity.

The interrelated, interdependent nature of the four Ps of creativity is consistent with research considerations. Mumford (2003) expressed the need for more integrative models as well as increased attention to the effects of creativity on people and social systems. The former consideration could be viewed as a need to examine the combined influences that contribute to the production of creative product that is reflected by the interdependence of the four Ps. The latter describes looking at the complex phenomenon of creativity and the influence its practice has on the individuals and the system it is functioning within. This changes the nature of the examination from the influence of the four Ps on organizational creativity to the influence of creativity on the four Ps and on the organization.

Introduction

There are many different definitions of creativity, even in the scientific literature on the subject. All of them emphasize originality; without originality, there can be no creativity. Yet there is more to creativity than originality. Originality is necessary but not sufficient for creativity. There must also be some effectiveness, usefulness, or fit. Without that, original things may be bizarre and useless. Creativity things are thus both original and effective. This applies to artifacts and products, such as inventions, artworks, and designs, but also applies to the personality traits that are shared by creative individuals. These traits give the individual the capacity to generate original and effective ideas. Indeed, the bipartite definition recognizing originality and effectiveness applies to all expressions and definitions of creativity.

Fifty years ago, an alliterative scheme was proposed in an attempt to account for approaches to creativity. It is usually called the *four P topology*, but as the title of this entry denotes, that label is out of date. This entry covers the four Ps, but it also goes into some detail about what has occurred in creativity and innovation studies since it was first proposed. As such, this entry is a kind of review of creativity studies, using the alliterative P framework as a way of structuring the various theories of and perspectives on creativity.

Person

One common perspective is that certain individuals have a personality profile that supports creative thinking and behavior. The core characteristics of this personality profile include openness to experience, wide interests, autonomy, nonconformity, and intrinsic interests. Each of these is actually a somewhat general label. Autonomy, for example, is sometimes labeled independence. More important is that there are logical ties among these traits. A nonconformist, for example, will appear to be autonomous, and someone with wide interests probably must have be open to (broad) experiences. The person perspective on creativity does not entirely focus on personality. It includes other personal tendencies and capacities, some of which are intellectual, temperamental, or attitudinal, and others reflect habit, values, and self-concept. Specific theories also include particular defense mechanisms (e.g., sublimation).

There are vocal critics of the personality (or "person") perspective on creativity. They point to the fact that the presence of most or even all of the traits listed above does not guarantee creative behavior. Additionally, it appears that there are notable variations among domains. Someone creative in the sciences may be dissimilar to someone who is creative in the arts, just to name one example. Individuals in different domains seem to have different profiles, so there is not a single profile of a creative person.

Still, all of personality theory is this way: Traits provide the potential to respond and behave in particular ways. They do not guarantee specific actions. Behavior is based in part on traits and capacities but also on the environment and context. This is why later versions of the 4P topology include potential as one of the Ps or categories. It is also why there are many theories of creativity that focus on the environment or context. The original 4P framework was developed over 50 years ago, at a time when environmental influences were labeled "press factors," the idea being that the environment imposes pressures on the individual.

Press and Place

The original "Analysis of Creativity" article, from 1961, labeled environmental factors "press," but actually there were two kinds of presses. According to Henry Murray, who wrote extensively about environmental influences, there are alpha presses and the beta presses. The alpha press is the environmental pressures that have an impact as part of the object world. The beta press is also a result of environmental pressures, but these have an impact only when individual perceives and assigns significance to them. This is an important distinction because each individual has different perspectives and interpretive tendencies and thus reacts to the environment in unique ways. The same environment may positively influence some people but not others. It is another example of why "potential" must be included in creativity theory. The environment may put someone in a position where creative action is likely, or even encouraged, but the actual impact is uncertain. Interpretations determine the actual result. Environmental press factors thus only have potential impact.

A clear example of alpha press could be stimuli that lead our sensory system to react automatically, such as a loud noise. When a loud noise stimulates the sensory system, people perceive the sound as unappealing. Music, however, is a beta press: There is room for interpretation and variations among individuals as to what is comforting, exciting, and aesthetically appealing.

There are probably more beta presses than alpha influences on creative behavior. In educational settings, different students may require different things before they are comfortable being unconventional and creative. This is illustrated by one of the many resources that may be considered when trying to construct an environment that is clearly conducive to creativity, namely time. Creative work often requires time. Time is an important resource. Time limits can motivate some students, while for others time limits are distractions that inhibit the creative process. In a corporation setting, budgets and their impact on resources of all sorts represent beta factors. Consider a company that relies on effective advertising to promote its products. When budgetary constraints are imposed, some organizations and members of organizations may not be able to produce effective, attractive advertising. For others, "necessity is the mother of invention," and limited resources can suggest innovative use of what is in fact available.

The Process Perspective

The paragraph above described how certain environmental factors may have an impact, especially after an individuals interprets their significance.... This is just one of the many ways whereby creative products – be they ideas, patents, inventions, designs, or whatever – depend on a process. The environmental factor is not perceived simultaneously with the interpretation; the latter follows the former. Time elapses. It is a process. And this is a huge simplification because in actuality, there are probably a large number of potential influences on the individual, and the process is in fact quite complex. It is not just one press factor and one interpretation. No wonder creativity is often viewed as a syndrome or even a "complex."

Many process theories of creativity delineate the process and attempt to identify specific stages. The best known stage model of the creative process was outlined by Graham Wallas in his book from1926, *The Art of Thought*. He described four stages: preparation, incubation, inspiration, and verification. In the preparation stage, individuals define problems and gather information which may contribute to solutions. Preparation may involve observing, listening, asking, reading, collecting, comparing, contrasting, and analyzing. More current research includes problem identification and problem definition as part of preparation. These are quite important for creative thinking.

The second stage is incubation, which allows individuals to step back from the problems and contemplate a wide range of solutions and perhaps considering alternatives and previous relevant experience. In this stage, individuals are relaxed and take time away from the task. The length of optimal incubation depends on each individual. It could last minutes, days, and even several months. That is of course consistent with the idea of beta presses in that there are individual differences rather than an absolute and universal process or time limit.

"Illumination," the third stage, occurs at a moment of insight when an idea makes itself known. Illumination is often equated with "Ah ha!" or "Eureka!" moment. It is characterized by a sudden realization. Importantly, it may just be that the realization is sudden but the process leading up to it is, as Gruber (1985) put it in his case studies of famous scientific discoveries, *protracted*.

The final stage is "verification." During this stage, new ideas or solutions can be carefully evaluated and implemented and tested to insure that they work. This is quite important because creativity is more than originality. A creative solution must solve a problem. A creative idea must indeed work. If an idea or tentative solution is not effective, the individual can go back to the previous stages if they think that the ideas should be prepared or incubated again. This is known as recursion.

Although dating back to 1926, Wallas' stage model is still cited more than any other. Newer models have been proposed, but most parallel that of Wallas. There is a two-tiered model, for instance, which includes problem finding, ideation, and evaluation on the primary tier and knowledge (procedural and declarative) and motivation (intrinsic and extrinsic) on a secondary tier. Another fairly new model was proposed by Michael Mumford, in the *Creativity Research Journal*. It points to (a) problem finding, (b) information gathering, (c) information organization, (d) conceptual combination, (e) idea generation, (f) idea evaluation, (g) implementation planning, and (h) solution monitoring. The parallel between the newer models of the creative process and Wallas' (1926) model are no doubt quite clear.

Products

Creative products are remarkably varied. Rhodes felt that creative products were tangible forms which materialize from an idea. Later immediate products, such as ideas, were distinguished from ultimate products, like inventions, novels, and patents. There are intermediate products, as well, such as paintings, poems, designs, musical compositions, or some type of performance. These may be performed at a professional level, or they may be more personal with no competition, social judgment, or lasting impact. Note that some products may be intangible, but they can still be counted as products.

The vast majority of studies of creative products have examined socially judged products. These investigations tell quite a bit about professional levels of creative talent. They indicate what kind of political and cultural milieu is conducive to creative work and how productivity varies through the lifespan, just to name two types of analyses. But investigations of professional products say nothing about everyday creativity, intangible creative efforts (e.g., self-expression), and creative potentials. They have the advantage of being highly objective: Products can be counted and experts can be identified and employed for reliable judgments. But to apply findings to the creative process or to the fulfillment of potential requires inference. Investigating products is a bit like enjoying a sporting competition by looking at the final score. You only learn something about the result and have no idea how it came about. Perhaps the clearest finding from studies of creative products is that the quantity of productivity is related to its quality. Yet this too may characterize experts and eminent creators and not everyday creativity.

Persuasion

Simonton (1995) suggested that the original 4P framework is no longer adequate for coverage of

creativity studies and that a fifth category, which he called persuasion, would be a useful addition. The central idea is that highly creative people or products change the way that others think. They are in that sense persuasive. There is some overlap with the product approach, then, at least when products and performances are socially judged. It is more of a social and attributional perspective, however, for the emphasis is on social reactions to creative work rather than on the tangible product. It does apply best to the highest level of creative activity, and especially the creative work of eminent individuals who are in a position to influence the way that others think. The persuasion perspective does not apply well to the creative efforts of individuals who are merely involved in self-expression rather than professional achievement.

One way to view the efforts that could be judged to be creative and thus are persuasive is with Csikszentmihalyi's (1990) systems theory. It describes how an individual may draw from an existing field and produce something of note. That may attract the attention of gatekeepers working within that same domain (e.g., architecture, mathematics, the visual arts), who change their ideas about what is useful and original. After a time, the entire field absorbs these new ideas, and they are no longer new and different but have become part of the knowledge base of the field. At that point, the ideas can influence individuals who are new to the field – and the cycle beings all over again. Clearly the first product of note, which got the cycle started, must be persuasive. Experts in the domain in question must attribute value and originality to it.

Hierarchical Theory of Creativity

An even newer and more dramatic restructuring of the original 4P topology was proposed by Runco (2007, 2008). It identified bridges and processes among the perspectives (e.g., creative processes required for creative products). It was a restructuring in that a hierarchy was formed. Several of the perspectives (i.e., products, persuasion) had assumed that creativity required a performance or manifestation of some sort (usually a product), while the others (personality, process, press) gave weight to aspects of creative potential. Indeed, the highest level of the hierarchical theory has two categories: creative potential and creative performances. Figure 1 presents a summary of this hierarchical theory.

The hierarchical theory makes assumptions about creativity explicit. It acknowledges that the things under creative potential do not guarantee actual productivity. It is practical in that it allows a discussion of the creative potentials of children, who are not productive and "persuasive," as well as the creative achievements of eminent individuals. It is a functional view, however, because it is easy to see how things representing creative potential might develop such that actual performance is likely. However, the actual creative performances are not always guaranteed. Then again, it could be that one of the attractions of the theory captured in Fig. 1 is that it points to things that can be encouraged (i.e., certain traits, supportive environments, divergent thinking) in order to insure that creative potentials of everyone – not just those already creatively productive – are fulfilled and creative accomplishment is highly probable. This would certainly be beneficial for society as a whole. There may be no greater benefit from creativity research than just that – the fulfillment of creative potentials.

Conclusions and Future Directions

Interesting new research is being conducted with all kinds of products of the creative process. There are studies of websites, for example, and even studies of culinary presentations. Personality research is also going strong, with a particular interest in self-efficacy as related to creativity. Related research is examining the role of values in the formation of the personality that is likely to invest in creative behaviors.

Future research should examine the hierarchical framework and especially its predictions about a separation of potential from performance. It would be enormously useful to be able to identify the kind of potential that is the most likely to eventually turn into actual creative performance. A related direction for research would be to find out what it takes to make the fulfillment of potential the most likely. Surely educators, parents, and managers would appreciate knowing how to fulfill potential! This is not to say that the original 4P framework is entirely outdated. Indeed, future research might use modern brain imaging methodologies in order to investigate the creative process. This has been the most difficult area to study because the process is a moving target, and a subjective one at that, but brain imaging might capture the workings of the creative process without stopping the flow. Clearly there is much yet to be done in studies of what is among the most important of human capacities, namely, creativity.

Freedom and Constraints in Creativity

John Haworth
Manchester Metropolitan University,
Manchester, UK

This entry draws on practice-led research by the author into creativity and embodied mind in digital fine art (Haworth 2010) www.creativity-embdiedmind.com. Freedom and constraints are central to the creative process in fine art. This is particularly the case where the making of fine art utilizes digital media. Large numbers of images can be taken with the digital camera, and the mobile phone camera readily facilitates recording the visual in everyday life. With digital tablets and artists' software, images can be manipulated in situ, if desired. Access to laptop and personal computers makes possible extensive rapid manipulation and exploration of the visual. This can be combined with additional visual material and text scanned into the computer. Outputs from digital media can be presented in a wide range of formats, including video installations, CD-ROMs and e-books, large format and small-scale photos, and prints, on a wide range of materials, which can also be combined with additional drawing, painting, and collaged material. 2D and 3D structures can be produced without the intervention of the hand by rapid processing technologies. This extensive freedom results in a wide choice in the creative process and the necessity for selection, which is significantly influenced by constraints based on personal, cultural, systemic, and social factors.

A significant factor in the interaction of freedom and constraints in the production of art work is the nature of the creative process. Scattered throughout the writings of Merleau-Ponty is an Embodiment Theory of Art, which he uses to support his embodiment theory of perception (Haworth 1990, 1997). This views the artwork as "enriched being" in its own right, as distinct from an analog for an external truth or essence, as traditional aesthetic theory claims. It proposes that this enriched being is not produced primarily by intentional acts, the traditional view, but by the reciprocal influence of consciousness, body, techniques, and materials. It "gives visible existence to what profane vision believes to be invisible" (Merleau-Ponty, "Eye and Mind" 1964a, p. 166). Merleau-Ponty (1964a) drew on the writings of modern artists and concluded that the painter's vision is not a view on the outside but a concentration or coming to itself of the visible (p. 181). He considered that works of art contain matrices of ideas that have their origins in embodiment (Merleau-Pony 1964b in Signs, p. 77). He also claimed "that modes of thought correspond to technical methods, and that to use Goethe's phrase 'what is inside is also outside'" ("Sense and Nonsense" 1964c, p. 59). As Merleau-Ponty indicates, we do not see the world but see with the world. In artistic terms, different media with which we interact have different voices which play a part in the creation of enriched being, perception, and consciousness.

Research conversations undertaken by Haworth (1997) using the perspectives of Merleau-Ponty were held with internationally famous artists in order to gain further insights into the creative process. The artists included the printmaker Michael Rothenstein, who can be considered a paradigmatic case for Merleau-Ponty's theory of art. They also included the conceptual artist Sol LeWitt, whose statements emphasizing the importance of "the idea" would at first sight appear to contradict this theory. An investigation of the working process of Sol LeWitt, however, shows support for Merleau-Ponty's theory, while also pointing to the importance of capitalizing on randomness. These and other "research conversations" undertaken by the author into the creative process in fine art support the view of cognition as embodied action and emphasize the importance of both pre-reflexive and reflexive thought in guiding action. They show a search for viable alternatives, rather than a search for the ideal, and an intimate reciprocal influence between the person and the artwork in the various ways of probing the environment.

Johnson-Laird (1988) argues that freedom of choice occurs par excellence in acts of creation, but that the set of choices is constrained, and that the paradox of creativity leads to the view that there are many criteria on which the creator must rely and that by no means all of them are available to overt inspection. Some of these are common to many practitioners and constitute the genre or paradigm. Other criteria are unique to individuals and constitute an individual style of thought within the more general framework. Merleau-Ponty (1964b) in his writings on the embodied nature of creativity and consciousness emphasizes that an artist's style is not something developed consciously in order to depict the world but is an "exigency that has issued from perception" p. 49. It is a personal system of equivalencies that the artists make for themselves for the work, which manifests the world as they see it: "it is the universal index of the 'coherent deformation' by which he (the artist) concentrates the still scattered meanings of his perception and makes it exist expressively" (Merleau-Ponty 1964b).

Practice-Led Research

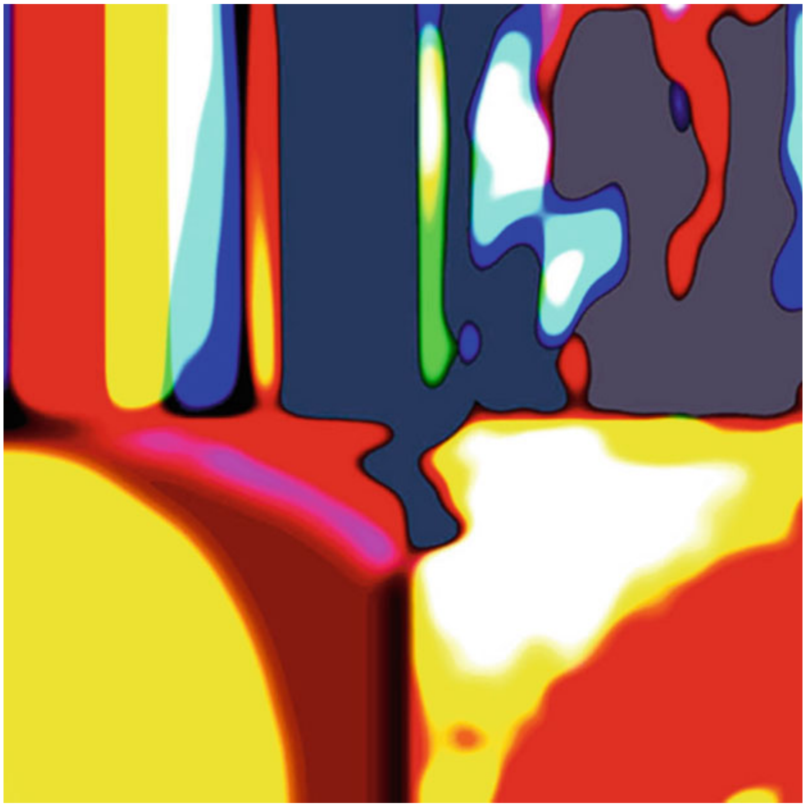
A project by the author combining research and practice investigated "creativity and embodied mind in digital fine art."

The project was funded under the Innovation Awards Scheme of the Arts and Humanities Research Board in the UK. It commenced in January 2002 and lasted for 1 year (Haworth 2010). The first person method of investigation used in the project was concerned with the practice of digital fine art printmaking, which at some stage in the working process involves the computer using Photoshop software, and in many cases commences with a photograph. The digital print medium, with its fine surface quality and potential to incorporate and transmute imagery, is particularly attractive as a conduit for the idea of the vibrant transience of reality. This is explored while probing the pixels and listening to the voices emanating from the medium. The resulting work shows the important interaction with technology in the way we see and portray the world. The prints also show an important influence of geographical place, culture, and events. The work has been exhibited internationally. Examples of the prints can be seen in the gallery at www.creativity-embodiedmind.com and www.absolutearts.com and on CD-ROMs deposited at the British Lending Library.

During the making of the prints, a log is kept of both the technical and thought processes involved. Notes are made on the interaction with the medium, and on the development of the work and emergent meanings, and reflections on the creative process. An account follows in relation to one of the prints (Fig. 1), as an example of the documentation undertaken, and an illustration of freedom and constraint in the creative process. A further print (Fig. 2) shows the potential of a personal body of art work for enhancing freedom of thought, stimulating innovative connections, and embryonic themes, though it is also recognized that routine themes can perhaps constrain creativity. Another print (Fig. 3) shows the value of an interdisciplinary approach to creativity.

This entry then addresses the interaction between freedom and personal, cultural, systemic, and social constraints noted in the introductory paragraph.

This print was made shortly after the tragedy of September 11th in the USA. However, it drew on elements which had been worked on before that date and imagery that emerged afterward. It is composed of four prints done separately but with an overarching concern about the vibrant transience of reality. The prints were fading edge, fragmenting edge, broken edge, and fallen square. Some of the material and imagery in these prints came from scanned textures and colors made using turpentine on printing inks on large pieces of paper, making marks with broad pallette knives. Other imagery was from the light of the sun setting on water on a harbor front, the surface of which was whipped by the wind. Some of the colors and lines came from front page pictures of the September tragedy. A previous edge print was about the contrasting sharp glow of life in the Arizona desert. The fragmenting square was in part about the breakup of this. When the four prints were put together and printed, the image



Freedom and Constraints in Creativity, Fig. 1 "Fragmenting Square": (90 × 90 cm on canvas and on paper)

looked uninspired compared with each of the individual images. The combined image was altered using the auto-levels and equalize functions, and the Gaussian blur filter which helped to combine and change some of the shapes, while at the same time integrating them. The contrast function was then used to reduce most of the blur, which seemed excessive in this print. Various areas of the print were then selected and colors changed. As is well known, the square has been an important element in the work of modernist artists searching for pure form and beauty and absolute truth and meaning. The postmodern age questioned the viability of this. September 11 saw further crumbling of the certainties. But perhaps the print contains delicate potentials for growth and relationships.

The print shown in Fig. 2 was made after visiting the Gerhard Richter retrospective exhibition at the Tate Modern and the occupation at St Paul's Cathedral in London. Photographs were taken of the occupation, which was protesting about inequality and the unfair way austerity was being implemented. The occupation was by people from different backgrounds coming together to discuss change. There were no set leaders, more a heterogeneous group. It followed similar occupations in different countries, including Tahrir Square. Another influence was a visit to Tenerife and an appreciation of the black volcanic lava which can help to sustain growth in the arid country and which is often formed in a circle with, sometimes, an outer band of lighter colored rock, the formation supporting a plant. Drawings of this and the circle at Tahrir Square were made, as well as shots taken of protests at the square shown on the TV. Fragmenting square hangs in the studio. Work on New Square was layered onto the digital image of fragmenting square, with different possibilities explored. Further explorations will be undertaken, in what could be an emerging theme. Interestingly, photos of the circular Large Hadron Collider are in today's papers 13 12 11 with news imminent of the Higgs

Freedom and Constraints in Creativity, Fig. 2 New Square 90 × 90 cm on canvas and on paper

boson and the implications for the origins of the cosmos.

"A day in the life of————" shown in Fig. 3 is part of a project on "The Way We are Now" combining the author's practice-led research into digital art with his research into well-being, funded by the Economic and Social Research Council in the UK www.wellbeing-esrc.com, Haworth (2011). This interdisciplinary work is an example of recent developments in art-science research in the UK, where artists and scientists combine to bring scientific insights to a wider audience, using the medium of art. "The Way We are Now" is a digital art work first presented at the 5th IMPACT International Print Making Conference in Tallinn, Estonia, October 2007. The conference had a concern with investigating slices of time and the production of political-poetic statements. The project used the mobile phone/camera to take a picture of what one was doing and answer several questions on subjective well-being in response to a signal preprogrammed on a random basis in the mobile phone, eight times a day for 7 days. Additional photos of events in the newspaper each day were also taken. The images for the 7 days were produced on a large format print on canvas. A paper on "The Way We are Now," including the image, can be downloaded from the websites at www.haworthjt.com. Prints could be produced for each of the four seasons. "A day in the life of———" is 1 day from a 7-day print. An innovation is that the answers to the questions on subjective well-being are color coded and shown alongside each image. "A day in the life of ——" with instructions on how to undertake the project, and the color codings, was shown in a gallery of art works specially curated to accompany an international conference on "Towards a Science of Consciousness" in Hong Kong 2009. The project could be undertaken by different size groups, locally (Kellock et al. 2011), regionally, nationally, and globally, and made available on a dedicated website, and shown in exhibitions,

Freedom and Constraints in Creativity, Fig. 3 "A day in the life of———" 60 × 163 cm on paper suspended from wooden poles

to produce a social mirror of consciousness. Some work along these lines is now being undertaken by other researchers and by the BBC.

The practice-based research making many digital art prints shows that the process of exploration with the computer generates and reveals possibilities and visual experiences, as well as speaking to initial expectations. The process of exploration becomes a vehicle for seeing which is influenced by the technology. Visual explorations undertaken with the computer can influence what one "sees" in the world, what comes into focus, and what demands attention, influencing what is recorded experientially, mentally, and digitally. In turn, this influences further explorations with the computer. Artistic vision is constantly reshaping itself in interaction with the world, including technology, geographical place, culture, and events. As cognition and emotion are intertwined, feelings influence seeing, as well as the reverse. Expression is also influenced by the tools and techniques that are available, and with the interaction with materials, with different potentialities and "voices" emerging.

As variations on images can be produced extremely rapidly in digital art, selection is necessary. This can involve a "feel" for the image, against an overarching concern, which itself may have taken years to emerge and be still unfolding. It generally involves a deep knowledge of the art world. The artist is situated in a tradition of art, which influences perception. It influences the way we see things and the possibilities we have for expression. Any artwork is influenced by a conscious awareness of tradition, even if it is fighting against that tradition. These potentialities are both informed and appraised by communities of practice. Thus, both "actor centered" and "veridical" decision-making are intertwined in the process of selection.

As part of a further Arts and Humanities Research Board award for practice-led research, a workshop was held on "Freedom and Constraint in the Creative Process in Digital Fine Art," Haworth et al. (2005) (see also workshop 2 at www.creativity-embodiedmind.com and Haworth (2006)). The workshop was attended by internationally known British artists and academics from different disciplines. Papers presented at the workshop showed that:

- Computer-aided art manifests a diversity of practice, in which the fusion of thought and action is critical to the creative process.
- Technology influences perception and thinking, while at the same time concepts, ideas, and feelings influence the use of technology.
- In the use of technology in the process of making art, many unexpected effects can occur. These can be critical to the creative process, enhancing freedom of choice. In turn, however, choice can be tyrannical, if it is not embedded in constraints, which may originate from the individual, group, and society.
- Advanced technology is leading to the emergence of a tacit digital creative practice and a nurturing environment.
- Dynamic interactive techniques enable the viewer to have an active role in creating or changing the art object.

In line with new conceptions of what it is to be a human being in the world, and how we come to understand things and act in innovatory and creative ways, the workshop emphasized that creative thought can be largely unconscious. Also, that creativity involves the interaction of thought, body, techniques, and materials. The importance of bringing tacit knowledge into visibility was recognized.

In a systemic view of creativity, Csikszentmihalyi (1988) argues that creativity is the product of three main shaping forces: a set of social institutions, or *field*, that selects from the variations produced by individuals; a cultural *domain* that will preserve and transmit the selected new ideas or forms to the following generation; and the *individual* who brings about some change in the domain which the field will consider to be creative. Abuhamdeh and Csikszentmihalyi (2002) consider that the *field* has a perpetual need for novelty and that as a result the field's aesthetic preference is guaranteed to change constantly. The field includes all the individuals who act as gatekeepers to the domain, including art critics, art historians, art dealers, art collectors, and artists. Arguably, digital art and its practitioners are expanding the range of ideas and forms considered acceptable by the field, while at the same time broadening and democratizing the field (see Paul 2004). It can also be added that social factors, including government policies and funding, also have a significant influence on both the field and the freedoms and constraints influencing creativity, such as education, training, and access to resources.

Of course, the field is not a unified whole. There are separate overlapping divisions. In the Manchester Buy Art Fare in 2011, one floor containing many galleries from around the country showed primarily works of art done by the hand, including paintings, drawings, and some non-digital prints. On the floor above, the Manchester Contemporary hosted more conceptual and digital art. An artist has the freedom to chose fields or, as is increasingly being done, combine traditions. But there are constraints of what feels right, of what sells, and of who art is for.

Conclusion and Future Directions

In conclusion, it can be seen that there is a complex interaction between freedom and constraints in creativity, involving personal, technological, and social factors. The enhancement of invention and innovation requires cognizance of all these factors and a consideration of who innovation is for.

From Personal to Impersonal Exchange in Ideas

Eskil Ullberg
Interdisciplinary Center for Experimental Science, George Mason University, Fairfax County, VA, USA

Synonyms

Development economics; Economic development; North–south economic integration; Patent exchange; Patent markets

Introduction

Technology – human ideas on using the laws of nature – has always been at the heart of economic development. With the patent system, first introduced in Venice in 1474, technical ideas became tradable in their own rights. Such exchange promises gains in impersonal markets based on the patents, changing the economic organization and structure, and shifting the risk bearing and risk sharing between specialized firms for invention, intermediary trading/investment, innovation, and customers, resulting in a potentially more efficient sharing of risk and thus potentially a more performing economic system.

The topic discussed here are mechanisms and contracts for coordination *between* hierarchies, rather than *within* hierarchies, based on the patent system as an exchange system. Government subsidies and secrecy are replaced by *markets* (using excluding and transferrable rights for economic gains through private investments) and *openness* (publication of the ideas for social gains) as policy, by the use of the patent system, providing private and tradable property rights on the ideas themselves. The performance and behavioral characteristics of such markets in patents with prices are elaborated upon with reference to experimental economics studies. The entry outlines the general economic proposition and discusses such exchange markets, based on principles and practices of the patent system and individuals, firms, and nations exchanging technology based on the patent system.

The first section deals with the economic history of the patent system (productivity). The economic principles (exchange) that it was built on and its impact on economic structure (specialization) then follows. Finally, emergent and experimental impersonal exchange mechanisms (coordination) are discussed.

The Patent System as a Trade System

Technology has always been at the heart of economic development. This knowledge has been kept private by a variety of means throughout history, but through the patent system, technology has become *tradable* in its own right. An excluding and tradable asset – a private property right on an idea to solve a technical problem – is created that opens for a market in technical ideas, a process that has been going on for more than half a millennium.

The theme here is the transition of trade in technical knowledge and ideas from a *personal* exchange of know-how, trade secrets, etc. to an *impersonal* exchange of patents in organized markets with transparent prices. This is thus a political economic problem. The transition has today reached a stage in which patents have become similar to physical assets with respect to validity, tradability, and geographic presence. This transition has an increasing impact on general economic activity, given the key importance technology has for economic development. The more tradable intellectual property rights (like patents) create the foundation for efficiency gains which are at the heart of economic activity. Similar gains from specialization to those of industrial products and services can be expected. The mechanism described is thus a *producer* market in patent-protected technical ideas used (or not used) in new products and services in the *consumer* market. There are three values to be concerned with here: technology value (personal exchange), patent value (impersonal exchange), and consumer value (product and service exchange).

Patents are tradable private property rights on technical ideas. Patents are granted by the state and give the holder excluding, transferrable and licensable rights for *technical* ideas in exchange for disclosure of these ideas through publication. Recently in the USA, nontechnical ideas related to business processes have also been granted patents. Other intellectual property rights have similar properties for other ideas, such as copyrights, trademarks, etc. There are currently seven intellectual property rights granted under the World Trade Organization (WTO) agreement on Trade-Related Aspects of Intellectual Property Rights (the TRIPS agreement): Copyright and related rights, Trademarks, Geographical Indications, Industrial designs, Patents, Layout designs of integrated circuits, Protection of undisclosed information. (In addition, provisions for national control of anticompetitive practices in contractual licenses are granted, to stop practices that may have adverse effect on trade and impede transfer and dissemination of technology.)

However, the standard literature on the economic analysis of patents has mostly been based on the *products* and expressed in terms of divergence between social and private gains

(Arrow 1962; Plant 1934; Nordhaus 1969, 1972) or increased return from international trade in products (Krugman 1990; Schumpeter 1934). In the standard analysis, patent rights on technology are mostly treated as product monopolies. However, there is a lot of different technologies, public and private as well as hundreds or thousands of patents from tens to hundreds of inventors/owner that go into a *single* product or service today. This takes the discussion of a product monopoly far from the core of the economic process at hand: creating new technical solutions, and combining it with extant technology that typically come from different sources, creating a coordination problem.

Such an analysis, based on *monopoly* pricing of *products* (product value) – which is a *static* analysis based on monopoly theory assuming perfect information and has no institutions – may miss essential gains from a patent system coming from the *dynamic*, and often highly *competitive* exchange in technology, between specialized agents trading the *patent rights* (technology value), and may lead to results that exclude trade aspects of technology altogether.

The results of exchange in ideas between agents, on the other hand, may then result in:

(a) The *risks are shifted* from the inventor toward the innovator (and ultimately the consumer) when competitive demand-side bidding is present. Such shift results in a more competitive technology market and thereby technology-based economic growth.
(b) The *dynamic* market efficiency (as measured by the use of technology by innovators) is likely to increase when demand-side bidding is present due to the dynamic value of the patent system.
(c) *Coordination* through price signals would guide the investments in new technology areas. This view means that the demand for new technology, due to need for productivity increase, in turn creates demand for research (not the other way around). North (1981, p. 17) comments "one can view the expansion of basic knowledge as a derived demand for technological advance". The contention in this entry is that it is very difficult ("impossible") to dynamically efficiently allocate resources for invention and execute the allocation of a patent right under real world conditions in a *linear* fashion without a market, thus trying to explain the key role of the patent system in this coordination process. There are simply too many combinations. The role of the patent system thus plays an important role in coordinating the ideas of the world in a market. Krugman (1985) contends that supply side investments in technology (by governments) – thus a linear approach – may simply lead to excess capacity and disappointment. The problem of comparative advantage between nations when it comes to technology (knowledge) may therefore be solved through markets in ideas with demand-side competition, expressing their expected values ultimately through prices.

The economic relevance of these arguments is shown in two controlled laboratory experiments exploring the performance and behavioral properties of markets in patents (Ullberg 2011).

The Economic History of the Patent System: Productivity

Intellectual property and technology in particular have always been at the center of economic development. Technological progress is considered by many sociologists, and economic historians and technology historians, the single most important factor that has raised the standard of living for mankind (Leslie White, Gerhard Lenski, Alvin Toffler, others). Such knowledge has been protected for private use through a variety of means of nondisclosure throughout history, such as guilds, trade secrets in firms, vertical integration, explicit nondisclosure agreements, joint ventures, mergers and acquisitions, and classified military secrets. Guilds had private rules to pay for inventive activity within the community with royalties on their use to keep the art private within that "industry." As firms became organized (hierarchy), they began remuneration of in-house inventors. But through the patent system, technical has become tradable, impersonally and in its own right. The development of the patent system has taken place over a period of more than 530 years, beginning in Venice in 1474.

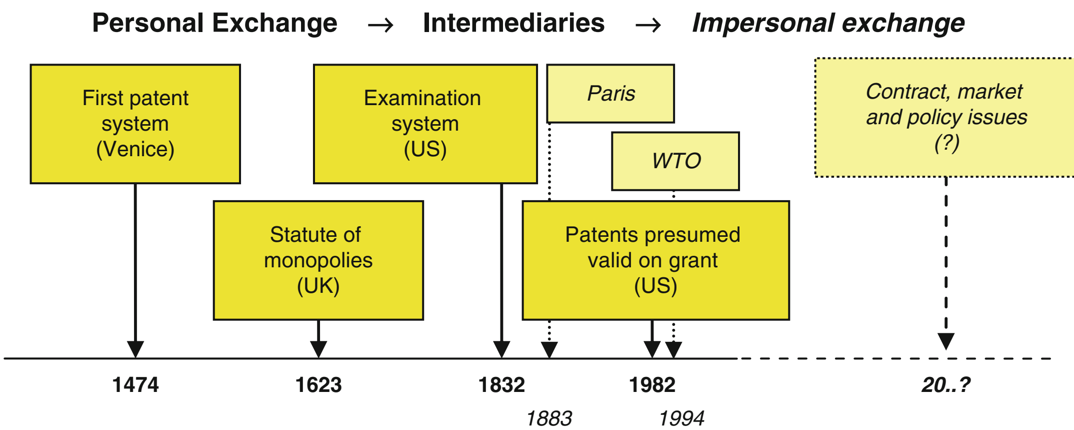
This step was thus preceded by the guilds system and other ways to keep knowledge private. An even earlier step is claimed by Kaufer (1989, pp. 1–2) to be a change in view in society of *manual* labor, during the early Middle Ages (520 AD-), from "not deemed worthy of educated men" to "manual labor as cooperation with God in the task of creation." Kaufer continues: "In the Middle Ages, the pace of technological change accelerated dramatically. Italian cities like Florence, Lucca, Milan and Venice became leaders in artisan production. However, secrecy, often enforced in the Italian city-states by draconian penalties, was used to protect technological advantages and avoid the disclosure of important know-how. This propensity changed with the emergence of a patent system." The recognition of the rights to intellectual work that was made in the fifteenth century – 950 year after manual work was considered worthy of educated men in Europe – appears to have opened the way for a *policy* on impersonal exchange in technical knowledge.

These initial "industrial" patents can be seen as issued to attract, i.e., *import*, technology for the benefit of economic development of the city and later nation state. The value was in the manufacturing of the inventions. This appears to be a *political economic* motivation. Venice had lost trade (years before fall of Constantinople in 1453) and needed to renew economic development. These patents spread north and in the UK were often sold or given to "the friends of the king" (Klee 1998) who traded them in exchange for market access to the UK for often *imported* manufacturing technologies. In 1623, in the UK, the crown's "industrial" monopolies were abolished after government abuse (using sale of monopolies to fund wars with France) and replaced by 14-year patents for product and process inventions, limiting the scope of protection from manufacturing areas to a much narrower product or process scope (de facto importing technology and exporting products). The parliament now controlled the issue of patents, not the King. The UK transition to a patent system can be seen as a battle of who should decide on what patents to be granted. The patents should also be given to the "true and first inventor," thus the originator of the idea, not the "importer" of the idea. The concept of "honoring the inventor" of 1474 now appears to be expressed in more stringent terms.

This step probably also introduced "blocking" as a strategy as competing technologies were developed. Another motivation across Europe was, according to some, to bring out technology from the guilds (who developed much of the technology in preindustrial Europe and much opposed the development of a patent system) and make the technical knowledge more useful to society by making it more public (through disclosure) and keeping its ownership private at the same time (giving excluding rights to inventors). The UK patent law is also the model of US patent law. In 1836 in the USA, examination was "invented" and patents were granted with presumed validity and in 1982, also in the USA, the benefit of the doubt was given to the inventor, the agent taking the risks. This last step turned patents into assets much like physical assets with respect to legal validity and tradability, starting what is now commonly referred to as the "Pro-Patent era."

When patents are granted by the patent office, they are only *presumed* valid. They can always be challenged in courts and *deemed* valid (upheld) or invalid (invalidated). Until 1982, the burden of proof was on the patent holder when a patent was challenged, giving the benefit of the doubt to *society*, but after 1982, the benefit of the doubt was given to the *inventor*, making the patent a much more asset-like *private* right.

On the international scene, the Paris convention from 1883 opened for international protection of patents and processes under non-discriminatory terms (national treatment) and giving the inventor a 1-year priority to file internationally (from date of invention/filing), expanding the *export* of patented technology, initially often accompanied by manufacturing ("foreign direct investments"), and in 1994 through the TRIPS agreement by WTO, minimum standards for patent protection were set



From Personal to Impersonal Exchange in Ideas, Fig. 1 From personal towards impersonal exchange in patents

for member countries, including provisions for transfer and licensing of patents, creating provisions for a global exchange in technology.

Regional and global harmonization attempts are the Patent Cooperation Treaty (PCT), the international filing system run by the World Intellectual Property Organization (WIPO) in Geneva, and the European Patent Convention (EPC), the European filing and granting system run by European Patent Office and Organization (EPO). The PCT has recently adopted provisions, making it one step closer to a global patenting system by amending Chapter II. PCT was originally thought of to be an "extension" of the Paris convention. In the end, all patents are still national or legal equivalents to national patents.

There are increasingly calls for global harmonization of the patent system. This may create a "one size fits all" patent system, asking nations to give up national sovereignty over patentability to a world economic organization. It may be preferable from an institutional learning and economic efficiency point of view to have, at least for now, competing national/regional systems. Competition means that certain economic qualities may develop better (such as exchange). This does not mean that the *procedure* has to be that different but that certain provisions are made for countries with national competitive advantage in certain areas. This is in any way how the system has been used historically. One can compare it with the international monetary system in this aspect. The trend, however, is clearly toward harmonization, especially since the TRIPS agreement. Legal harmonization was tried before 1883 but a system of *principles* of national treatment and priority year was put in place instead. At some point, a world economic standard may be useful on patents.

A central theme in the development of the patent system can be characterized as moving from a *personal* exchange (secrecy, guilds, joint ventures, etc.) toward an *impersonal* exchange of technical knowledge by means of developing more asset-like and internationally valid patents. The risk in such transactions is thereby reduced – through proper integration of information and rules in institutions with good governance – and incentives for trade are created. Efficiency gains can be expected from such impersonal exchange. See Fig. 1.

This long history and acceptance in a majority of nations makes the patent system one of the more global economic systems today, and least regulated from a trade perspective. Most recently, there have been calls for a global patent system (harmonization) from industry and WIPO and for patent reforms in many countries, including the USA. However, competing systems may foster better economically viable patent systems over time than a standard set by administrators from essentially the developed nations. The general theme now seems to be adaptations for a more standardized way to deal with patents in a global economy, a key issue being to keep the incentives to invent and trade technology with the developing nations, thus preserve property rights for a competitive market in new technology expanded to North–south exchange.

The Economic Principles of the Patent System: Social and Economic Exchange

A Market Exchange

The patent system includes both a *social* exchange mechanism, through its public disclosure of the invented technical solution, and a *market* exchange mechanism, by receiving an excluding and transferrable right to use that idea for a limited time.

With respect to market exchange, the patent systems of today typically give the holders these two rights: the right to exclude and to transfer or license that right, creating the fundamentals for a market in ideas. These rights are thus transferrable for the holder and limiting action rights for others. In statute law, Intellectual Property Rights, of which patents are one of today seven (in TRIPS), are construed as a "chose in action" which differ from physical assets which are construed as a "chose in possession." However, Coase's view that physical property rights are really a bundle of limiting action rights (". . .a right to perform certain (physical) actions.," (Coase 1960), p.44) suggests that there may be some important similarities in the economic value between these two assets.

The excluding right also gives the patent *two* strategic values: to exclusively use the technology in new, better products and services for a competitive advantage when compared by the consumer with alternatives not having these features or efficient processes, or to block others from using the competitive technology by "sitting on" the contract and instead using existing technologies of the firm. These values will be referred to as the *investment* value and the *blocking* value. Here a dynamic is introduced that appears not to be captured in the neoclassical product monopoly (the competitive selection, allocation, and exchange process of technical ideas appear not to be included, at least not explicitly).

These rights are today used in very sophisticated and strategic ways: to exclude others, to collaborate by cross-licensing portfolios of technology, to collaborate in global standards, to license for money, etc. Thus introducing exchange in technology through intermediary of monetary and financial markets. This allows extending the number of people and firms in the cooperation, thus potentially increasing the value from exchange in the ideas themselves.

Since scientific and technical research is a global activity since some time, manufacturing is almost global and product and service markets are becoming global, protection of new ideas is often sought where there is *competition* in research, manufacturing, or sale of products/services. The system is used to protect the coordination of activities performed in different nations, making use of national competitive advantages. This means that not only the main developed economies are critical for protection ("the West"), but also the developing economies where much manufacturing and also increasingly research is done and soon the least developed economies who begin to put an emphasis on education and property rights. The key issue then becomes *market access* for research, manufacturing, and sale of products/services. Patent active companies create portfolios of patents which they trade with other firms, for example, in manufacturing countries for market access in other countries through licensing, cross-licensing, etc.

Patents are in this aspect similar to other rights and assets that create market access. Today, for all practical purposes, a single product contains hundreds or thousands of patents, creating more of a competitive market for *technology* than anything close to a monopoly. For example, a car may contain 20003000 patents from 200-to 300 *different* patent holders (Source: EPO). A smartphone may contain 250,000 patent claims which may represent tens of thousands of patents from hundreds of patent holders. (Source: public news sources.) Such a fragmented patent landscape also creates a complex combinatorial problem to obtain access to a complete "technology portfolio" that is practically useful in a product. The latter problem is a market organization problem.

The lack of exchange mechanisms for these valuable and dispersed rights may also be a driving factor to try to develop mechanisms for exchange of quality patents. In the telecom business, where interoperability is a key, international standards are negotiated and when including patents (because patents are by definition state-of-the-art and therefore helpful in getting acceptance for the standards), patent holders must sign off their rights under "Fair, Reasonable, And Non-Discriminatory" terms (RAND or FRAND). These kinds of problems are described, for example, by Heller (2008) in Gridlock economy. An answer may be combinatorial auction markets to recombine "too narrow" rights in useful blocks. A characteristic of this development is therefore the use of the patent system for strategically using or blocking competitive market access.

A Social Exchange

The patent holder still has to pay for the right like in the early days. Firstly, inventors "pay" by disclosing the invention at a level such that a "man skilled in the art can reduce it to practice" (Typical patent system criteria for disclosure of inventions). This informs everybody else about where the company is going with their products (it takes time between invention and production). This "social contract" is a key incentive to further research by "teaching the world" about the inventions. A more subtle side of this is that by seeking patent protection you are also disclosing what *problems* you are working on as a firm which may reveal a future strategic positioning, making the timing of patenting a rather difficult issue.

However, such information obtained through disclosure data also informs competitors and research organizations where *not* to put their research money and therefore directs the research in *other* fields, an alternative to head-on technology competition. The social exchange thus has a coordinating function for research as well, driven by the economic potential of creating a competitive privately held technology. If commercially successful or not, it will be known in due time. Others may then try other areas with outcome observed. There is thus a possibility for one company to intentionally try a new field for the benefit of others – there may be something out there for everyone – hoping that others will reciprocate later, competing and cooperating at the same time. (This is not to be confounded with a joint-venture type of research effort). This may be seen as a *social exchange* among inventive companies made possible by the patent system.

As mentioned in the previous section, making private technology publicly known was also a motivating factor behind the patent system. Today, the publication system of the patent office (after the 18 months) allows for public information about patent applications, grants, and expired patents to be accessible by all. The patent products are therefore publicized by the state.

A possible R&D agenda for companies with respect to patents is therefore: (1) learning about technology through disclosures and staying out of infringement claims; (2) using expired technology and getting new ideas; (3) developing new ideas into their own inventions; and (4) protecting and using them for products or trade.

However, research indicates that about 50 % of ideas are protected by trade secrets (keeping the ideas private) and roughly 30–35 % are patented, making trade secrets still the most common way to protect ideas (EU Project research report).

Secondly, there is a fee to the patent office (the state), typically starting low and growing exponentially, allowing the inventor to pay if the invention is successful or drop it before any value has been realized.

In the USA, a fixed fee has been used but the fee structure is under change to a system more like the European exponential fees. These have the advantage that commercially viable patents are often renewed and other patents dropped. This has resulted in an *average economic life* of European patents of about 7 years (around 2005), far from the 20 years of *legal* life. The exponential pricing means "subsidy" of short lived /poor quality patents by longer-lived quality patents, an issue of interest for competition authorities.

This fee was originally given by "the friends of the king" to the king but now typically goes to the patent office (often ministry of justice or commerce) or directly to the treasury, often generating a revenue to the state. There is thus a financial incentive for the state to have quality patents, which are used for a long time. There is also an incentive for the inventor to reduce time to market (or the blocking right) not only for the limited time a patent is granted but also for the increasing renewal fees. The successful inventor then still "gives back" some of the profits to the state.

The scope of claims in one patent differs between systems. In the USA, many claims are allowed for one invention, whereas in Japan, only one claim is allowed per patent. This makes US and EU patents broader and, if upheld, powerful, whereas Japanese patents are weaker. The distinction is a result of an ongoing debate on the scope of a patent. Broad patents may lead to more risk-taking and investment in radically new ideas, whereas narrow patents may lead to smaller "inventive step" in the patents. See, for example Nordhaus, others. A resent short study by Crouch (2008) shows that the complexity of the applications is increasing in initial claims and total claims measured by issued claims.

These rights and obligations refer to the two parts of a patent: the disclosures (description of the invention) and the claims (list of granted excluding and transferrable rights). The patent system can therefore be considered an *exchange system* between inventors (information) and the state (money). This makes the patent system a complex policy issue and in a market analysis as in this case, the patent system becomes an agent (a legal environment).

The Economic Principle of Trade in Technology

The principles have thus remained more or less the same for the 530 years since its legal conception, but the Crown is now replaced by parliaments, broad "industrial" privileges replaced by narrower product and process inventions given to individual inventors or assigned to firms (after some compensation) and "unlimited" or variable temporal rights, largely with a standardized time period of 20 years.

An important characteristic of the historic narrative – briefly presented here – is that the development of the patent system appears to have been motivated by trade in technology. This motivation is different from the motivation referred to in most economic textbooks of creating incentives for *inventions* in a closed economic environment (Plant, Arrow, Nordhaus, et al.) without including national comparative advantages (as Richardo, Hecksher-Olin, et al.), economies of scale (as Krugman, et al.), or other motivational factors of trade. According to Plant, the patent system as such lacks theoretical economic principle (Plant 1934, p. 51), simply creating scarcity, but looking at the system as an exchange (trade) system introduces the *economic principle* of trade and specialization as a motivational ground for the patent system.

In summary, the intention appears to originally have been to attract inventions made *elsewhere* and *import* them to Venice to further economic development there. The first patents were related to water pumping, a German mining technology imported to Venice for use in mines on the main land controlled by Venice (Kaufer 1989). Later on, the international system (1883) allowed for export of patent-protected products, thus, *import* of technology for the receiving country, leading to economic development through, among other things, foreign direct investment. This appears to be the same mechanism at play as in Venice but at a product and process level.

Litigation or Cooperation

Negative effects of this kind of trade have also developed. Since 1982, the rights have become more valuable as the burden of proof changed and infringements leading to litigation became costly. The average court settlement was around $m1–2 in the 2000s.

This has led to the emergence of a "patent market" in litigation. In this market, the judges set the prices. In order to avoid litigation, licensing agreements are increasingly made as out-of-court settlements under the threat of litigation costs (and/or uncertainty outcomes). Such settlements may "crowd out" smaller inventors as court costs literally explode. This can be both a good and a bad development. So-called patent trolls amass patent portfolios secretly and then ask for licensing fees. The good part is that users are more careful with what technology is used, but the inventors must be able to defend their newly acquired rights.

The rights have thus become tradable and the licensing has allowed gains from specialization to emerge. One example is the university and (small) business patent collaboration (the Bayh-Dole act in the USA). Other examples are technologies such as IT and biotech where technology is often developed by smaller companies or specialized research centers and development by patent portfolio holding "marketing" companies. A broadening of patentable subject matter to nontechnology (business methods) has also been made, primarily in the USA. One motive has been to give protection for new non-technologies such as financial "technologies" and software. This is a very contentious issue and may well be reversed back to technology, the original patent system idea.

The change in the presumption of validity appears not to have been followed up by a legal procedure to give incentives to negotiate but to litigate.

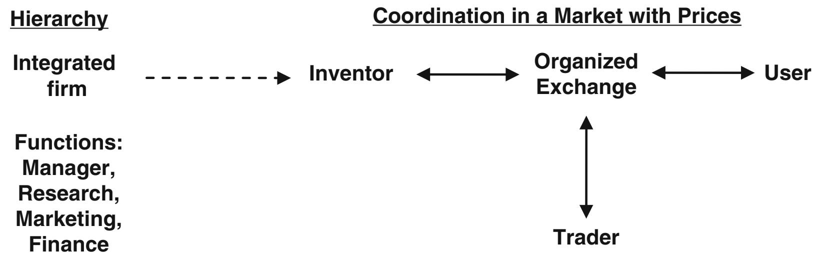
The Economic Structure and the Patent System: Specialization

Economic Organization and the Patent System

The development of the patent system as a trade system has given rise to specialized agents for different economic activities related to using technology, which is a *dynamic* economic change. The principle of personal exchange is here at work: the economic organization changes. After the 1836 patent reform in the USA, the possibility of impersonal patent trade led to a rise in *specialized inventors* and market trade in patents, facilitated by *specialized patent attorneys* acting as intermediaries in this market (Lamoreaux and Sokoloff 1999, 2001). However, after some time, the integrated hierarchical model dominated. The reason why mergers and acquisitions dominated as an innovation strategy for the first 150 years is likely to be a problem of: (1) transaction costs favoring M&A strategies; and (2) the way the patent system claims are organized, i.e., how the rights are construed, affecting the success of the underlying principle of tradability. It seems the patent policy focus has been on granting patents on technology and possibly less on the economic use of patents for trade. A shift to a "patent trade policy" may be economically efficient, facilitating the "trade value" of the patent system to be realized. Since the 1982 changes in the USA, when the legal validity and possibilities to litigate patents increased drastically, patent licensing has literally exploded and today accounts for up to \$0.5trillion in the USA, and \$1trillion in IP trade (including patents, copyrights, etc.), which is about 1 % of the USA's total trade in products and services. (See, for example, U.S. census bureau on international trade and licenses and www.inventionstatistics.com on US patent licensing.) Similar developments can be seen in other countries. The specialization enabled by the patent system has gradually changed the business model from the *hierarchically* integrated firm as basis for economic organization *toward* a business model in which specialized agents coordinate their activities through a market ultimately with *prices*. See Fig. 2.

Such trade and specialization in patents described in the previous sections clearly give reason to believe that there are also essential gains from trade in technology made possible through the patent systems. The development of the patent system to make patents more tradable like physical assets is thus resulting in a *reorganization* of the economic activity at the core of the economy.

Assuming the historic importance of technology to economic development, any changes in gains from trade in patents with respect to this "new" economic organization will therefore "multiply" into the whole economic system. Baumol (2002), Schumpeter (1934), and others contend that the greatness of the capitalist system lies in its incentive to create inventions. Several attempts in the last 10 years have been made to trade patents in more asset-like markets like



From Personal to Impersonal Exchange in Ideas, Fig. 2 Change in economic organization using a patent market

patent auctions, but to date, no organized markets with transparent prices similar to the impersonal trade of commodities in commodity markets and shares in financial market have emerged. An important reason for this market failure is that it appears to be difficult to find ways (rules) to create efficient trading – it has to reduce the risk the interaction between firms.

At the heart of the development from hierarchy to coordination in markets can therefore be seen the patent system's ability, as an institution, to *reduce risk* in the system in trading technical knowledge and the *dynamic efficiency* of the mechanism designs for such markets.

Impersonal Exchange Mechanisms for a Market in Patents with Prices: Coordination

In the previous sections, it was shown how the patent system gives economic incentives for a shift from personal to impersonal exchange in technology through the dual rights of exclusion and transfer which leads to a new economic organization of specialized agents. The coordination in a hierarchy (firm) is (gradually) replaced by coordination through a market (institution) with prices.

In this section, I propose to present key real world considerations placed on a dynamic microeconomic system design.

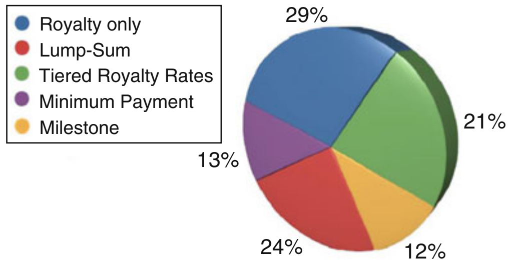
The focus on transparent prices and coordination makes the emphasis on factors important for increasing dynamic market efficiency. Since the *contract* used to trade and the *mechanism designs* (rules) are key factors in obtaining market efficiency (or contributing to market failure), these will be discussed first. In this case, a more subtle aspect is also how the patent system itself is important, how the rights are *construed* and *granted*, and how the *validity* of patents is realized. One could say that the contract between the patent holder and the state is *incomplete* upon grant. See (Hart 1988), others on incomplete contracts. The *intermediaries*' role (traders) in creating the dynamics is also discussed briefly.

A Linear Contract

To capture the dual values of the patent, the blocking value and the investment value, I propose using a *linear contract*. (There is a rich literature on linear contracts. Basically these contracts are contingency contracts on, for example, revenues.) There are two reasons for the choice of linear contract. Firstly, the linear contract is a common contract that is used in today's *personal* exchange. It is difficult to get access to pricing information on patent contracts but one source of data on patent licensing contracts informs that 50 % of contracts are linear, i.e., there is some fix component such as a lump sum payment combined with a royalty component on revenues in unit or dollar sales (Royalty Patents Inc, in Washington DC). See Table 1. This suggests that in half of the cases, there is an incentive to give a fixed payment upfront and in others, not. There appears however always to be a royalty. They are only in 50 % conditional on "signing" for the royalty part sometimes conditional (milestone). In other words, risk sharing is always present but risk transfer only in 50 % of the cases and then sometimes conditional (milestone). The typical transition from personal to impersonal markets often follows, when it comes to the contract, the contract already used in the personal

From Personal to Impersonal Exchange in Ideas, Table 1 Types of payments in patent agreements

Royalty only	50%
Royalty only	29%
Tiered royalty rates	21%
Fix payment and Royalty	50%
Milestone Payment	12%
Lump sum payment	24%
Minimum Payment	13%

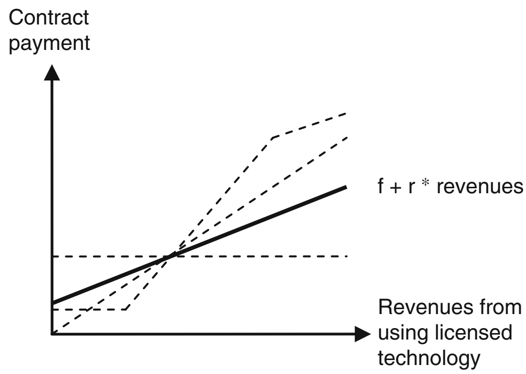


exchange. The NY stock market is an example here and commodities markets. However, there is at some point an agreement, or standardization, upon what kind of contracts that can be traded. This agreement is an important factor in creating efficiency and transparency.

The Linear Contract and Risk Sharing

Typical linear contracts studied in the literature have followed similar functional characteristics with input from fields other than patents. These contracts allow for a royalty to kick in at a certain level (minimum volume), tiered (different royalty rates given the usage/volume), flat fee, flat royalty, or a strict linear combination (minimum payment). See Fig. 3. It is the simple linear contract that is chosen in this study to capture both a fix (minimum) and a (constant) royalty payment.

With reference to Arrow (1962), a fix-price market is used to *transfer* the risk and separate derivate markets, one for each state of nature, are used to *share* the risks (Arrow-Debreu securities). The linear contract *combines*, in one contract, what the functioning of a fix-price transfer market and derivate markets for each and every state of nature do to achieve optimal allocation of risk sharing *and* risk bearing in the economic system. In the proposed study, risk transfer and risk sharing are thus negotiated in the same contract, reducing the number of markets needed to one.



From Personal to Impersonal Exchange in Ideas, Fig. 3 Different types of linear contracts

A Linear Contract Mechanisms

Mechanisms to trade such a linear contract are in the beginning of development. Similar contracts appeared at the heart of "the marginal cost controversy" where Coase (1946) suggested that an optimal system of prices may not be a single price per unit but instead a multi-part system of pricing. This approach goes hand in hand with the observations and discussion regarding an optimal pricing system for technical ideas based on the patent system.

Conclusions and Future Directions

The transition of exchange in technical ideas has come far in the first 500 years and attained an important role in coordinating firms, universities, and inventors in their pursuit of technical solutions for increased productivity. The impact of the patent system is now approaching the doorstep – it seems – of organized exchange in ideas. Advances in mechanism and contract design may be what are needed to make such organized markets efficient enough as a system of pricing for technical ideas.

Game theory; Innovation; R&D

Definition

Game theory is a mathematical approach to the modeling of strategic interaction among independent agents that recently become one of the most powerful analytical tools in economics, especially in microeconomics and industrial organization. In particular, game theory, among other applications, offers a way to formulate predictions, delivers prescriptions and recommendations for decision makers, and helps to develop and implement efficient strategies.

The Levels of Game-Theoretic Analysis of Innovation

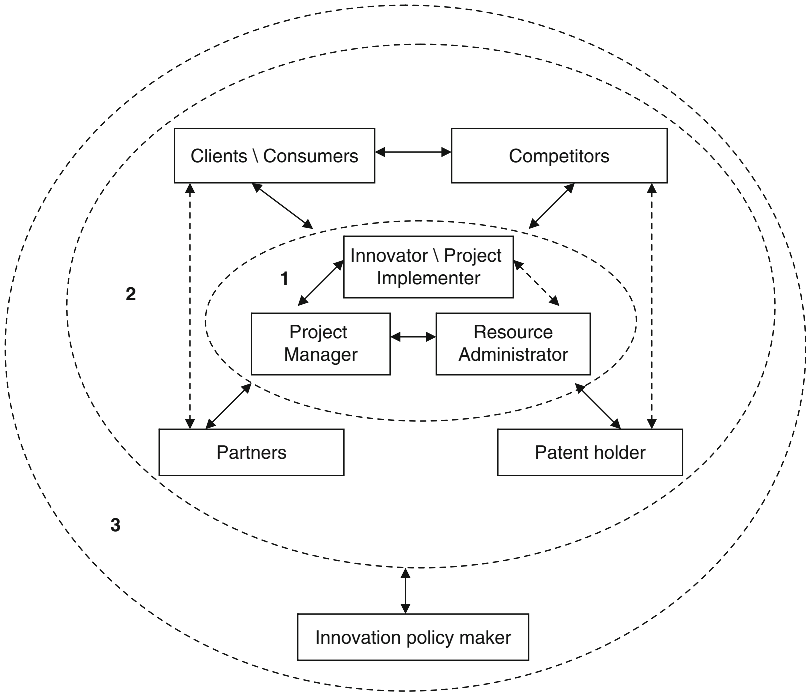
The main directions of game-theoretic analysis of innovation can be divided into three levels of innovation interactions or three types of innovation games:

1. Intraorganizational game, which is played within a firm; in this game, main players are an innovator (idea generator, project initiator or implementer, etc.), a project manager, and/or resource administrator.
2. Interorganizational game, where the main players are a firm, its competitors, its partners (e.g., venture inventors, distributors, suppliers, outsourcing allies, research centers), clients (customers), and sometimes a patent or other intellectual property holder.
3. Metaorganizational game, where the main players are a social planner (innovation policy maker, government, a social or government institution, e.g., a research foundation) and an aggregate innovative entrepreneur. The structure of all levels and their relations are depicted in Fig. 1.

The main objective of analysis on the intraorganizational level is:

1. To find and substantiate optimal variants of organizational and economic interaction of innovation process participants (inventor, innovation entrepreneur, project manager, investor, project implementers, etc.)

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,



Game Theory and Innovation Analysis, Fig. 1 Innovation game levels: (*1*) intraorganizational game, (*2*) interorganizational game, (*3*) metaorganizational game (Source: The author's own conceptualization)

2. To secure a high level of creative activity of idea generators and project implementers
3. To effectively stimulate knowledge sharing in the firm

The existing literature mostly concentrates on the interorganizational and metaorganizational levels. On the level of interorganizational interaction, game theory models help to define optimal competition and cooperation strategies, in particular, to determine optimal R&D expenditure, optimal mechanism of financial relationships for innovation participants (royalty, fixed payment, innovation project profit or revenue sharing amount, etc.), the best time to introduce a new product into a market (time to launch innovation), to develop the most profitable licensing agreement, to select the right project or make a right choice of investment alternatives or innovation strategy, etc.

On the macrolevel, innovation games describe the interaction between an innovator and a social planner of innovation policy (e.g., government). The main questions are the following: What is the optimal configuration of intellectual property rights (IPR) policy? What are the welfare implications of licensing? Which industry and market structure provides the highest incentive to innovate? Game-theoretic approach helps to construct the optimal government policy with respect to innovation activity, to maximize the capitalized value of net social surplus, to enhance technological innovation and international competitiveness, etc.

It is important to note that a model initially developed for innovation analysis on one level can be often adapted to the analysis on another level (model transfer). For example, an intraorganizational knowledge sharing agent-based model can be also adapted for the analysis of interorganizational interactions in an innovation consortium.

The reviewed literature concentrates mostly on noncooperative games; however, cooperative game models are also used, mostly to solve the problem of optimal sharing of innovation project outcomes among the member of innovation

Game Theory and Innovation Analysis, Table 1 Analyzed problems and modeling techniques for different types of interaction games

Level of interaction	Modeled problems	Types of model
Intraorganizational	Team building in R&D	A static game of 2 or *n* players
	Stimulation of innovative activity	Dynamic 2-player games
	Knowledge sharing in an innovative firm	A static 2-player game
Interorganizational	The choice of an R&D strategy (R&D expenditure, product differentiation, etc.)	A Stackelberg game of *n* players
	The choice of an innovation strategy (independent, initiative, cooperative, etc.)	A differential game of *n* players
	The choice of optimal parameters of a licensing contract	A 2-player game
	The interrelation of a patent holder and innovative firms	A dynamic noncooperative game
	Patent race	A cooperative game
	The cooperation of R&D consortium partners	An asymmetric game of 2 players
		A static or iterated "prisoner's dilemma" game
Metaorganizational	Optimal innovation policy and government interventions in R&D	A Stackelberg game of *n* players
		A dynamic game of *n* players
		A cooperative game

Source: The author's own conceptualization

alliances. In most cases, the specificity of innovation process is often "hidden" in a model. It is typically assumed that an innovation process results in low-cost or quality improvement technology. Hence, researchers often go from latent and nonmeasurable variables (e.g., R&D effort) to some aggregate variables (e.g., R&D costs depending on R&D effort).

A survey by Baniak and Dubina (2012) demonstrates a clear tendency of stable and rapid growth of a number of publications on game theory applications to innovation analysis during the last 3 decades. The summary of the innovation problems modeled with game theory and model types used is given in the Table 1.

Conclusion and Future Directions

Game theory models sometimes result in conclusions contrary to intuition and common sense, but these conclusions, as numerous computer and laboratory experiments and real practice demonstrate, are often more useful and applicable than intuitive decisions and common sense. A wide spectrum of successfully analyzed and solved problems as well as the powerful logical and mathematical methodology of game theory give an idea that the game-theoretic approach will take an important role in innovation research during the next decade.

Introduction

This entry describes, defines, synthesizes, and reviews the topic of gender and innovation, which is an emerging field of research evoked by the need for more inclusive innovation policies, innovation networks, and innovation processes.

Over the last two decades, innovation has become an increasingly common subject of political action and scientific studies in Europe and worldwide. This interest emanates from the widespread understanding that development and dissemination of innovations transforms the economy to become more dynamic and knowledge-based. This vision permeates OECDs innovation strategy as well as the new European Union strategy *Europe 2020* and its flagship initiative *Innovation Union*. Simultaneously, the need for more inclusive and creative policies, processes, and networks of innovation has been articulated by gender scientists and gender equality officials (Schiebinger 2008; Fürst Hörte 2009; Danilda and Granat Thorslund 2011; Schraudner 2010). This need is motivated by the fact that most Western policies and research studies on innovation have prioritized a narrow range of actors, areas, and innovations at the expense of other creative and innovative spheres (cf. Blake and Hanson 2005; Pettersson 2007; Lindberg 2010, 2011). Innovation is an area that traditionally has been characterized "either by gender-blindness or male dominance" (Ranga and Etzkowitz 2010, p. 1). Nevertheless, gender analyses have a "potential to enhance human knowledge and technical systems by opening them to new perspectives, new questions and new missions" (Schiebinger 2008, p. 4). In this entry, the prevalent research of gender and innovation will be summarized and reviewed in order to clarify the scope and effects of this dawning field of research.

The entry starts with introducing two theoretical concepts intended to clarify the relation between gender and innovation: doing gender and gender mainstreaming. This is followed by a review of existing research on gender and innovation, which is synthesized in the light of the two theoretical concepts presented at the start. Finally, conclusions are drawn, and future directions in research on gender and innovation are distinguished.

Concept No. 1: Doing Gender

In order to understand how gender is relevant to the field of innovation, the theoretical concept of doing gender will here be highlighted. This concept provides a framework for understanding how gender can be analyzed in policies and organizations. Doing gender constitutes nowadays one of the main approaches employed in contemporary gender research (Gunnarsson et al. 2003). According to the doing gender approach, gender is not a given natural dimension but is constructed in social interactions, and by this, existing gender differences can be analyzed and changed. Gender is then regarded as an ongoing activity and interaction performed among and between women and men in organizations and society (West and Zimmermann 1987). Everyday practices and activities are thereby related to an institutional and structural level. Gender is consequently related to innovation by policies, processes, and networks of innovation being characterized by gendered practices and frameworks at individual, relational, structural, and symbolical level. By viewing gender as an accomplishment, as in the doing gender approach, the attention is shifted "from individuals to interactional and institutional arenas, thus opening up opportunities for change" (Danilda and Granat Thorslund 2011, p. 51).

One of the classic contributions of gender research relies on the principles of doing gender as it exposes how gender often is done in ways that create dichotomies, for example, between men and women or between femininity and masculinity (Hirdman 1990). This leads not only to segregation – for example, on the labor market – but also to hierarchies where areas associated to men and masculinity often are ascribed higher value – for example, by higher wages, faster careers, and political prioritization (Gunnarsson et al. 2003; Lindberg 2010; Schiffbänker 2011). This implies an uneven distribution of power and resources between women and men. Gender is consequently related to innovation by the uneven distribution of power, resources, and status between women and men, as well as between services and manufacturing industries, in policies, processes, and networks of innovation (Pettersson 2007; Lindberg 2010; Danilda and Granat Thorslund 2011).

Contextual variations are an important part of doing gender, distinguishing how gender is done in different ways in different times and places. The focus on everyday practices underlines the possibility of doing things differently (Gunnarsson et al. 2003). According to the doing gender approach, it is not compulsory that the doing of gender ends up in segregating and hierarchical patterns. Quite the opposite, since it – at the individual level – is possible to act in ways that break this trend, opening up – at the structural level – for more dynamic and nuanced perceptions of the world. Such acts can be interpreted as a way of "undoing gender" (Wetterer 1999). Concerning the relation between gender and innovation, such a change in the doing of gender could imply a different pattern of prioritization, esteeming actors, industries as innovations not by their gendered nature but by their potential to evoke creativity and societal development (Andersson et al. 2009; Lindberg 2010; Danilda and Granat Thorslund 2011). However, it is not always easy to bring about change since the dominating structures can be tenacious, reacting with resistance when challenged. The resistance reveals that there is power relations involved, requiring negotiations about "what men and women are allowed to do, how they are allowed to behave and how men and women are to be ranked and valued" (Kvande 2003, pp. 37–38).

Concept No. 2: Gender Mainstreaming

In order to understand how gender is relevant to the field of innovation, this entry will now be continued by highlighting the concept of "gender mainstreaming." It was introduced at the end of last century after the United Nations Fourth World Conference on Women in Beijing 1995 to involve broader areas of policies and actors into gender equality targets. Gender mainstreaming is primarily used as an overarching strategy of gender equality efforts in policies and organizations. As a strategy, it implies that gender equality is to be addressed in all policy and organizational areas as well as in all phases of decision making and implementation (Rees 2005). In research, gender mainstreaming is analyzed theoretically due to its varying content and effects. Walby (2005) and Squires (2005) have launched two alternative ways of classifying efforts to mainstream gender in policies and organizations, which both cast a light on the relation between gender and innovation.

There are many ways of defining gender mainstreaming and many ways of implementing it in practice (Walby 2005). One definition is provided by Rees (2005, p. 560), stating that gender mainstreaming is "the promotion of gender equality through its systematic integration into all systems and structures, into all policies, processes and procedures, into the organization and its culture, into ways of seeing and doing." Another definition is maintained by True and Mintrom (2001, p. 28), proposing that gender mainstreaming is to be understood as "efforts to scrutinize and reinvent processes of policy formation and implementation across all issue areas to address and rectify persistent and emerging disparities between men and women."

Walby (2005, pp. 323–324) highlights two general ways in which gender can be mainstreamed.

Firstly, there is a strategy of integrationism that promotes gender mainstreaming as “a way of more effectively achieving existing policy goals” and thus fails to challenge prevalent policy paradigms. Secondly, there is strategy of agenda setting that implies “the transformation and reorientation of existing policy paradigms, changing decision-making processes, prioritizing gender equality objectives, and rethinking policy ends.” In this context, the term transformation is to be understood as “neither the assimilation of women into men’s ways, nor the maintenance of a dualism between women and men, but rather something new, a positive form of melding.” As Walby notes, while the strategy of agenda setting means that gender mainstreaming is less likely to be rejected in mainstream policy making and organizations, it is more likely to have only a limited impact on segregating and hierarchical gender relations.

Squires (2005, pp. 368–371) suggests a different way of categorizing efforts to mainstream gender in policies and organizations. She discerns three types of strategies: inclusion, reversal, and displacement. She connects the strategy of inclusion to a liberal type of feminism, seeking gender neutrality and conceiving people as autonomous. What is mainstreamed in this category is primarily formal equality of opportunities, realized by bureaucratic policy processes. The strategy of reversal is associated to the stream of radical feminism, seeking recognition for a specifically female gendered identity and explicitly talking of women as a given category. Mainstreaming is here seen as a way to include women’s voices. Squires links the strategy of displacement to a postmodern type of feminism, using gender as a verb instead of as a noun. It is problematized how discourses ascribe gender to people, attributes, and activities. Gender mainstreaming is then equivalent to norm diffusion, acknowledging a broad spectrum of identities, experiences, and visions.

Walby and Squires thus identify a range of manners in which gender can be mainstreamed in policies and organizations. These manners do not necessarily have to be seen as alternatives to each other. Squires underlines that the three strategies she discerns are to be regarded as complementary rather than competing or incompatible. Ultimately, she concludes that gender mainstreaming is most likely to be truly transformative when all three strategies are implemented side by side. In theoretical studies of gender mainstreaming – as well as in practical efforts to mainstream gender in policies – it is however important to distinguish which strategy that is being employed. This is since the different types differ in their effects on gendered structures in policies and organizations. These differing effects are relevant not least when relating gender to innovation, since policies, processes, and networks of innovation are gendered in different ways. This will be exemplified in the last section of this entry.

Gender Research on Innovation

Having set the scene by introducing the gender theoretical concepts of doing gender and gender mainstreaming, this section summarizes and reviews prevalent gender research on innovation.

Gender has been advocated as a relevant aspect in relation to innovation within a number of research fields, for example, feminist science and technology studies, political science, history of science, business economics, and human geography (c.f. Hacker 1989; Blake and Hanson 2005; Papouschek et al. 2006; Pettersson 2007; Schiebinger 2008; Ranga and Etzkowitz 2010; Schraudner 2010; Danilda and Granat Thorslund 2011; Ekman et al. 2011). There, it has been highlighted how the dominating image of innovation and innovators builds on stereotypical notions of gender, promoting men and masculinity as the norm. According to Nyberg (2009), this gender imbalance leaves innovative opportunities unexploited, thus hampering political prospects of continuous economic growth. In order to make better use of these innovative opportunities, Ghaye and Gunnarsson (2009) suggest the creation of “cultures of appreciation,” improving innovation within organizations. Such cultures effectively address gender issues since the positive and creative sides of the organization and the employees are accentuated, reaching beyond hampering gender stereotypes. Schiebinger and Schraudner (2011, p. 154) mention the innovation potential of "gendered innovations" which are defined as "the process that integrates sex and gender analysis into all phases of basic and applied research to assure excellence and quality in outcomes."

Existing gender stereotypes in policies, processes, and networks of innovation can be challenged by acknowledging that innovative activities occur also "in economic sectors and by actors that are typically ignored or undervalued by current research and by policy" (Blake and Hanson 2005, p. 681). Integrating other innovative employment fields like services and creative industries – both in the private and public sectors – widens the understanding of innovation and acknowledges the contribution by women-dominated professions (Nählinder 2005, 2010; Papouschek et al. 2006; Pettersson 2007; Schiffbänker 2008; Lindberg 2010; Ranga and Etzkowitz 2010). This can be reinforced by acknowledging the importance of the nonprofit sector for innovation beside the public, private, and academic ones, implying an expansion of the Triple Helix model of innovation networks into a Quadruple Helix model (Carayannis and Campbell 2010; Lindberg et al. 2012). A democratization of innovation can thus take place "through extending the circle of actors who take part in the process," which also increases the likelihood of evoking "responsible innovations" (Gustavsen 2011, pp. 4–5). Thereto, a broader view on innovation has been suggested, embracing not only technological/manufacturing innovations but also social and organizational innovations (Blake and Hanson 2005). Consumers are thereto claimed to be interested in products that "break with traditional gender stereotypes" (Danilda and Granat Thorslund 2011, p. 55). In these ways, gender aspects are increasingly acknowledged in studies of knowledge production and innovation (Schiebinger 2008; Ranga and Etzkowitz 2010).

Some of the gender research performed on innovation has specifically focused innovation policies, since they affect the availability of financial resources for initiating innovation networks and innovation processes. Sweden is predominant in the pioneering work performed on gender in innovation policies, but some studies have also been carried out in Norway, UK, and USA. Some of the Swedish research studies include Pettersson (2007), Fürst Hörte (2009), Andersson et al. (2009), Lindberg (2010), and Danilda and Granat Thorslund (2011). The studies in Britain and the United States have been performed by, for example, Rees (2000) and Blake and Hanson (2005), and in Norway by, for example, Foss and Henry (2010) and Kvidal and Ljunggren (2010). The conclusions uniting these studies of the gendered nature of innovation policies are threefold:

1. Public investments in innovation networks primarily prioritize men, male-dominated networks, and male-dominated sectors of the economy.
2. Public promotion of innovation is hampered by gendered stereotypes, ignoring the innovation potential among certain actors, industries, and innovations.
3. Public programs usually describe innovations and innovation networks with reference to mechanical machines and technical products rather than human relationships and services, which can be interpreted as masculine traits.

Fürst Hörte (2009) discerns two levels of gender aspects in innovation policy: gendered structures in innovation policy programs and gendered structures within the innovation networks being promoted by such programs. Pettersson (2007) clarifies that gendered divisions in innovation policies are seldom elaborated in national policy programs. Pettersson and Saarinen (2005) state the same for the innovation networks being promoted by such programs. In order to address both these levels, a double strategy has been suggested, promoting gender mainstreaming in already prioritized innovation networks at the same time as promoting innovation networks within industries employing most women (Fürst Hörte 2009; Lindberg 2010; Danilda and Granat Thorslund 2011). Within innovation networks, nonnormative thinking might strengthen weak links innovation milieus by allowing them to reach beyond gendered stereotypes. Normative thinking is thus regarded as an obstacle to innovative thinking, since gender diversity is claimed to improve creativity and decision making (Andersson et al. 2009; Ghaye and Gunnarsson 2009; Danilda and Granat Thorslund 2011).

Within innovation policy programs, the importance of broadening the spectrum of actors, areas, and innovations being prioritized has been emphasized (Rees 2000; Blake and Hanson 2005; Pettersson 2007; Lindberg 2010). This suggestion is motivated by a survey of prioritization within innovation policies and regional growth policies of different innovation networks in Sweden 2002–2010 (Lindberg 2011). The results exposed that in 80% of the cases, manufacturing industries and new technologies (e.g., ICT, biotech, fiber optics) industries were prioritized, both of them representing men-dominated industries. In a fifth of the cases, services and creative industries were prioritized, representing industries employing most women. This pattern of prioritization creates a segregation and hierarchy between men and women in relation to innovation since these two groups are being unequally involved in policy programs promoting innovation due to a difference in the estimation of their importance for innovation.

Broadening the spectrum of actors, areas, and innovations being prioritized in innovation policies to a less gender segregating pattern would mean to include services and creative industries to a greater extent than today. This would increase the inclusion of women in innovation policies and ascribe women and men equal importance for innovation, thus making the segregation and hierarchy between these two groups less distinct (Pettersson 2007; Lindberg 2010). An increased emphasis upon services and creative industries in innovation policies is in line with predominant policy efforts to transform Western societies and economies to become more knowledge-based (cf. Rees 2000). Pioneering research studies expose, however, that these industries entail a complicated reconciliation of working time and free time (Papouschek et al. 2006; Schiffbänker 2008). People in these industries suffer from long working hours, work extending to evenings and weekends, difficulties with planning ahead, dependency on commissioners, and economical risks. This means that the diminishing gender segregation and hierarchy attained by including services and creative industries in innovation policies might be counterpoised by the poor working conditions in these industries, making it hard to maintain a bearable work-life balance. It is thereby not guaranteed that “broadly framed networks [. . .] necessarily produce responsible innovation” (Gustavsen 2011, p. 5).

In order to challenge and change prevalent gendered structures in innovation policies and practices, suggested measures have to be able to reach beyond the distinction between “men” and “women” and provide the grounds for an equal estimation of different groups of industries, irrespective of their gender distribution (Lindberg 2010, 2011). Gender mainstreaming in innovation policies and practices requires a transformed perspective on economic development and innovation and increased reflection on which actors are seen as assets and what sectors of the economy are seen as “strong” or useful in innovation policies and innovation networks (Pettersson 2007). Such a transformed perspective harmonizes with Rees’ (2005) definition of gender mainstreaming, stating that a gender perspective is to be integrated into ways of seeing and doing, into systems and structures, into all policies, processes and procedures, and into the organization and its culture. It is also supported by Schiebinger’s (2008, p. 4) definition of gendered innovations as “transformations in the personnel, cultures, and content of science and engineering brought about by efforts to remove gender bias from these fields.” Such transformations seem to be supported by the overall trend in innovation theory and practice, pinpointed by Ranga and Etzkowitz (2010, p. 3):

> Innovation theory and practice is in the midst of a shift in focus from product and process innovation, primarily in the private sector, to innovation in services that are located in the public as well as the private sector. This transition has profound consequences for the visibility of the gender dimension in innovation.

Synthesizing Gender and Innovation

This section synthesizes the review of existing research on gender and innovation using the two theoretical concepts of doing gender and gender mainstreaming.

The ongoing construction of gender, pinpointed by the concept of doing gender, is detectable in innovation policies, processes, and networks (cf. West and Zimmermann 1987; Gunnarsson et al. 2003). In the promotion and practices of innovation policies and networks, gender is done when certain actors, sectors, and innovations are distinguished in a manner that is congruent with the sex-segregated labor market, thus reinforcing the gendered pattern of keeping women and men apart. On the symbolical level, gender is done when differing value is ascribed to the distinguished actors and sectors in relation to innovation and economic growth, thus reinforcing hierarchical gender relations (cf. Blake and Hanson 2005; Pettersson 2007; Lindberg 2010).

Efforts to integrate gender in innovation policies, processes, and networks are reflected in the concept of gender mainstreaming (cf. Rees 2005; Squires 2005; Walby 2005). One of the mainstreaming strategies – integrationism – is visible in the attempts to relate gender and innovation by assuming that there is a potential for gender equality to contribute to increased economic growth. As a strategy of integrationism, this kind of relation does not challenge existing policy paradigms and thus has limited likeliness to change masculine norms in innovation policies and practices. However, its coherence with all-embracing policy goals, such as economic growth, increases its likeliness to be accepted by policy makers and brought into the policy agenda (cf. Walby 2005). Similarly, the attempts to relate gender and innovation by securing equal access for women and men to apply for funding of innovation networks and innovation processes – thus using the strategy of inclusion – are more likely to be integrated in the policy agenda since they "only" demand formalized rights to gender equal influence and benefit from regional policy programs and projects. They do not promote a gender perspective on the goals of innovation policies, nor do they challenge the segregating notions of "women" and "men" as unified – but separate – groups (cf. Squires 2005).

In contrast, the attempts to relate gender and innovation by highlighting the contribution made by women in services and creative industries – thus using the strategies of agenda setting and reversal – do challenge existing policy paradigms by reorienting existing policy goals, for example, by highlighting alternative ways to achieve innovation and societal development. They thus challenge masculine norms in innovation policies and practices. At the same time, they lower their likeliness to be accepted on the policy agenda. They recognize the importance of including a multitude of experiences and perspectives in policies, processes, and networks of innovation. But they also tend to reinforce those very dualistic notions of gender that constitute the base of segregating and hierarchical gender orders. The attempts to relate gender and innovation by questioning the differing estimation of women and men – and of services and manufacturing industries – in relation to innovation reflect the strategy of displacement. Such attempts assume that there are so many individual variations within each of these categories that it is more fruitful to analyze how gender is "done" in each situation where women and men are ascribed different attributes, competences, and interests, thus limiting people's prospects to contribute to creativity and innovation (cf. Squires 2005; Walby 2005).

In relation to the classifications of gender mainstreaming, the doing gender approach seems to share more features with the strategy of agenda setting than the strategy of integrationism (cf. Walby 2005). This is since the first-mentioned strategy tends to bridge dualistic gender constructions and challenge their static appearance in a way that accords with the understanding of gender as continuously constructed as advocated in doing gender. Those links between gender and innovation that embrace the strategy of integrationism are hence more likely to challenge and change prevailing gendered norms in policies, processes, and networks of innovation. The deconstructive stance of the strategy of displacement is similar to the understanding of gender as continuously constructed and thus possible to change, as proclaimed in the doing gender approach (cf. Squires 2005). The links between gender and innovation that cohere with this strategy are thus more likely to evoke less segregating and hierarchical gender relations in innovation policies, processes, and networks than the ones accepting the dominant gendered norms of innovation. As Squires emphasizes, however, are the different strategies of gender mainstreaming not to be regarded as mutually exclusive. Instead, they are most likely to be truly transformative when implemented side by side.

Conclusion and Future Directions

The review of prevalent research on gender research and innovation reveals four explanations of the relevance of gendered structures on innovation policies, processes, and networks. These four explanations are the following:

- The potential for gender equality to contribute to innovation and growth
- Differing estimation of women and men – and of services and manufacturing industries – in relation to innovation
- The contribution to innovation by services and creative industries
- Unequal access to funding of innovation networks and innovation processes

Each of these explanations relies on specific strategies of gender mainstreaming, evoking different kinds of changes in gendered structures of innovation policies, processes, and networks. The main conclusion to be drawn is that their understanding of gender as continuously constructed varies as well as their potential to challenge masculine norms – differences that might be overcome in policy and practice by combining available strategies. It still remains to be scrutinized, though, to what extent each of the four explanations actually manages to change segregating and hierarchical notions of gender in practice. This calls for further empirical studies of innovation policies, processes, and networks, tracking the long-term effects of gender equality interventions. It also remains to be scrutinized whether recently established policies, processes, and networks promoting innovation in services and creative industries are more capable of changing segregating and hierarchical notions of gender than those focusing manufacturing and hi-tech industries.

Genius

Andrei G. Aleinikov
International Academy of Genius, Monterey, CA, USA

Synonyms

Brilliance; Superachiever; Superior creative power; Superior intellectual power

Definition

A genius is a person top-valued by the society for the uniquely expressed highly innovative vision of the world.

Introduction

A popular online encyclopedia directly states at the beginning of the article on genius, "There is no scientifically precise definition of genius, and indeed the question of whether the notion itself has any real meaning is a subject of current debate" (Genius, Wikipedia, retrieved Dec. 23, 2011).

The mission of this article is to prove the opposite: to provide a scientific definition of genius and to prove that the phenomenon of genius exists and is worth researching.

The issue of genius is extremely complex. It involves biological, psychological, and social aspects of human beings whose achievements are considered to be extraordinary. Since the phenomenon of genius falls under the jurisdiction of many sciences, the approaches differ dramatically, the opinions on the issue are contradictory, and the myths are abundant. The fact that may strike an independent observer most is that there is no special science studying genius.

This situation may be called the genius paradox. Geniuses like Aristotle, Giordano Bruno, Galileo, Copernicus, Isaac Newton, Louis Pasteur, Albert Einstein, and Madam Curie created the scientific basis for modern civilization. Many of them are credited with establishing new sciences: Euclid – Geometry, Claude Bernard – physiology, N. Zhukovsky – aerodynamics, and Gregor Mendel – genetics (with the theory of inherited features). As a top achievement, Hermann von Helmholtz is sometimes called the "father of three sciences." However, those who made all those scientific discoveries and created all sciences have not been studied scientifically. It looks like a proverbial situation "shoemaker without the shoes" reached the level of genius because geniuses that created all sciences have not created the science of genius itself. Therefore, to resolve the genius paradox, geniusology, a science of genius, was offered. Geniusology was first mentioned at the Teachers' Conference in Singapore in 2003 and first published in 2004 (Aleinikov 2004). Some elements of geniusology, like the new definition of genius, megacreativity, and genius classification, appeared earlier (Aleinikov 2002a, b).

Traditional and Modern Views on Genius

There are thousands of books and articles on intelligence and creativity as well as hundreds of definitions of genius. Since the most popular definitions call genius "a super intellectual power" or "extraordinary creative power," many researchers study psychosocial background, developmental, cognitive, educational, and other aspects of a genius to figure out how a person may have achieved the top level of creativity or intelligence.

Meanwhile, the term "genius" became very popular and overused. For example, after the introduction and popularization of IQ tests, some applied the term "genius" to those who scored high on the tests. However, Dr. Abbie F. Salny, supervisory psychologist, American Mensa, clarified the confusion by answering the question, "Are there really any true geniuses?":

> Genius may be in the eye of the beholder. Furthermore, a true genius may not score particularly well on a standard group IQ test. We know a Nobel Prize winner who never scored at Mensa level on a school IQ test… And really, those who are

what we may call a genius don't need a score to prove it. (Salny 2009, Retrieved from http://permianbasin.us.mensa.org/resources/questionofgenius.html Dec.23, 2011)

In reality, the IQ tests show that individuals who score high have wide knowledge and are able to solve intellectual puzzles (problems). However, it is only the real life that can show how impressive their achievements would be in order to be considered geniuses.

The same may be stated about the Torrance Tests of Creative Thinking (Torrance 1974). They measure creative abilities (some score lower, some higher), but whether these abilities will be used to get the top achievements to be recognized as geniuses is up to the person and society he or she lives in.

Another example of the term "genius" being extremely popular and attractive is the creation of the MacArthur Fellowship, nicknamed "genius award." It is given by the John D. and Catherine T. MacArthur Foundation each year to 20–40 Americans showing "exceptional merit and promise for continued and enhanced creative work." This award actually is a genius way to support potential geniuses, who, as Oscar Wilde states, "are born, not paid," and whose work is often "nothing for use or profit" (Schopenhauer).

Traditionally, the phenomenon of genius is defined through:

- Hard work – "Genius is one percent inspiration and ninety-nine percent perspiration" (T. Edison). H.W. Austin echoes Edison by saying, "Genius, the power which dazzles human eyes, is oft but perseverance in disguise."
- Intellect – Genius is a superior intellectual power, and people with a high IQ are geniuses (as in Stillson 1998).
- Creativity – Genius is a superior creative power (Gelb 1998; Michalko 1998; Simonton 1999; Sobel 1996; Thorpe 2000).
- Some dominant feature (imagination or sensitivity) – "The source of genius is imagination alone, the refinement of the senses that sees what others do not see, or sees them differently" (Eugène Delacroix).
- Some unusual ability – "Genius is an ability to see through to the essential" (unknown author). "To see things in the seed – that is genius" (Lao-tzu).
- Power of talent – "Talents are buffaloes, and the most powerful of them are geniuses" (Jules Renard).
- Originality – "The principal mark of a genius is not perfection but originality, the opening of new frontiers" (Arthur Koestler).
- Error, mistake, and incident – "It [genius] is personality with a penny's worth of talent. Error which chances to rise above the commonplace" (Pablo Picasso).
- Madness or mental disease – Mad genius controversy (Durrenberger 1999).

Many of the studies of genius are individual-centered, while in reality, the concept of genius is both social and individual in nature. A simple mental experiment makes it obvious. Even in the case of the most well-known definition stating that genius is extraordinary intellectual power, there is no such thing as an extraordinary intellectual power individual who grows up in isolation and lives alone somewhere on a desert island. In such a hypothetical case, first of all, there would be no learning from the society, no language, and no societal problems to solve; second, there is no comparison against the other minds in the field for measuring social achievements; and third, there is no social recognition... and consequently there is no genius. From this point of view, genius is a social status (name, concept) *given* by the grateful society as an "award" to some individuals with outstanding contributions to humanity.

In some works on genius, authors choose to take one fate, one individual, and research one life while trying to reveal the genius behind (Gleick 1993; Seifer 1998). Then there are those who compare a few geniuses in hope to deduce a list of common features (Gardner 1993) and those who research larger groups (Bloom 2002). Many authors attribute genius to a divine intervention (see William Crashaw's idea in the list of quotes below). Some try Darwinian (scientific) approach to creativity and genius (Simonton 1999).

The path to establishing a new science repeats itself in many domains. As in many other fields, literature comes first. Numerous literary biographies of geniuses provide metaphoric, poetic, and picturesque descriptions that depict the sociocultural background of the phenomenon. Then some well-established branches of science research separate aspects of genius that form a kind of a transition from mythology to science with its precise terms, abstract notions, and repeatable and testable objective data. Finally, the need for generalizing the research data on genius becomes obvious, and consequently, there appears a separate science with a multidisciplinary approach to coordinate and organize these findings. This science, geniusology, has its own objective and its own research methodologies to discover the regularities and laws of genius development.

In the history of science, when a new science appears, it unites the efforts of an individual researcher and research groups which contribute to a common goal – an adequate reflection of the phenomenon.

To follow this path of the development, it would be correct to start with mythology.

Myths of Genius

The issue of genius is surrounded by a number of myths that feed public imagination. Some of the most popular myths are summarized below:

Geniuses Are Born

When people say that geniuses are born, not made, they mean that the main contributor to genius is genetics. Inherited features do matter, but without proper upbringing and education, even the best genetic material is doomed. "Genius without education is like silver in the mine" (Benjamin Franklin). On the other hand, even the best training and education would not make a genetic imbecile a genius. The approach is not "nature or nurture," as some people tend to state it, but "nature and nurture." Only a combination of both produces proper results.

Genius Must Be Visible in Childhood

This myth comes from the confusion of prodigy and genius. It is prodigy that is visible in childhood. Only 5 % of prodigies show up on the genius level – the others burn out and end up in oblivion. On the other hand, many of the recognized geniuses were considered dumb in childhood. Einstein, for example, who was a dyslexic, began to speak at about three and needed tutoring in school. Another example, little Pablo Picasso survived elementary school only by having his father sit in the classroom (to protect him from ridicule).

Genius Is Talented in Everything (Gifted)

The idea that geniuses are well rounded and talented in everything is very popular. Otto Weininger calls it "universality" (see quotes below). This myth is only partially true. There are geniuses in history, like Leonardo da Vinci, Johann Wolfgang von Goethe, and Mikhail Lomonosov, who were talented in everything; however, there were also hundreds of recognized geniuses who were not that gifted but exhibited brilliance only in one field.

Genius Is Accidental

This point of view is supported by serendipity – the science of accidental discoveries. The discovery of x-rays by Röntgen is one of the classical examples. History states he "accidentally" noticed some shimmering lights in the darkness of the room when an electrical discharge was passed through the cathode tubes blocked by cardboard that should prevent light from escaping. He called the unknown rays "x-rays." Another famous example of "serendipity" is Henri Becquerel's discovery of radioactivity. There was no sunshine needed for his experiments for several days; so he put the uranium compound crystals away to the drawer on the photo paper. Then "accidentally" or in impatience he developed films and found white spot in the form of the crystal on the film. He correctly concluded that uranium compound crystal even without being exposed to sunlight emits some rays that penetrate the light resistant paper. This is how radioactivity has been discovered. These discoveries may seem accidental, but both Röntgen and Becquerel were researchers, and had complex equipment in their labs, and experimented with cathode tubes and uranium ore... If not them, then earlier or later somebody else would have had such an "accident."

Geniuses Are Mad

The myth about geniuses being mad is supported by literature and movie industry. For instance, the movie *A Beautiful Mind* dramatized the genius/madness relationship of the Nobel Laureate John Nash. Some people state it less offensively: a genius and an insane person are two points of a cut-and-open circle. Some authors show that highly creative people have a larger chance of being mentally ill. Others disagree. Genius, however, is more visible and attractive to media, while thousands and millions of mentally ill people stay in mental clinics, kept away from the public and publicity. In any case, the issue is so attractive that the first in the world *Encyclopedia of Creativity* – an outstanding collection of research in itself – does not have an article on genius but offers an article on genius/madness controversy (Durrenberger 1999).

On the other hand, since genius is always far ahead of the society he or she lives in, the society is often merciless and does a lot to make this genius seem mad (see the citation by Jonathan Swift, Oliver Wendell Holmes, and Heinrich Heine below). Moreover, some societies are mad. Take, for example, the Nazi Germany from where Einstein and other scientists had to run away. The answer to the question, "Who is crazier?": Einstein poking his tongue out (very popular photo) or the society that burns books in the streets and Jews in the concentration camps, is obvious.

Modern Views on Genius (Highlights)

Media Approach

Contemporary media is glorifying genius on the one hand and making fun of it on the other, but the fact is – media is attracted to genius. Some popular magazines dedicate entire issues to genius. There are articles, books, and Web sites on genius. The issue of genius continues to attract the public. The case of Grigory Perelman, who solved the Poincaré conjecture, was named "a mathematical genius" but refused to receive the Fields Medal and $1,000,000 prize, is but one of the recent examples.

Genius Quotes

Some quotes about genius (retrieved from http://www.theabsolute.net/minefield/genqtpg.html) to reflect the common knowledge include:

- Geniuses are like thunderstorms. They go against the wind, terrify people, cleanse the air. (Kierkegaard)
- A genius is one who can do anything except make a living. (Joey Adams)
- Genius is born, not paid. (Oscar Wilde)
- Genius is not so much about new ideas as it is about clarity of ideas. Two people can have the same idea yet it will be genius in the one and mediocrity in the other. (Kevin Solway)
- Genius is the ability to act rightly without precedent – the power to do the right thing the first time. (Elbert Hubbard)
- Intellectuals solve problems; geniuses prevent them. (Albert Einstein)
- Philosophy becomes poetry and science imagination, in the enthusiasm of genius. (Disraeli)
- Neither a lofty degree of intelligence nor imagination nor both together go to the making of genius. Love, love, love, that is the soul of genius. (Wolfgang A. Mozart)
- The first and last thing required of genius is the love of truth. (Johann Wolfgang Von Goethe)
- Genius does what it must, and Talent does what it can. (Owen Meredith Earl of Lytton)
- Andy Warhol is the only genius with an IQ of 60. (Gore Vidal)
- Oh! how near are genius and madness! Men imprison them and chain them, or raise statues to them. (Denis Diderot)
- Genius. . .is the capacity to see ten things where the ordinary man sees one. (Ezra Pound)
- The principal mark of a genius is not perfection but originality, the opening of new frontiers. (Arthur Koestler)
- When a true genius appears in this world, you may know him by this sign that the dunces are all in confederacy against him. (Jonathan Swift)
- Thousands of geniuses live and die undiscovered – either by themselves or by others. (Mark Twain)
- The world is always ready to receive talent with open arms. Very often it does not know what to do with genius. (Oliver Wendell Holmes)

- Genius is the ability to reduce the complicated to the simple. (C. W. Ceran)
- Genius without education is like silver in the mine. (Benjamin Franklin)
- Everyone is a genius at least once a year; a real genius has his original ideas closer together. (G. C. Lichtenberg)
- When human power becomes so great and original that we can account for it only as a kind of divine imagination, we call it genius. (William Crashaw)
- Everyone is born with genius, but most people only keep it a few minutes. (Edgard Varese)
- Every man is a potential genius until he does something. (Sir Herbert Beerbohm)
- Universality is the distinguishing mark of genius. There is no such thing as a special genius, a genius for mathematics, or for music, or even for chess, but only a universal genius. The genius is a man who knows everything without having learned it. (Otto Weininger)
- Society is a republic. When an individual endeavors to lift himself above his fellows, he is dragged down by the mass, either by means of ridicule or of calumny. No one shall be more virtuous or more intellectually gifted than others. Whoever, by the irresistible force of genius, rises above the common herd is certain to be ostracized by society, which will pursue him with such merciless derision and detraction that at last he will be compelled to retreat into the solitude of his thoughts. (Heinrich Heine)
- It is the genius in reality and not the other who is the creator of history, for it is only the genius who is outside and unconditioned by history. The great man has a history, the emperor is only a part of history. The great man transcends time; time creates and time destroys the emperor. (Otto Weininger)
- Genius is its own reward; . . .The work of genius may be music, philosophy, painting, or poetry; it is nothing for use or profit. To be useless and unprofitable is one of the characteristics of genius; it is their patent of nobility. (Schopenhauer)

In the research on genius, a genius should be clearly differentiated from:

- A hero (one time act – usually a bravery act, often known to one country, like war or revolution heroes, but sometimes to the whole world, like Yury Gagarin – the first cosmonaut, astronaut)
- A celebrity (known to the people of the same generation but may be forgotten as time passes and culture forges ahead)
- A talent (bright, sparkling individuality, easy to learn, easy to produce but lacking originality, persistence, or dedication for high-level innovation)
- A national leader (political figures – well known to the public but just in line with other leaders. And leaders come and go. . .)

Genius is none of these with the exception of very innovative political leaders whose achievements are extremely valued by the society, like Peter the Great. Often, a genius may be unknown during one's lifetime but will be known in centuries to follow. Geniuses stay forever; see the profound thought of Otto Weininger in the quotes, "The great man transcends time; time creates and time destroys the emperor."

Origins and History of the Concept Development

Historically, the word *genius* can be traced back to Latin. In ancient Rome, a genius was understood as a deity or spirit that watches over each person from birth. At that time, it was customary to glorify the genius of the emperor, the genius of commanders, as well as on the lower level, to propitiate the spirits, like the genius of the location, house, and even gates for protection. This genius spirit was associated with wit, talent, some prophetic skills, and even generative powers. Etymologically, the Latin word *genius* came from the root *gignere* – beget, produce. The common root *gen* – produce – is now seen in the words *gen*eration, *gen*esis, *gen*etics, etc. The first usage of the word *genius* in the contemporary meaning "person of natural intelligence or talent" is recorded in the seventeenth century. The path of the meaning change from god-genius to human-genius resembles the path the word *creator* and its derivatives went through (see the definition entry on "▶ Creativity" in this Encyclopedia).

Research of Genius

Modern research on genius ranges from measuring the weight of Einstein's brain (after he died in 1955) to psychological research on genius/madness connection (see, e.g., http://www.scienceagogo.com/news/20020422222106data_trunc_sys.shtml Dec. 22, 2011).

Dean Keith Simonton, for example, developed the chance-configuration theory to analyze the scientific genius by using characteristics such as exceptional productivity, lifestyle, motivation, age and achievements, family background, education, and role models. Convinced that creativity can be understood best as a Darwinian process of variation and selection, he also made it clear that genius belongs to the level of metasciences, like philosophy, sociology, and psychology of science (Simonton 1999).

The research on genius, however, is contradictory, and some researchers openly express their frustration with the situation:

> After hours of research, days of discussion, interviews of few and surveys of many, our attempts at discovering the exact definition and cause of "genius" have been almost futile. There are no two sources that will give the same definition of genius, and in talking to several experts in the field of psychology, nobody could come to a consensus on what made a genius a genius (Arielle Olicker at http://www.sciencenet.emory.edu/mismeasure/genius/conclusion.html).

Similar to the research situation with the definition of creativity (Aleinikov 2000), there are four ways to deal with this multiplicity:

- To select one definition.
- To accept multiplicity.
- To consider all of the definitions, including the future ones, as being a reflection on the complexity of the phenomenon.
- To offer a universal (scientific) definition that would simplify the issue to its essence.

"Genius is the ability to reduce the complicated to the simple. (C. W. Ceran). "Genius is the ability to see through to the essential" (unknown author).

Many researchers choose the first option and use the selected definition as a working definition. Dr. E. Paul Torrance, "the creativity man," preferred the second option. While commenting on the situation with thousands of creativity definitions described in the book *MegaCreator: From Creativity to Mega-, Giga-, and InfiCreativity* (Aleinikov 1999b), he said, "Definitions will continue endlessly, but people will learn not to be disturbed by it and continue finding out more about creativity" (Torrance 2002).

Geniusology, the science of genius, employs the last two options on the list. First of all, it accepts all available definitions as a prescientific stage of studying a genius, and second, it offers a scientific definition.

Scientific View on Genius: Geniusology – The Science of Genius

Geniusology, a new science of genius, was first mentioned in 2003 (in Singapore) and then officially published in the USA in 2004 (Aleinikov 2004).

The results of research in science are represented by classifications. Objects and processes fall into some well-defined and logically differentiated categories. Classifications make reality much simpler. For example, the periodic table of elements (Mendeleev) introduced order into the large number of chemical substances. The genius idea that allowed Mendeleev to create such a classification was to use the atomic weight of chemical elements for this purpose.

First of all, the science of genius can employ the classifications of geniuses available in literature and in reality. Then geniusology can create an ideal (deductive logic) classification that includes all available and yet undiscovered types of geniuses, that is, a matrix with possible fill-ins.

Real-life classifications (prescientific) are often a conglomerate of empirical observations and theoretical explanations. Traditionally, they form a necessary foundation for large-scale generalizations. Below are all available classifications:

Since geniuses are human, and humans have to work for a living, the most obvious category of classification can start with the occupation:

- Science genius (like Isaac Newton and Albert Einstein)
- Technology genius (like Thomas Edison)
- Composing genius (like Wolfgang Amadeus Mozart and Ludwig van Beethoven)
- Medical genius (like Hippocrates)
- Teaching genius (like Maria Montessori)
- Business genius (like Henry Ford and Bill Gates)
- Military genius (like Alexander the Great)
- Organizational genius (like Napoleon: contrary to the popular opinion, he was not a military genius – he lost a number of wars and battles, but when defeated, he could come back to Paris and organize another army for another campaign within months)
- Artistic genius (like Pablo Picasso, Vincent van Gogh, etc.)
- Performing genius (like Charlie Chaplin, Nicolo Paganini, etc.)

This classification is naturally unlimited – new professions or fields appear and will arise. Athletes may say, "Why is there no athletic genius (like Hercules, Mohamed Ali, Michael Jordan, and Pele)?" Cooks may say, "Why not a cooking genius?" By the way, it was Abraham Maslow who said that a first-rate soup is more creative than a second-rate painting.

The next classification category is the degree of propagation of self-expression:

- Sleeping genius (never awake, passive, not applied) versus active
- Hidden genius (actively creating, but never seen, like Copernicus who allowed to publish his work only after his death) versus open
- Open genius (discovered, often suffering, like Galileo)
- Accidental genius (serendipity genius) – onetime event, momentous genius, like Joseph Rouget de Lisle, the composer of the Marseillaise (French national anthem), who, according to Stephan Zweig, never meant it to be an anthem and was even fighting against his song usage. . .but later buried near Napoleon
- True genius (longtime performing genius, like Mozart, Beethoven, Titian)

Finally, the next obvious category of classification is the degree of recognition:

- Unrecognized genius (0, zero recognition) like in the case of Gregor Mendel for 50 years before he was discovered and many others who have NOT been discovered yet.
- Recognized genius (from 1 to about 1,000,000) – already called a genius but still in the stage of recognition. Sometimes, the Nobel Prize winners make their top discoveries in young age but get the prize recognition for their contribution much, much later.
- Megarecognized (true) genius (over a million of citations, mentioning the name in prolonged time (centuries) and space (over the country borders)).

These empirical classifications of genius lead to a theoretically sound scientific classification of geniuses. One of them is built on the scientific model of genius in general (universal four-sided model of language, language awareness, speech, and heuristic act). Another one is based on the matrix of physical reality offered by Bartini and the scientific discoveries called the laws of conservation (Aleinikov 2005).

Scientific Model and Definition of Genius

Genius, in the traditional understanding (in the majority of cases, as it was mentioned above), is the peak of intellectual achievement or creative expression in some field (medium) for which the person is "awarded" this title by society.

In all definitions above, there is one element missing: the reflection system, the language, or the sign. The thing is that the achievement of a genius should be expressed in some semiotic system – the system of signs – and then published, exhibited, and publicized. Whether it is a formula, a theory, a discovery, a melody, a painting, a sculpture, or a pedagogical approach, it must be expressed in a system of signs. With this element added, the genius situation becomes a particular case in the universal state of order depicted by the universal model of sign, language, language awareness, speech, and heuristic act, first developed for creative linguistics (see "▶ Creative Linguistics" and Aleinikov 1988). This is a four-sided model in three dimensions. When a symbolic system is added to the equation, it allows people to visualize the genius activity of producing *newness* and transferring this *newness* to the society (see "▶ Novology" in this Encyclopedia).

Here is how the universal model of sign, language, speech act, and heuristic act looks:

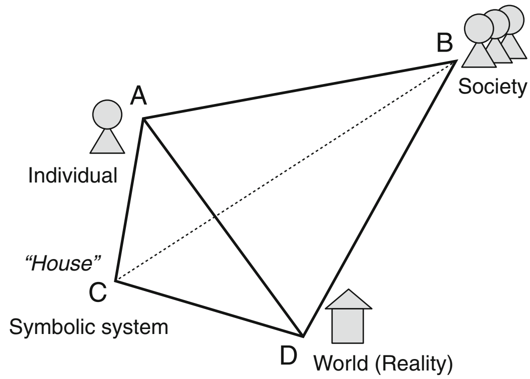
In general, as Fig. 1 shows, an individual (A) is the person who creates a vision of the world (D), expresses it in symbols of the system (C), and sends it to the society (B). Society is understood as any person, or persons, speaking the same language or using the same semiotic system. The message (AB) is received by the society (B), evaluated, and appreciated or not appreciated. The size and the depth of the message can be easily reflected by the size and the depth of the model. That is why some messages would be ordinary (low creative) and quickly forgotten, while the others – deep and original (highly creative) – would be remembered (= valued) for centuries.

In the particular case of a genius, the message (AB) is so uniquely expressed in a symbolic system (C) and reflects such a highly innovative vision of the world (D) that it is top-valued by the society (B) – that is why this individual (A) is named a genius.

Therefore, the model of genius must include four absolutely necessary elements – elements that are generic (universal for all):

- Individual (to learn, to comprehend social problems, to act)
- Society (to teach individual first and to evaluate the contributions later)
- Symbolic system (to express the vision – language, mathematics language, visual arts language, musical language, etc.)
- World (to be reflected by individual)

In addition to the universal (generic) elements of the situation, the description of a genius includes some more elements that characterize individuals that are specifically genius and not referring to all people. These specific elements



Genius, Fig. 1 Universal model of sign, language, language awareness, speech, and heuristic act

are "top-valued" by the society, "uniquely expressed," and of "highly innovative vision."

Therefore, a scientific definition of genius reads as follows: **a genius is a person (A) top-valued by the society (B) for the uniquely expressed highly innovative vision (C) of the world (D).**

Note that this definition does not mention creativity or intellect (to avoid controversy) but mentions checkable and repeatable elements, like symbolic expression, level of innovation, and top societal evaluations. This definition is also domain-free because it can be used for science, for technology, for arts, for education, etc. It fits all of the domains.

A properly built scientific definition should include only necessary and sufficient elements. The necessity is usually tested by mentally omitting one element and checking whether the concept still stands. The sufficiency is checked by applying the definition to real examples and checking whether all elements of the definition **together** are sufficient to cover life examples, where nothing else is needed.

Checking the primary elements of the definition for necessity:

- No person (individual) – no genius: neither machines (objects) nor groups of people are called geniuses.
- No society – no genius: there is no social evaluation at all, so there is no top evaluation.
- No uniquely expressed highly innovative vision – no genius: non-expressed originality cannot

be seen, read, heard, and consequently evaluated.

- No world behind the uniquely expressed highly innovative vision (empty, meaningless) – no genius: a nonmeaningful expression like accidental set of symbols, crazy and stupid combinations, etc., do not count for genius.

Checking the secondary elements (dependent on the primary) for necessity:

- B_1 "top-valued" – genius is the highest verbal award for a human being from the society. So it is not just "highly valued" (prize, fellowship, or medal) or "valued" – it is top-valued. There is no higher evaluation in the society than the rank of a genius. Rich and famous may be forgotten, geniuses are forever. No wonder, there are so many self-proclaimed geniuses and so much media noise about geniuses. For the definition check: no "top-valued" – no genius.
- C_1 "uniquely expressed" – articles, books, paintings, sculptures, movies, etc., all are unique expressions – no compilation and no plagiarism accepted. No unique expression – no genius.
- C_2 "highly innovative vision" – level of innovation matters: world-level innovation, versus country-level innovation, city-level innovation, and plant-, school-, company-, street-, family-level innovation. No world-level innovation (highly innovative vision) – no genius.

So, both the primary elements and the secondary elements are necessary.

Checking the terms for sufficiency:

Here are some examples from science, technology, and arts domains to test for sufficiency:

- Isaac Newton (A) in simple formulas (C_1) expressed his unique vision (C) of the world's mechanics (D), which saved the society (B) huge amount of resources that could have been wasted without calculations. For this highly innovative vision (C_2) of the world, he is considered a genius; mechanics is now called Newtonian physics, and there is a unit named Newton in honor of his name (B_1).
- Albert Einstein (A) uniquely (C_1) expressed his highly innovative vision (C_2) of the world (D) in the theory of relativity (C) that advanced the science of astronomy and led to many other discoveries, as well as the introduction of a new cosmological constant, for which the grateful society (B) top-valued (B_1) his contributions and considers him a genius.
- Thomas Edison (A) in over 1,000 patents (C) uniquely expressed (C_1) his highly innovative vision (C_2) of the technology world (D), which advanced social development immensely for which the grateful society (B) calls him a technological genius (B_1).
- Wolfgang A. Mozart (A) in numerous music compositions (C) uniquely expressed (C_1) his highly innovative vision (C_2) of the world sound harmony (D) that opened a new era in classical music, for which he is highly honored (B_1) by society (B), and his music can be heard everywhere.
- William Shakespeare (A) in unique poetic forms (C_1) expressed (C) his highly innovative vision (C_2) of the world of human feelings (D) for which he is top-honored (B_1) by the grateful society (B). By the way, out of 17,000 words that he used in his poetry 1,700 were new words! A very high level of innovation!
- Van Gogh (A) in uniquely thick strokes and basic color paints (C_1) expressed (C) his highly innovative vision (C_2) of the visual world (D) thus contributing to the creation of the new style of arts – impressionism. For this world-level innovation in the field of visual arts, he is top-valued (B_1) by the society (B). As an example, one of his simplest paintings – "Chair" – was once auctioned for $37,000,000.
- Andy Warhol (A) in uniquely multiplied sameness of the screen printed images of popular personalities and artifacts (C_1) expressed (C) his highly innovative vision (C_2) of the modern repetitious and full of advertising world (D), thus founding a new style of fine arts – Pop Art, for which the society (B) calls him a genius (B_1).
- Charlie Chaplin (A) in his uniquely entertaining manner (C_1) expressed (C) his highly innovative vision (C_2) of the "little-guy-in-the-big-city" world (D) for which the grateful (laughing to tears) society (B) calls him the genius of silent film (B_1).

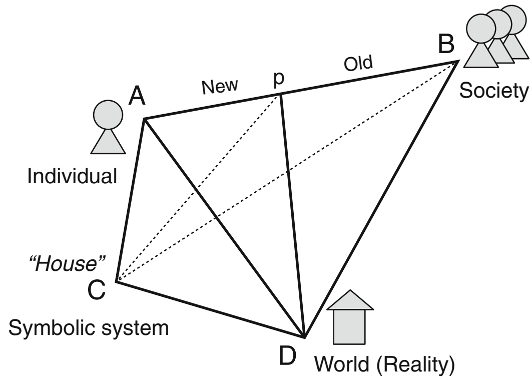
First of all, notice how the pattern repeats itself in the explanations above. It is exactly what science is: it provides testable and repeatable knowledge. Second, note how the scientific definition cuts off:

- Computer poetry and music (no A, individual).
- Self-proclaimed geniuses, as well as lower-level producers, who write, exhibit, perform, etc., but are not innovative enough and, therefore, not top-valued (no B, society; no B_1, recognition).
- Intellectuals or IQ test high-scored individuals that do not develop new vision and do not express it in writing and publishing, painting and exhibiting, dancing, singing, reciting, performing, etc. They may be lazy, too shy, and so on – reasons do not matter. Since there is no production expressed in symbols, no unique expression, no highly innovative vision, there is no basis for rewards (no C_1, unique expression; no C_2, highly innovative vision).
- Senseless, meaningless production in writing or performing – like “monkey typing” or mentally sick doodling that has no reflection of the world (no D, real world).

On the basis of such a universal model and definition, it is easy “to see” the essence of the genius and to visualize the genius situation. A genius is certainly not just the high IQ which is often simply knowledge of already known facts and patterns – far from something really new. These are not “new frontiers” (see the quote of Arthur Koestler). What new frontiers could be found in the book of puzzles or tests already created by somebody? The test taker merely follows the test creator and hundreds of those who took the test before in order to check its validity.

This graphic model (ABCD) also allows researchers to visualize the most important aspect for the explanation of the genius activity. It is the differentiation plane that cuts the old and the new in the message. This is how the cutting plane (CDp) looks in general:

It can be explained as illustrated by Fig. 2: any statement (report, article, book, research, painting, music show, theatrical performance, etc.) consists of the old (BCDp) and the new (ACDp)



Genius, Fig. 2 The new/old plane in the model

parts. In the case of genius, this new part (what genius has discovered and now communicates to the society) is much larger than the old part (what society already knows).

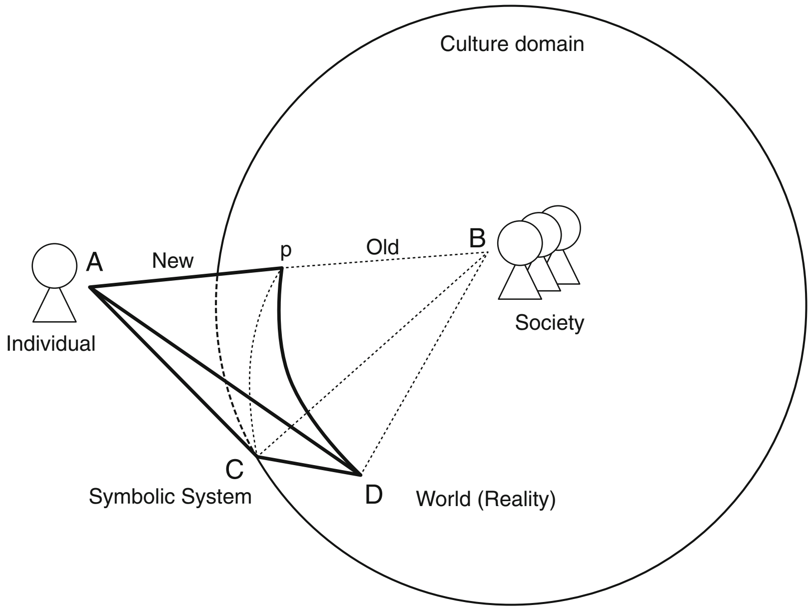
This is what the model of interaction in general looks like:

As Fig. 3 suggests, an individual (A) creates a new vision of the world (D), expresses it in the language (C) also known to the society (B), and sends a message (AB) consisting of known volume (pBCD) and also new volume (pACD). This is the modification of the figure published first in the article titled “Humane Creativity” (Aleinikov 1999a) to show how creative acts expand the society’s culture domain.

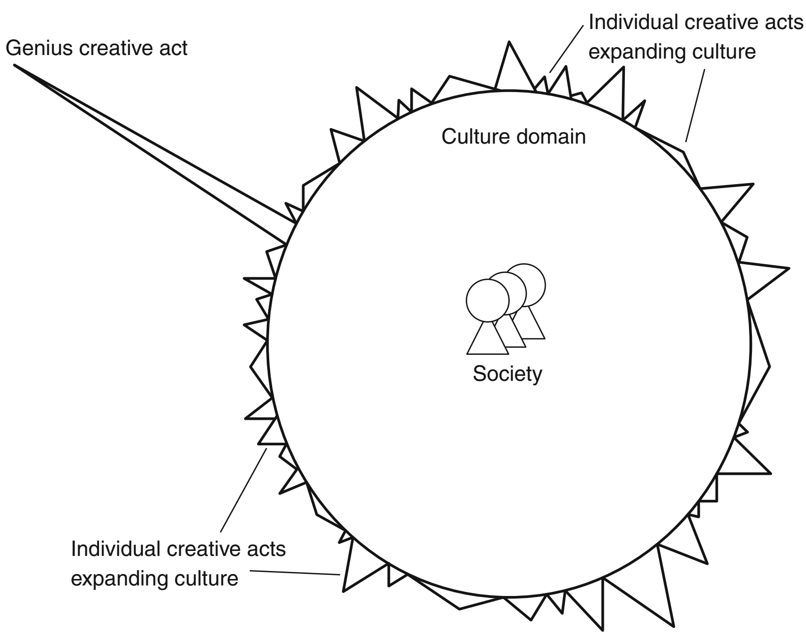
Now, applying it to the issue of genius, this is what the graph would look like.

As Fig. 4. illustrates, genius often makes a needle-shape shot into the future, and it takes several followers (disciples), then hundreds of researchers, and finally, thousands of commentators to explain the genius creative act, thus stretching the social culture (common knowledge, traditions, rituals) to the height of the genius ideas. Christianity and other religions are a great example.

This model also explains why the society does not understand genius and descends to ridicule (see above what Heinrich Heine, Mark Twain, and Oliver Wendell Holmes said). The needle-shaped long shot looks like having no or little foundation in the culture domain. It is often seen as “crazy,” it terrifies people as a statement or vision lacking “foundation” (see the quote by Kierkegaard).



Genius, Fig. 3 Model of creative act expanding culture



Genius, Fig. 4 Genius creative act expanding culture

Certainly, if genius is 50–200 years ahead of the society, it would take society 50–200 years of development to catch up with the genius. Only then, the society will appreciate the intellectual or creative power of the person and call this person a genius.

This model also shows that a genius is the fastest culture expander. A genius either produces ten/hundred times more (i.e., faster) than a talented person or is the first to arrive at a discovery (a highly innovative vision of the world). This is the essence of a genius and another short definition: **genius is the fastest culture expander!**

Speaking about speed, preliminary research shows that geniuses produce about 10 times more new ideas than talented people and about 100–1,000 times more than ordinary people. Geniuses produce so many new ideas that it dazzles the bystanders (see the quote of Ezra Pound above).

To measure the genius ideation productivity, in addition to Torrance's measuring of creative abilities (Torrance 1974), and Kirton's creative style measurement (Kirton 1994), geniusology introduced the ideation efficiency measurement and a new measurement unit (1 idea per second = 1 Alein). Consequently, there would appear new concepts of decacreativity (x10), hectocreativity (x100), kilocreativity (x1000), megacreativity (x1,000,000), and gigacreativity (x1,000,000,000) as the numerically defined concepts for measuring the efficiency of creative output (Aleinikov 1999b, 2002a).

In addition to the first (scientific) and second (graph-based) definition, geniusology offers a "genius-type" definition of genius. It was developed in one of genius thinking classes during the so-called genius definition exercise, where participants were allowed to use only two words for a definition. Such a two-word definition of a genius is **megarecognized megainnovator**. As in the case of megacreativity (Aleinikov 2002a), the words are spelled together. Only the Microsoft editing program and human editors prefer the spelling in four words. Even in four words, it is probably the shortest definition of a genius: **mega recognized mega innovator**.

Since genius is "the ability to reduce the complicated to the simple" (C. W. Ceran) and genius is "not so much about new ideas as it is about clarity of ideas" (Kevin Solway), geniusology, the science of genius, offers a simple, short as a formula and numerically precise "genius-type" definition: **genius is a mega recognized mega innovator.**

Note: In more traditional (less precise) words, it might be "a super recognized super innovator." The term *mega*, however, is preferable because it means "million" in science (megawatt, megahertz), while the word *super* does not have any mathematical equivalent.

A genius, therefore, according to this "genius-type" definition, has two sides united in one:

- Social recognition (over a million references, quotations, records in time and in space, i.e., over the centuries and over the country borders).
- The activity that caused (earned) this recognition – the activity of innovation that either includes over a million innovative acts or involves one or several acts that led to a million of innovative acts after its discovery. A good example of the latter is the discovery of x-ray (Roentgen) that spread to medicine, technology, geology, astronomy, and many other fields.

Finally, from the societal point of view, **genius is a social phenomenon of highly appreciated (valued) individual greatness**. Genius is just a social verbal award for individual's outstanding contributions for the benefit of society.

In general, in order to be accepted as a scientific definition, a definition should withstand counterexamples (mental experiments). For example, somebody states that "genius is a superior intellectual power." Then finding a genius (the person extremely famous for one's innovation) but not having a superior intellectual power would be considered a counterexample. For instance, Gore Vidal calls Andy Warhol, one of the founding figures of Pop Art, "**a genius** with the IQ of a **moron**." So the definition with "superior intellectual power" does not work for all geniuses. If there is at least one counterexample, the definition is not true.

Note that the definitions, offered by geniusology, withstand such a counterexample. Andy Warhol is certainly:

- A person top-valued by the society for the uniquely expressed highly innovative vision of the world
- A mega recognized mega innovator
- The fastest culture expander

The fact is that his influence spread over all medium from fine arts to TV and film industry, from literature to theater, and then to philosophy.

It was even called the Andy Warhol "empire," and some people rightfully doubt it could be done by a person with low IQ. Much closer to truth is the hypothesis that it was his play – the desire to be controversial, careless, and mysterious which attracted more viewers to the art, as was in the Salvador Dali's case as well.

Practical Applications of Geniusology

In Science

Studying geniuses and using genius methods of thinking brings outstanding results. As a case in point, studying the methods of Robert Oros di Bartini (Soviet air designer and physicist), the group of researchers from Monterey and Santa Cruz in California:

- Developed a new – mathematically simple and physically sound – vision of the world
- Introduced five new sciences and three new fields of research
- Discovered 11 new laws of conservation (for comparison: Isaac Newton discovered one, Johann Kepler – two)
- Offered 12 new measurement units for new physical reality (Aleinikov and Smarsh 2011).

In Education

The new scientific model of genius allowed educators to determine precise steps in developing genius habits, skills, knowledge, creativity, and innovation patterns both for children and adults. Genius Education Methodology (GEM) began its practice in 1995 with the opening of School of Genius in Montgomery, Alabama, and quickly spread around the world (Germany, India, Russia, Singapore, South Africa, Pakistan, Thailand, and the USA). GEM showed outstanding results in elementary, middle, and high schools, colleges, and universities, in teachers' and principals' education (for more details see "► Creative Pedagogy").

First of all, in its philosophy, GEM considers that there is a genius in every child and adult. It looks for what Plato seriously calls "peculiar bent of the genius" in each (echoed in the speech of Singapore's Minister for Education, Wong 2001) and many other authors mention with irony (see Mark Twain, G. C. Lichtenberg, Edgard Varese, and Sir Herbert Beerbohm in quotes).

Then GEM defines five steps to the genius level and develops specific methodologies to maintain the interest of the learner until it becomes internal motivation and makes the person being educated an idealearner (genius learner), who learns by oneself – no other motivators (exams, tests, grades, diplomas, awards) needed. Just as Schopenhauer stated, "Genius is its own reward." Learning genius thinking methods makes children so interested in studying that it changes their lives.

Some examples of teaching the genius thinking methods to children:

- Thirteen worst sixth graders of the school, selected by teachers out of 1,200 students as "doomed to fail," after a 3-day intervention, pass all the exams (math, science, english, and mother tongue) and proceed to the next level of academic education. This is 100 % success (Jiemin Primary School, Singapore).
- One of these pupils, an 11-year-old boy, invented a new skateboard by using a genius thinking method (creative activity), entered it in a contest in Japan (innovation activity), won the contest, traveled to Japan to participate in the ceremony, received $1,500 as winning prize, and gave his father $500 for "being a good father."
- A 12-year-old girl from Felton, California, who studied Bartini's methods, discovered two new laws of conservation and used one of them to solve the Great NASA Gravity Mystery ("Pioneer 10, 11 Anomaly"). For details see http://globalscience.ru/article/read/212/ and http://globalscience.ru/article/read/321/).

The main achievement of GEM, however, is that teachers after this pedagogical intervention see their students and their own professional duties in a totally different way. For saving geniuses in children and adults on four continents, media labeled Genius Education Methodology (GEM) "the GEM of education."

For comparison, there are other approaches to genius education and training. Genrikh Altshuller, for example, teaches the genius life strategies as chess game strategies (weak move, better move, the best move), and a person can follow these strategies to win the game of life and after life (Altshuller and Vertkin 1994).

China Daily reports that several "genius training camps" have been established in major cities across China, with one in Beijing (retrieved from http://www.chinadaily.com.cn/china/2006-05/19/content_594875.htm). The approach, however, is the "genius = high IQ" approach.

Conclusion and Future Directions

Genius is an extremely complex subject to study, and therefore, a separate science, geniusology, is evolving to study it. The science of genius is created with the purpose of understanding what genius is and how it is affected and reflected at all levels, ranging from the physical to the societal. Its mission is to research genius lives, genius learning, genius thinking, genius solutions, genius ideas, genius imagination, genius character, genius feelings, genius habits, genius skills, genius upbringing, genius environment, genius growth and decline, etc. Every aspect of genius and every bit of knowledge about genius is extending human understanding of genius, thus increasing the probability of improving the humanity scientific, technological, educational, and social achievements. Geniusology is being built around one object to study, which unifies research efforts, but it also incorporates diverse, multidisciplinary approaches [see "▶ Transdisciplinary Research (Transdisciplinarity)"] to be developed by academics, scholars, and researchers from all disciplines. Geniusology embraces cognitive, computational, mathematical, and educational approaches. The first geniusology results include both theoretical and practical achievements, such as a new vision of the genius world, new definitions of genius, new model of genius, new measurements, new measurement unit, and finally Genius Education Methodology that applies the research results to the educational practice. The inclusion of the educational aspect ensures that geniusology does not become a pure science: it needs testing and retesting in education; it needs educational and industrial applications to save geniuses, to develop geniuses, and to model geniuses.

Geniusology, as a new science with its "love" (Wolfgang A. Mozart) for genius and "love of truth" (Johann Wolfgang Von Goethe) about genius, is a vast field of research that is open to thousands of researchers. It opens new horizons or "new frontiers" (Arthur Koestler) for discoveries (see "▶ Invention Versus Discovery"). It embraces all previous empirical findings, all the data gathered by researchers, and builds new theories. Just as "philosophy becomes poetry" (Disraeli), the poetry becomes philosophy, and a set of definitions randomly taken from the list is used for illustration of the new science. Geniusology analyzes all types of reasoning: analogy reasoning and mathematical reasoning. It must research all types of logic: formal, modal, dialectical, deontic, and even "iron" logic; all types of problem-solving: trial and error, lay and scientific problem-solving, creative problem-solving, innovative problem-solving, etc. Geniusology creates a passionate tribute to the genius of creation, genius of arts, genius of education, and certainly genius of science!

In the future, geniusology must unite the studies of intelligence and multiple intelligences with studies on creativity (see "▶ Science of Creativity") and innovation (social newness) because genius is the combination of the top intelligence, top creativity, and top social orientation. Geniusology must study the strategies of genius thinking and the strategies of genius living, the strategies of genius solutions of the open-ended and ambiguous problems. Geniusology must investigate creative methodologies and innovative leaps, motivational, emotional, and social contexts of genius lives, as well as sociocultural, economic, political, historical, and environmental factors, causing genius and developing the genius. Geniusology must study cross-cultural (see "▶ Creativity Across Cultures") and intracultural genius. It must develop measurements of genius activities, abilities, and even products. It must find out the roots of greatness and eminence, giftedness and talent in all spheres of human life from arts and science to politics and war.

Geniusology achievements can result in new learning technologies, including intelligent tutoring systems, new visualization tools, computer-supported collaborative environments, new digital libraries, and real-time assessment tools. Obviously, there is place for mathematical, statistical, and computational modeling that will help to develop new tools and technology to support the science of genius. Countries that begin to apply the science of genius and its innovative methodologies can achieve a breakthrough in development in 10–20 years when children who went through GEM grow into genius thinkers, make their genius discoveries, patent and implement their inventions, and create their masterpieces in arts.

Key Concepts and Definition of Terms

World Society

From the perspective of modern systems theory in the tradition of Niklas Luhmann, *world society is a global social system that comprises all communications and actions* and makes them mutually accessible. There exists no social entity outside world society, and only events and actors which are processed in communication can be part of society. Without being established in communication, society cannot deal with them.

All other social systems can be regarded as internal structures of world society, which are also composed of communications and actions. The main *types of social systems are society* itself (segmentally differentiated in function systems), *organizations and interaction systems*. Social systems of different types are not mutually exclusive but rather overlap (or interpenetrate) each other.

Function Systems

Functional differentiation can be seen as the dominant structural principle of world society. While premodern societies were societally stratified (dominated by one vertical hierarchy that claimed validity for all social spheres), modern society (understood as one world society) is internally segmented in a growing plurality of thematically specialized function systems. *Function systems are thematic specifications of communication* like politics, the economy, law, religion, art, sports, the health system, the mass media, science, and education. A societal function system emerges when it succeeds in establishing a unique (functionally specialized) communicative domain, which clearly distinguishes itself from other domains.

To distinguish itself from its environment, each function system uses its own, unique symbolic generalizations as *success media and binary codes for processing its operations*. For example, the political system uses the medium of power and operates in the code of powerful/subject to power, the economic system deals with the medium of money and operates along the binary distinction of paying/not paying, and the legal system communicates in the medium of law and uses the code legal/not legal. Media and binary codes increase the probability of otherwise improbable communication (e.g., the exchange of money against goods) and allow for subsequent communication of the same type (e.g., using received money for further purchases). The binary code makes it possible to identify communications of the same type. By linking them, operational closure and the self-production of a function system can take place. Each of the success media and respective binary code only has validity within the thematic domain of its function system.

Two crucial consequences follow from this concept. First, *the arrangement of function systems in world society is segmental*. They exist in parallel to each other in a nonhierarchic order. Interdependencies between function systems may exist, but no function system can subordinate or substitute the operations of another one. Second, the *thematic focus of each function system is* per se *a universal one* which cannot be reduced to a local or regional context. Globalization is not only driven by the political and/or the economic system but also by the emergence and expansion of all other function systems as well, which all claim worldwide relevance for their thematic specialization.

While function systems constitute thematically specialized communicative domains of global reach, they cannot interact with other systems in their environment. They observe their environment for events which can be dealt with in their respective code. But this is only internal communication within the function system. To communicate with other social systems, function systems depend on organizations (Luhmann 1997: 843).

Organizations

Organizations are another crucial structural component of world society. The emergence of formal organizations is closely related to the genesis of function systems (Stichweh 2007: 137). One can speak of a coevolution of both types of social system. Functional differentiation is a prerequisite for the emergence of organizations, while organizations simultaneously promote the expansion and the unfolding of the internal complexity of function systems.

Organizations distinguish themselves from their environment via the *principle of membership*, which is tied on conditions and regulated formally. Membership allows organizations to define their boundaries to the outside as well as behavioral expectations toward their members inside. *Decisions*, which can be attributed to their members or to the organization as such, are the *core operations of organizations*. The recursive connection of its own decisions leads to operational closure of the organization. This operational closure of the organization is the prerequisite for its informational openness. Only on the basis of its own decisions, an organization can observe its environment and communicate externally (Luhmann 1997: 835ff).

The formal organization represents a principle, which is orthogonal to functional differentiation (Stichweh 2011: 5). Organizations can (and have to) switch between different functional domains. However, they also tend to focus on the binary code of respectively selected function systems. This leads to the emergence of specialized types of organizations, for example, to companies and banks in the economic system or to courts and prisons in the legal system.

Nation States

After WW II, a major structural change in the political system of the world society came to completion. The formerly stratified structure of colonial states and large empires, which subordinated local regimes as provinces or colonies in their respective sphere of political control, was substituted by a *segmented structure of formally equal nation states* (Stichweh 2010: 299), a development that led to the establishment of more than 130 new nation states since 1945 (Meyer et al. 1997: 158).

Nation states are territorially bound. Since they are political organizations, their primary function is to generate collectively binding decisions for their members by which they facilitate the *inclusion of their members in the global political system*. Modern states can also be regarded as welfare states insofar as they *moderate the inclusion in other function systems* (e.g., the economic, the legal or the health system, the education or the science system). However, nation states cannot politically control these function systems. Rather they have to focus on providing access opportunities to autonomously operating function systems, for example, by providing pools of candidates for inclusion into the respective thematic domains (Stichweh 2010: 305).

Universities

In mediaeval times, the university emerged as a place to accumulate societally relevant knowledge, knowledge that could claim universal relevance. The most important knowledge domains were law, medicine, and theology, supplemented by various types of arts (e.g., grammar, rhetoric, arithmetic) (Stichweh 2006: 33f). Since this time, the main function of universities has been to *provide (higher) education*. Following Kade (2005: 19f), one can claim that universities (in their role as entities of the education system) use two related success media, *knowledge and certificates*, in conjunction with their respective binary codes knowing/not knowing and passed/not passed.

In the eighteenth century, the amount of socially available knowledge started a huge expansion, a process that also led to the differentiation of scientific disciplines and disrupted the former hierarchy between knowledge domains. Research as a systematic activity to generate new knowledge became a professional activity. Universities became the main *places where research is performed and the validity of knowledge is certified*. In their role as entities of the research system, universities use two other success media, truth and (scholarly) publications in conjunction with their respective codes true/not true and published/not published. Scholarly publications rather than classic texts became the content of higher education; the systematic and never ending test of its validity (true/not true) rather than the mere reproduction of knowledge became a crucial principle to gain insight during the educational process.

Combining these considerations, one can say that universities produce and reproduce themselves by three types of communication: *“the communication of knowledge, called ‘teaching’* [or better: ‘education’]*; the communication of problems and questions of ignorance, called ‘research’; and the communication of decisions on teaching* [education] *and research, called ‘the organization of a university’”* (Baecker 2010: 358).

Political actors may set political limits to these activities and try to influence the organizational structure of universities, and economic actors may offer incentives for universities to focus their activities on certain topics. Both may link specific utilitarian expectations with their engagement. And (especially American) universities have proven to be responsive to their poly-contextual environments. But external interventions and utilitarian expectations cannot determine the way in which a university operates internally, which is the communication in the codes of the education and the research system and the communication in its own decisions as an organization. In this *“focus of trusteeship”* in the development of secular knowledge and learning, the university is *“perhaps the most important structural component of modern societies that had no direct counterpart in earlier types of society”* (Parsons 1961: 261).

The Global University System

The global university system is not a function system in the sense described above. Rather it is an *interorganizational system that is based on* *relationships of observation*, interaction, cooperation, and competition between organizations (Stichweh 2009: 2).

While in the past, the development of universities largely depended on the development of their respective national university systems, which only occasionally learned from each other, mainly from the perceived centers of the global university system, the situation is fundamentally changing since the midst of the twentieth century, especially since the 1960s. *International governmental organizations*, like the OECD (e.g., "Education at a Glance"), UNESCO (e.g., the ISCED-classification), or the World Bank, started to gather data on education and research to *systematically compare and to offer advice to national systems*.

Based on these data, one can, for example, observe an increase of the participation rate in higher education between 1900 and 2000 from less than 1% to about 20% of the age cohort worldwide. Enrolment ratios continue to climb rapidly; in some industrialized countries, they are well beyond 50% already (Schofer and Meyer 2005). Especially since the 1960s, exponential growth took off on a global scale. This *growth in enrolment ratios is accompanied by a rapid proliferation of universities and the differentiation of types of higher education institutions*. The International Association of Universities (IAU) currently lists more than 17,500 institutions worldwide, a number that is growing constantly.

The emergence of *higher education research as a distinct research field* also can roughly be dated in this time. Authors like Joseph Ben-David (1977) or Burton Clark (1983) started to systematically *compare selected national systems* mainly from European and North American origin. More recent research also compares *clusters of national systems*. For example, Pechar and Andres (2011) analyze different types of welfare regimes and their impact on higher education: conservative regimes (in Continental European countries) combining medium public expenditures on higher education with low/no tuition fees, social democratic regimes (in Scandinavian countries) combining high public expenditures with no tuition fees, and liberal regimes (in Anglo-Saxon countries) combining medium/high public expenditures with high tuition fees. Similarly, Marginson (2011) identifies a "Confucian model" (in Southeast Asian countries), which combines low, but focused public expenditures with high tuition fees. These are important differences in the global university system.

An even more interesting phenomenon is the emergence of *regional, transnational forms of coordination between national systems*. The most prominent example is the Bologna process, which is establishing the European Area of Higher Education (EAHE) via the introduction of a joint academic degree structure, of the European Credit Transfer System as a joint measure to weight and transfer course certificates, and of joint standards and guidelines for quality assurance in higher education. The Latin American and Caribbean Area for Higher (ENLACES) seems to aim in a similar direction, but is less developed yet. More advanced seems to be the emergence of *regional qualifications frameworks*, which foster transnational comparisons and the transfer of degrees, for example, the European Qualifications Framework (EQF), the Southern African Development Community Qualifications Framework, or the Southeast Asian Nations Framework Arrangement.

Having been squeezed between the academic profession and the state, the traditional university (especially in Europe) had much resemblance with both an assembly of a guild and a subunit of the state bureaucracy but often lacked a strong organizational identity of its own. Its members tended to have stronger loyalty to their respective disciplinary communities and to the state administration than to their home institution, which left the internal organization of the university fragmented in small fiefdoms, a situation that led to the description of the university as a loosely coupled system. External relations were often maintained as personal relations of individual professors. This situation has been changing in recent decades since *universities are increasingly turning into organizational actors*. Krücken and Meier (2006) identified four related elements, which characterize this transformation: the trend toward accountability and external quality assurance (which addresses the university as an autonomous organization), the definition of organizational goals (which requires internal coordination of expectations), the emergence of formal structures (which represent a growing variety of administrative and supportive instead of traditional academic tasks), and the raise of the management profession (which specializes in performing these organizational task).

This emerging organizational actorhood is a prerequisite for universities to develop *organizational relationships*, for example, for the exchange of larger amounts of staff and students, for the cooperation in joint research projects, or for the provision of joint study programs. It also offers universities the possibility to create and join *organizational associations* based on criteria of location (e.g., European University Association), disciplinary specialization (e.g., Association to Advance Collegiate Schools of Business, World Veterinary Association), or status consideration (e.g., League of European Research Universities). These organizations of organizations serve as exclusive clubs, which promote joint interests but also develop expectations and set standards for the behavior of their members, similarly to what scientific associations did for individual academic members.

Another phenomenon that addresses individual universities and fosters their observation, comparison, and competition is the *emergence of national and global rankings of universities*. At a national level, the first rankings based on reputational methodology have been established in the USA a few decades ago and can currently be found in more than 40 countries. At a global level, university rankings only exist since the turn of the century. Their most prominent examples are the Shanghai ranking and the Times Higher Education Supplement ranking. Even if the methodologies of these rankings are still contested, but their results have gained tremendous attention and huge influence on the self-perception and the decision making of universities. While in the past, institutional comparisons were rather restricted to a regional space (and universities were often content to blend in into their regional contexts), national league tables and global rankings *expand the cognitive spaces for comparisons* (and encourage competition among universities to improve or defend their status). Remarkably, global rankings also seem to steer the competition between national systems by offering indicators to measure progress of their developments. One of the results is the aspiration of several national governments to heavily invest in selected institutions to push them into the perceived league of *world-class universities*, even if the rationale behind these plans in some cases seems to be one of national pride and of politically profitable ambition rather than of sorrow economic calculation (Wildavsky 2010: Chap. 4). For some countries, this also means a step toward more stratification and a departure from prior attempts to create homogenously composed national university systems.

Mobility of staff and students always has been an important characteristic of universities. In this sense, they always have been international organizations even if this mobility has often been a random or at least unsystematic effect. Becoming more entrepreneurial, the *search for talents and for revenues on international and global markets* becomes a strategic endeavor for universities, even if they remain territorially located organizations. However, this peculiarity of universities is beginning to change as well. In difference to economic multinationals, which have a long tradition in establishing subsidiaries in other countries, universities have started to experiment with *offshore branch campuses* only in the 1990s. In the meantime, 162 branch campuses have been established, predominantly in the Middle East and in Southeast Asia (Wildavsky 2010: Chap. 2).

Digital media contribute to many of these developments and lead to the *virtualization of universities*. In their aim to establish presence in the World Wide Web, universities create self-descriptions of increasing complexity and post them on their home pages or portals. These self-descriptions, but also centralized enterprise systems for accounting, reporting, and documentation, foster the integration of universities as organizations and their addressability for external communication. Computerized or at least computer-aided forms of research become widespread in all disciplines, but additionally, digital media change the ways in which research is organized, communicated, and published. Similarly, digital media change the production, distribution, and accessibility of learning materials, which has consequences on the production structure of higher education. Given the ubiquitous availability of content, assessment of self-directed learning will become a more important part of education than the mere distribution of knowledge. And, if higher education is about the alphabetization at an academic level (i.e., educating students in the ability to read and to write scholarly texts), it becomes a new task for universities to foster literacy in selecting, analyzing and understanding digital forms of academic knowledge resources and databases, and in producing academic publications in new digital formats and genres (Pfeffer 2012).

Theoretical Background and Open-Ended Issues

World society is a distinct layer of reference, the starting point of macro-sociological analysis, not its empirical result (Hasse and Krücken 2005: 187). There are not too many theoretical concepts available that deal with the analysis of world society. Maybe the most prominent alternative to modern systems theory is the strain of neo-institutionalism that has been developed by John Meyer and the so-called Stanford School, which also conceives the nation state as an organizational phenomenon within world society. In this concept, world society comes to existence through global processes of modernization which spread "world cultural models" or "taken-for-granted scripts." The worldwide dissemination of these rationalistic models or scripts shapes organizational forms and assumptions on which activities have to be done. This neo-institutional approach has also led to an impressive body of empirical research. The studies on the proliferation of the modern nation state and on the exponential growth of participation in higher education are important examples, which have been mentioned above already.

However, given its specific interest in the proliferation of world cultural models or global scripts, this approach focuses on the observation of processes of standardization, on significant similarities, and on trends toward isomorphism. In difference to that, systems theory is more interested to observe the evolving complexity and differentiation of world society. It is therefore better equipped to deal with phenomena of innovation at the level of society, which mainly take place when new functions emerge and new organizational forms are developed.

Implications for Theory, Policy, and Practice

Theories of the world society in general and the concept of the global university system in particular can help to avoid methodological nationalism, the tendency to take the nation state as the main source, the dominant actor, and the sole end of innovation, and social developments, especially when it comes to universities. This does not mean that the global level is the only relevant for further considerations, which substitutes all other structures. Rather, these concepts help to observe the increasing complexity in the environment of universities, the multiplicity of contexts to refer to and the increasing variety of organizational actors to deal with.

From a theoretical perspective, it seems crucial to conceptualize and analyze phenomena like international organizations, regional (transnational) organizations, and organizations of organizations in the global university system without following merely political or economic considerations. From a political perspective, nation states should depart from ideas of unilateral control of their universities, or of nationally closed higher education and research markets, which requires new, innovative concepts of higher education and research policies. From the practical perspective of the individual university, it seems reasonable to acknowledge the limitations (and benefits) of any given local or national environment. But simultaneously, every university should use the expanding cognitive space of the global university system to search for the most appropriate peer organizations to compare with, to compete with, and to cooperate with. The better a university is in positioning itself within the global university system, the lesser it will be passive object of external influences.

Conclusions and Future Directions

While in the midst of the twentieth century, the global university system could adequately be described as a system of national university system, the situation is heavily changing since the 1960s. All over the world, participation rates in higher education grow exponentially, the organizational types of higher education institutions diversify, and their overall number continues to expand. In many countries, universities have started to break loose from rigid administrative control by their national governments and are increasingly developing organizational identities and actorhood. Additionally, new organizational actors of various types gain importance.

To observe further innovations in the global university system, a wide range of questions emerges:

- What are the most important *international organizations* for the global university system (in addition to OECD, UNESCO, the World Bank, etc.)? How can they be compared and analyzed in their influence on the global university system?
- What are the most significant examples of *regional (transnational) coordination between national systems*? Can similar coordination mechanisms be found within large national systems (e.g., USA, China)? Will they lead to a polycentric structure in the global university system or should a center-periphery structure rather be expected?
- Where can examples for *organizational associations* be found in the global university system and in how far do they foster a differentiation of organizational types?
- In comparison to global rankings, would *network analysis*, for example, based on bibliometric indices, data on research collaborations, and student exchange programs provide alternative pictures of the relevance and connectedness of individual institutions in the global university system?
- In how far does the emergence of international and global markets for higher education and research change the balance between public and private contributions? What could be defined as *public goods in the global university system* and how could they be provided?
- *How comprehensive or specialized* should individual universities and national university systems become in positioning themselves within the global university system?

At the moment, research on the global university system still is rather scarce. To answer some of these questions will change this.

Cleantech; Environmental innovations; Green economy; Green growth; Renewable energy; Sustainable development

Introduction

The last few years have seen the emergence and gradual development of a number of innovative environmental products, services, and technologies, hence the rapid growth of a tangible "green" business/economy which is developing today all around the world and which is becoming increasingly organized through the formation of coalitions/clusters/networks of "green entrepreneurs."

However, green entrepreneurship remains understudied in the literature. Therefore, the contours of the phenomenon are rather fuzzy. At the same time, green entrepreneurs are still facing substantial economic and noneconomic barriers that hamper their development.

Environmental Innovations and "Green Business": A Great Potential Entrepreneurship Opportunity

Broadly speaking, environmental innovations can be defined as new or modified processes, techniques, practices, systems, and products to avoid or reduce environmental harms. When widening the scope, it comprises all the activities related to the environment, all sectors of cleantech (fuel cells, new materials, energy efficiency, etc.) and renewable energies (agro-fuels, solar and wind energy, biomass, etc.), and all the activities designated as being "low carbon."

For many experts, the challenging issues related to sustainable development (SD), to the preservation of the environment, and to the attenuation of climate change effects give rise to a continuous stream of significant innovations that may even constitute a "new techno-industrial paradigm." For the entrepreneurs (and investors), green business is therefore a great opportunity of profit in many sectors. Indeed, various converging trends provide clear evidence that "green markets" are now substantial and grow rapidly.

This structural momentum – that President Obama has designated as being a "Sputnik moment" in his 2011 *State of the Union* address – reflects a change in the way different stakeholders perceive environmental issues in four key areas (Hamdouch and Depret 2010). Firstly, the environment has become a global and long-term challenge. Secondly, the deterioration of the environment can no longer be solely attributed to industrial production processes, and consumption patterns now feature prominently in the equation. Thirdly, the limited, corrective, and local management of ecological and climatic degradation is gradually being replaced by the conviction that protecting actively the environment is not necessarily harming growth, job creation, and competitiveness. Fourthly and lastly, decision-makers have understood that a sustainable innovation policy is likely to promote radical environmental innovations with the ability to set in motion the cumulative and long-term development of competitive green sectors at a global and continental level.

The global turnover generated by the market of post-carbon and environmental goods and services exceeds $5,000 billion (BERR 2009). This estimation is recouped by various other indicators or concrete evolutions observable in several specific areas (environmental technologies, environmental goods and services, clean technologies or energies, renewable, etc.). Indeed, most available studies emphasize the fact that green markets are now reaching a "critical mass," display high growth rates, and should continue to develop in the next future, particularly in renewable energies and energy efficiency.

At the corporate level, a growing number of companies are now adopting a "corporate social responsibility" (CSR) and sustainable development (SD) approach in their organizational and strategic orientations and are also investing and diversifying more and more in green activities. At the same time, following the Kyoto Protocol ratification, R&D expenditures, as well as the number of patents and of commercialized innovations in the environmental field has literally boomed. Lastly, there is now a move toward the formation of networks and clusters focusing on activities, research, and innovation in these environmental fields (Depret and Hamdouch 2012).

This fast-growing trend is also observable in the world of finance where both the number and the size of merger and acquisition deals have substantially risen in the recent period. Equally, some key actors in the financial field (venture capital companies, ethical funds, and several pension and investment funds) are more and more attracted in investing in the environmental business. Finally, one should notice the recent fast development of emission or pollution bonds and carbon fund markets within the key financial places.

At the institutional level, the context for the development of the green business is also increasingly becoming more favorable thanks to various factors, especially the works of the IPCC, the "TEEB report," and the "Stern report"; the increase and volatility of raw materials and energy prices; the installation of the Obama Administration in the United States; the financial, economic, and social consequences following the subprime crisis; etc. Equally, and in relation with the factors noted above, the "new green economy" ambition is now provoking a growing commitment in many countries and regions of the public authorities but also of the civil society. This commitment stems partly from an emergent and consolidating change in mentalities and behavior of consumers/citizens but also from the conviction that recovery from the crisis requires a more sustainable economic growth pattern. By a matter of fact, this new "ecological awareness" translates very concretely in the privileged role given to the "green growth" theme in public policies, as asserted by the new institutional, fiscal, and social policy orientations which aim at creating favorable conditions for the economic development/consolidation of green industries (Hamdouch and Depret 2010).

Missing Green Entrepreneurs in the Economic and Managerial Literature

For all the reasons examined above, green markets appear today as a great strategic opportunity for many entrepreneurs who see in them the chance to win the new global competitive race based on SD, CSR, and green growth approaches.

It may then appear surprising that this entrepreneurship phenomenon around environmental activities has barely been addressed in the economic and managerial literature on entrepreneurship and clustering that has proliferated in recent years (see this volume). Even worse, there are hardly any publications, case studies, or best practices released by academics, journalists, or experts on "green entrepreneurs" though some of such entrepreneurship dynamics is a truly visible phenomenon today in many countries (see Cooney 2008; Isaksson 2009; Warren 2009; Horwitch and Mulloth 2010; Koester 2010; Wüstenhagen and Wuebker 2011).

Green Entrepreneurship: A Reality, But a Contrasted Phenomenon

The contours of the green entrepreneurship phenomenon remain rather fuzzy, notably because green entrepreneurship displays differentiated realities depending on the countries or sectors considered (Hamdouch and Depret 2010; Depret and Hamdouch 2012).

Still, several statistical data and stylized facts are available which attest of the reality and ongoing dynamism of green entrepreneurship in the key developed and emerging countries.

From an economic point of view, the markets of "post-carbon and environmental goods and services are concentrated around only few key Developed Countries and Emergent 'players'" (BERR 2009).

Indeed, most leading green clusters are located in these countries (Depret and Hamdouch 2012). This is a core factor for spurring green entrepreneurship as innovation clusters and networks facilitate greatly the creation of start-ups through the provision of human resources (especially managerial skills) and the funding needed in the accomplishment of entrepreneurial projects (see entry "▶ Clusters" in this volume).

By a matter of fact, the green entrepreneurship phenomenon relies heavily on the growing support of funding and investment institutions that are attracted by the economic potential of innovating projects in the environmental field. Investments in cleantech have increased rapidly during the last few years (see UNEP and Bloomberg New Energy Finance 2011).

From a technological point of view, about three quarters of financial investments in renewables are devoted to wind energy and take the form of asset finance of utility-scale projects due to the very high cost induced by this king of energy generation. Indeed, venture capital (VC) and private equity (PE) firms invest very few in wind energy. Rather, they invest in solar energy or, to a lesser extent, in biofuels, particularly because they consider that the chance is higher for a new entrant to take competitive advantage in the latter than in the former sectors.

From a geographical point of view, financial investments attracted by China, India, and Brazil were as important as those attracted by the USA and Europe taken together. Developing countries are today far more important than developed countries on public market investments and in asset finance for utility-scale projects. However, VC and PE investments in cleantech are clearly concentrated in North America, while Europe and South America lag behind and Asia is nearly absent regarding these sources of funding.

In Search of Specific Green Entrepreneurship Policies

The main green clusters are located precisely in those countries and regions where the public authorities (national, regional, or local) adopt an active environment and innovation policies (Hamdouch and Depret 2010). Indeed, depending on their geographical location, green entrepreneurs benefit from a contrasted specific green entrepreneurship (national) institutional context with its strengths and weaknesses.

However, and paradoxically, including in the main countries engaged in green growth strategies, "green entrepreneurship policies" are practically nonexistent. For the most, the policies dedicated to the "green business" are not specifically oriented toward green entrepreneurs. At best, these policies target small and medium enterprises that are innovating in green sectors and offer to them support via financial, fiscal, or regulatory mechanisms that have been used for other high-tech sectors (IT, biotechnology, etc.): "loan guarantee programs" (which back private loans to promising companies with new technologies); regional clusters technical and financial assistance (by facilitating access to angel investments and VC) to entrepreneurs and early stage companies; business plan contests (prize awarded to winning competitors to help them finance their project); subsidies, grants, and tax exemptions; public-private partnerships for R&D; etc. At worse, the policies engaged support as much – if not more – the "Greening Goliaths" (large companies or incumbents) as "Emerging Davids" or new entrants (Hockerts and Wüstenhagen 2010).

Green Entrepreneurship and the Development and Diffusion of the Green Business: A Hurdle Race

The development of green technologies is constrained by a series of both economic/financial and non-strictly economic (mainly psychological and institutional) inhibiting factors and obstacles (Depret and Hamdouch 2012).

The Economic/Financial Constraints and Barriers are Clearly the Most Important Green Entrepreneurs Must Deal with

Firstly, green technologies often depend upon the availability or constitution of a critical mass of knowledge, (multidisciplinary) competences, and (human and managerial) resources that are complex, cumulative, and, for the most, still embryonic or difficult to access. This is notably the case for human capabilities as green jobs require new "blocks of competence" for the integration of the environmental dimension in work attitudes and professional behavior. From this point of view, considerable efforts must be devoted for the mobilization and training of the manpower, for the acquisition of new knowledge and know-how, and for informing employees about new green technologies and services and their market potential. Equally important here is the need for a close coordination among a great

Green Business and Entrepreneurship, Table 1 Technology risk/capital intensity green projects funding matrix

		Technological risk	
		Low	High
Capital intensity of project	High	**Project finance/existing firms**	**Hard to fund ("valley of death")**
		E.g.: wind farms, utility-scale solar, "first-gen" biofuel refineries, fabs for solar cells using, established technologies	*E.g.: first commercial plants for unproven solar cell technologies, advanced biofuel refineries, offshore wind farms, carbon sequestration*
	Low	**Bank debt/existing firms**	**Venture capital**
		E.g.: wind and solar components of proven technologies, internal combustion engines, insulation/building material, energy efficiency services	*E.g.: energy efficiency software, lighting, electric drive trains, fuel cells/power storage, wind and solar components of unproven technologies*

Source: Authors, adapted from Ghosh and Nanda (2011, pp. 8–9)

number of heterogeneous and geographically dispersed actors. This coordination often goes through the formation of interest coalitions, vertical and horizontal partnerships, interorganizational networks as well as social and political networks, clusters, etc. (see above).

Secondly, green business implies huge R&D, production, and commercialization costs, notably in energy sectors. Indeed, investing in greentech is usually more costly than investing in polluting technologies because "green entrepreneurs" must face the problem of "double (environmental and technological) externality" that environmental innovations bear. Following this, the financial uncertainties that usually characterize investments in the green business can be high enough to discourage risk bearing by private or even public investors. This is particularly the case for emerging green technologies that require costly research infrastructures and huge basic research efforts that both can hardly be engaged by the private sector. Also, given the challenges characterizing the ongoing and future environmental and climatic issues, the (very) long-time scale underlying the required investments is obviously beyond the financial short-medium constraining time horizon that most private investors and entrepreneurs must usually face. Moreover, as financial markets are both incomplete (future generations do not contribute to the funding of current investments; the market does not allow an efficient inter-temporal allocation of risk bearing) and imperfect (risk aversion and excessive cautious attitude of investors and savers, lack of fair valorization of natural resources and pollution costs, risks related to spillovers appropriation, incomplete information, etc.), long-term and risky projects can hardly find their required financing.

Thirdly, green entrepreneurs need to get access to differentiated sources of funding depending on the evolution stage of their project: public subsidies, seed capital, public equity, and VC for the first stages of the project and savings and banking resources during the further development of the project. Moreover, depending on the type of project they undertake, the risk is high for green entrepreneurs to get trapped within a technological, commercial, or managerial "valley of death" at one moment or another of their evolution (see Table 1). One key obstacle here that green entrepreneurs (especially those involved in radical innovation fields) must face relates to the structural weakness of VC and PE investments. Indeed, less than 4% of total financial investment comes from VC and PE. The explanation for this situation is threefold. First of all, venture capitalists are rather cautious regarding green sectors, which they still consider as being too new and risky. The very emergent character of some green technologies, the uncertainties surrounding the relevant business models to be implemented, and the difficulty to exit from a still too narrow market are the main reasons for such reluctant attitude of VC and PE investors. This explains, in turn, why the supply of VC and

PE funding for clean energy is concentrated among few key players (Ghosh and Nanda 2011). At the same time, it is perhaps not surprising that some of the biggest VC/PE deals in renewable energy were made by companies supported by government loan guarantees (UNEP and Bloomberg New Energy Finance 2011). Equally important as an explanation is the fact that VC and PE are primarily invested in early stage projects, which are less capital intensive than more mature (and highly capital consuming) projects (Ghosh and Nanda 2011). Finally, as some of the most massive environmental technologies (wind turbines, utility-scale solar infrastructures, energy efficiency technologies, etc.) are supported by incremental rather than radical innovations and are also run by large companies, their funding rely more on project finance resources, bank loans, and stock markets than on VC or PE investments. Moreover, VC investments "have begun to move away from radical technologies related to energy production and are increasingly focused on energy efficiency, software, energy-storage and transportation" (Ghosh and Nanda 2011, p. 2).

Fourthly, green entrepreneurs are confronted with important risks (scientific or technological, economic, and legal) that render their financial prospects even more problematic. These risks are susceptible to generate sunk costs (related to the infrastructure, the maintenance of equipment, the training of workers, etc.) that may prove to be significant. This is particularly the case in certain industries (automobiles, energy, building materials, etc.) where several alternative (and noncompatible) green technologies are competing within a standardization process. In this context, there is a risk that "the winner takes it all" and/or important switching costs arise for those trapped in "loosing" technological choices. Equally, learning and experience effects, network effects, and other kinds of "increasing returns to adoption" can deter the entry of pioneer entrepreneurs in green markets, especially those which are either emerging ones or hardly "contestable" by newcomers.

For all these reasons, the transitory intervention of public actors (whatever their nature and forms of intervention) along with the risks taken by the entrepreneurs is often indispensable for the emergence and development of a viable green business. Specifically, only the State is able to mitigate market uncertainties, both through the pooling of the diversifiable risks and by directly taking in charge the consequences of the extreme and nondiversifiable risks. Besides, the State should also create a "favorable environment" for long-term investors.

However, public funding is not a panacea because it also creates at least three additional sources of uncertainty for the entrepreneurs or investors. The first one relates to the possible capture by a small number of powerful/better informed "players" (large companies or lobbies) of a large portion of the public funds offered. The second source of uncertainty is the creation, through the public intervention, of "bubbles" around green technologies or market niches that may ultimately prove to be economic or technological "deadlocks." Finally, unless the public policies devoted to the development of green markets and technologies are clear, credible, and coherent over time in their deployment, it is likely that the public intervention results in a failure.

Psychological and Institutional Obstacles also Play an Inhibiting Role, Though not as Visible as Economic and Financial Barriers

The first difficulty comes from the fact that the transition toward a green or carbon-free economy generates different forms of inertia and resistance (stemming from the sectors that should bear the costs for this transition and from their lobbies) that can slow/block the development of green markets and, as a consequence, discourage green entrepreneurship.

Secondly, purchasing behavior of key clients (households, companies, local public authorities, etc.) for green technologies/products/services can hardly been anticipated *ex ante*. This is the case on the one hand because this behavior depends on the evolution of the preferences of the actors (sensitivity to the economic environment, quality of the available information, "fashion" and "bandwagon" effects, influence of eco-labels, etc.).

These preferences cannot be easily quantified and are traditionally rather conservative and routine-based. On the other hand, clients' price sensitivity and their consent to pay for green products depend greatly on the changes affecting relative prices, which themselves are influenced by many exogenous factors: increase in the prices of key natural resources and energy sources; economic life duration of technical equipment; level of eco-taxes, nature of environmental regulations, and importance of public subsidies in favor of environmental R&D efforts; degree of standardization and substitutability of the alternative green technologies/products/services that are available; intensity of learning effects and their impact on costs/prices reduction over time; etc. As a consequence, there still are many uncertainties regarding the growth rhythm, the robustness, and the solvability of the demand for green products, even if the trend is positively oriented.

Thirdly, green entrepreneurs often face technical or institutional problems relatively hard to be overcome. This is the case when some key infrastructures or technical networks (energy, transports, etc.) are weak or even lacking. There is also a difficulty related to the scarcity of some natural resources or raw materials that are indispensable for certain green technologies. This scarcity is problematic not only because it increases the price for such resources but also because it confers a monopoly power to those actors (notably, certain large companies and countries) that own, preempt, or produce them (Depret and Hamdouch 2012). Finally, extra-economic barriers relate frequently to administrative or bureaucratic rules and behavior, especially when these are connected to political/strategic reasons (national security, sovereignty, geostrategic bargaining power…). Equally important is the absence or weakness of adapted regulations and financial public support to green entrepreneurship and business development.

Conclusion and Future Directions

As it stands today, green entrepreneurship becomes more and more a visible phenomenon though its very industrial bases and development patterns remain unclear. In particular, the economic, political, competitive, and psychological context which conditions this development is as uncertain as contrasted from one country to another. To be sure, whatever the place, green entrepreneurs need "green (new) business models," "green (academic or technical) education and training, "green customers/citizens," "green investors," and "green governments" and "green entrepreneurship policies."

At the same time, one can wonder if green entrepreneurship should be envisaged and analyzed as a specific phenomenon or if it relies on the more standard factors that support innovative entrepreneurship generally speaking, whatever the business sector or innovation field considered. More precisely, are risks borne by green entrepreneurs higher than for other kind of entrepreneurs? Does green innovation emergence and dissemination depend on the same support mechanisms (clustering and networking dynamics, partnerships with large companies, etc.) than innovation in general?

Finally, the emphasis put today on greentech is probably excessive as it is likely that green services, the emergence of new amenities, and the search for solutions toward better quality of life may well also constitute significant opportunities for green entrepreneurs.

These issues are still under question and require further theoretical and empirical investigation, both on the motivations and strategies underlying entrepreneurial behavior in green sectors and on the territorial-institutional specific settings that favor at best green entrepreneurship at the geographical level.

Green Economy

▶ Green Business and Entrepreneurship

Green Enterprising and Green Entrepreneurs

Aljona Sandgren
School of Business, Åbo Akademi University, Turku/Åbo, Finland
Department of Physical Geography and Quaternary Geology, Stockholm University, Sweden

To have innovative ideas is not enough; one needs to bring innovations to society. Entrepreneurs are the necessary link in bringing new ideas to the market and society (Audretsch 2007). Green enterprising is a relatively new concept which needs to be further developed, denoting a bottom-up approach to solutions to environmental challenges, broader than cleantech as it is not just about technology. There is a general need for rethinking our understanding of entrepreneurship and entrepreneurs, our present practices and processes, applying new social science perspectives. Meaning and understanding, how you think about phenomena, is important as this influences our actions. The aim of this entry is to offer an analysis of entrepreneurship in general and green entrepreneurship in particular, based on a literature review supported by results from case studies of entrepreneurs, focused on environmental solutions, in Sweden and Russia. What are the main drivers of green entrepreneurs? What is the importance of cultural, historical, social, and economic factors? Results from this study, including theoretical reflections, will be used here as illustrative examples of green enterprising.

Entrepreneurship today became a banner word, seen often both in developed and developing countries as a solution to many societal and economic problems. The meaning of this term however, varies as there are many different interpretations and understandings. Mainstream definitions have their roots in the ideas of classical and neoclassical economists', who, according to Schumpeter (1954) and Blaug (2000), fail to distinguish the role of entrepreneurs from the capitalist, the owner of capital or manager with an emphasis on profit maximizing. Entrepreneur is often identified narrowly as the rational calculating man, homo *oeconomicus* who acts according to preferences, based on the rationality of his/her choice.

During recent years there are attempts to broaden the view of entrepreneurship, and new terms arise such as *cultural* (Wickham 1998), *social/public* (Steyaert and Hjorth 2006; Nicholls 2006; Bjerke et al. 2007; Gawell et al. 2009), *academic* (Etzkowitz and Leydesdorff 2001; Shane 2004), *green* (Isaak 1998; Schaper 2005, 2010), or entrepreneurship for sustainable development. The main driver for *social/cultural* entrepreneurship, for example, as Kirby (2003) argues is not wealth creation or business capability but creativity, the enrichment of life, by challenging convention and by opening up ways of thinking and behaving that previously did not exist.

Referring to social and/or public entrepreneurship, researchers emphasize that entrepreneurship belongs to society and not just the economy: The focus is on citizens not merely consumers. Social entrepreneurship, as mentioned above, is about making a difference, solving a problem, and the willingness to bring change into society. In connection to social entrepreneurship, it would be important to mention another significant feature of entrepreneurship pointed out by some researchers such as *organizing* (Bjerke et al. 2007). *Organizing*, creating organizations for the realization of visions, ideas, and opportunities, characterizes entrepreneurship as a form of interhuman creativity. This means that it is not only about creating new products or services but also about forming associations, communities, and commitments to activities in the public arena. It is necessary to keep in mind, however, that such interhuman activity is rooted in its own cultural context – habits, traditions, and attitudes.

Green Entrepreneurship/Enterprising

Among researchers focusing on green entrepreneurship theory there exists a clear distinction between *commercial* and *social* entrepreneurs, for example, commercial and social ecopreneurs (Pastakia 1998), green and green–green (ideal type) (Schaper 2005). According to the researchers, *commercial ecopreneurs* are those who seek to maximize personal (organizational) gains by identifying green business opportunities. Social ecopreneurs are those who seek to promote eco-friendly products/technologies either through market or nonmarket routes. However, based on the discussion in this entry and the broader understanding of the nature of entrepreneurship, the division between *commercial and noncommercial entrepreneur* seems problematic.

The definition suggested here is: *Green enterprising* is based on bottom-up approaches, challenge driven rather than market or technology driven. It is about the process of creating and acting, finding and implementing innovations and/or solutions to environmental challenges, new creative combinations of phenomena which could be old or recently invented, learned/developed.

The meaning of *green* in this context is "the coherent pursuit of social and environmental aims while being sustainable, not damaging to the environment or preventing environmental damage" (GEF 2011). It is a mindset and an intention, or it is an existentialist commitment as suggested by Isaak (1998).

The word *enterprising* here was chosen (1) partly because of the rather confusing connotations linked to the narrow understanding of the word entrepreneurship, (2) partly because it is a verb form, highlighting the ongoing activity or process, and (3) it includes many varieties of social endeavors not easily classified as entrepreneurial activity.

In order to understand the nature of entrepreneurship and green entrepreneurship in particular, the author of this entry prefers to take as the point of departure Schumpeter's (1911) definition, which is nonmainstream, with its emphasis on breakthrough innovation and which allows us to consider entrepreneurs as change agents in society. As Michael Schaper (2005) underlines, economies – and societies, for that matter – do not change simply because of inevitable sets of circumstances or trends; they can only transmute when there are people who individually set new directions, suggest new ways of doing, and then successfully become role models. In line with the ideas of Schumpeter and Schaper, entrepreneurs are such individuals. It is important to notice that entrepreneurs are to be found not only within SMEs but also within large enterprises, as so-called intrapreneurs, according to Pinchot (1985), and within the public or not for profit sector – as mentioned above.

The term *green enterprising* functions as an umbrella concept, including all aspects and activities of contemporary entrepreneurs, people with proactive attitude to life and challenges, acting with passion for the better of others and self to a certain degree, are involved in different kind of economic activities such as searching funds, investments, and project financing. Enterprising here is about entrepreneurship in a broader understanding which will be developed below.

Greening of business is a term for making an enterprise greener, decreasing harmful environmental impact (not just paying lip service to environmental concerns in society, by superficial means, so-called greenwashing).

Green enterprising is broader than cleantech, seen as an investment category (or sometimes, as in EU, overlapping with environmental technology, ETAP 2004). Green enterprising includes technology, products, services, practices and processes, new solutions or combinations, sometimes a system of solutions. The underlying idea could appear simple but none the less prove to be smart (as crayfish used for cleaning water, Vodokanal, Russia).

Green entrepreneurship could materialize for many reasons and be:

- *Driven by intention*, challenge or problem based, emanating from environmental and social concerns. In the interview cases, Swedish SME's Solvatten and Scarab, both focused on innovative solutions, based on research, for providing clean water in developing countries, the guiding motivation being a concern with poverty and disease in developing country contexts.
- *Based on an innovative idea* (invention or process): Swedish Biofuels has developed, through advanced research, an alternative fuel made from biomass, which could, in part, substitute fossil fuels in jet engines.
- *Based on solution*: In this case, there is a new solution for financing and ownership of alternative power. O2 Vindel, a Swedish wind power company, develops, runs, and sells wind power. Many of the plants are owned by smaller private companies or by Swedish municipalities. Ecoprom, based in Russia, servicing companies in the field of water supply, sewage, and ecology, and organizing solutions in disaster areas, based on biotechnology.
- *By chance or by seeing a green opportunity*: The Russian company Promelektronica was originally developing advanced navigation equipment for ships, filling a gap after the dissolution of the Soviet Union. They also, including monitoring the quality of the marine environment, developed computer-based antennas and aerials, meteorological support and parameters of the marine environment or subsystem. Mobile monitoring devices now developed can provide automatic reporting about water quality.
- *Greening of business*: The Research and Production Enterprise n.a. Komsomolskaya Pravda is a research based company in Russia focused on energy savings and recycling of plastics. Also, they are now treating their own waste water and are not polluting anymore. They have developed a scientific production and an association for recycling. They produce light diodes and power efficient lighting fittings. Plastic materials and products, made from recycled materials, are provided for other companies. Some new products are based on super high molecular polyurethane research together with information technology in cooperation with universities.

Motivation and Intentions

Analyzing the difference between entrepreneurs in general and green or social entrepreneurs in particular, the argument here is that motivation and intentionality are the significant distinguishing features. The intentions and goals of entrepreneurs, their consciousness, and their values based on moral principles (Bromme 2011) play a crucial role for the direction of their entrepreneurial activity.

There is a common view in Western societies, however, that market is the main driving force behind social and green entrepreneurship. Government's role is to regulate opportunities for market and quasi-market solutions to be used by the self-driven, energetic, and calculating individual. USA has a developed system of supporting entrepreneurs by different structures, incentive system, a network of venture capitalists, and business angels. During the annual Swedish–US entrepreneurial forum, aiming at generating economic opportunities for green entrepreneurship in Sweden and the United States (ESBRI 2011), a question was raised: How entrepreneurship could be promoted in Sweden?

In countries such as Sweden or France, with traditions of large enterprises and strong government, people are more likely to choose the security of working within established enterprises, having regular income rather than living under great uncertainty as entrepreneurs do. It is not the case in Russia, however, where entrepreneurship is a way of survival (Sandgren 2004).

Passion or Interest?

Understanding the sources of human motivation behind green entrepreneurship can be helpful in answering the above mentioned question. Is it really the market which drives people in their actions? Roger Scruton (2012) argues, however, that market solutions subsume human motivation under the model of cost and benefit by seeing rationality in instrumental terms. According to him our moral motive is bound up with our sense of who we are. It is intrinsic, and not instrumental values are behind our moral motives. This argument is fully supported by the interviewed entrepreneurs and green entrepreneurs in particular: *I am a person driven by personal interest and involvement. I must be able to be that in everything...I want to contribute something in the wider context (LM)*. . .*I wanted to make a difference, to solve a problem: I wanted to do something for the environment* . . .*Saw the problem: polluted water. Wanted to help women (PW) I have always been engaged in social problems, since 1968, poverty and environmental problems, developing countries (ASä).*

Passion/love, an idea or vision is what drives entrepreneurs and not possible future profits as expressed in interviews: . . .*without passion you cannot stand all failures and rejections..You burn for an idea and spread your passion to others* (from an interview, PW, 2011). The reason behind is as interviewees say: *It takes a long time before you can make any profit/get results* (*ASä*, 2011). Therefore, the idea behind enterprising should be strong enough to keep entrepreneurs going all the way, despite failures and often a long time, toward success. It takes at least 2 or 3 years before one can get positive results, and it often demands a lot of efforts and extra working hours.

The dichotomy between passion and interest was discussed by Albert O. Hirschman already in 1977, as pointed out by Hjorth and Johannisson (1997) noticed that passion was separated and replaced by interest in the development of capitalist society, which needed control over citizens. Passion with its roots in spontaneity intuition and chaos rather than order is not easy to control. Interest (mostly materialistic wealth) in opposite can be steered and regulated by law, rules, and structures. Therefore, the emphasis has been on the calculating rational man, *homo oeconomicus*, and not on the passionate one. This separation of passion from interest, however, is problematic, as could be concluded from the interviews and stories told by entrepreneurs, who build their businesses and create possible profits on the basis of their passions.

Being Proactive

There are debates in media and research about what role individuals can and should play in solving the societal/environmental problems. Is it the responsibility of the government to act for the better of its citizens, leaving to individuals the more passive duty of not to harm as some researchers suggest (Bromme 2011, forthcoming)? The argument here, however, is that proactive attitudes and a bottom-up approach to solving societal/environmental problems are significant characteristics of the entrepreneurs and in particular, social and green entrepreneurs. Proactive behavior or *doing the thing* (*I am a doer*, LM, 2011) also means that you are not waiting for somebody to take care of your problems and that you are willing to make a difference yourself, that is, meaning here that individuals matter.

This raises another dilemma, can such entrepreneurs be considered as activists, as some researchers suggest? If activism is defined broadly, many social and green entrepreneurs could be considered as activists to a certain degree, but it would be going too far to identify them as activists fully. Entrepreneurship is not just an idealistic action, even pursuing idealistic goals; it always includes some kind of economic activity. This issue, problematizing the possibility of combining material gains for oneself with altruism toward others, again leads to the issue of separation of passion from interest. To conclude, there is a gray zone, making it difficult to decide whether our actions should be considered idealistic or entrepreneurial (even in its broader meaning). This is one of the reasons for the preference here for the term *green enterprising*, with its broader more inclusive connotation.

As discussed above, entrepreneurs act according to their own ideas, values, and moral principles, not waiting for the market or government to take the initiative. This is of course not to say that government policies or support structures do not play a significant role; entrepreneurs need support and encouragement in different forms, first of all, financing in different forms, as investments and grants, or crowd funding as a possible alternative, as well as tax incentives and regulatory infrastructure, as mentioned by the interviewees in Sweden and in Russia.

Entrepreneurship: A Liberating Force?

> Entrepreneurship is about freedom and the possibility to influence and steer your own time (LM)

Another motivation mentioned by the interviewees is freedom. Being able to raise money for *what you want to do*, becoming self-reliant, makes entrepreneurship, to a certain degree, a liberating force. As interviewees confirmed, they choose to become entrepreneurs because they wanted to be in charge *of their own time and to work on their own terms*, even though it could mean more work and less security as well as no guarantee for success. Uncertainty and risk is the price they pay for such freedom. Risk here, however, should be seen from a broader perspective as ownership is not a necessary characteristic of entrepreneurs, according to Schumpeter, but instead in relation to one's own reputation in case of failure, etc. Attitudes in society which allow for failure are important for entrepreneurship to develop, as you learn from your mistakes. In some countries/cultures, however, such as in Sweden, failure is not easily accepted by the society, which influences entrepreneurship negatively, because of the tendency not to trust an entrepreneur who has once failed in business.

Emphasizing the importance of freedom and autonomy for entrepreneurs, it should be made clear that this does not always make entrepreneurs comfortable to work with. They could cause turmoil in organizations, especially large hierarchical establishments with strong emphasis on control.

Entrepreneurs as Contrarians

> ..The driving force or motivation is the ability to think in new ways and go against the current. (LM)

Entrepreneurs in large organizations/corporations – so-called intrapreneurs – could be compared to rebels, following the ideas of Pinchot (1985), who "ask for forgiveness rather than for permission." Intrapreneurs often work "underground," developing the ideas they believe in, which could be different from the official ones. They may work alone or in a smaller group of people whom they trust.

Intrapreneurs do not easily accept the status quo of things in the organization, and their ideas may lead to change in the organization where they work. Being able to go the alternative way requires, as mentioned, a strong sense of autonomy and courage. *Contrarians*, as Edward C. Johnson, owner of Fidelity Investments (1996), calls them, oppose orthodox thinking, and according to him, this is the company's key to success. Through freedom to try new ideas, learning from mistakes, the company builds on its successes. In any case, it is a great challenge for leadership and management to consider such contrarians as assets in the organization, providing them with an allowing and encouraging atmosphere or giving them a *space for play*, as Hjorth (2006) argues. Intrapreneurs need a space where they can try out their new or crazy, at least in the eyes of others, ideas for finding new creative solutions. Otherwise there is a risk of losing such people or their commitment.

In this context it is important to point out the difference between management and entrepreneurship as representing two different rationalities (Hjorth and Johannisson 1997; Sandgren 2012). Management and managerialism as an ideology is striving for control and order which is contradictory to some distinguishing features of entrepreneurship and entrepreneurs, mentioned above, such as the strong sense of autonomy and passion as their primary motivation.

Another significant factor is the breakthrough nature of innovations, which presupposes critical thinking, questioning of norms and established orders, searching for alternative ways and solutions, could be regarded as troublesome by managers. It is important, however, to understand this mentioned above difference in rationalities in order to balance power and control and the independent and passionate nature of entrepreneurs in the organization.

Entrepreneur: An Artist?

> I am an artist . . .being an artist helps me in finding solutions (PW)

Creativity is indeed an important component of entrepreneurial activity, as confirmed in the literature and by the interviewees. However, this is not always understood by researchers who view entrepreneurship from the narrow perspective of being primarily a process of moneymaking or as a management activity. As confirmed by one of our interviewed green entrepreneurs, *creativity is needed – not only in terms of the original idea but also in the implementation of the solution – to see the whole picture, the business solution.* In the era of the knowledge society, creativity and innovation is becoming even more crucial for societal and economic development. Creativity in relation to entrepreneurship and innovation, however, is not always a pleasing activity as pointed out by Alf Rehn (2010) in his book *Dangerous Ideas*. Creativity could be of a rebellious character; by challenging norms, being provocative and even uncomfortable for others, as mentioned above, in this way leading to breakthrough innovations.

Fostering creativity was an important component of their upbringing and early development, as confirmed both by the Swedish and Russian entrepreneurs, with an allowing atmosphere at home and/or being involved in different creative activities outside home. However, not many had entrepreneurs as parents, or role models in this sense, which contradicts some common hypotheses. This is not to diminish the inspirational value of role models and good examples. In this context, it could be added that all the interviewed green entrepreneurs mentioned a love of nature, learned in childhood. This was the basis of their values, motivation, and actions later in life, which confirms the argument above that entrepreneurs act according to their intrinsic values.

Concluding Remarks

To summarize the analysis of interviews on motivation behind entrepreneurship in general and green entrepreneurship in particular, the ambition here is not to give the complete picture of all possible characteristics of entrepreneurship; the aim is rather to help in our understanding that entrepreneurship is a complex, broad, and holistic concept which is made up of many different features, sometimes presupposing each other or interdependent. As confirmed by the interviewees, passion and moral principles, which are rooted in our sense of who we are, are the main motivation of green entrepreneurs (as well as entrepreneurs in general) in particular and not interest (profit). Another distinguishing feature is the proactive attitude and bottom-up approach to solutions. Striving for self-reliance as a necessary condition for freedom and autonomy is important for many entrepreneurs. Breakthrough nature of innovations presupposes the ability of critical thinking and a rebellious nature of creativity. On the basis of these characteristics, it is possible to claim that the general understanding of entrepreneurship is becoming broader as economic/materialistic goals are combined with more altruistic (humanistic, idealistic) ones, and in many cases there is no clear division between for profit or not for profit entrepreneurial activities, as also found in our case studies.

How we define social phenomena is crucial for our understanding and actions. In our view, green enterprising is a useful and broad concept, embracing a variety of entrepreneurial activity including social and public actions. In this way, passion and interest are no longer separated. Individuals matter in this bottom-up, proactive approach to tackling environmental challenges, which implies that individual initiative is important along with the government action.

Health of Entrepreneurs

Olivier Torrès
University of Montpellier South of France, Montpellier, France

Stating the Existence of a Blind Spot

The French economy has very few statistics regarding occupational health in SMEs, particularly with regard to the employer. This fact, however, is not specific to France. At the current time, it seems that there is very little work and very few statistics from abroad either on this theme. There is thus an almost universal lack of information. Occupational health appears to have been pushed away from the entrepreneurial realm.

Nevertheless, one of the founding works on occupational medicine, written by Ramazzini in the 1700s, is entitled the "Traité de la maladie des artisans" (Treaty on the illnesses of craftsmen) (De Morbis Artificum Diatriba). Its aim, wrote Ramazzini, was to understand through observation why certain trade associations seemed preserved from certain dangers, such as the plague, for example, when others presented on the contrary much stronger prevalence. As man spent more time working than doing anything else, the conditions in which he did it, as well as the fact of handling certain harmful or healthy substances inherent to his business, were able to explain his health. Occupational medicine was born.

The most notable and most decisive progress with regard to occupational health came undoubtedly from Louis René Villermé who, in the nineteenth century, was interested in the work conditions of the working class in a context of increasing industrialization. His major work, the *Tableau de l'état physique et moral des ouvriers employés dans les manufactures de coton, de lain et de soie* (Table of the physical and moral state of the workers employed in cotton, wool and silk factories), which was first published in 1840, was the origin of a law limiting child labor in factories. The role played by Villermé and the rise of industrial hygienism explain why occupational medicine focused on the effects of mass industrialization on health at work.

Occupational medicine probably has a more social mission than other medical disciplines: its genesis in the nineteenth century and its extensions in the twentieth century have, over time, defined an implicit social purpose, to defend the weakest (the work of women and children) and especially the underprivileged classes. In such a context, the working class becomes central, and "workerism" still remains strongly anchored in the writings of contemporary occupational doctors. René Barthe, who was the inspiration for the law of July 28, 1942 in the Vichy regime which established occupational medicine as an obligation and was the author of the first "Que Sais-Je," on occupational medicine, in 1944, declared "Let us be the good 'housekeepers' of our factories, as our farmers are the good

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8, © Springer Science+Business Media LLC 2013

"housekeepers" of our land. This essay aims to present this new culture, which is a permanent effort for a better life for our working class world" (Barthe 1944, p. 9). The question of workers' health remained for a long time and is, even today, a profound identity marker for occupational medicine. It is moreover in the bastions of industry that developed the first initiatives for a chair of occupational medicine, such as in Lyon in 1930 or in Lille in 1935, in the heart of the mining cottages of the mining industry in the North. Today, there is still a strong tradition for occupational medicine in Lille.

In France, occupational medicine has been highly structured since the law of 1946 (Desoille 1958). It focuses almost exclusively on the occupational health of employees. Barthe considered that a "definition of Occupational Medicine is easy to find if we restrict ourselves to its general principle: it is a Social science directed toward the protection of employees in their very place of work" (Barthe 1944, p. 6). This focus on employees only has had two consequences.

On one hand, occupational medicine has allowed numerous forms of social progress to develop and analysis of employees has been perfected with subtle subcategorizations: workers are divided into qualified and unqualified. Similarly, statistics make a distinction, with good reason, between executives and senior executives. On the other hand, the disadvantage is that the self-employed are totally excluded from the tables and any data calculated on such matters. Only directors with employee status are covered by occupational medicine, although only 170,000 companies have such directors and are a tiny minority with regard to the 2,411 million nonwage earners counted by INSEE (National Institute for Statistics and Economic Studies) in France in 2008.

For this reason, as soon as it is a question of nonwage earning independent workers, there are less statistics, and those that are there are more vague because they are very heterogeneous. Sometimes storekeepers and craftsmen are included. Sometimes there are the liberal professions, as if master bakers or stonemasons can be compared with professionals such as attorneys and lawyers! Where are the business managers, who are neither craftsmen, nor storekeepers, and even less liberal professions? How do we make a distinction between the leaders of very small firms, small firms, and medium-sized companies?

Do the statistics for occupational health take into account managerial contingencies, in particular those related to the size of workforce? Experts were skeptical at first, but no longer have such doubts today. The concept of SME, taken in its full complexity, is not a relevant category for the medical sciences. Nevertheless, independents work in conditions with many particularities.

Although health is an essential topic, the health of business managers is an unrecognized aspect. Nevertheless, the health-capital of the director, whether he is a craftsman or a storekeeper, is probably the first immaterial asset in the company because dependence on the director is all the greater if the company is small, and this is precisely the main feature of small shops and the craft industry (Mouzaoui and Horty 2007). Henri Fayol, in his *Administration Industrielle et Générale* makes health and physical strength the first cardinal value of the business manager. "The qualities and desirable knowledge for all CEO are as follows:

1. Health and physical strength
2. Intelligence and intellectual strength
3. Moral qualities: well-thought out, firm desires, and perseverance; activity, energy and, if necessary, audacity; the courage of responsibilities; a feeling of duty; and a concern for general interests
4. Good general knowledge
5. Administrative capacities
6. General notions of all the main functions
7. The widest possible range of skills in the particular profession that is characteristic of the company"

The director's health is often synonymous with the good health of the company, whereas on the contrary, a health problem can bring down the whole company (Chao et al. 2007; Massey et al. 2004).

Fayol adds that "the absence of health can cancel out all other qualities together"

(Fayol 2005, p. 84). It is enough to think of the devastating effects which a health problem can have on small-sized companies, as Chao et al. (2007) do with AIDS to show the value of cross-referencing medical sciences and entrepreneurship sciences. All these considerations plead in favor of a study of the health-capital of directors, in the style of what Bournois and Roussillon (2007) did in the context of the directors of large groups, but instead adapting it to the specificities of SMEs (small- and medium-sized enterprises).

The objective of this contribution is to draw up a corpus of hypotheses on the occupational health of entrepreneurs. Then, it presents the fundamental equation for entrepreneurial health. What researchers know about the working environment of entrepreneurs pushes them to believe that their working system is pathogenic (work overload, stress, uncertainty, loneliness…). But, in reference to the works on "salutogenesis" (Bruchon-Schweitzer 2002) which can be traced back to the middle of the 1990s in the field of health psychology, this entry will show that these negative effects are probably compensated for (in whole or in part?) by a system of beliefs which can be beneficial for health. The key question is to know in which direction the scales are tipped.

Given what is at stake, studying the beliefs, attitudes, and behaviors of entrepreneurs with regard to physical and mental health is a surprisingly virgin field of research (Kaneko et al. 2011). The results of such research could be very interesting. The initiative behind the AMAROK observatory, the first observatory for entrepreneurial health, is part of this perspective. Certain aspects of this observatory are presented in the conclusion.

The Failings of Health Statistics for Entrepreneurs

"Self-employed" is a banner label for all independent workers with no employer, employers themselves, and home helps. In 2008, they represented 9 % of the active population in France. The lowest percentage (5 %) is found in the Paris area, while Languedoc-Roussillon has the highest, with 13.5 %. To answer the question of the health of this population, the observer is obliged to notice that the existing statistics are profoundly insufficient, both at the quantitative and qualitative levels. The first notable fact is the almost total absence of data on the health of SME directors. It is true that SMEs are not regarded as a relevant dimension for studies on health.

Among the most commonly selected variables, there is a high frequency of age; gender; average revenue; socioprofessional categories; level of study; and, to a lesser extent, place of residence and marital status. It is thus very difficult to obtain statistics which are dedicated exclusively to SMEs.

It is, however, possible to obtain some statistics which get closer to the world of SMEs, even if they do not exhaust the subject: it is the statistics which are interested in the social and occupational group of craftsmen and storekeepers. Even if these statistics are invaluable when it comes to tackling the problem of the health of directors of SME, they are nevertheless presented under a common category of extremely heterogeneous situations. These statistics often group together the category of storekeepers with that of craftsmen. However, the trade and craft industries have notable differences with regard to the relationship to work and know-how and trade union representativeness (Medef/CGPME for the trade vs. UPA (Professional Union of Craftsmen) for craftsmen).

Similarly, craftsmen develop the use of manual work much more than in trade, and manual work often involves a more intense use of the body, which can result in specific pathologies. Shopkeepers and craftsmen are thus two similar fields of activity as they are often keen to preserve their independence but which nevertheless have differences. These differences, in terms of health, deserve greater differentiation.

But the worst is that sometimes studies are based on figures which mix craftsmen, tradesmen, and liberal professions. Although the liberal professions are also concerned by independence, as evidenced by the professional orders which govern them, they have very considerable differences with craftsmen and tradesmen. For example, the "level of study" variable is generally high in liberal professions and much lower among craftsmen and tradesmen. Yet, it has been proven that this variable has an impact on health (Bruchon-Schweitzer 2002). Another variable that has an incidence on health is the capacity for organization of liberal professions when in work collectives.

Lawyers, chartered accountants, medical specialists, solicitors, land surveyors, and receivers work much less on their own than previously. Increasingly, they group together as partners, which greatly facilitates the pooling of means (secretarial department, office) and resources (clientele, network), as well as making possible a better management of absences, particularly in case of illness or vacation time. In addition, the feeling of loneliness is reduced, and certain works have shown that loneliness has a pathogenic impact on health (Bruchon-Schweitzer 2002). Storekeepers and craftsmen, on the other hand, are often very much alone in their jobs, and this can be an almost insoluble problem when they fall ill or wish to take time off.

Another point which deserves to be underlined is the total ignorance of the size of the staff for which storekeepers and craftsmen are responsible. Although most storekeepers or craftsmen work alone, sometimes with the assistance of their spouses or children (what statistics refer to as family help), many businesses have employees, sometimes several dozen. This gives these storekeepers/craftsmen the role of an employer business manager. But the statistics never provide information regarding the size of the company of which the storekeeper or craftsman is the director. In other words, the size of the staff is never indicated, and it is a shame, as it is a situation which strengthens the impression that the statistics for health in the work place are not interested in SMEs.

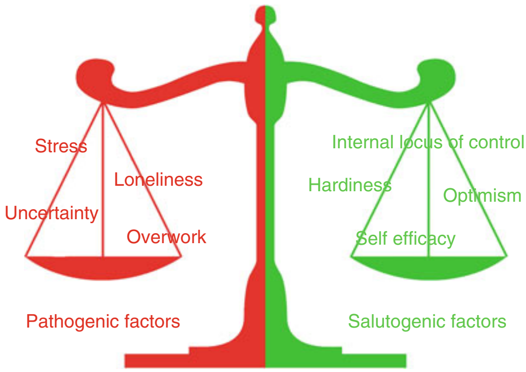
In spite of all these limitations associated with the heterogeneity of the craftsmen and storekeepers socioprofessional category and the even greater heterogeneity of the craftsmen, storekeepers, and liberal professions category, we can, by cross-referencing the few statistics available, nevertheless obtain a body of evidence which converges on the same observation: craftsmen and storekeepers sometimes have a state of health more like that of workers than that of senior executives.

The Entrepreneurial Health Equation: Pathogenic Factors Versus Salutogenic Factors

The health of entrepreneurs is subject to permanent conflict between pathogenic factors, which have a negative impact on health, and salutogenic factors, which are beneficial. The equation for entrepreneurial health is thus:

On the one hand, although occupational doctors have long been aware that overwork, stress, uncertainty, and solitude are long-term pathogens for employees (Leclerc et al. 2008; Niewiadomski and Aïach 2008), they have never wondered what effect these factors have on employers. But how is it not possible to see just how much entrepreneurs often accumulate these four factors? Many works have been published on overwork and the resulting increase in stress (Buttner 1992; Akande 1994; Mcdowell-Larsen 2007; Ahmad and Salim 2009) among company owners, who often work more than 60 h a week (Boyd and Gumpert 1983; Roussillon and Duval-Hamel 2006). Uncertainty is also one of the fundamental elements of the entrepreneur, one of whose characteristics is that he has variable income, unlike the regular monthly salary paid to employees. In certain sectors, the order book does not go further than a few months in advance, sometimes just a few weeks in times of crisis. The director must deal with this uncertainty on a permanent basis. Finally, Gumpert and Boyd (1984) have insisted heavily on the isolation, or even solitude, of directors, to the extent that the use of entrepreneurial networks, or associations of peers, is often salutary. Such isolation makes the director fragile, and when difficult decisions – such as redundancy – have to be made, directors are often filled with doubt and remorse (Torrès 2009).

On the other hand, health psychologists (Bruchon-Schweitzer 2002; Fischer and Dodeler 2009) are aware that the internality of the locus of control, endurance (hardiness), self-efficacy, and optimism are all salutogenic… even though they have never noticed that they are simply entrepreneurial attitudes and beliefs! Once again, how is it possible to not notice that these are characteristics that are often associated with entrepreneurs? Although empirical studies hoping to validate the



Health of Entrepreneurs, Fig. 1 The entrepreneurial health equation (Source: Torrès 2012)

locus of control theory have never been able to establish even a modest correlation between this psychological characteristic and entrepreneurs, it nevertheless remains positive (Janssen and Surlemont 2009, p. 41). Verstraete (1999, p. 165) also evokes the importance of the internality of the locus of control in entrepreneurial behavior. Finally, Filion (1997), by identifying the works from what is known as the "school of characteristics," showed that optimism and perseverance are psychological traits common to entrepreneurs. The same can be said for self-efficacy (Bradley and Roberts 2004). Entrepreneurship, is it good for health (Volery and Pullich 2010)? (Fig. 1)

Hence, this fundamental equation for entrepreneurial health: on the one hand, we accept the work of occupational medicine is interesting; there is a system of constraints to which a large number of directors are subject and which seems to be pathogenic. And, on the other, recent works from the field of health psychology, which show that the entrepreneurial attitude and belief system is in fact salutogenic. The question this raises is thus how do we know when the scales are going to tip one way or another?

Conclusion and Future Directions

It was in the aim of resolving this entrepreneurial health equation that the initiative of creating the AMAROK observatory is appeared, the first such structure for the health of SME owners. AMAROK is an Inuit name that means wolf. It refers to a legend, the moral of which is that a society must protect those who support it.

AMAROK is an observatory with a scientific and experimental vocation, the aim of which is to study the beliefs, attitudes, and behaviors of SME owners, craftsmen, and tradesmen with regard to their physical and mental health. Based on the theories governing the specificity of SMEs, this observatory also aims to devise and propose practical actions in the field both in terms of prevention and cure. The priority population is that of SME owners and craftsmen.

The objective of this observatory is to combine medical and entrepreneurship sciences. The AMAROK project is complex and requires a multidisciplinary approach. The scientific skills mobilized involve occupational medicine and public health, entrepreneurship and management, health and workplace psychology, as well as the economy and geography of health. However, this observatory remains anchored primarily in management science because the ultimate purpose is to improve SME management.

By combining the two sides of the employers' health equation (i.e., the pathogenic and salutogenic aspects), AMAROK hopes to attain an ambitious goal: ideally, AMAROK would like to produce the first medium-term statistics on the health of employers. The issues at stake are perfectly matched to this ambition.

- Either AMAROK discovers that the owners of SMEs, craftsmen, and tradesmen put their health in danger without their knowledge and brings to light a public health scandal
- Or, on the contrary, AMAROK will discover that entrepreneurship is beneficial for health. In the latter case, AMAROK will have one of the best arguments for promoting human-sized enterprises and craft industries: SMEs are good for your health!

In the medium term, the aim of AMAROK is to create one of the first epidemiological records of a cohort of SME managers. The stakes are high because the sums involved are substantial and the commitment must be long term (one to several decades) (Bousquet; Dreyfus Daures, Demoly, 2004). It is important to know that there is no such register anywhere in the world.

Healthcare and Innovation

Piera Morlacchi

Synonyms

Medical innovation

Innovation is viewed as fundamental in healthcare, leading to advances in medicine, and individual and public health but also to economic growth and generation of wealth. When people think about innovations in healthcare, they normally focus on technological innovations such as drugs, devices, and diagnostics that have advanced medical practice and the treatment of diseases. This leaves a gap and, therefore, a need to further define and explain the nature of "healthcare systems," "healthcare innovations," and "healthcare innovation process."

Health, Healthcare, and Healthcare Systems

Health has been defined by the World Health Organization (WHO) as "Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" (WHO 1946), and healthcare is about the prevention, treatment, management of diseases and illness, and the preservation of health and well-being through the services delivered by healthcare providers. These healthcare providers include medical and allied health practitioners and professionals such as physicians, nurses, medical technicians, therapists, pharmacists, nutritionists, paramedics, complementary and alternative therapists, and community health workers.

Healthcare or healthcare system is the organization of the healthcare services to meet the needs of a target population. There is a wide variety of healthcare systems around the world which are characterized for instance by different levels of access, funding, and structure of provision of healthcare services. The main actors which are common to many healthcare systems are hospitals and other medical facilities (e.g., primary care centers, clinics, and other specialized medical facilities such as IVF clinics), universities and research institutes, industrial firms and their suppliers (e.g., pharmaceutical companies but also specialized suppliers of electronic components for medical devices and of reagents and animal models for scientific laboratories), governments and public agencies (e.g., National Institute of Health (NIH) in the USA), regulators (e.g., Food and Drug Administration (FDA) in the USA and the National Institute of Clinical Excellence (NICE) in the UK), payers (e.g., third-party payers in USA like Medicare and Medicaid), professional bodies and societies, medical charities, patient associations, the media, and the public at large. Most people have direct experience of part of the healthcare system constituted by the providers and facilities involved in the delivery of healthcare (e.g., physicians, nurses, and hospitals), whereas other parts of the system such as the healthcare industry (e.g., medical device sector) and the medical research community (e.g., research centers and academic institutions) are less visible.

Healthcare is important also in economic and financial terms in many countries around the world. With its subsystems such as healthcare delivery and healthcare industry, it is one of the largest and fast-growing industries in developed countries and consumes high rate of gross domestic product (GDP) also in developing countries.

Healthcare Innovation

In order to understand healthcare innovation, it is useful to start with what is known about innovation more in general. Innovation refers at the same time to something new (e.g., a product, process, or an idea) and to the act or process of innovating, which is coming up with an innovation. Other terms used to indicate the innovation process or parts of it are technological change, technological progress, technological evolution, and technological development. Innovations can be classified according to "types" (e.g., new product, new methods of production, new ways to organize business) and to how radical they are compared to what is already in use (e.g., radical vs. incremental innovations). Among other findings, studies of innovation have pointed out for instance that although an important distinction is normally made between "invention," "innovation," and "diffusion" – where invention is the first occurrence of an idea, while innovation refers to the first attempt to use out an idea and diffusion to the spread of it in practice – those are stages of a continuous process. A "linear model of the innovation process" sees it as constituted by a sequence of activities that goes from basic research through applied research, targeted development, manufacturing and marketing, until adoption (or diffusion), and use. A more simplified version is a two-step model that distinguishes only between development and diffusion. The linear model of innovation assumes that either scientific research and technological development ("technology push" model) or market demand ("demand pull") are the main drivers of innovation. Although the linear model has been shown inadequate to represent what happens in empirical terms where feedback mechanisms and loops among different stages can be observed, this simplified view of the innovation process remains widely held in the public at large and in some parts of the medical community. A more productive approach to understand innovation is to unpack different stages of the process such as development and diffusion and the feedback mechanisms and loops among them.

From studies of innovation in different domains, it became clear that the organization for innovation and innovation processes can have varying configurations in different contexts and evolve over time. It follows that general findings and theories about innovation need to be validated in specific contexts. This is the case for innovation in the context of healthcare where innovations and the processes that lead to their development and use have some specific characteristics. The popular image of healthcare or medical innovation is the one in which a group of biomedical scientists in a research laboratory come up with an idea that moves in a linear manner from the bench to the bedside. However, innovation studies have shown that this linear conceptualization of medical innovation is misleading. Important issues are related to the nature of healthcare innovations, their development, diffusion in healthcare organizations, and regulation of the overall innovation process.

The Nature of Healthcare Innovations

When people think about innovations in healthcare, they normally focus on technological innovations such as drugs, devices, and diagnostic that have advanced medical practice and the treatment of diseases such as antibiotics, pacemakers, and ultrasound. Other health innovations such as clinical procedures (e.g., minimally invasive cardiac surgery), organizational innovations (e.g., intensive care units or ICUs), and infrastructural innovations (e.g., such as information and communication technologies such as computer-based hospital information systems) have less visibility and have been less studied.

The Development of Healthcare Innovations

Although healthcare innovations and the dynamics of their innovation processes are quite diverse, studies have focused on the study of technological development in medicine and in particular drugs. General findings on technological development in medicine are the importance of the interaction between developers, clinicians, and regulators; the feedback mechanisms between different steps of the development process and between the development and use (including diffusion); and the importance attributed to randomized clinical trials to provide evidence of efficacy for new treatments.

Pharmaceutical innovation is useful to illustrate some of these findings in the context of the development of new drugs. Research on pharmaceutical innovation has highlighted that it is science-based or depending on advances in life sciences (e.g., molecular biology), lengthy and expensive, and uncertain. The process of drug discovery has become increasingly complex and sophisticated. It was based on random screening of compounds to find new drugs until 1940s, later on began a transition to a more "guided" process or "drug development by design" drawing heavily on advances in molecular biochemistry, pharmacology, and enzymology until 1970s, and more recently on tools of genetic engineering. After a new drug has been identified, it goes through a development process that includes preclinical research (e.g., animal testing), clinical trials (i.e., testing in humans), and in some cases regulatory approval. Clinical trials are a set of procedures used to collect data on safety (e.g., adverse drug reactions and adverse effects of other treatments) and efficacy of new drugs, used both in the process of development and regulatory approval of new drugs and other therapeutic interventions. It can take between 10 and 20 years between the start of the process of discovery and when a new drug reaches the patients for normal clinical use, and many new drugs considered promising in drug discovery fail to do so. The development of a drug does not end necessarily with the adoption in clinical practice because new indications for existing drugs can be found (e.g., use of beta-blockers in the treatment of heart disease) or better compounds can be developed from learning by using in the treatment of patients. Close relationships among industry, academia, and government have been always crucial to drug discovery and development, because basic biomedical and clinical knowledge created in university and public funded settings are exploited in industrial laboratories, which also conducted basic research and drug discovery. However, over time, the division of labor between actors involved in the process has changed leading the industry to focus their investments more on final stages of drug development and testing and to leave the initial and more uncertain stages to academia and publicly funded research institutions.

Although the development of other medical technologies like devices and diagnostics are less studied than drugs, some general findings like the importance of the interaction between developers, clinicians, and regulators or casted difference of industry, academia, and government, and the importance and role of research, regulation, and uncertainty also stand in these contexts, but some differences can be noticed. For instance, the process of development of new devices and diagnostics is in many cases shorter than drugs, even when regulatory approval is necessary before introducing a product on the market (e.g., hip replacements). Moreover, although also a large proportion of the market in the medical device and diagnostic sectors are concentrated in the hands of a few multinational firms, differently from the pharmaceutical sector (also including the biotechnology side of it), they are populated by large number of small firms that contribute to innovation dynamics.

The Diffusion of Health Innovations in Healthcare Organizations

Research on the diffusion of medical innovations focuses on explaining why and how an innovation spread and got adopted in clinical practice or generally used. Studies on the diffusion of innovations in healthcare organizations pointed out the following factors: the nature of the innovation itself in terms of, for instance, complexity of use, relative advantage to existing technologies, and possibility to try and observe the innovation; the adoption and implementation processes also in terms of communication and influencing process (e.g., existence of innovation champions and lead users); and the organizational context and its immediate environment (e.g., reimbursement mechanisms that shape financial incentives for the purchasers such as hospital administrators to adopt new innovations, but also reputational effects brought by the adoption of new technologies).

The Regulation of Healthcare Innovation

In many countries, healthcare and healthcare practices are highly regulated (e.g., standardization of medical practice through guidelines which are issued by professional bodies with the aim of guiding decisions and criteria regarding diagnosis, management, and treatment in specific areas of healthcare). This extends also to healthcare innovation, where both innovations and the process that leads to their development and use are regulated. Healthcare innovations such as drugs and devices are reviewed and evaluated by appointed bodies in each country (e.g., in the USA is the Food and Drug Administration (FDA)) on the basis of data on safety and efficiency collected in some cases through clinical trials before they are introduced in clinical practice and released on the market. The level of scrutiny depends on the level of risks attributed to different products, and in some cases, the monitoring of their performances continues also after they have been introduced in the market (e.g., risky new devices such as pacemakers and heart valves are evaluated before their introduction on the market but also after they are introduced in clinical practice through the compulsory reporting of adverse events and malfunctioning, and defective products can be ordered to be recalled).

The Nature and Direction of the Healthcare Innovation Process

The Nature of the Healthcare Innovation Process

Although the nature of innovation process in healthcare can be characterized as dynamic and systemic, a linear view of the medical innovation process still prevails. The assumption of the linear model is that scientific knowledge developed through basic scientific research and engineering knowledge developed in the biomedical field or through technology transfer from other fields (such as in the case of laser and ultrasound) are driving innovation in healthcare. However, the linear conceptualization assumes first of all that it is possible to make a clear distinction between research and development on one hand and adoption and use on the other, whereas in many cases, like medical devices but also therapeutic drugs, the development does not end with the adoption of an innovation, but there are incremental changes. Moreover, the development occurs not only in industrial R&D laboratories but also in the context of clinical practice. This is the case for laser that was introduced for the ophthalmologic and dermatological purposes, but new indications of use were discovered in clinical practice such as in oncology, thoracic surgery, gynecology, and other specialties. An alternative conceptualization to the linear model is a dynamic (or more evolutionary) model where there are feedback mechanisms in the process between the phases of adoption and use and applied research and development, i.e., after the introduction of the first-generation innovation in clinical practice through learning by using important information about improvements can be generated and embodied in new generations of the innovation.

The interactive and distributed nature across time and space and across areas of medical practice and institutions of healthcare innovation process can be labeled as "systemic." It follows that approaches that study the systemic nature of the healthcare innovation process focus on the components of the system or actors and their interactions in specific contexts. The difference among some approaches is in the way in which they determine the boundaries of the systems: national and regional approaches focus on geopolitical boundaries and sectoral or technology approaches identify actors that operate in the same product market.

The Role of Users and Other Actors

The development and use of new medical innovations is also shaped by the demand for these innovations, which is traditionally related to the needs and preferences of users like physicians and the end customers, i.e., the patients. Physicians are users of medical technologies, but they play an important role also in their development, establishing a close interaction with manufacturers. The supply and demand of healthcare innovations has complex dynamics that go beyond the interaction between developers and users. In recent years, the innovation process in healthcare came to be more and more significantly influenced by other groups of actors such as hospital administrators, payers, and regulators but also patients and their families, patient (advocacy) groups, and the media. However, there is still a limited understanding of how the interaction of supply and demand influences the aim, direction, and rate of innovation in healthcare.

The Direction of Healthcare Innovation

In recent years, the biomedical perspective of health has been challenged by evidence that the steady reduction in mortality and increased longevity in many developed countries in the last century was mainly due to improved sanitation and nutrition and general improvements of living standards and not to advances in medicine. Furthermore, healthcare and medicine are becoming more and more driven by science, technology, and industry on a global scale. Finally, the current trend of healthcare expenditures is unsustainable, both in developed and in developing countries.

This problematic situation has triggered different reactions. One of these is the rise of the complementary and alternative medicine (CAM) movement, where patients turn to health practices other than Western medicine (e.g., acupuncture, chiropractic, Ayurveda, etc.) to deal with illness and well-being. Currently, there is also an intense scrutiny of pharmaceutical industry by part of the biomedical community, the media, and the public at large of the pharmaceutical industry, previously considered unquestionable and viewed as the producer of life-saving products. Pharmaceutical productivity has declined and new drugs are difficult to come by, and the costs of developing them increased together with the total R&D expenditures. Moreover, there are still unmet medical needs and health inequalities, especially in areas such as infectious diseases where drugs are available but not affordable for many in developing countries. Finally, the discussions about the role of public and private sectors in healthcare are leading to examples of social experimentation (e.g., public-private partnerships) and measures of cost savings and efficiency making it difficult to see how they can solve fundamental issues in healthcare affected by the need of dealing with chronic diseases in an aging population and the costs of high-technology medicine.

Studies of Healthcare Innovation: Unpacking the Economic, Social, Political, and Ethical Aspects

The study of healthcare innovation is characterized by multiple approaches and areas of interest that is undertaken in many separate academic fields. Traditionally, approaches such as economics of innovation, health economics, and innovation management have focused on the economic, financial, and managerial aspects of innovation. Science and technology studies that have focused on health and medicine have taken more sociological and historical approaches to study the development and use of medical innovations, focusing on the controversial and negotiated aspects of them such as in the case of allocation of resources between basic scientific research on finding cure for diseases and public health measures for prevention or ethical issues on emergent and promising but risky new technologies like xenotransplantation (i.e., the use of animal organs in humans) or stem cells. Another field involved in the study of healthcare innovation is medical sociology where a more critical approach is taken for instance to explore "biomedicalization" or how healthcare and medicine have become increasingly driven by science, technology, and industry on a global scale, leading to unpack and study in depth several processes such as the increasingly scientific and technological nature of medicine, the transformation on how biomedical knowledge is produced, distributed, and consumed, and the political economy of biomedicine (Clarke et al. 2003). An evaluation of healthcare innovations that aims to be comprehensive and multidimensional is a challenging undertaking. The multidisciplinary field of health technology assessment (HTA) examines beyond costs, efficacy, and safety the social, political, and ethical aspects of the development, diffusion, and use of health technologies. The ethical aspects of healthcare innovation like organ donation, healthcare rationing, and questions related to emergent technologies in biology and medicine stem cells, genomics, and human enhancement are also studied in the field of bioethics.

Conclusions and Future Directions

The debate about high-tech medicine and its impact on the raising of costs of healthcare pointed out that the fundamental problem in today's healthcare systems is the weak correlation between the types of innovations generated by the innovation process driven by the medical research community and industry and the needs of healthcare delivery. However, solutions on how to close the gap between medical research and healthcare delivery or how to innovate the healthcare innovation process are hard to come by. Disruptive healthcare innovations that are at the same time affordable to all should be the priority for theory, policy, and practice.

Business; Individual initiative; Industrial activity; Industrialization; Risk

The economic theory of the entrepreneur is defined in the analysis of R. Cantillon at the beginning of the eighteenth century, who draws a distinction between those who are a "known quantity" and those who are an "unknown quantity," the entrepreneur belonging in the second category. That is effectively how the framework of the entrepreneur is constructed. The entrepreneur is the economic agent who supports risk emanating from the erratic functioning of the market. However, Cantillon distinguishes neither risk nor uncertainty. About a century later, J-B Say defined the entrepreneur as the intermediary between the savant who produces knowledge and the worker who applies it to industry. In this way, Say introduces a nodal element in the definition of the entrepreneur: innovation. Schumpeter too joins the original diptych. He, along with Cantillon and Say, constitutes the founding fathers of the theory of the entrepreneur. Both Schumpeter and Say, as distinct from Cantillon, put the accent on the introduction of novelty (and thus innovation) into the economy.

The object of this entry, then, is to revisit the work of those economists who since Cantillon have placed the entrepreneur at the heart of the analysis of capitalism. In this context, the marginalist theory initiated by Léon Walras stands out because, although well-founded on the base of liberal market economics, it notably promotes the hypothesis of market transparency and thus the *absence* of uncertainty.

Economic agents, who are considered as rational beings (perhaps better expressed as beings whom there is no reason *not* to consider as rational), take decisions (e.g., an entrepreneur who takes a decision to invest, based on a rational cost/benefit analysis, is being assumed that he has available to him all information necessary for such analysis) At almost the same moment in 2011, the Austrian economist Carl Menger (1840–1921) places himself also in the marginalist paradigm without, however, signing up to the same definition of rationality. For Menger, the rationality of economic agents is limited. Going on from this Austrian "current," the economic analysis of the entrepreneur has been able to develop fruitfully over the course of the twentieth century. Joseph A. Schumpeter, R. Coase, F. von Hayek,

L. von Mises, I. Kirzner, and others would seek to replace the uncertainty and risk at the heart of their economic model by giving space to the emerging concept of the entrepreneur.

The heroic entrepreneur is the one who formed the link between the preindustrial period (around the end of the eighteenth century) and the industrial maturity of the start of the twentieth century. He built a new economic and productive logic on the ruins of the feudal system.

The general idea advanced by R. Cantillon or J-B Say is that the weight of the market economy rests on the entrepreneur, while the greater part of the population (including the country's leaders) seems to ignore or pretend to ignore him. From another angle, en economist such as Karl Marx highlights the nodal role (albeit temporary) of the *bourgeoisie* which contributes through its entrepreneurial dynamism to increasing the speed of technical progress. But that argument shifts all the risk on to the weakest segment, the proletariat. Marx, like Schumpeter, is an economist of transition who concentrates on the procedures of the passage from the capitalism of the heroic entrepreneurs toward socialized entrepreneurs. Following on, Walras reinvents a liberal model (the theory of pure and perfect competition) where uncertainty and risk have been ousted. And by the same token the entrepreneur. Walras succeeds, almost in spite of himself, in demonstrating up to what point the entrepreneurial function is intimately linked with the uncertainty/risk diptych.

The Economic Thought of the Entrepreneur During the First Industrial Revolution

Richard Cantillon: "People of Unpredictable Worth"

Close to being a physiocrat, Richard Cantillon (1697–1755) was also a critic. However, if he shares an important aspect of physiocratic analysis, he privileges the virtues of free exchange. In this context, the entrepreneur occupies an important place. The entrepreneur assumes the role of the managed order of the mercantilists. He takes on, too, the role of the prince, great organizer of the mercantilist order. Cantillon in fact distinguishes two types of economic agent, those of predictable worth, and those of unpredictable worth. He classifies the entrepreneur in the second category. The entrepreneur takes risks in committing himself firmly, without guarantee as to the solvency of his client or his backers. Without fortune of his own, thanks to his projects, the entrepreneur manages to bring progress to the economy, but society does not trust him and rejects him.

Cantillon was himself an entrepreneur, even a kind of adventurer. He associated himself with John Law and died in obscure circumstances (probably by assassination). But if the economy is the science of business, as Schumpeter held, Cantillon was most certainly a great economist, since he accumulated a sizeable fortune, precisely thanks to his capacity to take risks in his affairs just as in life. His main work "Essay on the Nature of Commerce in General" was only published in 1755, several years after his death. In this work, the entrepreneur embodies what would later become the "invisible hand" of Adam Smith in the form of "catalyst of production and exchange."

Cantillon did not have primacy in this idea. He was preceded in his task by other distinguished authors. In 1675, Jacques Savary published "The Perfect Merchant" a veritable best seller on the right of merchants. But this work appears to be rather a code of business practice than a manual of political economy. It was Cantillon who gave a new dimension to the entrepreneur by conceptualizing his behavior. He distinguishes two types of economy, a centralized economy (symbolized by a great managed domain along feudal lines) and the managed economy. In the first system, wealth is concentrated in the hands of landowners; under the "new" system, it is the entrepreneurs who concentrate the wealth. The task of the entrepreneur is to identify demand and to manage production so as to satisfy it. He takes risks and scouts out the way ahead to find potentially profitable activities. The entrepreneur is present both in production (farming, manufacturing, and the provision of services) and in exchange (wholesaling and retailing). The first are the productive entrepreneurs and bring together a wide range of professions, bookmakers, carpenters, doctors, lawyers – even beggars and thieves. On the other hand, he accords only little importance to manufacturers, with the exception of cloth makers – doubtless because, in the seventeenth century, this represented a fairly well-developed industrial activity.

Adam Smith: The Invisible Hand Masks the Entrepreneur

Smith (1723–1790), contrary to Cantillon, was not an entrepreneur but an academic. He travelled widely in Europe and sympathized with the philosophers of the Enlightenment. However, he expressed little interest in the entrepreneur as such (such doers of projects inspired little confidence in him). His underlying sentiment was that only the market is capable of bringing wealth and prosperity, without overshadowing the state, as a reducer of uncertainty, and whose role is to create an environment propitious to the development of business. His analysis is contained in the famous concept of the "invisible hand" according to which the sum of individual interests is equal to the general interest.

In the whirlwind of business, enterprises are created and developed. The same applies to the ownership of capital. Smith interested himself in the development of limited companies. The separation between management and ownership seemed to him likely in the longer term to damage individual initiative. The shareholder has no particular interest in the future or the enterprise apart from the dividends which he may be able to withdraw as net company worth progresses. Companies having shares are by their nature less efficient than companies managed directly by their owners, since the interests of the shareholders are not necessarily the best interests of the company. This tends not to be the case for the shareholder who thinks strategically in terms of accumulating or trading blocks of shares. As in Schumpeter nearly two centuries later, capitalism seems to lose its soul in socializing itself.

Jean-Baptiste Say or the Profession of the Entrepreneur

Jean-Baptiste Say (1767–1823), in the image of Cantillon, accords a central role to the entrepreneur. In his time, he was the best known of all French economists. He obtained the first chair in economics at the Collège de France and at the National Conservatory des Arts et Métiers and was a minister of finance during the first empire. One of his brothers founded the sugar refiners Say, which in 1973 became Béghin-Say. He was also a journalist. Adapting the ideas of Adam Smith, which he attempted to popularize in France, in 1803, he published his Treatise on Political Economy, where he identified the advantages of free enterprise and the market. This treatise was poorly received by the government of the day. He was unable either to publish a second edition or to carry on the profession of journalist. He became an entrepreneur, creating a business in cotton which had all the hallmarks of modernity for the times. The business prospered rapidly.

Undoubtedly benefitting from his theoretical certainties and his entrepreneurial experiences, Say defined the "profession of the entrepreneur" according to the following criteria:

1. The entrepreneur acts for his own account. But entrepreneur and chief executive are not entirely synonymous. The entrepreneur does not necessarily have recourse to the labor input of others. He sets up his business mainly through a desire for independence.
2. He can carry on different professions – clock maker, farmer, dyer, etc. It is in innovating that he becomes an entrepreneur because he is an intermediary between the worker carrying out his tasks and the original work of the scientist. Say thus distinguishes three kinds of "industrial operations," "scientific research," "its application by the entrepreneur," and "its execution by the worker." This art of "application," which forms an essential part of production, is the occupation of a class of men that we call entrepreneurs of industry (Say, cited by Boutillier and Uzunidis 1995, p. 17). In this sense, his work is productive in the same way as that of the scientist or the worker.
3. He is the principal agent of production. The other operations are of course necessary for the creation of products, but it is the entrepreneur who gets the process under way,

who gives it a vital impulsion, and who recovers the value at the end of the process (Say, cited by Boutillier and Uzunidis 1995, p. 18).

4. Production is the application of science or of "notions." This application concerns the whole of the "needs of man." In order to satisfy these needs, the entrepreneur must prove he possesses a "certain intellectual combination." It is a question of appreciating not only the physical needs of man, but also his "moral constitution" (his customs and habits, his tastes, the degree of civilization he has attained, the religion he professes). The entrepreneur must be endowed by providence with a certain "capacity of judgment." It is he who judges the needs of his fellow men and above all the means of satisfying them and who formulates the end according to the means available to him. The union of these qualities in a single individual is uncommon because "this type of work demands moral qualities which are rarely found in a single person" Say (cited by Boutillier and Uzunidis 1995, p. 18).
5. The entrepreneur organizes and plans production and bears all the contingent risks. This is in sharp contrast to those secondary agents he employs: "a clerk or a worker receives his salary or other remuneration whether the enterprise is in profit or loss" (cited by Boutillier and Uzunidis 1995, p. 18).
6. The profits are thus not the "fruits of despoliation" because their achievement depends on a great number of uncertain factors which the entrepreneur cannot control. He must be ready to bear all the consequences of bankruptcy should it occur.
7. The entrepreneur combines the "natural productive services," such as those of work and capital and must be aware of the state of the market. His head is accustomed to an ongoing series of calculations so that he can "compare the costs of production with the value of the product when it is put on sale." Say, just as later Schumpeter, puts the accent on the entrepreneur's capacity for innovation. In order to surmount the multiple obstacles raised before him, there is no way he can accommodate routine. He must ceaselessly invent, that is to say, to have "the talent to imagine all at once the best targets for speculation and the best means of attaining them."

The Entrepreneur in the Neoclassical Theory

Léon Walras and Carl Menger: The Diverging Marginalists

At the end of the nineteenth century, the neoclassical economists recentered their work on the founding principles of Adam Smith (competition and private property) and forged a series of scientific investigatory tools. The enterprise disappeared and became a combination of factors of production, in other terms, a function of production. This concept of the function of production forms an abstraction as much of the enterprise as of an organization composed of a varying number of individuals and which obeys a grouping of functional rules laid down by the entrepreneur as decider. The model of pure and perfect completion evacuates the uncertainty and the risk. In this conceptual setting, the entrepreneur in fact disappears – not on account of the bureaucratization of productive activities (cf. development of managerial capital) but because the risk (and consequently the profits) disappears. In the neoclassical theory such as formulated by Léon Walras (1834–1910), the entrepreneur is a sort of intermediary between the markets (factors of production, of goods etc.) who bends without resisting to the will of the market through the price mechanism. Among numerous criticisms levied at the Walras model that of Joan Robinson is entirely pertinent, not to say debunking, since she affirms that the pure and perfect competition model can only function efficiently within a planned economy, in other words, in the absence of uncertainty and risk. We can add to the rout of Walras that the pure and perfect competition model is not a representation of economic reality but a kind of deal which the real economy endeavors to approach.

A paradox? Walras has not constructed a clear theory of the entrepreneur, even though the thinking behind it is based on free enterprise. The entrepreneur is an economic agent just like the worker or the consumer. The Walrasian entrepreneur, in contrast to the descriptions given by Cantillon or Say, is not an exceptional individual. Nor is he distinguished by exceptional faculties. In the Walrasian theory, the theory of the entrepreneur, that of the firm and of production, is superimposed on one another. The entrepreneur can be perceived as a function of production in the same way as the firm, a kind of black box whose workings remain unknown. Walras also affirms that the function of the entrepreneur corresponds to a service given free of charge.

In lesson n°19 of "Elements of Pure Economy," whose first edition dates from 1874, Walras (1988) describes the entrepreneur as a personality (he can be either an individual or a firm) who purchases raw materials from other entrepreneurs, then rents a parcel of land from a landowner, pays a wage for the personal services of his workers, pays interest on capital to his backer(s), and finally, heaving applied productive processes to the raw materials, sells for his own account the products obtained. The entrepreneur has thus for his task, with regard to the present definition, to combine these different resources. Walras pursues his definition and specifies that there exist different types of entrepreneurs, in agriculture, industry, and commerce. Whatever the sector of activity where he operates, the entrepreneur makes a profit if he sells his products or goods at a price higher than the costs of production.

Explaining innovation or economic crises did not fall within Walras' ambitions. Is it perhaps for this reason that he casts aside the entrepreneur in imagining a world without either uncertainty or risk?

Carl Menger: The Limited Rationality of the Entrepreneur

Although generally associated with the works of Walras as cofounder (with S. Jevons) of marginalism, Carl Menger (1840–1921) built a different theoretical framework, since he placed the accent on uncertainty which influences, and is influenced by, the rationality of economic agents. His economic analysis (contrary to that of Walras) tends to retrace the evolving dynamics of capitalism by putting the accent not on situations in balance but on imbalance. The essential cause of progress resides in the growth of knowledge. But where does such growth originate? And what are the economic agents that mobilize it? The answer is relatively contrasted. The process which leads economic agents to take decisions is relatively more complex than that imagined by Walras, in the first place, because the information available to the economic agents is not only objective but also a great deal more diffuse. This knowledge is capable of being mobilized into action, that is to say, across the interactions of individual behavior patterns. In his way, and well before the birth of theories on social networks, Menger puts the accent on the formation of networks of social relations which play a nodal role in the formation of business opportunities.

Thus, Menger puts the accent on the process of apprenticeship during which the agents acquire knowledge. Such knowledge is in some degree discovered by particular economic agents. But Menger also puts the accent on the acquisition of knowledge linked directly to the activities in which the economic agents are engaged. Throughout the acquisition of knowledge the economic agents create, without the intention of so doing, institutions which permit them to reduce uncertainty. Such social institutions are the spontaneous result of the interactions of individual behavior, interactions which permit in particular the mobilization and the spread of tacit knowledge. The discovery of this tacit knowledge stems from a limited number of individuals showing innovative behavior. These individuals are in some way "agents of clairvoyance."

These agents do not possess in themselves a maximizing behavior. They pursue objectives of their own in a context of uncertainty and consequently are susceptible to error. No two individuals have the same vision of the world, for each individual has his own such vision. One can speak in this sense of limited responsibility, even though this concept correctly stated only goes back to the end of the 1940s under the pen of H. Simon. The Mengerian entrepreneur acts in a context of uncertainty. He has no objective vision of the economic situation into which he is plunged. His vision is subjective because it depends on the position he occupies in the market but equally on his own identity. Each economic agent is unique and marked by his own characteristic traits.

Alfred Marshal: Managers and Entrepreneurs

Alfred Marshall (1842–1924) was Professor of Economics at the prestigious Cambridge University. Among his various students was the (later) illustrious J. M. Keynes. Keynes, like his teacher, never ceased to rework the neoclassical model. He is highly critical in his *principles of political economy* with regard to the world of business, for the modern economy "provides new temptations for dishonest conduct in business. The progress of science has permitted the discovery of new ways of giving things an appearance other than reality .... The producer is now far removed from the final consumer, and his misdemeanors do not receive the severe and prompt punishment which falls on the head of a person obliged to live and die in the village where he was born."

For the term "competition," he substitutes the expressions "freedom of industry or work" or "economic freedom" and emphasizes that nearly all the inventions without number which have been given to us by the power of nature have been the products of independent workers. From the primitive society to which he often refers, Marshall shows that the economy has progressed and that the division of labor has become considerably more complex. In this context, the entrepreneur has secured for himself an important place. The localization of industry and the appearance of the system of capitalist entrepreneurs were parallel phenomena due to the same general causes, and each one helped the progress of the other. "Economic freedom" led to the triumph of "the men most capable of founding a business, and organizing and managing it." This is without calling to mind the "most clairvoyant" (economic) agents of Menger.

The appearance of the entrepreneur predates capitalism. In the proto-industrial system, the entrepreneur reigned over what is now called working from home, "a system of small tradespeople managed by the workers themselves ...." Then came the system of large firms, where the entrepreneur specializes in one function of management and organization of the firm. These upheavals, which put an end to the customs which had become "too late to train oneself and too blind to act only when the time to act is already past," call out to "the men of energy", ready for anything, counting only on themselves, and "considering their success as being due to their own energy." The spirit of enterprise which inhabits these men is what distinguishes the modern economy from the primitive economy.

The entrepreneur is nonetheless an unloved creature. His fortune is often suspect in the eyes of the common man, despite which the profits he earns are no more than the just remuneration for his labor. The entrepreneur is an entrepreneur because he manages "to do noble and difficult things simply because they are noble and difficult" (Marshall 1919, vol. 2, p. 391). Despite this, the evident hostility of society adds a bitter pill to the actions of the entrepreneur!

In *industry and trade* (1919), Marshall interests himself in economic history from the angle of concentration of capital. He distinguishes several types of firms typical of different stages of economic history. The typical firm takes on at least two different forms: the individual firm, embodied by the entrepreneur, owner of the capital, and then the limited liability company, embodied by the manager (the shareholder plays a relatively minor role). During the preindustrial period, entrepreneurs were the businessmen who purchased goods in a particular locality and resold them in another. Such traders all through the Middle Ages ran great risks, and international trade offered wide possibilities for economic initiative and perspicacious foresight. From the industrial revolution onwards, the industrial entrepreneur occupied a central position. He had to be able to estimate with precision the required investment and recruit the necessary labor. From the end of the nineteenth century, the socialization of capital divided the function of the entrepreneur between on the one hand the manager and on the other hand the shareholders. The manager took charge of the strategic direction of the business, but he is a salaried member of staff, and thus takes none of the risks inherent in management. In the case of failure he risks, according to Marshall, simply put, his reputation and his employment. The shareholders, in contrast, bear the risks but delegate nearly all their functions as owners of the business to the managers.

Thus the entrepreneur and the manager divide the market between them. The first survives thanks to his dynamism and his capacity for innovation. The second relies on the solidity of a large organization which shields him from the dangers of uncertainty. Certainly, he is lacking in energy and initiative relative to that deployed by the entrepreneur, nevertheless the important financial means at his disposal allow him to put to use the entrepreneur's new ideas. The role of each one is clearly different. The entrepreneur is not obliged to justify the decisions he takes. This is the reverse of the case of the manager who must obtain the approval of his board of directors and possibly the whole body of shareholders meeting in assembly. Marshall puts the accent on the charisma of the entrepreneur which allows him to motivate his personnel. The vitality of the small firm is closely linked to the qualities of its owner, more diligent, more assiduous in watching over the business, and more intimately connected with a multitude of details.

In a larger organization, on the other hand, the working ambiance is far more codified, even coasting along as the result of bureaucratic habits such as to impede any initiative which might disturb it. The main fault of large firms lies in their excessively centralized administration. To the extent that this risks imposing higher costs on smaller firms, the entrepreneur gives way to the manager. Large firms dominate numerous markets by reason of the superiority of mass production methods. However, certain sectors of production, or certain steps in the production process, are less expensive to carry out on a small scale, thus a division of labor exists between large and small firms. Furthermore, if the entrepreneur does not disappear, his independence is clipped because his order book depends on the activities of large firms. The state has to accompany this evolution of the productive system, by putting in place legal mechanisms to guarantee the contribution of each shareholder. Its role is to maintain confidence, by guaranteeing the stability and harmony of the working of the market thanks to public services rendered by the police, the justice system, and the construction and maintenance of infrastructures.

Two worlds coexist for Marshall, that of the small, innovatory firm (which by definition is exposed to uncertainty and risk) and where the entrepreneur has a key role, and the large firm, having a share capital, and which rests on a bureaucratic organization and mass production. The large firm has the capacity by virtue of its size to control the market (it plays an important role in the fixing of prices at high levels). The small firm (just like the artisanal proto-industrial business) is close to the consumer and knows his or her needs, in contrast to large industrial groups. Inevitably its situation is more precarious.

The Economists of Transition

We have grouped together three economists, Marx, Schumpeter, and Coase, under the title "economists of transition." There is no question here of evoking the progress of mechanisms of the planned market in the direction of capitalism, or the reverse, but rather of studying the mechanisms involved in the transition of the heroic entrepreneur to the socialized entrepreneur. What are the spurs to growth in the size of firms? What becomes of the entrepreneur in an economy dominated by large firms? Finally, if a certain trend in the concentration of capital has been in progress since the beginning of the twentieth century, is this process in fact unacceptable?

Karl Marx: Entrepreneurs or Capitalists

Karl Marx (1818–1883) is not a theoretician of the entrepreneur; however, an in-depth reading of his works is rich in information as to the role and the place of this figure in the dynamics of capitalism. Marx (2004), though, rarely employs the term "entrepreneur," preferring the word "capitalist." The latter is frequently qualified as "fanatical agent of accumulation" who "forces men without mercy or truce to produce for the sake of producing. . ..” “Accumulate, accumulate! That is the law and the prophets”. One could equally well replace “accumulate” with “innovate.” The propos of Marx are not necessarily distorted. Nor does he abandon the term of entrepreneur, to which he always attributes a place and a precise role in the dynamic of accumulation. According Marx, the movement of social accumulation thus presents, on the one hand, a growing concentration in the hands of private entrepreneurs of the reproductive elements of richness, and on the other hand, the dispersal and multiplication of points of accumulation and of relative concentration, which repel reach other from their own particular orbits.

The capitalist entrepreneur is caught up in a kind of endless spiral. His capacity for initiative (of action) is limited by the coercive law of the market. He is, besides, alienated from the worker he exploits. In the *Communist Party Manifesto* Marx and Engels (2005) qualify the bourgeoisie as the agent without will of his own and with no resistance to the forces of industry.

Even though Marx may have qualified capitalism as revolutionary on the technological level, he failed to establish an explicit relation between innovation and the entrepreneur. Invention had become “a branch of business” and the application of science to immediate production determines inventions at the same time that it solicits them.

Marx concentrates his analysis on the general dynamic of the accumulation process. Capitalism is caught up in a kind of dynamic which overtakes it, but which, it also seeks to master. Competition is tough. Uncertainty is high. The sharks eat the minnows. Business must either expand or disappear. The competition which is the quintessence of capitalism adapts itself. Large firms emerge (performers on an international scale) which seek to control more and more tightly the uncertainty proper to the functioning of the market. Productive activity becomes more and more socialized. Capitalism changes its nature. Marx leans on the theory of the end of history (which Schumpeter also takes up), where he evokes the possibility of a new form of organization of the economy where the market and private property have disappeared. The state would then take over the management of things. In the absence of the market, uncertainty and risk are also eliminated, and consequently, the entrepreneur can force open the market with no resistance. However, the entrepreneur is not perceived by Marx as an autonomous economic agent, master of his own decision-making. Capitalism, founded on the principles of competition, and consequently on risk, evolves progressively towards a managed economic system, where risk and uncertainty have all but disappeared in the same way as all the other economic principles attached to capitalism, whether it be the market, prices, or currency.

Joseph A. Schumpeter: The Metaphor of Capitalism

At the beginning of the twentieth century, J.A. Schumpeter (1883–1950) developed his theory to compensate for the gaps in the Walrasian model (which despite this he admired), and which had proved incapable of providing explanations for technical progress, growth, or even economic crises. Against this, the Schumpeterian entrepreneur introduced the idea of movement (1980, 2010). Schumpeter defined the entrepreneur as the economic agent who innovates. But this is an irrational agent in the Walrasian sense of the term. His behavior is not guided by any economic calculations. In the image of what was the very existence of Cantillon, the Schumpeterian entrepreneur is a player. He assumes in his basic conditions both success and failure at the same time.

The entrepreneur is the motor of “creative destruction.” According to Schumpeter, capitalism, let us repeat, constitutes by its nature a type or a method of economic transformation and not only is it never stationary, but it could never become so. Then, he explains that the fundamental impulsion which starts off and maintains the capitalist machine owes its being to new products of consumption, new methods of production and transportation, new markets, and new types of industrial organization – all the elements created by capitalist initiative. He calls this evolutionary process unique to capitalism the process of creative destruction. This process of Creative Destruction constitutes the basic element of capitalism: it is this element that in the last analysis comprises capitalism and any capitalist firm must, with good grace or otherwise, adapt to it.

The motivation of the Schumpeterian entrepreneur resides in the challenge, change, and the game. His aim is to go against the established economic order. The entrepreneur is thus instrumentalized in order to explain the dynamics of capitalism or "economic evolution." The most important idea that we retain is that of innovation by opportunism. Innovation is not limited for Schumpeter to the creation of new products or the introduction of machinery into the workshops. Innovation is, roughly speaking, that which allows the entrepreneur to grow his business and his dominant position on the market. Additionally, even if the entrepreneur is not entirely certain of the effect of his discoveries, the latter can become, in the case of success, a means of conferring on him provisionally, (through its effects on competition) a monopoly position. By the power of innovation, the entrepreneur goes beyond the limits of his own market; he establishes his own rules, so as to master the uncertainty otherwise inherent in the functioning of the market. Human motivations are never strictly individual but always form part of a social and historical reality. In other words, the entrepreneur invests in such or such a sector of activity because it is the state of the economy, of society, science, or technology which permits him to do so, while bringing solutions to the problems posed. The Schumpeterian entrepreneur is the economic agent who introduces "new combinations of factors of production" which provide by the same token opportunities for investment. Such factors manifest themselves in multiple forms: the making of new products, transferring of production methods from one branch to another, opening up of new sales outlets, development of new sources of raw materials or of semimanufactures, and achievement of new market powers (e.g., a monopoly). These new combinations appear very close to the practices denounced by Marshall, according to whom businessmen hold up the progress of science in order to put a new appearance on things in an artificial way.

The characteristics of the Schumpeterian entrepreneur are the following:

1. His independence is limited by the effects of competition and consequently by uncertainty.
2. The execution of new combinations is "difficult and only accessible to people having the quality of strong determination." Only a few people "have the aptitudes needed to be able to take charge in such a situation."
3. Being an entrepreneur does not always signify "having lasting relations with a particular business." One is not an entrepreneur for life. The entrepreneur is only an entrepreneur when he puts into practice new combinations of production factors. Such a situation is by definition unstable because, by virtue of the dynamic of creative destruction, other entrepreneurs can be led to innovate, and this process is ongoing. Whence comes a virtually permanent situation of uncertainty in which the function of the entrepreneur is embedded.
4. Being an entrepreneur is not to be summed up by combining the factors of production, an activity which (maybe paradoxically) becomes routine. But only the entrepreneur can bring to bear new combinations of production factors. Managing the daily business of production is part of routine. This is not the function of the entrepreneur. Our eyes, someone is in principle not an entrepreneur unless he carries out new combinations; furthermore, he loses his character (as entrepreneur) if he continues to carry on the existing business without breaking out of the already established procedures.
5. The entrepreneur links the world of technology with that of the economy in introducing his new combinations of production factors. Achievement of this objective carries risk. That is why it interests the entrepreneur.
6. The quest for profit is secondary, although that does not mean to say it is neglected by the entrepreneur. He is a kind of gambler for whom the joy of creating carries him forward on the wave of research intrinsic to the gain. But, if profit merely crowns the success of new combinations of production methods, it is the expression of the value of the entrepreneur's

contribution to production, just like the salary is to the worker.

7. The Schumpeterian entrepreneur is a clever calculator because he is able better than others to predict the course of demand, which gives him a degree of power to channel the uncertainties he faces.
8. The Schumpeterian entrepreneur has charisma and authority. The importance of authority cannot be absent; it is often a question of surmounting local resistance, of winning relationships, and being able to support heavy challenges.
9. But the term "leader" does not turn the entrepreneur into the equivalent of a military chieftain. The entrepreneur does not distinguish himself by specific qualities. The task of the leader is very special: he who can master it has no need of specific connections, nor any particular intelligence, nor to be interesting or cultivated, nor to occupy in any sense a "higher ground"; he may even appear ridiculous in social situations where due to his success he may find himself. By his very essence, but also by his history (the two do not necessarily coincide) he is, away from his office, typically seen as a *parvenu*; he is without tradition, what is more he is often uncertain of himself, he appears anxious, in short he is everything but a leader. He is the revolutionary of the economy – and the involuntary pioneer of social and political revolution. His own colleagues disown him whenever they manage to steal a march on him, so effectively that he runs the risk occasionally of being excluded from the ranks of established industrialists.

A number of economists have attempted to search in the economy for the true Schumpeterian entrepreneur. But the entrepreneur described by Schumpeter lacks consistency. One cannot find an individual who embodies the stipulated qualities in a durable way. For example, Henry Ford only became an entrepreneur when he created the "model T"? For Schumpeter, being an entrepreneur is not a profession and certainly not a lasting state of affairs. Did not J.K. Galbraith try to affirm this when he wrote that one may compare the existence of the great entrepreneur to the male *aspis meblifera* which accomplishes the act of procreation at the price of his own existence?

The condition of the entrepreneur is therefore not a permanent state. Anyone is in principle only an entrepreneur if he puts into practice new combinations – and thus he loses this quality if he continues thereafter to manage the business according to existing principles – consequently, it is comparatively rare to see someone remain an entrepreneur on top form for decades; whereas, the businessman who has never been an entrepreneur, to however modest a degree, is a far more common species. The existence of the entrepreneur is consequently a precarious and uncertain one. But, that is not only on account of the place and the role attributed to him in a capitalist economy; it lies in economic theory so far as it exists. The entrepreneur, and most particularly the Schumpeterian entrepreneur, incorporates a dynamic disembodied from capitalism.

The general definition which Schumpeter gives to innovation suffices largely to explain profit as an exceptional and temporary source of revenue which rewards the entrepreneur, that is to say, the economic actor who has taken the risk of breaking the monotony of the Walrasian equilibrium, a situation where profit is nil.

The link between "innovation," "entrepreneur," and "economic growth" is brought about by the concept of the arrival of a group of entrepreneurs in a strategic market. This phenomenon is for Schumpeter the start of a long cycle of expansion. These pioneering entrepreneurs play an essential role because they "suppress the obstacles confronting others not only in the branch of production where they feature, but also, conforming to the usual nature of obstacles, they suppress them ipso facto in other branches of production. The example works by itself; many gains made within a particular branch serve other branches as well, as is the case for the opening of a market, an abstraction stemming from circumstances seemingly of secondary importance which soon appear: increase of prices etc.... This is how the action of the first leaders exceeds the immediate sphere of their influence, and the whole group of entrepreneurs increase business still further than would otherwise be the case. Thus the national economy is affected faster and more completely than would normally be thought in the process of reorganization; this constitutes the period of lift-off."

R. Coase: Alternatives to the Market

Coase (1910–) does not go along with the same theoretical current as Marx and Schumpeter. He asks neither the question of the disappearance of the entrepreneur nor that of capitalism; the theoretical model which he constructs belongs rather to the set of problems of transition such as we have posed in the above arguments. Coase even imagines an extreme situation where the market becomes confused with one sole and single firm, a situation of absolute monopoly, where uncertainty has disappeared and there the firm in question has complete freedom to fix prices. But this situation only corresponds to an academic case study set by Coase. He does not envisage it as a situation likely to arise. Coase distances himself from the neoclassical definition of the firm; he conceives the firm not as an instrument of production, but an as organization. It is not a question in the Coase analysis of the size of the enterprise (by what criteria in any case should this be defined? By the number of employees? By the amount of capital employed?). But the firm is conceived as an organizational form standing as an alternative to the market. Two alternatives can be offered: either the entrepreneur is himself responsible for production or else he delegates this task to other firms by means of subcontracting. In this case, the activity of production takes the form first and foremost of a contractual relationship. Coase thus plays in a dialectic fashion on a particular relationship between the firm and the market. The setting up of a firm encompasses within itself the functions of the market, at the same time, endogenizing the uncertainty proper to the functioning of the market itself.

The Coase analysis constitutes an important theoretical advance for the neoclassical theory because it leads towards legitimizing the existence of the firm in the eyes of those fervent liberal economists who are partisans of the market. But, the Coase analysis also brings to bear a pertinent explanation as to the size of firms (which distinguishes itself from basic analyses of pure and perfect competition, in the first place that of the atomicity of the market). The size of a firm grows when additional transactions (which may be exchanges coordinated by the market, that is to say by the price mechanism) are organized by the entrepreneur. The size of the firm shrinks when the entrepreneur abstains from such transactions. It is then possible to deal scientifically with the question of the size of firms.

The advantages of internal coordination do not lead towards the universal firm because the creation of a firm also implies costs to be set principally against the decreasing yields of management. For Coase, there exists an optimum sharing of coordination between the firm and the market which allows determination of the size of the firm thanks to reasoning at the margin. A firm grows when additional transactions (which might be exchanges in the context of the price mechanism) are organized by the entrepreneur, and it diminishes when the entrepreneur fails to pursue such transactions.

Coase (1937) resumes his argument by setting out three situations in which a firm might assume a growth trend, which would allow it by the same token to take on the functions of the market, and consequently to channel the uncertainty inherent in the working of the market:

1. If the number of transactions increases, while the costs of the organization and their elasticity remain weak.
2. Still within the hypothesis of an increase in the number of transactions, if the entrepreneur is unlikely to commit errors and the rate of errors decreases.
3. When the offer price of production factors falls (or increases only slightly) the size of the firm can increase to a significant extent.

However, to the extent that the size of the firm increases the organizational costs, losses due to errors can increase. But, these organizational costs can be reduced thanks to technical innovation. Coase gives the examples of the telephone and the telegraph, as innovations reducing organizational costs.

Following on from the contribution of Coase, Williamson (1986) brought together the contributions of two other economists, North and Akerlof. The contribution of the first resides in the existence of institutions, while that of Akerlof resides in the asymmetry of the information existing between sellers and buyers, which leads the first to keep their best products to themselves and to select inferior goods to sell. The institutional environment determines the rules of the game so far as concerns the methods of governance. The firm and the market are, for Williamson, the two institutions of the economy. However Williamson's contribution includes other aspects: the use of concealed information is also an important aspect of the economic game which goes beyond the Walrasian hypothesis of the maximization of profits; Williamson considers that economic agents act by opportunism which he defines as being the will of individuals to act in their own interests by voluntarily pursuing the deceit of others. In these conditions, uncertainty results not only from the opacity implicit in the behavior of some economic actors, but also from the deliberate will of certain economic agents to develop concealed strategies. These strategies have precisely as their aim the attempted channeling of the uncertainty inherent in the functioning of the market. Under these conditions, what is the fate of the limited rationality sketched out by Menger? Williamson postulates implicitly that economic actors seek to combat uncertainty by creating their own sources of information, which by virtue of their strength in the market-place impose themselves in the face of other protagonists.

We are thus placed in the following situation: either the firm (which is essentially according to Coase a collective object, centralized and planned) or the market which responds to a spontaneous order and a decentralized decision process. The firm (contrary to what Coase affirms) does not present itself as a tangible, material reality.

It seems to grow or to regress according to the progression of an environment which is itself shifting, and which changes in accordance with movements in prices. In these conditions, growth in the size of firms is seen as a means of counteracting the uncertainty inherent in the working of the market whilst itself forming part of the market mechanism. Thus, the Coase analysis tends to show in an implicit way that firms, whatever their size, are capable of adaptation. During the 1970s Williamson (1965, 1985) followed in the same direction in stressing that the costs of transaction, as put in evidence by Coase, are linked principally to the degree of complexity and uncertainty in the economic environment. Of course, demonstrably the hypothesis of market transparency rejects uncertainty.

Conclusions and Future Readings

Inserted into the market economy (by reason of its uncertainties) the entrepreneur is by definition a risk-taker. The entrepreneurial function is closely linked to the risk taken in a situation of doubt or uncertainty. It is in seeking to avoid or reduce risks that the entrepreneur plays his role of innovating. Innovation thus acts as a relative reducer of uncertainty because it endows the entrepreneur with a temporary power of monopoly; by his innovation, the entrepreneur contributes to the transformation of the market. But, in this permanent movement of uncertainty there can be no final result in the permanently enveloping mist of the business world. Now, it is precisely by means of these keywords that the function of the entrepreneur has been progressively and more precisely defined ever since the eighteenth century, at the dawn of industrialization (cf. Cantillon). Ever since then, the theory of the entrepreneur has been enriched, but the duo uncertainty/risk still remains at its base.

As an agent for change, the entrepreneur is singled out by his capacity to take risks, and forms part of the "people of uncertain worth." Even the term entrepreneur lends itself to confusion as it designates from the outset a character undoubtedly real in economic life, despite economists frequently using the term as a metaphor. The paradox of the theory "of the entrepreneur resides in the very term of entrepreneur which designates a kind of economic actor who can without difficulty be identified as such in the real economy (e.g., head of a business), but from another perspective, this is not the position that economists adopt, whatever their position may actually be. In fact, the entrepreneur does become a metaphor, that of movement or progress in a capitalist economy.

The entrepreneur, from Cantillon to Coase, materializes the movement of the economy, in its dynamic, growth, or in a recession the contrary. He is identified with risk taking since in a context of uncertainty he detects investment opportunities by anticipating the needs of consumers. By innovating, that is to say, by launching a new product or service on the market, he creates a pocket of uncertainty both for his own business and for others because he is incapable of anticipating the reaction of consumers. Will they accept or avoid the novelty?

Higher Education and Innovation

Elke Park
Institute for Science Communication and Higher Education Research (WIHO), University of Klagenfurt, Vienna, Austria

Synonyms

Disruptive innovation in higher education; Higher education institutions; Teaching and research/teaching-research nexus; Tertiary education; University (research university); University governance

Introduction

The two main functions or contributions by higher education institutions to innovation processes in today's knowledge society are **teaching** and **research.** On the one hand, universities and other higher education institutions (HEI) fulfill the task of educating and training a skilled workforce capable of dealing with the – increasingly complex – demands of the knowledge economy and the labor market; on the other, they act as central institutions in the creation of new, original insights and ideas, and among other players, they still play a fundamental role in the production of knowledge (see also contributions on *University Research and Innovation*; *Mode 1, Mode 2 and Innovation*; *Mode 3*). HEI thus occupy a central position in innovation processes and societal and economic development, in fact, higher education has been considered "a cornerstone of the global knowledge society" (UNESCO et al. 2009).

Whereas traditionally universities or HEI where shielded from market pressures, operating in a protected realm believed to be most conducive to scientific inquiry and the production of scientific knowledge, a process of organizational change has affected institutions of higher learning and research which increasingly opened universities up to market forces. It has been argued that a marketization or quasi-marketization (Musselin 2010) of higher education has occurred. This process is also related to the transition from elite to mass higher education starting in the 1960s as the organizational setup of elite higher education began to prove increasingly insufficient in accommodating mass access to tertiary education. Today, teaching and research are considered valuable "products" of HE, providing the basis for sustainable economic growth as "science and technology are seen as the main source of **competitive advantage** on the national and regional level" (Carayannis and Campbell 2012, 2). Restructuring processes within higher education also aim at "unlocking and capturing the **pecuniary benefits** of the science enterprise" (ibid.). Thus, market mechanisms of supply and demand and, more generally, capitalist modes of production, for example, specialization or differentiation processes, aspects of "mass production," competition, and the ultimate rule for cost efficiency increasingly apply in and shape higher education.

The Teaching-Research Nexus

Teaching and research – at universities, these two functions or outputs of higher education were linked in a special way since the inception of the modern research university in the early 1900s. The specific connection between teaching and research has been the characteristic of the Western research university ever since, and to many it still represents the ideal of what it is that higher education does. However, over the last 30 years, a rupture of the teaching-research nexus took place, a separation of tasks based on an increasing differentiation of or within HE institutions. Schimank and Winnes (2000) speak of pre-Humboldtian systems where teaching and research are institutionally separated (as in France) or post-Humboldtian systems where teaching and research take place at the same institution but are funded separately and carried out by different staff (as in the UK). Still, the most prominent and influential model based on a unity of teaching and research within one institution and in the person of the professor was the Humboldtian model which originated in Germany in the early 1900s and heavily influenced the US-American system (especially on the graduate level). The unity between teaching and research was first proclaimed and instituted by Wilhelm von Humboldt, and it represents a special way of producing, expanding or advancing, and disseminating new knowledge. What happens at a (research) university, how does the process of knowledge production ideally works at these institutions? According to the very influential Humboldtian ideal a professor shares his or her knowledge and research interest and the questions and problems he is working on with his students in the setting of a seminar or discussion round (later, labs), and he or she involves them in his or her research and in turn receives input, critique, feedback, and new ideas by his students who are supposed to grow themselves in the process both as independent thinkers and as experts in the field. Also, students are not merely "taught" – teaching as a mere appropriation of content is, in Humboldt's view, the task of secondary education – they are expected to engage independently on (research) questions and problems provided by their professor or mentor who acts as their supervisor, not their teacher (see Humboldt 1993, 191). Ideally, the most talented students would be selected to remain and progress on to an eventual career in academe or research. This is, simply put, the basic functioning of the modern research university, the teaching-research nexus in practice. In short, it is learning (research) by doing (research). However, finding or securing a place and making it to this elite circle of students engaging in discussions with the most eminent experts of their field, was limited to a small elite of the population that underwent severe – and highly socially predetermined – selection processes before entering tertiary education.

The Massification of Higher Education

With the onset of massification of higher education in the 1960s and 1970s, political leaders increasingly recognized that economic growth could only be sustained through an increase in the qualification of the workforce (see Fischer 1974, 591 in Preglau 1986, 194), and massive spending in secondary and higher education followed. Vice versa, a growing middle class recognized – and realized – the potential for social mobility through (higher) education. General demographic changes (population increase, with the baby-boomers entering higher education in the 1960s) further contributed to the phenomenon of rapidly rising student numbers. The 1960s are thus considered the "take-off phase" of mass (higher) education (Preglau 1986, 202). Accordingly, student enrollment grew at a rapid pace, and the quantitative increase in student numbers over the last 50 years is rather impressive: Since 1960, student enrollment in the USA more than quintupled (a 560 % increase, compared to a 72 % population increase); in Germany, more than six times as many students were enrolled at universities in 2009 compared to 1960 (a rough 640 % increase); at Austrian universities an almost eightfold student increase occurred since that time (790 %) (Data for the USA: Schuster and Finkelstein 2006, US Bureau of the Census; for Germany: Statistisches Jahrbuch der BRD; Statistisches Jahrbuch der DDR; for Austria: Hochschulbericht 1969; uni:data, www.bmwf.gv.at). Further, these numbers pale in comparison to Asian tigers such as China and Korea which show even higher growth rates (see Brandenburg and Zhu 2007 for a discussion of enrollment numbers in China, for example, accepted students after entrance exam in 1976: 270,000, in 2007: 5.67 million).

Martin Trow (1973, 7) has identified three phases in the evolution of higher education: an elite system (participation less than 15 % of the age group), mass higher education (participation between 15 % and 50 %), and universal higher education (participation more than 50 %). Today, some countries (Korea, Canada, and Japan) already exhibit universal participation rates, while most OECD members currently show tertiary attainment rates at around 40 % (OECD 2011, 40).

Differentiation of Higher Education Institutions

Under the circumstances of mass or universal higher education, the above-mentioned special institutional setup and focus of research universities following the Humboldtian model became problematic. Policy makers, expert organizations, and higher education researchers alike increasingly insisted on the necessity of a differentiation and diversification of HEI by also including and fostering other HE institutions focused more on teaching and knowledge proliferation as well as training in practically oriented skills: Guri-Rosenblit et al. (2007, 1, also quoted in Meek and Davies 2009) summarize the two main arguments advocating increased institutional diversity in higher education:

> First, most experts agreed that it is impossible to teach all of the large numbers of students in research universities which are extremely expensive to sponsor. Therefore, it seemed obvious that other types of higher education institutions geared mainly for teaching and professional training are appropriate for absorbing the growing numbers of students (Clark 1983; Trow 1973, 2000). Second, a growth of diversity of backgrounds, talents and motives of job expectations among the rising number of students should be accommodated by heterogeneous higher education providers.

Again, with participation rates of over 40 % in many, if not most, industrialized countries, policy makers were confronted with the following problems: (a) if providing – expensive – research-oriented training for more than half of the population or age group is financially viable; (b) if the "production" of a research-oriented workforce makes sense in regard to the demands of the labor market; and ultimately (c) if research training is in fact what most people aspire to or expect from their education, if it fits their needs and capabilities and corresponds with participants' own goals. It is often claimed that more practice and learning-oriented programs better serve the needs of the workforce and the labor market. On the other hand, in defense of the research university, it can be argued that the cognitive abilities developed in research-focused training, namely, independent, critical thinking, and the ability to extract relevance out of a vast knowledge base, are exactly the qualifications needed in today's ever more complex labor market (see also Huber 2004).

A recent OECD report further underlines the importance of a diversified range of institutions in a HE system. First, highlighting again the argument for cost efficiency, Lynn Meek states that while "recognizing the importance of both research and research-intensive universities to the development of knowledge economies it needs to be recognized that no nation can afford to fund all of its universities at a level commensurate with world-class research universities" (Meek and Davies 2009, 64). She goes on to say that the quality or success of a higher education system is based not so much on the number of "world class" research universities but instead relies on a balanced "world-class system" of higher education with highly differentiated institutions answering to a multitude of demands: "There is evidence to suggest that world-class systems of higher education are differentiated systems. These are systems that address the increasing needs of society and the diversity of student backgrounds that result from massification" (ibid.).

Accordingly, a variety of institutions emerged in the field of tertiary education over the last 50 years, and the numbers of institutions focusing on teaching and knowledge proliferation in more applied, practical fields increased rapidly: polytechnics (UK), universities of applied sciences (Germany, Austria, Switzerland), or community colleges in the USA. The latter saw especially high enrolment growth rates over the last 30 years (currently 44 % of undergraduates are enrolled at community colleges) with peaking growth rates during the economic crisis of the late 2000s (see Fry 2009).

On the other hand, especially in systems where diversification is not – or only slowly – taking place vertically between institutions, an internal horizontal differentiation within institutions can be observed (see Chiang 2012, 140; also Guri-Rosenblit et al. 2007; Clark 1997). On the European continent, a shift of research-based teaching (i.e., the teaching-research nexus) to the higher levels within an institution (to the graduate level or doctoral education) is currently taking place. It can be argued that due to the growing complexity and specialization of the knowledge base which has to be appropriated and taught in the first place on the undergraduate level (and can no longer be provided by secondary education alone, as Humboldt envisaged it) research-based training in its original sense makes most sense on the graduate level. Clark 199, 246 states that "the trend from elite to mass to universal higher education brings enormous growth in the teaching of beginning and intermediate students who ostensibly must master codified elementary materials before they can go forward to advanced work." Experts agree that a strong research focus on the undergraduate level would have adverse effects on learning as it leads to a "patchy coverage" of the curriculum (Trowler and Wareham 2007: 3–5. quoted in Meek and Davies 2009, 70ff). Thus, truly research-based training is more and more reserved to the graduate level. What occurs on the undergraduate level is teaching. This clearly noticeable shift is much deplored especially in the German-speaking countries (see also Clark 1997, 247) where a tendency to increasingly turn university education on the undergraduate level into school instruction ("Verschulung") oriented toward a fast appropriation of content in the curriculum met with strong protests and was criticized as the beginning of the end of the Humboldtian ideal of the university. This was also related to changes brought about by the so-called Bologna process and the harmonization of European degrees introducing the three-tier structure of bachelor-master-PhD. In the Anglo-American area, especially in the US where the

Humboldtian model (i.e., seminars) was emulated originally more on the graduate level, the undergraduate level traditionally had a broader focus aimed at providing a general education (Clark 1997, 248) and was less targeted on research training in one specific discipline. Research orientation there traditionally took place in graduate schools.

Equity and Access to Higher Education

The teaching-research nexus and the traditional Humboldtian research university which provided the prominent model for HEI over much of the last two centuries is under siege. Due to the massification of higher education and the concurrent attempts to accommodate rising student numbers at a low cost, a clearly visible differentiation is taking place. Research-based teaching is either shifting to the top levels within an institution or to top-level research universities within a HE system. Will this result in a new elitist function of the research university with only a select few progressing on to the top tier of university education (this time ideally based on merit and accomplishment not on social status, however, the line is thin here)? Will research-based training as a consequence only take place in a small elite sector and will this most expensive form of training be reserved again to a minority? Finally, will it lead to the resurrection of new (old) elites with socially or financially disadvantaged groups receiving their training in lower-ranking, more practically oriented, and cheaper colleges or online classes? Indeed, recent studies begin to show that, as a result of differentiation processes, socially disadvantaged groups tend toward nonresearch-oriented forms of higher education – such as UAS in Germany – while more privileged groups opt for an education at research universities (see, for example, Lörz 2012).

In highly differentiated systems such as the USA or the UK, it is certainly positive that cheaper forms of instruction provide access to those parts of the population that formerly did not participate in higher education – which is why US president Obama referred to community colleges as the "unsung heroes" of the American education system, because they – in principle – provide open access with at least theoretical possibility to move up to higher, even the highest-ranked institutions if qualified. However, institutional stratification as a result of massification is considered highly problematic on the European continent. There, especially in the German-speaking area, the free and open access to the best possible (research-based) education for all is considered a societal accomplishment (and a human right) and a powerful social and political achievement and agenda which is not easily abandoned or given up in favor of more hierarchical structures. Providing research-based training to all students is a mission laid down in most institutional charters of German-speaking comprehensive research universities, a claim that is becoming increasingly harder to fulfill for all students on all levels. Access to these institutions – some of them the top universities of the respective countries – is, with few exceptions, open to all high school graduates with little or no tuition fees. It must be noted that the open access policy in these countries originated from a tradition where only a very small elite was able to complete secondary education and thus obtained the right to enter university. As a sign of the ongoing persistence of these traditions, the tertiary attainment rates in countries with full open access policies to research universities are still notably lower than the OECD average (see Pechar 2010). Today these systems struggle with severe financial difficulties possibly to the detriment of both teaching and research at these institutions. European comprehensive "mass research universities" face a dilemma as they try to accommodate both being a top-rated research university based on the Humboldtian model and providing (research-based) training to comparatively very high numbers of students while at the same time confronted with shrinking government funding: These universities, often being left to deal with this problem autonomously, struggle in trying to make the impossible possible.

Research and Institutional Prestige

Ironically, an increased focus on research in recent years has partly counteracted the development toward institutional differentiation and the rupture of the teaching-research nexus. Research output denotes status in academe; it is one of the main pillars of institutional reputation, and thus the basis for success in the HE marketplace by attracting more or better students and/or increased funding (see Luhmann 1970). This development was in large parts also fostered by popular university rankings which exhibit and promote a strong focus on research performance. Thus, many institutions tried to follow and emulate the model of the research university, for example, Universities of Applied Sciences in Germany are trying to raise their status by incorporating scientific practice into their profile, mission, and activities; they try to improve their standing by focusing more strongly on research either by increasing the publication output of faculty or by incorporating more "scientific" methods and standards in teaching. A strong focus on research has partly also had detrimental effects on the quality of teaching within research universities. Teaching was neglected as it did not count as strongly in performance evaluations; however, there are signs and initiatives which begin to reward excellence in teaching more strongly. Still, most institutions orient themselves toward the ideal of top research institutions in order to gain visibility on rankings and institutional prestige to attract students and/or funding.

"Disruptive Innovation" and the Challenge or Opportunity of Online Learning

A strong proponent for increased differentiation between institutions and a separation of the teaching-research nexus is Hayden Christensen, Harvard business scholar and cofounder of the concept of "disruptive innovation." He argues that "the historical strategy of trying to be great at everything and mimic institutions such as Harvard is not a viable strategy going forward" and favors an increased focus on "institutions focused solely on knowledge proliferation": Advocating a clear separation of teaching and research between institutions and limiting research-based learning to a smaller number of institutions, he claims in the pronounced jargon of business economics (teaching and research are considered two different "business models") that

> [Research] institutions of higher education remain vital – indeed those that focus on research as well as those that train people for the academy will still be critically important for the country's future. Most of America's elite colleges and universities will continue to fulfill this job. But we should no longer force those institutions that are focused on teaching and learning to compete on the same metrics and play by the same rules. Pushing these institutions to adopt a mission of knowledge creation has created institutions that have two conflated value propositions and business models – and added significant overhead costs. We need institutions focused solely on knowledge proliferation – and need to regard those that do a good job on this dimension as being of high quality at what they were meant to do. (Christensen et al. 2011, 5)

In this context, the business scholar applies his concept of "disruptive innovation" to higher education. According to Christensen, disruptive innovation occurs when a formerly sidelined or "low-end" product enters or "disrupts" a domain (or market) that was formerly only accessible or reserved to a limited few because its products and services were complicated, expensive, and inaccessible, to allow a **whole new population of consumers** access to a product or service (e.g., the personal computer vs. the mainframe computer, mobile phones vs. fixed lines, and US community colleges vs. 4-year colleges (see Christensen et al. 2011, 2 for a detailed definition). In higher education – a domain which could certainly also be considered as historically only accessible to consumers with a lot of money or a lot of skill – Christensen sees the use of new media and online learning as the product or element resulting in a process of "disruptive innovation" as it offers cheaper and easier to use products that can serve new audiences. Computer-based online education and the use of new technologies in (higher) education has been a frequently debated topic for almost two decades now with little concrete or visible changes taking place so far; however, this could be about to change: Christensen states that, today, growth rates in online learning are increasing rapidly, and he estimates that, while roughly 10 % of students in 2003 took at least one online course, the fraction grew to 25 % in 2008 and was nearly 30 % in the fall of 2009. He projects it will be

50 % in 2014 (Christensen et al. 2011, 3). The use of computer-based online learning would certainly cut costs – and make education more affordable thus providing a financially viable transition from elite to mass education. According to Christensen, a diversification of tasks and purposes (community colleges vs. elite research-oriented universities) would also lead to the inclusion and participation of students who were formerly not able to attend higher education institutions ("and if a postsecondary education is fundamentally affordable – meaning lower in cost, not just price – this will also answer the question of how to extend access by enabling students to afford a higher education," ibid., 9).

Increased access via new technologies is certainly a good thing, both economically and personally, however, while the use of online-based learning could provide cheaper access to higher education, the question remains if institutional differentiation as outlined by Christensen would result in a new institutionalization of elites and an increased social segregation whereby lower social status groups attend cheap online programs or community colleges and elites afford top research universities (see above). It is argued here that the most fascinating, possibly revolutionary and truly disruptive aspect of online-based learning technologies and the use of social media in higher education is not the emergence and use of "cheaper, nonresearch-based schools for the masses" but possibly – as an increasingly less utopian vision – the free or remarkably cheaper access to knowledge on the undergraduate level at all HEI, including top-tier research universities. Already, Princeton and other top-tier US research universities are beginning to offer so-called "massively open online courses" (MOOC) whereby thousands of students from all around the world participate in online classes linked by social media, thus, also providing for the possibility of interaction (see Kolowich 2012). Knowledge, even at the highest possible level and at the highest quality, is free (freely accessible). This could indeed be considered a fundamentally disruptive innovative process, seriously undermining the cost-efficiency argument that guided policies and strategies in higher education in recent years and troubled (European) HE systems still maintaining full open access to top research universities. While private universities in the USA do not yet foresee accreditation mechanisms (Princeton so far declines offering certifications for free online courses), others, especially state-run institutions show a certain willingness to issue certifications. This development could provide state-funded universities with a possibility of maintaining open access while – to an extent – disregarding or alleviating cost-efficiency considerations and at the same time providing education for all that in terms of quality does not necessarily have to be inferior to classroom instruction. In fact, it most likely surpasses overcrowded classrooms with little to no personal contact to a professor as it often is the case at mass research universities today. The free access to knowledge through the internet for those who are motivated, interested, and capable of learning is actually the most fascinating aspect of "disruptive" new developments in higher education. It could contribute to fundamental changes in higher education by challenging the driving argument for cost efficiency which implies that research-based training for all is too expensive. A "seminar" supervised by a professor, guided by his research questions – the Humboldtian model – could in theory also be possible for hundreds of thousands of students, although practically the system works better on the undergraduate level or in the humanities where lab equipment is not necessary even on the graduate level. MOOC do not necessarily have to be limited to the mere proliferation of knowledge, in the sense of passive appropriation of content which already increasingly takes place on the undergraduate level in open access universities today, but would allow for interaction and participation, for questions and new ideas, and for the assignment of tasks – in short, for research-based teaching in the Humboldtian sense. In fact, the teaching-research nexus could be maintained rather than disrupted through the use of new online technologies. Obviously, practical problems, for example, how to effectively tutor and grade tens of thousands of students present themselves. Suggested solutions include peer tutoring by students or the use of artificial intelligence in evaluating and sorting students' contributions (see further Kolowich 2012). Also, ideally, research output could be enhanced by increasing the brain-pool working on and discussing a problem in new online fora. Through online learning, a truly disruptive innovation could lead to the replacement of more traditional forms of higher education, and by entering elite institutions, it could have an equalizing effect where cost – at least on the undergraduate level – no longer matters. It is argued that higher education, however, "has yet to experience the kind of disruption and subsequent gains in productivity realized by other knowledge-based industries" (http://icw.uschamber.com/publication/college-20-transforming-higher-education-through-greater-innovation-smarter-regulation).

On the Marketization and Commodification of Higher Education

"Cost efficiency, productivity gains, and new 'business models' offering products and services at a lower price" judging by the terminology used in policy making and research higher education has turned into a market or quasi-market and, to a certain extent, market-like structures of supply and demand have taken over the sector. Knowledge and educated human "resources" have become a direly needed and valuable good, a tradable commodity; in fact, a nation's competitiveness and ultimately its economic stability strongly depend on the output of HEI. It is argued here that massification – triggered by the insight that education is "good" to attain, both on the individual/personal level to promote life chances and on the system or state level to promote productivity and thus revenue – has currently resulted in a marketization or "capitalization" of higher education or, rather, an approximation toward capitalist modes of production in higher education.

It was shown above that the onset of massification of higher education in the 1960s was accompanied by a massive increase of state funding. Following the enormous expansion of the postsecondary education sector, this generous funding level could not be sustained, and since the 1980s the (public) funding level for universities has relatively decreased leading some to speak of an ongoing "fiscal crisis" for universities (Ordorika 2006: 2–3, quoted in Meek and Davies 2009, 46). Universities and other HEI are increasingly forced to act in a market-like environment competing for scarce resources faced with societal pressures for more direct "return on investment." Not only has the funding level relatively decreased, the formerly untargeted distribution of funds to universities has given way to conditional funding based on tangible and measurable performance and output. Institutions are held more directly accountable for the effective and efficient use of public funds, and they have to show – tangible – results to justify public investment. Why this "withdrawal of the state" expressed most notably in the reduction of public resources or the "reduction of trust" by society (Ordorika 2006, 2 and 10 quoted in Meek and Davies 2009, 44) at a point when the significance and increased importance HEI play in the societal innovation and production process should have become most obvious? First, it could be argued that, with participation rates of over 40 % untargeted resources growing equally in proportion to student numbers and allocated mostly to – expensive – research universities could simply no longer be sustained at the same level as in an elite sector (and it must be noted again that historically the state only sponsored a very small elite and its access to higher education): It was increasingly recognized that "nations will attempt to structure their higher education systems in order to produce the highest educated population at the lowest possible cost" (Meek and Davies 2009, 64). Clark 1997, 247 argues that "governments increasingly indicate that they are not prepared to pay the unit costs of mass higher education at the level of elite education. [...They] also make clear that they are not willing to pay throughout a national system for the increasingly high costs of research and research-based teaching and learning." Thus, vertical differentiation between institutions was enhanced. Second, the role of the state vis-à-vis its agencies has changed dramatically over the last 30 years: governments were apparently no longer willing or able to maintain direct control either due to an increased complexity which can simply no longer be steered centrally or because of an underlying belief that a sector of this importance could best be "regulated" by (partly) opening it up to market or market-like forces and by introducing managerial concepts such as efficiency, performance, and accountability in the steering process. This neoliberal agenda which has pervaded political systems and their subunits also strongly affected HE systems. Ironically, but not surprisingly, it is the success, importance and size of the sector from a former elite sector to an almost all encompassing one that contributed to its marketization as the outputs of HE turned into central "products" of the knowledge economy. One author argues, "Once they have conceded that knowledge is a commodity to be traded, universities become subject . . . to the full and ruthless protocols of the market" (Bertelsen 2002, 1 quoted in Meek and Davies 2009, 53).

Changes in University Governance

In Europe, the concept of new public management (NPM) which originated in the 1980s in the UK drastically altered the relation between the state and its agencies, among them higher education institutions and universities. The basic idea behind the concept is a more market-oriented approach to public management and administration by emulating practices derived from private enterprise in the public sphere (Park 2012b), with the aim of achieving (cost-) efficient results and to enhance the "productivity" of the respective sector. European universities – such as other publicly funded bodies – have been radically transformed in line with the demands of this central new approach to public management. According to Ferlie et al. (2008) NPM-inspired reforms in higher education are characterized by an increased level of competition and financial pressures, a stronger vertical differentiation between institutions, a heavier emphasis on performance, and the introduction of nonacademic executive leadership as well as a top-down management style. De Boer et al. (2007) further establish five relevant dimensions of NPM in the governance of HE. On the basis of these criteria, the authors formulate a hypothetical "NPM standard" which would ideally be set to: (1) state regulation = low, (2) academic self-governance = low, (3) external guidance = medium to high, (4) managerial governance = high, and (5) competition = very high. Their so-called governance equalizer, an analytical tool comprised of these five dimensions, enables them to measure the extent of NPM policy in the various national higher education systems. The UK currently still represents the European system closest to this hypothetical NPM standard, whereas in other European HE systems, only certain aspects of the NPM scheme were implemented, with each country showing a specific combination or focus (see Park 2012b). In the course of NPM-inspired reforms, a decoupling from state authority and the direct control of the state took place in several countries. In the Netherlands and Austria, for example, universities were turned from state agencies into autonomous entities under public law competing for funding and students; they are thus no longer directly responsible to the state or the ministry in their internal steering processes. Control is exerted indirectly through ex-post-evaluation and performance measurement to justify the spending of public funds and at the same time to create competition for public funding among institutions (the most notable example would be the rigorous RAE in the UK). Institutional autonomy is also counterbalanced by an increased influence of various external stakeholders ("stakeholder guidance"), such as governing boards composed also of members of private industry, and the state has become merely one stakeholder.

Further, as a result, the internal organization and governance mechanisms at universities underwent unprecedented transformation processes in the last decades. One of the most drastic effects as a corollary of NPM-inspired reforms on universities has been the curtailing of academic self-governance. Whereas traditionally the academic profession – or the so-called academic oligarchy (Clark 1983) referring to the full professoriate, not all university employees – had a strong influence on the internal governance of their institution ("republic of scholars"); the steering of universities is now increasingly turned over to professional executive university managers who are expected to guide the institution effectively through an ever more competitive HE landscape. The degree and importance of collective decision making and academic self-governance by scholars has been a longstanding characteristic of the Western university. For centuries, professors represented in collegial bodies such as the academic senate and other committees decided collectively upon most internal and academic matters in often cumbersome and slow procedures – a decision-making process possibly unfit for flexible, quick reaction to market pressures. Thus, in many countries following the NPM paradigm, nonacademic and more top-down leadership structures were established which challenged the once "donnish dominion" of scholars over their institution (Halsey 1992). Strategic decisions are now increasingly taken by management (the president, vice-chancellor, or in the rectorate), whereas formerly the rector was considered a *primus inter pares* simply voicing the decisions the collegiate arrived at communally. In some countries, the once powerful senate has been reduced to dealing with purely academic matters, such as the development of curricula (see also Park 2012b). The university as an independent and self-governing entity shielded from outside pressures is turning into a more corporate entity following organizational models derived by private enterprise.

This shift toward more entrepreneurial notions of the university as an organization is also reflected in changes of employment contracts and employment relations. The marketization and "capitalization" of HEI also had drastic effects on the academic profession, and in the last decade a trend toward more flexible work contracts and increasingly insecure employment situations at universities emerged as management is aiming to maintain institutional flexibility. Academic tenure, generally understood as permanent employment until retirement with a high degree of dismissal protection for professors, was once considered the "cornerstone" or the "sacred cow" of the academy. Also, academic self-governance relied to a large degree on the power and privileges of full professors. It can be argued that currently an "erosion of tenure" (Park 2012a) is taking place referring both to the shrinking numbers of tenured positions within universities and the diminishing strength or degree of employment protection tenure offers. The "rise of the part-time profession" (UNESCO et al. 2009) and the increase in off-track appointments have recently been regarded as the most important development and prominent "threat" to the "full professor." The American Federation of Teachers states: "In recent years, the most notable – and potentially the most destructive – trend in higher education has been a significant shift away from employing tenured and tenure-track faculty members in favour of employing full-time non tenure-track faculty members, part-time/adjunct faculty members and graduate employees" (AFT, American Academic 2009, 3). Schuster/Finkelstein (2006) even speak of an "appointment revolution," and they demonstrate that the proportion of full-time faculty who were in fixed-term contracts (non tenure eligible) was barely perceptible in the 1960s but has risen to over a quarter of the full-time faculty over the last 30 years. Finkelstein (2007, 149) shows that 58,6 % of new hires in 2003 were nontenured, off-track positions. The full-time professoriate is in retreat and a recent UNESCO report concludes pessimistically: "The professoriate faces significant difficulties everywhere [. . .and] the decline of a real full-time professoriate is undermining high-quality higher education." (UNESCO et al. 2009, 89f., see also Park 2012a).

Conclusions and Future Directions

It was argued here that the massification of HE and the problems associated with effectively financing growing student numbers and accommodating various differing needs both on the personal as well as on the system level resulted in an increased differentiation of HE institutions. The (Humboldtian) research university based on a unity of teaching and research no longer serves as the sole model for higher education institutions; in fact, the teaching-research nexus is only upheld in an increasingly smaller segment of the higher education sector, possibly leading to a renewed elite function of the research university. Systems where the research university still serves as the prominent model are currently encountering severe financial difficulties. Further, changes in higher education policies over the last 30 years were fueled by an underlying belief in the regulatory forces of the market and ultimately answer to the argument for cost efficiency. On the organizational level, the question arises if the university is turning into a business organization like any other, a knowledge producing and/or disseminating firm with private-sector employment regulations and increasingly less staff participation in the decision-making process. A firm competing for funding and students, trying to prevail in a competitive market setting relying on effective strategic management to find their market "niche" – be it world-class research on the one hand or affordable quality education on the other.

In relating the above to the discourse on innovation, innovation is conceptualized here as constant renewal or change, as a process of "creative destruction" in the Schumpeterian sense, continuously bringing about new and "better" or more efficient ways of doing things. It is also an essentially capitalist notion or endeavor, as constant innovation and improvement leading to growth is at the core of capitalist modes of production. In the words of Josef Schumpeter: "This process of Creative Destruction is the essential fact about capitalism. It is what capitalism consists in" (Schumpeter 1950, 83). It is based on the underlying assumption of getting more or qualitatively better output with less effort thus "incessantly revolutioniz[ing] the economic structure *from within*, incessantly destroying the old one, incessantly creating a new one" (ibid.). This was already stated by Marx who claimed that "the bourgeoisie cannot exist without constantly revolutionizing the instruments of production, and thereby the relations of production, and with them the whole relations of society" (1848).

Leaving normative assessments aside, besides unleashing an enormous creative potential and power, capitalist modes of production can also have an equalizing effect, as (certain) hierarchies stand in the way of and hinder optimal output (they are simply not as efficient) as is evident in the transition from feudal to modern structures. The development from craft shop to factory is often quoted as an essential innovative step. Interestingly, governance changes at (European) universities over the last 30 years make for an impressive example for a similar transition. Humboldtian research universities were transformed from self-governing organizations resembling a feudal guild structure of ordinary professors or chair holders who ruled their institution as members of a privileged "estate" to a more capitalist notion of the university with strong leadership and nonacademic management vis-a-vis employed staff or knowledge workers. Also, under the conditions of mass higher education, the master/apprentice relationship between professor and student can no longer be upheld. The personal "craft-shop style" formation of the Humboldtian model possible in times of elite higher education is increasingly impossible to sustain unless extreme costs are incurred.

It remains up for debate if specialization/differentiation and NPM-inspired practices and policies in higher education can be termed as "social innovation" (in the sense of finding new and better or more efficient ways to distribute funds, or the search for creating more efficient or beneficial regulatory frameworks, for example), a "societal innovation" or merely an "organizational innovation process" (aiming toward more cost-efficient results under the conditions of mass production). What seems clear, however, is that innovation and thus capitalist modes of production itself have taken hold of an age-old bastion of social organization – next to the catholic church, the university is considered one of the oldest surviving institutions of the Western hemisphere (Stichweh). Innovation enters the system itself, and it is undergoing a process of change or renewal based on considerations of cost efficiency. Constant innovative effort and improvement are at the heart of the capitalist enterprise; in higher education, this translates to how to make education and knowledge production more or most efficient, how to educate the largest amount of people with the least amount of cost, or how to organize and foster scientific research most optimally in order to guarantee economic advantage.

However, and most importantly, it was argued here that currently a change or "revolution" in the means of production in the higher education sector is on the verge of taking place: Innovation as creative destruction has brought about a change in the way teaching and research are carried out by introducing new, computer-based modes of (higher) learning. It is important to note that this change was initiated by technological advances and innovation not by social innovation per se which seems to follow and again appears derived. As a – utopian, but increasingly visible – outlook and conclusion to this segment, the special creative destruction processes inherent in capitalist modes of production highlighted by both Schumpeter and Marx could – through new modes of production, that is, social media and computer-based technologies – initiate a truly disruptive innovation process in higher education fundamentally challenging the argument for cost efficiency currently plaguing systems maintaining full open access policies (and thus – paradoxically – challenging the capitalist paradigm based on cost efficiency itself). Innovation could contribute to turning higher education and especially research universities into an easily affordable and accessible and at the same time extremely valuable product open to all.

How does Material Culture Extend the Mind?

Material Culture and the Brain

Humans rely extensively on material culture when they are thinking, including when they are involved in reasoning tasks that require creative solutions. Examples are measuring devices like compasses and barometers; external memory aids like calendars, books, and maps; calculating instruments like abaci and slide rules; and highly specialized tools like imaging software. Even a brief look around one's desk suffices to indicate that humans are surrounded by artifacts that are specifically designed to perform a variety of cognitive tasks. Why do humans rely so extensively on external tools? What are the kinds of cognitive tasks that material culture helps them to accomplish? How are they instrumental in helping them complete such tasks? This entry of the extended cognition literature will look at these questions in more detail and pay special attention to their relevance to creativity, starting out by considering different ways in which material culture enhances cognition and then briefly reviewing three models of extended cognition. This entry ends by outlining practical applications of the extended cognition literature for innovators.

Extended Cognition: Key Concepts

Epistemic Actions

Kirsh and Maglio (1994) draw a useful distinction between *epistemic* and *pragmatic actions*. Like pragmatic actions, epistemic actions involve some physical manipulation of the external world, for example, a Scrabble player who rearranges tiles on her tray, an engineer who draws a diagram, or a carpenter who makes a pencil mark on a piece of wood to indicate where sawing has to take place. The chief difference between pragmatic and epistemic actions is that the main aim of pragmatic actions is to bring about changes in the world, for example, driving from home to work, whereas epistemic actions are mainly performed in order to aid and enhance cognitive processes, for example, driving around in order to explore the neighborhood one just moved into. Although epistemic actions are primarily aimed at acquiring information and improving cognitive performance, they have pragmatic consequences as well. Drawing a map does not physically alter the environment, but makes it easier to navigate – one does not have to level the terrain or fell trees to get a comprehensive overview. Carpenters who stick to the dictum that one should measure twice and saw once avoid wasting material.

Epistemic actions are often performed in the context of creative problem solving. “Creative problem solving” refers to forms of problem solving that involve the generation of solutions that go beyond established action patterns, or that combine existing ideas in new ways, for example, by applying an approach used in one domain to a different domain. Performing epistemic actions helps one to test run novel combinations of ideas and behavior patterns in a virtual manner, avoiding the costs of real-world trial and error. Epistemic actions are therefore vital to creativity. Examples include an engineer who tinkers with a prototype in order to test the effects of varying parameters to her design and a composer who tests the effects of different harmonic structures in a novel composition by trying them out on the piano.

Epistemic Tool Use

Many animals rely on epistemic actions. Ants make pheromone trails to find their way back from a food source to the nest; birds and other territorial animals frequently inspect their territory to check for intruders. However, tool use specifically aimed at gaining knowledge – known as *epistemic tool use* or *epistemic engineering* – remains rare in the animal kingdom. No animal has ever been observed to make tools (i.e., intentionally modify objects) primarily for cognitive functions. Humans, by contrast, make use of a myriad of artifacts that are specifically designed to help them fulfill epistemic actions. Early examples of epistemic tool use include a 30,000-year-old lunar calendar from Abri Blanchard (French Pyrenees), which not only kept track of the phases of the moon but also of its actual position upon its ascent in the spring sky, and a notched bone from Ishango (Congo) dated to about 25,000 BP, which has notches grouped in numerically interesting ways, for example, prime numbers (De Smedt and De Cruz 2011). These examples predate the earliest emergence of writing by over 20,000 years.

Epistemic tool use is not only ancient but also cross-culturally ubiquitous. Even people with a relatively sparse material culture rely on epistemic engineering. For example, traditionally, Australian aboriginals (who lived a nomadic lifestyle that precludes hoarding large amounts of material culture) used message sticks to relay coded information to distant groups; bark paintings, which captured features of the landscape, like water sources and mountains; and cave paintings, which remarkably preserved biological knowledge of species that have gone extinct for thousands of years, such as fruit bats and giant marsupials (De Smedt and De Cruz 2011). Epistemic tool use is a human universal and has been so for thousands of years. The next sections will review some of the ways in which epistemic tools help humans to perform disparate cognitive tasks, with a focus on creativity.

Lightening Cognitive Load

Perhaps the best-known function of epistemic tools is to extend and supplement human biological memory. Keeping the diverse elements of a complex task in memory is cognitively demanding, and there is always a good chance that some elements get misrepresented, overlooked, or forgotten. By externally representing elements of a task, the mind is relieved from having to represent them internally and can focus better on creative aspects of the enterprise.

Even for those cognitive tasks that can be held in biological memory, it makes sense to use external representations that simplify them. For example, while many people would be able to mentally calculate 231×43, a pocket calculator is faster and less error prone. Drawing up to-do lists, subdivided in urgent, less urgent, and contingent tasks, relieves a person’s memory from keeping in mind what to do next and reduces the chance of overlooking pressing assignments. Interestingly, external representations can differ in the way they lighten cognitive load, as Zhang and Norman (1995) showed in their comparison of different numerical notation systems. They found that nonpositional systems like Roman numerals are more challenging to calculate with than positional systems, in particular, because the former offer fewer opportunities to perform some parts of the calculation externally, while the latter allow, for example, for carrying numbers. By contrast, nonpositional systems provide straightforward, visual representations of quantity that positional systems lack. For example, one can see at a glance that XXXIII is larger than XII, whereas a user of Arabic numerals needs to retrieve the values of 1, 2, and 3 from memory to assess whether 33 is larger than 12.

Improving Conceptual Stability

Creativity involves a complex manipulation of conceptual structures. These need to be represented in such a way that some parts of the representation can be altered (e.g., combining new ideas with old ones) while at the same time keeping other parts unaltered. For instance, the available physical space where an architectural solution needs to be implemented typically remains unchanged regardless of the solution that carries the day. Hutchins (2005) notes that the complexity of creative tasks can be greatly increased if the stability of the representation is improved. One obvious way to increase conceptual stability is to simply carry out creative solutions in the real world instead of representing them mentally. Painters, for example, often test different compositional ideas on their canvas by lightly outlining them (as x-rays of historical paintings indicate), or even by altering their design while the painting progresses (the older layers with earlier solutions, the so-called *pentimenti*, are sometimes still partly visible). This allows them to accurately assess the effects of compositional alterations. Also, they typically do not mix colors mentally, but directly test different color combinations on their palette. When reasoning about features of the environment, it is often cumbersome and suboptimal to make an internal, mental representation of them. When testing compositional ideas in the mind, it is difficult to keep some elements unchanged while altering others. By using the external representation as its own best model, a designer can directly interact with it, making her thinking easier, faster, and more reliable. Because they do not involve internal reconstruction, such real-world interactions with the environment are less liable to error.

Making Hidden or Nonobvious Properties More Explicit

Although the world is often its own best model (Brooks 1991), it is not always possible to rely on direct interactions with the world to solve creative problems (e.g., in architectural or airplane design). Moreover, making a new external representation of some features of the world sometimes reveals properties that were hitherto hidden or nonobvious. Kirsh (2010) provides the example of visual designers, who shift between scale models, pen-and-paper diagrams, computer-generated fly-throughs, and various other media. By making multiple representations, they discover structural properties that were previously undetected. A 3D model allows engineers to approach the design from different angles. By observing it from unusual viewpoints, they can see structural relations and detect violations of constraints that would not be detected otherwise. Scale models have the advantage that their relations logically and physically are independent from the designer. Unlike a mental representation, an actual physical model needs to be self-consistent. It can be examined and manipulated independently of the designer's prior ideas and allows for discussion, since its structural elements are there for all to see. Pen-and-paper diagrams do not allow for such rich and detailed inferences (especially not the multiple angles), but allow one to keep a sense of the big picture, the basic ideas underlying the design. Fly-throughs, on the other hand, can give one a phenomenological impression of what the design would look and feel like once executed.

Providing a Handle on Concepts That Are Difficult to Grasp

Not all ideas are equally easy to comprehend and handle. Cognitive anthropologists have examined how the structure of the human mind influences the way we acquire and transmit ideas. Consider a child who learns that a platypus is an animal. From this information alone, she can rely on a rich body of knowledge she already possesses: she can infer that platypuses need food and drink, can reproduce, will die, and so on. The concept platypus is thus a relatively easy concept to learn.

One cannot rely on this earlier-stored tacit knowledge for all concepts. Few people have a good grasp of quantum mechanics or relativity theory, because both run counter to our commonsense conception of physics. Even a concept like heliocentrism is difficult to represent, as is clear in people's inability to solve problems such as why there are different seasons. Most laypeople think it is because the Earth is closer to the Sun in summer than in winter, but realize this cannot be correct, since this does not explain why seasons differ between geographical locations. External representations, such as a model of the solar system that clearly indicates the eccentricity of the Earth's orbit, can facilitate this. Without external representations, some solutions to cognitive problems are almost literally unthinkable. For example, mathematical solutions like algebraic rules to solve second- and higher-degree equations would be impossible without some way of representing these problems externally, either through symbols, as in western mathematics since the sixteenth century, or diagrams, as in ancient Greek and medieval Islamic mathematics.

Costs of Epistemic Tool Use

Epistemic tool use clearly provides many cognitive benefits, but may also carry cognitive costs. In a world where large chunks of information can be stored and transmitted with high accuracy, thanks to its external storage and where diverse channels can be used to transmit these, people can have too much information pushed at them, resulting in a cognitive overload as irrelevant data do not get filtered out. This problem, however, is not so much caused by the amount of information but, rather, by lack of control over it. Employees who return to work from an extended holiday are typically confronted with a large pile of paper mail and dossiers, an overflow of unanswered e-mails, and recordings of missed phone calls. All this information must at least be sifted through in order to decide whether and how to respond, causing stress and anxiety.

Potential cognitive costs not only present themselves for information that is provided but also for information one can freely retrieve. Take the so-called Google effect on memory. In a series of experiments, Sparrow et al. (2011) presented participants with a large set of trivia they had to type on a computer. Half of the participants were told they could use the computer to retrieve facts later on; the others were told the computer would erase the typed information. Participants who thought that they could not rely on the typed notes showed a superior recall. Those who were deceived into expecting they could use the typed notes recalled the information poorly. In a variation on this experiment, Sparrow et al. (2011) let students type information in several folders on a computer. Again, the subjects who were led to believe that they could retrieve the data later on were less good at recalling the facts they stored. Strikingly, they were better at remembering where it was stored than at recalling the information itself. The widespread use of search engines and digital storage thus alters the way human natural memory functions: people shift from recall of facts to recall of where these facts are stored. This in itself may not be a problem, but it can become a problem if information becomes temporarily unavailable, or gets accidentally destroyed (e.g., hard drive failure). As the authors were finishing this entry (January 19, 2012), there was a blackout of Wikipedia, causing disruption and frustration among students and redaction rooms worldwide.

Theoretical Background and Open-Ended Issues

Material culture plays an indispensable role in human reasoning processes. There are several theoretical models to describe how material culture accomplishes this: internalism, active externalism, and cognitive integration.

Internalism

Internalism is the standard view in cognitive science. It maintains that although epistemic actions play an important role in improving our cognitive capacities, they are not genuinely part of cognitive processes. Internalists think that cognitive processes are as a matter of fact purely intracranial, that is, they only take place inside the skull. An analogy with pragmatic tool use, offered by Adams and Aizawa (2001), illustrates this. A person who uses lopping shears to cut thick branches is accomplishing something he would not be able to do with his bare hands, but this does not imply that the muscular processes within his hands and arms actually extend into the shears. Similarly, although microscopes and diagrams are involved in our epistemic actions, this does not imply that one should attribute cognitive agency to these objects. Some authors writing in the field of extended cognition (e.g., Menary 2007) have criticized internalism because it places severe constraints on what counts as cognitive. Obviously, creative reasoning also relies on internal cognitive processes, such as when one makes a chain of associative thought or when ideas one has previously been "brooding on" combine to yield a sudden insight. However, as outlined in section "Extended Cognition: Key Concepts", without external media, creative solutions would be highly constrained, not only in their complexity (purely internal mental representations are hard to stably keep in memory), but also in their kind (some creative solutions are literally unthinkable without external representations). Hence, internalism does not seem to be a fruitful theoretical model to explain what goes on in creative reasoning.

Active Externalism

Active externalists think of cognition as a coupled process, where internal cognitive operations causally interact with epistemic actions. For example, multiplying two numbers using pen and paper consists of internal cognitive processes (e.g., mental arithmetic) coupled with external cognitive processes (e.g., carrying numbers, writing down results). A possible worry is that by granting cognitive status to epistemic actions, one might overextend cognition to every object that is somehow causally involved in cognitive processes. Do a pencil and notepad become part of cognition because these objects were used in a cognitive task? To adjudicate which instances of epistemic tool use are cognitive, Clark and Chalmers (1998) propose the parity principle. Roughly, this holds that if one characterizes a process that takes place in the brain as cognitive, one also ought to characterize a structurally similar process that takes place outside of the brain as cognitive. Take an Alzheimer's patient who relies on a notebook to keep track of facts and appointments: if one is happy to concede that the neurologically normal person is informed by her (internally stored) beliefs about facts and appointments, one should, according to Clark and Chalmers (1998), also regard the externally stored information in the notebook of the Alzheimer's patient as beliefs and thus treat his use of the notebook as cognitive.

Cognitive Integration

Although the parity principle may be useful to overcome some traditional ways of thinking about cognition, it is quite limited when it comes to describing what actually goes on when one is engaged in epistemic tool use. Indeed, in many cases, thinking with the help of external media is radically different from thinking in a purely internal way. An engineer who engages in real-world interaction with a model or pen-and-paper diagram is thinking in a very different way compared to one who ponders about his design using mental representations only. The real-world interactions allow for more consideration of details and can bring to light properties that remain undetected when engaged in internalized cognition. Thus, some authors (e.g., Menary 2007) have argued that the parity principle may not be a good starting point for thinking about extended cognition. Cognition should not be limited to those instances of intracranial processing and external actions that happen to be isomorphic to them, but rather, cognition should be conceived of as an integration of internal and external processes. This involves a causal, dynamic interaction between both types of processes, where the practices of manipulating external objects can lead to structural changes in the way internal cognitive processes take place. The Google effect on human memory, where an increased reliance on the Internet and other external sources has altered internal memory processes, provides a good example of such integration.

Practical Applicability of Extended Cognition Research for Creativity and Innovation

This entry of the extended cognition literature indicates that humans rely on material culture to perform a variety of epistemic actions. These are not merely duplicates of internal cognitive processes but are often structurally very different. Although the extended cognition literature is at present mostly concerned with describing how material culture enhances human cognition, one can draw some practical conclusions for its role in human creativity and innovation. As reviewed here, epistemic actions provide a handle for ideas that are difficult to keep in mind; they allow one to detect properties that are not obvious and improve conceptual stability. Given that different external representations facilitate diverse solutions, creative workers frequently use disparate media to work on the same problem. The chance that an undetected problem or unconceived solution becomes apparent increases as one uses different ways to externalize the problem one is working on. However, engaging in epistemic actions does present a cost in terms of time, energy, and resources. Using a new software program can provide benefits, but requires an initial learning period before these become apparent. Developing external representations (e.g., scale models) requires time, money, and energy. Individual reasoners will therefore have to make trade-offs between what they are willing to invest in the development of external representations that aid their cognitive processes (e.g., make a computerized fly-through or a scale model) and the expected payoffs of this in facilitating or promoting creative solutions.

Since humans have access to a variety of epistemic tools to an unprecedented extent, innovators will need to consider carefully when deciding which tools they will use. For tasks that require creative solutions, it seems important to choose external media that:

- Help to lighten cognitive load, so that more attention and cognitive resources can be devoted to envisaging new solutions
- Enhance conceptual stability, which allows one to consider more complex problems and to develop more true-to-life solutions
- Bring to the fore features that were previously undetected, increasing the pool of possible creative solutions
- Allow to represent ideas that are hard to conceive internally, expanding the range of novel ideas that can be applied in problem solving

Conclusions and Future Directions

The role of material culture in human reasoning, especially in tasks that involve novel, creative solutions, is substantial and unavoidable. Coming up with creative solutions would not only be more cumbersome and labor-intensive – without epistemic tools, some solutions would just be unthinkable. Recognizing the importance of epistemic tool use for creativity highlights the importance of choosing good external representations. Sometimes, the world is its own best model, but in many cases, innovators need to develop new external representations to solve creative problems. By choosing the right epistemic tools, one can facilitate creative discovery to a considerable extent.

The cognitive study of the use of material culture can benefit significantly from a closer look at real-world examples, and this is an important direction where future research can be carried out. Until now, a large part of this literature has been concerned with in vitro psychological studies that take place in the laboratory, where the available epistemic resources are highly restricted (e.g., Kirsh and Maglio 1994; Sparrow et al. 2011). Next to this, mostly theoretical and philosophical considerations play a role (e.g., Clark and Chalmers 1998). Examining the actual practice of creative individuals like engineers or architects at work in R&D departments or design studios can bring to light *what* informs the choices made by creative individuals about *which* epistemic tools they will use. Such in vivo psychological studies have up to now mainly been conducted in science labs and military settings (see, for instance, the work of Bruno Latour, Kevin Dunbar, and Edwin Hutchins).

Studies like these can shed light on what drives real-world creative work and the role of epistemic tools therein, for instance, trade-offs between time and money constraints and the advantages of epistemic engineering.

Idea-Marathon System (IMS)

Takeo Higuchi
Idea-Marathon Institute (IMS Institute)/
University of Electro-Communications,
Tokyo, Japan

Synonyms

Brain-writing; Continuity; Self-Brainstorming

What is Idea-Marathon System?

Idea-Marathon System, so-called IMS, is a philosophical approach of creativity, to build up a habit of daily thinking and immediate writing in one's notebook along with a consecutive number to each idea. IMS was created by Takeo Higuchi in 1984. Higuchi has been writing these days 50 ideas everyday, often with drawings in his 408 notebooks as of Oct, 2012, accumulating more than 360,000 ideas in his notebooks.

Principles of Idea-Marathon

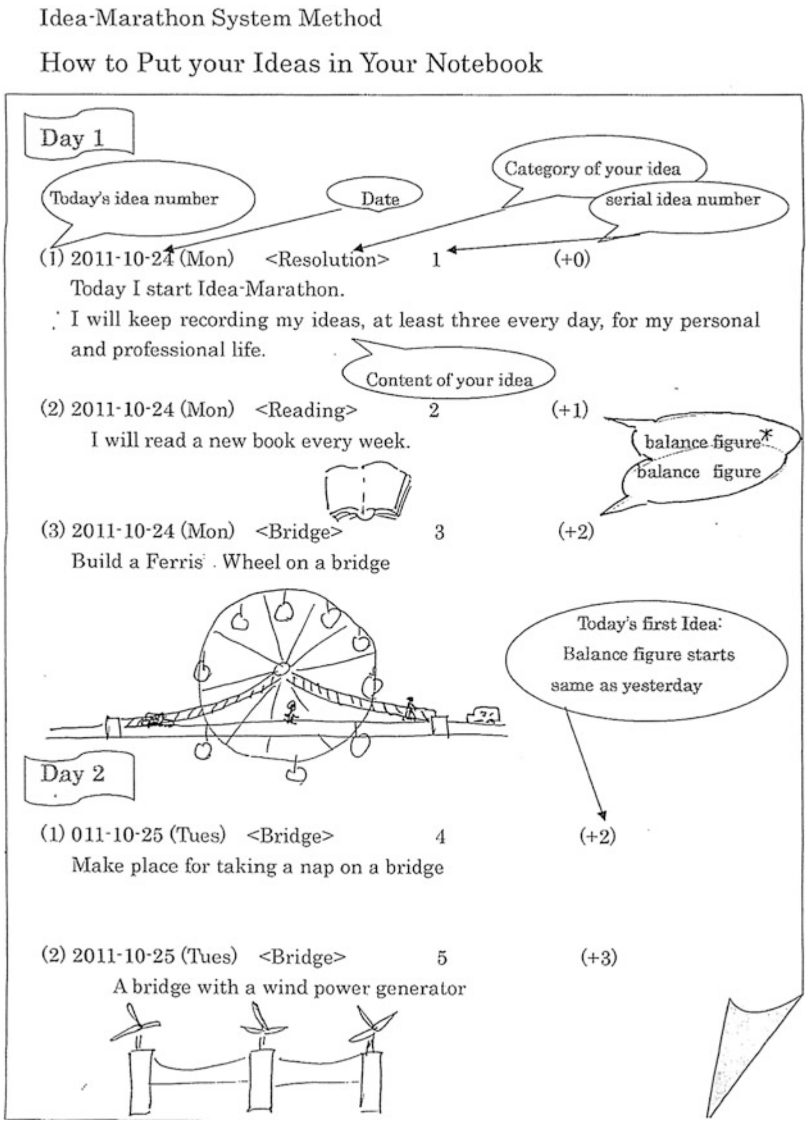
1. Keep using notebooks of the same kind.
2. Generate new ideas everyday to write in the notebook chronologically with idea numbers.
3. Draw pictures for your ideas as often as possible.
4. Talk to your neighbors.
5. Review your ideas.
6. Implement the best ideas out of stock.

Unique points of Idea-Marathon (IMS) are that it is done DAILY so that IMS will become a habit for at least 3 months.

What to Record Idea in IMS

In Idea-Marathon, there are no limits for idea creation. We often can get interesting ideas for

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,



Idea-Marathon System (IMS), Fig. 1 Balance Figure

our work and specialty when we are thinking about something other than our work and specialty.

We can write ideas of hardware and software, better solution, improvement, concepts, project ideas, long range plan, dreams, doubt, checking points, good own jokes, sketches, poems, essay's title, novel's scenario, etc., almost everything out of our brain. Each idea will be written in the notebook like the following example (Fig. 1):

Your balance figure remains even (+0) when you keep writing one idea every day. And if you put forward more than one idea in a day your balance figure will be +1 or more.

IMS Effectiveness for University Students

Empirical quantitative analysis of Idea-Marathon was done by T. Kawaji, M. Higa, and Y. Nakaji of Otsuki City College in 2011. As the result, IMS practice for 3 months showed significant effect in Fluency of Ideas and

Originality of ideas while not effect in Flexibility (Kawaji et al. 2011).

Accumulation Effect or Progressive Stock of Ideas in Notebooks

If one keeps Idea-Marathon with the average of two ideas per day, after only 1 year, one has a stock of 730 ideas in notebooks, 2 years – 1,460 ideas, 10 years – 6,300 ideas. In case any ideas written in notebooks, our brain keeps vague but widely scattered image-like memory of ideas inside brain. Therefore, if we keep a large quantity of our ideas in our notebooks, it starts to resonate with our brain. Our brain is getting faster and stronger in creative power and reaction with the back-ground stock of ideas written in notebooks. One's creative confidence will also be increased accordingly.

Ideas and Ideation

Brainstorming; Divergent thinking; Flexibility; Fluency; Originality

Introduction

Ideas are meaningful units of thought. In fact, they represent the most useful unit of thought. There is no way to pinpoint some of the dimensions of ideas since they vary so much (e.g., your idea of "a good time" is probably more complex than your idea of "your favorite color"), but this is in fact part of their utility. They can be defined such that the variation and flexibility are retained. Ideas are smaller than concepts, which are also varied but cover entire categories of thought (e.g., "funny movies"). Ideas can be quite precise. They are the smallest meaningful unit of thought.

Ideas often make themselves known to the individual (in consciousness) in a verbal form, but it would be a huge mistake to see them as always verbal. Ideas occur in all modalities and perhaps in all domains (e.g., music, mathematics). It is typical to think about ideas in some verbal form, but that is just because it is most common to represent thinking with words. The same tendency is apparent in the research on ideas: it is easiest to study words when they are represented in words. Yet ideas need not be verbal. And an important part of the ideational process is in fact preverbal. This is when thoughts (and perhaps emotions) coalesce into meaning.

Ideas play an important role in creativity and innovation. Simply put, most creative breakthroughs, inventions, innovations, and original contributions of any sort begin with an idea. The more significant the creative or innovative product, the more likely it is that other things (revision, communication, judgment, evaluation) are required after the initial idea, but still, the process begins with an idea. That is why there are programs to stimulate ideation (e.g., brainstorming) and several tests of ideation (divergent thinking tests, such as the *Torrance Tests of Creative Thinking* or the *Runco Creativity Assessment Battery*) and why there is a long history of interest in ideas and ideation (Runco 1991, 2008, 2012).

The History and Philosophy of Ideas

The interest in ideas and ideation goes back millennia. PLATO discussed ideas in his *Republic*. There he used the allegory of a cave, with shadows seen by the cave dwellers merely representations of deeper forms. These forms, then, cast shadows which in turn conjure ideas.

John Locke, seventeenth-century author of *An Essay Concerning Human Understanding*, was also explicit about ideation and the concern for ideas. He discussed them as part of his epistemology, the key idea being that we are not born with ideas preformed. Each of us is a tabula rasa, or blank slate, and knowledge and ideas are acquired from experience. Locke suggested that simple ideas are reactions to sensory information and interaction with the environment. These can grow into complex ideas when they are combined and sometimes when divided.

Other philosophical treatises have developed theories of ideas (e.g., David Hume, William James, Alexander Bain), but it has not been only the philosophers who, throughout history, have pondered the origin of ideas. There is, for instance, a long-standing interest in, and debates about, ideas and ideation in the field of jurisprudence. Much of this focused on criteria and methods for recognizing original ideas as part of intellectual property and protection.

Several aspects of ideas seem to have remained constant through history. Ideas are usually associated with knowledge, for example, or are involved with the ontology of knowledge. PLATO suggested that knowing ideas is impossible, yet the observable world (the allegorical shadow) is a mimesis, a parallel of the form (the object which casts the shadow). The association of knowledge and ideas is currently a matter of debate. Many in the cognitive sciences see knowledge as static and dependent on experience. (Personal or reflective experience may be all that is involved; it is not necessarily experience with the objective world.) Ideas may be independent of experience or, more likely, personal constructions that may or may not be the result of thinking about experience. In the terminology of the cognitive sciences, some intellectual processes are top-down and being with thinking, while others are bottom-up and reactions to experience and sensory information. Often these work together; our thoughts draw from interactions with the natural environment but also draw from our imagination and inferences. Ideas, in this light, may result from an interplay of top-down and bottom-up processes. They are not, however, solely dependent on knowledge. Again drawing from the cognitive sciences, the information we hold in long-term memory is often factual and just information, sans personal input and interpretation. This kind of information is not ideational. Admittedly, the process leading up to the formation of an idea (or construction of an interpretation, for that matter) is not well understood. Headway has been made since new brain imaging technologies have been brought to bear. fMRI research, for example, shows that insights may occur as the individual works with factual knowledge, but eventually switches (due to "decisions" of the prefrontal lobes) to a broader activation of knowledge (in the right hemisphere) such that new options can be found.

Another interesting example from the history of ideas and ideation involved Alfred Binet, author of the first test of mental ability. (The procedure for standardizing that led to the IQ was after Binet's work. Binet recognized that ideas are related to fantasy while perception contributes to the experience of reality. Since perception is closely tied with the physiological contributions of our sensory systems, ideas allow transcendence of physical and temporal laws held by common perceptions. Furthermore, when ideas and perception align, they aid in adaptation to our physical surroundings. The external validity provided by our environment allows substitution of ideas for sensation and provides a coupling that appears as perception. Both ideas and perceptions occupy space in our personal realities.

As an aside, Binet's work exemplifies early empirical research on the topic of ideas. He is famous for his work on the psychometrics of IQ, but when he was working, there were fewer distinctions among modes of thought than there are today. Just as Binet did not have the concept of an IQ at his disposal, so too did he lack (as did all of the behavioral sciences) the distinction between *convergent* and *divergent thinking*. Yet Binet's first test of mental abilities actually contained tasks that required the examinee to draw from long-term knowledge as well as tasks that allowed the examinee to product multiple ideas. You might even consider this a kind of historical preverbal process, at least in that Binet was testing both convergent and divergent thinking even though he did not have the labels for them. Those labels were not suggested for another 50 years. Applying this analogy of preverbal processes a bit further to the history of ideas and to Alfred Binet, it is interesting to see how the lack of the distinction (and labels) for convergent and divergent thinking constrained Binet's thinking about possible modes of thought. This is certainly how it works on a personal level (and perhaps on a historical level as well): once you have the labels and concepts about a subject, you can delve into it, but without the labels and concepts, you can't think much about it at all.

Original Ideas and Divergent Thinking

There is a large literature on divergent thinking that has direct implications for our understanding of ideas and ideation. Indeed, this area of research has no doubt contributed more than any other to such understanding. It is a fairly rigorous area of research, spanning just over 50 years, with innovations in both the tasks designed to elicit ideation and the analytic approaches applied to the resulting ideation. J. P. Guilford is usually credited with initiating this line of research in the late 1940s. He developed a structure of intellect model which ostensibly covered all modes of thought. Just before his death, Guilford (1988) claimed that he had identified 180 distinct modes! Many of them reflected what he called convergent thinking. This is usually used when an individual encounters a task or problem for which there is one correct or conventional answer. If asked to name the largest ocean on Earth, for example, there is one correct answer. Divergent thinking, on the other hand, is used when the task at hand is ill-defined and open-ended. The individual can product many ideas. He or she can in fact think in different directions and, as a result, find original ideas (rather than just the correct ones elicited by convergent thinking tasks).

The technology of divergent thinking defines several kinds of ideation. There is, for example, *ideational fluency*. This is simply the productivity of an individual and operationalized as the number of ideas generated to any one task. Ideational originality is operationalized as the number of unique or novel ideas (usually statistically determined). Ideational flexibility is operationalized in terms of the number of conceptual categories in an individual's output. If asked to name bodies of water on Earth and the person responds with "Atlantic Ocean, Pacific Ocean, Lake Erie, the Mississippi River, and my bird bath," he or she will probably receive a flexibility score of four (one for oceans, one for lakes, one for rivers, and one for baths). Ideational flexibility is very important in that it is indicative of a kind of adaptability. Flexible individuals can cope with changes or surprises much better than an inflexible, or rigid, person. Originality, on the other hand, is indicative of creative potential. Indeed, originality is necessary (but not sufficient) for creative thinking. Fluency is actually predictive of both originality and flexibility. It does not replace them, but it is likely that a fluent individual will be original and flexible – likely, but not absolutely certain. Of course someone can have one idea, but it is an incredibly original one!

In 1962 Mednick published the very influential paper, "The Associative Basis of Creative Thought." This described how new ideas are found and had implications for a theory of how fluency is related to originality. Mednick's (1962; Mednick and Mednick 1967) theory received partial support. His idea of remote associates, for example, usually holds up. In particular, when faced with an opportunity to produce various ideas, the first things most people think of are conventional and obvious. Only after they are depleted do most people turn to more original ideas. Note the implication that time may be needed to find original (and therefore creative) ideas. Mednick's own Remote Associates Test has not fared as well. It presents three concepts to an individual (e.g., Meadow: Mowing: Hay::), and the respondent must think of a third concept that is connected to them (Grass). The problem with the RAT is that it tends to be verbally biased: people with good verbal skills usually do well and people with poor verbal skills do not. Still, Mednick was able to infer that ideas are often associated by acoustics (they sound alike), by functionality, or experientially.

Various technologies are now available to mimic associative tendencies (e.g., the Semantic Web). One kind of software uses an algorithm in assignment semantic proximity to a pair of words. These powerful computations of semantic similarity power a bulk of our Internet search engines and often allow the individual at the keyboard to find what he or she is looking for, despite inaccurate queues. Given the ubiquity of these technologies and their apparent context validity, the psychometric potential of semantic analysis will increase in relevance as associative theories of ideation evolve.

Other assessments have been developed, in addition to tests of divergent thinking and the *Remote Associates Test*. The *Runco Ideational Behavior Scale*, for example, is a self-report that asks the respondent how often they have produced certain kinds of ideas and in what settings. Some measures examine ideational skill, but instead of looking to the productivity or originality of ideas, they look at evaluative tendencies. The rationale for these tasks is that the production of ideas is only one of several important skills involved in creativity and innovation. Not only is it important to produce good ideas, it is also important to be able to judge ideas, to evaluate them, and to know when you have in fact found ideas with potential. Such evaluative skills are moderately, but not overwhelmingly, correlated with divergent thinking and the production of ideas. It is as if producing ideas gives individuals experience at judging ideas (the more you produce, the more experience you will have examining them), but there are people who are good at one or the other (divergent thinking or idea evaluation).

Conclusions and Future Directions

Ideas are a part of intellectual property, innovation, everyday creativity, and world-changing insights. They are a part of every day. They are not easy to define in any way that implies universality, but to do so would probably mean that the result is artificial and not indicative of spontaneous ideation. Still, ideas are as operational as, say, "bits" of information (not a binary digit "bit" used in computer code, but a "bit" used in the cognitive sciences to describe units of information processed in short-term working memory). Bits also vary from person to person and must be defined on a level that allows such variation. The technology of divergent thinking indicates that ideas are defined in a fashion that allows scientific study. There is a huge literature on divergent thinking, and much of it is experimental or quasi-experimental and moderate in internal validity.

Numerous innovations have taken place in the research on ideas and ideation. The literature summarized herein has identified the best tasks and assessments for particular populations, for example, and research has demonstrated that familiar tasks elicit a large number of fairly unoriginal ideas (probably because the person can draw from experience), while unfamiliar tasks are better for eliciting original ideas. Several new indices of divergent thinking (e.g., transformational power, appropriateness) are being used in ongoing research, and associations between ideation and intrinsic motivation, attitude, and values are being examined, often with cutting-edge statistical methods. Future directions include a study of the interstices of thought – what happens between ideas? – and their neurological basis. Given the value of ideas for various kinds of thinking, including creativity and innovation, no doubt these areas will soon receive the attention they deserve. Ideas about them are already being offered in various theoretical discussions.

Identifying and Assessing Creativity

Robina Shaheen
The Open University, Milton, Keynes, UK

This chapter discusses the methods for identifying and assessing children's creativity and outlines the various behaviors found in the classroom as well as reported findings from existing creativity research on the most and least valued student traits by teachers. This is followed by a section on assessing creativity and includes the need for creativity assessment, as outlined in the educational policy documents of various countries as well as general literature, and the various assessment instruments which are in use. Following this are the findings from a large-scale mixed-methods study, conducted in Pakistan, which looks at the teachers' views on ways to assess primary school children's creativity as well as policy provisions for this and primary school children's performance on the Torrance Tests of Creative Thinking (TTCT).

Identifying Creativity

Some of the behaviors which are said to be found in the classroom when children are being creative include those outlined by the UK government, as part of the initiative to promote creativity in schools. These include:

Questioning and challenging: ask "why?" "how?" and "what if?"; ask unusual questions; respond to ideas, questions, tasks, or problems in a surprising way; challenge conventions and their own and others' assumptions; and think independently.

Making connections and seeing relationships: recognize the significance of their knowledge and previous experience; use analogies and metaphors; generalize from information and experience, searching for trends and patterns; reinterpret and apply their learning in new contexts; and communicate their ideas in novel or unexpected ways.

Identifying and Assessing Creativity, Table 1 Most valued pupil characteristics from the ideal pupil checklist

Fryer and Collings (1991), $N = 1{,}028$	Sen and Sharma (2004)	Torrance's experts in Sen and Sharma (2004)	Stoycheva (1996)
Considerate (45)	Doing work on time, healthy, sincere	Courageous in conviction	Sincere
Socially well adjusted (29)	Courteous, competitive	Curious	Curious
Self-confident (26)	Self-confident, neat, and orderly	Independent in thinking	Thorough
Independent in thinking (23)	Courageous in conviction, desirous of excelling		Healthy
			Persistent
		Independent in judgment	Sense of beauty
Curious (20)	Affectionate, industrious	Willing to take risks	Sense of humor
		Intuitiveness	
		Becomes preoccupied with tasks	Independent thinking
	Curious, independent in thinking, refined, free of coarseness	Persistent	
	Physically strong, socially well adjusted	Unwilling to accept things on mere say	
	Remembering well, versatile	Visionary	
	Altruistic, energetic, determined, persistent		
	Popular, well liked		

Source: Fryer and Collings (1991), Sen and Sharma (2004), and Stoycheva (1996)

***Envisaging what might be*:** imagine, seeing things in the mind's eye; see possibilities, problems, and challenges; ask "what if?"; visualize alternatives; and look at and think about things differently and from different points of view.

***Exploring ideas, keeping options open*:** play with ideas; experiment, try alternatives and fresh approaches; respond intuitively and trust their intuition; anticipate and overcome difficulties, following an idea through; and keep an open mind, adapting and modifying their ideas to achieve creative results.

***Reflecting critically on ideas, actions, and outcomes*:** review progress; ask, "is this a good...?" and "is this what is needed?"; invite feedback and incorporate this as needed; put forward constructive comments, ideas, explanations, and ways of doing things; and make perceptive observations about originality and value (QCDA 2009, p. 1).

Studies into teacher views about creativity have shown that certain student characteristics are more valued than others. Some of these studies used the Torrance's Ideal Pupil Checklist which contains over 60 characteristics (also refer to ► Creative Behaviors and ► Creativity Across Cultures). The most valued characteristics across studies are shown in Table 1.

There is a difference in the most valued traits of students in that independence of thinking is among the top in the Torrance's experts rating and Fryer, but it is not in Sen and Sharma (India) or Stoycheva (Bulgaria). Many of the most valued traits in the Sen and Sharma's study are different to the other studies.

The top-rated least valued trait by Torrance's experts is "conformity"; however, although this is also in the Sen and Sharma's list, it is not among the highest rated (refer to Table 2). Obedience is another trait which is among the least valued in studies other than Sen and Sharma's, which shows that there are differences in teacher views across countries. Other creative behaviors outlined using different instruments include:

- Has interesting, uncommon ideas
- Shows great curiosity and interest in things others are not interested in

Identifying and Assessing Creativity, Table 2 Least valued pupil characteristics from the Ideal Pupil Checklist

Fryer and Collings (1991), $N = 1{,}028$	Sen and Sharma (2004)	Torrance's experts given in Sen and Sharma (2004)	Stoycheva (1996)
Negativistic (62)	Fearful, apprehensive	Conformity	Bashful
Haughty and self-satisfied (48)	Disturbs procedures and organization of group	Willing to accept judgments of authority	Haughty Self-satisfied
Stubborn and obstinate (48)	Haughty and self-satisfied	Fearfulness	Timid
Disturbing group organization and procedures (44)	Timid, shy, bashful	Timidity	Sophisticated
Domineering (43)	Stubborn, negativistic	Obedience	Quite
	Talkative	Courteousness	Obedient
	Faultfinding, objecting	Promptness in doing work	Faultfinding
	Critical of others	Socially well adjusted	
	Unsophisticated	Haughty and self-satisfied	
	Conforming	Neatness and orderliness	

Source: Fryer and Collings (1991), Sen and Sharma (2004), and Stoycheva (1996)

- Quickly understands real-life problem situation and suggests nontrivial but effective solutions

However, in research studies in which teachers were asked to describe their students so that a new teacher could become familiar with them, it was found that creativity and related behaviors was not among the most important characteristics and outlined by very few teachers. The ranking of creativity-related behaviors from a list of 61 items was low, perhaps indicating that the findings depend upon the instruments used, as the following shows:

- Searching for novelty, interested in the unknown, showing creative preference (49th)
- To do very well in uncommon situations (61st)
- To have original ideas (25th)
- A climate for creative work (37th) (Stoycheva 1996, p. 1)

Assessing Creativity

The Need for and Problems of Assessing Creativity

The Assessment and Learning Research Synthesis Group (ALRSG) in their review protocol for systematic review of research on "The impact of the use of ICT for assessment of creative and critical thinking skills" state that

> . . .if valued goals of education are to be effectively taught, they need to be effectively assessed. (ALRSG 2003, p. 8)

The NACCCE (1999) report defined assessment as the process of "judging pupils' progress and attainment" and made recommendations that "all schools should review their provision for creative and cultural education." It went on to highlight that

> reliable and systematic assessment is essential in all areas of the curriculum, to improve quality of teaching and learning and to raise standards of achievement. This is as true of children's creative and cultural education as for all other areas of education. (p. 124)

McCann (undated) also emphasizes that ". . .creative processes and products be part of the overall assessment plan in the curriculum," arguing that

> . . .in schools, work that is not linked to standards and assessed in some systematic way is treated as less important and less vital to educational purposes. When work is not assessed, it is treated as if it does not "count." (p. 9)

There are a number of reasons outlined for the need to assess creativity. It can lead teachers to prepare and plan for it (Rogers and Fasciato 2005) as well as to create the required environment (Foster 1971) and encourage it (Compton and Nahmad-Williams 2009).

Assessment of creativity is said to be a neglected area despite its importance. This is regarded as a reason for concern keeping in view the high profile that creativity currently has and its linking with education for preparing children for the future (ALRSG 2003). The cause for this neglect may be that assessment for creativity is regarded as "problematic" (Scoffham 2003, p. 5), "difficult" (Thorne 2007, p. 24), and "challenging" (Feldman and Benjamin 2006, p. 332).

There are various reasons given why assessment of creativity is seen to be difficult despite being investigated for over a century. These include having no definite standards or standard methods (Afolabi et al. undated). There are also said to be definitional problems in that creativity is no longer defined as production of something novel; rather, it also includes the outcome being useful. This makes it difficult to assess particularly since what is of value may differ from culture to culture (Scoffham 2003). In fact, some are of the view that the question of whether or not creativity can be assessed depends upon the definition of creativity adopted (Cartier 2001) and in order to assess it a definition is needed (Rogers and Fasciato 2005). Other problems include the different opinions over what is deemed as creative across different subjects and using instruments based on Western ideas in other cultures (Rudowicz 2003). In summary, McCann (undated) states that assessment is challenging because creative work is

> . . .multi-faceted, multi-layered, and do not yield a single, correct, and easy-to-score response. (p. 9)

Instruments for Assessing Creativity

Nevertheless, despite the attributed problems of creativity assessment, many efforts have been made resulting in the development and use of various methods and instruments. Fishkin and Johnson (1998) outlined 60 instruments for use with school-age children. These were grouped into process, personality, products, press, combination measures, and systems or procedures approach. Hennessey and Amabile (1993) grouped assessment methods into three categories: personality inventories, biographical inventories, and behavioral assessments (p. 7). Afolabi et al. (undated) divided these into ten categories: divergent test, attitude and interest inventories, biographical inventories, personal inventories, teacher nomination, peer nomination, supervisor ratings, judgments of products, eminence, and self-reported creative activities and achievement (p. 2). These are not without criticism either. One of these is that they are not adequate for the task (Loveless 2002). There are also problems of reliability and validity (Diakidoy and Kanari 1999) as well as "subjectivity and bias" (Afolabi et al. undated, p. 4). In the case of tests, there are also scoring problems (McCann, undated).

Children's creativity, it is claimed, can be assessed informally or formally using "tests or expert judgments" (Sharp 2001, p. 6). Tests which have been used in education and regarded as the most popular are the divergent thinking type which includes the Torrance Tests of Creative Thinking (TTCT) (1974) and the Wallach and Kogan (1965) tests (Plucker 2001). Such tests are also said to be effective when used to evaluate the effect of programs introduced to develop creativity (Fishkin and Johnson 1998). The TTCT (also called the Minnesota Tests of Creative Thinking) has been used across the world from Brazil (Wechsler 2006) to India (Misra et al. 2006) and "remain the most widely used assessments" (Sternberg 2006, p. 87). It is regarded as appropriate for identifying and educating gifted children but more so for "discovering and encouraging everyday life creativity" (Kim 2006, p. 11) being useful for researchers and teachers for assessing children's creative abilities.

However, despite much praise for the TTCT, it is not considered as useful if teachers are interested in day-to-day changes in children's creativity. For this, the Consensual Assessment Technique is suggested to be more appropriate. This uses judges who "are familiar with the domain to independently evaluate products and then reach consensus" (Fishkin and Johnson 1998, p. 43). In this, the respondent is asked to complete a task, and then experts in that particular "domain" such as poetry are required to rate the creativity of the product (Hennessey and Amabile 1993).

Other tests which have been used in classroom setting include the Remote Associations Test (RAT), which requires respondents to find connections between items. However, it has been criticized for being more of a measure of intelligence than creativity (Taylor 1975). There is also the Guilford's Unusual Uses Test which requires the respondent to come up with as many names for common objects as possible (Hennessey and Amabile 1993). Instruments which collect data about the personality and attitude aspects based on details of past achievements are not regarded as good for primary school children. The approaches in which information about the creative environment is collected are said to lack "well-researched" instruments; however, one of the instruments given in this category and the only one related to classroom observation for creativity is the "Classroom Creativity Observation Schedule (CCOS)." Other more recent measures are combining the standard measures with some alternative approaches such as "performance assessment techniques" which include "direct writing assessments, open-ended written questions, hands-on experiments, performances or exhibits, and portfolios." But evaluating children's work requires "clear standards and knowledgeable judges" (Fishkin and Johnson 1998, pp. 42–43).

All measures, however, are said to have their strengths and weaknesses. It is therefore suggested that in order to assess children's creativity, multiple measures should be used (Plucker 2001). The measures used will depend upon the assessment purpose and the definition of creativity adopted (Fishkin and Johnson 1998) as well as the aspect of creativity that is of interest such as the "product, process, person, and environment" (Auh 2009, p. 1). Taylor (1975) suggested that thought be given to how the creative process occurs over long periods of time using a variety of techniques. The methods for assessment, whichever used, will have some implication for the way teachers "think about creativity" (Hennessey and Amabile 1993, p. 9).

Identifying and Assessing Creativity, Table 3 Teachers' preferred criteria for assessing creativity in pupils' work

Assessment criteria	Percentage of teachers reporting the criteria
Imaginative	87
Original for pupil	85
Showing initiative	79
Pleasing to pupil	74
Expressing depth of feeling	70
Useful	13
Accurate	6
	$N = 1{,}028$

Source: Fryer and Collings (1991)

Teacher Views on Assessment of Creativity

Studies of teacher views on creativity assessment have shown mixed attitudes. Fryer and Collings (1991) reported that three quarter of the teachers said that test scores were not useful for assessing children's creativity. The preferred assessment criteria were as given in Table 3 which includes, as the top rated, imagination and originality in the pupils' work.

In another study of UK trainee teachers ($N = 315$), it was found that 12% of all respondents (Rogers and Fasciato 2005) said creativity could not be assessed. This study included teachers from two universities, and 43% from one said they were certain that it could be assessed and 12% from the other. The majority of the teachers said that assessment should be informal. It should be assessed "in order to share ideas and develop enthusiasm and creativity even more." Some suggested assessing children's implementation of their ideas, while others suggested assessing the process rather than the outcome, yet some said that children should not be assessed on their creative ideas. Some trainees suggested that pupils could assess their own creativity as well as being assessed by the teacher.

However, the teachers were of the view that assessment could pose certain problems as well. It could lead to discouragements, which raises the question, the author says, of whether creativity should be assessed. It was also considered as subjective, as it may mean different things to different people and may be different in different areas. Teachers felt that they lacked set criteria and guidance for assessing creativity and thus were unprepared. They wanted a creativity definition and criteria for assessment. Some said that "creativity is individual" and so there cannot be any criteria for assessment or that there is no one way of assessing it since pupils are creative "in different ways" (Rogers and Fasciato 2005).

Having discussed the existing literature and findings from previous research, the identification and assessment of creativity seemed to be the two weaker areas. In this, Foster (1971) was of the view that the chances of teachers being able to identify creativity can be increased if they have

> . . .sound knowledge of the psychological bases of creativity, an understanding of the creative process and personality, an awareness of the conditions which are likely to elicit creative response.

With this, teachers can also attempt to assess creativity. However, he was apprehensive about this as he stated:

> . . .this seems like an entire study of a subject in itself which teachers need to master, [it has] implications for teachers training and may be very difficult in countries where teachers barely manage to have mastery of the subjects they teach, however the positive side is that once mastered it can be applied to all subjects where only the contents will differ. (p. 53)

This completes the discussion on the various methods and problems related to identification and assessment of creativity. It has been found that research carried out in different countries shows that the teachers, to some extent, value different characteristics for creative students. The remaining chapter presents the findings from a large-scale study conducted in Pakistan related to the question of assessment of creativity. First, the findings from the review of the educational policy and primary curriculum documents are presented, followed by the primary school teacher survey, and lastly, the creativity scores obtained from administering the Torrance Tests of Creative Thinking (TTCT) to primary school children.

Assessment as Outlined in the Policy Documents and National Curriculum

The assessment system in Pakistan has been widely criticized in policy documents, as the White Paper states:

> . . .the examination system like most others is compartmentalized into a limited role of promoting or failing the student. Even within this limited role there are shortcomings that have serious consequences for the quality of the learner produced in the country . . .Since the "learning" is rote based, assessments simply test the memory (Aly 2007, p. 20).

In the Green Paper, it is stated that

> in Pakistan the assessment systems are usually designed to measure individual student ability to move further up the system and there are critical examinations at the matriculate and intermediate levels that determine the career options for students.. . .there is general criticism that these assessment systems encourage rote learning and selective study. (Aly 2006, p. 8)

The National Education Policy, 1998–2010, outlines the assessment mechanisms but not the contents with reference to assessment of creativity (Government of Pakistan 1998). The White Paper for review of this policy defines the five "pillars of quality" which also include assessment (Aly 2007, p. 17). In reviewing the National Curriculum for Science, Mathematics, and English, it was found that all three provide assessment guidelines. In the math curriculum, the assessment objectives include developing relationships, identifying patterns, making predictions, hypothesizing, deducing relationships, identifying problems, planning and conducting investigations to solve problems, and proposing solutions to problems, all related to creativity. The science curriculum advocates assessment which must be:

> Open-ended, allowing for discussion and revision of new understanding
>
> Tolerant of divergent thinking and promote the notion of no "one right answer" (Ministry of Education 2006b, p. 67)

In the science curriculum, it is also emphasized that such test items be used which measure students' achievement in problem-solving skills and analytical and creative thinking (Ministry of Education 2006).

The English curriculum outlines a range of assessment methods, including use of multiple-choice items. The different types described include "best answer type" and "incomplete statement" type, both of which are said to measure "higher order thinking," and also the multiple response type which is "used in dealing with questions to which more than one clearly correct answer exists" (Ministry of Education 2006, p. 154). However, following this is a contradiction in that

> it is recommended that only correct answer type and best answer type multiple choice items should be used. (Ministry of Education 2006, p. 154)

The English curriculum further states that assessment

> requires students to create or produce their own answer in response to a question or task. This allows teachers to gain insight into students' thinking and creative processes, and to assess higher order thinking.... (Ministry of Education 2006, p. 155)

It can be seen from the evidence above that the curriculum documents allow some role for creativity in assessment.

Methods Reported by Teachers for Assessing Children's Creativity

Teachers have reported using a number of methods for assessing children's creativity (Table 4). It has been seen from the classroom observation that children are only asked questions which require recitation of previously learned information, they are also only invited to talk for this purpose as well, there is no practical work in class, and group work is a rarity. It is therefore questionable if all these techniques are really used for assessment at all. Teachers do take exams, mark children's work, and listen to them recite learned text ("sabaq") verbally, which are the only methods of assessment observed in most schools. It is therefore interesting that more teachers have not reported using these as compared to other methods. The fact that 80% of the teachers reported that they use reciting previously learned text as a way of assessing children's creativity implies that creativity is rote learning and regurgitating information which shows a different understanding of creativity held by teachers. This would imply that creativity means learning and regurgitating learned facts. There was not very much variation in the teachers' views on methods to assess children's creativity, across the background variables; however, there were fewer teachers reporting using some of the methods from the other public sector and those with no professional qualification. This research did not involve any further work on assessment in the classroom; therefore, more cannot be said.

From the open comment section, the methods outlined for assessing children's creativity are given in Table 5. One of the interesting things is teachers outlining that they use methods in which children do things such as observation, designing questions, and asking questions rather than the teachers doing this and also giving children material beyond the curriculum. It is also interesting that teachers are reporting that they assess by getting children to obtain answers, whereas in the lessons, as the findings from the classroom observation show, it is the teachers who give children the answers. Perhaps these are methods not used but suggested for assessing creativity.

Torrance Tests of Creative Thinking (TTCT)

The Torrance Tests of Creative Thinking (TTCT) were developed by Dr. E. Paul Torrance in 1966. There are two versions of the test, TTCT-Verbal and TTCT-Figural. Each of these has two forms, A and B. In this study, the TTCT-Figural Form A was used because it was deemed as the best possible instrument which can be implemented, translated, understood, and scored with given the time scale available. In each of these activities, a shape or a number of shapes are given as a stimulus. In activity one there is an egg shape, in activity two there are 10 incomplete figures, and in activity three there are 30 pairs of vertical parallel lines. The respondent is instructed in each activity to use the given shapes to draw something (picture, object). The essential thing is to make these shapes part of the drawing. The instructions urge the respondent to think of something which no one else will think of and to keep adding ideas so that the drawing tells an interesting and exciting story. Once the drawing is complete, they are required to add a title which is "clever" and "unusual," helping to tell the story already started in the drawing (Torrance et al. 2008 p. 2; for more details refer to Torrance 1979; Torrance and Safter 1999). The test requires 30 min of working time, 10 min for each activity. Additional time is required for initial interaction with the children. The TTCT tests for "creative thinking abilities" which are described as a "constellation of generalized mental abilities that are commonly presumed to be brought into play in creative achievement." Although there is a debate about the terming of these abilities, Torrance has however maintained that "high degrees of the abilities measured by tests such as TTCT increase the chances that the possessor will behave creatively" (Torrance et al. 2008, p. 2). These abilities are part of a model for studying and predicting creative behavior (Torrance and Safter 1999, p. 51). A description of the creative abilities scored for in this study is provided in the next section which describes the methods used to administer the TTCT.

Method Used to Administer the TTCT

The TTCT test booklet (originally in English) was translated into Urdu and recomposed, making it the 38th language into which the TTCT has been translated so far. The Urdu version of the test was then pretested in the UK with one child and 30 class five children in Pakistan. These children were of mixed academic abilities. The test was revised in the light of findings obtained from pretesting and then administered by the researcher to 154 children from 17 primary schools in Pakistan using the procedure described below. The schools were both from private and public sectors as well as urban and rural locations consisting of both single and mixed gender student intake.

In each school, an introductory meeting was held with the head teacher to discuss the nature of the test, the number of class five children required to participate, and their selection criteria. If there were more than 10 children in the class, then a group was selected consisting of academically high-, average-, and low-performing students. In mixed sex schools, an attempt was made to select an equal number of girls and boys for each of the three categories. All the children participated in schools where there were fewer than 10 children in the year group.

Once the children were selected, familiarization activities were conducted for rapport building to create a more relaxed, friendly, and nonevaluative atmosphere. The activities included introductions, telling jokes, discussing likes, favorite TV programs, celebrities, cricket, and a magic trick. The children could easily relate to and talk on these topics without hesitation or shyness. One of the things which helped to develop a closer rapport was the researcher also sharing information about herself and answering the questions asked by the children as well relating to them as their "baji" (elder sister) rather than a teacher or researcher.

As an introduction to the test-type activities, the children were asked to describe ways in which they could improve their schools. This was aimed at stimulating them to think in the manner required for the TTCT activities. Another step toward this was asking them if they do drawing as the test is drawing based, although the aim is not to test their ability to draw. The children were then given the test booklet and asked to fill in their identification information on the front page such as name, age, and gender. They were then asked to look at the picture on the cover page of the test booklet and generate as many ideas about what the picture could possibly represent. They could share ideas with each other and work in groups for discussion. It was emphasized that there were no wrong responses and everybody's answer could be different. The drawing could represent anything, and everybody must try to think of something different. For children who found this activity difficult, the researcher pointed to sections of the picture and asked what they thought it could be or generated the first idea. The children's responses were noted and used as a means to appreciate and encourage their ability to generate ideas. After this, the test activities were administered.

For each of the three activities, the children were asked to turn to the required page. The researcher also showed the page, indicating to the stimulus and the accompanying instructions. The instructions were read out loud from the Urdu instructions manual, and the children followed the written text from their own test booklets. They then read the instructions either silently or aloud, and some were asked to repeat these. Effort was made to ask those children who, it was felt, may not have understood. This was also a means of verification to check that the instructions had been understood, and if not, they were repeated again both in Urdu and the local language. Children were encouraged to ask if they did not understand instructions or the meaning of any words. For example, in one government girls school, one girl asked what the word "ajeeb-o-ghareeb," that is, "unusual and original," meant.

It was felt that conceptually some of the instructions did not convey the meaning and were not understood by the children such as "using the stimulus to make a picture," "adding ideas to ideas to tell a story," and "connecting ideas." In this regard, efforts were made to find examples to clarify the instructions. Some of these examples included finding a word to complete a sentence, arm being part of the body, and threading bead after bead to make a necklace. In a school where the building was without a roof, this was used as an example of the building being incomplete until the roof was added.

Children were encouraged to ask questions even during the activities, and in order to answer these, the researcher went to them to prevent others from being disturbed. Those who did not start immediately or at all were encouraged to draw anything. Continuous encouragement and motivation was given throughout the test, and instructions were reinforced, particularly if the children were making random drawings and not using the stimulus. Some children repeatedly erased their drawings so much so that erasers were taken from them so that they concentrated more on their drawing rather than erasing. This may have been due to the children being unsure of their drawings being "right" or appropriate such as heart, alcohol bottle, or simply that it was not a good drawing.

If children had writing problems, they were advised to complete the pictures first and then after the test were helped to write the suggested titles. Since writing seemed to be a problem for a number of children in different schools, the researcher included, as part of the instructions, to write without worrying about spelling. It was hoped that the fear of misspelling a word would not prevent the children from doing the activities.

In case children finished before time, they were encouraged to continue adding more detail as some had the habit of working quickly, usually the children regarded as bright by the teachers. In order to explain that there was a time fixed for each activity but at the same time trying not to create a test-like atmosphere, examples were given where timings are important, for example, one-day cricket match and school timings. Some children were very keen to work beyond the activity time and were worried that they had not finished. When two boys were asked to stop drawing and give titles, they said, "we haven't finished pictures yet, how can we write the titles."

Once the three activities were completed, the researcher checked each child's booklet. The purpose of this was to ensure that all titles had been added and writing was legible. If children had difficulty with writing, the researcher supported by writing down the titles suggested. If a title was not added but picture drawn, then the child was asked to add a title. Some of the children had written titles in the local language such as "Saraikee" and could not be understood. In this case, the children themselves were asked to elaborate or the translator was asked. The booklets of children who were shy or seemed to be easily intimidated were checked last and not in the presence of other class children.

The test booklets were scored using the guidelines provided. The scoring provides information about the "creative functioning of a child" (Torrance et al. 2008, p. 1) and results in five norm-referenced and thirteen criterion-referenced measures (also known as creative strengths). The norm-referenced measures are fluency, originality, elaboration, abstractness of titles, and resistance to premature closure. The criterion-referenced measures (the checklist of creative strengths) are emotional expressiveness, storytelling articulateness, movement or action, expressiveness of titles, synthesis of incomplete figures, synthesis of lines, unusual visualization, internal visualization, extending or breaking boundaries, humor, richness of imagery, colorfulness of imagery, and fantasy. The results discussed in this chapter are related to the norm-referenced measures only, and a description of these "creative abilities" is provided next:

- Fluency is the ability to produce alternatives, and it is claimed that those who produce many alternatives have a greater chance of generating more workable solutions and succeeding in problem solving (Torrance and Safter 1999, p. 58). Creativity itself is considered by Torrance as a "special kind of problem solving" (Torrance 1970, p. 2). The fluency score represents the ability to produce a large number of images.
- Originality involves "getting away from the obvious and common place or breaking away from habit bound thinking." It is stated that the measure of originality predicts creative behavior more accurately than other measures such as fluency (Torrance and Safter 1999, p. 87).
- Elaboration is the "ability to develop, embroider, embellish, carry out ideas" and it is claimed that in reality "the ability to elaborate, work out plans, implement, and sell solutions is important" (Torrance and Safter. 1999, p. 109).
- In order to successfully solve problems and produce something creative which is also valuable, it is important not to become entangled in the information available. This is the rationale behind "abstractness of title" where the ability "to produce good titles involves the thinking processes of synthesis and organization" (Torrance et al. 2008, p. 12). Producing something of value is considered by many as a definition of creativity.
- The "psychological openness" of a person is considered to be an important and accepted

characteristic of a creative person. This involves not jumping to premature conclusions but rather taking time to understand the problem, considering the important factors involved, thinking of alternative and better solutions (Torrance and Safter 1999, p. 117), and considering the available information (Torrance et al. 2008, p. 13).

With a description of the various scoring criteria (creative abilities), the next section discusses the scores obtained by Pakistani primary school children beginning with the fluency scores.

Pakistani Children's Performance on the TTCT

Fluency Scores

Most children exhibited some ability to generate ideas and alternatives which indicates that they are able to solve problems and provide solutions. This is shown by their attainment of raw fluency scores (total fluency score for three activities), with almost 60% of the children achieving scores in the range of 40–60%. In fact, 23% of the children obtained at least 70% and above (Table 6).

The fluency scores when examined independently for each activity showed that children performed better in activity two. There is a positive relationship between the percentage of children and the percentage of fluency scores obtained. In fact, majority of the children (70%) obtained scores from 70% to 100%. This may have been due to having more time to complete fewer shapes, that is, 10 pictures in 10 min, or that the stimulus shapes appeared more meaningful and easily triggered children's thinking to generate ideas. Therefore, the type of initial shape, the number of shapes, and the amount of time given to complete the activity may affect the child's performance on fluency. Almost one third of the children obtained 100% fluency scores for this activity. These children were from private, government, rural, urban, all boys, as well as mixed sex schools. This shows that having a high level of fluency ability does not perhaps depend upon the school sector, location, or gender of students. However, no girl from an "all girls" school achieved 100% score which may be attributed to the difference in the school environments. There were more boys achieving 100% fluency score than girls which indicates that boys are perhaps more fluent in their ideas and that there may be a relationship between the ability to be fluent and the child's sex and/or the type of school they attend (in terms of student gender).

For activity three, the scores obtained by children were not as high as activity two. Initially, as the scores increase, the number of children obtaining these also increases, but beyond 40% of the scores, this trend then reverses with fewer children obtaining higher scores. The highest percentage of scores (60%) is obtained by only 11% of the children. Only 2% of the children obtained full scores. These were from both government and private schools although belonging to the same district. The low scores for this activity are in contrast to activity two. One of the reasons for this may be that there were three times as many pictures to complete, 30, but the time given was the same (10 min) as in activity two. In this regard, it may be said that where time is limited, the children's ability to solve problems is perhaps also limited. Another explanation for the poorer performance in activity three is that the same stimulus, pair of lines, is repeated each time which may not give fresh food for thought, may reduce interest and motivation, and may cause boredom. It may also be that this activity required children to rely more on their imagination which was difficult because they are more used to recalling and regurgitating facts. Both children and teachers in Pakistani schools are very particular about getting things right, and it may be that more children spent more time on each picture in an attempt to get them right, while a few who may not be so right answer fixated, and do not usually get things right, worked faster and finished more drawings, hence obtained higher scores.

In summary, children overall performed well on the fluency criteria although the scores were better for activity two than three.

Originality Scores

While the children were able to demonstrate that they could generate ideas (fluent) and hence be on the path of creative behavior, they showed poor performance on the originality criteria. This is shown by the majority of the children achieving less than 40% originality score (Table 7). This means that they were unable to break away from the "obvious," "common," and everyday way of thinking. The performance on the measure of originality is regarded as a better predictor of creative behavior than other measures such as fluency (Torrance and Safter 1999, p. 87) which indicates that with the obtained scores, Pakistani children have demonstrated very little creative behavior.

The achievement of low originality scores could perhaps be explained by the fact that children are not into the habit of generating original ideas and work and therefore have not been able to display the desired ability which would show indication of creative behavior. In fact, there is evidence, gathered as part of this study through teaching observation, which shows that teaching in the schools does not involve activities which encourage and develop their abilities to be original. The major and only focus is on knowledge acquisition through rote memorization and regurgitation of the learned material. However, having said this, it is important to mention that teaching in these schools also does not include activities to specifically develop children's fluency ability; nevertheless, children performed better in this as already discussed. This perhaps means that it is more difficult to be original than fluent and that the ability to be original perhaps comes with more guided practice. In this, the children's ability to understand the test instructions may have also influenced their performance particularly as the children are unlikely to have been exposed to the terminology used in the test as evidenced from the lack of its use in the textbooks which is the only teaching material used in schools by both teachers and students. Another important factor contributing to the low scores may have been the children's fear of getting things wrong as many asked during the test "what if I get it wrong?" and "can I draw anything?" despite being repeatedly reassured that nothing they draw is wrong and they are free to draw anything.

Source: Shaheen (2011)

On a positive note, it is interesting to note that there were also a few children who obtained scores as high as 80% and 60%, and therefore this raises further questions of how, despite all children going through same school routine, they are able to perform better and whether teaching for abilities such as originality is solely down to school or there are other influencing factors such as just natural ability, family background, and environment.

The discussion regarding originality has so far focused on the total scores obtained by children; however, a closer examination of the scores for each of the three activities showed that children obtained relatively higher scores for activity two than three as described below.

Examination of the originality scores obtained on each of the three activities showed that for activity one, less than half (42%) of the children ($N = 154$) were able to produce something original. Some examples of these include pictures such as "bird-balloon," "butterfly-spider," and "chicken egg and a baby inside." Less children producing something original can perhaps be attributed to the difficulty of the shape, despite being given 10 min to work on this single drawing as compared to 10 in activity two and 30 in activity three. This highlights the need to give time to develop ideas to produce something original. It may also be attributed to the fact that since it was the first activity in the test, the children may have been nervous, unsure about what to do, and out of their comfort zone since they were not being asked to reproduce something previously learned which is what they are habitually required to do. The pictures drawn by the children for this activity were categorized, and it was found that many things drawn were common everyday objects from the children's surrounding environment, such as names of animals, plants, fruits, and body parts. However, the list used to determine the originality of these responses is not produced based on the Pakistani context which raises the question of the difference it may have made to the originality scores if such a list existed and was used. This is perhaps a limitation of the TTCT list itself for use in different contexts.

For activity 2, almost half (49%) of the children obtained scores within a range of 40–60%, while 20 were able to obtain 80%. There were also nine children who demonstrated (obtained zero scores) no originality. These were from all boys, mixed sex, rural, government, and private schools. Those who achieved full scores (3) (Table 8) were from rural, urban, government, private, all boys, and mixed sex schools. This is interesting since the mean originality score was higher for children from private schools, but the two boys obtaining 100% originality scores were from rural government schools and the girl from mixed sex school. This shows that the variation in originality ability is perhaps not due to school sector but something else, perhaps the individual child.

Source: Shaheen (2011)

The originality scores for activity 3 showed that majority of the children scored lower on this with 125 children obtaining scores between 10% and 40%. Only 22 obtained scores between 50% and 80%, and no child obtained a score beyond 80% (Table 9). This pattern may be explained by the fact that children also performed lower on fluency for activity three which left less figures to be scored for originality and/or that the children drew pictures which were less original. There were also 8 children who obtained zero scores who were almost all from rural, government, and boys' schools which raises questions about the government schools and their current ability to develop children's originality.

Another criterion through which the children's originality was assessed included their ability to join one or more shapes given in the test to complete a picture. This is called the "bonus" scores for originality. Children performed very poorly in this as well. No child obtained any bonus scores for originality for activity 2 which is surprising since children produced combinations of things (the requirement for obtaining bonus scores for originality), using the stimulus in activity one where they were not required to do so.

One of the explanations for this is that they were not provided instructions to do this and following instructions is the core of their teaching. If the children had been told that they could join figures together to make something, it would have been interesting to see the results. For activity three, 92% (154) of the children achieved a zero score, four children obtained 30% ($N = 13$), and two obtained 100% who were from urban private mixed gender schools. This perhaps shows that a coeducation gives a freer environment which is more conducive for enhancing the ability to be original.

In summary, few children obtained bonus scores for originality, over one third of the children produced something original for activity one, whereas the originality scores obtained for activity two were higher than three. This may be because for activity two children had higher fluency scores. Since the shapes in activity 2 are more suggestive than those in activity 3, one would assume that this may restrict children and prevent them from thinking beyond the obvious and rather recall and reproduce things from their existing experiences than making something new. Whereas in activity three where the shapes are less suggestive, one would assume that they provided more freedom for children to let their imagination go wild and come up with weird and wonderful things. But the less suggestive shapes in activity three giving lower fluency and hence originality scores mean that children may have felt more comfortable with the clues in the shapes in activity two than thinking for themselves which is something they are not habitually required to do. This is because it has been observed in classroom teaching that all answers are provided by the teachers in the lessons so children do not have to think for themselves.

The ability to generate ideas and original ideas (fluency and originality) seems to go hand in hand as there is the highest correlation, which can be explained by the fact that the more objects/pictures are drawn, the greater the chance of generating some original ones. It also indicates that creativity in the sense of producing something original is not a short snappy process but one that involves repeated effort (producing many ideas); hence, it could be said that idea generating is a prerequisite to producing original ideas. An important aspect which has emerged from the above discussion is that there appears to be a high correlation between fluency and originality as found in the scores for activity two. This has also been found by other authors such as Torrance himself. Besides this, the children have shown better performance on fluency criteria than the originality criteria which leads onto the next aspect of assessment, the elaboration criteria which assessed the children's ability to elaborate their ideas and produce something which is creative but at the same time valuable without becoming entangled in the information available.

Elaboration Scores

The majority of the children obtained a raw elaboration score in the range of 30–50%, while only 13 obtained a higher score than this. This included one girl who scored 100% (Table 10). She was from a mixed sex urban private school which perhaps suggests that girls may be better at developing and implementing ideas. It is also important to mention that the four children who obtained zero scores were all from rural government schools.

A comparison of elaboration scores across the three activities showed that these were higher for

activities which contained more figures to complete, for example, 48 children obtained 20% for activity one where there was only one stimulus, 52 children obtained 20% for activity 2 where there were 10 figures, but 58 children obtained 60% for activity 3 where there were 30 figures. This perhaps suggests that children perform better if there is more choice for elaboration and more opportunities to exhibit this ability.

In summary, the overall low score on elaboration may be attributed to the fact that children had to work within a limited time which left them less time to add detail to their drawings. However, more importantly, this poor performance shows the children's lack of ability to further develop ideas to produce something creative. Further to producing something creative is the ability to communicate what is produced. In the test, the children were provided an opportunity to exhibit this ability through thinking up abstract titles for their pictures. This required them to synthesize and organize the information they had from their pictures. The children's performance on this criterion (abstractness of title) is discussed next.

Abstractness of Title Scores

The children seemed least able on this measure of creativity as evidenced by 60% being unable to produce any abstract titles. However, the remaining were able to produce the required titles and obtain scores ranging from 10% to 30% (Table 11).

Although the aggregate score for abstractness of title was low, more children had higher score for activity 2 than activity one. This can perhaps be attributed to children having more chances to exhibit this ability in activity 2 because they had more drawings to do than in activity 1. For activity one, 81% of the children failed to score, and only 12 achieved a score of 3, which was the highest obtainable. Those who achieved the maximum score were more boys and from urban private schools. Although the scores for activity two were higher than for activity one, these were still low with the highest being 30% obtained by 3 of the children and 105 obtaining no score who were more from private sector schools than government. These low scores indicate the children's inability to synthesize and organize information and communicate it in a creative way through providing written titles.

Premature Closure Scores

The children's performance on premature closure is better than that on the abstractness of titles although still weak with majority of the children obtaining below 50% scores (Table 7). Only 14 children were able to achieve a score between

60% and 80%. The highest score of 80% was obtained by only two children (Table 12). The low scores can be explained by the fact that children are not required to do such activities, hence, not trained to think this way and cannot do what is being asked. It may also be due to the fact that children are more hesitant to give unusual titles, afraid that they may get them wrong or afraid of the response it may attract. One child wrote “alcohol” (forbidden in Muslim cultures), and when I asked him to tell me what he had written, he whispered this to me.

Resistance to premature closure is about being open enough to be able to make what Torrance called the “mental leap” (2008) which it is claimed makes possible original ideas. The children’s low scores on this criteria again have shown that they have not been able to open up their thinking which would have enabled them to produce something creative which can again be attributed to the rigid and repetitive routine they are expected to follow daily in schools, rote memorize material and regurgitate it.

This completes the primary school children’s performance on the five norm-referenced measures of creativity, and it has been seen from one criterion to the next that most children have not performed well. Nevertheless, it is admirable at the same time that children did demonstrate some performance, more on some criteria and less on others despite being totally new to the test and the test-type activities. In total, their overall performance can be seen through their creativity index score which is discussed next.

Creativity Index

Almost all children showed some creativity as evidenced by their attainment of scores on the creativity index. The majority, 140, achieved scores ranging from 30% to 60% with only seven achieving 70% of the CI score which was the highest obtained (Table 13). In this, there were more boys than girls. All these children were said by the teachers to have creativity, but only one was said to be high academic performing, while the remaining were rated as average in their studies. Children who achieved scores above 50% were children from private, urban, and mixed sex schools.

Intercorrelations Among the Separate Assessments of Creativity

There is a high correlation between the separate elements of creativity and the overall indicator of creativity (creativity index) (Table 14), which is what we may expect considering that each

Identifying and Assessing Creativity, Table 14 Intercorrelations among the separate assessments of creativity, along with correlation of each with the creativity index (Pakistan)

Ability	Creativity criteria				
	Originality	Elaboration	Abstractness of title	Resistance to premature closure	Creativity index
Fluency	0.7	0.5	0.2	0.5	0.7
Originality		0.5	0.2	0.5	0.7
Elaboration			0.4	0.5	0.8
Abstractness of title				0.3	0.6
Resistance to premature closure					0.7

Ability	Creativity criteria				
	Originality	Elaboration	Abstractness of title	Resistance to premature closure	Creativity index
Fluency	0.8	0.25	0.23	0.61	0.73
Originality		0.26	0.28	0.57	0.75
Elaboration			0.48	0.28	0.68
Abstractness of title				0.39	0.67
Resistance to premature closure					0.74

Source: Torrance (2008)

element contributes toward the overall creativity. However, there is variation in the contribution of each element which may indicate that children are stronger on some aspects while weaker on others such as the ability to add abstract titles. However, it could also be that this is due to weakness in the children's writing ability, that is, the ability to express creative thoughts in words, and not the ability to think up abstract titles. Hence, it may be that the method being used to test this creative ability is inhibiting children from exhibiting it because of poor writing ability. It could also simply be that children are not required to do such activities, hence, not trained to think this way and cannot do what is being asked. It may also be due to the fact that children are more hesitant to give unusual titles, afraid that they may get them wrong or afraid of the response it may attract. One child wrote "alcohol" (forbidden in Muslim cultures), and when I asked him to tell me what he had written, he whispered this to me. Similarly, the correlation of this score with other elements is also low, with a common variance of 4–9% indicating its independence and the fact that it may be testing something different.

The ability to generate ideas and original ideas (fluency and originality) seems to go hand in hand as there is the highest correlation, which can be explained by the fact that the more objects/pictures are drawn, the greater the chance of generating some original ones. It also indicates that creativity in the sense of producing something original is not a short snappy process but one that involves repeated effort (producing many ideas); hence, it could be said that idea generating is a prerequisite to producing original ideas. What is interesting from the findings when compared to those of other countries such as the USA (Table 15) is that the correlations are highest for both, which seems to point to the fact that these elements of creativity are common in children across cultures.

The children in Pakistan may be required to be more particular and detailed in their routine school work partly because of the tradition of learning whole chunks of text and reciting it in lessons or regurgitating it in exams, which may explain the high correlation of elaboration with fluency, originality, and closure as compared to the American scores, with a common variation of 16–25%; for American children, this is 4%. This also shows that children with the ability to embellish their work may be more likely to be fluent in their ideas, original, and able to resist the temptation to quickly complete their work in the easiest possible way rather than deeply think about what they are doing. From this, it could be said that children who exhibit one type of creative ability are likely to exhibit a number of others. This therefore indicates that separate elements of creativity may vary in their strengths and weaknesses but are likely to be present to some degree with one affecting the other.

Conclusions and Future Directions

In this chapter, the findings have been presented from the policy documents and the teacher survey regarding assessment of creativity in primary school in Pakistan. Also presented are the primary children's creativity scores as obtained on various criteria of the TTCT.

It has been found that Pakistani obtained low scores on the TTCT measures of creativity. Although in this they may have perhaps been disadvantaged as the TTCT-type activities are not part of their teaching, it is very clear that children are unable to generate, develop, and communicate original ideas, all of which requires them to use their ability to synthesize, organize information, and remain open enough to move beyond the everyday, common way of thinking. These findings raise questions about the extent to which the primary education system in Pakistan is supporting children's creativity. In this, it could be argued that despite the policy provisions and directives for inclusion of creativity into the education system, there are gaps at the implementation level in schools. The children's poor performance on the TTCT has shown that just enabling children to acquire knowledge through rote memorization and regurgitation of these facts is doing little to develop their creativity. These findings call for immediate and radical interventions to develop children's creativity through education if creativity is to be used as a tool for the country's progress and development. Unless this is done and some outcomes emerge, it is very difficult to accept existing claims of creativity being a tool for achieving economic progress and development.

Imagery and Creativity

Barbara Colombo and Alessandro Antonietti
Department of Psychology, Catholic University of the Sacred Heart, Milan, Italy

Synonyms

Imagination; Mental image; Visualization

Key Concepts and Theoretical Background

Mental images – a kind of representation people often employ in everyday life (Antonietti and Colombo 1996–1997) – play a facilitating role in thinking processes as a means of *simulation* and as a means of *symbolization* (Kosslyn 1983).

As simulation cognitive tools, images allow people to anticipate mentally the actual operations and the physical changes and provide an internal representation that keeps an analogical correspondence with the outside world. As symbolization tools, mental images stand for objects or concrete events, which are replaced by conventional signs. In the first case, images are useful because they offer the opportunity to view the mental consequences of the situation that the representation in verbal or abstract terms does not make immediately obvious. In the second case, images help individuals to mentally manipulate the elements of a situation, because mental images require less memory load than other representations, thus prompting at smooth and rapid transformations of the elements.

With more specific reference to creativity, the search for similarities and differences and the identification of links between distant realities – operations which are assumed to be involved in creativity – are facilitated by mental images that are sensitive to structural symmetries and organizations (Shepard 1978). These mental images permit people to modify data so that the changes which are to be produced in reality may be more flexibly stimulated in the mind. Furthermore, mental images allow a person to reorganize the way in which he/she represents a situation, so that it can be reconsidered in a more productive manner. Finally, the mental representation of information in a visual form can help people by providing a pictorial counterpart of abstract concepts, thus allowing individuals to represent simultaneously various elements of a situation so that they can identify the relationships between those elements. Mental images can therefore help the creative process because they are a kind of representation which is particularly flexible, easily convertible and useful to combine multiple elements into a new concept (Antonietti 1991).

Biographical Reports and Experimental Findings

Several autobiographical reports suggest that mental images have significantly contributed to scientific discovery (Shepard 1978). For example, the French mathematician Jacques Hadamard used visual representations when he thought of algebraic problems. Hadamard relied on these mental images especially when problems become too complex, so much so that the visual encoding allowed him to have a simultaneous understanding of all elements of the problem. Another example is Albert Einstein's use of mental images while working on the theory of relativity. Einstein, at the age of 16, imagined himself traveling at the speed of light sitting on the end of a light beam with a mirror in front of him. In this mental image, the observer could not ever see the image of the traveler. The light and the mirror, in fact, were traveling in the same direction and at the same speed, so that the mirror was always a little ahead of the beam and that the traveler could not reach the mirror and could not see his reflection. From this mental image, Einstein concluded that there can be no observer (i.e., nobody) that can reach or exceed the speed of light. Thus, it passed the assumption, shared by physicists afterward, that an object could achieve any speed, given a sufficient enough acceleration, and hence, the way for the subsequent theory of relativity was opened. A final example is that of Nikola Tesla, who used mental images in the process of inventing neon lights and self-starting engines. He, in fact, used to develop images of mechanical models that ran in his mind for several weeks in order to determine which parts were subject to premature wear.

These autobiographical anecdotes are confirmed by research (Roskos-Ewoldsen et al. 1992). In adults, high correlations have been found between the use and control of mental images and divergent thinking, ideational fluency, and ability to rebuild squares from cuts (a task which is assumed to be associated to the creative manipulations of the given elements). Furthermore, it was found that originality in thinking is associated with the tendency to process complex mental images. Finally, the ability to compose mental images is related to creativity too: Finke (1990) showed that the synthesis of mental images is particularly effective in inspiring original objects that can be used in everyday life.

Not only transformation of mental images but also a static feature, that is, vividness, has some functional significance, especially in situations of intellectual impairment, as suggested by some studies on so-called idiot savants. Research by Selfe (1983) indicated that children with autism and mental retardation with strong artistic skills possess high visual abilities: they use photographically realistic proportions more than normal children for the representation of three-dimensional space as well as the size, distance, and occlusion of overlapping objects. For idiot savants, mental images are one of the forms of representation which they use to perform intellectual operations which majority of people cannot perform (Treffert 2000).

Positive correlations between imagery vividness and divergent thinking skills have been reported, whereas no correlation between vividness and flexibility of thought was found. However, the ability to form vivid mental images is a skill which is separate from the ability to transform images. Kosslyn (1983) supported the componential nature of imagery by showing that at 5 years it is possible to distinguish four distinct types of imagery skills: image generation, maintenance, inspection (scanning), and rotation. The distinctiveness of these skills is supported by research showing that the vividness of the mental image, the main feature in the generation and maintenance of mental images, is not correlated with visual-spatial ability measured by tests based on the rotation and the synthesis of figures.

Implications for Practice

Eckhoff and Urbach (2008) maintained that imagery is crucial for educators to promote creative thinking in informal and formal learning environments. Imagery promoted creative language skills linked to poetry writing. The spontaneous use of imagery in preschool playing behavior was predictive of creative skills in older children and adults. The link between imagery and creativity also appeared to be in the opposite direction: creativity induced a more frequent and complex use of mental imagery.

These findings support the attempts to enhance creativity by means of training activities based on imagery. This can be achieved both by devising structured educational programs aimed at improving mental visualization skills and at addressing such skills to the accomplishment of creative task (Mc Kim 1980) and by inducing people to develop the spontaneous tendency to rely on mental images when creativity is needed in everyday-life situations (Shone 1984).

Western culture has generally underestimated the power of visual thinking. In many theories, both philosophical and psychological, images are considered preparatory or auxiliary forms of thinking, which play the role of substitutes of more sophisticated forms, such as logical, verbal, or mathematical thinking. Imagery is viewed either as a set of cognitive representations and strategies that precedes the development of nonvisual ways of reasoning (a sort of “springboard” for abstract thinking) or as a sort of “crutch” which abstract thinking relies on when one is in trouble (e.g., when he/she needs to explain a concept to a person for whom it is difficult to follow logical arguments).

In other cultures, however, is not so. For example, in certain nomadic tribes, shepherds are aware of the lack of some sheep in the herd, not counting the animals one by one but through a simple “look” thrown to the flock: a function that Western schools have accustomed pupils to play through a mathematical procedure is here performed through an intuitive and fast visual process. This explains why in some cultures children’s games also insist on the development of capacities of the latter type. For example, in some parts of Africa, a childhood favorite play is to build piles of stones and then determine their number simply by looking at them: the child who approached more to the exact number of stones piled up won the game. Imagery strategies are used also for solving complex problems. For example, for the inhabitants of the Polynesian islands, orientation in navigation is established by means of a spatial mental model, rather than through a complex system of calculations.

There are populations who pay very special attention to images, in particular to images that occur while dreaming. Reporting and processing dreams are an important part of youth education in some tribes of Central Malaysia. Every morning, children and adults talk about the dreams of the night. The aim is to help those who have made a dream in which negative elements (fear, death, and so forth) occurred to take advantage of these experiences to turn them, in reality, toward positive goals. In fact, who told the dream that was later the subject of the discussion within the tribe is invited to dream it again differently during the day. From this second dream, the individual has to come back with something creative that could be communicated to others so to accomplish an action, an inspiration for a piece of art (a poem, a song, a dance, a sculpture, a story), or the solution of a problem. For example, a child has dreamed of meeting a scorpion on the path and escaping from it. The child is then asked to revise the dream during the day. After several attempts, the child communicates to the elders of the tribe that he reached the desired outcome: In his mind, he saw the scorpion that blocked the passage; he went to call his older brother, who took the scorpion by the tail and let the path free.

Educational practices in various Eastern cultures make use of imagery as a technique to help one to overcome emotional or relational problems creatively. This is an example. There was a famous wrestler called O-nami (literally, Great Waves). He was the strongest, but when he had to compete in front of an audience, his shyness made him weak enough to be defeated by the worst of his colleagues. O-nami was entrusted to the wisdom of his Zen master, who thought to solve the problem in this way: “Your name is Great Waves – he said – So, next night you will stay in the temple and you will imagine to be those waves, those huge waves that destroy anything they meet in front of them. Do so and you will be the greatest wrestler in the country.” O-nami meditated the next night: He was no longer the fighter, but he imagined to be a great wave. In the morning, O-nami participated in the wrestling contests and won.

From all the suggestions reported above, it is clear that visual mental images can be highly effective to inspire insights and original ideas to be applied in everyday life, and as a consequence, people should be trained to use visualization creatively.

Conclusions and Future Directions

Training procedures and operational guidelines are extremely useful to strengthen both imagery skills per se and to improve their use to foster creative thinking. Few experimental studies have been carried out to assess the capacity of the imagery training to increase creativity. However, existing research data indicate that it is possible to improve the flexibility with which people perform mental figural synthesis and originality of the products that are generated in this way. In fact, with regard to the imaginative strategies followed, the comparison between pre- and posttraining showed that experimental groups had test-retest differences which reflect and increased mobility and transformation of mental images in comparison to control groups. Overall, data suggested that imagery training induces a greater dynamism for imaginative synthesis. One may conclude that the repeated exercise of the combination of images, far from generating repetition and mechanical executions, can stimulate new and more creative solutions, supported by enhanced flexibility in the processing of figures.

Imagination: A Cognitive Science Approach

The term "imagination" is used in two general senses. The first is synonymous with "creativity." The second sense, and the one that will be explored in this entry, refers to the ability to create and experience virtual situations in the mind that are independent of sensory input. For example, a person might picture what a new sofa would look like in her living room, dream of walking through a jungle, or entertain a hypothetical situation in which the Renaissance never happened.

Our imaginative abilities have given our species a great evolutionary advantage. In the Upper Paleolithic, humans were able to produce tools days before using them, created dwellings designed for lengthy occupation, and made stylized tools, cave paintings, and burial practices. All of these practices seem to require imagination, typically imagining possible futures. Harris (2000, pp. ix–xi) suggests that this might have been key to the success of our species, particularly in competition with the Neanderthals, who, lacking these behaviors, were likely to have lacked imaginative abilities.

Imagination can be roughly grouped into two kinds: sensory and suppositional (Goldman 2006). Sensory imagination refers to internally generated sensory-like imagery in the head, such as picturing a tree, hearing a voice or music in your head, or imagining the smell of cinnamon. Sensory imagination can be completely internal, as when dreaming, which is a kind of natural virtual reality. Imagination can also occur in the presence of normal perception, such as when, with one's eyes open, one imagines a new color on a wall. In these instances, imagination works as a kind of augmented reality. Though not related to the senses, motor and emotional imagery is often included in this category, such as imagining running or being happy (Markman et al. 2009, Chapter 18). Sensory imagination uses the same parts of the brain as perception (Kosslyn 1994), just as motor imagery uses the same brain areas as action (Markman et al. 2009, Chapter 2). As such, imagery can interfere with perception (Kosslyn 1994). For example, if you are trying to see something while you are vividly imagining something else, your perception will be compromised.

Sensory imagination also goes by the name of "mental imagery" and has received a great deal of scientific investigation, particularly for visual imagery.

There are two hypothesized formats that can represent visual information. The first, descriptive representations (Kosslyn 1994), are sentence-like statements, such as “ocelot in tree.” The second format, depictive representations, represents visual things at the level of points of color at particular locations. In computer graphics, this is known as a “bitmap.” In a bitmap, there is no explicitly represented content. To know that an ocelot (a South American wild cat) is in the picture, perceptual processes would need to be applied to the bitmap. In the descriptive representation, by contrast, the existence of the ocelot is explicit, as the symbol representing an ocelot would be present in the description.

The theory of visual mental imagery (which is somewhat controversial) holds that the human brain represents visual memories as descriptions but can transform those descriptions into depictions (called enactment-imagination, or e-imagination by Goldman 2006). Although the processes that do this are still poorly understood, the end result is theorized to be an activation pattern in the spatially organized neurons in the visual cortex (Kosslyn 1994).

It is generally assumed that perceptual reinterpretation is the function of visual mental imagery. For example, when asked how many chairs one has in one’s house, one typically will need to visualize a walk-through and count the chairs imagined to eventually arrive at an answer. After doing this once, however, the number of chairs in the house is stored as a descriptive memory and might be retrieved in the future without needing to use mental imagery and counting. Studies supporting this theory show that the same areas of the brain used for visual perception are used when generating mental imagery. However, behavioral evidence for people’s ability to use mental imagery for reperception has been inconsistent.

Although psychologists have studied how people can perceive and manipulate mental images and their effects on sport performance and depression, there has been relatively little work on how these images are generated and composed from descriptive long-term memories. Open questions include the following: What determines the relative amount of confabulation and memory retrieval in recollection? Does a mental image require refreshing from long-term memory? Is the answer different if the image is rotating? When imagining a new scene, such as a playground, how does the mind determine when to stop adding objects to the imagined scene? How do we keep from believing the things we imagine (e.g., if we imagine we can fly, how do our minds keep track of what is imagined and what is real)? How do causal mental models interact with visual memory for mental simulation and planning? When one imagines oneself doing something, when do they take a first-person point of view (in which it appears as it would if they were doing it), and when do they take a third-person point of view (as it might appear in a video)?

Suppositional imagination need not have any sensory element. It is pretense, or the hypothetical entertaining of counterfactuals (Markman et al. 2009, section III). For example, one might imagine the stock market crashing, how someone feels (also known as empathy, using theory of mind, or affective forecast), what the world would have been in like if President Kennedy had not been assassinated, or that one owned a pet ocelot.

Many real-world instances of imagination involve both sensorimotor and suppositional elements. This kind of imagination is studied with different subfield labels. “Mental modeling” studies the working internal representations people have and create to understand systems such as calculators and written descriptions. It has important implications for educational and interface design. “Chronesthesia” is mental time travel, that is, imagining the past (called recollection, retrodiction, or retrospection) or the future (called episodic future thought, forecast, or prospection). “Mental simulation” is a person’s sensory imagery informed by nonsensory understanding of systems, such as physical restraints. One might use mental simulation to decide if a sofa could fit through a given door. Mental simulation in a scholarly context is often called “thought experimentation.” “Pretend play” is treating objects as though they are something else, as when children use stones and sticks to represent teacups and people or when they have imaginary companions (Markman et al. 2009, Chapter 14; Harris 2000).

More familiar phenomena such as planning, dreaming, daydreaming, and fantasizing are subjects of study that also use both sensory and suppositional imagination.

Imagination is also studied with an eye toward how it can affect performance, memory, and mental outlook. Imagining doing something before you do it facilitates performance. Mental practice has been found to be helpful for over 20 sports, including pure muscle strengthening. Use of imagination can alter stereotypes (Markman et al. 2009, Chapter 3).

When we remember things that have happened to us, although it feels sometimes that we are recalling a veridical representation of what happened, it is actually an imaginative reconstruction based on a few accurately remembered elements. In fact, every time we remember an incident, we subtly change the memory itself. This benefit of imagination is also a drawback, as we sometimes remember our imaginings as real events. This happens not only upon recall of actual memories but when asked to imagine a completely new episode. There is a large literature describing this "false memory" effect (Garry et al. 1996).

Another drawback is that when planning for the future, one of the major uses of imagination, people tend to underestimate task-completion times (Buehler et al. 1997). This is, in part, because when imagining another situation, perhaps in another time (e.g., the future) or place (e.g., California), we imagine the only difference being the one under consideration or the most salient feature. For example, people will mistakenly believe they would be happier living in California when the good weather is the most salient difference with where they are currently living (Schkade and Kahneman 1998) and will fail to imagine unforeseen but inevitable difficulties that interfere with plans in the future (Lam et al. 2005).

Computer scientists have done work to automate imaginative abilities with computer programs (Ebert et al. 2002). Although most computer graphics are created by human designers, scientists in the graphics and artificial intelligence fields have made programs that imagine visual scenes. This work is referred to as synthesis, procedural synthesis, dynamic generation, procedural modeling, and visualization. Some programs create plants, others faces, mountains, planets, or cities. They have applications for the automatic creation of virtual environments and characters for art, entertainment (e.g., movies or computer games), and training.

Of the variety of methods that these computer systems use, I will describe grammars, fractals, and explicit knowledge.

A grammar is a set of rules that describe acceptable expressions. In language, a successful grammar will generate only grammatical sentences in a language. In procedural modeling of a city, the grammar would consist of rules describing, for example, what buildings can go next to others and what kinds of windows would appear on which buildings. In music, a grammar might describe what notes are allowed to follow other notes.

Fractals are shapes that are self-similar at different scales. For example, rivers often have a fractal structure, where the small branches upstream resemble the larger branching structures downstream. Fractals are particularly useful for describing natural scenes such as plants and mountains, as fractal geometry often appears in nature. In general, fractal geometry appears whenever a system needs to maximize the area of something in a finite space.

The benefit of grammatical and fractal descriptions is that they can generate many combinations of acceptable outputs with a relatively small description. The downside is that it is difficult for them to take larger context and common sense into effect.

Finally, procedural modeling can be done with explicitly encoded knowledge. For example, to describe a building, the knowledge base might have representations indicating that all rooms must have doors and that ceilings need to be higher than six feet tall. The system can then generate new buildings that satisfy the constraints in the knowledge base. The downside of this is that the knowledge takes a great deal of time and effort to put into the system. In particular, large knowledge bases are prone to contradicting themselves and become unwieldy.

Conclusion and Future Directions

We know little of how human minds decide what goes into an imagined scene (with the exception of the mental modeling literature) and how these things are transformed into mental imagery. Computer scientists have developed methods for automating the generation of scene descriptions as well as their visual rendering.

We know a fair bit about the nature of mental images in people, what we can and cannot do with them (e.g., rotation, reperception), and how they affect our mental states, creative processes, and performance.

However, as a scholarly discipline, imagination is fragmented by methodology (e.g., philosophical argumentation, psychological experimentation, and computer science program implementation) and phenomena of interest. In the future, interdisciplinary cross talk should shed light on the unexplored areas of this important topic.

Introduction

Creativity is a gifted ability of humans in thinking, inference, problem solving, and product development (Beveridge 1957; Csikszentmihalyi 1996; Holland et al. 1986; Matlin 1998; Smith 1995; Sternberg and Lubart 1995; Wang et al. 2006; Wilson and Keil 1999). A creation is a new and unusual relation between two or more objects that generates a novel and meaningful concept, solution, method, explanation, or product. Creativity has been perceived diversely and, sometime, controversially in psychology, intelligence science, knowledge science, and cognitive science (Csikszentmihalyi 1996; Guiford 1967; Leahey 1997; Mednich and Mednich 1967; Matlin 1998; Sternberg and Lubart 1995; Wallas 1926; Wang et al. 2009a, b). Creativity may be treated as a form of art that generates unexpected results by unexpected paths and means. It may also be modeled as a scientific phenomenon that generates unexpected results by purposeful pursuits. Matlin in 1998 perceived that creativity is a special case of problem solving (Matlin 1998). From this perspective, he defined creativity as a process to find a solution that is both novel and useful. However, problem solving often deals with issues for a certain goal with unknown paths. Therefore, creation is much more divergent than problem solving, which deals with issues of both unknown goals and unknown paths for a problem under study.

Human creativity may be classified into three categories known as the abstract, concrete, and art creativities. A scientific (abstract) creation is usually characterized by a free and unlimited creative environment where the goals and paths for such a creation is totally free and unlimited, while an engineering (concrete) creation is characterized by a limited creative environment where a creative problem solving is constructed by a certain set of goals, paths, and available conditions. The third form of creation is the art (empirical) creation that generates a novel artifact in order to attract human sensorial attention and perceptual satisfactory.

This entry formally investigates into the cognitive mechanisms of creation and creativity as one of the most fantastic life functions. The cognitive foundations of creativity are explored in order to explain the space of creativity, the approaches to creativity, the relationship between creation and problem solving, and the common attributes of inventors. A set of mathematical models of creation and creativity is established based on the cognitive properties of human knowledge.

Cognitive Foundations of Creativity

Human creativity as a gifted ability is an intelligent driving force that brings something into existence.

Definition 1. *Creativity* is the intellectual ability to make creations, inventions, and discoveries that brings novel relations, entities, and/or unexpected solutions into existence.

Definition 2. A *creation* is a cognitive process of the brain at the higher cognitive layer that discovers a new relation between objects, attributes, concepts, phenomena, and events, which is original, proven true, and useful.

Taxonomy of Creations

Various creativities and creation processes may be identified such as free/constrained creativity, analytic/synthetic creativity, inference-based creativity, problem-solving-based creativity, and scientific/technological/art creativity. The entire set of creativities can be classified into three categories according to their creation spaces, approaches, and problem domains as summarized in Table 1.

It is conventionally perceived that creations and discoveries are usually concrete and tangible. However, more creations and discoveries are abstract or intangible, such as new languages, theories, methods, and doctrines. Therefore, it is noteworthy that a much larger portion of human cognition information is abstract knowledge and wisdom beyond the base-level concrete knowledge about the physical world in the knowledge hierarchy (Wang 2009d). The abstract creations

In Search of Cognitive Foundations of Creativity, Table 1 Taxonomy of creativity and creation

No.	Category	Type of creation	Description	Reference
1	Creation space	Free	A creation process with an unlimited creation space S_c, which is determined by unconstrained sets of alternatives N_a, paths N_p, and goals N_g	Def. 4
2	Creation space	Constrained	A creation process with a limited creation space S_c' where one or more conditions such as the goals N_g', paths N_p', or alternatives N_a', are limited	Def. 5
3	Approach	Analytic	A top-down creation process that discovers a novel solution to a given problem by deducing it to the subproblem level where new or existing solutions may be found	Def. 7
4	Approach	Synthetic	A bottom-up creation process that discovers a novel solution to a given problem by inducting it to a superproblem where new or existing solutions may be found	Def. 8
5	Approach	Inference-based	An abstract creativity based on the deductive, inductive, abductive, and analogy inference methodologies	Def. 9
6	Approach	Problem-solving-based	A novel solution for a given problem by creative goals and/or creative paths	Fig. 1
7	Domain	Scientific (abstract)	A free and unlimited creative environment where the goals and paths for such a creation is totally free and unlimited	Section "Introduction"
8	Domain	Technological (concrete)	A limited creative environment where a creative problem solving is constructed by a certain set of goals, paths, and available conditions	Section "Introduction"
9	Domain	Art (empirical)	A free and unlimited creative environment where a novel artifact is generated that attracts human sensorial attention and perceptual satisfactory	Section "Introduction"

and discoveries are formed as a result of human intelligence by creatively mathematical, logical, and causal reasoning.

The Space of Creativity

Definition 3. A *creation space* Θ is a Cartesian product of a nonempty set of baseline *alternatives* A, a nonempty set of *paths* P, and a nonempty set of *goals* G, i.e.,

$$\Theta \triangleq A \times P \times G \tag{1}$$

where $\times$ represents a Cartesian product.
On the basis of the creation space, the nature of free and constrained creativities can be explained.

Definition 4. A *free creativity* is a creation process with an unlimited creation space S_c, $S_c \subseteq \Theta$, which is determined by unconstrained sets of alternatives N_a, paths N_p, and goals N_g, i.e.,

$$\begin{aligned} S_c &\triangleq N_a \bullet N_p \bullet N_g \\ &= |A| \bullet |P| \bullet |G| \end{aligned} \tag{2}$$

Equation 2 indicates that the creative space of a free creation may very easily turn to be infinitive, because N_a, N_p, and N_g can be extremely large. Therefore, the cost or difficulty of creation is often extremely high. That is, only mechanical and exhaustive search is insufficient for potential creations and discoveries in most cases, if it is not directed by heuristic and intelligent vision. In other words, creations and discoveries are usually achieved only by chance of purposeful endeavors of prepared minds, where an appreciation of highly unexpected result is always prepared. This is also in line with the empirical finding of Pasteur as stated that "Creation always favorites prepared minds (Beveridge 1957)."

Definition 5. A *constrained creativity* is a creation process with a limited creation space S'_c, $S'_c \subseteq S_c \subseteq \Theta$, where one or more conditions such as the goals N'_g, paths N'_p, or alternatives N'_a, are limited, i.e.,

$$S'_c \triangleq N'_a \bullet N'_p \bullet N'_g = |A'| \bullet |P'| \bullet |G'|,\ A' \subset A \wedge P' \subset P \wedge G' \subset G \quad (3)$$

Usually, a scientific and art creation is characterized as a free creation process, while an engineering creation is featured as a constrained creation process.

Approaches to Creativity

A variety of typical approaches to creation have been identified in literature, such as divergent production (Guiford 1967), remote association test (Mednich and Mednich 1967), analysis/synthesis (Wang et al. 2006), and inferences (Wang 2007c). Wallas identified five stages in a creative process (Wallas 1926) as follows: (1) *preparation*, (2) *incubation*, (3) *insight*, (4) *evaluation*, and (5) *elaboration*. Csikszentmihalyi pointed out that creativity can best be understood as a confluence of three factors: a *domain* that consists of a set of rules and practices; an *individual* who makes a novel variation in the contents of the domain; and a *field* that consists of experts who act as gatekeepers to the domain, and decide which novel variation is worth adding to it (Csikszentmihalyi 1996).

The approaches to creativity can be categorized into three categories known as the analytic, synthetic, and inference approaches.

Definition 6. The *analytic creativity* is a top-down creation process that discovers a novel solution to a given problem by deducing it to the subproblem level where new or existing solutions may be found.

Definition 7. The *synthetic creativity* is a bottom-up creation process that discovers a novel solution to a given problem by inducting it to a superproblem where common or general solutions may be found.

Definition 8. The *inference creativity* is an abstract creation process based on the deductive, inductive, abductive, and analogy inference methodologies.

Wallas (1926), Beveridge (1957), and Smith (1995) pointed out an important phenomenon in human creativity known as *incubation*.

Definition 9. *Incubation* is a mental phenomenon that a breakthrough in creation and problem solving may not be achieved in continuous and intensive thinking and inference until an interrupt or interleave action is conducting in a relax atmosphere.

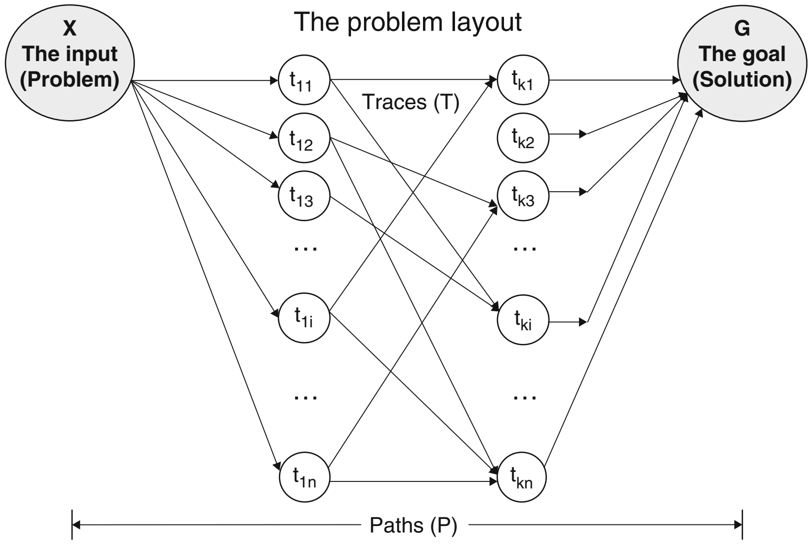
Incubation is often a necessary process in the middle of creation and discovery. The cognitive mechanism of incubation can be explained by the subconscious processes of the brain (Wang2012d) related to thinking and inference, such as perception, imagination, and unintentional search, which are involved in complex thinking and long chains of inferences. Whenever there is an impasse, incubation may often lead to a creation under the effect of active subconscious processes. Incubation has been observed playing an active role in the creation process by researchers.

As creativity is a novel or unexpected solution to a given problem, a creation may be perceived as a special novel solution in problem solving where the problem, goal, or path is usually unknown. Therefore, the study on creativity can analogue to the theory of problem solving (Wang and Chiew 2010). The solutions S and paths P in problem solving can be illustrated in Fig. 1.

In the layout of Fig. 1, a creation is a search for the unknown goals, unknown paths, or both under a given problem or a set of coherent problems. Therefore, creations can be classified into the categories of goal-driven, method-driven, and problem-driven. Among them, the problem-driven creation is a full open process because both goals and paths are unknown for the given problem.

Formal Models of Creation and Creativity

On the basis of the discussions on the cognitive foundations of creativity, a more rigorous



In Search of Cognitive Foundations of Creativity, Fig. 1 The layout of the solution space in problem solving

treatment of it can be developed in this section on the mathematical models of creation and creativity.

The Tree Structure of Human Knowledge

It has been empirically observed that the tree-like architecture is a universal hierarchical prototype of systems across disciplines of not only science and engineering but also sociology and living systems. The underlying reasons that force systems to take hierarchical tree structures are as follows: (a) the complexity of an unstructured system can easily grow out of control, (b) the efficiency of an unstructured system can be very low, and (c) the gain of system by coordination may diminish when the overhead for doing so is too high in unstructured systems.

An ideal structural form for modeling a knowledge system and the creation space of humans is known as the complete tree (Wang 2007a).

Definition 10. A *complete n-nary tree* $T_c(n, N)$ is a normalized tree with N nodes in which each node of T_c can have at most n children, each level k of T_c from top-down can have at most n^k nodes, and all levels have allocated the maximum number of possible nodes, except only those on the rightmost subtrees and leaves.

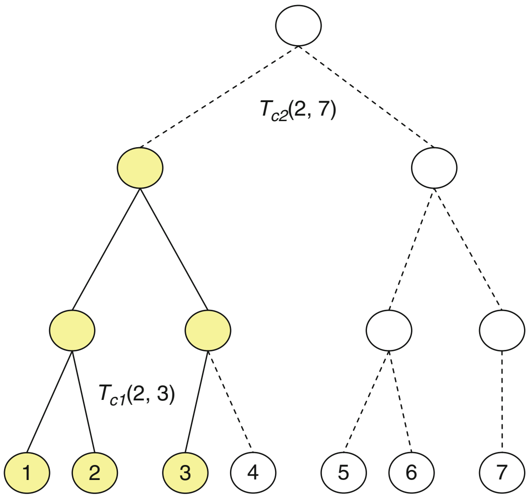
It is noteworthy in Definition 10, a tree said to be *complete* means that all levels of the tree have been allocated the maximum number of possible nodes except those at the leave level and the rightmost subtress. The advantage of complete trees is that the configuration of any complete n-nary tree $T_c(n, N)$ is uniquely determined by only two attributes: the unified *fan-out* n and the number of leave nodes N at the bottom level. For instance, the growth of a system from complete tree $T_{c1}(n_1, N_1) = T_{c1}(2, 3)$ to $T_{c2}(n_2, N_2) = T_{c1}(2, 7)$ is illustrated in Fig. 2.

Theorem 1. The *generic topology of normalized systems* states that systems tend to be normalized into a hierarchical structure in the form of a complete n-nary tree.

Systems are forced to be with tree-like structures in order to maintain equilibrium, evolvability, and optimal predictability. The advantages of the hierarchical tree structure can be formally described in the following corollary.

Corollary 1. *Advantages of the normalized tree* architecture of systems are as follows:

(a) *Equilibrium*: Looking down from any node at a level of the system tree, except at the leave level, the structural property of fan-out or the



In Search of Cognitive Foundations of Creativity, Fig. 2 The growth of a complete tree of hierarchical systems

number of coordinated components are the same and evenly distributed.

(b) *Evolvablility*: A normalized system does not need to change the existing structure for future growth.

(c) *Optimal predictability*: There is an optimal approach to create a unique system structure $T_c(n, N)$ only determined by the attributes of the unified fan-out n and the number of leave nodes N at the bottom level.

Based on the model of the complete tree, the topology of the knowledge space for creation can be denoted as a concept tree with each node of the n-nary complete tree as a concept.

Definition 11. A *concept tree*, $CT(n, N)$, is an n-nary complete tree in which all leave nodes N represent a *meta-concept*, and other nodes beyond the leave level represent *superconcepts*.

For instance, a ternary CT, $CT(n, N) = CT(3, 24)$, is shown in Fig. 3. Since the CT is a complete tree, when the leaves (components) do not reach the maximum possible numbers, the right most leaves and subtrees of the CT will remain open.

A set of useful topological properties of CT is identified as summarized in (Wang 2007a). CT can be used to model and analyze the knowledge space of creativity. It also shows that a well-organized knowledge tree in the brain is helpful for creation, because it can greatly reduce the cost and complexity for search.

Measurement of Creativity

On the basis of CT, the extent of creativity can be quantitatively analyzed by the relational distances between two or more concepts in the concept tree as shown in Fig. 3.

Definition 12. The *relational distance* of a creation, δ, is a sum of the distances δ_1 and δ_2 of a pair of concepts or objects c_1 and c_2 to their closest parent node c_p in a given concept tree CT, i.e.,

$$\begin{aligned}\delta(c_1, c_2) &\triangleq \delta_1 + \delta_2 \\ &= |c_1 \leftrightarrow c_p| + |c_2 \leftrightarrow c_p|\end{aligned} \tag{4}$$

where $\delta_i = |c_i \leftrightarrow c_p|$ denotes the distance between a concept c_i and its most closed parent concept c_p shared with the other given concept.

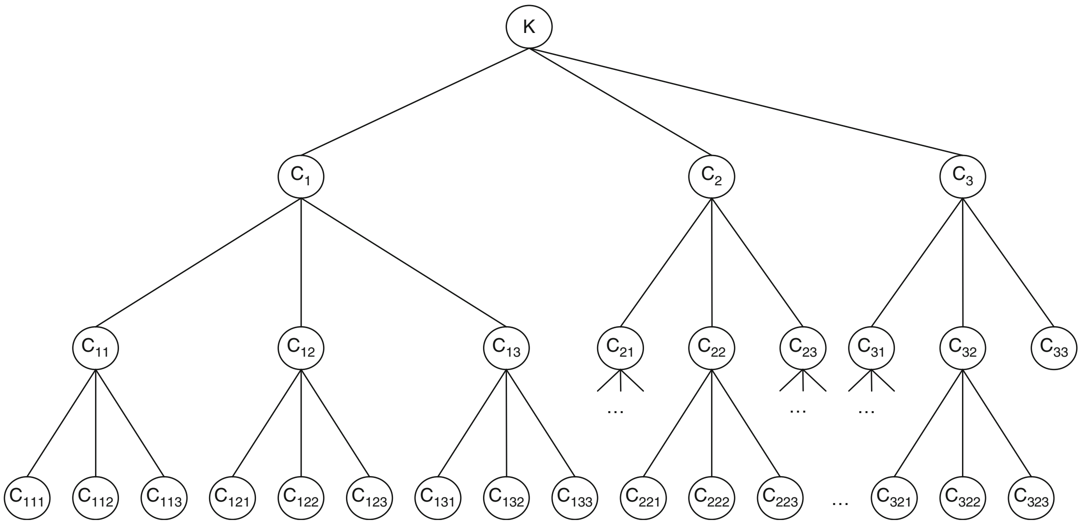
According to Definition 12, the minimum creation distance $\delta_{\min}(c_1, c_2) = 2$ when any pair of concepts at the same level of the CT under the same parent node.

Definition 12 can be extended to a more general case where multiple concepts are involved in a creation based on a given CT as follows.

Definition 13. The *general relational distance* of a creation, δ, is a sum of $n, n > 1$, subdistances δ_i, $1 \leq i \leq n$, between all individual concepts c_i and the closest parent node c_p in the given knowledge space modeled by a CT, i.e.,

$$\begin{aligned}\delta &\triangleq \sum_{i=1}^{n} \delta_i \\ &= \sum_{i=1}^{n} |c_i \leftrightarrow c_p|\end{aligned} \tag{5}$$

Example 1. Given a knowledge space modeled by a CT as shown in Fig. 3, any potential pairwise



In Search of Cognitive Foundations of Creativity, Fig. 3 A ternary concept tree $CT(3, 24)$

or multiple creation distances can be determined according to Definition 13 as follows:

$$
\begin{aligned}
\delta(c_{111}, c_{113}) &= |c_{111} \leftrightarrow c_{11}| + |c_{113} \leftrightarrow c_{11}| \\
&= 1 + 1 = 2 \\
\delta(c_{121}, c_{323}) &= 3 + 3 = 6 \\
\delta(c_{111}, c_{113}, c_{121}, c_{323}) &= 3 + (3 - 2) + (3 - 1) \\
&\quad + 3 = 9
\end{aligned}
\tag{6}
$$

It is noteworthy that the creativity of a creation is proportional not only to its relational distance but also to its originality and usefulness.

Definition 14. Assume $O = \{0, 1\}$ is a Boolean evaluation for the false or true originality of a creation, M the total number of nodes at level k out of the d level creation space for a given CT. Then, the extent of *creativity* C is a product of the creation distance δ, the size of the creation space M, and its originality O, i.e.,

$$
\begin{aligned}
C &\triangleq (\delta \bullet M) \bullet O \\
&= \delta O \bullet \sum_{i=0}^{d-k} n^i
\end{aligned}
\tag{7}
$$

where n is the fan-out of the given CT.

Example 2. Based on the three solutions as given in Example 1, assume their originalities $O_1 = O_2 = O_3 = 1$, then the creativities of the three solutions can be quantitatively evaluated as follows:

$$
\begin{aligned}
C_1 &= \delta_1 O_1 \bullet \sum_{i=0}^{d-k_1} n^i = 2 \bullet 1 \bullet \sum_{i=0}^{3-2} n^i = 2 \bullet (1+3) = 8 \\
C_2 &= \delta_2 O_2 \bullet \sum_{i=0}^{3-1} n^i = 6 \bullet (1+3+9) = 78 \\
C_3 &= \delta_3 O_3 \bullet \sum_{i=0}^{3-0} n^i = 9 \bullet (1+3+9+27) = 360
\end{aligned}
\tag{8}
$$

Obviously, Case 3 represents the greatest creativity among the three cases.

Corollary 2. The creativity of a creation is proportional to the product of the creative distance and the size of the creation space, subject to a satisfactory originality.

Corollary 3. The larger the size of the creation space, the greater the chance for the generation of a creation.

Further elaborations of Corollary 3 will be discussed on the relationship between the creation space and knowledge properties in the following section.

Knowledge Science Foundations of Creativity

On the basis of Corollary 3, it is recognized that the knowledge spaces and capacities of individuals may significantly influence the chance of one's creativity. According to the object-attribute-relation (OAR) model (Wang 2007d) of the internal knowledge representation in the brain, knowledge of an individual can be modeled as a concept network, which is configured by a set of concepts and their semantic relations (Wang 2007d, 2008b).

Definition 15. The *knowledge space K* of an individual is proportional to both the number of concepts, n, and the number of their pairwise relations in one's long-term memory (LTM), i.e.,

$$K = C_n^2 = \frac{n!}{2!(n-2)!} \tag{9}$$

where higher-order relations among concepts can be reduced into multiple pairwise relations.

A fundamental question in knowledge science is to what extent the differences of knowledge spaces could be among individuals. This question can be modeled by contrasting an expert with coherently m disciplinary knowledge K_Σ and those of m experts with separated single disciplinary knowledge K_m. A quantitative analysis of this problem, i.e., K_Σ vs. K_m, is formally described in the following principle.

Theorem 2. *The power of multidisciplinary knowledge* states that the *ratio of knowledge space* r_Σ between the knowledge of an expert with coherently m disciplinary knowledge K_Σ and that of a group of m experts with separated single disciplinary knowledge K_m is:

$$r_\Sigma(m,n) = \frac{K_\Sigma}{K_m} = \frac{C^2_{m\bullet n}}{\sum_{i=1}^{m} C_n^2} = \frac{\frac{(mn)!}{2!(mn-2)!}}{\frac{m(n)!}{2!(n-2)!}} \approx \frac{(mn)^2}{mn^2} = m \tag{10}$$

where n is the number of *average knowledge objects* (or concepts) in the discourses of multiple disciplines.

Theorem 2 indicates that the difference of knowledge spaces in term of the ratio, K_Σ vs. K_m, is m. In other words, an expert with coherently m disciplinary knowledge has a knowledge space that is m times greater than the sum of the group of m experts with separated single disciplinary knowledge. Based on Theorem 2, a new question may be raised as follows: What is the difference between the knowledge spaces of the m disciplinary expert, K_Σ, and that of an individual, K_1, from the group K_m? This problem can be reduced to one that seeks K_Σ vs. K_1 as stated in the following corollary.

Corollary 4. The *first property of knowledge* is that the *ratio of knowledge space* r_1 between the knowledge of an expert with coherently m disciplinary knowledge K_Σ and that of an expert with single disciplinary knowledge K_1 is:

$$r_1(m,n) = \frac{K_\Sigma}{K_1} = \frac{C^2_{m\bullet n}}{C_n^2} \approx \frac{(mn)^2}{n^2} = m^2 \tag{11}$$

Corollary 5. *The second property of knowledge* is that the more the interdisciplinary knowledge one acquires, the larger the knowledge space, and hence the higher the possibility for creation and invention.

Corollary 5 provides a rational explanation for another fundamental question in knowledge science: Which is more important in knowledge acquisition if there is a need to choose the preference from broadness and depth for an individual's knowledge structure? According to Definition 15, Theorem 2, and Corollaries 4 and 5, a rigorous answer to this question can be formally expressed in the following corollary.

Corollary 6. *The third property of knowledge* is that, in knowledge acquisition toward creativity and naval problem solving, broadness is more important than depth in one's knowledge structure.

The above corollary can be proven by Eqs. 10 and 11 as provided in Theorem 2 and Corollary 4, which is perfectly in line with the philosophy of holism. Corollary 6 also explains why most interesting problems in research are often at the edges of conventional disciplines. Therefore, the maintenance of a global and holistic view is one of the fundamental insights of scientific creation and knowledge development.

Analyzing the complexities and speeds of knowledge creation and acquisition, it is noteworthy that, on one hand, the creation of new knowledge requires tremendous time, effort, and ingenuity. However, on the other hand, learning and acquisition of such knowledge are relatively easy, fast, and only need normal intellectual ability. For example, the development of mathematics from arithmetic to calculus had to go through several centuries. However, all undergraduate students can learn and use all of them in the first year of university studies. In another instance, the digital computers have been created and developed as a result of over 60-year effort. However, digital computer architectures and principles can be understood and learnt by students and practitioners with a few months training. These phenomena in knowledge science can be described more formally as follows.

Corollary 7. The *fourth property of knowledge* is that the *effort* of knowledge creation, E_c, is far more greater than that of its acquisition, E_a. Therefore, the *speed* of knowledge creation, V_c, is far more slower than that of its acquisition, V_a, i.e.,

$$\begin{cases} E_c \gg E_a \\ V_c \ll V_a \end{cases} \tag{12}$$

Corollary 7 reveals another significant property of knowledge. That is, although human brains are capable to pragmatically and systematically learn existing knowledge, there is no systematical and predictable approach to create and discover new knowledge. This is because creativities that result in new knowledge are driven by curiosity and random processes, often by chances of well-prepared minds within an extremely large state space and capacity of synergized knowledge. It is noteworthy that the creation of knowledge is a conservative process, which establishes a novel relation between two or more objects or concepts by searching and evaluating a vast space of possibilities in order to explain a set of natural phenomena or abstract problems (Wang 2009d). Since the memory capacity of human can be as high as $10^{8,432}$ bits as quantitatively estimated in (Wang and Wang 2006), the complexity in search for new knowledge is necessarily infinitive if not a short cut shall be discovered by chance during extensive and persistent thoughts. However, the acquisition of knowledge is simply a process of adding a new relation into LTM of an existing knowledge structure. Therefore, the effort for acquiring a piece of existing knowledge is much lower than that of knowledge creation.

Attributes of Inventors and Researchers

A number of typical attributes sharing by inventors have been studied by Beveridge (1957). In his book on *The Art of Scientific Investigation* (Beveridge 1957), Beveridge perceived that the research scientists are fortunate in that in their work they can find something to give meaning and satisfaction to life. Beveridge identified a set of attributes required for researchers and inventors, such as enterprise, curiosity, initiative, readiness to overcome difficulties, perseverance, a spirit of adventure, a dissatisfaction with well-known territory and prevailing ideas, and an eagerness to try his own judgment, intelligence, imagination, internal drive, willingness to work hard, perseverance, and tenacity of purpose (Beveridge 1957).

In studies of inventive behaviors of creation in cognitive psychology, Sternberg and Lubart's (1995) elicited the following set of attributes of inventors known as intelligence, knowledge, motivation, appreciation, thinking style, and personality. Contrasting the two sets of attributes identifies by Beveridge and Sternberg/Lubart, it is interesting to note that the former would have understood scientific creation and invention deeper than the latter, because the former has much firsthand insight in research and discoveries than that of psychological observations on inventions.

Beveridge believed that an insatiable curiosity and love of science are the two most essential attributes of scientists. He pointed out that a good maxim for researchers is look out for the unexpected. He described that creators are those whose imaginations are fired by the prospect of finding out something never before found by man, and only for those will succeed who have a genuine interest and enthusiasm for discovery (Beveridge 1957). Another crucial attribute is perseverance or persistence as Pasteur wrote: "Let me tell you the secret that has led me to my goal. My only strength lies in my tenacity (Dubos 1950)." Pasteur has also revealed that "In the field of observation, chance favors only the prepared mind."

It is noteworthy that the above investigations into research itself and researchers have overlooked a more significant attribute for creativity and discovery ability, i.e., *mathematical skills* or the *abstract inference capability*, because mathematics plays the ultimate role of meta-methodology in science and engineering creativities. Actually, mathematical skills and abstraction capability are the most important foundation for efficient scientific creation and invention, which enables a scientist to inductively generalize a hypothesis into the maximum scope, usually the infinitive or the universal domain based on limited empirical studies and/or mathematical/logical inferences. It is noteworthy that mathematics is the generic foundation of all science and engineering disciplines, as well as all scientific methodologies. To a certain extent, the maturity of a discipline is characterized by the maturity of its mathematical means (Bender 2000; Zadeh 1965, 1973; Wang 2007a, 2008a, 2008b, 2012a). One of the major purposes of cognitive informatics is to develop and introduce suitable mathematical means into the enquiry of natural intelligence, computational intelligence, cognitive science, and knowledge science. The studies on denotational mathematics (Wang 2008a, 2008b, 2012a), such as system algebra (Wang 2008c), concept algebra (Wang 2008b), RTPA (Wang 2002b, 2008d), inference algebra (Wang 2011a, 2012b), and visual semantic algebra (VSA) (Wang 2009b) are fundamental endeavors toward the formalization of the entities that are conventionally hard-to-be-formalized.

According to cognitive informatics (Wang 2002a, 2003, 2007b, 2009a, 2009c, 2010, 2011b, 2012c; Wang and Wang 2006; Wang et al. 2006, 2009a, b), significant cognitive attributes related to creativity are those of knowledge organizational efficiency, searching efficiency, abstract ability, appreciation of new relations, curiosity, induction, and categorization, because those identified in the list are fundamental cognitive mechanisms and processes of the brain at the layers of metacognition and meta-inference according to the layered reference model of the brain (LRMB) (Wang et al. 2006), which are frequently used in supporting higher-layer cognitive processes.

Conclusions and Future Directions

This entry has presented the cognitive process of creation and creativity as a gifted life function according to the layered reference model of the brain (LRMB) (Wang et al. 2006). The cognitive foundations of creativity, such as the space of creativity, the approaches to creativity, the relationships of creation with problem solving, and the attributes of inventors, have been explored. A set of mathematical models of creation and creativity has been developed based on the hierarchical structures and properties of human knowledge known as concept trees. The measurement of creativity has been quantitatively analyzed. The knowledge science foundations for creativity have been systematically explored.

In this entry, a creation has been defined as a novel and unexpected solution, which is a subset of the entire set of the creation space that meet the criteria of *novelty, originality*, and *utility*. The extent of creativity has been modeled as proportional to the product of the creative distance and the size of the creation space, subject to a satisfactory originality. Various creativities and creation approaches have been identified such as free/constrained creativity, analytic/synthetic creativity, inference-based creativity, problem-solving-based creativity, and scientific/technological/art creativity. The entire set of creativities has been classified into these three categories according to their creation spaces, approaches, and problem domains.

According to Corollary 7, as well as observing the history of science development and human civilization, it is noteworthy that a modern society must encourage creativity and inventions of their elites. Because they are the locomotive for knowledge advancement who form an indispensable engine for the society, based on it the entire society will be enhanced and benefited.

Corollary 8. The *fifth property of knowledge* is that whatever the champions can achieve in knowledge development will then become the norm of the entire society.

That is, according to Corollary 8, no matter how fast the champions may run in creation and knowledge development, everybody in the societies can follow. However, in sports, hardly few may catch up the world record of a champion. Therefore, it will never be underestimated that how much a society may gain from the leading intellectual forces in creation and knowledge generation.

Introduction

Everyone agrees on the importance of entrepreneurship in the development of regions and its contribution to generate innovation and economic growth. To better understand this phenomenon, the determinants of entrepreneurship have attracted the interest of several researchers. Some are interested in the individual factors; others looked at the determinants related to the environment in which individuals are situated.

Moreover, many researchers have shown that entrepreneurship is a function of the interaction between the individual determinants and other environmental determinants.

The main goal of this entry is to provide a road map for researchers interested in the individual determinants of entrepreneurship. It tries to review the major individual factors that prior researchers have suggested should influence the entrepreneurial activities.

The origin of individual determinants of entrepreneurship as a research topic has its roots in the 1960s in the classic entrepreneurship literature. This literature attempted to explain the creation of new venture with a focus on personality traits and characteristics of entrepreneurs. The board conclusion of this literature is that determinants related to the individual are composed of special qualities and motivations that endowed entrepreneurs with unique abilities or driving forces encouraging them to create new ventures.

A growing literature examines the impact of individual determinants on entrepreneurship. Researches emphasize the importance of personality traits and characteristics in the decision between self-employment and salary work. Authors identified two categories of explanations. The first class emphasizes entrepreneurial motivations. Previous researches have explored several motivations and their effects on entrepreneurship.

Entrepreneurial Motivations

The Need for Independence

The most studied motivation in this context is the need for independence. Individuals having a preference for autonomy desire freedom from organizational constraints and control from supervisors (Schein 1990). They want to work independently and be "their own boss." They prefer to be maximally free in their work so that they can define their own objectives and achieve them as they would like. They want to take the responsibility to fix their own decision instead of following the orders of others. To achieve all these ambitions, individuals having a need of independence turn away from salary work and prefer to move towards an entrepreneurial career.

The Need for Achievement

Within the research domain of personality traits and entrepreneurship, the concept of need for achievement (nAch) or the need for personal development has received much attention. Mc Clelland (1961) identified it as a key influencing personal characteristic on the creation of new ventures. This motivation is related to the need for the individual to learn every day, to exercise his creativity, and to innovate. Individuals with a high need for achievement have a strong desire to set their own goals and carry them out. They want to take responsibility for actions and do well in competitive situations. They dislike routine activities, and they have a tendency to choose difficult tasks. While those with a low need for achievement choose very easy tasks in order to reduce the risk of failure. Thus, they consider the creation of business as a challenge to meet which encourages them to create their own businesses.

The Locus of Control

The locus of control is another motivation of interest, which emerged from Rotter's (1966) original research on entrepreneurs. Rotter (1966) argued that individuals having a high internal locus of control believe that they will realize their success by their own actions. They have the perception that all events are under their control so that they do not attribute outcomes to the chance or external environment. However, individuals with an external locus of control believe that the result of an event is out of their control. Individuals having an internal locus of control prefer to pursue an entrepreneurial career because they desire situations in which their personal actions have a direct impact on outcomes.

Thus, the study of the most considered entrepreneur's motivations like the need for independence, the need for achievement, and the locus of control is relevant because they have been interpreted in the entrepreneurship literature as potential internal driving forces among entrepreneurs.

Entrepreneur's Qualities

The second class of explanation of self-employment emphasizes entrepreneur's qualities that are necessary to become an entrepreneur. The decision to create a new business has been considered in many researches as a function of the qualities associated to the individual. Entrepreneur's qualities are defined as the skills and abilities of an individual encouraging him to create a new venture.

Entrepreneurial Self-Efficacy

One of the key factors that have received attention is entrepreneurial self-efficacy which is developed by Bandura (1977) and has been demonstrated to play a crucial role in the development of entrepreneurial intentions and actions. The concept of self-efficacy or self-confidence is based on individuals' self-perceptions of their skills and abilities to succeed in creating new businesses. These perceptions are able to increase the level of interest in pursuing an entrepreneurial career. Individuals with high entrepreneurial self-efficacy are also more likely to believe that they possess a viable idea for a new venture. They exert more effort for a greater length of time and persist to achieve this idea and to improve their performance.

Risk Tolerance

The classic work of Knight (1921) stresses the importance of risk tolerance in the entrepreneurial decision. Risk tolerance consists of a general tendency to pursue and take calculated risks. Entrepreneurs often accept uncertainty; however, other individuals desire to avoid risk because they are afraid of failure. As a result, they prefer easy and safety situations because there is a high chance of success. In a recent study, Fairlie and Holleran (2011) note that creating a new business is inherently risky, and individuals who are more risk tolerant have higher levels of entrepreneurial intentions and opportunity-identification efficacy.

Creativity

In addition to these individual determinants, many other significant factors have been identified by an important number of researchers. Schein (1978) found that individuals with a strong creativity and innovative anchor are motivated to create "something new" for the chance to use their skills to innovate and develop new ideas. They are characterized by the ability to produce an original and useful work in the same time.

Some Empirical Studies About Individual Determinants of Entrepreneurship

A large number of empirical studies examine whether these motivations and qualities in addition to other identified characteristics are important determinants of entrepreneurship.

In his study, Hornaday (1982) lists 42 attributes of entrepreneurs. These attributes include need for achievement, risk-taking propensity, and internal locus of control. Additionally, he notes the importance of other special qualities such as dynamism, adaptability, taking initiative, and the ability to resolve problems in the creation of new ventures.

In a study based on 40 success stories of entrepreneurs, Hernandez (2006) explored the reasons why individuals start enterprises and make career choices. The results of his research indicated that the main reasons individual's start enterprises are passion, self-realization, autonomy, authority, financial success, and difficulty to find a salary work.

A recent empirical study of Fairlie and Holleran (2011) tried to examine the influence of several personality characteristics on the creation of new ventures in Germany. On the basis of a large representative household panel survey, they found that tolerance to risk, entrepreneurial ability, and locus of control are important in determining who creates a new venture. Moreover, they identified extraversion and openness to experience as key influencing factors on entrepreneurship. Extraverted individuals are defined as self-confident, ambitious, energetic, sociable, and dominant persons. With regard to openness to experience, it consists of the individual's ability in looking for new experiences and exploring novel ideas.

Conclusion and Future Directions

Thus, this entry contributes to review the major individual determinants (and does not provide an exhaustive list of these determinants) that prior researchers have suggested should influence entrepreneurial activities. The literature analyzing this question has examined the impact of personality traits on the creation of a new venture. Authors identified two categories of explanations. The first class emphasizes entrepreneurial motivations such as the need for achievement, the locus of control, the need for independence, the need for approval, and the need for personal development. The second class of explanation emphasizes entrepreneur's skills and qualities such as self-efficacy, risk preference, creativity, and dynamism.

Studying the individual determinants of new firm creation is relevant. However, the entrepreneurial phenomenon is multidimensional and cannot be fully understood by only individual factors. There might be important and interesting interaction effects between the qualities and motivations of the entrepreneurs and factors related to the environment in which he is situated.

This may explain why the focus of entrepreneurship research changed in the late 1980s with authors proposing a more holistic approach taking into account both individual and environmental determinants at different stages of the entrepreneurial process. Then, the inclusion of both individual and environmental factors in understanding entrepreneurial behaviors is crucial in theoretical as well as empirical studies.

Introduction: Key Concepts and Definitions

Industrial Atmosphere and Industrial Districts

The term "industrial atmosphere" is used in economic literature in relation with the issue of localized business activities and more specifically with the notion of "industrial district." The latter notion describes geographical concentrations of firms characterized by specific relationships among participants. Industrial districts are localized clusters of firms, generally small or medium firms, where special modes of business cooperation among firms can be found, be they rivals or based on customer-supplier relationships, with some degree of loyalty and cooperative attitude creating a peculiar business-friendly "atmosphere" in the local industry.

Italian Industrial Districts

The modern economic literature on districts is based on the observation of specific forms of localized industrial activities that emerged in Italy during the 1960s and 1970s, called "Italian industrial districts." These localized clusters of firms defined the new industrial model of the "Third Italy," the structure, mechanisms, and rationale of which differed from both the classical industrial development of the Italian northwestern region, in the Milan-Turin-Genova triangle, and the underdeveloped "*Mezzogiorno*" of Southern Italy. Economic studies on Italian industrial districts such as the Prato textile industry, for instance, describe clusters of small firms mostly specialized in a single production phase and linked together in a complex process of cooperation and competition giving birth to an "industrial atmosphere," meaning close business relationships among participants. These relationships are based on technological information sharing, loyalty, social and family ties, interpersonal friendship, and cooperative connections (Becattini 1989, 1991).

Overview

From a historical viewpoint, localized clusters of firms have been initially observed and analyzed by Alfred Marshall in the British industry of the nineteenth century. Modern analyses owe much to Marshall's founding intuitions. In the first section, the works of the famous Cambridge master will be evoked to show how a peculiar "industrial atmosphere," as he called it, emerges from the historical, geographical, and organizational characteristics of localized industrial activities. The second section focuses on the specific role of entrepreneurial activities in the crystallization of industrial atmosphere.

Marshallian Industrial District and Industrial Atmosphere

The notion of industrial atmosphere was first coined by Alfred Marshall. In Marshall's *Principles* (Marshall 1920), the concentration of specialized industries in particular localities is considered as one of the main forms of industrial organization leading to economic development. Industrial localization and the division of labor and its influence on machinery, production on

GREDEG research group (*Groupe de Recherche en Droit, Economie, Gestion*), a joint unit of the University of Nice – Sophia Antipolis and CNRS (*Centre National de la Recherche Scientifique*).

a large scale, and business management are the main causes of a long-term tendency to increasing returns. Alfred Marshall first pointed to the industrial atmosphere of some clusters of firms such as Sheffield's cutlery industry, a prototypical example of this form of industrial organization in the nineteenth century. For Marshall, interestingly, an industrial district is not simply a localized industry. Inside the district, interactions among firms matter because they give birth to external economies leading to aggregate outcome equivalent to scale economies that can be observed in big firms.

According to Marshall, people following the same skilled trade take great advantages from near neighborhood to one another. These advantages come from knowledge sharing leading to the diffusion and enhancement of knowledge, the seizing of new ideas that are simply "in the air" among participants, and the speeding up of the innovative pace. In Marshall's words:

> The mysteries of the trade become no mysteries; but are as it were in the air (. . .) Good work is rightly appreciated, inventions and improvements in machinery, in processes and the general organization of the business have their merits promptly discussed; if one man starts a new idea, it is taken up by others and combined with suggestions of their own; and thus it becomes the source of further new ideas. (Marshall 1920), p. 225

The reasons for a geographical concentration of firms may be various, depending on local resources, physical conditions, demand conditions, etc., whereas Marshallian industrial districts are more significantly characterized by a particular combination of competition and cooperation through which entrepreneurial talent must be allowed to express itself. In districts, some relationships prevail among firms; firms specialize in particular phases of the productive process from where on they interact through many forms of cooperation, subcontracting, and exchange processes. Thus, because of this dense network of relations, subsidiary industries devoted to small phases of the productive process but working for a large number of neighbors are able to use and maintain machinery of a very specialized character. Another advantage of industrial districts is the existence of a local market for special skills where employers are likely to find a good choice of workers of many different skills. However, according to Marshall, whereas small districts specialized only in one kind of work can rapidly lose their advantages, the most efficient forms of cooperation are seen in large industrial districts and large manufacturing towns where many specialized branches of industry are put together into an "organic whole."

In *Industry and Trade*, the author explicitly uses the term "industrial atmosphere" to express the environment into which the firms are immersed and obtain "more vitality than might have seemed probable in view of the incessant change of techniques" (Marshall 1919, p. 287). Marshall explains in detail how the problem of the scale of production can be overcome if small and medium firms closely collaborate. The most common system used by English firms was interfirm cooperation or, as Marshall calls it, "associated action" among firms in the same district (see Belussi and Caldari 2009, pp. 338–339).

According to Giacomo Becattini, the main revivalist of the Marshallian approach, "the term localization stands for something other than an accidental concentration in one place of production processes which have been attracted there by pre-existing localizing factors. Rather, the firms become rooted in the territory, and this result cannot be conceptualized independently of its historical development" (Becattini 1990, p. 40).

Thus, the origin and development of an industrial district is not simply the local result of the matching of some sociocultural characteristics of a community, of historical and natural conditions of a geographical area, and of technical aspects of the production process. It is "also the result of a process of dynamic interaction (a virtuous circle) between division-integration of labor in the district, a broadening of the market for its products, and the formation of a permanent linking network between the districts and the external markets" (Becattini 1990, p. 44).

Marshall's approach to interfirm relations cannot be separated from his conception of the dynamics of industry developed in the *Principles*. His vision of firm and industry shows a great homogeneity because it inextricably links the principle of organization resulting from the division of labor, and the principle of substitution which is mainly based on the evolutionary notion of natural selection in which entrepreneurship plays an important part.

Entrepreneurship and Industrial Atmosphere

Industrial districts are a special form of industrial organization which needs a cognitive interpretation of industrial atmosphere. The latter is mainly based on the emergence and intervention of entrepreneurs whose abilities and competence are, for the most part, to organize the division of labor and specific forms of cooperation among competitors. Take, for instance, the "*impanatore*" of Italian textile industries of the twentieth century; this entrepreneur is instrumental in the linking up of customers located outside the district and the different suppliers working inside of it at various levels of the supply chain. The *impanatore* mainly plays an architectural role for the district, giving instructions or advice to the suppliers for organizing, or reorganizing, their production processes according to his knowledge of the changes of customers' taste and needs.

Entrepreneur, Undertaker, and Promoter

The analysis of geographical concentration of firms is inseparable from a vision of the economic actor embedded in complex social relationships and business relations assuming honesty and good faith. The importance of neighborhood is central to this idea: "the desire to earn the approval, to avoid the contempt of those around one is a stimulus to action which often works with some sort of uniformity in any class of persons at a given time and place" (Marshall 1920, p. 19). In this neighborhood, entrepreneurs are those who take the risks and the management of business and participate to the organized industry.

The central figure of the "undertaker" is the main spring of economic development. The undertaker must deploy "ability" which corresponds to knowledge, a quality which can be acquired and improved by education and learning. On the other hand, the undertaker must also exhibit "energy," synonymous with creativity and innovativeness. Business management is considered as part of industrial organization and necessitates the following abilities, listed by Marshall: an entrepreneur must be endowed with "a thorough knowledge of things in his own trade," "power of forecasting the broad movements of production and consumption," and the capacity of "seeing where there is an opportunity for supplying a new commodity that will meet a real want or improving the plan of producing an old economy"; finally, the business manager must be "able to judge cautiously and undertake boldly," and he must be "a natural leader of men" (Marshall 1920, quoted by Pesciarelli 1991). The entrepreneur's role is improved particularly through the advantages of large-scale production. The emergence of joint-stock companies studied in *Industry and Trade* (Marshall 1919) gives rise to another entrepreneurial figure, the "promoter," who organizes industrial cooperation on purely business lines and forecasts future businesses based on new inventions leading to new opportunities and new profitable alliances between industries.

Localized Knowledge and Innovation

The emergence of different kinds of territorial development and industrial districts in the twentieth century called for a general analytical background that could be used to explain, not only the districts of Northeast and Central Italy but also other forms of industrial localization experienced in different countries and regions, such as Orange County and the Silicon Valley in California, or some attempts of industrial development areas in the Third World, such as the shoe industry in Rio Grande do Sul. In these territories, small and medium firms substituted for mass production and large firms using heavily structured production processes based on machinery and unqualified workers. Industrial districts were characterized by flexible regimes of production using more specialized workforce and decentralized forms of coordination in which market relations and reciprocity replaced the managerial hierarchies of multidivisional corporations (Piore and Sabel 1984).

However, during the last two decades, localization phenomena turned back to more traditional modes of organization because of globalization and the emergence of new technologies (especially ICT) and when leading innovative firms were taken over and merged into bigger corporations. This is the reason why, for instance, the success stories of some famous Italian districts of the 1970s came to an end (Prato district, Benetton system).

The modern approach to localized industries proceeds from a reflection on technological progress which is structured around two main themes: (a) specific human resources obtained through localized learning processes and (b) organizational framework characterized by cooperative links among participants. In this modern context, the innovative process takes the form of a collective learning activity sequentially organized along the different phases of the production process. Thus, innovation becomes endogenous to the dynamics of industrial development (Lecoq 1993; Antonelli et al. 2008).

Entrepreneurial alertness is still at work in this framework. Industrial dynamics is mainly dependent of actors who organize complex processes, but the classical notion of district cannot cover the entire logic of the phenomenon. Industrial territories such as those of the nineteenth century described by Marshall were specialized in a single industry like the cotton industry in Lancashire or Sheffield cutlery trade. Likewise, their modern Italian equivalents specialize, for instance, in the textile industry as in Prato, or pottery in Sassuolo. More generally, industrial districts greatly differ according to the way complementary activities are organized; the main activity develops a large range of secondary activities, be they horizontal or vertical, along the different phases of the production process. These activities can also differ because of more or less formal social relationships and differently structured social networks. Finally, they also diverge because of the disparity among training institutions and the divergence in cooperative relationships.

Conclusion and Future Directions

The common central aspect of the various forms of localized activities that can be observed in modern industry lies in the fact that they incorporate a dense network of local communities and neighborhood interactions. The background created by close and tangled up relationships between the organization of productive activity and the functioning of social structure is at the basis of contextual connection and business cooperation which explain the very meaning of "industrial atmosphere." The coherence of this complex "organic whole" is not attained by chance or any natural process or market mechanism; the viability of the system must be organized by specific actors who take care of the durability and continuity of the industrial atmosphere. Different sorts of atmospheres can be found depending on the nature of the localized network: in a science park driven by start-ups, business angels, and academic entrepreneurs; in an industrial district dominated by buyer–supplier relations; in a knowledge-based metropolis; or in a localized system of innovation organized by innovative institutions. The mix of localized knowledge, competitive spirit, emulation, and cooperation that exist in these different industrial milieus is the basic material of the kind of entrepreneurship that is exerted in them.

Future developments of the concept lie in the possibility of maintaining a creative industrial atmosphere in large multidivisional and multiproduct firms. This can be obtained by encouraging the emergence of islands of corporate entrepreneurship in the administrative ocean of giant companies.

Information Asymmetry and Business Creation

Pierre Barbaroux
French Air Force Research Center, BA 701-EOAA/CReA, Salon Air-France, France

Synonyms

Adverse selection; Market failures; Moral hazard

Definition

Information asymmetry is considered by economists as a major source of market failures. When an information asymmetry affects the quality of a good, a service, or a project, it is likely to generate a failure in the process of allocating resources. Akerlof (1970) first demonstrated that "when there exist information asymmetries between buyers and sellers, high- and low-quality goods and services can coexist in the marketplace" (Nayyar 1990, p. 514). This situation induces search costs for buyers who have "to determine the quality of goods and services they buy" (Nayyar 1990, p. 517). Because of information asymmetry, "prices do not accurately convey all information necessary to coordinate economic decisions" (Eckhardt and Shane 2003, p. 337). More precisely, scholars discriminate between two types of information asymmetry: moral hazard and adverse selection. The latter are central features of principal-agent relationships which characterize standard agency theory. As Picard (1987, p. 305) observed, "moral hazard results from the inability of the principal to monitor an agent's actions while adverse selection corresponds to the inability of observing an agent's private information." Guesnerie et al. (1988, p. 807) referred to the notions of "hidden knowledge" and "hidden actions" to identify these two sources of inefficiency in resource allocation. Hence, moral hazard and adverse selection, respectively, emerge when buyers are (1) incapable of evaluating the quality of goods and services or (2) unable to observe "either the seller's characteristics or the contingencies under which the seller operate" (Nayyar 1990, p. 517). If a market exhibits these two types of information asymmetry, "bad-quality providers can enter the market and drive out the good-quality providers by so lowering price that the latter cannot obtain returns on their investments for competence enhancement" (Nayyar 1990, p. 517).

Research Questions

The literature investigating the relationships between information asymmetries and business innovation focuses on three subthemes: (1) the financing of innovation, (2) the relationships between information asymmetries and business opportunities, and (3) the impact of information asymmetries on collaborative approaches to innovation.

Information Asymmetries and the Financing of Innovation

Within the context of capital markets for R&D, information asymmetries between entrepreneurs (agents) and investors (principals) about what the entrepreneur knows and does are likely to create what Akerlof (1970) called a market for lemons. Therein, a funding gap might emerge because entrepreneurs hold information that potential financiers do not possess and/or cannot observe. The risk is that only undesirable transactions will be accessible to investors "by raising entrepreneurs' sunk costs" (Shane and Cable 2002, p. 365), provoking a market failure when high-quality entrepreneurs leave the market (Emons 1988). As Aboody and Lev (2000, p. 2750) argued, "the uniqueness of R&D investments makes it difficult for outsiders to learn about the productivity and value of a given firm's R&D from the performance and products of other firms, thereby contributing to information asymmetry." In addition, it has been demonstrated that "market players in closer touch with a firm and its business (. . .) are those who possess better information about that firm" (Bharath et al. 2009, p. 3215). It follows that when entrepreneurs seek financing, financiers must address two problems: information disclosure and opportunism. As Shane and Cable (2002, p. 364) argued, "entrepreneurs are reluctant to fully disclose this information to potential investors because such disclosure will make easier for other people to pursue the opportunity" (e.g., through imitation). In addition, since entrepreneurs hold information that investors lack, they "may act opportunistically towards them (. . .) because entrepreneurs vary in their ability to identify and exploit opportunities" (Shane and Cable 2002, p. 364). In this context, scholars investigated how seed-stage venture capitalists manage to mitigate the effects of information asymmetries. In particular, scholars addressed the following question: how do potential investors find ways to confront the difficult challenges of identifying and selecting promising ventures to fund?

As Shane and Cable (2002, p. 364) explained, "three mechanisms –the allocation of contractual rights, the staging of capital, and risk shifting- led entrepreneurs to self-select and disclose information in ways that overcome this information asymmetry." The explanations provided by economists – namely, the allocation of contractual rights, the staging of capital, and risk shifting – are considered by the authors as incomplete for at least two reasons. "First, the over optimism of entrepreneurs (. . .) undermines the effectiveness of the contractual mechanisms described by economists" (Shane and Cable 2002, p. 366), making self-selection ineffective. The argument brought by the authors is that early-stage investors cannot shift all the risk of investing in a new venture to entrepreneurs and "must make investments that risk the total loss of their capital" (Shane and Cable 2002, p. 366). In addition, information disclosure through patenting for example (Antelo 2003), cannot lead outsiders (i.e., venture capitalists) to gain all the private information they need. As Kyle (1985, p. 1326) argued, although insiders' information get progressively incorporated into market signals through information disclosure, "not all information is incorporated into prices."

Contrasting economists' explanations, organizational theorists have generally proposed that potential investors rely on social relationships to select which ventures to fund. Scholars have argued that two different mechanisms – information transfer through social ties and social obligation – influence investors' decision. Adopting a socio-organizational lens, Shane and Cable (2002, p. 366) contended that "social obligations between connected parties, and information transfer through social relationships, influence venture finance decisions." On the one hand, social ties enable investors to obtain private information about the ventures to fund and their potential opportunities. The foregoing argument is consistent with a self-interested approach to investors' behavior, the latter exploiting their social capital to identify and select better projects. On the other hand, direct and indirect ties "create social obligations between the parties, which cause them to behave generously towards each other" (Shane and Cable 2002, p. 370). By referring to these two complementary mechanisms, the authors underlined the role played by entrepreneurs' reputation in providing investors with additional information about his or her capacity of implementing, managing, and developing the venture which, in turn, "help disentangle the effects of social obligation and information access" (Shane and Cable 2002, p. 371).

It should be noted that the creation of a spin-off company is likely to hamper the effects of information asymmetries on venture finance decisions. Basically, a good reason for founding spin-offs is the reduction of information asymmetry. Following Woo et al. (1992, p. 435), "the proposed benefits of spin-offs have often been articulated under the guise of an improved agency relationship between shareholders (principal) and managers (agents)." Within this framework, the benefits in a spin-off lie in the reduction of information asymmetries characterizing the evaluation of firm's activities. As Krishnaswami and Subramaniam (1999, p. 78) argued, spin-offs enable the bidder "to value the separate entities better and thus the standard adverse selection problem that arises under information asymmetry is mitigated." Spin-off decisions, therefore, are likely to protect the firm from misevaluating its profitability and operational efficiency, in particular when "the spin-off is motivated by a need to raise external capital" (Krishnaswami and Subramaniam (1999, p. 79).

Information Asymmetries as Sources of Opportunities

Information asymmetries arising from investments in R&D and innovation projects are also viewed by scholars (notably those belonging to the Austrian tradition in economics) as sources of opportunities. Elaborating on the works of Hayek (1945) and Kirzner (1973), Ardichvili et al. (2003, p. 108) defined an opportunity as "a chance to meet a market need (. . .) through a creative combination of resources to deliver superior value." In its most elemental form, it describes "a phenomena that begin unformed and become more developed through time" (Ardichvili et al. 2003, p. 108). As a result, opportunities are likely to be limited in time. Shane (2000, p. 451) further suggested that "opportunities exist because different people possess different information." It follows that "everyone in society must not be equally likely to recognize all opportunities" (Shane 2000, p. 451) merely because people differ according to their prior knowledge, the latter being determinative for their ability to *discover* entrepreneurial opportunities.

As Eckhardt and Shane (2003, p. 339) explained, discovering an opportunity "is far from the trivial exercise of optimizing within existing means-ends frameworks because it requires forming expectations about the prices at which goods and services that do not exist yet will sell." However, the discovery and exploitation of (valuable) opportunities is likely to generate entrepreneurial profits which, in turn, might provide financiers with positive returns on investment (Eckhardt and Shane 2003). Since entrepreneurs hold information about what they know and do outsiders do not possess, scholars indicated that they can earn rents by exploiting information asymmetries, the latter being considered as a source of monopoly power. In particular, as Davis (2001, p. 327) argued, rents can be obtained by combining four information-oriented strategies: "(1) publish the details of the innovation in return for legal protection (patents, copyrights, and the like), (2) keep the information inside the firm (secrecy, tacit, and firm-specific knowledge), (3) make the information selectively available to others on an informal basis, and (4) widely disseminate the information making it freely accessible to all comers." In doing so, firms seek to control how information about the characteristics of their innovations get revealed to the market in order to confront potential competition (through imitation for example) and ensure sustainable profitability.

Within this framework, information asymmetries "can be a potent source of competitive advantage" (Nayyar 1990, p. 517), in particular, for firms that are capable of diversifying their offers through the implementation of an effective communication strategy. Miller (2003) introduced a three-step model that exemplifies how firms convert asymmetries into resources enabling them to benefit from competitive advantage. The author demonstrated that building capabilities out of asymmetries involves that the firm is capable of doing "three things well:

1. Discover the asymmetries (. . .) and discern the potential between them
2. Turn asymmetries into capabilities by strategically embedding them within an organizational design configuration that exploits them and sustains their development
3. Match asymmetry-derived capabilities to market opportunities" (Miller 2003, P. 965)

Therein, the identification and selection of valuable asymmetries require both internally and externally oriented processes, including experimentation, incremental learning, organizational introspection, reflective inquiry and search for weaknesses, and bootstrapping on emerging capabilities (Miller 2003, pp. 965–968).

Information Asymmetries and Collaborative Innovation

In the recent years, scholars reported many examples of successful companies that invented and commercialized new products and services by participating in collaborative networks (Nieto and Santamaria 2007). Collaboration enables the firm to access to a variety of external and internal sources of innovation that can be used in combination to generate new ideas, incorporate them into new products and services, and capture value from their commercialization (Chesbrough and Appleyard 2007). As Abramo et al. (2011, p. 885) suggested, "private enterprises use collaboration to solve specific technical or design problems, develop new products and processes, conduct research leading to new patents, recruit university graduates and access cutting-edge research." Within this framework, the firm must confront the challenge of selecting the "right" research partner based on their private information about the quality of the scientific knowledge available on the market and its cost. Here again, information asymmetries make it difficult for private companies to discriminate between the variety of offers. When market fails to provide agents with complete information, the selection of partners is guided by socio-organizational factors. In particular, "geographic and social proximity (. . .) should play a determining role in the choice of research partner" (Abramo et al. 2011, p. 85). Therein, social capital, direct and indirect ties, and reputation effects are likely to guide the firm in identifying promising research partners if information about their quality is lacking. Tödling, Lehner, and Kaufmann (2009) supported this assertion indicating that collaborative innovation "draw on new scientific knowledge generated in universities and research organizations" and that "the exchange of this type of knowledge requires personal interactions" (Tödling et al. 2009, p. 59). The adoption of collaborative business model therefore is likely to enable partners in innovation projects to mitigate the effects of information asymmetry but necessitate interaction and communication through formal (e.g., licensing, spin-offs) and informal (e.g., sociocultural proximity) relationships.

Conclusions and Future Directions

The relationship between information asymmetries and business creation is a key issue for both scholars and managers. Future research efforts could be directed towards deepening our understanding of how various stakeholders involved in business creation and funding (entrepreneurs, investors, public agencies, etc.) manage to balance (1) information asymmetries as sources of opportunities and (2) the sharing of information (and knowledge) as it enables collaboration and reduces financial and technological risks. This might lead to depart from market-driven models of information asymmetries to promote an entrepreneurial approach to business creation. The latter would insist on critical resources enabling agents to deal with information asymmetries and exploit opportunities such as relational networks, communication strategies, fiscal incentives, and public/private partnerships. This, in turn, would enlarge our understandings of the role played by information asymmetries on the nature and logics of business creation.

Theoretical Foundation

Studies about business creation and business monitoring have multiplied and branched out over the last 30 years. For the sake of clarity, concepts are based on a classification adopted by business specialists Gilbert, MacDouglas and Audrestch (2006), i.e., approaches based on the theory of growth – with a focus on the individuals, business life cycles, strategies, population ecology, resources and coherence. In each of these, determinants are analyzed that either complete or respond to one another. Among others, analyzing the environment of business creation processes is key for approaches based on strategies, resources, and population ecology (Hrisman et al. 1999).

In these three approaches, analyzing the environment allows the entrepreneur to spot opportunities and make choices. As established for corporate governance practices (OECD 1999), information is at the heart of environmental analysis. Depending on the norms, this can either have an implied or implicit dimension, or an explicit dimension. In the latter case, it materializes as an information monitoring system that can be defined as an informational process through which an organization scans its environment to decide and act to pursue its objectives.

Research about business creation – which, depending on the author, is presented either as a result or as a process – is always centered on three notions: the entrepreneur, the new company, and the environment in which the process occurs (Marchenay and Messeghem, 2001). This environment is all about understanding and apprehending favorable and unfavorable factors. Studies of the couple "new company/its environment" deal with the forms it can take, the various possible locations (science parks, nurseries, etc.), and the business segment's characteristics (maturity, turbulence, etc.), as well as performances and the problems that are occurring (Porter 1985). It is then important for the creator to be given notions of environmental scanning in order for him/her to use it as a tool to orient his/her activity.

The very first paper about business intelligence dates back to 1974 and explains how environmental analysis must be conducted – not omitting to mention that the method and the tools it proposes are those used by US intelligence agencies.

Terminological confusion must be highlighted here, that arises from using an expression which simultaneously embodies two concepts: the monitoring process in itself, and the result of this monitoring process. Hence, "environmental scanning" or "business monitoring" now describes the process in itself, while "business intelligence" or "competitive intelligence" correspond to the end product of this process.

Business Monitoring Process

The scanning/monitoring process is described as a system by Dutton, Frayer, and Narayanan (1983), based on several subsystems, and relying on information provided both by external players and the organization itself. The macroenvironment has a political, an economical, a sociological, a technological, an ecological, and a legal dimension. The identified players are the clients, the suppliers, the employees, the unions, the partners, the competitors, the governments, the networks, the media, and the press conglomerates. The inner environment of the company consists of its resources, its culture, its strategies, its governing body, and its structure (Davenport and Prusak 1998; Kahaner 1996).

The main system of the business monitoring process comprises three elements, namely, the inputs, outputs, and cycle. Inputs refer to the many needs of the company's players. Listed by several authors (Beal 2001; Bryant and Richardson 1999; Fuld 1995), these needs pertain to identifying clients, markets, competitors, suppliers, and partners. Outputs refer to information products aimed at making decisions and taking action. Depending on the phase of the cycle, these can either be data, or information, or knowledge. There are several steps in the business monitoring cycle:

- Defining the need
- Collecting information, using a list of formal and informal sources of information
- Assessing the truth of, and validating, information relatively to the needs, through a workgroup
- Analyzing and interpreting the groups of documents to outline the emerging trends, spot weak signals, and make recommendations
- Disseminating information

Although spying is illegal and not part of the business monitoring process, protecting information should be added to that list, as violating it is more and more common practice in spite of rigorous ethics.

Conclusion and Further Reading

Information technologies play an important role in implementing business monitoring within companies, irrespective of their size and the phase of their life cycle. The ever-growing number of data mining software is now pushing science parks and nurseries to get their smaller companies acquainted with them, thereby giving them access to a better knowledge of their external environment – which for them is an asset both to predict potential external threats and to take advantage of every opportunity.

Innovation and Democracy

Ludger Helms
University of Innsbruck, Institute of Political Science, Innsbruck, Austria

Synonyms

Democratic reforms; Democratization; Political change

The connections between innovation and democracy are numerous and complex. Many recent contributions to the field center on "innovating democracy" (Goodin 2008) in terms of designing, implementing, and using new or "unconventional" forms of decision making in democratic systems. But while this perspective covers a huge and quickly expanding field, and may capture some of the most intriguing aspects, it certainly marks not the only way of looking at innovation and democracy. The structural capacity of democratic systems to generate innovation in politics as well as in other areas, such as technology and science, constitutes another key component of the larger subject. The brief overview that follows considers both of these different, but related, topics.

Before we turn to this, a working definition of both key terms is in order. *Democracy* is here referred to as "a political system in which different groups are legally entitled to compete for power and in which institutional power holders are elected by the people and are responsible to the people" (Vanhanen 1997, p. 31). It is difficult to find a similarly clear-cut and substantive definition of innovation in the political science literature. Recent attempts to describe innovations as "special subsets of change" (Newton 2010, p. 4) are not fully convincing. *Innovations* are about change, but are nevertheless closer to reform than to change because change is neither an equivalent to nor necessarily the result of conscious and deliberate action. The latter, however, characterizes innovation as well as modernization and reform. What separates both innovation and reform from mere modernization is in particular the degree of projected change. But it remains difficult to establish what exactly distinguishes the former two from each other. As Ken Newton suggests, a meaningful general conceptualization of innovation may center on introducing "new ways of doing things" (Newton 2010, p. 4). By contrast, reforms tend to focus specifically on altering established rules or procedures. Reforms are also usually launched (if by no means always demanded in the first place) by actors who possess a special authority to formally initiate reform processes, which cannot be considered a necessary requirement of introducing innovations.

Democracy's Capacities for Innovation

From a normative perspective, democracies would appear to provide excellent conditions for innovations in such different areas as arts, science, and technology. Of the two main ideas, or principal norms, defining liberal democracy – freedom and equality –, especially the former is essential for making democratic political systems innovation-friendly environments. The free flow of ideas is strongly conducive to innovation (if not necessarily to invention and creativity which can be found even in contexts characterized by strong structural barriers against innovation). The possible effects of equality on the innovation capacity of different societies are more ambiguous. On the one hand, a strong commitment to equality may result in a wide distribution of resources within a given society which is likely to benefit the cause of innovation in different areas. On the other hand, a strong emphasis on equality in organizing a given society may make it harder for innovative actors to acquire an exposed position and prevail in the competition between innovation and established norms and practices.

Democracies also, and in particular, share a strong normative commitment to *political* innovation. As John Keane has pointed out, "When democracy takes hold of people's lives, it gives them a glimpse of contingency of things. They are injected with the feeling that the world can be other than it is – that situations can be countered, outcomes altered, people's lives changed through individual and collective action" (Keane 2009, p. 853). Even more to the point, Michael Saward has observed that "the story of democracy is nothing if not a story of innovation. One of the defining features of democracy may well be its restlessness, dynamism and comparative openness to new ideas" (Saward 2000a, p. 3). The latter properties are not just general defining characteristics of liberal democracies, however, but play a crucial role in the maintenance and persistence of democratic regimes. Indeed, the prospect of future change and political innovation is central for legitimizing democratic politics and democratic systems, and it is of special relevance to those citizens who are not supporting the government of the day (Anderson et al. 2005).

Further, democracies are not only characterized by a general appreciation of innovation and change in different areas, they also incorporate a special mechanism designed to bring about innovation in politics: elections and alternations in government. In fact, the single most important function of democratic elections is to be seen in empowering the citizens to "turn the rascals out," to clear the way for a fresh start. Other things being equal, major policy innovations in democracies are most likely to occur in the aftermath, and as a result, of alternations in government. This key assumption, which is explicitly spelled out particularly in some concepts of party government (Katz 1987), is obviously based on several other assumptions, including in particular that the different parties competing with each other for governmental office have reasonably different policy agendas.

But the structural capacity of democratic systems to bring about innovation is not exclusively concentrated in the hands of the governing elites. The opposition has long been acknowledged as "the other mover of politics," and the opposition actors performing innovation-related functions (at the level of public agenda setting and beyond) include both fully institutionalized actors, such as the parliamentary opposition in parliamentary democracies, and much less institutionalized actors, such as social movements (Helms 2010).

From an empirical perspective on the West European parliamentary democracies, one of the first things to mention about democracy's capacity for innovation is the fact that wholesale changes in the party composition of governments mark a comparatively rare occurrence. Often, elections tend to produce governing coalitions that include at least one party that has been a member of the outgoing coalition which, other things being equal, reduces the innovative potential of newly formed governments (Ieraci 2012). The innovative potential of (be it wholesale or partial) alternations in government is further reduced if there is a strong policy convergence of the parties competing for office, as Peter Mair suggests to be the case in much of Western Europe (Mair 2008).

Apart from the suggested trend toward policy convergence of the parties, that can be observed in some but by no means all established liberal democracies (Budge et al. 2012, pp.66–70), the innovation capacity of newly incoming governments, including majority single-party governments, has arguably always been overestimated. There is a strong element of inheritance in public policy even under the most favorable institutional and political circumstances, as Richard Rose and Phillip L. Davies have shown for the British Westminster democracy (Rose and Davies 1994). Even radical governments rarely repeal much of the legislation of the previous administration. This notwithstanding, all other things being equal, the overall capacity for innovation of newly incoming single-party governments in majoritarian types of democratic systems is larger than that of coalition governments operating in politically and institutionally complex systemic environments.

In presidential democracies, such as the United States, the closest equivalent to majority single-party governments in parliamentary democracies are administrations facing a legislative branch that is being controlled by the president's party ("unified government"). *Ceteris paribus*, their legislative leverage and capacity for innovation are larger than that of administrations operating under the conditions of "divided government" which can, to some extent, be compared with minority governments in parliamentary democracies. The political history in the United States since 1945 has been marked by a high share of "divided government" (in fact, more than two-thirds of all post-war administrations fall into this category) and, more recently, a strong trend toward party polarization (Baumer and Gold 2010) – a combination that has made the implementation of innovative policy agendas more difficult to achieve than ever.

In all those politically and institutionally different contexts, individuals can make a difference (Greenstein 1987), and innovative leadership is possible (Moon 1993). However, even if governmental decision makers are able and willing to initiate innovative policies, democratic governance requires the substantial support from social actors and society at large as well (Bevir 2010). What has been said about political reforms – that the process of institutional reform only begins after its passing and implementation (Scharpf 1987, p. 144) – would appear to hold just as true for political innovations.

Much research on the social aspects of innovation focuses on learning. If learning is conceptualized as "socialization in routines of proven value" (Ober 2008, p. 19), there is indeed "an inherent tension between learning . . . and the redeployment of knowledge for innovation," and "too much learning can compromise competitive advantage" (Ober 2008, p. 19, 274). If, by contrast, the emphasis is on learning something new, innovation – or more specifically the successful dissemination of innovations throughout society – has convincingly been conceptualized as a learning exercise (Rogers 2003). However, as Richard Freeman has argued, ultimately the successful diffusion of an innovation is at least as much about teaching as about learning (Freeman 2006, p. 370). And indeed, teaching – in terms of public leadership advocating innovative solutions to collective problems – is at the very heart of innovative or, more precisely, innovating democratic leadership.

Innovating Democracy

The overarching aim of democratic innovations in different areas and at different levels of democratic political systems can be seen in "improving the quality of democracy" (Geissel 2010, p. 164). There is an understanding in the recent comparative literature that there is no compelling reason to count only those innovations as genuine innovations that have not been tried and observed anywhere else. A "relative newness," that is, the novelty of a given idea within the boundaries of a given system, tends to be considered a sufficient defining feature of democratic innovations. This seems reasonable; otherwise, there would be little to study. In particular, comparative research in democratic innovations would bereave itself the valuable and important opportunity to study the differing effects of similar democratic innovations in different contextual settings.

Kenneth Newton has usefully distinguished between "top-down innovations" and "bottom-up innovations" (Newton 2010): Top-down innovations tend to focus on political structures and processes, in particular on the institutions of democratic government that regulate the performance of politicians and make them more accountable and responsive to the general public. By contrast, bottom-up innovations tend to focus more on the input of citizens into the political system; they are primarily concerned with improving the capacities, knowledge and participation of citizens in order to empower them to play a more active part in public affairs.

Both of these two main categories comprise a host of different ideas and measures. Arguably the single most important distinction within the category of top-down innovations relates to innovations that center on *horizontal* accountability, that is, on the relationship and the accountability between the branches of government, and those centering on aspects of *vertical* accountability, that is, accountability of government to its citizens. Most ideas and measures relating to horizontal accountability are concerned with expanding the control capacities of parliaments and courts toward the executive branch. Ideas and measures seeking to improve the state of vertical accountability in democratic regimes are usually not confined to aspects of democratic responsibility but extend to the related area of democratic responsiveness. Term limits for elected representatives and the possibility of recalling them before the end of the regular term are examples for democratic innovations in this area (Newton 2010, pp. 7–8).

Democratic bottom-up innovations comprise a vast number of rather different measures and ideas. Some agendas seek to transform and expand voting rights regimes, for example, through reducing the voting age (with ideas ranging from slightly below the legal age of majority to voting rights from birth) or through providing noncitizen residents or even noncitizen nonresidents with affected interests with the right to vote. Such innovations in the realm of representative politics (many of which have not been put into practice anywhere) have been accompanied by expansive agendas that seek to break the monopoly of representative democracy through the introduction of new forms of citizen participation. Within this category, it is ideas for introducing and/or expanding direct democracy that possess by far the most impressive historical track record reaching back to the early days of the progressive era (Cain et al. 2003 pp. 5–6), and political scientists have to work hard in order to capture the latest developments and the growing pluralism in real-world democracies (Altman 2011). However, it is "co-governance," direct citizen involvement in the activities of the state, and other forms of consultation and deliberation that have found most attention among contemporary scholars of innovative democratic procedures (Goodin 2008; Smith 2009).

The ubiquity of projected democratic innovations in different countries makes it all but impossible to identify any clear-cut cross-national trend. However, as Michael Saward has observed, to the extent there is a common denominator, most democratic theorists and democratic activists share a special commitment to, and appreciation of, new ways of constraining conventional democratic majorities and ways of building new majorities of a special sort (Saward 2000b). There is also a broad consensus that even the most radically innovative ideas at the level of direct democracy and/or deliberative democracy would not, and should not, abolish representative democracy as the bedrock of contemporary liberal democracy. The future of representative democracy may be difficult and demanding, but there would appear to be no credible alternative to an institutional formation that has proven for more than 200 years to possess a resilience being unmatched by any other form of organizing individual and collective action (Alonso et al. 2011).

Some of the most serious challenges of the decades ahead relate to safeguarding the accomplishments of democratic development into what could be described as an age of unprecedented global interdependence. While democratic innovators in nation-states, or in subnational entities, can draw on the experience of neighboring states or communities, there is little, if any, lesson-drawing when it comes to designing and implementing innovative solutions to global democracy. All the more so, genuine and ingenious innovations in democratic institutional engineering will be needed to master the towering challenges of an increasingly interdependent world, and to use the power of innovation for the sake of democracy's futures.

Conclusion and Future Directions

Innovation and democracy are likely to remain important subjects of political and social research whose complexity seems bound to increase further. A considerable proportion of future efforts will have to be spent on linking different strains of political and social research on "innovation" that share little more with one another than the use of the same key term. There is a fast-growing body of research focusing on innovation policy (see, for example, Llerena and Matt 2010; World Bank 2010; Bauer et al. 2012) that has been consciously omitted from the brief overview above, mainly because it has evinced conspicuously little interest for democratic issues. Some authors of course have sought to reach beyond treating democracy as a mere background condition of innovation processes. For example, Eric von Hippel has looked more specifically into the possibilities of democratizing innovation processes. However, in his work "democratization" is understood to mean no more than "that users of both products and services – both firms and individual consumers – are increasingly able to innovate for themselves" (von Hippel 2005, p. 1), which according to this author applies to information products such as software as well as to physical products. There is ample room for introducing considerably more demanding conceptualizations of democracy and democratization to the study of innovation policies.

Another link to be established and developed is that between political research on innovation and democracy, and the quality of democracy. While the innovative capacity of different political regimes (for example, as described above, in terms of government alternation) has been acknowledged as a crucial component of a given polity's overall democratic performance in many classic contributions to political theory, innovation has failed to be specifically included in the numerous more recently construed indices of democratic quality. Some of the foremost challenges in this area relate to specifying what exactly a reasonable amount of innovation, or the absence of it, may actually mean for the democratic quality of different political regimes. As with, for example, transparency whose true relevance for the concept of democratic governance is brought to bear only in combination with accountability, innovation (as conceptualized above) would appear to represent not so much a goal in itself but rather a crucial means for achieving other meta goals of democratic governance.

Introduction

Entrepreneurship is an ambiguous concept unless it is contextualized. The focus in this entry is the role of the entrepreneur within the context of innovation. Thus, if a business activity is conducted under what Schumpeter (1939) calls "competitive capitalism," then there is no innovative activity and the market is operating as a pure neoclassical mechanism in which the "nirvana" of market efficiency in the allocation of goods and services is achieved. This is a static equilibrium position in which there is no change, no economic development, and no entrepreneurs to drive innovation. All that is needed are efficient business managers. As a result, in neoclassical economics, entrepreneurship is merely seen as agency in any form of business activity, including routine managers. This, in one fell swoop, conflates the original work of Schumpeter and his entrepreneur with the mainstream market conception of an entrepreneur who simply operates a business.

Baumol (1968, p. 1) rejects the conflation of managing a business and the higher responsibility of driving free enterprise:

> The entrepreneur is at the same time one of the most intriguing and one of the most elusive characters in the cast that constitutes the subject of economic analysis. He has long been recognized as the apex of the hierarchy that determines the behavior of the firm and thereby bears a heavy responsibility for the vitality of the free enterprise society. In the writings of the classical economist his appearance was frequent, though he remained a shadowy entity without clearly defined form and function.

The role of the entrepreneur has proved difficult to formalize within the innovation process. Well expressed by classical economics writers, notably Adam Smith and Karl Marx, Schumpeter (1912) reintroduced endogeneity of innovation in the capitalist process after the 1870s marginalist absorption of classical economics into the neoclassical mainstream placed innovation firmly into the "black box," making the entrepreneur invisible. Despite Baumol's oft-cited 1968 quotation above, due to the nature of the neoclassical model itself, economists have not been able to find a way to formally endogenize the entrepreneurial function. A very large increase in the number of innovation studies and the bringing of technology into the endogenous growth function still cannot fill in the gap. To his credit, Baumol has made attempts to incorporate entrepreneurial behavior into the economics mainstream. The task is not easy when a major intellectual in neoclassical economics needs three books to do this (Baumol 1994, 2002, 2010). While this effort is commendable, and in particular Baumol (2010) serves a useful purpose in further conceptualizing (along the lines of Schumpeter) the role of the entrepreneur in the economy from a rich vein of historical studies, the actual integration of the dynamic role of the entrepreneur in the static neoclassical model remains problematic.

Baumol models the decisions of entrepreneurs by an optimality algorithm where new and innovative entrepreneurial activities are subject to known constraints. If the economy is at an equilibrium measured in a static state, then the algorithm has a clear resolution, and the role of the entrepreneur is insubstantial. Leave it to the routine manager. At this equilibrium, a potential exit exists where the dynamic entrepreneur is in her/his element. It is an "escape hatch" from the static state. Where is Baumol's optimizing entrepreneur at this point? It is at this very point that optimality breaks down because there is no way any optimal algorithm can provide an answer to this exit point. There is no theoretically logical and consistent way of escaping static optimality unless a stochastic shock is devised, which removes the endogeneity of the entrepreneurial spirit. Baumol (2010, p. 70) himself admits this optimality problem by stating: "…nor does it provide any rigorous standards by which the issue can be judged."

The contradictions within the neoclassical economics model in addressing innovation and the role of the entrepreneur responsible for such activity lead to a lack of a rigorous research model for future study. In the next section, imperfection in the market is seen as the way out of equilibrium, but is in effect "no way out" from a theoretical perspective. Having rejected this standard approach, it is necessary to reconceptualize the entrepreneur within a realist complex systems framework. This is the task of the following section "Risk and Uncertainty" provide the appropriate concepts from which to further develop this realist systems model of creative entrepreneurship, as set out after the entrepreneur is clearly delineated. The impact of this systems model on business creation and the path of economic development complete the realist account. The conclusion then sets up a more fruitful research path for entrepreneurship studies within a more coherent economic framework than the bland characteristics-based studies that have multiplied in the literature and encouraged by the individualist-based neoclassical model.

Market Imperfections

Baumol (2010, p. 100) states: “In order to achieve optimality, one must eliminate the externalities and then correct any new, undesired redistribution effects that result.” This is the neoclassical market imperfections argument justifying public policy actions to “correct” for externalities and “address” inequality of distribution issues. Such actions brings one back to the static model and its inability to handle dynamic variables. What is the “correct” action if there is no rigorous standard to evaluate public policy actions? Thus, lack of an optimal endogenous entrepreneurial escape from the static state, although termed “market imperfections,” can be more accurately described as a systemic failure of markets (Smith, 1998). This failure leads to total inability of the neoclassical abstract market mechanism to provide theoretical understanding or empirical guidance for action.

Without the rigor of a static model to provide algorithmic precision, economists revert to metaphysical analogies (Robinson 1962) to provide what Taleb (2008, pp. 62–84) calls a “narrative fallacy” in order to provide some meaning and causality to an event that is not able to be given a rigorous analysis. The problem arises when a metaphysical narrative is presented to rationalize an axiomatically rigorous model. This occurred in a powerful way at a symposium on entrepreneurship in the Carnegie-Mellon University, Pittsburgh in November 1997, when two Nobel Laureates in Economics were on a panel and asked to depict how entrepreneurs operate in the context of equilibrium in the market mechanism. Each presented a starkly different scenario.

Architect of the general equilibrium model, Kenneth Arrow, describes entrepreneurs as “dragging” markets out of equilibrium by innovative activity that is inconsistent with providing the same type of goods and services. In effect, successful innovation disrupts equilibrium. Arrow continues by explaining that the process of moving back into equilibrium can be discerned when other entrepreneurs follow the “first-mover advantage” entrepreneur and diffusion of innovation occurs. This process of “follow the (innovation) leader” continues until the market becomes again one in which there is a homogenous product with many sellers meeting the demand of many buyers. The proliferation of such homogenous markets delivers a general equilibrium.

The inspiration behind the concept of bounded rationality, Herbert Simon, describes the same process in very different terms. Simon depicts the entrepreneur searching in a world of discontinuities for opportunities to innovate. The successful entrepreneur finds a new good or service that creates a fresh market into which other entrepreneurs quickly follow, but the rush to market by followers leads to only a temporary equilibrium in which supply meets demand. Followers will continue to produce leading to overproduction and disequilibrium. Such disequilibrating markets provide the basis for new discontinuities and, thus, new opportunities arise.

The two metaphysical analogies described above clearly show that the neoclassical market equilibrium approach with its imperfections arising from the innovative activities of entrepreneurs is an inappropriate framework of analysis. The rest of this entry addresses entrepreneurship and the role of innovation as a dynamic concept within a complex adaptive system (CAS). Holling (1973) identifies the strength of relationships within a particular CAS, such that the more stable a relationship within a complex system, the less resilience the system possesses. In this context, the maintenance of equilibrium within a system endows a system with greater stability, but with less capacity to absorb variations with significant fluctuations. The essential aspect of innovation is change, so a framework that can adapt to change from first principles is a much more appropriate vehicle to understand the entrepreneurial process and the entrepreneur how instigates this change. More recently, Archer (1995) has extended the CAS model by arguing that the behavior of such a system is not a simple and direct consequence from an external stimulus. As a system becomes more complex, it develops endogenous autonomous processes that determine its behavior, such as adjusting the system to better deal with external influences. This is a better approach to systematizing the endogeneity of the entrepreneurial spirit that so troubled Baumol across three books.

Entrepreneur

Schumpeter (1912) brings the endogenous entrepreneur onto the center stage economic analysis unlike any writer previously. The entrepreneur for Schumpeter must be seen as the human agency, via innovation, to economic development. It is this agency role that makes the development process non-deterministic and instead, adapting to complex changes: "The economy does not grow into higher forms by itself" he says. "The history of every industry leads us back to men and to energetic will and activity. This is the strongest and most prominent reality of economic life." (Schumpeter 1912, p.75) In other words, human agency via the entrepreneur is involved in effecting the innovations required for economic development.

In trying to understand the totality of the economy, Schumpeter divides economic processes into three categories or classes: "...into those processes of the circular flow; into those of development; and into those which impede the latter's undisturbed course." (1934, p. 218). Throughout his body of work, he refers to the processes of the circular flows in the market process as "statics," and those of economic development in which innovation resides as "dynamics." As Schumpeter states in his first published book:

> This distinction is crucial. Statics and dynamics are two totally different areas. Not only do they deal with different problems, but they use different methods and they work with different materials. They are not two chapters in the same theoretical construction – they are two totally different buildings. Only statics has been worked on sufficiently, and this book mainly addresses this kind of problem. The analysis of dynamics is still in its beginnings; it is a 'land of the future'. (Schumpeter 1908, p. 626, translation cited in Swedberg 2007, p. 30).

Schumpeter's thinking on that "land of the future" would emerge 4 years later in *The Theory of Economic* Development (Schumpeter 1912). By "circular flow" or statics, Schumpeter means that part of the overall economy that can be conceptualized as operating as a general equilibrium system under stationary conditions as proposed by the neoclassical economists. Within this system, commodity and product prices settle at levels that cause supply and demand in each market to be matched and *homo economicus* is rational and narrowly self-interested as he seeks to maximize his economic gain. Incremental quantitative growth is achieved through stimuli such as changing consumer tastes in conditions of gradually increasing population, saving, and capital accumulation. Importantly, there is no endogenous development that results in qualitatively new phenomena.

Schumpeter, by this distinction between statics and dynamics, places the entrepreneur clearly into the dynamic process and questions the role of the entrepreneur in the neoclassical model. Either neoclassical theory accepts that its statics is only a partial analysis of a more complex real system, and cannot, therefore, make valid knowledge claims about the entire system, or it is claiming that the entire real economic system behaves as a self-reinforcing system in static equilibrium that maintains itself. The former interpretation can be seen as a realist view on the static approach that qualifies any knowledge claims deriving from it. The latter interpretation is fundamentalist and susceptible to knowledge claims derived from static analysis techniques and, thus, questions the role of the entrepreneur within the neoclassical system.

In Chap. 2 of the second edition of *Theory*, Schumpeter describes the individuals who carry out new combinations as entrepreneurs.

He immediately qualifies this, saying the concept is broader than a single individual:

> . . .we call entrepreneurs not only those 'independent' businessmen in an exchange economy who are usually so designated, but all those who actually fulfil the function by which we define the concept, even if they are, as is becoming the rule, 'dependent' employees of a company, like managers, members of boards of directors, and so forth. . .(Schumpeter 1934, pp. 74–5).

The reason for this formulation is explained in a note to the second edition (1934) he challenges ". . .one of the most annoying misunderstandings that arose out of the first edition." This was the suggestion that, in a variation of the "great man theory," he had identified the individual entrepreneur as the prime cause of innovation and hence economic change. "If my representation were intended to be as this objection assumes, it would obviously be nonsense" he says and points out that his concern is not with ". . .the concrete factors of change, but the method by which these work. . ." An individual is ". . .merely the bearer of the *mechanism of change*" (Schumpeter 1934, p. 61n, emphasis in the original), or simply, the agency for introducing novelty into the organization. Such novelty is regarded by Schumpeter as disruptive to the current *status quo* in the production system, whether that is the firm, industry, or the economy. Schumpeter categorizes this novelty into five types of discontinuous development: introduction of new products and new production processes, opening of new markets, acquisition of news sources of inputs, and reorganization of firms or industry sectors (Schumpeter 1934, p. 66). All five types can be new to the organization, to the industry or even to the system widely. Entrepreneurs who introduce novelty into their organization are effectively conducting diffusion of innovation (Rogers 1995).

Schumpeter has an example of railways and mail coaches which provides great insight to this dynamic mechanism of change and the role of innovation. His concern is not with the nature of any underlying technology *per se*, but with changes in its economic use. Mail coaches and railways in the nineteenth century were the temporal stages of development in two distinct means of transporting goods and people. The former were wheeled and freely steerable on any surface hard enough for the wheels to turn without a resistance greater than the power of their locomotive force, typically a team of two, four, or six horses. Mail coaches were an incremental technological development of a transport tradition that can be traced back through Roman chariots to the earliest and simplest of flatbed wagons that must have quickly followed the invention of the wheel.

The steam-driven locomotives with which the Liverpool to Manchester passenger and freight services began in 1830 were also an incremental technological development, this time of wheeled vehicles running on a prepared track that bears their weight and guides the vehicles and acts as a limit to their range and direction. The origins of this form of railed transportation can be traced back to at least the Greeks and Romans (Lewis 2001). Even the steam engine was not new technology in 1830. The earliest engines were novelties invented by Hero of Alexandria in the first century AD and practical stationary engines had been undergoing incremental development since Thomas Savery's invention for pumping water in 1698. However, none of these incrementally developing technologies had resulted in the type of discontinuous economic change with which Schumpeter is concerned until the performance of George Stephenson's Rocket at the Rainhill Trials in 1829 demonstrated that a mobile version of a steam engine on rails could be used to transport large numbers of people safely over long distances at speed (Encyclopedia Britannica 1984).

Success of the steam locomotive resulted in an economic discontinuity caused by change in the way in which people and goods moved around Britain. Before 1830, the primary means of land transportation was by horse-drawn mail coach, and steam locomotives progressively displaced the coaches after that date. It was not new technology *per se* that had produced the change, but a new combination of existing technologies brought forward by the entrepreneur. Thus, what is "new" for the entrepreneur is not technical

I

knowledge, nor ability to finance innovation; instead, it is the skills and characteristics the entrepreneur brings to development in the sense of a transition from one norm to another which is not reachable through a series of incremental steps, i.e., when the change is discontinuous and disruptive. Conversely, he considers that "mere managers" have the ability to implement incremental change, i.e., that which *can* be decomposed into a series of infinitesimal steps. Since this, by definition, includes all incremental innovation intended to optimize processes or offer slightly improved versions of existing products and services, conclusion can be drawn that there is no role for the entrepreneur in such continuous innovation.

This interpretation is supported by concrete examples of how businesses organize for the two different types of change. For example, to bring a new product to market teams are typically formed outside the normal hierarchical management structure and only exist temporarily while engaged in this activity. Introduction of new products is one of Schumpeter's five types of discontinuous development. Once introduced as a new product, the tasks of launch, support, and maintenance (including release of new versions) is typically the responsibility of a permanent unit within the normal hierarchy of the firm. A similar situation prevails in software development, where a specially formed project team will carry out the development of new application software, while a separate support department will handle the subsequent maintenance and new releases. More generally, organizations implementing small process improvements to production or administration systems will normally entrust these to existing line management. It is only when attempting more complex and revolutionary process re-engineering that the task will be allocated to a specialist project team outside the day-to-day management structure.

The distinction in an organization is between the "dynamic" entrepreneur as a mechanism of change vis-à-vis the "static" manager as a mechanism of consolidation. Across organizations, Baumol (2010) makes clear there are two different types within the category of "dynamic entrepreneur." Crucially, and most importantly, there is the "true" productive entrepreneur as a person (or team) which is productive in a welfare-enhancing development process that adds to productive wealth. This is the type that Schumpeter envisages in his works. In contrast, Baumol recognizes also the "disruptive" entrepreneur who is unproductive since the activity being engaged is only rent-seeking, like identifying previously unused speculative or illegal opportunities. The term "disruptive" is used by Baumol in a subjective manner to indicate economic activity that is antisocial and unethical, while the same term is used by Schumpeter in an objective manner to indicate the outcome of discontinuous development. When used in the context of Baumol's subjective definition, the term needs to have quotation marks around it, i.e., "disruptive."

The "disruptive" unproductive entrepreneurs look initially to be adding value through employment or stockholder value, as did the entrepreneurs who innovated the sub-prime mortgages and collateralized debt obligations during the early 2000s (see Kregel 2008). Further down the track, such activity unravels into major costs to society and to the business community in general that far outweighs any initial positive value, as exhibited by the Global Financial Crisis that resulted in a banking collapse in September 2008, followed by the long-running "Great Recession" (see Arestis and Karakitsos 2010).

A question arises for the dynamic entrepreneur, be it productive or "disruptive." Is the change arising from innovation something the entrepreneur can calculate the risk of within the probabilities of failure and success? Or, instead is the change so novel and fundamental that no risk assessment can be made, leaving incalculable uncertainty in its wake that needs to be "managed" in the best way possible.

Risk and Uncertainty

There is much confusion in the entrepreneurship literature over the risk/uncertainty dichotomy, despite the clear distinction made in economics by both Keynes (1907) and Knight (1921). All the entrepreneurship textbooks identify entrepreneurs as being *risk-oriented*, but then emphasize that risk assessment is required in order reduce *uncertainty* on "wild chances" through business planning and preparation (Frederick et al. 2006, p. 31). This merging of the risk/uncertainty dichotomy distorts the entrepreneurs role, since "...[p]rofit arises out of the inherent, absolute unpredictability of things...that cannot be anticipated..." (Knight 1921, p. 281). The issue is that risk assessment is possible and recommended under continuous incremental innovation, where "things" are not unpredictable. Whereas, discontinuous innovation has such high level of uncertainty that risk assessment is impossible, with only some general scenario planning for different contingencies within a CAS is the only feasible approach. The risk/uncertainty dichotomy thus reflects the continuous/discontinuous distinction adopted in this entry based on the Schumpeterian perspective.

From this risk/uncertainty dichotomy, it transpires that the entrepreneur is not the same as the capitalist. Only the capitalist bears the risk of an investment failing. As Schumpeter (1934, p. 75n) makes clear: "Risk obviously always falls on the owner of the means of production or of the money capital which was paid for them, hence never on the entrepreneur as such." Some entrepreneurs are owners and thus take on risk and the role of capitalist, just like some entrepreneurs, as described in the previous section, can be technologists who take on the technical implementation. In this context, risk is an activity undertaken by the capitalist and not the entrepreneur.

What an entrepreneur takes on, Schumpeter argues, is the significant uncertainty involved in the introduction of new disruptive combinations due to the indeterminate nature of novelty. The depth of analysis typically required for the risk-oriented decision-making within the static state "circular flow" of incremental innovation is not available for discontinuous innovation due to the lack of relevant data for the latter decisions. The entrepreneur must, therefore, be comfortable operating with uncertainty and making decisions by "instinct" or "gut feel." This is related to another neoclassical axiom that is challenged in this continuous/discontinuous distinction. The axiom states all economic agents are rational and self-interested, which is essential for a robust equilibrium algorithm to exist. However, when there is discontinuous innovation, such a decision cannot be analyzed or rationalized in any coherent approach, since there can be no concept of rational choice in an environment of indeterminate uncertainty.

When it comes to entrepreneurial motivation, Schumpeter rejects narrowly defined hedonistic motives. Hedonism requires one to ignore uncertainty in the search for rewarding financial risks (e.g., trading on the stock market), whereas the entrepreneur needs to engage with uncertainty that requires much intellectual activity. In this context, entrepreneurs tend to be workaholics and "...activity of the entrepreneurial type is obviously an obstacle to hedonist enjoyment...usually acquired by incomes beyond a certain size, because their 'consumption' presupposes leisure" (Schumpeter 1934, p. 92).

At several points, Schumpeter draws comparisons between the characteristics of entrepreneurs and "mere managers" in the circular flow. Managers, in trying to keep their jobs and making an impact with the owners or directors, must consider that decision-making is based on the market and by the previous state of the business. Managers learn to read the signs, such as changes in demand from customers, from training and experience, and then adjust productive resources accordingly. Neither directing nor directed labor therefore exercises any real leadership over the business: The managers respond to consumers and workers respond to their managers. Day-to-day management of the business, in so far as it consists of adapting to normal fluctuations in supply of goods and services and the demands of customers, involves no creative input whatsoever and does not require handling uncertainty (Schumpeter 1934, pp. 20–2). In striving for the optimal methods of operation, managers tend to seek the best method of those that are familiar and have been tried and tested in practice.

The innovation decision-making of endogenous entrepreneurs under uncertainty occupies a different plane of activity. This is different because entrepreneurs in this world of uncertainty are one in which they elect the most appropriate method possible, which, by definition, may be untried, untested, and unfamiliar (Schumpeter 1934, p. 83). This means that optimizing rationality under *homo economicus* conditions is not an option. Such optimizing decision-making behavior is not an option due to the lack of data and inability to even identify where the data can be obtained (Courvisanos 2009). In this world of uncertainty, entrepreneurs conduct satisficing behavior under procedural (or bounded) rationality as explained by Herbert Simon (1976). This type of satisficing decision-making opens the door for new venture business creations that are truly innovative.

Business Creation and Innovation

Of course nothing in the Schumpeterian interpretation of an entrepreneur suggests that people who possess the ability to fulfill an entrepreneurial role may not be engaged on continuous innovation activities within the firm or organization. However, they are not acting as an entrepreneur when they do so and their entrepreneurial skills and capabilities are therefore latent and dormant. Neither does it mean that innovative entrepreneurial activity cannot take place within a firm; simply that business creation that is truly innovative has to consist of disruptive discontinuous change.

Throughout his career, the economic phenomenon that most fascinated Schumpeter was that of economic development, and it could only be seen in the context of history. As Michaelides and Milos (2009, p. 496) explain, "Schumpeter's notion of development is viewed. . .[as a]. . .theoretical approach of integrating theoretical and historical concerns." Schumpeter did not reject the usefulness of the popular equilibrium model as an analytical tool to analyze the stationary state of "ordinary routine work" (Schumpeter 1939, vol I, p. 40). However, he realized that the "circular flow" equilibrium of stationary capitalism with static markets could not explain the dynamics of economic growth.

In *The Theory of Economic Development* (Schumpeter 1912), three characteristics of economic development are specified. These three characteristics are the essence of disruptive business creation that Schumpeter calls "creative destruction." First characteristic of such development is the need to be endogenous to the economic system and not a reaction to external events or other stimuli. Second characteristic is based on business creation as discontinuous which does not occur in smoothly changing processes. In fact, Schumpeter explains it is at the trough of business cycles that such creative destruction is bound to be more successful, as there are around many failed previous continuous incremental innovations. Third characteristic is that such business creation is disruptive to the *status quo*, with old equilibrium conditions – and old competitors – all being radically changed. As a result, "creative destruction is the essential fact about capitalism" (Schumpeter 1942, p. 83) and the entrepreneur is the prime agent of this economic change. The endogenous stimulus is, Schumpeter argues, innovation which he sees as the creation of "new combinations" based around the five types of discontinuous development.

As his thinking developed, by 1942, Schumpeter was suggesting the disruption caused by innovation is traumatic, especially as new firms produce new products by innovative processes that puts old firms out of business. Such trauma led Schumpeter to predict that once these new businesses become powerful large capitalist firms, they will cease to be innovative, and this could threaten the viability of capitalism. Hamdouch et al. (2008) identify the integration of the two Schumpeterian models of small innovative entrepreneur and large firm "intrapreneur" into a new broader "networked" model based on strong collaboration and clustering activities using modern information technology. This network model has allayed the lack of innovation in emerging new industries like biotechnology (Hamdouch and He 2009) and software industry

(Salavisa et al. 2009), while established older industries like automotive and electrical appliances suffer from lack of disruptive innovation in order to merely fortify their market position (Buxey 2000).

From this economic development perspective, Schumpeter contends that expansion of credit is an important, but only secondary, part of the growth mechanism. Thus, the management of general levels of interest rates by central banks is ineffectual in stimulating recovery from a recession. Thus, with "quantitative easing" or lowering interest rates, firms reason that it better (as Schumpeter says) to cease:

> . . .to wonder why. In fact, it can be argued that the outcome is likely to be worse due to a two-fold dampening effect on the discontinuous innovation required to generate the growth required for the economy to emerge from recession. (Schumpeter 1935, p. 8).

Schumpeter (1935, p. 8) goes on to note that: '. . .any satisfactory analysis of the causes [of the cycle] must start with what induces that credit expansion. . .' and unless that credit demand is coming from entrepreneurs for the purpose of initiating discontinuous innovation, the expected economic development will not occur. Increasing the availability of cheaper credit to firms within the circular flow – as the US monetary authorities are doing to stimulate the economy out of a post-GFC stagnant malaise – will have the effect of, in the worst case, reducing costs, the benefit of which is returned directly to shareholders as companies seek to maintain their levels of dividend payouts to shareholders. In the best case, the reinvestment of profits stimulates investment in adaptive improvement which, by supporting the longevity of established businesses, reduces the likelihood of creative destruction occurring. In fact, the risk-adversity of firms in the circular flow and their reluctance to undertake any investment in recessionary conditions may tend to make the former outcome more likely than the latter. This is what Schumpeter refers to as the "two-fold dampening effect"; one is the increased dividend payout, the other is the reinvestment in minor incremental innovation.

A more effective monetary policy in recessionary conditions may be to hold general levels of interest rates steady while implementing policies to improve the flow of lower cost credit to potential entrepreneurs. Analysis of such a proactive policy is beyond the scope of this entry, but the objective would be to increase the flow of credit to dynamic discontinuous entrepreneurs while restraining the availability of credit to existing businesses.

Conclusion and Future Directions

This entry has taken a discernibly strong Schumpeterian perspective to entrepreneurship, since this perspective is the *only* rigorous approach that unites entrepreneurs with innovation without conflating the innovation process with simply the operation of a business. In neoclassical economics, there is no such clear perspective since it lacks an economic development approach, leaving entrepreneurship to be merely the organizing agency of the available resources of land, labor, and capital within a static equilibrium model. Instead, what is required by economic thought for future analysis is a dynamic complex adaptive model implied by Schumpeter with his description of innovative movement into disequilibrium. A growing body of evolutionary and neo-Schumpeterian economics provide this dynamic Schumpeterian perspective that has much to offer future economic analysis, but only if this "supply-side" is combined the "effective demand-side" work of Post Keynesians and Kaleckians on investment, consumption, and income distribution which determine how economic development out of innovation materializes (Courvisanos 2012b).

There are some significant implications that arise from the discussion above that provide clear suggestions for future research directions. One is systematizing endogeneity of the entrepreneurial spirit within a complex adaptive system and rejecting the static market equilibrium approach. This would then provide basis for better economic development models of national economies and major regions. Another suggestion is the role of the dynamic entrepreneur in combining existing technologies into new areas of activity that eventually diffuses such innovation to become major industries. This would then provide basis for better analysis of the role of the entrepreneur in the path of creative destruction. Third suggestion is based on satisficing decision-making under uncertainty that evaluates new venture business creations that are truly innovative. This would then provide basis for better understanding of role of uncertainty in innovation decision-making in the context of intuition and sensitivity to change. Final suggestion is based on the role of innovation in cycles and crisis, such that passive monetary policy to stimulate economies is ineffective. This would provide basis for distinctly proactive public policies that create "room to move" for new trajectories that reject incumbent powerful monopolies, but also do not eulogize small business operators (for more on this, see Courvisanos 2012a).

Introduction

Following the OECD Oslo Manual (2005), *an innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization, or external relations. [. . .]*

A product innovation is the introduction of a good or service that is new or significantly improved with respect to its characteristics or intended uses. This includes significant improvements in technical specifications, components and materials, incorporated software, user friendliness, or other functional characteristics. Product innovations can utilize new knowledge or technologies or can be based on new uses or combinations of existing knowledge or technologies. [. . .]

A process innovation is the implementation of a new or significantly improved production or delivery method. This includes significant changes in techniques, equipment, and/or software. Process innovations can be intended to decrease unit costs of production or delivery, to increase quality, or to produce or deliver new or significantly improved products.

Techniques from applied mathematics belong to the main drivers of product and process innovations. For a range of examples, see Levy et al. (2011) or RICAM Video (2007).

The typical steps in the mathematical treatment of an industrial problem are the following:

1. Ask the right questions.
2. Formulation of mathematical models for the relevant phenomena to be covered: Translate the industrial problem into a problem in mathematical language.
3. Calculate a solution of the problem, typically by numerical simulation on computers.
4. Interpret and verify the results.

In most cases, this is not a sequential procedure but requires several iterations. It may also happen that reasonable solutions for a specific problem cannot be obtained within reasonable time, within a given budget, or due to a lack of data.

An Example from Heavy Industries

Blast furnaces have been in use for iron production at least for the last 2000 years (Fig. 1).

Innovation by Applied Mathematics, Fig. 1 Blast furnace of the Chinese Han dynasty (Source: Private photograph)

A modern blast furnace may be in continuous operation for 10 years and may produce 5 million tons of metallic iron per year. Questions of interest are as follows:

- How does the chemical analysis of the iron ore influence the properties of iron and slag?
- How much energy/coke/hydrogen is used per day?
- Can the operator influence the daily production?
- Can the melting point of iron or the viscosity of the slag be influenced by additional materials like limestone? How can this be done methodically?

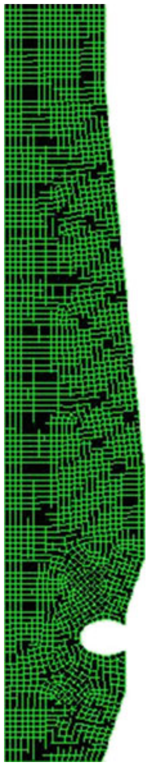
A mathematical model of a blast furnace covers the following phenomena:

- The flow of solid iron ore, coke, additional materials from the top to the bottom.
- The flow of reduction gas (hydrogen, carbon monoxide) from the tuyeres at the bottom to the top.
- A range of chemical reactions. To obtain a detailed understanding of the process, up to 40 or 50 chemical reactions and their kinetics have to be taken into account.
- Energy balance: The melting point of iron is between 1,400 °C and 1,500 °C. During the residence time of the iron ore in the furnace, its temperature has to be increased from surrounding temperature to the melting point.

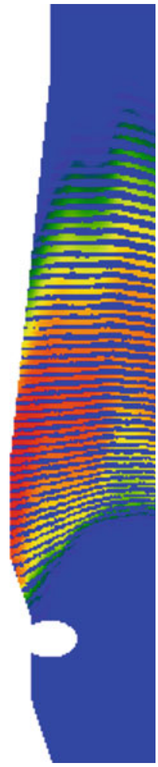
These phenomena are coupled: Chemical reactions may produce energy or consume it and may need a certain temperature level to start. Increased temperature influences the flow behavior of the solids; coke is finally burnt and thus changes from the downward solid flow to the upward flow of carbon monoxide and dioxide. The layerwise charging of iron bearing layers and coke is essential to avoid an obstruction of the gas flow.

The mathematical translation of these phenomena leads – by taking into account conservation of mass, momentum, and energy – to a system of nonlinear partial differential equations describing, e.g., the temperature or the concentration of iron oxide FeO of a point (x, y, z) at time t. These equations are coupled in the sense that, as an example, the temperature at a point is influenced by the history of particles reaching that point, and, on the other hand, the temperature is a main driver for the kinetics of chemical reactions.

The solution of the coupled blast furnace model cannot be derived by applying analytic formulae but has to be obtained by numerical techniques. For these, the calculation domain (the furnace) is meshed by a finite element grid (Fig. 2). It turns out that the simplification of



Innovation by Applied Mathematics, Fig. 2 Typical calculation meh in a 2D calculation (Source: MathConsult)



Innovation by Applied Mathematics, Fig. 3 Concentration of FeO. The highest concentration is reached in the *red* layers. Coke layers between are *blue* (Source: MathConsult)

rotational symmetry is reasonable, which decreases the computational effort significantly. Nevertheless, as the thickness of the iron ore and the coke layers have to be resolved, a typical spatially two-dimensional blast furnace simulation needs 800.000 unknowns for which the equations are solved.

The numerical treatment of these coupled equations requires techniques from fluid dynamics and from chemical engineering in combination with sound programming skills. Additional difficulties arise from the different time scales (the gas flow is 1,000 times faster than the solid flow) and from discontinuities between the layers.

The interpretation of the results and their verification by measurements may, at least during the first modeling iterations, lead to the insight that additional chemical reactions have to be taken into account or that other phenomena may be neglected without a significant change in the results.

Depending on the number of chemical reactions to be considered and on the size of the numerical grid, a real world process day is computed within 2–5 h on a conventional personal computer. The results show a very good coincidence with experimental measurements. For details, see Fig. 3 (Engl et al. 2007).

There are several innovations related to this kinetic blast furnace simulation:

– New operational conditions of a blast furnace (e.g., different raw materials, a different burden distribution, or a more aggressive firing with additional fuel leading to an assumed higher productivity) may be analyzed in advance by computer simulation before an operational strategy is chosen. Such computer experiments are typically much cheaper and environmentally friendly.
– In the plant engineering and construction, different geometries of blast furnaces may be studied.
– The online control and monitoring of a furnace may lead to a safer operation, longer maintenance intervals, and therefore a higher productivity.

Sources of Innovation by Applied Mathematics

The mathematical modeling of industrial processes by applying conservation principles from physics has a long tradition since the development of modern calculus from the nineteenth century onward. However, an accurate quantitative analysis of industrial processes by means of manual calculations is often not possible due to the nonlinearity or the complexity of the process.

With the breakthrough of computer power and computer availability during the last decades, the numerical simulation of industrial processes has become feasible for a wide range of applications. On the hardware side, standard personal computers of today are certainly 1,000 times faster and have 1,000 times the memory of expensive workstations in the late 1980s. Even smartphones are equipped with more memory.

For the rapid development in mathematical simulation of complex processes, at least two more pillars have been essential.

The careful analysis of numerical algorithms for (here) differential equations has led to new methods of solution techniques, which often require much fewer iterations than conventional solvers. Parallelization, multigrid techniques, and preconditioning yield additional orders of magnitude in calculation speed.

Of equal importance is the development in software design and the availability of tools for rapid prototyping of small and medium-sized problems. Modern software architecture leads to a better usability and reusability of mathematical software for different application fields and to better maintenance properties of mathematical algorithms.

Automotive Industries

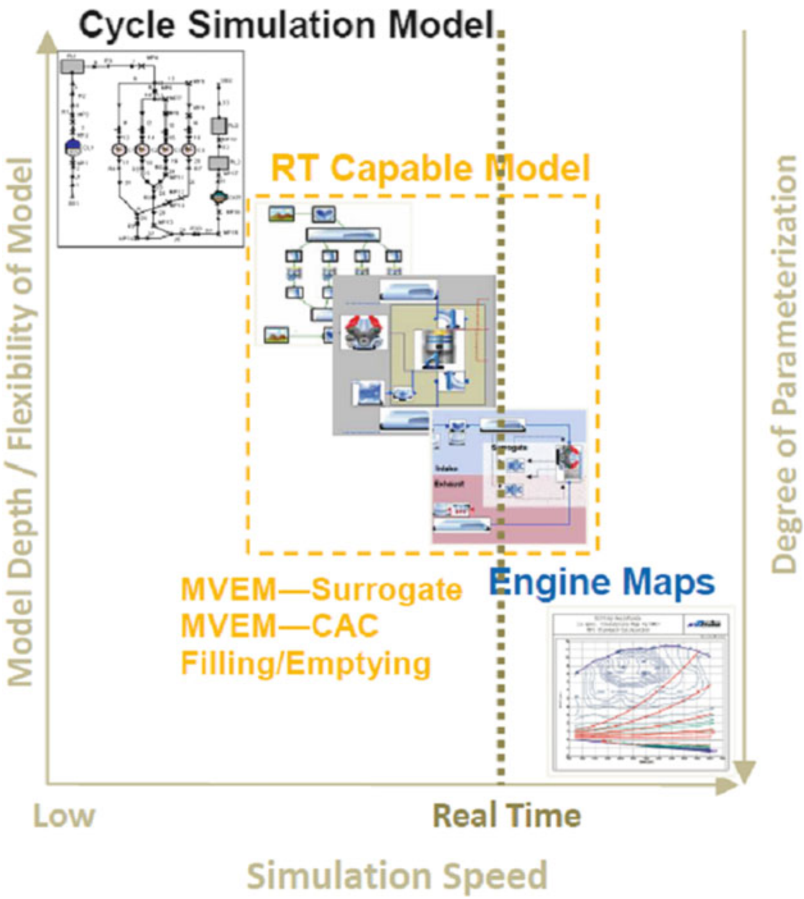
The technical specifications on modern cars are more and more demanding: Engines are either combustion or electrical engines or a combination of these. Although cars are significantly heavier than 20 years ago, fuel consumption should be reduced, the exhaust gas should satisfy tight environmental requirements, maintenance intervals are increased, and the safety of drivers and passengers is improved continuously.

Mathematical modeling and simulation in automotive industries are key factors to reduce development cycles, to optimize exhaust gas and its catalytic aftertreatment, and to adjust cars to the environment in which they are used.

Automotive simulation is also a good example to demonstrate multiscale modeling and different modeling depth (Fig. 4): For the detailed analysis of the combustion process, a three-dimensional fluid dynamics simulation will be necessary, which may take hours or even days to simulate a few combustion cycles; on the other hand, for the setup and optimization of the interaction between power train, gear box, wheels, brakes, and several more aggregates, a coarser modeling makes sense. So-called surrogate models, often realized as support vector machines or as neural networks, are used to obtain very fast input–output relations either from measurement data or by offline training cycles based on detailed simulation. In the past years, these surrogate models allowed to combine virtual engines and test beds of physical engines. Obviously, in such environments, the simulation software must be at least as fast as the physical motor and simulate each millisecond of physical time within a millisecond on the computer.

Mathematical Simulation in Medicine and Biology

Modern medical imaging would not be possible without mathematical computation. The basis of computerized tomography (by utilizing X rays in various directions) is the Radon transform, which was introduced by Johann Radon in 1917. Using other sources of waves leads to magnetic resonance tomography, electrical impedance tomography, or to medical ultrasound. When inverting raw data obtained from different imaging instruments, it is essential to take into account the noise characteristics of the specific instrument and to apply specific mathematical inversion algorithms.



Innovation by Applied Mathematics, Fig. 4 A schematic view of the relation between simulation speed and model depth in automotive simulation (Source: MathConsult and AVL List)

Systems biology is a relatively young biological discipline that claims to consider cells and organisms as entities in a holistic way. At the same time, it focuses on the interplay of components from the molecular to the systemic level. Quantitative measurements and recordings of biological processes are merged with advanced mathematical methods to yield predictive theoretical, mostly computational, models of biological systems. High mathematical complexity arises from the fact that the metabolism of the cell is the set of several thousands of catalyzed biochemical reactions resulting in molecular concentrations of a large number of substrates, products and enzymes as functions of time (Engl et al. 2009).

A major goal of systems biology is to provide an understanding of properties and behavior of cells or organisms emerging as consequence of the interaction of large numbers of molecules, which organize themselves into highly intricate reaction networks that span various levels of cellular or organismal complexity. The number of nodes in metabolic networks amounts to several thousand molecules.

Computational Finance and Risk Management

Computational finance, as it is widely understood in the mathematical finance community, deals with the valuation, the risk analysis, and the risk management of financial instruments like bonds, swaps, futures, options, and arbitrarily complex derivative or structured instruments (Albrecher et al. 2012). The necessary steps for valuating such financial instruments are as follows:

– Choose one or more models for the stochastic behavior of the underlying. This underlying may be the quoted spot price of an equity share, a Libor rate, or a foreign exchange rate.

– Determine the parameters of the model in a stable and robust way by utilizing market data of liquid instruments. Note that there may be severe traps hidden in this model calibration, which may yield misleading results.
– Valuate the derivative or structured financial instrument by applying numerical techniques. These are typically Monte Carlo techniques, methods form partial differential equations, or Fourier-based methods.

The requirements on the response times in quantitative finance are quite strict, so that almost real time calculation is needed.

The developments on the financial markets since 2007 showed that risk controlling and risk management need mathematical tools even mightier than those used at the trading floors in order to analyze market, credit, and liquidity risk properly.

Applied Mathematics and Education

It is observed that in high schools around the world, there are typically no real world problems to be solved, but intersections of planes are calculated, tangents on ellipses or hyperbolas have to be determined, or integrals have to be calculated by hand. (These are tasks that a computer (or even a cell phone) can do better.) For the sake of calculations, the steps (1), (2), and (4) of the Introduction are underweighted, and doing the calculations (3) lies in the main focus. See also Ziegler (2011), Wolfram (2010).

Doing more experimental mathematics (like in http://www.myphysicslab.com/dbl_pendulum.html) might bring curiosity back to school.

Conclusion and Future Directions

The mathematical modeling and numerical simulation of complex systems allow product and process innovation in a wide range of application fields. A few of these, in which the author was personally involved, have been mentioned, but there are many more areas in which research, development, and innovation are not possible without the heavy use of mathematical simulation.

While mathematical simulation has been used in physics, astronomy, and mechanical and chemical engineering since the emersion of computers, during the last years, heavy progress was made, e.g., in systems biology, drug design, and nanoscience.

The progress in modeling capability by a deeper understanding of the relevant processes and in computer hardware and algorithm development will allow problems to be tackled which today are out of simulatory reach.

Innovation in Business: Six Honest Questions

Anne Stenros
KONE Corporation, Espoo, Finland

Synonyms

Creative leadership; Design thinking; Innovation practices; Research and innovation

The Right Questions

> *Complex problems have simple, easy to understand, wrong answers.*
> Henry Louis Mencken (1880–1956)

> *I keep six honest serving-men*
> *(They taught me all I knew):*
> *Their names are What and Why and When*
> *And How and Where and Who.*
> By Rudyard Kipling, *Elephant's Child* (1902)

The fundamental idea behind creative activity and creative problem-solving – which is the cornerstone of innovation – is to question, that is, to ask the right question. Whatever the product, service, process, or solution, the crucial point is to answer the right question or rather questions. What, why, when, how, where, and who tell you everything essential that creative questioning includes. Deriving from the poem by Rudyard Kipling, these can be called *The Six Honest Questions*, with which one can achieve genuinely new answers and furthermore radical innovations that create something new. By answering deeply the questions of the six "serving men" about form, process, place, and time as well as competence and goals in addition to the user and the context, one can find the path leading to the future – the homeland of innovations.

Another way to examine this issue is to question the practices employed for seeking answers and to focus attention on those stages of the process and working methods which actually destroy creative thinking and prevent its development as well as, ultimately, the actual use of creativity and its realization. Ryan Jacoby, the head of IDEO, New York, has described *Seven Deadly Sins of Innovation* (Walter 2012) which in practice block the emergence of significant innovations. Most companies have processed the product development of innovation work, although the process as such does not guarantee the emergence of innovations – rather the opposite, in fact. According to Jacoby, the obstacles to innovation or innovation killers are the following seven business culture practices:

The Seven Sins of Innovation (as interpreted by the author)

1. *Thinking the answer is in here, rather than out there*. It is necessary to get out of the comfort zone in order to challenge the existing norm. One should look around and be open to external possibilities. In global competition, normal is not enough.
2. *Talking about it rather than building it*. Innovation should be an action, a verb, and an aspiration. There is a great slogan in the end of the famous IBM Innovation Man video: "Stop talking, start doing." Learning by

doing also speeds up innovation development since by doing so, one also has to apply tacit knowledge.
3. *Executing when one should be exploring*. Too often experts and managers rush forward when they should be taking a closer look instead, to study, to research, and finally to understand more profoundly the issue at hand. Making final decisions too early might lead to fatal decisions in long-term thinking.
4. *Being smart*. That will kill debate and block new ideas. Ideas are so fragile, as Jonathan Ive had said that you should protect them against intellectual attacks and indifference in order to keep them alive. Creative culture does not need "smarties."
5. *Being impatient for the wrong things*. Developing radical innovations takes definitely more time and resources than developing incremental ones. There should be a match between what is expected and what can be achieved.
6. *Confusing cross-functionality with diverse viewpoints*. Diversity is a key to innovation; different functionalities do not guarantee diverse approaches if the people do not have genuinely different backgrounds and competences.
7. *Believing process will save everything*. This is the most fatal single sin: trusting in the process to solve the problems and generate innovations. Many innovations happen by accident or they are done by taking another path rather than following mainstream thinking and processes.

True creative leadership, which is a prerequisite for innovation work, is by nature a visionary searching, guided by genuine, right, and honest questions. It does not follow predetermined processes and formulas but rather proceeds by questioning both methods and practices, finding its own genuine and unique path.

What: First Versus Fast Follower

Most national and regional innovation programs emphasize customer-oriented innovation and the importance of the customer-centered design that supports this. Different types of user experience tests and usability-simulation methods solidify the notion of the customer's omnipotence: people first! In the worst case, this situation leads to responsibility for developing products and the product needs actually being transferred to the end users, whose needs and wishes are then directly implemented in products and services – without ever questioning their true rationality, needfulness, and sustainability.

Two famous architects have decided on the opposite approach in their work, and both have attained a reputation as superb, visionary designers among the public and professionals alike. Architect Frank Gehry has wisely observed (Bell 2012):

> You can't just build a building based on what the clients say, because their vision is based on what's normal. How do you get out of the normal? You've got to question everything. Spend time with the user group. Glean all the information you can. And then throw it all away and begin to play.

Many gradually developed product improvements and small-scale innovations can emerge through the customer's wishes and insights – but real, radical, and creative innovations demand the ability to see further into the future while simultaneously still understanding the users' need continuum. Without "throwing ourselves into the creative play," it is impossible to detach oneself from the convention and step outside the comfort zone, which is where significant new insights and innovations emerge.

It is also a question about corporate culture and the role of the company: does it want to be first or a fast follower? The latter depends literally on the customer as, when asked, the user usually says he wants something like his "neighbor" – that is, a competitor – has. The first-mentioned builds his products and services on the foundation of a vision and turns it into a story which also extends into the future. Products of this kind, which look creatively into the future, change and revolutionize the world, creating new-generation products, services, and users.

The same creative freedom and the responsibility it entails were referred to by architect

Louis I. Kahn in the following quotation (Johnson 1975):

> I don't believe in need as force at all. Need is a current, everyday affair. But desire – that is something else again. Desire is the forerunner of a new need. It is the yet not stated, the yet not made which motivates.

Gehry's juxtaposition of the ordinary with the special gains support from Kahn's emphasis on the time dimensionality of innovation from the present into the future. A need-based product is already in existence – but a desire-based, aspirational product or service is the forerunner of a new need, thus pointing strongly into the future. It is something which has not yet taken on a concrete form; it is something which is still on the way. In innovation work, these "forerunners" Kahn refers to are signals of change, out of which significant new drivers in products, the economy, society, or culture may emerge. By understanding these drivers of change, it is possible to navigate to the future and create new, currently hidden future needs.

The desirability of Apple products and services is based on the fact that the company has succeeded, time after time, in surprising its users positively with new and unique products and services which have no predecessors in history. The crucial characteristic of innovation is that it surprises – usually even the person who made it – with the power it gains among users in the market as well as in the influence it ultimately has on the way of life and on society. Apple's products and services are a good example of how innovations can create new, emergent needs and transform familiar practices.

Why: Exploring Versus Executing

Questioning is part of the very core of innovation work: it forms the critical framework against which the assigned task, the problem itself, and any demarcation are tested. The most innovative team never accepts the problem as such as their starting point, preferring to ask each time: why this question in particular? Why-questions are among the toughest conundrums in science; by their nature, they are explanatory of a phenomenon and not descriptive of it. It is harder to ask the question why something is meaningful than to describe how it is meaningful. When profound questions have to be faced in innovation work, the answer cannot be only on the product level; the solution also takes a stance on its social influence and even its potential impact on human behavior. Social innovations are usually answers to why-questions and to great challenges: in addition to individual solutions, they also take a stance on the general social and philosophical-ethical discussion.

To creative people, why-questions are important: with them, creative curiosity is channeled toward new, unknown regions to discover what is essential in the answer. Core questions also generate far-reaching replies. These are so-called killer questions, which point beyond conventional solutions. In the future, more and more frequently, the race will go to boldly and profoundly phrased questions – not answers that lean on the normal and conventional.

Answering why-questions also creates new experiences for users. Power questions often lead to "killer applications," that is, products and services that change human behavior and the value chain paradigm. Sohrab Vossoughi, Ziba's founder, president, and chief creative director, has said (Vossoughi 2012):

> What Apple offers is an Apple experience. There is no equivalent Samsung experience. Crafting a consistent, compelling experience is extremely difficult. It takes nothing less than company-wide commitment to a purpose and a vision of what the world ought to be like: how it should look, feel, sound, and evolve over time.

> *I send them over land and sea,*
> *I send them east and west;*
> *But after they have worked for me,*
> *I give them all a rest.*
> By Rudyard Kipling, *Elephant's Child* (1902)

When: Flux Versus Flexi

Years ago, in the futurologists' conference, inventor Ray Kurzweil opened a talk by saying: "*Timing, timing – timing*." One of the most important elements of inventions and innovations is their timing: if a product or service is too futuristic, it will be left unexploited; on the other hand, if it is behind the times when it enters the market, it will no longer meet the criteria for innovation as it has no novelty value.

Today we talk about the flux environment of constant change in connection with business and innovation work. This means that long-term planning is almost impossible and that innovation has to be of a flexible, rapid, and agile nature, taking advantage of opportunities opened up by various situations. Reading the signs of the time correctly will rise in importance as a central part of the new creative activity. We will need more and more understanding of the future direction in support of creative product development and innovation work.

In his book *The Act of Creation* (1964), Arthur Koestler wrote about how a creative invention or innovation demands the right spirit of the times, "ripeness," for it to become possible and to win the acceptance of society (Popova 2012):

> The 'ripeness' of a culture for a new synthesis is reflected in the recurrent phenomenon of multiple discovery, and in the emergence of similar forms of art, handicrafts, and social institutions in diverse cultures. But when the situation is ripe for a given type or discovery, it still needs the intuitive power of an exceptional mind, and sometimes a favourable chance event, to bring it from potential into actual existence. On the other hand, some discoveries represent striking tours de force by individuals who seem to be so far ahead of their time that their contemporaries are unable to understand them.

The correct timing of an innovative product and service demands background work and above all vision, without which even the best idea cannot hit the "nerve of the times" and create new markets or reach new users through new needs.

The clock speed of corporate research and innovation work could as well be ahead as behind. Only the most visionary leaders can read and recognize the signs of the times correctly and respond to them in an anticipatory way time after time – mastering flux.

How: Navigating Versus Planning

Maps surround us and guide us – Google Map, GPS location, navigators, personal navigation systems (PNS) – these are all linked materially to travel today, on land, sea, and air. Actually, cartography has become one of the great innovation potentials for the future. Smart phones have put the user in the mobile map hub, unlike in the past, when the central hub of maps was always a fixed geographical spot where everyone wanted to be. Simon Garfield has pointed out (Thorpe 2012):

> The amount of interest in maps and globes at the moment has probably got something to do with the fact that we are all able to find ourselves on maps now at the touch of a screen. – It used to be Jerusalem that was placed at the centre of Christian maps, or in China, it would have been a place called Youzhou. Now for the first time we are all at the centre.

The mapping of the world and voyages of exploration have a long history. There was a time when possession of a map also meant power, like the great seafaring nations and trading cities. Metaphorically, one can also chart the future with voyages of exploration. Like explorers, it is possible to develop skills and knowledge with which to understand and navigate flux and the opportunities of the future. In his book *Futuring: The Exploration of the Future* (2004) Edward Cornish recognizes seven characteristics in the work of explorers which are also significant in probing the future (Cornish 2004).

The seven lessons of the great explorers (as interpreted by the author):

- *Prepare for what you will face in the future*. One cannot forecast the future with certainty, but the more one study the possibilities of the future, the better one is prepared to face it. This applies also to the constant change or flux.
- *Anticipate future needs*. This means to be aware of what kind of competences and capabilities is needed next. Old tools can hardly craft tomorrow's products and services. One should also be aware of the changing environment; what applies today will not necessarily apply tomorrow.
- *Use poor information when necessary*. Fuzzy logic is the essence of creative work; there is no definitive right or wrong answer for many of the questions related especially to radical innovations in their early stage. Creative work is built on possibilities and probabilities.
- *Expect the unexpected*. One should not be afraid of facing the strange and the unknown,

that is, the land or seas of truly creative and revolutionary ideas. The further the distance, the bigger the resistance by mediocrity.

- *Think long term as well as short term.* There should be the good understanding of the life cycle and the impact of solutions – great innovations are also sustainable, they support economic, environmental, and social balance for years to come.
- *Dream productively*. Even super-ideas must have their roots somewhere. They should have good soil for growth potential that will nurture their blossoming. Sometimes grassroots are the best ground for high-growing ideas and their implementation.
- *Learn from your predecessors.* Tacit knowledge is something that cannot be bought with any amount of money. The better the teachers there are, the better the understanding one can develop. Great minds have a lot to give.

Visionary innovation leaders have never respected known borders: they are not afraid to cross the boundaries between sectors, to blend divergent methods together, or to open up new perspectives. They have an inborn ability to integrate different scales, large and small, rational and irrational data, short- and long-term goals, as well as facts and visions. They chart the unknown, in many ways and from many directions, creating a unique, visionary whole. Creative leaders are today's cartographers, whose maps lead one into unknown waters with vision as a beacon. This is why they are trained to meet the challenges of a changing environment and to exploit them – according to the situation and in a timely manner.

> *I let them rest from nine till five,*
> *For I am busy then,*
> *As well as breakfast, lunch, and tea,*
> *For they are hungry men.*
> By Rudyard Kipling, *Elephant's Child* (1902)

Where: Openness Versus Ownership

In the future, research and innovation work will become increasingly open and global as well as decentralized and mobile. This will mean that companies will seek research partners where the best global expertise is found. Decentralized research will also support a new feature of corporate innovation work, that is, close presence and collaboration with its research and product development organizations located around the world. The 24-h clock speed of companies' product development work will require innovation no longer to be concentrated in a single, large research center, but rather it will be operationally fragmented worldwide as needed. Companies will increasingly seek research partners in various "creative centers" – urban innovation hubs, more and more of which will constantly be formed. Future innovation work will also be "brain hunting," in which individual talented people will be found both locally and globally. In all, it will be a matter of optimizing local and global manufacturing and research relative to the available and necessary creative capital.

Open research and innovation work will also necessitate open science, which means open data and open access to data such as transparency of publication as well as citizen science and participatory research. Open science will raise the standard of research, making it more transparent and raising its profile, thus accelerating the development of science as a whole. Ideally, open science will unite the common goals of professional researchers and those of (professional-) amateurs in the form of collaboration for the common good.

Another part of the future's open research and innovation ecosystem will be an open and innovative educational system, which will be geographically within reach of everyone through the Internet (Dizikes 2012).

> "This is the new classroom", as Professor Anant Agarwal, president of edX, said when showing a picture of Mongolian students, studying with the aid of edX online course materials, to the audience at the "Future of Education" conference. EdX is a not-for-profit enterprise of its founding partners Harvard University and the Massachusetts Institute of Technology that features learning designed specifically for interactive study via the web. Along with offering online courses, the institutions will use edX to research how students learn and how technology can transform learning–both on-campus and worldwide.

Both mentally and geographically, research and innovation work can today be done almost anywhere. In China, for example, the future innovation ecosystem is being dynamically developed through such things as redirecting research centers to think tanks. China is also encouraging both social and innovative entrepreneurship more than previously.

Future generations will learn and do research side by side, in a multicultural environment and simultaneously in many places around the world. With the help of the new networked model, teaching and research work will be more efficient and will have greater impact with the same resources. The most important influence, however, will be in the social dimension of the results: how well new innovations serve society and how broadly they affect people's living conditions, behavior, and culture.

> *But different folks have different views;*
> *I know a person small –*
> *She keeps ten million serving-men,*
> *Who get no rest at all!*
> By Rudyard Kipling, *Elephant's Child* (1902)

Who: Mavericks Versus Managers

The strategic application of design – *design thinking* – has gained ground in the past decade, not only in the development of products but especially in the development of service innovations. Companies have created the same kind of processes for design as for product development or manufacturing, in order to integrate and streamline its impact. However, regrettably often this has led to an opposite trend: the narrow-based use of design as one element in assuring a product's attractiveness and quality. Many leading thinkers of design have recently begun to talk about creative capital or creative leadership instead of design management and design thinking. A rising trend is to understand the total significance of creativity in research and innovation work: in ideation, research, processing, implementation, and even use. Creativity with all its dimensions is the connecting thread running through all innovation development.

The Creative Industries KTN in the UK has carried out extensive research on future priorities in innovation from the perspective of Britain's competitiveness. The research focuses in particular on the growing importance of experience-led innovation which is based on a deep understanding of human behavior and its drivers (The Creative Industries 2012).

Experience-led innovation is based on the notion that the producer of an innovation and/or designer takes first responsibility for designing a product or service. This takes place by deepening the understanding and vision of what people really expect from the future, but which they are not yet able to recognize and express explicitly. Experience-led innovation plumbs deep waters, seeking answers with the help of all six "honest serving men": the questions what, why, when, how, where, and who.

Today design is understood as a central, essential part of innovation, not only for consumer goods but also for many B-to-B products. Technology alone is no longer enough of a competitive edge – instead, companies stand out from the competition primarily through high-end design. Also in user interfaces and in the user experience, design plays a central and constantly growing part. When demand intensifies between well-designed technology products, it can already be seen that even design is no longer enough on its own to differentiate the product and make it desirable in the eyes of the user. This sparks the question: what next?

John Maeda, President of the Rhode Island School of Design, has recently stated how the requirement for good design will expand "beyond" the potentialities for design in the future and how the next vital innovation factor will be art – or rather the uncompromising stance of artists, creative individuals, and their passion for their work, reflecting their profound values continuum and their strong commitment. Maeda has said (Maeda 2012):

> But what people want today goes well beyond technology and design. They don't just want four wheels and a means to steer, or to be surrounded by music and information wherever their eyes and ears may roam. What people are looking for now is a way to reconnect with their values: to ground how they can, will, and should live in the world. – The innovation now needs to occur elsewhere. Outside the design. Into, quite frankly, the world of art.

According to research called *Artistic Interventions for Innovation* (2012) in the CreativeClash program carried out by the European Union, artistic intervention has a generally positive impact on innovation and especially in the following three cases:

- *Developing services, products, and processes innovation*: disruptive thinking, creative approaches, and new methodologies of interaction generate new ideas.
- *Supporting social innovation*: improving social relations among employees and enhancing new skills contribute to creating better working conditions, social cohesion, and inclusion.
- *Rethinking ways of relating to users and communities*: artistic processes help identify or refine corporate culture and values, supporting the development of creative communication strategies.

But above all, the passion and unremitting stance of creative individuals is the factor that makes the difference. Creative individuals' desire to ask tough questions and to find tough answers – their ability to seek the truth is unmatched. Maeda describes this complexity as follows (Maeda 2012):

> Designers create solutions – the products and services that propel us forward. But artists create questions — the deep probing of purpose and meaning that sometimes takes us backward and sideways to reveal which way "forward" actually is. The questions that artists make are often enigmatic, answering a why with another why. Because of this, understanding art is difficult: I like to say that if you're having difficulty "getting" art, then it's doing its job... The artist needs to understand the truth that lies at the bottom of an enigma... Art speaks to us as humans, not as "human capital." Art shows us that human beings still matter in a world where money talks the loudest, where computers know everything about us, and where robots fabricate our next meal and also our ride there. Artists ask the questions that others are afraid to ask and that money cannot answer.

According to the current concept and practice, innovation is not exclusively produced by engineers – it is a joint development (co-creation) by engineers, designers, and researchers, a multidisciplinary team of science and economy. In the future, this multidisciplinary sphere of innovation will also include artists and independent, creative individuals with the ability to see intuitively into the future, to build a vision and to navigate there, at the same time serving as a catalyst in transforming the innovation culture. Future innovations will be made in a genuine multidisciplinary environment, in the nexus of art and science, technology and design, and natural sciences and anthropology, where ideas that transform the world and our understanding of it will be enriched and refined.

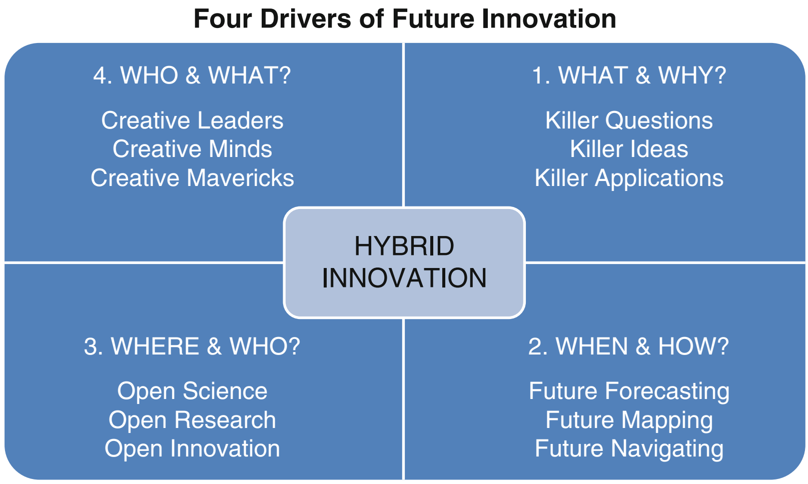
Because of the extensive availability of data (everyone has access to the same data), competition over ability and talent (editing and application of data) will intensify in innovation. In reality, we are already moving on from an information-based innovation system to a talent-based system. It has been found in many contexts that competition for talent will be the core of innovation work in the future, as innovation will tomorrow be primarily the work of pioneers – mavericks, who are independent thinkers and incorruptible visionaries. They will open the window to the unknown and take development forward. They will be at once interpreters and cartographers of the future. Many artists are by nature independents of this kind, going their own way, rather difficult members of the working community – but they are essential to innovation precisely because of their bold characters and visionary attributes. As Bob and Gregg Vanourek has said (Vanourek 2012):

> Mavericks are the independent innovators or performers – often quirky – who do not run well with others. They think and act differently. Many mavericks take mischievous delight in shaking things up... Mavericks can be exceptional innovators, critical in our ultracompetitive world.

> *She sends 'em abroad on her own affairs,*
> *From the second she opens her eyes –*
> *One million Hows, two million Wheres,*
> *And seven million Whys!*
> By Rudyard Kipling, *Elephant's Child* (1902)

Future: **Six Honest Answers**

Many successful innovations of the future will be social by nature – meaning that they will have



Innovation in Business: Six Honest Questions, Fig. 1 The hybrid innovation model. Four drivers of future innovation based on the six honest questions (Source: Anne Stenros 2012)

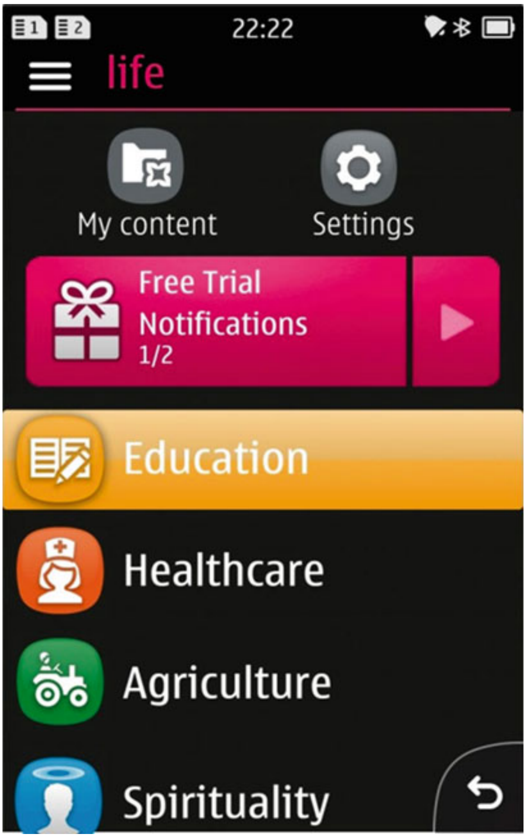
a significant impact on society. Tomorrow's innovations will be sustainable in nature – that is, they will change human behavior and habits for the better and improve the quality of life. Significant innovations of the future will also be the best examples of transformation between technology and art, science and art – they will be not only of instrumental value to their users but their significance will itself be greater than their practical value.

However, the most important innovations of the future will most often be hybrid models, in which, for example, collaboration between art and technology or art and science generates a social innovation. These hybrid innovations will also provide a solution to the great global challenges: environmental questions, the trend in urbanization, food and water supply, and renewable energy sources. Hybrid innovations will also in general answer all six honest questions – with profound and honest answers (Fig. 1).

Of the social innovations made possible by technology, more and more will come from the bottom of the "pyramid," that is, from developing countries and from the needs of their populations. A good example of this is the Nokia Life service (2009), which featured India-focused, hyper-local, SMS-based service and content production for people in developing countries. The service is intended for the 1.2 billion people who do not have phones with data communication capability. The basic idea of the service is that access to information and data supports and makes it possible to improve people's lives and living conditions. The starting point is content-driven design and the aim is to create social experiences around increasing and distributing information.

Nokia Life services involve education, health, agriculture, and entertainment. The service producers include local ministries, NGOs, and international specialist organizations. A mobile phone gives the user access to learning content for school grades and English and local information about various everyday matters such as health, weather conditions, and selling prices of agricultural produce. The service does not aim to make a profit, and income is ploughed back into further developing the service. The innovative service now has some 80 million users in India, China, Indonesia, and Nigeria (Fig. 2).

A classic example of an innovation spanning the boundaries of modernity, technology, and art is the BMW Art Car concept dating back to 1975. What began as a one-off artistic experiment by Hervé Poulain has grown into a considerable collection over the decades. Poulain, who was enchanted by speed and its beauty while taking part in races at Le Mans, first invited four artist friends – Alexander Calder, Frank Stella, Roy Lichtenstein, and Andy Warhol – to paint BMW racing cars. Since then, artists including Ernst Fuchs, Jeff Koons, and Olafur Eliasson have added their visions of speed to the BMW Art Car collection. The end result is the



Innovation in Business: Six Honest Questions, Fig. 2 Nokia life tools (Photo credit: Nokia)

transformation of a practical object into a work of art – the conversion of concrete into conceptual, everyday into timeless, and technology into pure art. In its essence, the Art Car – concept is all about humanizing technology – giving a face and personality to the anonymous (BMW Classics 2010) (Figs. 3, 4).

A good example of a new kind of pioneer, an independent creative, is artist/designer/inventor Thomas Heatherwick, whose diverse output is astonishing in its innovativeness. Heatherwick combines technical wizardry with artistic vision and functional implementation in an extraordinarily interesting way. A famous example of his work is the sculpted, rolling bridge; the aim of which is to make movement itself a particular feature of the bridge (Fig. 5).

Multidimensional innovations may appear just as much among services as in products. The world-famous chef Ferran Adrià, who is renowned for his experimental cuisine and creative cookery, has started the elBulli Foundation in connection with his restaurant – "a centre of innovation allied with digital technology that would rethink haute cuisine in a way that would offer other creative endeavours a road map for innovation." According to Adrià, in cooking as in business or art, there is no process without an idea. The foundation focuses on understanding the nature of creativity and its fundamental question: where do ideas come from, and how do we best foster them? As Adrià has said it by himself, "Creativity is important. Innovation is also important. But the capacity to transform yourself is even more important" (Williams 2012).

Adrià's work has always been characterized by experimentation and a radically innovative take, and this has made him a leading name in his field. In accordance with its character, an innovation center must break barricades: Adrià aims to unite science and art and philosophy and technology "into a creativity-generating universe," which will yield today's most valuable raw material: creativity and talent. In accordance with the experience of the elBulli restaurant, operations are guided by five subdivisions: organization, philosophy, products, technology, elaboration, styles, and characteristics (Williams 2012) (Fig. 6).

A pioneer of the future's multidimensional hybrid innovations is *Little Sun*, a small and simple portable flashlight using solar energy, which is also an everyday art object. The lamp was designed by artist Olafur Eliasson, who is famous for his treatment of light in his works. *Little Sun* is intended particularly for conditions in developing countries where grid electricity is not available. The object combines the latest LED technology and artistic vision in a way that creates something new. The lamp makes it possible to work and read after sundown without electricity, which is beyond the reach of one fifth of the human race. Eliasson believes his Little Sun can change these people's lives in a positive way. A 5-h charge in sunlight provides 5 h of light in darkness (Fig. 7).

Innovation in Business: Six Honest Questions, Fig. 7 Little Sun lamp by Olafur Eliasson (Photo credit: Little Sun)

Eliasson himself replied in an interview in The Guardian to the question of why he got started on this social innovation project (Higgins 2012):

> Art is always interested in society in all kinds of abstract ways, though this has a very explicit social component. The art world sometimes lives in a closed-off world of art institutions, but I still think there's a lot of work to show that art can deal with social issues very directly... People want beautiful things in their lives; they want something that they can use with pride . . . everyone wants something that's not just about functionality but also spirituality.

Little Sun superbly and profoundly answers the six honest questions:

What – a light for life

Why – improving the quality of life and inspiring to change

When – extending the hours of daylight in darkness by enabling more time for daytime activities

How – by transforming technology through art into an object of delight beyond its practical use

Where – giving access to light in areas not on the power grid

Who – to be used by those who are in the bottom of the pyramid, in this case 20 % of the world's population

As Olafur Eliasson sums up by himself: "An artwork is never just the object; it is also the experience and its contextual impact, how it is used and enjoyed, how it raises questions and changes ways of thinking and living. The same is true of Little Sun."

Future innovators will be creative leaders, creative individuals and creative mavericks who make their visions a beacon to others so that we can guide ourselves toward a better tomorrow for individuals and communities alike. Their role is to keep the light of creativity alive.

> *It is also a way of using the Little Sun to guide yourself, as*
> *if it were an eye*. – Olafur Eliasson

Conclusions and Future Directions

In today's world, the future is mostly unpredictable. However, the further we look, the better we will understand the transformation we face. The complexity of the everyday and great challenges calls for increasing creativity in solving problems sustainably. A new breed of hybrid innovations is emerging from demanding surroundings: responsible innovations which are capable of answering all the questions. In the future, art and science will bridge the gap between two different ways of seeing the world – and solve the problems of coexisting for the benefit of all. Creative industries will have a stronger say than ever before in building a better future and well-being. More artist-innovators – Leonardos of today – are on the way.

Innovation in Defense Technologies

Guy Ben-Ari

Synonyms

Defense technology; Military technology

Introduction

Innovation in defense technologies has traditionally been both a driver of invention, creativity, and entrepreneurship and a beneficiary of these. Technology and knowledge acquired in the development of defense goods, services, and processes were critical elements in the development of commercial technologies, and civilian innovations have contributed greatly to new defense technologies (Ruttan 2001). This entry covers the topic of innovation in the context of defense technologies. It will first briefly discuss defense innovation as a public good. It will then present the concepts of "demand pull," "technology push," "spin-off," and "spin-on" in a defense innovation context. Lastly, this entry will use these concepts to present two models for thinking about innovation in defense technologies. Note that this entry does not cover social innovations for national defense, i.e., innovations in the way defense establishments organize for and fight wars, as expressed in their organizational structures and in military doctrine, strategy, or tactics.

In discussing innovation in a defense context, it is important to accept that national defense is to a great extent an exceptional case in economics and public policy. As an almost pure public good, defense is nonrival (consumption by some does not leave less for others) and nonexcludable (nobody can be excluded from consuming it). As a result of the free-rider problem that exists for all public goods, public investment is a key element in the provision of national defense, and this also holds true for defense innovation. In effect, the benefits of an innovation that contributes only to national defense will not be captured by the entity delivering it. Furthermore, since the ability and legal right to acquire and wield military capabilities reside almost exclusively in national governments, the customer base for defense technologies, and therefore also of the creative and entrepreneurial processes that deliver them, is very limited. Essentially, the market for innovation in defense technologies is a monopsony with buyers almost completely dependent on – and reactive to – the end customer (Dombrowski and Gholz 2006).

"Demand pull" refers to the desire of users of defense technologies – whether they are national governments or nonstate actors – to access technologies that will contribute to achieving swift and decisive victory against an adversary. Ideally, these are technologies that an adversary is not aware of and/or cannot defend against,

I

thereby creating what Lorber has termed "technological surprise" (Lorber 2002). However, such groundbreaking technologies are few and far between, and the more common demand is for defense technologies that will improve an organizations' ability to conduct its defense missions. "Demand pull" may also occur as a result of intelligence gathered on the capabilities of adversaries, which could require that new countermeasures be developed (Rosen 1991). The entity requesting the capability is often also the one that funds its development, and it is most likely to turn to technology suppliers that it has relied on in the past.

"Technology push" is the process by which new technologies are proposed to potential end users by the entities that developed them. For defense technologies, these entities can be organizations that have a history of supporting the defense establishment, such as defense companies or government laboratories, or entities that have generated a capability for a different customer but have also identified potential defense applications for it, such as individual inventors or companies developing commercial goods and services.

"Spin-off" occurs when technically sophisticated defense technologies are developed (often in parallel to institutional innovations), and the know-how accrued in their development is utilized in the development of goods, services, and processes for commercial purposes. "Spin-on," on the other hand, refers to the process in which civilian innovations are transferred to military applications. It is worth noting that the question whether defense spin-offs to the civilian technology base enhance economic growth or whether spending on defense innovation is a net cost due to its high opportunity costs and the ability to spin commercial technologies for military uses continues to be hotly debated in the literature.

Using the concepts discussed above and keeping in mind the public good nature of defense overall and defense innovation in particular, two basic models for innovation in defense technologies can be constructed. The first is the linear model, whereby a novel product, service, or process that is intended for military use is researched, developed, tested, and marketed to a military customer. The second is the nonlinear model, in which during testing or deploying of an existing product, service, or process – either military or commercial – a different application for use in defense is identified and explored.

The linear model of innovation for national defense has been observed throughout history but has been particularly prevalent in the decades after World War II with the rise of large-scale government defense research and development (R&D) establishments. The model fosters an innovation process that begins with basic or applied research, evolves into technology development and testing, and eventually delivers an end result to the customer which is deployed and disseminated within the defense organization. Key actors in this model are government laboratories and companies that make up the defense industrial base as well as certain research universities. Under this model, innovation can be initiated through a technology push by entrepreneurial innovators or demand pull from defense customers. This type of defense innovation is capital intensive and therefore usually funded either directly by national defense entities or indirectly through independent R&D (IR&D) of the institutions in which it is conducted. In the past few decades, it has resulted in innovations such as nuclear weapons, satellites, and stealth technology, as well as in commercial spin-offs such as jet engines and airframes, satellites, robotics, digital displays, and nuclear power.

The nonlinear model of innovation for defense purposes is also centuries old. It initiates innovations relevant to defense technologies at later stages of the innovation process (i.e., during testing and after deployment in the field as opposed to the R&D phases) and in institutions and disciplines that are not funded by defense establishments or by defense firms. In recent decades, many innovations in this model emerge from the global commercial marketplace in areas such as communications, sensors, cyber security, data fusion, and data management. As the commercial world demands higher performance and sophistication and reduces the life cycles of products, both the rate and the quality of nondefense innovation are constantly improving. Nonlinear innovations are also increasingly appearing in the hands of users, i.e., the soldiers who are issued a new capability – military or commercial – and utilize it in a way that is different from its original intent. This model presents more instances of spin-on than spin-off and more examples of radical innovation than incremental innovation (Boot 2006). The steam engine, the telegraph, the internal combustion engine, radio, the automobile, and the airplane are all examples of nonlinear innovations that originated from outside formal defense establishments yet resulted in breakthrough defense technologies. Many such nonlinear defense innovations were converted into defense technologies as a result of technology push on the part of their entrepreneurial developers, but demand pull is not uncommon either; formal defense entities have often recognized the military potential of commercial innovations and initiated processes to integrate them.

The policy implications for practitioners and students of innovation in defense technologies are different for each of the two models. For the linear model, the key policy challenge currently requiring attention is that of the increased complexity associated with providing innovative defense technologies via a linear process. While current and future security threats across the globe have created an appetite for increasingly complex R&D programs to deliver the next generation of defense capabilities, technology has evolved at a higher pace than have the policy frameworks and the management tools that are needed to bring R&D programs to successful fruition. As a result, defense innovation attempted under the linear model in recent years is costing significantly more and taking significantly longer to the point where it is no longer economically viable (Ben-Ari and Zlatnik 2009). This is not a new phenomenon; there has in the past been tension between the increasing complexity of required defense technologies and the policy and management tools available to provide them. To resolve this tension, new policy frameworks, governance models, and management structures were introduced that enabled organizations to advance to the next level of complexity. For example, the US Navy developed the Gantt chart to build the ships of World War I and PERT (the Program Evaluation and Review Technique) in the 1950s to help manage the Fleet Ballistic Missile program. However, the defense innovations that have been under development in the past 20 years or so require new policy frameworks and management models if they are to be completed within the time frame and budgets allocated to them and in a manner that is relevant to the military customer.

For the nonlinear model of innovation in defense technologies, the important policy challenge of the day is to identify and support innovations and innovators that are relevant for defense yet who emerge either in unexpected phases of the defense innovation process (e.g., within the testing, evaluation, and end-user communities) or outside the defense community altogether. Examples of the former include German soldiers in World War II using 88-mm antiaircraft guns as antitank weapons, the conversion of the C-130 cargo aircraft into the AC-130 ground attack aircraft during the Vietnam War, and, more recently, Canadian soldiers in Afghanistan intentionally driving their main battle tanks over improvised explosive devices, thereby using them as crude mine-sweeping tools. Examples of the latter include the use of smart phones as navigation and positioning devices and social networks as communications and knowledge-sharing tools in numerous militaries during operations in Iraq and Afghanistan. Such harvesting and reuse of military and commercial technology to generate innovative defense capabilities currently do not regularly occur at a formal, institutionalized level. Yet, the advent of what has recently been referred to as the BRINE revolutions, i.e., breakthrough technologies in biotechnology, robotics, information technology, nanotechnology, and energy, means that even more innovations with relevance to defense will be available for those militaries smart and fast enough to incorporate them into their arsenals (Wells 2012). Similarly, the increase in user-centric innovation (Van Hippel 2006) is not bypassing the military, and soldiers now have more ability than ever before to put both military and commercial technologies to use in innovative ways, essentially becoming inventors and technology entrepreneurs on the battlefield. The challenge for defense policymakers is to create an environment that fosters the harvesting of new commercial innovations and the creative redeployment of existing military technologies.

Conclusion and Future Directions

Ultimately, however, the most groundbreaking technology innovations for defense will not in and of themselves confer victory to the forces wielding them. If there is one consistent lesson that the history of defense innovation teaches, it is that without the social innovations discussed at the beginning of this entry, i.e., innovation's organizational structures, military doctrine, strategy, and tactics, innovations in defense technologies will be ineffectively utilized and sometimes not utilized at all. For example, during World War I, the British were the first to develop and use tanks but did so in small numbers and without adjusting their military doctrine accordingly; it was the Germans in the years before World War II who recognized the full potential of their adversary's innovation and innovated their own defense strategy to accommodate what by then was a well-known military technology. Thus, the military advantage gained from an innovative defense capability may go to the fastest adopter of the innovation and not to its first user. In addition to addressing the innovation challenges outlined above, defense policymakers will also need to tackle the issue of implementing organizational and cultural change to successfully incorporate new products, services and processes in their defense establishments.

Forestry as a "Future Sector"

Forests are known to produce timber in the first place, and this is also the main income source for most forest owners. At the same time, it is also widely known that forests provide many more benefits to society: They provide landscape amenities and opportunities for recreation; they conserve biodiversity and protect environmental features; they deliver clean water and offer protection against natural hazards such as landslides, rockfall, or avalanches; and last but not least, they are a source for renewable energy and are an important means to mitigate climate change through their ability to sequester carbon. All of these goods and services, in fact, are increasing in significance. It seems that the image of forestry is currently changing from a quite traditional and declining sector to a "future sector" which offers solutions to a range of challenges that our society is facing today. Innovation plays a key role in making the sector able to fulfill this promising role.

What this entry aims for is to understand current innovation processes in the sector, including supportive and hampering factors, institutional conditions and drivers, the relevant policies and innovation systems, and success and failures.

Relevance and Innovation Fields

In order to understand innovation processes, it is necessary to look at spatial and sectoral, individual, and institutional factors. In the case of forestry, there are specific features that characterize the sector as well as condition the related innovation processes (Weiss et al. 2011a). In respect of the spatial dimension, there are at least two specifics to be considered: First, forestry production is dependent on the natural site conditions and mostly takes place in rural areas. Second, some of the forest products are territorial goods and services in that sense that they carry the very place of production as a strong characteristic. While timber is (normally) a commodity which is traded globally and uniformly, other ecosystem services of forests are bound to the site of production: This is true, for instance, for some recreational services where the experience is connected to a certain landscape, and it is true for protective services when a certain forest protects the neighboring field from wind erosion. The marketability of forest-based territorial goods and services is often limited, a fact which makes business difficult but all the more call for innovation on institutional or policy level. The many forest-based value chains differ strongly, whether regarding, for example, the traditional timber construction that does not look so traditional any more today or the recent rise of the energy production on the basis of renewable sources that is still undergoing fast technological changes. Forestry and the forest-based industries thus look very colorful, particularly when studying innovation.

Relevance of Innovation in the Forest Sector

The study of innovation in the forest sector is relevant in several respects: First of all, as in any other sector, international competition is growing also in the forest-based industries. Steady innovations are crucial to keep pace with global competitors, in terms of costs and quality. Another aspect is that the forestry sector – providing a range of ecosystem services and amenities – contributes to the quality of life in rural areas. Furthermore, forest-based products (including energy) use renewable sources and, therefore, contribute to the sustainability goals that are formulated in many policies. The forest sector also provides income and employment opportunities in rural areas, which often face a decline in their economic significance. This in turn relieves urban areas from migration pressure and provides health and recreation to all citizens.

These particular roles of the forest sector are increasingly recognized by policy makers and included in policy programs. The new interest in renewable energy sources and renewable materials comes from various policy fields, and the related opportunities are often not yet seen so clearly by actors within the sector. Ironically, forestry actors continue to praise the many benefits that forests provide to society but often do not see the new opportunities that arise from nature conservation policies, integrated rural development, sustainable development, climate change mitigation, and many others. It can be said that forestry and the forest-based industries play an important role in rural economies and have a strong potential to contribute to a sustainable global future, particularly in the following fields:

- Recreation and tourism
- Nature protection, biodiversity conservation, and landscape amenities
- Protection against natural hazards and erosion and protection of clean drinking water
- Bioenergy production and climate change mitigation
- Bio-based products, including food, fibers, chemicals, and wood construction

The forest sector is often considered as a mature, "low-tech," and declining industry. With the notion that our economy changes into a service economy and that our society changes into an information society, research and high tech receive a high level of attention in the media, in the public, and in policy as if they were the only source for economic growth and innovation. This is not true (Hirsch-Kreinsen and Jacobson 2008): Studies show that low- and medium-technology sectors still play a major role for employment and growth. Although these sectors invest less in research and development, they are still relevant for innovation. Innovations in mature sectors occur in different forms. Wood processing industries, for example, use sophisticated technologies in their production. By this, they are important also for the future development of information technologies. In other fields, for instance, in the production of berries and mushrooms, innovations rather come from new networks, organizational forms, or marketing methods and are important even without any connection to high technologies. We will further see that – being a sector with high social and environmental importance – institutional innovations play an important role in forestry. This is, however, not yet clearly seen by policy makers (Weiss et al. 2011a).

State of Research

There is a broad range of aspects that are highly relevant for the study of innovation and that have been studied in the field of forestry (Weiss 2011). On personal level, several aspects had been studied in forestry, such as value systems, entrepreneurial orientations and business goals of forest owners, and the diffusion of innovation, for example, in Scandinavia and Central Europe. A considerable body of literature exists on the financing and marketing of forest ecosystem services (timber and non-timber forest goods and services), in particular but not exclusively in southern Europe. In respect of organizational innovations, especially the role and function of forest owners' associations was studied. The supporting and hampering factors in the innovation processes and the contribution of forestry to rural development were studied from innovation systems and regional governance approaches. The role of different actors, networks, and clusters were studied for territorial goods and services and wood value chains.

Research that specifically addresses innovation processes in the forest sector started rather recently. In Europe, a strong push was given by the work program of an innovation-oriented research group within the European Forest Institute (Rametsteiner et al. 2005) and by two recent COST Actions (COST is a European program for connecting researchers within certain thematic "actions"). The COST Action E30 on the "Economic integration of urban consumers' demand and rural forestry production" gathered researchers from the field of innovation and entrepreneurship in forestry and the forest sector and was especially dedicated to entrepreneurship aspects of small-scale forestry, the multifunctional use of forests, as well as the timber and wood industries (Niskanen et al. 2007). The COST Action E51 "Integrating Innovation and Development Policies for the Forest Sector" particularly looked at the policy dimension of innovation (Rametsteiner et al. 2010) and at the innovation processes on the ground (Weiss et al. 2011a). It covered the two major production fields: territory-based goods and services (the provision of recreational services, non-wood forest products, and carbon sequestration) as well as wood-related production chains (furniture, timber frame housing, bioenergy, and timber harvesting operations) and included institutional and instrumental aspects (networks, clusters, forest owners' associations, and the European Union LEADER instrument for rural development).

Currently Important Innovation Areas

Currently, important innovation fields in forestry are found within territorial goods and services and in wood-related production chains. According to an expert survey in 18 European countries (Weiss et al. 2010), new wood products are developed in the fields of bioenergy, wood construction, and wood modifications. Bioenergy production in various forms – including solid wood, biofuel, and biogas – is the innovation field that yields highest attention. Within territory-based services, different ecosystem services of forests are important, particularly environmental services and recreational and educational services. New recreational services such as guided tours or hiking or biking trails seem to be the most important in terms of frequency although it has to be noted that they are in most cases not so much developed for profit but rather because of external pressure (Rametsteiner et al. 2005).

There are important differences between the two innovation fields: Within the wood value chain, process innovations (new harvesting technologies, use of ITC, logistical rationalization, as well as prefabrication and modular systems in the timber industry) as well as organizational novelties are important in the countries (horizontal and vertical cooperations and cluster initiatives). While in the field of wood production, horizontal and vertical cooperation can be solved among firms, for territorial services institutional innovations such as regional cross-sectoral coordination processes seem of particular importance. It seems that for territory-based services, the coordination of actors is more complex and needs activities on institutional level. The significance of regional cross-sectoral coordination mirrors the challenge of how to organize the provision of territory-based services which often has to involve many providers (landowners) and users (e.g., tourism).

Forestry Innovation Systems

From several studies of innovation processes and policies on institutional and firm levels, we are able to characterize typical forestry innovation systems. They can largely be described as sectoral innovation systems in that they are strongly governed by sectoral actors and policies. Only in countries such as Finland, where the forestry sector is perceived as contributing significantly to the GDP, forestry and forest-based industries are recognized by the national innovation systems. Furthermore, regional innovation systems are highly relevant, particularly when it comes to territorial goods and services, but this is hardly realized by the relevant actors – both from outside and inside forestry.

Unfortunate Frame Conditions for Forestry

The preconditions in forestry are not supportive of innovations. The one main important obstacle to innovation is the high fragmentation of forest ownership in many countries. The average size of private property is very small in many European countries, often below 10 or below 20 ha. This implies that the income from forests is negligible or at least not the main income source for many forest owners. Very few owners actually work full time in forest management; most owners do not even have any relevant education or training.

According to a survey of forest holdings in Central Europe (Rametsteiner et al. 2005), practically all of the work in forest holdings <100 ha is done by family members, of whom virtually nobody works full time in forestry. In small forest properties, forest work is usually not outsourced. There are strong indications that forest work remains simply undone if family members do not find the time. It is evident that these owners hardly develop any innovative management approach for their forest property, even if they would be highly innovative in their main occupation. Even in farm forests, there is seldom an innovative attitude toward their forests when the main farm product is from agriculture. A large majority of forest owners thus have one simple goal, namely, to maintain their forest (Rametsteiner et al. 2005). On the other hand, only very few people intend to abandon forestry altogether or to sell their property.

Innovation Activity in Forestry

The described unfortunate conditions in forestry result in a rather negative picture with regard to the overall level of innovation activity in the sector: Particularly in small forest holdings, there is little innovation activity, innovations are mostly incremental, and there is hardly any start-up activity in the sector (Rametsteiner et al. 2005). When looking more into detail, however, there are a few remarkable facts that show a more positive picture: Larger forest holdings (>500 ha) are as dynamic as an average EU manufacturing SME. Furthermore, forest owners in many countries have, at least verbally, an entrepreneurial orientation. This implies that forest owners or managers are not by themselves unwilling to innovate (a widely held opinion) but that it is more due to the framework conditions. Given the right conditions, forest owners are possibly more prepared and willing to actively pursue market opportunities through innovative approaches than national policy makers often consider them to be. This result then also implies that the right policy measures might be able to successfully change the situation. In the following, we will see that the innovation systems, however, are not well prepared to support innovations in forestry.

Weak Support from the Institutional System

A range of weaknesses are found with regard to the forestry innovation system and related policies (Rametsteiner et al. 2005): First of all, the national innovation systems usually do not include forestry matters. There are hardly any interactions between forestry actors and actors dealing with existing national innovation policies. But also within the sector, there are usually no comprehensive innovation policies formulated. Furthermore, the group of institutions, which is active in innovation-related matters, is usually very small and restricted to the forestry field. Often, as in Italy or Austria, forestry interest groups dominate the picture, but public administration and research and education institutions are hardly mentioned. In other countries, public administration and research organizations dominate, but forest owners' organizations have no significant role there. It is very typical that there is a lack of interaction with other sectors. Forestry institutional systems have strong sectoral boundaries, even to the wood and agricultural sectors and even more to other sectors such as energy, tourism, and nature conservation, where a considerable part of innovations are currently occurring (and are expected to occur in the future).

The forestry innovation system is active in the fields of technological and organizational innovations and in the diffusion of certain preselected innovations. Typical areas of activity are mechanization of forest work and, recently, the forming of forest owners' cooperations. Except for some selected topics – such as bioenergy or forest education – product and service innovations are rather disregarded. Specific support aiming at the development of new products and services is practically missing (Rametsteiner et al. 2005). Case studies of forest-related innovations in tourism or bioenergy reveal that the initial support for the development of these new innovations rather comes from regional-level ad hoc networks and from other sectors but not from the forestry innovation system.

Misconception of Supporting and Impeding Factors for Innovation by Institutional Actors

It seems that the institutional system does not fully understand the needs of forest holdings when it comes to innovation support. The forest holdings survey in Central Europe (Rametsteiner et al. 2005) shows that institutional-level actors assume different factors to be important for innovation processes. They underestimate the importance of information as an essential factor. With regard to impeding factors, the institutional system actors tend to overestimate the difficulties forest owners face with administrative and legislative obstacles. These certainly exist and are also pointed out by forest owners to be important. However, financing and know-how are much more a concern for forest owners. This finding has quite important implications on the design of innovation support activities.

How Well Are Innovation System Functions Fulfilled?

Three basic functions have to be fulfilled by innovation systems (Edquist and Johnson 1997):

reduction of uncertainties by providing information, the management of conflicts and cooperation, and the provision of incentives. The institutional system actors in forestry do fulfill those functions yet with limitations:

– Information provision is lacking for new markets and opportunities: Forestry agencies – authorities and interest groups – provide important forest-related information. They provide good information on traditional forestry topics, but there are severe information lacks about new market fields such as tourism and nature conservation. Only when not too far from the traditional timber production, institutional actors have built up new knowledge on new areas, for example, on biomass use.
– Weak conflict management and coordination with other sectors: In the coordination among foresters and forest owners, the institutional actors do well, but they are weak in the coordination with actors from other sectors. Even the coordination with sectors in the wood chain proves to be difficult.
– Little consideration of innovation support principles when providing incentives: Forestry subsidy measures such as the support of investments for the mechanization of forest work (forest roads, harvesting machines) or the support of cooperations (e.g., forest owners' cooperations) are hardly written from an innovation perspective. Financial incentives are therefore mostly conservative, and their design often disregards basic principles of innovation support. Two such principles are to systematically support new and risky projects or to limit the support to the starting phase. In practice, considerable incentives are provided for the diffusion of already known and preselected technologies or organizational rearrangements, but only little incentives are provided for the development and pilot testing of new ones. It is furthermore only seldom that the grant of support is restricted to the starting phase of a certain project or the stage of innovation development in the sector.

As a result from these weaknesses, it can also be observed that a considerable financing potential is hardly tapped by forest owners, namely, non-forestry funding sources, for example, from innovation or structural funds. Forestry companies and also supporting agencies very often do not know about non-forestry programs that could be utilized for supporting and financing forest-related innovations.

Policy Support

Innovation in forestry may be supported by competitiveness, innovation, and entrepreneurship policies in general or by the forest sector policies. Unfortunately, the general innovation support is often not used by the sector, and comprehensive and focused innovation support policies within the sector are rare (Rametsteiner et al. 2005). A detailed analysis of in how far and in which way the aspect of innovation is integrated into sector-relevant policies (Weiss et al. 2010) found that the relevance that is put on the topic of innovation not always goes along with the same understanding of innovation policy, traditional or systemic. Policies that mention many innovation-related goals and give innovation a rather high importance are the national reform programs, rural and regional development programs, and forest sector strategies. These policies tend to follow rather a systemic understanding of innovation. The forest programs and renewable energy plans are much less innovation oriented and represent a rather traditional view on innovation. The sustainable development strategies are a third type: They do not mention innovation frequently but often follow a systemic understanding of innovation.

Innovation issues are not systematically integrated into forest policies, and innovation is not specifically supported. The policies hardly support radically new ideas but only the diffusion of current solutions and technologies that are already known. This confirms earlier results from innovation research which say that the institutional system of mature sectors rather focus on rationalization and diffusion of innovation and are less oriented at the development of new products or services (Breschi and Malerba 1997).

For an effective support of innovation, the coordination of policy fields is important, the more so for a diversification into new forest goods and services. Formally, forest policy documents seem to be relatively well coordinated with other sectors, and even without a generally strong systemic orientation of innovation policy, there is a focus on cross-sectoral interaction. In relation to other traditional sectors, it seems that forestry is rather used to coordinate across sectoral boundaries (Weiss et al. 2010). These results contradict to what is known from extensive forest policy research in Austria. For the example of Austria, it can be shown in detail that other sectors hardly play a role in the sectoral innovation system; this is certainly true on national level, even if not so pronounced on local-regional levels. These contradictory results may be explained by the lacking implementation of the coordination goal. Furthermore, the coordination with other sectors is often rather forced because of strong interests from other social groups, and the mode of coordination is often more a negative than a positive coordination.

What are the factors behind the strong orientation of forest policies at timber production and the slow uptake of new policy goals and innovation fields in forest policies? The policy analysis explains it by the power of the related interest groups which are behind those goals: Forest industries aim to keep the production source oriented at timber and may hinder a stronger multifunctional use of the forests – as shown on the example of selected cases in Austria, France, and Scotland (Buttoud et al. 2011). Vice versa, new uses of the forest for other purposes are typically introduced from outside sectors such as energy, biodiversity conservation, or recreation.

Another factor may be the self-understanding of institutional actors with regard to innovation support: They often see innovation as a sole market issue and feel their role primarily connected to public goods. Traditionally, forest authorities were concerned with ecosystem services from a public good perspective: They provided regulatory limits for the use of the forest resource in order to secure a basic provision of the "nonmarket" benefits of the forest. Today, the trend is to give also their provision more in the hands of the market, but the role of the public administration is not yet clearly defined. At the same time, the private actors still expect state activity when it comes to the support of non-wood goods and services from the forest (Weiss et al. 2011b). This seems to be an indication that non-wood forest goods and services are still not seen as an important business opportunity.

In conclusion, the role of policy in innovation support in forestry can actually be seen paradoxically: Although innovation and market-based instruments become more important, state actors do not lose importance. The public financing of ecosystem services is growing, and public instruments need to be made more efficient through clearly defined goals. The scope and use of mixed public-private mechanisms such as contractual agreements, tendering schemes, or cap-and-trade schemes are increasing. The creation of new markets, for example, in carbon trade or nature conservation (conservation banks), is still only in an initial state. And finally, also in the field of traditional markets, the institutional-level actors have their tasks to fulfill: promoting entrepreneurship and innovation, providing market information, or supporting interaction among landowners and across sectors. As described, innovation support instruments such as the provision of seed money or providing support infrastructures for the development of new business activities such as extension services or rural development agencies are still a field to develop in forestry (Weiss et al. 2011b).

Conclusion and Future Directions

Although forestry is a traditional sector, there is an increasing interest in the important role that forests, wood, and non-wood products have for the sustainable development in Europe: These contributions range from recreational services and biodiversity conservation to the possible reduction of greenhouse gas emissions through the use of wood in construction and to the provision of new jobs in rural areas. Still, policy measures for the provision of forest ecosystem services do not come under innovation support while this is the case in the field of new timber or bioproducts.

This entry argues for a stronger role of institutional actors and policy in innovation support in the sector and a more systemic orientation of innovation policies. There is a too narrow focus on research which totally misses the needs of the sector enterprises in their innovation efforts which rather lie in the provision of information and cooperation support. Measures are needed to facilitate the two-way communication between researchers and the firms. Innovation support infrastructures such as cluster organizations and regional and rural development agencies need to be fostered as intermediary agents. They are important complementary knowledge and capacity providers. Developing and supporting networks, education, and training would be important fields of activity.

We always have to keep in mind, still, the particularities of the forestry production: The marketing possibilities are limited. All the more important are social, institutional, and policy innovations. Further specific challenges are the dominance of small and micro family businesses and the prevailing traditional business fields and non-research-intensive technologies. Traditional innovation policies fail because of their too strong focus on research and high-technology support and because of their orientation at larger firms. Small businesses are still disadvantaged by most industrial policies.

Forces of production theories; Systemic innovation, theories

For Marxists, radical economists, but also Classical economists, the historical context determines for most part the order of priority of the scientific phenomena to study, the techniques (methods and tools) to use, as well as the social use which will be made of the results. They highlighted three stages in the transformation of the production forces of capitalism: meetings of workers isolated under the same management, followed by the division of the work and the differentiation of the tasks, then by the clear separation between intellectual and manual work. In today's global economy, a fourth stage in the productive organization appears: an organization based on the spatial de-concentration of the achievement of this production and on decisional, financial, and informational centralization that the applications of contemporary science allow. This fourth stage is the one of the unprecedented marketability of science, organized as a network by enterprises and states in a clear technological aim.

All science would be superfluous if the appearance and the essence of things became confused (Marx 2012, vol. 3). The research of the essence of things is generally commonly accepted as being the aim of the scientific activity but the historical context determines for the most part the order of priority of the things and the phenomena to dissect, to understand, and to know the techniques (methods and tools) to use to penetrate the essential, as well as the social usage which will be made of the essence extracted. At the moment in time when, according to Marx (1993), industry has already reached a very high level, invention becomes a branch of business, and the application of science to the immediate production determines the inventions, at the same time as soliciting them. Then, for Habermas (1973, p.43), with the arrival of industrial research on a large scale, science, technique, and exploiting found themselves part of the same system. Capitalism provided the framework for the systematic application of science to production, which in turn gave impetus to the development of scientific knowledge concerning laws of nature and of the world. Capitalism redirects, in accordance with a productive end, a reserve of scientific and technical knowledge built up, making science a productive strength at the service of capital. Giving a scientific character to production is therefore the tendency of capital. (Marx 1993).

The Myth of Innovation: From the Formation to the Private Appropriation of Production Resources

Science, in the same way as technique, is always historical. But in capitalism, science is considered as a tank of knowledge from where technique feeds (see Nef 1953). It is considered as a tank of forces of production because the work process has become a technological application of science (Marx 1993). The growth in the size of the company and the amount of capital held or raised has furthered the enrolment of science in immediate production. (a) The domestic markets of the big industrial and international countries are getting bigger. (b) The social division of labor is extended. (c) Enterprises, in a context of competition, have to bear rising total costs. (d) Enterprises focus their strategy, on the one hand, on the achievement of high external economies (or externalities) and, on the other hand, on business intelligence in order to benefit from all profit opportunity. The usual term is that of externalities which can be defined (A. Marshall 1890) as being positive or negative effects, which involve an activity of an economic agent outside this activity or that the agent is subjected to from outside. The most attractive for a company is to achieve, in a setting favorable to investment, substantial external savings, without having to bear the slightest cost that its activity creates for the community as a whole (pollution or various nuisances). It is important therefore, to underline, that taking private property for granted, the private agent will create various effects on the local community, but in return, he will expect from the community means and opportunities to enlarge his property (assets) or where necessary, to defend it. The application of science to the economic activity of such and such a company or group of companies makes innovation the main function of growth and commercial strength.

The liberal and neoliberal economic thinking has, only very recently, been able to find some arguments to justify forming, in the aim of making them available to private firms, scientific and technical resources. The liberal economists are quick to thank R. Solow (1956) who started new methods of research into the links between technology and growth.

Firstly, as a residual factor of growth, new techniques have become a very popular subject of research with the neoliberals. The standard neoclassic growth model was changed drastically by the introduction of technical progress and innovation in the liberal approaches to accumulation. To consider, for example, that the activities giving birth to the diffusion of technical and scientific information have a positive impact (in terms of creation of wealth and profits) which is greater collectively than individually is a significant advance compared with the mechanical and ahistorical equilibrium of the original model. The question of economic repercussions on the community, of individuals' actions, especially concerning scientific production and commercial development, points the analysis toward the socio-holistic approach to the economy applied successfully by the classical authors. Innovation, more particularly, defined by J. Schumpeter (1982) as a new combination of productive resources, corresponds to a process of generation and private appropriation of a set of resources (scientific, technical, and financial) which, combined by the company or a group of companies, results in new products, the opening of new markets, and new organization. The conception of new products is a very important element in innovation. It is here that the large firms, with huge resources at their disposal, have a great advantage. They can fund research teams and experiment with a large number of innovations in the hope that one of them will stand out from the crowd, wrote J. Robinson in 1977. The supply creates its own demand, thanks to the insight, and the fighting spirit of the entrepreneur, then of the large firm. The second stage of the innovation process (appropriation) prevails these days over the first one (the generation). The company tends to take advantage of its environment rather than to invest in it, for instance, in all the stages of technological creation, which can be explained by the fact that the investments in the acquisition (appropriation) of production resources are less costly than those devoted to the formation of these resources. This also makes the neoliberals say that the collective profitability of the capital can be high, whereas the private profitability can become insufficient.

If the neoclassical economists struggled to get out of their model's dead end, a long time ago Marx himself and the economists who applied his method showed, as did L. Karpik (1972), that science becomes the base of industry; it is in this way that "heteronomous science" (which corresponds to the research applied to both the experimental development of new techniques and production methods and to finished goods) marks time on "autonomous science" (let us say basic research with no recognized private profit-making aims). The production process therefore determines the appearance of new techniques and defines their use. To do this, it directs the application of the scientific knowledge and defines the boundaries of scientific research. An organic relationship is thus created between science, technique, innovation, and society. And it is in this that technology (and innovation), as a transformation of knowledge into production and accumulation knowledge, is a social fact.

Marx's reasoning is as follows. First theoretical statement: Capitalism cannot exist without revolutionizing constantly the means of production, and therefore the production relations, that is to say, all the social relations. The means of production required to produce the different goods (destined for consumption or for production), after they have been adapted and used for private purposes to be transformed into capital, characterizes the state of the social relations. The quantitative expansion and the efficiency with which the capital is developed as fixed capital broadly indicates to what extent the capital is developed as capital, as being the power over the living work and to what extent it is subjected to the production process in general (Marx 1993). The technological use of science is the essential factor in the development of fixed capital; this being an index which shows to what extent the universal social knowledge has become a direct productive force. The development of (fixed) capital enlarges the scale of production at the same time as prompting this enlargement, requiring in parallel the specialization and the overlapping of different work forces which are more and more complicated: simple work/complex work, living work/dead work, socially necessary work, collective work, etc. Salaried work, and the salaried class as a capitalist norm of participation in the accomplishment of production and the social organization becomes the driving force behind accumulation.

Second theoretical statement: The general development of the production forces is the development of all the means (material and immaterial) that science in the hands of the capital injects into the production, natural forces, in the form of means of production, enabling higher usage value with less work (Marx 2012, vol. I). Science becomes capital under the pressure of the competition and possible political and social disputes. The authority of the capital and the power on the market of a given company depends on its capacity to make profits, to accumulate. Innovation is therefore essential in the daily battle that firms undergo to avoid the numerous barriers (lack of demand, increase in price of production resources, emergence of new competitors, social problems, restricting regulations, etc.) which can block the road to prosperity. Science is therefore called upon more and more; the new technology which it will create must be more efficient (allowing a greater mastery of the work process) and must achieve new exchange values (i.e., guarantee accumulation). The speed of the renewal of the capital is dependent on the accumulation barriers which play a major role in defining the integration of science into both production and the general development of the forces of production.

Third theoretical statement: For Marx, competition requires a continual increase in capital and imposes pervading laws of capitalist production as external coercive laws to each individual capitalist (Marx 2012, vol. I). To limit the risk of disappearing (through over-investment in relation to the solvency of the market in question), the firm must innovate and at the same time grow. Depreciation and centralization go hand in hand. Innovation links the two together: It allows the depreciation of the already old capital whose profitability has slumped; it creates a favorable climate in which to make further investments and it favors "creative destruction" (Schumpeter) and the involvement of finance, the merging of capital (centralization) forming huge companies so that the capital and its development appear as the starting point and the end, like the motive for and the objective of the production. For this reason, the capitalist economy tends to develop its production forces as though it only had the absolute power of the company as a limit. But this tendency enters into permanent conflict with the restricted objective, taking advantage of the existing capital (Marx 1993). The periodic crises mean the destruction of part of the existing production forces. About a century later, J. Schumpeter described as "creative destruction" the process of destroying old capital by new productive combinations which create, from their introduction to the market, new opportunities for profit and investment (Schumpeter 2006). The resumption of accumulation after the said destruction will not be possible without thorough modification of the foundations and the norms of accumulation (new social organization of work, new competition rules, new technology, new institutional forms of management, and economic regulation).

Innovation, Networks, and the Power of the Firm

As soon as the capital takes over the social production, the technical progress reflects the more or less significant changes (marginal or radical) in the techniques and the production methods, together with the social organization of the working process and thereby the historical type of society (Marx 2012, vol. II). The three stages in the transformation of the production forces of capitalism (meetings of workers isolated under the same management, that of the holder of the capital, followed by the division of labor and the differentiation of the tasks with the setting up of a salaried management team in the factories, then by the clear separation between intellectual and manual work which determine the status of scientific and technical workers compared with the immediate commercial objectives of the production process) are conceptually linked to the formation and the evolution of the "collective worker."

Capital instigates cooperation among the workers for the accomplishment of a given production. This results in collective of workers all the while depriving the staff of any role in the organization of their work, any control over their contribution (value added) to the production, and finally of any role in evaluating the use value that their workforce represents for the capital. A. Smith's spirit lurks: The machine was created by the division of labor. He also remarked that the specialization of labor will lead the worker to discover sooner or later the means to reduce the difficulty of his task. But these "minor innovations" are not the only ones; according to A. Smith, other inventions are a consequence of the work of scientists which consists in observing distinct physical and technical processes (Smith 2012). These inventions, when marketed, will represent the major innovations of the future.

The stages of the capitalist production organization therefore precede the technical transformations and transform science into a productive force and define technology as production knowledge. Innovation and more particularly, technology, said J. K. Galbraith (1967), undergo a major organizational effort, but it is also the result of the organization. This basis of perception of the evolution of production forces under the constraints of accumulation has inspired some of the neoclassical economists. The positive externalities, the increasing returns, or even the human capital are the concepts which illustrate in different words the state of the collective of workers and the state of the socialization of the capitalist production such as has been noticed since the beginning of the 1980s. The current phenomenon of a "knowledge-based economy" (see, for example, Laperche et al. 2008) is the continuation of the formalization of the scientific and technical knowledge and of the organization of science as a domain for accumulation whose origins date from the middle of the nineteenth century. Indeed, with the creation of schools and specialized publications, knowledge and all sorts of scientific and technical information is diffused. The process goes therefore progressively from a series of empirical results, logically organized, to a strictly scientific knowledge which results from experiments willingly carried out, not more uncertainly endured (see particularly: Noble 2011).

However, what it must emphasize is that the explanation that the superiority of the social return on investment in research and in innovation in companies in comparison to the return on the individual capital lies in the increase in the number of factors determining the profit-making potential in a given company. These factors (education, environment, health, finance, inter-industrial relations, communication, requirements and aspirations, etc.) of a general nature influence the marginal cost of a company or an operation and, with everything equal, have an effect on the return on the capital invested. The firm, in a competitive situation, be it apparent or latent, must appropriate these factors or at least monitor their impact on the profitability, or even better, take advantage of (abundant production resources which could be taken over, the opening of new markets) the noncommercial logic which these factors generate and reproduce (and nowadays this is how innovation is defined).

The firm, by investing in R & D, or by taking over small innovative companies, or by collaborating with other companies as strong as itself (joint research programs, cross-licensing, etc.) or with government research bodies (universities, for instance), appropriates knowledge which is the essential factor of competitiveness. Large companies consider that the knowledge which is vital for competitiveness entirely covers fundamental knowledge and insist that the university research institutes, with whom they sign research partnerships, accept their own criteria on who should be considered as "public" or "private" (Laperche et al. 2008).

It is the fourth stage in the organization of production: the combination in the same group of staff paid by the company itself and a salaried staff paid by other organizations, but appropriated by this company which makes use of the said group. The company keeps control of the group which is itself composed of productive capacity, trained and employed in various areas and by various social production entities (Laperche et al. 2008). This decentralization process of the constitution and the management of the private work groups affects all institutions. The diversification of the canals of scientific and technical knowledge and information transfer from public training centers for production resources (e.g., universities) toward the companies is proof of this; the refinement of the legal and financial system for the appropriation of the value constituted in the public sector by the company is further proof of this; the multiplication of the different levels of social status and salaries of the salesmen of all sorts of manual and intellectual competence is yet more proof.

The large controlling firm (or on a joint basis several large companies) constitutes the crux of the deployment of the production process. Having concentrated its means of production, defined, and divided up the production tasks and put together directly controllable collective of workers, it is becoming these days a decentralized organization and management center for its production resources. Capitalist production operates at the moment as if the power exercised by a firm on the market (and the coordination of the functions and activities that it can impose on it) was a factor of economic power (and of centralization of the ownership of the capital) more important than the power given by its own assets (scientific, technical, industrial, and financial).

But this is forgetting that this firm's power is a result of its financial capacity and of its potential concerning information. This "information potential" includes all information (scientific, technical, industrial, financial, commercial, political, sociological, etc.) which a company has access to, and can transmit to the market. Information and finance together enable the constitution and management of working groups which are geographically dispersed and remote (investment in industrial cooperation relations, in protecting the technological assets, in the appropriation of scientific knowledge and the creation of new products, in the coordination, using telecommunication means, of the different activities, etc.) (Laperche and Uzunidis 2008).

Technological innovations are today the outcome of this integrating decentralized process. They also provide the possibility for the process to be achieved and to prove itself more efficient (in relation to the costs of large amount of capital) than the huge factory which employs hundreds of people. The debates on the "networks" focus as much on the flexibility (to create or destroy production capacity according to the economic circumstances) that the large firm's decentralized management of the production provides, as on the increase in the firm's capacity to appropriate a large quantity of resources without investing in their formation. The large firm has turned into a center of concentration of the production resources, but also of formation and flexible coordination of collective of workers, depending on the accumulation requirements and the fluctuation of markets. It calls for cooperation and goes on toward this convergence by applying the strategies of growth and integration.

This coordination and innovation process, both flexible and evolutionary, imposes on the firm the pressing need to be provided with the different types of technological and intellectual means to acquire and combine uninterrupted flows of material and immaterial resources. The "knowledge theory" applied to the company says: The ability to adapt and the efficiency of the company depends on its cognitive categories, on the interpretation codes of the information itself, on the tacit skills, and its procedures in solving the problems it encounters (Dosi et al. 1999). The scientific, technical, and industrial information as a system of knowledge (Knowledge-capital) which is articulated, formalized, and likely to be communicated or transferred is a means of production, identifiable as such the use of which provides innovation for the economic process and the accumulation of capital. The task of the "technostructure" consists therefore of finding the balance between managing the "partnerships" and developing the internal instruments of organization (see Laperche et al. 2006).

Faced with the complexity of the private innovation process, M. Castells (1998) went as far as to maintain, quite cleverly, that the fundamental unit of the economic system is no longer the entrepreneur, the family, the firm, or the state, but the network composed of different organizations. Regarding innovation, the division of labor and the very refined specialization of skills in scientific research and experimentation remove any possibility of autarkical organization of the technological production. The network unfolds as a private form of organization of the instrumentalization of science. Partnerships between companies and between state research bodies and companies, and a whole panel of technical, financial, and commercial contributions, illustrate the theories of the classical economists (e.g., A. Smith and K. Marx) for whom once the capital takes over the social production (and enlarges its market by appropriating the resources at the time), the economy is subject to technical transformations and changes in the social organization of the production.

Conclusion and Future Directions

The new era of capital is not so much apprehended by the technological progress, but by the new way in which the production process is organized and developed. The industrial applications of science are the result of this, but also what prompts accumulation, the means to succeed, and also the cause of crises (Noble 2011). The current theories of networks, externalities, competition, and open innovation are based on an acquired principle: the benefits of the market, and on common finding that the market must not only be developed, organized, and regulated, but that it must also be created and preserved.

For the radical economists, the socialization of capitalist production has indeed taken on such dimensions that from now on, the appropriation of the technological elements gathered by the large companies is less costly than the raising of capital for their formation. The big firms are becoming, using relations of power, convergence centers for science and techniques, which they combine to supply their innovation process. To get from the stage of the concentration of production to the current stage of the contractual integration of the centralized property, capitalism has invented a new accumulation framework; the economic policies of "contesting the monopolies," privatization, flexible work management, international financialization, and integration have to a certain extent succeeded in depreciating the old capital, but they have also created the context of securitization and marketability of all individual and collective assets (science is of course part of this). In these conditions, how can economists be surprised by the regulatory power of finance? The system works by trial and error, finance facilitates the task. But in doing so, it directs the applications of science to production, it becomes a selection criterion to the research programs and at the same time, it weakens the potential for radical systemic innovations.

The age of the "captains of industry" is a bygone era (Boutillier and Uzunidis 1999). State management of innovation which the neoclassical economists are calling for shows, on the one hand, that the appropriation of scientific resources by companies is considered as one of the State's main economic reasons and, on the other hand, that the obstacles to accumulation become insurmountable without the organizing and planning role of the state. The introduction of commercial logic into scientific research falls within the scope of an innovation policy, but more surprisingly, so does the economic efficiency of the "network."

Opportunities recognition; Spin-off; Start-up; Technology

Innovation opportunities are often recognized and valorized by new small companies. This chapter goes into details about the capacity of firms to seize innovation opportunities depending on their size. Then, the mechanisms mobilized are described, and the main sectors where start-ups are operating are listed. The question of the financial structure of start-ups is finally studied.

Introduction: Innovation, the Ability to Grasp New Opportunities

Innovation may be defined as a dynamic process to modify the functioning modes and the organizations of companies in order to develop new businesses (Boly 2009). These adjustments may concern new equipment, production processes, core competencies, and organizational variables such as the type of responsibilities assumed by employees, control processes, and information procedures (Simon 1979). One particular and radical form of this type of evolution is company creation: start-up launching among others. Generally, a start-up company is considered as a structure recently launched and based on up to date technological knowledge. Its potential development capacity and its reward profile are potentially important, but the associated risk is also high.

The aim of the innovation process is to invest in new economical areas: the company faces new customers, valorizes new knowledge, takes into account new constraints, and manages new relations (in terms of the nature of the interaction) with its present external stakeholders but also with new ones (this includes suppliers, partners, institutions). Consequently, innovation does not only concern the technical domain and the development of a new activity. Moreover, the ability to identify new opportunities constitutes a major asset for innovators. The behaviors and thought processes mobilized by entrepreneurs to see the unique potential in a situation and create an organization to pursue it are key success factors, while other individuals, when presented with the same information, either fail to see the opportunity or choose not to pursue it (Parks 2005). Note that entrepreneurs' skills are not the only explanation of the capacity to seize opportunity. As customers needs, technology, regulation, and political context evolve, innovation opportunities may be seized by entrepreneurs able to determine these new economical areas and acting in a favorable environment.

Finally, Parks (2005) suggests that innovation opportunity recognition is based on three compounds. The first component is the founding entrepreneurs who decide to create firms to pursue entrepreneurial technology ventures. The second component is the organization they build around themselves and how this collective organizational knowledge and experience (mostly in customer problem solving) impact on the success of the venture. It seems that in the field of high technology, expertise and experience constitute requirements in order to recognize opportunities within a mass of information and observation. Up to 50% and 90% of start-up ideas come from prior work experience. The final component of the process is the technology on which the venture is based, how this technology develops and evolves due to interaction with the founding entrepreneur, and the knowledge of the firm. The paper goes into greater detail about this theoretical model.

Are Start-up Organizations Adapted to Invest in Innovative Domains to Grasp Innovation Opportunities?

Organizations grow by gaining efficiencies of scale and scope in specific core competence areas that, ultimately, become core rigidities (Leonard-Barton 1992) or core incompetences (Dougherty 1995). Some scholars use the term "knowledge tunnel" to describe the incapacity to detect new market emergence. Moreover, innovation requires new production processes and new skills, and as a result, innovation requirements are often in contradiction with mainstream organization. Consequently, companies often hesitate to launch innovative projects, which require long-term R&D periods before ensuring a real return on investment. As a consequence, scholars conclude that radical innovation cannot be effectively managed within the confines of the firm, and they prescribe external incubators or investments in start-up firms and venture funds as the source of organic renewal for large established companies (Campbell et al. 2003). On the other hand, big companies attest to financial, human, and material resources that strengthen the innovative processes, and the innovative capacity of many international companies is evaluated as high (Wang et al. 2008) (Yam et al. 2004). One hypothesis is discontinuous innovation processes associated with disruptive technologies are better adapted to start-ups, whereas continuous innovation processes associated with sustaining technologies is better suited to large companies. However, a better understanding of the link between the size of the company and its ability to seize innovation opportunities remains a major research concern.

In fact, three scenarios may be defined at the beginning of the innovation process:

– An individual launches a start-up: thanks to their own entrepreneurial skills, a manager creates an ex nihilo organization able to develop knowledge and valorize it on the market.
– A big company launches a project through a team organized as a start-up: some individuals of the company work in an autonomous context within the company; the venture group is in charge of R&D tasks but also of the launching period. This may include the standardization of the business activity.
– An existing company establishes a partnership with a start-up. Different forms of partnership may be distinguished. Some companies organize venture capital structures. They act as financial institutions and provide funding to newly created companies. Hence, Aster Capital is a corporate capital fund federating Rhodia, Schneider Electric and Alsthom. Aster is more precisely dedicated to start-up support and participates among others to the development of Optireno, a start-up in the field of insulation. The objective is to get financial rewards or to facilitate any possible further purchasing procedure. The start-up development is accelerated thanks to this financial support and represents a possible temporary external structure seizing an innovative opportunity in place of the big company. Some companies directly acquire shares in young technological structures but some others establish strategic and technology partnerships. Procter and Gamble as well as Veolia, put researchers and equipment at the disposal of start-ups in order to strengthen their R&D. They previously negotiate the exclusive valorization of the new technology on certain markets which are strategically important for them, while the start-up runs the findings in any other domains.

Linked with these three scenarios, different business models are established within the start-ups:

– Business models based on the autonomous development of the company: they are characterized by the progressive growth of the capital
– Business models integrating the future purchasing of the start-up by large companies: important funds are invested at the very beginning in order to accelerate the R&D tasks
– Codevelopment business models: investments are calculated aiming at an acceptable return on investment by each partner

In conclusion, even if inner structures such as interdepartment teams, new business divisions, or new venture groups may be dedicated to innovation, start-ups are common organizations in the field of innovation.

Opportunities Seizing Mechanisms Associated with Start-Ups

An innovation opportunity is defined as an exogenous favorable context (market demand, time to enter this market among others) associated with an idea of a new product, technology, or service.

Technology transfer from national scientific community to economic stakeholder represents a way for companies to seize disruptive innovation opportunities. The major implication for technology transfer and commercialization is that the more channels of communication that exist between the technology source and the technology recipient, the more likely the technology will find its way to the market (Kassicieh et al. 2002). The company, managerial (especially those centered on learning), and scientific competences have long been associated with the capacity to succeed in the technology transfer process. Thus, two scenarios appear:

– The development of laboratory spin-offs
– The creation of a start-up by a former member of a research laboratory

In these two cases, people developing the research are also involved in the definition of application opportunities and in the development of the corresponding activities. In some countries, these mechanisms are stimulated with specific procedures, including the ability for a national researcher to take entrepreneurial leave or to invest in a spin-off. Finally, opportunities are seized by "direct human transfer."

Another mechanism observed in the opportunity recognition phase can be found in the local social network that entrepreneurs manage. The meeting and confrontation of people from the same geographical area, each having part of the required knowledge to launch an innovative activity, is one source of development (Lakoff 2008). Opportunities are then valorized thanks to local confrontation. National institutions try to stimulate this mechanism through policies favoring networking or clustering. Klevorick et al. (2005) investigating the source of knowledge of start-up states that the primary sources are customers and suppliers before academic structures (biology is an exception). Then start-ups emerge when a combination of expertise and experience (technology, marketing, distribution) gives a new expertise large companies do not have (Carayannis and Alexander 2002).

Foreseeing is a third mechanism. After treating information, entrepreneurs develop a vision, a description of a scenario for the future. These include future market specifications, new uses, new production constraints, and new needs. Thus, they use their own expertise or external knowledge to elaborate a strategy and the associated technologies. Anticipation is then the very first step in opportunity recognition.

Main Start-up Launching Sectors

Statistical data is not easy to collect, as long as "start-up" is not a reference term in national statistics institutions; moreover, the term "new technology" corresponds to a wide range of situations. Consequently, company creation databases are used to evaluate start-up launches.

Start-ups seems mainly to seize opportunities in the fields of information technology (software and services), telecommunication, electronics and electricity, chemicals and pharmaceuticals, new materials, and biotechnology. In France, the two first domains represent 75% of the total number of start-up creations.

Start-up Financing

The financing of the different phases of the life cycle of an innovative process, product, or service is one of the main issues of innovative start-ups. Different possibilities exist at each stage; these include public financing, permanent capital, long-term loans, short-term loans, and the role of the different actors, shareholders, bankers, politicians/policy makers, suppliers, and clients. Based on data collection campaigns within a multisector start-up panel, it is possible to determine general trends about the capital required depending on the type of technology developed.

At the proof of concept stage, little money is generally spent at this stage. At least, it could even be a serendipitous result or a kind of "by-product" of a more global research activity (Table 1).

On a second phase, based on feasibility and repeatability, the enrichment of the concept is achieved; the aim is confirmation, still at lab level, that the technologies to implement the concept are reliable. The possibility of reproducing the experiment with other operators and machines and initial conditions are also tested. Finally, the opinion of some of the main market stakeholders may be collected. Consequently, money is spent on experiments, tests, characterization, industrial property studies, and protection and premarket studies. Equity capital (when the company is already created), other public funds, and/or semipublic funds contribute to the financing (Table 2).

The third phase of industrialization is crucial and risky: it consists in developing knowledge to master the technology from lab level to an industrial scale. All the support activities are organized: sales and marketing, maintenance, and supply chain management. Generally, at this stage, larger investors are involved in the venture: initial investors have to adapt to this capital enhancement. Moreover, venture capital is needed and business angels may be associated. Other more institutional schemes may also be activated, technology transfer fund among others.

Innovation Opportunities and Business Start-up, Table 1 Step one – proof of concept (Source: Authors)

Risk extremely high		
Start-ups Steps	Financing	
	Needs	Sources
Ideas, concepts detection	Initial tests	Generally invisible when performed by public
Valorization services? Industrial liaison offices		R & D activities
Sensitization of students/researchers		Generally not individualized when performed by private
IP concerns (initial initiatives)		R & D activities
Analysis of the other projects of the laboratory		

Innovation Opportunities and Business Start-up, Table 2 Step two – feasibility and repeatability (Source: Authors)

Risk very high		
Start-ups Steps	Financing	
	Needs	Sources
IP protection (formal) – partnership agreements	Support to IP protection	Equity capital (shareholders, finance market)
Choice of the next steps (internal valorization in other research projects, sale to external existing company, start-up . . .). Scenario building	Pre-market studies	National, regional, local public financing schemes for R&D and tech transfer . . .
	Research for R&D partners	
	Technology broker hiring	Risk capital setups
Complementary studies	Development specialist hiring	Business angels
"Production" of the first samples – trials/tests		

Innovation Opportunities and Business Start-up, Table 3 Step three – industrialization. Step four: Continuous innovation dynamic (Source: Authors)

Risk still high		
Start-ups Steps	Financing	
	Needs	Sources
Engineering studies	Cofinancing of innovation project – industrialization	Equity capital (shareholders, finance market)
Research of financial (technical market) partners (capital increase, participative loans)	Phase Support to finance engineering	National, regional, local public financing schemes for R&D and tech transfer
Complementary studies (e.g., aging)	Support to market strategy elaboration	Risk capital set ups
Application exhaustive exploration, selection of first market segments)		Risk capital Long-term loans (quasi proper funds)
Investments (machines, people, demonstrators, market)		

The observation campaign within the studied start-up panel concludes that the ratio between the amounts of money required for step three is between 50 and 100 times higher than step two (Table 3).

At step four, processes are operating and products or services have been recently launched on the market, technical aspects required improved. A continuous innovation activity is managed, either to suppress defects observed at user level, improve performances, or allow access to new markets. At this stage, the necessary funds may be covered partially by the company outcomes, but complementary loans are often mobilized (Table 4).

If the new activity is successful (Table 5), operating costs are covered by the exploitation, but the increase in sales very often produces an increase in operating capital needs which could be covered by short-terms loans. Some contradictions have to be treated since some financing schemes (e.g., innovation loans) ask for the money to be paid back from the first sales when the needs in operating capital are highest. Precise treasury prevision and management is a key factor, and trust between all partners is challenged here. Finally, in order to wait for the dividend distribution period, different

Innovation Opportunities and Business Start-up, Table 4 Step four – continuous innovation dynamic (Source: Authors)

Risk		
Start-ups Steps	Financing	
	Needs	Sources
Technology (processes, products) updating	Support for consulting services	Equity capital (shareholders, finance market)
Services offer permanent analysis and upgrading	Support to strategic intelligence and knowledge management	Long-term loans (quasi proper funds)
New competitors (“fast second”)		Short-term loans (running capital increase for exploitation)

Innovation Opportunities and Business Start-up, Table 5 Step five – operation (Source: Authors)

Normal risk		
Start-ups Steps	Financing	
	Needs	Sources
Strategic decisions: internal production investments, contracting, client/supplier relations. . .	Support for financing productive investments (warrant for banks, incentives . . .)	Sales (margin, profit) if necessary short terms banks loans
Networks, clusters	Support to market studies and market development	Shareholders running accounts
Market penetration	Support to export	Banks (running capital needs)
	Support do staff recruitment	

financial possibilities are mobilized depending on the different levels of risk: the higher the risk, the higher the need of permanent funds. Since innovative start-ups or innovation projects are risky, manager attention is directed toward structural funds and low interest rates. Consequently, short-term money is not suitable for their development. Securing the financing scheme and using various possibilities of constituting the permanent capital are crucial strategic actions which are to be taken into account as much as technology or market.

Conclusion and Future Directions

Start-ups are adapted to innovation opportunities through specific processes of recognition considering the type of sector and technology considered. Start-ups represent more or less sustainable organizations able to develop technological knowledge and the associated business activities. Their ability to seize opportunities highly depends on the manager profile, the organization, its structures, and the type of technological sector concerned. The phenomenon of start-up development highly proves that technology is a complex system based both on scientific knowledge and also on connected knowledge (any expertise allowing to valorize a specific scientific skill into an industrial competence).

Considering financial aspects, a better understanding of the adequation between the amount of money required and the nature of the corresponding funds at each step of the development cycle of start-ups still remains necessary.

Innovation Policies (vis-à-vis Practice and Theory)

Stefan Kuhlmann
Science, Technology, and Policy Studies (STePS), University of Twente, Enschede, Netherlands

Synonyms

Governance; Innovation policy; Innovation practice; Innovation theory

Innovation-driven economic and social change is a significant characteristic of today's economies and a driving force for international knowledge production, competition, and trade; this holds certainly for industrialized countries, but increasingly also for a growing number of late industrializing countries. National, often also regional, governments pursue, more or less explicitly, *innovation policies*, which can be defined as "as the integral of all state initiatives regarding science, education, research, technology policy, and industrial modernization, overlapping also with industrial, environmental, labor, and social policies. Public innovation policy aims to strengthen the competitiveness of an economy or of selected sectors, in order to increase societal welfare through economic success" (Kuhlmann 2001, 954). Public innovation policies reflect the "innovation culture" of a given society, not at least characterized by the particular interrelation of economic, knowledge-producing, and policymaking actors and organizations ("Triple Helix"), at various levels of action ("multilevel innovation system").

The concept of public innovation policy is built on the assumption that "innovation" – a perceived or intended process of material, social, and often also cultural change, incremental or disruptive – can be "governed." The present entry (largely drawing on Kuhlmann 2007) offers four considerations of this supposition: First, an illustration will be presented of *why* the

Innovation Policies (vis-à-vis Practice and Theory), Fig. 1 Innovation practice, theory, and policy as dancing partners (Source: Kuhlmann 2007, 5)

governance of innovation is an issue of concern and that there are governance routes of different character and quality. Second, three forces of the governance of innovation will be addressed: The (1) dynamics of *innovation in practice*, the (2) role of *public policy*, and (3) the role of *Innovation Studies*, as "theory in action." In order to illustrate the mutual interaction of the three forces, a metaphor will be used (following Kuhlmann 2007; Kuhlmann et al. 2010). Innovation practice, policy, and theory can be seen as "*partners on a dancing floor*," moving to the varying music and forming different configurations (see Fig. 1). Taking a closer look at the dance floor, one can see two of the dancers, innovation practice and policy, arguing and negotiating about the dance and music while the third, theory – not always, but often and to an increasing extent – provides the other two partners with arguments and sometimes also with new music: Practice and policy increasingly have expectations vis-à-vis the contribution of social science-based intelligence to their dance. Hence, the third consideration: (3) *Innovation Studies*, by now a widely respected academic field of interdisciplinary knowledge and research, may experience a tension between participating in the dance and academic discourse at arm's length to practice. Yet, there is a chance that Innovation Studies can cope with this tension and, in fact, make it a source of increased *reflexivity*. The fourth consideration will (4) exemplify some ways of deliberate interaction of Innovation Studies as theory in action, taking a closer look at *"fora" for the debate of innovation issues* and the role of research-based "strategic intelligence."

First Consideration: Why "Governance of Innovation"?

A better understanding of the governance of innovation both in terms of driving forces and with respect to the room for maneuver in policymaking is a precondition of successful practical attempts at shaping the character and direction of innovation processes or even changing them.

Innovation occurs within or vis-à-vis evolving "regimes." The term *regime* was first introduced by Nelson and Winter (1977) to characterize patterns in technical and economic change such as the frameworks of engineers in an industry constituting the basis for their search activities. Van den Ende and Kemp (1999) define a technological regime "as the complex of scientific knowledge, engineering practices, production process technologies, product characteristics, user practices, skills and procedures, and institutions and infrastructures that make up the totality of a technology" (835). Rip and Kemp (1998) add to the "grammar" of a regime explicitly the policies and actions of other innovation actors including public authorities.

Regimes differ in terms of the character and quality of their *governance*. The notion of governance is used here as a heuristic, borrowed from political science, denoting the dynamic interrelation of involved (mostly organized) actors, their resources, interests and power, fora for debate and arenas for negotiation between actors, rules of the game, and policy instruments applied (e.g., Kuhlmann 2001; Benz 2006; Braun 2006). Innovation governance profiles and their quality and direction are reflected not at least in the character of public debates between stakeholders, policymakers, and experts. Think of the debates on genetically modified organism (GMO), or debates on the governance of an emerging, cross-cutting innovation field such as "nanotechnology."

In a report of a European Expert Group on "Science and Governance" (Felt et al. 2007), two basic types of what the authors call "regimes" of innovation were identified:

- The regime of "*economics of technoscientific promise*": Promises to industry and society, often far reaching, are a general feature of technological change and innovation, particularly visible in the mode of governance of emerging technosciences: biotechnologies and genomics, nanotechnologies, neurosciences, or ambient intelligence, all with typical characteristics: They require the creation of a fictitious, uncertain future in order to attract resources and political attention. They come along with a diagnosis that "we" are in a world competition and that "we" (Europe, the USA, etc.) will not be able to afford "our" social model if "we" don't participate in the race and become leaders in understanding, fuelling, and exploiting the potential of technosciences. The regime "works with a specific governance assumption: a division of labour between technology promoters and enactors, and civil society. Let us (= promoters) work on the promises without too much interference from civil society, so that you can be happy customers as well as citizens profiting from the European social model" (Felt et al. 2007, 25). Under this regime of technoeconomic promises, politics, science, and industry take the lead, while the innovation needs and expectations represented in the society appear to remain in a rather passive consumer role.
- The second regime, "*economics and socio-politics of collective experimentation*," is characterized by emerging or created situations which allow to try out things and to learn from them. The main difference with the other regime is that "experimentation does not derive from promoting a particular technological promise, but from goals constructed around matters of

concerns and that may be achieved at the collective level. Such goals will often be further articulated in the course of the experimentation" (Felt et al. 2007, 26f). This regime requires a specific division of labor in terms of participation of a variety of actors, investing because they are concerned about a specific issue (see also Callon 2005). "Users matter" in innovation (e.g., Oudshoorn and Pinch 2003). Examples of such demand- and user-driven innovation regimes include the information and communication sector (where the distinction between developers and users is not sharp), or the involvement of patient associations in health research (e.g., Boon et al. 2008). The concept of "open innovation," debated around the user-driven development of non-patented Open Source software, and more generally in Chesbrough's influential book (2003), is largely overlapping with the collective experimentation concept. The governance of such regimes is precarious since they require long-term commitment of actors who are not always equipped with strong organizational and other relevant means, and there is always some room for opportunistic behavior. Nevertheless, the promise is innovation with sustainable effects.

In other words, the governance of innovation and related policies are neither neutral nor innocent. The precarious governance of the experimentation regime or the missing emphasis on stakeholder inclusion and demand-orientation indicate that strategists and policymakers may run the risk of missing valuable opportunities offered through variety and experimentation in the development of innovation processes. This leads to the second consideration.

Second Consideration: Three Interrelated Forces of Innovation Governance and Their Dance

An analysis of the governance of innovation has to cope with at least *three major forces*:

First force: While since the 1950s in economics and sociology "*science*," "*technology*," *and* "*innovation*" processes were plotted as a sequence of activities of institutionally and organizationally distinct units ("linear approach"; Bush 1945), this has changed in the course of the 1980s and 1990s. Today science, technological development, and innovation are conceived by most scholars as *overlapping fields of social practice*, forming a shared "space" of interactivity, driven by knowledge dynamics, economic forces, and framed by inherited institutions. Most concepts emphasize the interactive character of idea generation, scientific research, development, and introduction of innovative products and processes into markets or other areas of use – take as a simplifying tag the pervasive concept of an alleged new "mode 2" of knowledge production suggested by M. Gibbons et al. (1994). Eventually, the mode 2 perspective on knowledge production and innovation is building on a long strand of studies into the relation of science and technology (e.g., Zilsel 2003; Rip 1992) and, at least implicitly, alluding to older, more systemic concepts (e.g., List 1856). The evolutionary approach of Nelson and Winter (1977), the innovation system tradition as inspired by Freeman (1987) and developed further by many others (e.g., Lundvall 1992; Edquist 1997; Hekkert et al. 2007), take on board an interactive, holistic understanding. Also studies into the social construction of technology (Bijker et al. 1987), "system transitions" in socio-technical landscapes, related regimes, "innovation journeys" and niche management (see e.g., Geels and Schot 2007; Van de Ven et al. 1999), technology assessment and its "constructive" turn (Rip et al. 1995), understand science, technological development, and innovation as a an interactive social continuum.

Second force: If the dynamics of science, technological development, and innovation are interwoven in practice, then "*policy*" and "*governance*" in a given innovation field will reflect this heterogeneity. Today, innovation policy is characterized by an "increasing 'sophistication' of policy instruments" (Boekholt 2010, 334). Concepts on innovation policy have evolved from a linear model to a more systemic and even "holistic" model of innovation policy (e.g., Smits and Kuhlmann 2004). Consequently, the scope and variety of involved organized actors (such as science organizations, industries, governmental agencies, parliaments, nongovernmental organizations) has become broad and heterogeneous. Actors have different interests, resources, and power, and they negotiate in various interlinked arenas on all kinds of rules and policy instruments. Political science studies have shown that the patterns of policy governance for science, technology, and innovation develop mostly in an incremental and only rarely radical way (Bozeman 2000; Larédo and Mustar 2001; Biegelbauer and Borrás 2003; Edler 2003). The organizations involved in policymaking and the arenas for the negotiation of options and decisions are mostly characterized by institutional inertia. They evolve to path dependence, interwoven with historical innovation regimes. One can analytically distinguish between two types of policy rationales in the context of science and innovation (EPOM 2007): "*Knowledge production policy rationales*," on the one hand, are built on causal beliefs, often derived from Innovation Studies' insights, about the production of knowledge, providing a theoretical framework for the type of policy proposed, especially with socioeconomic arguments. An advanced production rationale is characterized by the fact that knowledge is often tacit, partial, scattered and collectively distributed, and built through collective processes of creation, sharing, access, diffusion of knowledge, and more generally through learning processes. "*Governance policy rationales*," on the other hand, reflect general causal beliefs in the political system about how the state should govern (EPOM 2007). An advanced governance policy rationale is offered by a "decentralized multi-space model, with a growing importance of a large variety of public and scientific interest groups (public opinion, consumers, patients, NGO, etc.) willing to be associated into the policy design, with a high heterogeneity among them (in terms of level of knowledge, means of expression, financial resources, representativity, etc.)" (EPOM 2007). Following this rationale, the actual policy choice and mixes depend on negotiation and learning processes in the development of a given regime: Whether the future governance of nanotechnologies, for example, will be driven mainly by technoeconomic promises or by socio-political collective experimentation hinges not at least on the way how the involved heterogeneous actors in multi-space articulation processes will interpret the production rationales associated to nanotech.

Third aspect: Social science research, in particular Innovation Studies, can turn into "*theory in action*." Given the variety and potential complexity of governance in the practice of innovation as well as in related policymaking, actors tend to develop assumptions or "folk theories" on governance, simplifying, guiding, and stabilizing their action: Innovators and policymakers develop rules of thumb based on experience, own analysis, or prejudice – or they refer to and utilize expertise based on Innovation Studies. Take, for example, the utilization of the "System of Innovation" approach: This analytical concept, a heuristic developed by economists and innovation researchers since the late 1980s, has been increasingly utilized by policymakers around the world. Innovation systems have been conceptualized as the "biotopes" of all those institutions which are engaged in scientific research and the accumulation and diffusion of knowledge, which educate and train the working population, develop technology, produce innovative products and processes, and distribute them; to this belong the relevant regulative bodies (standards, norms, laws), as well as the state investments in appropriate infrastructures. Innovation systems would extend over schools, universities, research institutions, industrial enterprises, the politico-administrative and intermediary authorities, as well as the formal and informal networks of the actors of these institutions (Kuhlmann 2001). The innovation system concept turned out to appeal to policymakers a lot, not at least because the systemic perspective provided an argument for a broadened scope and reach of public innovation policy (Smits and Kuhlmann 2004). Many used it as a sort of programmatic device: Since a number of years, for example, the Swedish state office for innovation policy calls itself "Governmental Agency for Innovation Systems."

Actually, when taking a closer look, it turns out that the very concept of innovation systems while being designed by innovation researchers had at the same time been inspired and strongly supported by Scandinavian policymakers (see Carlsson et al. 2010) and by the Organisation for Economic Cooperation and Development (OECD) (Lundvall 2007) – the concept became "theory in action." Scholars could have tried to maintain academic distance to the lifting of their concepts and findings by policymakers or practitioners in innovation – but they chose to offer the policymakers information, heuristics, analysis, and theory, longing further than their "folk theories." In other words, they danced with innovation practice and policy and even jointly composed new melodies.

Considering innovation practice, policy, and theory as "partners on a dancing floor," moving to varying music and exposing different configurations, one can interpret the "regimes" of innovation and their evolution from the perspective of learning. The ideas, rationales, and instruments – finally the governance – of innovation and related policy emerge as a result of interactive learning between actors involved in innovation practice, intervention strategies and policies, and Innovation Studies and theory. Figure 1 (above) represented an attempt to characterize the dance of the three groups. Practice, policy, and theory can be conceived as dancing partners in a performance setting. The dancers observe each other and react on the partners' movements: They copy, comment, complement, counteract, neglect, learn, and thereby create and change configurations. Sometimes innovation practice is the driving force in a configuration, sometimes theory, sometimes public, or private policy.

Learning on the innovation policy dance floor may occur as first-order or as second-order learning. According to Argyris and Schön (1978), *first-order learning* links outcomes of action to organizational strategies and assumptions which are modified so as to keep organizational performance within the range set by accepted organizational norms. The norms themselves remain unchanged. *Second-order learning* concerns inquiries which resolve incompatible organizational norms by setting new priorities and relevance of norms, or by restructuring the norms themselves together with associated strategies and assumptions, hence escaping tunnel vision and crossing borders. In other words, while first-order learning would help to improve the expression, harmony or elegance of an otherwise unchanged dance (or make an innovation regime more effective), second-order learning would help to change the melody and the dance (or introduce new directions and modes of governance).

Third Consideration: The Potential of Innovation Studies as a Dancing Partner

Today, Innovation Studies are a respected academic field of interdisciplinary knowledge and research, loosely interlinked with Science and Technology Studies (STS; Hackett et al. 2007). In short, most of the enormous scope of topics covered by Innovation Studies and STS can be subsumed within two very general rubrics (Silbey 2006, 538): First, the institutionalization, reception, and appropriation of science and innovation and, second, the production of science and innovation as a social process. The first perspective is interested in the working of institutions, organizations, policies (expectations, rules, regulation, funding), strategy-making and planning, the assessment of potential developments and impacts of science and innovation, and their constructive shaping (Constructive Technology Assessment, CTA). The other, second perspective of studies adopts an anthropological view on the working of scientists, engineers, or users trying to reveal the intrinsic organization, culture, and epistemology of social groups. The ambition is to understand innovation not as a completely distinct realm of social action but like other social settings ruled by habits, rules, conflict, compromise, constructions, and narratives (Silbey 2006, 539). Consequently, this perspective concentrated rather on innovation as social practice than on policy. This approach, nevertheless, has an important impact on policy concepts: It helps to understand that modeling the governance of "innovation in the making" would fall too short if practice were conceptualized mainly in terms of functional and normative requisites, suggesting rather mechanistic designs of public policy ("mode 1"). Applying the constructivist approach to technological development and innovation as fields of social practice, strategists and policymakers developed more and more sophisticated policy designs ("mode 2"). The above-sketched "production governance rationale" can be understood as a result of this new perspective.

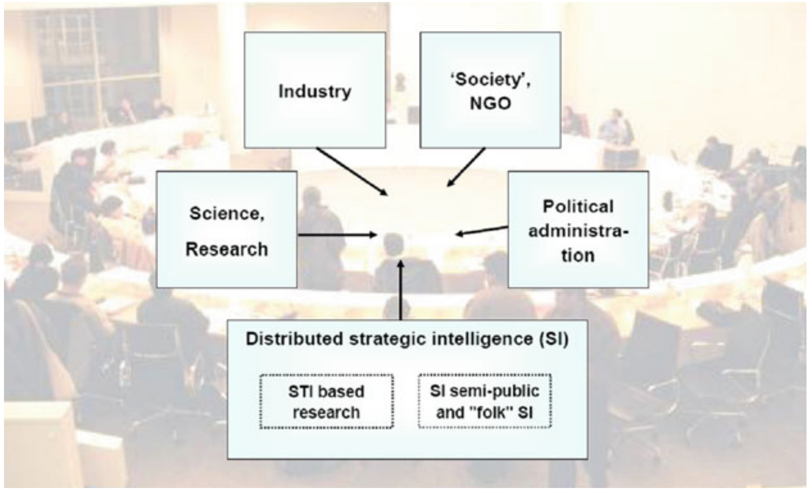
In short, one can state that Innovation Studies contributed a lot to a better understanding of the driving forces of each of the two other dancers, innovation in practice and policy, and became to some extent interwoven with them – sometimes very tightly, sometimes at some academic distance. Innovation Studies cope with this tension and even make it a source of increased reflexivity and enlightenment for their own purposes. The reflexive potential of Innovation Studies arises from the combined perspective of the interaction of practice, policy, and theory: Observing the dance and getting involved into it, Innovation Studies hardly can avoid adopting a *constructivist* position and *reflecting* upon their own impact on the dance and the evolution of images and beliefs of the other partners. And – one step further – Innovation Studies cannot escape questioning the origins and dynamics of their own beliefs. To which extend are they driven by concerns of practice and policy? Could such a drift be pictured as second-order learning, or are Innovation Studies scholars' beliefs sometimes also echoing the trends or fashions of their dancing partners or of the surrounding societal and cultural movement?

Obviously, Innovation Studies are not made up of one dominant theory; rather they appear as an assemblage of quite diverse intellectual strands, sometimes converging, sometimes diverting. Accordingly, innovation practice might prefer dances with other theory than public policy would like. In sum, there is no single recipe for coping with the ambiguity of being involved in the dance with practice and policy. Innovation Studies scholars moving with some passion on the dancing floor can only try to keep a precarious balance, based on some distance through reflection.

Fourth Consideration: Dance in Practice (Fora and Strategic Intelligence)

For a number of reasons, the governance of innovation and related policy has become ever more complex: Innovation processes themselves are subject of multiple forces and have become more uncertain; the number and heterogeneity of actors involved has grown, hence also the plurality of interests and values; and the borders between public and private spheres have become blurred. In order to cope with these challenges, actors seek to base their policy initiatives on increased interactivity, and often also on more evidence of actual or potential conditions, cost, impacts, etc. Interaction may be formally institutionalized and regulated, while in early phases, interactivity may occur in emerging spaces and semi-institutionalized platforms, where policymakers, public researchers, and industry as well as experts meet, articulate their views, provide intelligence in order to inform the process, and make attempts to set the scene. One means of organizing a policy-oriented discourse in semi-institutional environments are "fora," defined as *institutionalised spaces specifically designed for deliberation or other interaction between heterogeneous actors* with the purpose of informing and conditioning the form and direction of strategic social choices in the governance of science and technology (see Fig. 2, and Edler et al. 2006).

Fora can be seen as a dancing floor, a meeting place for innovation practice, theory, and policy with two related effects: (1) Interactive learning of policy analysts, policymakers, and relevant stakeholders and (2) improving the functioning of science and innovation policy and strategy. Fora can adopt several governance functions on the dance floor: They can offer a general, nondirected policy discourse, or offer policy information on specific issues, or prepare policy planning and development (visions, agenda,



Innovation Policies (vis-à-vis Practice and Theory), Fig. 2 Forum for debates of science, technology, and innovation issues (Source: Kuhlmann 2007, 17)

implementation), or facilitate the resolution of conflict and the building of consensus, or they can improve the provision and application of policy intelligence (e.g., see Edler et al. 2006).

In practice, there are manifold variations of fora. A specific characteristic of the sort of forum I am alluding to is the prominent role played by "*strategic intelligence*" (*SI*). SI has been defined as a set of sources of information and explorative as well as analytical (theoretical, heuristic, methodological) tools – often distributed across organizations and countries – employed to produce useful insight in the actual or potential costs and effects of public or private policy and management. Strategic intelligence is "injected" and "digested" in fora, with the potential of enlightening the debate (Kuhlmann et al. 1999).

SI can draw on semipublic intelligence services (such as statistical agencies), on "folk" intelligence provided by practitioners, and in particular on Innovation Studies. Meanwhile, a number of formalized methodologies, based on the arsenal of social and economic sciences, have been introduced and developed which attempt to analyze past behavior ("Evaluation"; e.g., Shapira and Kuhlmann 2003), review technological options for the future ("Foresight"; e.g., Martin 1995), and assess the implications of adopting particular options ("Technology Assessment"; e.g., Rip et al. 1995). Also, other intelligence tools such as comparative studies of the national, regional, or sectoral "innovation performance" were developed and used (e.g., the European "Community Innovation Surveys (CIS))".

Providers of SI play a number of roles in fora, often in combination: as a facilitator or moderator taking advantage of methodological capabilities, as an enabler or teacher supporting critical analysis and self-reflection (bird's eye view), as provider of issue expertise, or as entrepreneur using fora for advancing SI application in policymaking and for disseminating results (Edler et al. 2006).

Conclusion and Future Directions: "Strategic Intelligence" and New "Spaces" and New Models for Innovation Initiatives

Arenas of innovation policy have become more complex and sometimes unclear during the last two decades. Next to national governments, semi-independent regional and transnational institutions and agencies entered the arenas, partly as cooperation partners and partly as competitors. At the same time, public policymakers are confronted with multinational companies developing their innovation projects across the globe, drawing on public policy support wherever easily available, irrespective of the location of exploitation of innovation returns. National innovation policy will remain relevant, but actors will be urged to change their perspectives and policy designs: Hierarchical, fragmented, or stubborn strategies will fail in this complex environment.

Furthermore, many late industrializing countries have started to develop own innovation policy approaches, many of them drawing on the model of western industrialized countries. Yet, there are also more radical views, arguing that innovation policies are inspired on the wrong models, aiming at solving the wrong policy problems, too narrowly defined, too poorly managed and implemented, and/or lack the necessary supportive conditions from society due to historical, cultural, and political reasons (e.g., Rennkamp 2011). In particular, another concept of "innovation" will be required, beyond the presently prevailing business orientation, including aspects of social novelty and development, new ideas improving quality or quantity of life, not necessarily linked with economic profits. "The ultimate end of social innovation is to help create better futures" (Pol and Ville 2009, 884).

Hence, it will be crucial to systematically understand the diverging perspectives and interests of competing actors, to make them transparent and debatable – not aiming at weak compromises but stimulating learning capacity. This will require new interinstitutional and also international "spaces," fora where heterogeneous actors from different arenas meet and interact. "Strategic intelligence" can provide background information and alternative scenarios of potential future challenges for reflection. Otherwise, innovation policymakers will be reminded of the limits of an instrumentalist understanding and see "how great expectations in Washington are dashed in Oakland" (Pressman and Wildavsky 1973).

Innovation Policy Learning

Peter S. Biegelbauer
Department Foresight and Policy Development, Austrian Institute of Technology, Vienna, Austria

Definition

The term innovation policy learning stands for the change of innovation policy-relevant knowledge, skills, or attitudes, which are the results of the assessment of past, present, or possible future policies (Biegelbauer 2013).

Emergence of the Term and Development of Research

The approaches utilizing notions of policy learning share a conviction that the activities of policy-makers can be explained by understanding these actions in terms of feedback cycles used in order to assess previous actions. Policy-makers engage in learning in order to make sense of the world they live in, to gain a better understanding of the effects of their policies, and to arrive at better decisions in the future.

The notion "innovation policy learning" can be traced back to two different discussions, one rooted in political science and the other in economics. In political science, learning has been discussed as a category of policy analysis since the 1960s, when Karl Deutsch introduced his cybernetics of government (Deutsch 1966). Another milestone for the development of the term was Hugh Heclo's book on British and Swedish social policy (1974), in which he writes: "Governments not only 'power' . . . they also puzzle. Policy-making is a form of collective puzzlement on societies behalf" (Heclo 1974, 305). With this terminology, he captured one of the basic premises of the discussion on policy learning, namely, that political action cannot be explained alone by looking at interests and institutions and how they relate to power, which would be the classical categories of political science. Rather policy-makers also engage into efforts to solve what they perceive to be policy problems (Bandelow 2003; Biegelbauer 2013).

Similarly influential is the "advocacy coalition framework", developed mainly by Paul Sabatier (Sabatier and Weible 2007). In this framework, political processes are located in policy subfields, which are characterized by competing advocacy coalitions that may or may not change their belief structures through learning. At about the same time Peter Hall found that the change from Keynesian to monetarist economic policies in the early 1980s was best explained through social learning. His theory engulfs three targets of policy change, settings of policy instruments, policy instruments themselves, and finally policy paradigms, which are the ideational structure policies are embedded in and which most importantly explain the scope and the workings of policies. Social learning proper encompasses the change of policy paradigms, something happening only rarely (Hall 1993).

In the 2000s, policy learning approaches have been further developed, through, for example, critique of key terms (Maier et al. 2003), the further expansion of concepts of social learning (Oliver and Pemberton 2004), the advocacy coalition framework (Sabatier and Weible 2007), and of interpretative approaches (Grin and Loeber 2007), which also have integrated ideas from organizational sociology (Argyris and Schön 1978).

The second debate in which the term innovation policy learning is rooted stems from evolutionary economics. Neoclassic economic theory originally has exogenized innovation as a factor of economic development (Biegelbauer 2000). Yet with a number of empirical studies analyzing the production factors' input on growth carried out in search for new growth models, a new set of models was created in the late 1970s (Rosenberg et al. 1992). Joseph Schumpeter's vision of a dynamic and evolutionary economy (Schumpeter 1971) was integrated into a number of studies (e.g., Nelson and Winter 1982; Carayannis and Ziemnowicz 2007), which transcended the disciplinary boundaries of economics and led to a view of economic growth and technological change, which has increasingly been rivaling the neoclassical economic model ever since.

The key difference between the old neoclassical models and the newer Schumpeterian ones is that the latter are more dynamic in their evolutionary perspectives (Hofer 2003). With regard to technological change, this means an endogenization of the innovation process. Similar to the neoclassical model, the new models see technological change as the main driving factor for economic growth. However, since the new models are interested in explaining technological change, they assume the production function to include factors such as the level of technology or more broadly the stock of knowledge, investments into R&D, skills of the work force (human capital), indicators of the complexity of institutional arrangements, and the like, aside physical capital (Biegelbauer 2000).

In evolutionary economics, an important mechanism for the creation of knowledge and skills is learning. This notion has been developed especially by Bengt-Age Lundvall's concept of the "learning economy" (Lundvall 1992). Lundvall has differentiated between different forms of knowledge and skills, some of which had been rather neglected by economic theorizing before. This is especially the case with non-codified knowledge which accrues through "learning by doing" and forms an important knowledge base upon which a lot of innovation activities are based.

The wider framework of Lundvall's conception of a learning economy is the concept of "national systems of innovation" (Freeman 1987; Lundvall 1992; Nelson 1993), "the network of institutions in the public and the private sectors whose activities and interactions initiate, import, modify and diffuse new technologies" (Freeman 1987).

The notions of learning economies and national systems of innovation transformed in an ongoing process what was before science, technology, higher education, and industry policies into innovation policy (Biegelbauer and Borrás 2003; Edler 2003; Carayannis and Campbell 2006). This move impacts on the selection of policies as well as on the ways policies are perceived. Policy instruments have become more complex and are constructed to fulfill a multitude of purposes for the needs of a multitude of actors, and their effects are expected to be systemic (Kuhlmann and Smits 2004; Weber 2009). These changes have been interpreted as policy learning closely connected to the developments in the area of evolutionary economic innovation theory (Mytelka and Smith 2001).

Ramifications for Innovation Policy and Policy Analysis

A number of policy instruments have been devised to foster policy learning: evaluations, benchmarks, foresight exercises, impact assessments, expert commissions, and studies have been utilized to make policy-making ever more evidence-based and rational (Biegelbauer 2007, 2009; Biegelbauer and Mayer 2008).

Especially the European Union has built a whole learning architecture as part of the Lisbon Agenda and the Strategy 2020, both featuring the main goal of making the EU the most innovative and competitive region of the world. These strategies make use of the open method of coordination and its plethora of learning instruments. The exact nature of the open method of coordination, for example, the degree of its formality, differs from policy field to policy field (Borrás and Greve 2004; Borrás and Radaelli 2011). In RTDI policy, it engulfs a variety of rather informal networks, projects, and platforms in which experiences with RTDI policy-making are to be analyzed and exchanged (Lisbon Expert Group 2009). An important role plays a set of indicators, the Innovation Union Scoreboard, which has been developed in order to ease a systematic comparison of the EU member states' experiences – the Innovation Union Scoreboard covers the 27 EU member and 7 additional countries with 25 innovation research-related indicators as part of the EU's Strategy 2020, which has replaced the EU Lisbon Agenda in 2010 (Biegelbauer 2012).

In the 2000s, efforts have been made to integrate the two strands of research described here, one from political science and another one from evolutionary economics, in order to better understand innovation policy learning. This has taken the form of historical analyses of innovation systems and innovation policy on national (Biegelbauer 2000) and supranational (Edler 2003) levels, of comparisons of national systems of innovation (Biegelbauer and Borrás 2003), analyses of the relation between innovation theory and policy development (Mytelka and Smith 2001), critique of (naive) benchmarking exercises (Lundvall and Tomlinson 2001), and the open method of coordination in innovation policy (Lisbon Expert Group 2009).

Conclusions and Future Directions

From the research on innovation policy learning, several conclusions can be drawn for the further development of policy analysis. First of all, the concentration in the research field on rational decision-making in the sense of the maximization of personal utility should be balanced with other perspectives on decision-making processes. Policy-making is not only about a quest for power and influence, it is also about gaining knowledge, solving problems, and dealing with historically contingent norms and practices in the form of institutions, discourses, and culture (Gottweis 1998; Prainsack 2011).

Second, these different factors, for example, interests, cognition, institutions, discourses, and cultures, all play a role in the policy-making process, which is much messier, less sequential, and rational as usually depicted in the statements of politicians, accounts of journalists, but also social scientists (Hoppe 2009; Biegelbauer 2013).

Third, there is an urgent need for a fine-grained empirically driven policy analysis recognizing the messiness of decision-making processes instead of producing more schematic depictions of policy-making utilizing models of lower solution. Such a policy analysis could lead to a deeper understanding of the interplay of factors leading to policies and stay closer to accounts of policy-making one can hear from policy workers once the microphone has been turned off. Such a policy analysis could further our understanding of policy-making, and it moreover would be also useful for providing orientation and reflection knowledge for politicians and civil servants.

The Concept of Innovation

Goswami and Mathew (2005) have given a detailed literature review on the definition of innovation. Myers and Marquis (1969), Zaltman et al. (1973), and Drucker (1985) looked at innovation in the point of view of technological innovation. Lundvall's (1992) definition of innovation includes non-technological innovations, including institutional innovations. Freeman (1988) emphasized on the role of social and educational innovations (pp. 339–341). Carlsson and Stankiewicz (1995) extended the definition of innovation to include the development of new organizational setups. Schumpeter's definition sums up the following forms of innovations: (1) introduction of new product or qualitative change in existing product, (2) process innovation new to an industry, (3) opening of a new market, (4) development of new sources of supply for raw material, and (5) other inputs and changes in the industrial organization. Boer and During (2001) defined innovation as the combination of creation of a new product–market–technology–organization. Carayannis and Campbell (2012) defined "quadruple helix" model, under which government, academia, industry, and civil society are seen as key actors which promote a democratic approach to innovation through strategy development and decision-making with the key stakeholders acting as catalysts resulting in socially accountable policies and practices. The authors speak of three modal approaches: the first mode is the primary educational system and basic research which create knowledge, second mode constitutes application of knowledge in practical solving of problems, and third mode is the creation of knowledge cluster or network for creation, diffusion, and application of knowledge.

India's Historical Quest for Knowledge and Innovation

Indian Upanishad (Dasgupta 2001) speaks of four forms of education: learning from the teachers, learning through self-reflection and introspection, learning through peer interaction, and learning in time context through experience. Upanishads describe five layers of knowledge: knowledge for satisfying basic needs, knowledge for developing means of existence, knowledge for psychological well-being, knowledge based on rational thinking, and knowledge of purpose.

India's quest for knowledge began in the prehistoric period, with the discovery of zero and alphabetic numerical from 200 BC to 600 AD which replaced all other forms of numeration systems. Arab traders picked up the new numeration system, which subsequently spread to Europe.

Indian discoveries in astronomical science have been popularized by Al'Beruni. The Srimad Bhagvat Gita is the treasure house of spiritual knowledge, morality, ethical way of life, and knowledge of highest pursuit of differentiation between good and evil. Kautilya's Arthashastra, which disseminated ethical codes of conduct in administration and accounting rules, arguably was the first work ever on principles of governance. India's expertise in various fields of knowledge had attracted expedition by foreign travelers like Huin Tsang, Marco Polo, and Vasco Da Gama. India had developed skills in metallurgy in ancient times, and the iron pillar near Qutub Minar stands testimony to the fact. One of the oldest universities in the world, Nalanda University, established in India sometime between the fifth to the twelfth century, catered to the needs of 10,000 students from all over the world.

The eighteenth century saw emergence of another string of famous scientists in various domains of science and mathematics like Meghnad Saha, Chandrasekhara Venkata Raman, Jagadish Chandra Bose, and Srinivasa Ramanujan. The twentieth and twenty-first centuries saw human interest in multidisciplinary studies like biotechnology, genetic engineering, neurophysics, biochemistry, and econometrics. Edward Jenner (1749–1823), known as "father of immunology" and discoverer of vaccination against small pox, had originated his work in India. Taj Mahal the seventh wonder of the modern world is a spectacular masterpiece of architecture built by the Mughal Emperor Shah Jahan to commemorate the death of his wife.

Some works on knowledge economy highlight the contribution of knowledge-intensive industries like information technology industries to national productivity (Brynjolfsson and Hitt 2000; Gordon 2000). There is no denying to the fact that India is still moving ahead to assimilate itself in the modern knowledge economy brought in by the information technology revolution of the 1990s and signing up of the Intellectual Property Rights under World Trade Organization (WTO). Information technology, in the present era, provides the basic framework for acquisition and creation of knowledge repository on various domains and application and distribution of knowledge for betterment of the society.

The focus now in India has shifted substantially toward R&D and innovation having successfully registered several applications under US Patent and Trademark. Internet and broadband connections have penetrated to most urban household, but rural areas are still lacking on IT infrastructure. India has been included in the 34 nations under World Knowledge Competitiveness Indexes (WKCI). India, along with China, is considered to form the knowledge cluster of South Asia with three of its cities, Mumbai, Bangalore, and Hyderabad, enlisted among the 145 cities which form knowledge powerhouse under WKCI report. Revolution in the ICT has brought forth new opportunities by easy accessibility of knowledge at all levels. The knowledge workers, the managers, information technology professionals, the medico-professionals, lawyers, and educationists form a substantial part of the population than even a decade ago. Bangalore boosts to have nurtured three of the global leaders in software solution like Wipro, Satyam, and Infosys.

Present Scenario in Innovation and Entrepreneurship

After the modernization of Intellectual Property Right (IPR) in 1995 with full compliance with the World Trade Organization, there has been much focus in India toward promoting research and innovation and IPR infrastructure. India is considered to be the 24th largest patent office of the world in terms of number of patent filings by WIPO 2010. According to WIPO Statistics Database, July 2009, there have been 34,285 patent filings in Indian patent office out of which there are 4,145 resident filings. In fact annual growth rate of patent filings in India in 2000–2007 has been second largest with 24.5 % next only to China which has a growth rate of 32 %. Out of total filings India granted, there are 2924 nonresident patents and 1,396 resident patents. Relative specialization index, which shows a country's share in foreign oriented patents in a specific technology as compare to country's share in all foreign oriented patents, is especially high in organic fine chemistry (1.88), pharmaceuticals (1.672), food chemistry (1.13), and medical technology (0.711). India has filled 1,635 patents through business houses, 730 through government-owned organizations, and only 6 through other research institutes in 2000–2007. No patent has been filled by universities. India's research development expenditure is a little over 1 % in the last few years. According to WIPO Statistics Database and UNESCO, July 2008, the research and development expenditure (in millions of constant US dollars, based on purchasing power parities and lagged by 2 years to derive the resident filings to R&D ratio) of India is 0.398 which makes India 22nd ranked in R&D expenses. The figures for comparable economies are Brazil (0.519), Russia (3.385), China (2.439), and Republic of Korea (5.597). The average annual salary of researchers is US$11,526, and when adjusted for purchasing power parity, it is US $56,780. Bulk of R&D spending (about 75 %) is by government. The government agencies and pharmaceuticals form the bulk of patent filings in the US Patent and Trademark Office (USPTO) like Council of Scientific and Industrial and Research (CSIR), Dr. Reddy's Laboratory, and Ranbaxy Laboratory. In 2004–2005, out of total of 229 patents granted to Indian innovators, CSIR had 140. The research innovation in CSIR and other Indian research institutes has been in areas of pharmaceuticals and food chemicals (Chakrabarti and Bhaumik 2009). Out of the top 1400 global companies with highest R&D expenditures, there are only 15 Indian-based companies. By R&D as percentage of sales, these companies are Tata Motors (10.5 %), Mahindra & Mahindra (11.7 %), Bharat Heavy Electricals (3.1 %), Corus now part Tata Steel (5 %), Novelis (Canada) now part of Hindalco Industries (1.6 %), Reliance Industries (8.7 %), Ranbaxy Laboratories (6.7 %), Dr. Reddy's Laboratories (17.6 %), Sun Pharmaceuticals (23.1 %), and Cipla India (17.9 %). The software companies included in the list are Polaris, KPIT Cummins, Infosys, Aztecsoft, and Prithvi Information. The R&D innovations in software sector have mostly been by foreign companies. Of the top 50 most innovative companies by Business Week and Boston Consulting Group Survey 2009, there are three Indian companies: Infosys, Reliance Industries, and Tata group.

The major knowledge clusters in India are National Capital Region of Delhi, Mumbai, Pune, Bangalore, and Hyderabad due to the simultaneous existence of research laboratories, MNCs with high innovative index, and quality higher education institutes.

Efforts and Achievements in Application of Knowledge in the Present Era

Global innovation is recognized in form of product innovation, process innovation, and service innovation. Indian IP laws earlier allowed only process innovation. Indian pharmaceutical companies copied and developed low-cost molecules discovered in Western countries. With change of IP laws in 2005, product innovation has been allowed. Some of the ventures in India on product and process innovation are as follows.

Nanotechnology

On realization of the significance of nanotechnology in fields of health science and defense, there has been growing impetus on R&D in nanotechnology in Indian Institute of Technology, Indian Institute of Science, National Institute of Pharmaceutical Education and Research, and National Instrumentation Organization.

Innovation System of India, Table 1 Public and private partnership in nanotechnology (Source: Bhattacharya (author) 2011)

1.	Nano Functional Materials Centre, IIT Madras	Murugappa Chettiar and Orchid Pharma
2.	Nano Technology Centre, Univ. of Hyderabad	Dr. Reddy's Labs
3.	Centre for Interactive & Smart Textiles, IIT Delhi	ARCI, Hyderabad & Textile Industry
4.	Centre for Pharmaceutical Nanotechnology, NIPER, Chandigarh	Pharma industry
5.	Rubber Nanocomposites, MG University, Kottayam	Apollo Tyres
6.	Nanophosphor Application Centre, University of Allahabad	Nanotech Corp., USA

Besides, there are private–public partnerships as given in following Table 1.

There has been evidence of successful use of nanotechnology in the health sector like development of Nanoxel – indigenously developed nanotechnology-based drug delivery system for cancer treatment in Indian market by Dabur India, patented technology for gene repair therapy by Virtuous Innovation, a group company of Khandelwal Laboratories, etc. Success of nanotechnology has also been seen in other fields like creation of nano-shirts under the brand name of Park Avenue by Raymonds and successful launch of nanotechnology-based water purifier by Indian Institute of Technology (Chennai).

ICT-Based Inclusive Growth

Some of the ICT-based initiatives to ensure inclusive development have been in the field of telemedicine connecting 180 rural centers to 20 superspecialty health centers and more recently a tele-healthcare project which includes teleconsultation, tele-diagnostic, and tele-treatment. The project was initiated by Apollo Group of Hospitals at 24 clusters covering 50,000 villages around Aragonda village in Andhra Pradesh. Further there has been introduction of Max Vijay scheme, an insurance product targeted for deprived section of society to be sold by NGOs, microfinance organizations connected with IBM-designed wireless handheld devices, which enable data transfer through general packet radio service (GPRS) to the back end system and facilitate on-the-spot issuance of insurance policies.

In the education sector, EDUSAT is a satellite connectivity system which is used for teacher training and higher education programs in remote villages by Indira Gandhi National Open University. National Council of Education Research and Training (NCERT) also holds satellite-based interactive educational programs for teachers all over the country.

EducompTM MagiKeys solution is a unique software application that allows millions of government school students to surf the web, email, chat, and write documents in their mother tongue. It supports 11 Indian languages, namely, Hindi, Marathi, Gujarati, Kannada, Tamil, Malayalam, Punjabi, Urdu, Telugu, Bengali, and Konkani. Reliance Communications is collaborating with One Laptop per Child Foundation to provide network facility for providing every child with a low-cost, handy, rugged laptop to have a collaborative, joyful learning experience in 25,000 towns and 6,00,000 villages of India.

MCA21 is a Ministry of Corporate Affairs and Tata Consultancy effort for e-business transaction using direct identification number (DIN) and digital signature. State of Gujarat which has won the national award for best e-governed state has the largest optical fiber wire area network of 50,000 km in Asia. All activities of governances like procurement of business, taxation, and public grievance management are carried out mandatorily through the Internet.

EnAble India, an organization started by two soft engineers, works toward increasing employability of handicapped people by ICT-based training by using software like SAFA, a low-cost screen reader software based on windows, which transforms text on-screen into synthetic speech aimed for visually challenged people and also by creating digital audio books and other educational tools in collaboration with other NGOs. It also acts as a link with organizations which can provide employment opportunity for these people, by helping these organizations to create a barrier-free workplace.

Lifeline, a project initiated by One World Foundation in collaboration with CISCO and British Telecom, aims at providing its clients, the farmers, with requisite information on their queries using telephony and Internet in their mother tongue. Queries made through landlines or mobiles are passed through interactive voice response to a knowledge worker who tries to solve the problem with the help of database of 30,000 frequently asked question (FAQ) with answers or else refers it to an expert.

For providing white-collared employment to various unemployed youths, a project SMSOne was started by Pune-based entrepreneur under which an unemployed youth builds an SMS community of about 1,000 cell phone users in his area and provides them with news and updates through an SMS newsletter. The service is free of cost for the user and revenue is generated through advertising. Only one message per week is permitted. The news can be government messages, news and advertisements of shops of the locality, birthday alerts, and election propaganda of local leaders and politicians. CGNet-and ICT-based forum of journalists created by Shubhranshu Choudhary of Chhattisgarh that aims at ensuring public participation in development is a web-based discussion forum of ordinary people of local community which feeds in news related to tribal life, culture, farming, Dalit issues, the Naxal movement, education, gender issues, health, mining, employment, etc.

Some Innovative Business Models

Indian Premier League

In 2008, vice-president of Board of Control for Cricket in India (BCCI) Lalit Modi partnered with IMG executive Andrew Widblood to initiate Indian Premier League, a T-20 version of cricket, in which each match is to be of around 3 h with each competing to face 20 overs each. Teams were auctioned to leading business tycoons and Bollywood celebrities which ensured pumping in of huge money. The IPL was expected to generate revenue of nearly $2 billion in the period 2008–2019, including proceeds from TV rights ($918 million), promotion ($108 million), and franchises ($724 million). Players are being offered $1.55 million for an IPL season of about 5 weeks as against $50,000 to $ 1 million which they can earn playing their national team in a year, depending how engaging schedule their respective national teams have.

VNL

VNL, a start-up company, awarded as Telecom Asia’s best green infrastructure of the year in 2010 (http://www.telecomasia.net/content/ta-reader-choice-awards-2010-winner-list), is the first solar power-driven WorldGSM mobile service meant for rural areas with *low levels of average revenue per user (APRU)*. It has also been named as “Technology Pioneer 2010” by the World Economic Forum. It had to face the challenges of low power services, availability of less number of skilled engineers for installation and maintenance of the GSM system, and poor infrastructure.

The model developed requires less than 50 W power per base station and hence does not require power grid, nearly zero maintenance and entire base station can be packed into two carts and can be installed by even unskilled labor.

Narayana Hrudayalaya

According to the World Health Organization report, number of doctors per 1,000 population in India is less than one, and there is a requirement of 6,000 doctors, 1 million nurses, and 0.2 million dentists. Only 0.5 % of Indians have health insurance and out of pocket spending is about 85 %. About 2.4 million Indians require cardiac surgery per year and only about 60,000 operations are actually carried out. Narayana Hrudayalaya at Bangalore was established by Dr. Devi Shetty with the vision of providing highest quality healthcare services to patients with heart problem at lowest cost. It planned to achieve high volumes of OHS and catheterization operations per day which brought down the unit cost of surgery. Also high-cost machines are rented instead of purchasing to bring down the cost further. Suppliers are hired under short-term contract and low-cost dual medicines like cardio-diabetic medicines of Biocon are used for bringing down cost of medication. It has initiated India's largest telemedicine network and also has provision of mobile cardiac care. Dr. Shetty is also credited to have started the most successful microinsurance project in India called Yashwashini targeted for farmers of Karnataka. For INR 5 (US$0.11) a month, cardholders can have access to free treatment at 150 hospitals in 29 districts of the state for any medical procedure costing up to Rs. 100,000. It is now working to extend its clinical expertise to cancer with the launch of Biocon, a 1,400-bed facility providing treatment for head-and-neck, breast, and cervical cancers.

Apollo Hospitals which recently won the G20 Challenge on Inclusive Business Innovation has reached to masses in remote villages and semi-urban areas through their Apollo reach program.

Medical Tourism

Medical tourism in India as found by Brotman (2010) is outbound, inbound, and intrabound. Hospitals catering to both inbound and intrabound medical tours have shown significant profits with India's growing economy. Tourists from the USA prefer to go to developing nations for medical tours as many forms of surgery such as cosmetic surgery, dental reconstruction, and gender reassignments are not insured in the USA. Similarly, in Britain and some other European countries where healthcare is controlled by government healthcare system, long queuing for requisite operations may lead citizens to foreign lands (Horowitz and Rosenweig 2010). People also come here from different countries for certain specialized surgical operations like bone marrow transplant, joint replacement, and stem cell treatment for cancer which otherwise are not performed in their countries. Also, medical treatment cost in India is considerably lower. A heart valve replacement surgery would cost (Sinha 2008) patients $10,000 in Thailand, $12,500 in Singapore, $200,000 in the USA, and $90,000 in Britain and only $8,000 in India. While a bone marrow transplant would cost $30,000 in India, doctors in the USA would charge anywhere between $250,000 and $400,000 while those in the UK would charge $150,000. A cosmetic surgery would cost $3,500 in Thailand, $20,000 in the USA, and $10,000 in Britain and will cost only $2,000 in India.

According to the American Medical Association data, a spinal fusion would cost $62,000 in the USA, $5,500 in India, $7,000 in Thailand, and $9,000 in Singapore. Medical tourism in India is growing at the rate of 30 % annually. It is expected to reach $ 2 billion by 2012. Escorts, Apollo Group of Hospitals, Hinduja, and Jaslok are some of the major players in medical tourism. Indian medical treatments include alternative treatments like Ayurveda, Yoga, Unani, Siddha, and Homeopathy treatments (AYUSH). Medical tourism should be supported by insurance policy, travel support, online information on types of treatment availability, hospitality, and clean and hygienic condition in hospitals.

Teach for India Foundation

This is a nongovernment organization which trains young volunteers who are students of reputed educational institutes or professionals who are trained to educate underprivileged children through experiential learning. This initiative involves multiple credible stakeholders – Indian and United Nations' NGOs, corporates, educational institutions, and individuals – who will finally create an ecosystem of shared thought and knowledge.

Jugaad Innovation Complementing Systemic Innovation

Jugaad is an Indian method of playing around the legal system to create an innovative, sustainable economic product by mixing and matching local material (Radjou et al. 2012). For example, there is this product called MittiCool developed by Prajapati which is a refrigerator made out of clay.

Jugaad vehicles cost around INR 85,000 (less than US$2,000). They are powered by diesel engines which were originally intended to power irrigation pumps. They are known for having poor brakes and cannot go faster than about 60 km/h (37 mph). The vehicle is used to carry more than 20 people at a time in remote locations and poor road conditions. Today, jugaad is one of the most cost-effective transportation solutions for rural Indians. SELCO, which provides energy and power in underdeveloped villages in Karnataka, is perhaps a best example of jugaad technology. Another individual jugaad model was that adapted by medical practitioner Dr. Mohan. He experimented with a number of different ways to frugally yet effectively engage rural communities both as consumers (patients) and employees. He found that it was very difficult to motivate the team of highly competent technicians from his city hospital to continue work for a long time in remote villages. A training curriculum of three months duration was developed in the city hospital in Chennai to impart to youths of the villages basic skills of providing healthcare needs. These newly trained healthcare professionals would return to their rural homes, where they were more likely to want to remain. This in turn helped reduce costs and turnover. A cost-effective telemedicine platform was created with the help of Indian Space Research Organisation, which provided a roaming telemedicine van with a free satellite uplink to his clinic.

The dynamic director of SAP India is encouraging bottom-up approach for innovation through participative leadership. Employees are free to experiment with bold ideas during work hours which will improve their quality of life.

Shrishti, an autonomous organization under the government of India, promotes innovation at grassroots by awarding and supporting the best innovators and innovative ideas and creates a culture of participatory development. They are being supported by the Council of Scientific and Industrial Research, Indian Council of Medical Research, and Botanical Survey of India to add value to innovative ideas and traditional knowledge by converting them into useful products in areas of engineering, human health, agriculture, veterinary, and nutraceutical. Honeybee Foundation set up by Professor Anil Gupta maintains database of 10,000 grassroots innovations and helps to promote and commercialize them. Jugaad Innovation has already been adapted Indian firms such as Future Group, Suzlon Tatamotors, Yes Bank besides Indian subsidies like GE, Siemens, Philips, and PepsiCo.

Impediments to Innovation

1. *Lack of Innovation Culture*

   As Welzel–Inglehart cultural map puts India along with other developing nation at a position of higher survival values and low in self-actualization value. Hofstede (1991) scores also indicate that India has a low to moderate uncertainty avoidance, high power distance, low masculinity, and low individualism. Although it is only indicative, yet it reveals that Indians are probably risk-averse, hesitant to make important decisions in work-related matters, and probably lack attitude to take initiative. Mashalkar (2010) in his speech says that there are several ideas by Indians which have been converted into successful patented product by Japanese after research papers written by Indians related to same were published. The recently discovered "God particle" or "Higgs–Boson" particle are based on the works of Prof. Satyendra Nath Bose. Way back in 1924, Bose realized that the statistical method used to analyze the existent theories on the thermal behavior of gases was inadequate. He first sent off a paper on quantum statistics to a British journal, which turned it down. He then sent it to Albert Einstein, who immediately grasped its immense importance and published it in a German journal. Bose's innovation came to be known as the Bose–Einstein statistics and became a basis of quantum mechanics, which led to the discovery of this subatomic particle. Two of the most recent Nobel laureates from India in recent times, Amartya Sen for economics and Ramakrishnan Venkatraman in chemistry, are more known for their work abroad.

   Educational system has long been encouraging "rotting" rather than experimental learning in form of problem-solving, design, experimentation, etc., in the education curriculum. Evaluation in education should encourage subjective responses rather objective answers. Competency-based customized career plan and curriculum are required to be designed for each child.

2. *Lack of Innovation Ecology*

According to a National Knowledge Commission survey, the most important barriers to innovation, as perceived by both large firms and SMEs, are skill shortages due to the lack of emphasis on industrial innovation, effective collaboration for research between universities and R&D institutions, excessive government regulation, as well as insufficient pricing power to derive value from innovations. Further, it has been found, out of the graduates passing out of professional institutes (Mckinsey 2005), only 25 % of engineers, 15 % of finance and accountancy professionals, and 10 % of graduates with Indian degrees are employable by multinational companies. Fifty-four percent of the universities under University Grants Commission (UGC) are giving education in general discipline (Table 2).

Innovation System of India, Table 2 Distribution of central and state universities into types of discipline (Source: UGC Annual Report, 2004–2005)

Type	Number	%
General	126	54
Agricultural	35	15
Technological	14	6
Language	11	5
Medical	9	4
Law	6	2.6
Woman	5	1
Animal and fishery	4	1.7
Open	11	5
Others	16	5.7
Total	237	100

Further, the number of researchers in India has increased by only 20 % from 1991 to 2001 as compared to China where the comparative increase was about 80 % (Knowledge Commission Report). To develop quality researchers, India should promote university–industry link in running of PhD programs; for example, Reliance Life Sciences has developed a model under which they facilitate employees getting admission for PhD degree from Mumbai University. BITS Pilani similarly has Ph.D. program for working executives (http://www.knowledgecommission.gov.in/downloads/documents/moreQualityPhD.pdf). A report on 1473 NAAC accredited colleges between 2002 and 2004 shows that there are overall only 25.6 % Ph.D. teachers. Indian universities need to have good academicians with Ph.D. degree. According to Furqan Qamar and S. Sinha (2007), there are 57 % of teachers in higher education who are without M.Phil. and Ph.D. degree. With various universities not being able to fill up the posts under various reservation categories, universities are recruiting ad hoc and guest faculty.

To emphasize individual and industrial innovation, National Knowledge Commission (NKC) suggested to allow licensing and royalty arrangement in which the inventors as well as research institute would have share. To promote research several government programs have been initiated like the New Millennium India Technology Leadership (NMITL), Techno-Entrepreneurs Promotion Program (TePP), and Technology Development Board (TDB). To provide for need of talent pool, 8 Indian Institute of Technology (IIT) and 3 Indian Institute of Science Education and Research (IISER) are being opened. NMITL has so far evolve 57 largely networked projects in diverse areas, namely, agriculture and plant biotechnology, general biotechnology, bioinformatics, drugs and pharmaceuticals, chemicals, materials, information and communication technology, and energy involving 80 industry partners and 270 research groups.

3. *Lack of Venture Capital*

There is general lack of venture capital for start-ups who want to experiment with new ideas. The investment by venture capitalist has been in the late stage as can be seen from the Table 3 below.

To facilitate commercialization at early stage innovation, several incubation centers are being opened in all over the country like the ICICI Knowledge Park in Hyderabad; International Crops Research Institute for

Innovation System of India, Table 3 Venture capitalist investment at various stages of innovation (Source: Bhattacharya (author) 2011)

Stage of the company	Number of deals, 2006	Number of deals, first half 2007
Early stage	59	24
Growth stage	42	25
Late stage	104	67
PIPE	61	34
Buyout	11	6
Others	22	6

Semi-Arid Tropics (ICRISAT); Centre for Innovation, Incubation, and Entrepreneurship (CIIE) at Indian Institute of Management, Ahmadabad; National Institute of Technology at Calicut (NITC); and Society for Innovation and Entrepreneurship (SINE) at IIT Mumbai and at Vellore Institute of Technology (VIT). Some of the government initiatives taken are writing off research and capital expenditure in companies having in-house R&D centers, 10 years tax holiday to R&D companies approved by Department of Scientific Industrial Research (DSIR), no import duty charged on import for equipments by public R&D institute, and 125 % tax deduction on donation to research institutes carrying out social and statistical research.

4. *Corruption in the System*

Most studies validate the fact that either democracy or autocracy does not considerably able to combat corruptions. Corruption can only be prevented by greater accountability. In his keynote address at the Indian Independence Day Celebration of 2005 conducted by a nongovernment organization Nandini – Voice for the Deprived at Chennai, Mr. N. Vittal (2005), former Central Vigilance commissioner, said, "there are five basic reasons for corruption in India. (1) scarcity of goods and services; (2) red tape and complicated rules and procedures; (3) lack of transparency in decision-making; (4) legal cushions of safety for the corrupt under the "healthy" principle that everyone is innocent till proved guilty; and (5) tribalism among the corrupt who protect each other." The report of the Civil Services Examination Review Committee (October 2001), which was set up by the UPSC made the following observations:

> It is very crucial to understand what happens to the values and integrity, motivation and other qualities assessed at the time of recruitment after 10 years and 20 years of service. It is said that initially many of the officers have positive values, but they change during the course of service. When they appear before the UPSC interview boards, most of the candidates are idealistic, bright, committed and sincere. However, once they join the service, within a period of time they seem to become cynical, negative and possibly even corrupt. Even the most outstanding officers feel frustrated after their idealism has been dimmed by the systemic realities. Some of them succumb to pressures easily. Therefore, a deeper insight into the systemic mechanism is required to ascertain the causes affecting this change and take remedial action.

Corruption in the society has resulted in failure of several social development initiatives, like public distribution system and mid-day meal scheme. In a survey undertaken by Transparency International and Delhi-based Centre for Media Studies, it was found that value of corruption under PDS is as whooping as Rs. 375 crore per year. Kumar (2003) in his extensive study of corruption in India has indicated that implementation of the Prevention of Corruption Act (1988) has been a failure in India. He was of the view that the right to uncorrupted service should be made a fundamental right and right for jurisdiction against violation of this right should also be a fundamental right. Corruption can be thought of violation of human right as it has been established that only 17 % of the fund allocated by the government for poverty reduction actually reaches to the needy (Roy 2003) which is a great impediment to innovation for inclusive development. Citizens should be made aware of their rights and knowledgeable about government provisions which are meant for their development. The Mazdoor Kisan Shakti Sangathan, an NGO, had initiated awareness campaign and holding government accountable for any corruption or mismanagement of developmental fund in many parts of the country.

"India Against Corruption," a mass nonviolent movement started by veteran freedom fighter Anna Hazare to force the parliament to pass the "Lok Pal" Bill, which will put legislatures and administrators under its ambit for any acts of corruption, has been a huge success in the last few months.

Conclusion and Future Directions

India has an advantage of fast-growing GDP and large pool of English-speaking widely respected engineers and doctors. A combination of scientific temperament, quest for truth, and questioning mind which is the basis of Upanishad is required for India to innovate. Novelty will be developed if there is an infrastructure and ecology-supporting youths who think differently and seek a platform for their experiment with truth. A strong sense of ethics has to be inculcated from childhood to combat corruption which kills youthful zest for service and change catalyst. India must capitalize on its strengths in case of alternate medicine and supercomputers if it intends to be a global leader in knowledge economy. As defined in the "quadruple helix" model by Carayannis and Campbell (2012), there is need of a society which has a scientific and inquisitive spirit, government which stimulates entrepreneurial venture and industrial activism, and academia which envisages interdisciplinary research.

Synonyms

Enterprises; Entrepreneur; Innovation; Innovation networks; Innovative milieu; Proximity relations

Technological innovation is the surest way to restore, transform, and expand markets. The expansion of businesses and the globalization of markets have revealed the importance of local pockets of productive resources. The geographical proximity between science, technology, industry, and finance contributes to the emergence of innovations. Interactions are organized by the combined effect of private and public institutions. Currently, economists consider the "local economy" as a pertinent geographical and economic level of organization of production, and therefore, of new activities emergence, new goods and services, new jobs, new revenues... Over the past 40 years, the approach of innovation based on proximity – and especially the concept of innovative milieu (see for example, Aydalot, 1986) – has shown its always more and better relevance as a model of decentralized economic growth but also of enrichment of businesses' technological competencies, including international ones. These economists do not refer to a purely linear model of innovation (which would correspond to the idea that the increase in inputs – here the R&D – would meet the increase in outputs – innovations here) while identifying the need to increase spending on R&D to strengthen the knowledge base. They are more in an interactive vision, which emphasizes the importance of networks of public and private actors, at the territorial level, recognized as relevant to the development of the innovation policy (Tidd et al. 2005).

Indeed, in a changing and highly unpredictable environment, the enterprise, whether large or small, is at the center of public policies and of economists' concerns and sociologists' interests. Its main function – innovation – is regarded as the main source of job creation, wealth, and prosperity. But on two conditions: (a) the structures must be flexible enough so that the company can adapt itself to market fluctuations and (b) the constant renewal of its productive resources can only be achieved if the financial and industrial framework of the country or the region is sufficiently strong and diversified so that the company may combine networks of producers and consumers in the constitution of its supply and in creating a demand for its products. Once these two conditions are met, the creation of innovative small businesses and the strengthening of the innovative potential of large firms can be linked together. As a matter of fact, to strengthen the innovation potential of large firms and to facilitate the emergence of new businesses, specialists put forward the importance of innovation systems.

An innovation system describes the relationships between institutions (scientific, technological, industrial, commercial, financial, political), being public or private (companies, research laboratories and engineering, administration...). These relationships mostly consist of informational and financial flows and people movements. The purpose of such a system is to produce innovations (new organizations, new goods and processes, new resources, new combinations of productive resources). The systems are national (or local) with a focus in this case on the regulation framework. They can also be "private": In that case, the analysis focuses on the "network" which can be defined as a set of businesses legally and/or financially linked to one or several larger ones. The network is a system that is intended to make one (or more) production (s) integrated in a same value chain, and under the direction and coordination of parent companies.

An analysis from the innovative milieu gives the possibility to study the environment of businesses and understand their innovation dynamics. The systemic nature of relationships that characterize a social and economic environment explains what promotes or not innovation. But should we reduce innovation, product of the environment, only to interindividual exchanges leading to a new productive combination? Does it only result from a specific organization of economic relations? Our thesis is that the systemic environment does not only refer to economic interactions but also takes into account the social structures that are the source of innovative behavior. However, institutions (government, local authorities) take a significant role in the organization and evolution of socioeconomic structures. And in turn the innovative environment contributes to the performance of innovative companies by providing scientific and technical resources.

Proximity and Innovative Milieu as the Engines of Innovation

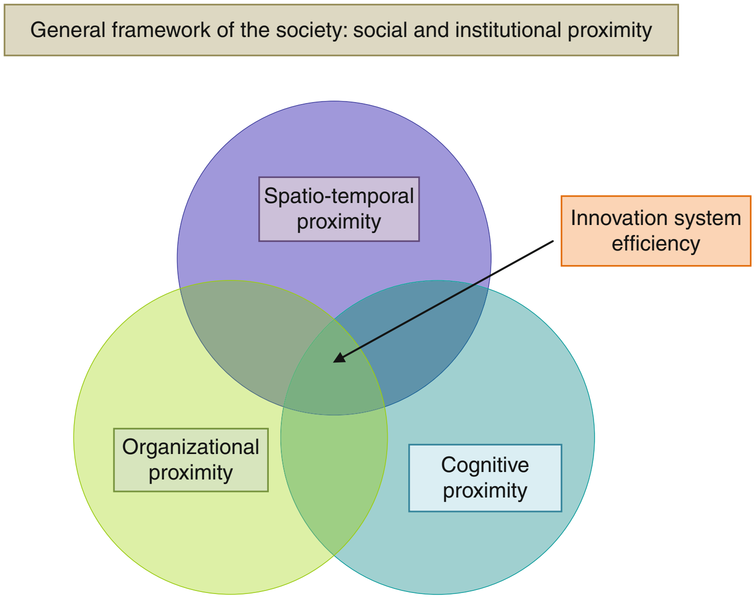
Proximity and Innovation

The notion of proximity is largely used today, both in industrial economics and economics of innovation. But the ambiguity of the term, as the variety and scope of its applications, implies a careful use of it. Proximity is linked to the existence of externalities that produce spatial agglomeration effects and territorial dynamics. **This is spatial and temporal proximity**. Other meanings were added to this first definition of physical or geographical proximity (Boschma 2005; Uzunidis 2008; Nooteboom 2009).

Another kind of proximity is **organizational proximity**. It refers to the coordination of activities within the organization and between organizations, whether this coordination is organized by the market (contracts) or by the hierarchy (ownership). The similar or different coordination arrangements within organizations (in the case of big corporations) or between the organizations may facilitate or not the creation of networks.

The specific activities involved in the production of new knowledge and in the associated interactions led economists to introduce, in addition to spatial and temporal proximity and organizational proximity, the concept of **cognitive proximity**. This refers to more or less formalized sharing of experiences, representations, codes, languages, and models resulting from and at the same time facilitating the communication of information within or between organizations. By nature, cognitive proximity has a special place in research activities, but it is also present through all kinds of communication flows within or outside the firm. In the case of interactions related to industrial research, cognitive proximity not only affects the internal interactions within research centers but also the external interactions with other centers of business services, as well as interactions with the environment (other laboratories and partners in research and innovation).

Other forms of proximity are identified and notably the **social and institutional forms of proximity**. They refer to the relationships



Innovation Systems and Entrepreneurship, Scheme 1 Forms of proximity and innovation system efficiency (Source: Authors)

that can be created at the microlevel (social proximity) and at the macrolevel (institutional proximity). They are the results of habits and routines built by the social and institutional history. As such, they can contribute to the good functioning or hinder the functioning of networks.

It seems relevant to suggest a three-dimensional approach to proximity, before presenting the importance of proximity in generating new businesses and launching innovations (Scheme 1). The following graph presents the ways the types of proximity interact. The more they are linked together, the more efficiently the innovation system may operate, that is to say generate new innovations and new businesses. The social and institutional forms of proximity are related to the functioning of the whole society and are not specific to an innovation system. This is the reason why there are presented outside the three dimensions of proximity.

The Local Economy as an Innovative Milieu

The local economy (or local productive system) can be defined as a geographic area formed as a set of systemic relationships between businesses and between businesses, state and local governments. These systemic relationships characterize the local area by a certain type of activities and final products. Economists observe and study this economy as a knot of productive relationships, which may contribute to the territorial organization (which has however remained national). They attribute qualifiers showing the dynamics of the combinatorial and complementary relationships between businesses of different sizes at the local level: "local production system" and "innovative environment."

The territorial efficiency of this mode of organization lies in what we call today the savings on transaction costs. The concentration on a single geographic location of the main players of the same production system (mainly the producers on the one hand and the users on the other) not only facilitates transactions but also the interrelationships of knowledge and trust between the partners. The formation and accumulation of skills will then form an "industrial atmosphere" conducive to condition the local labor market (Marshall 1919). This phenomenon, the industrial atmosphere, is connected to both the competence and experience of workers and also to the location of firms in the same area. In the sense of the Marshallian industrial district, the milieu gathers a population with proven expertise, a group of actors making up the various links of the same production system, and finally a know-how that defines the accumulated expertise. The main feature is the territorial organization of production, rather on a principle of collaboration and cooperation between different production units rather than on a hierarchical principle. Thus, the notion of solidarity among economic actors is very important. The local production system is mainly characterized by the proximity of productive units (individual businesses, services, research centers, and training…). These units maintain these relations of varying intensity that can take very different forms: formal or informal links, commercial or noncommercial alliances… These relate mainly to the flow of materials, services, labor, technology, and knowledge.

Basically, this is the GREMI (European Research Group on Innovative Environments: team of researchers from the Institute of Economic and Social Research at the University of Neuchatel, Switzerland) which, in 1985, developed the assumption that it is the regional communities that generate different forms of innovation (innovation-product-process innovations, organizational innovations, social innovations, innovations in training/qualification, etc.) (see Maillat and Perrin 1992). The explanation for the emergence of a "successful" region comes from the fact that it is primarily the latter that has managed its own capacity to develop new products, new technologies, and new organizations. This assumption, founder of the regional science, questions the traditional economic theories which on the contrary advocate a progress and a growth which main factors and engines mainly find their justification and their origin from the "outside" (so-called models of "development from the top").

Our central theoretical hypothesis to analyze the concept of innovative milieu, that is to say, the socioeconomic territory forged by history ("path dependence") is that it is the product of interactions of firms, institutions, and labor. These interactions are necessarily the result of reciprocal synergies (networks, linkages, partnerships, etc.) between the various local (public or private) agents of the economic and industrial development. We can take as an example the forms of cooperation between companies and research laboratories. Ultimately, it is primarily the socioeconomic, industrial, and scientific milieu that participates to the creation of new activities (including through entrepreneurship and spin-offs) and to the genesis of innovations. And it will "naturally" be done if certain conditions are met. Among them are the existence of, locally, a group of actors (companies, research centers and training, government, skills…); the existence of material, human, financial, technological, and informational resources geographically agglomerated; the existence of specific know-how giving the possibility of a quality of production; the existence of relational capital conducive to the formation of local, national, or international networks; and finally the existence of norms, rules, and values that determine the behavior of economic actors.

The concept of innovative milieu also highlights a strong principle in systems of innovation: it reinforces the idea that the innovative capacity of companies is closely linked to social, economic, and political issues surrounding them. The "innovative environment" most often designates the ability of a local economy to generate innovation through the emergence of new businesses and the location of more ancient firms in its geographical area, where the industrial exploitation of research organizes the creation of small innovative companies. The local economy takes the shape of a territorialized system of the exploitation/valuation of all kinds of capital and of market exchanges. Benefiting from a certain (legal and economic) autonomy of organization of productive resources, its primary characteristic is the formation and development of specific resources and the achievement of particular combinations of these specific resources. These are composed of capital and labor with specific forms and contents in relation to activities and specific sectors – specific in terms of technology, financial or demographic characteristics but also in terms of skills, qualifications, level of education, etc. The local economy becomes, then, an "innovative milieu," reducing the risks associated with the uncertainty of a given investment and initiator of the innovation process, including through business creation and the attractiveness of existing technology companies.

Enterprises' Strategies and Innovative Milieu

Understanding the Company

To understand and to study a company, the economist looks at the internal organization of production entities and their environment (market, competition, government…). His systemic vision leads him to consider the company as a living entity whose birth, growth, survival, and death are conditioned by a set of conflicting relations between the entity and its environment and between its internal organs. The economist goes so far as to say that a company as such has no meaning; what matters is its relationships with other companies, with the markets, or with institutions. This representation of the company highlights the role of trade, financial, or technology relations, generated by the company or to which it is subjected. Thus, we can then appreciate the role of a local innovation system or "innovative environment."

The company is commonly defined as an economic unit, a set of combined factors of production, whose activity results in the production of goods and in the provision of services sold in a market. Its objective is the achievement of sustainable profits, essentially higher than those of competitors and sufficient to finance its investments and growth. The expansion of its size is, for the enterprise, another condition that must preserve the attacks of competitors and of fluctuations in demand. The reality of the business is complex: the company is a legally independent center of decision that implements a strategy, sets goals, and creates the means to achieve it. The company is also a social organization that brings together people with different skills linked by hierarchical relations of power and responsibility. The economic independence of the company is relative. First, because the constraints imposed by its legal and commercial environment limit its room for maneuver. Its need to make a profit, a guarantee of good health, leads the company to get in conflict or cooperation with other companies, to change its status over the increase of its capital, to protect, diversify, and expand its markets. On the other hand, ownership of capital can sometimes belong, in whole or in part, to another company: subsidiaries and other companies subject to complex financial linkages and integration are dependent on decisions of the group to which they belong.

Decision and power are the hallmarks of business operations. The decision system of the company regulates its activities. It is constructed by the play of power and control between the company owners and is used to define the decision-making authority of its manager and staff. Generally, a decision is made at three levels of power: operational (production tasks in the company), management (organizational tasks and monitoring procedures), and strategic (task programming, planning, strategy). The charts that are set up according to this method reflect the administrative structure of the company. The chart of a company presents its hierarchies, its functions, and activities taking account of the place of decision, the information structure, the factors of consistency, and the center of dynamic operation. The functions provided by the organization are linked by (a) the order flow circulating from top to bottom between the three levels of authority which express some technical and decision-making rationality; (b) information, technical, economic, and financial flows between services, departments, and subsidiaries; and (c) financial flows generated by the activities of budgeting services, departments, and subsidiaries, but also through the implementation of contracts between the subsidiaries and the parent company and other independent companies.

The company is forced to increase its size (volume and value) in order to survive. It must indeed try to control its future in order to meet (in the best possible condition of profit-making and controlling as much as possible, financial and business risks) the expectations of its shareholders. To do this, it must reduce the market uncertainty by providing all necessary means to capture, sort, process, and use the largest quantity of economic, technological, financial, commercial, and political information. When the environment is quickly changing, the capital turnover and the pace of innovation evolve faster as well. . . the risk of failure in the process of "creative destruction" increases. The information then becomes the ultimate competitive weapon. Its mastery leads to the construction of barriers to entry. Not only does competition become imperfect, but it also becomes a power game (combining competition and temporary pacts of alliances and cooperation) between global industrial and financial groups. The place left to small entrepreneurs is then marginal and unstable.

Innovation and Investment Strategy

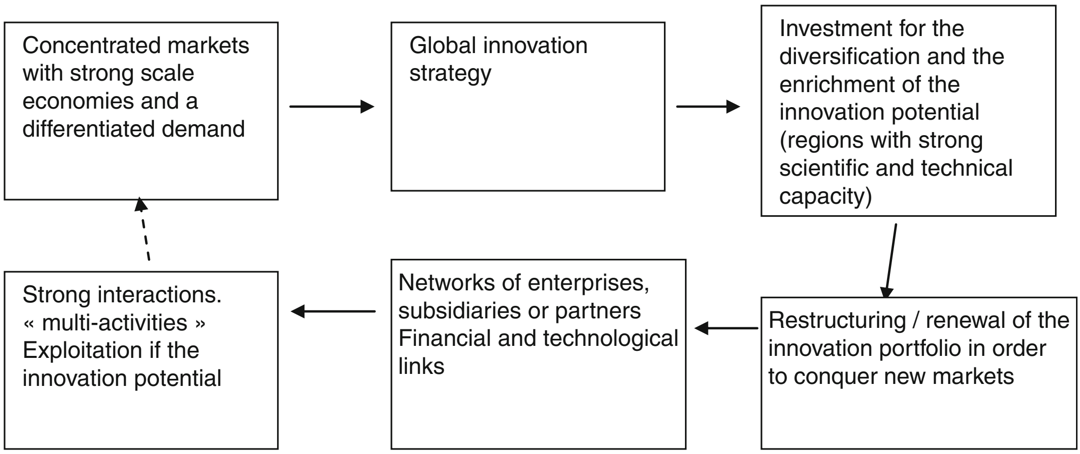
In this context, the choice of investing (whether to locate a company in a new place or to create a new business) is determined by the relative factors of centralization and decentralization. Centralization reflects the necessity to achieve economies of scale, to fertilize between projects, to communicate tacit information, to be in close contact with the functional departments of production and marketing, to control technology assets. . . Decentralization is explained by the need to access scarce skills, to benefit from externalities in an enabling environment, to be in close contact with customers and suppliers. . .

The nature of activities (technological level and degree of specialization) conditions quite well the level of compromise between, on the one hand, the search for externalities (agglomeration effects) and, on the other hand, the constraints of scale, of indivisibility, which conversely implies to concentrate locally the innovation resources.

Indeed, the enlargement, integration, and permanent renewal of markets, as determined by the combined evolution of profit and financial income, increase the business risks (how many products are withdrawn from the market before the investment made for their production is recovered and even before they are known by consumers?) and the financial risks (how many companies have faltered – see notably the examples of internet start-ups in the USA and Europe – for reasons of speculation and debt before they attack their market due to lack of customers?). The company has therefore to invest large amounts of capital to create an important information system, to protect itself from these risks, to constantly innovate, and to reassure its shareholders, its creditors, and its clients from all over the world.

The process of "permanent innovation" is the main feature of the global firm. This one is defined as a company whose organization is integrated by multiple information and financial flows and whose structures are largely decentralized: network firm with multiple affiliates and multiple partnerships with co- and subcontracting companies; company with a financial large amplitude in services and industry with high scientific and technical potential and benefiting from important external effects (clusters). It has a strong ability to innovate and to continuously adjust its structure and organization. It benefits from comparative and specific advantages of the different locations. It integrates into a "value chain" (R&D, logistics, innovation and financial engineering, manufacturing, assembling, marketing, and other services) all the activities it carries out all over the world.

The decentralized management options that the firm has added to the structural and short-term advantages offered by states and local governments determine the location of innovation activities of the global enterprise. This one in turn contributes to modify the development of chosen the territory. The globalization of firms' strategy (and notably of the innovative strategy) is explained by the concentrated structure of markets, characterized at the global by strong scale economies and a differentiated demand (for high, medium, and low income). To meet the consumers' demand, firms have to invest in the continuous expansion of their innovation potential (also called knowledge capital). To locate their innovative activities, they thus choose areas (territories) with a strong scientific and technical potential. These investments aim to renew their innovation



Innovation Systems and Entrepreneurship, Scheme 2 Location strategy of the global firm (Source: Authors)

portfolio to conquer new markets. Due to the costs and risks of the innovation process, big corporations develop networks gathering different enterprises, subsidiaries, and partners characterized by financial and technological links. Strong interactions emerge from these strategies. Firms develop multiple activities that aim to exploit their innovation potential (or knowledge capital). In turn, this contributes to the concentration of markets and leads to the deepening of inequalities between wealthy and poor regions (in terms of scientific, technological, and financial resources) (Scheme 2).

For global companies, the management of R&D and production aims to articulate the global strategic orientation with decentralized R&D – looking for a dynamic scientific environment and willingness to "stick" to the most dynamic markets. Then, "globalization" is not opposed to the strengthening of local interactions but tends to increase them.

Its local roots allow the company to benefit from a pool of resources (and sometimes a market) to amortize the costs associated with its investments in a constantly changing economy. But these local roots depend on the quality of the reservoir compared to the expectations of the company for its innovation and business development strategy. This explains the need for governments and local authorities to organize the development of resources. They have to facilitate the emergence of multiple innovation processes taking into account the competition-cooperation between the actors in an open economy. This is a system of supply of productive resources capable of generating a technological entrepreneurship and to attract large companies with assertive performance in innovation.

Policies of Emergence and Promotion of Innovative Enterprises

The Industrial Policy and the Formation of a Pool of Resources

Since the late 1980s, the financial, business, and production strategies of global firms have replaced the administered planning of territories, along with planning policy that has become deprecated. As a matter of fact, the opening of economies to competition (deregulation and contestability of markets in order to prevent the monopolistic practices) led to a strong overlapping of national economies to the point that the reasons (and objectives) of large international firms become reasons of state. Industrial policies are now focused on services and intangible and have an essentially territorial dimension. Cluster policy, implemented globally, reflects this orientation.

The role of the state in the formation and organization of a scientific and technological pool of resources for innovation and investment is essential and accurate. Public intervention has already exceeded the traditional areas of implementation and funding of a science and technology policy at the heart of which we find the public institutions of education and research. The conduct of the state in this area is increasingly comparable with the major industrial and financial groups, and the strong ties of interdependence between these organizations justify the transfer of resources from public to private. This means the formulation by the state of an innovation policy, in other words, the promotion of all means for scientific research, development, application, and technology choices to facilitate the creation and diffusion of new products and new processes. The intervention of the state and of local decision-makers in building and managing an "innovation system" can take various forms: granting activities that generate resources that can be individually or collectively appropriated by companies, creating mechanisms enabling enterprises to recoup their investments in research and development (e.g., patents that do not hinder the diffusion of innovation), and implementing procedures for cooperation between public and private entities aiming to ensure the financial feasibility of a private investment likely to have economic impact on a large scale.

The formation of a pool of productive resources that can be appropriated at any time by firms is now regarded by economists as the fundamental aspect of state intervention in the economy and in the organization of space. We may follow the reasoning of L. Branscomb and J. Keller (1998): noting that the creation and dissemination of knowledge increase the performance of a national or local economy (and of the companies that compose it), they put forward the idea that traditional science and technology policy (emphasis on finance and implementation of major research and development programs, primarily in the areas of defense, energy, space, and medicine) has been replaced by the policy of research and innovation. To be successful in terms of competitiveness, this policy must aim as much to the achievement of all public or publicly funded research programs as to the distribution of their results to "users" (businesses). The state should ensure the effectiveness of the procedures of research commercialization, by the regulations (protection of industrial property rights, antitrust laws, etc.), taxation, budget, etc., in order to create propagation effects. Economists conceptualize the formation of a "stock" (reservoir) of resources that are shared in these multiform, multifunctional, and multistakeholder cooperation processes.

The Promotion of Investments: Creation and Attractiveness of Enterprises

Local economies, in the "network economy," are now trying to grow by relying on private initiative, combined with a public and territorial focused policy. The attractiveness of investments, the ability to create business, and job creation define the performance of a local economy. All three indicators are related in time and space. But territorial institutions put forward a number of arguments to attract direct investment and create enterprises and jobs in the short term. There are two types of policies for growth and investment promotion: the short-term policy and structural policy.

The short-term policy refers to budgetary and fiscal measures with the aim of having rapid effects: create businesses to create jobs and attract production units to create jobs. As the expected results in terms of investment must be done very quickly, the government targets (a) companies with mobile production units (Fordist or heavy, for which the total costs of production are the factors that determine the choice of investment) and (b) potential entrepreneurs with low added value with an existing core business immediately exploitable. The main measures of this policy are:

– Financial incentives: direct allocation of funds to the investor (big company and entrepreneur) by the state or local government (investment grants, subsidies, subsidies for new jobs, subsidized loans)
– Fiscal incentives: reducing the overall tax burden of the investor (temporary tax reduction, exemptions from import duties of raw materials, intermediate goods, capital goods)

– Indirect incentives: to provide the investor with land, buildings, telecommunications facilities (see enterprise zones), privileged access to public procurement, flexible, part-time, fixed-term jobs, etc.

The structural policy refers to the industrial and innovation policy measures with the aim to establish or maintain a strong technological and economic specialization: enrichment of the scientific and technical potential in order (a) to facilitate the creation of innovative companies and (b) to attract large companies' centers of research and units of production specialized in high technology. The results are cumulative and visible in the long run. Governments develop instruments of commercial and technological watch to guide decisions in the constitution, the restructuring, and the enhancement of networks of innovation (investment and marketing).

The main measures of a structural policy of investment are:

– Public investment in creating the conditions for an endogenous growth in the long term: transport and communication infrastructures; facilities for education, research, and engineering performance; local financial system oriented toward innovation; complete health system; quality of life through cultural activities, organization of space, and leisure, etc.
– Implementation and funding of a research and innovation policy (instead of a purely industrial policy) whose objectives are: (a) the federation around a specific program of business skills, public institutions, and private research associations and institutions and (b) the networking of actors in research, industry, commerce, and forecasting for the implementation of value-added investment in a backbone area (and its niches) defined by the regulatory authorities.
– Creation of a center for the delivery of services and of financial means to businesses attracted by the project and to entrepreneurs specialized in the same field and in related activities (information engineering, development and socioeconomic studies), for example, the establishment of an observatory of the local economy with real organizational advisory power.

Innovation Systems and Innovation Networks

Business Creation in Local Innovation Systems

In a local innovation system, a particular emphasis is put on the creation of small innovative companies. In the current economic uncertainty and following the trends of decentralization, the creation of new businesses is as a matter of fact supposed to solve many problems related to the rigidities created by institutional intervention. Their flexible structures enable them to respond more readily to consumer expectations, and their failures do not threaten the financial and industrial structure of a country, region, or locality. The creation of small businesses is seen as a preferred means of industrial policy and planning. While large companies, made of various activities of production, finance, and marketing, are trying to organize markets and change technologies, through alliances, mergers, pacts, and political interference, the hope of economic revival is concentrated in small business. The small business fits perfectly with the needs of the economy. It is a formidable machine for the use and destruction of capital; it also presents itself as a sort of vector of values, to the extent that it establishes bridges facilitating the transport of productive resources (financial capital, technology, workforce different qualifications and skills) toward the activities, markets, and big businesses able to make a profit.

The entrepreneur is a figure, a concept, and a function difficult to define by the existing theoretical tools. Personal qualities and personality of the entrepreneur certainly play an important role in the decision to establish a small business. But undertaking, as a function and an act, is defined by the macrosystemic dynamics of accumulation and profit. This dynamics creates barriers and opportunities for personal enrichment which make an individual an entrepreneur and subsequently either succeed or fail. The fact is that "one is not born an entrepreneur, one becomes one": one becomes one through the mobilization of a potential of resources composed of capital, knowledge, and relationships (Boutillier and Uzunidis 2006). Capital is required for investment and operation; knowledge is needed for the choice and the decision; relations are important for the funding, the gathering, and the diffusion of the production.

The creation of a new business is thus the result of the emergence of a flaw in the economic structure made by (a) the differential of profit due to market imperfections and barriers to the mobility of productive resources and goods, (b) the institutional apparatus supporting and enhancing the entrepreneur function, and (c) the mobilization of the required expertise and capital. The current entrepreneur and his small business are therefore essential to (a) the coherence of large enterprises' entrepreneurial space, (b) the reactivation of local microsocial milieus, and (c) the alleviation of the burden of unemployment, inactivity, and precariousness. The creation of a business is a social act that is part of a social network or "social capital," which develops in a given social and economic environment. The network of social relations of any actor consists of a part of proximity social networks (usually consisting of parents and family), and other larger social networks (usually composed of neighbors, friends, professionals).

Entrepreneurs and Innovation Networks

We could say that currently small businesses are "created" by the combined action of governments and large industrial and financial corporations: to be competitive in international markets, a big business transforms its internal functions into independent units and often resort to small companies having a specific expertise. On the other hand, this process of outsourcing and the simplified organization of groups is facilitated by the legal and fiscal policies: the laws on tax relief for holding companies and on the extraterritoriality of financial subsidiaries give the possibilities to big companies to manage with more flexibility their partnership, subcontracting and licensing contracts. The financial control that this burst of production structures requires encourages the creation of small businesses that flourish in the "niches" of markets and in specific technology.

In the industrial history, a large enterprise concentrated its means of production, defined and compartmentalized production tasks, and built directly controllable collective of workers. It now becomes (it has now become) a center of organization and of decentralized management of its productive resources. The way production is now organized tends to mean that the market power of a business (and the coordination of functions and activities that it can impose) is a greater factor of economic power (and of centralization of ownership of assets) than the power that can give it its own (scientific, technical, industrial, and financial) assets. The market power of the company results from its financial capability (ownership of financial assets and ability to raise funds) and from its information potential. Information and finance are used to build and manage the group of small entities geographically dispersed and physically distant (investments in interindustry relations of cooperation, in the protection of technological assets, in the ownership of scientific knowledge, and in the design of new goods, in the coordination, by electronic means, of the various activities, etc.). The managerial coordination strengthens the role of the manager in industrial organization and subjects the entrepreneur to the decisions of the managerial power.

Small innovative firms are introduced into the networks formed by large groups and often coordinated in relation to the territory (Boutillier et al. 2008; Boutilier and Uzunidis 2010). This is the case of science parks where large firms having large technology and business advantages create themselves small innovative businesses (kinds of research laboratories) managed by entrepreneurs and researchers. In other cases, it is the managers of big businesses that are requested by the parent to create a company to experiment new technologies (intrapreneurship). It is not uncommon to see the emergence of a "speculative entrepreneurship" in favor of big businesses. These are highly skilled individuals who, assisted by soft loans and government subsidies, create a company to sell it to a larger one after the product or production process is developed. Connecting small businesses with large corporations is achieved through a financial and intelligence strategy. The venture capital (equity investment firms in the capital of a company that has just been created), business angels (wealthy individuals who invest in innovative projects), and other investors (pension funds are very active) commit capital in innovative new businesses (e.g., in information technology and biotechnology). In sum, complex innovation networks are built, characterized by diverse financial, technological, and informational links between different type of actors, which are all dependent from the ones to the others and which have strong (even if flexible) local roots.

Conclusion and Future Directions

Both the local and entrepreneurial aspects of innovation reveal the mechanics of formation and appropriation of all ingredients of productive activity. The issue of appropriability has become crucial for the operation (the location or creation) of a company. The company tends more to tap into its environment than to invest in the formation of its own resources, notably in all the phases of technology creation. This can be explained by the fact that investments in the acquisition (appropriation) of production resources are less expensive than those dedicated to the formation of these resources. This also explains the attractiveness (open economy) of an area benefiting from abundant scientific and technical resources. The creation of innovative or more traditional enterprises depends on the richness of the "milieu." If the factors related to education, environment, healthcare, finance, infrastructure, housing, etc., impact the marginal cost of a business or activity, they also impact the return on investment. Therefore, the idea of the "network" and of the "innovative milieu" appeared to establish itself in the observation and economic analysis.

The achievement of innovation networks follows four ways: reducing the spatial, organizational, and cognitive distance between firms of different sizes and between companies and institutions; the institutional support for the creation of a pool of resources into which businesses can tap; the creation of new scientific, technical, and commercial opportunities; and the support of the entrepreneurial process. These are the areas of industrial and innovation policy in most countries. The current focus is mainly placed on linking actors and less on investments in the constitution of the stock of scientific and technical resources from which the actors can act. However, the entrepreneurial dynamics of industrial countries will largely depend on this dimension in the coming years.

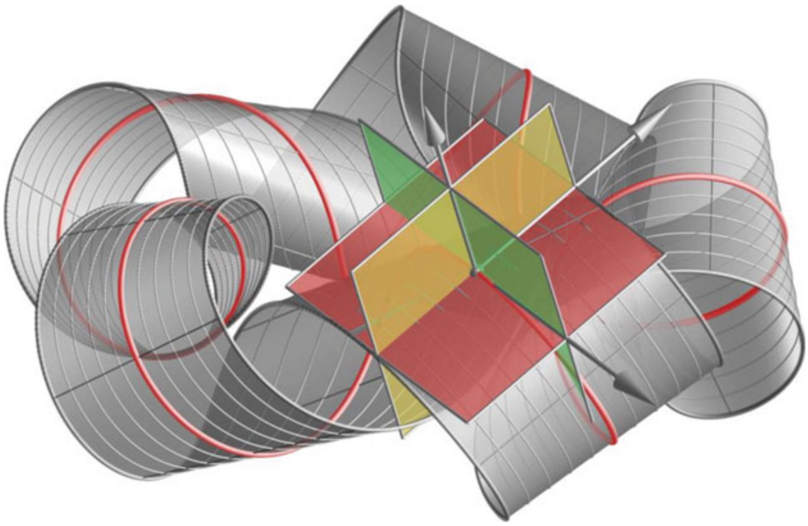
Architectural geometry; Geometrical design

Introduction

Geometry is one of the oldest sciences of mankind, dating back 5,000 years and more. Today it is considered a branch of mathematics and deals with questions of shape, size, relative position of figures, and the properties of space. The geometry of the ancient Greeks (Euclid, Archimedes and many others) served as a base for scientific developments in the two millennia that followed. From about 1800 until the computer age, Descriptive Geometry, introduced by Gaspard Monge, was the tool for developing many industrial products – especially for architecture. The rules and results of Descriptive Geometry also contributed to knowledge of design processes.

The introduction of digital production technologies in the automobile and aircraft industries required new geometric research for the design and development of 3D modeling software.

The last two decades once again brought remarkable innovations in the development of even more sophisticated software that – based on geometric and mathematical considerations – allows solving different kinds of problems that were more or less unsolvable so far.



Innovations in Geometry, Fig. 1 The accompanying "rectifying developable" of a *space curve* (Glaeser 2012)

Geometric Innovations in Modern Architecture and Industrial Design

Modern architecture and industrial design profit from the enormous increase of design possibilities. Creative architects and designers do not simply exploit the best CAD software, but rather want to engineer and design at the same time. This requires close cooperation between geometers, architects, designers and civil engineers.

Example 1: Approximation of Large Scaled Doubly Curved Surfaces

One of the problems that seemed impossible to overcome until very recently was to find surfaces that approximate doubly curved surfaces piecewise by single curved surface parts in a manner acceptable for the artistic designer. This requirement is so important because building costs of doubly curved surfaces tend to be very high. Figure 1 illustrates an important theorem of classic differential geometry: For any space curve, one can find a single curved surface (a "developable") such that the curve is a geodesic line that becomes a straight line when the developable is flattened into the plane.

The challenge is to choose space curves on a doubly curved designed freeform surface, such that the corresponding accompanying developables approximate the target surface as well as possible. When the chosen curves are geodesics on the surfaces, their rectifying developable will touch the target surface along the whole line. Neighboring rectifying developables intersect each other and form strips or "ribbons" like in Fig. 2 (Pottmann et al. 2008).

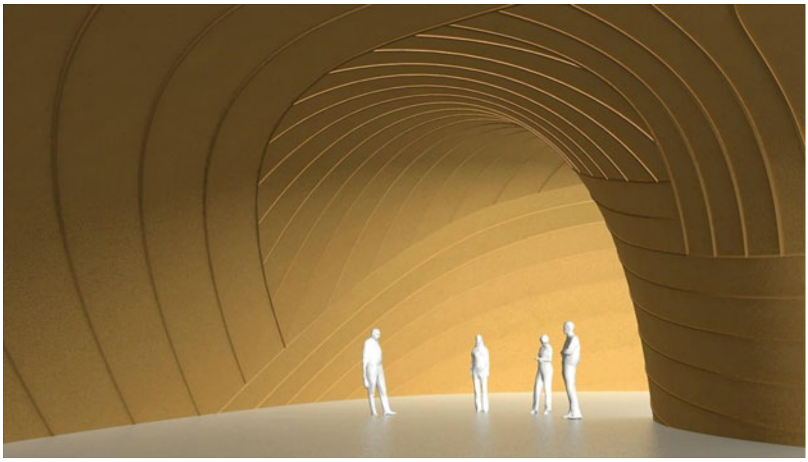
Figure 3 illustrates another way of finding developable strips by searching for series of planar quadrangles on the surface. Figure 4 shows an example of that kind of approximation.

Example 2: Curved Folding

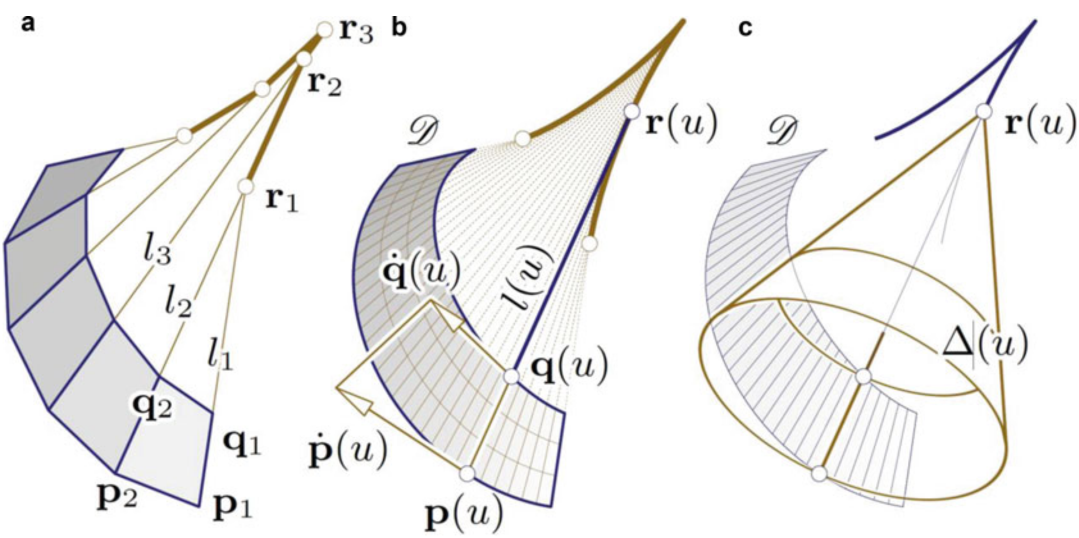
A problem that is also related to developable surfaces is a demand posed by industrial design: How could one fold interesting and practically useful shapes by means of scoring curves into a flat piece of material? Figure 5, e.g., shows what happens when only one curve – in this case a catenary – is considered (Kilian et al. 2008). Figure 6 shows two practically usable examples from industrial design and architecture. In both applications, construction costs are reduced considerably.

Geometry in Robotics

In robotics, geometric insights have lead to remarkable innovations (Lenarcic and Husty 2012). The kinematics of a manipulator or the



Innovations in Geometry, Fig. 2 "Rectifying developables" of geodesic lines on the target surface allow a rather smooth approximation by means of developable "ribbons" (Pottmann et al. 2008)

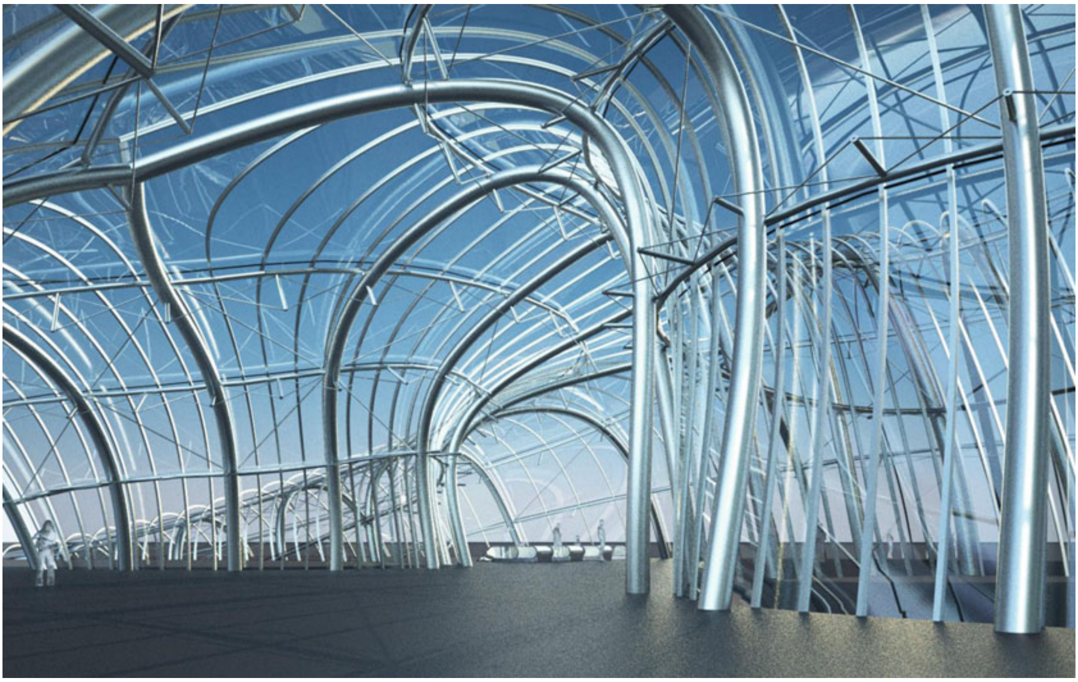


Innovations in Geometry, Fig. 3 Quadrangles on a discrete developable (Pottmann et al. 2008)

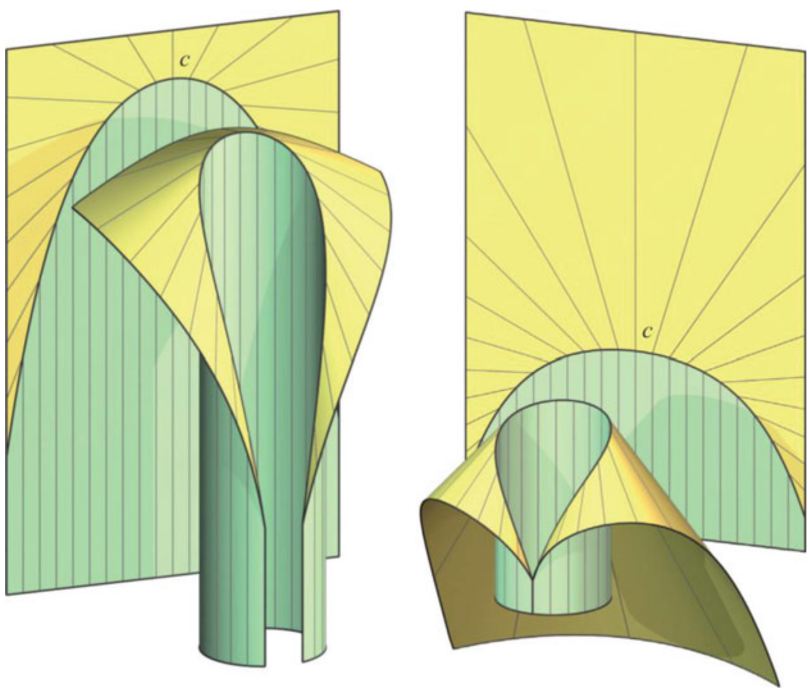
possibilities of moving the manipulator are meanwhile described by systems of algebraic equations. Thus, one can describe the working space of the manipulator by algebraic varieties which potentially split up into kinematically interesting components. In practice, one is mainly interested in mechanical restrictions or geometric limitations. The latter are called singularities and are – especially with parallel manipulators – described by fascinating algebraic objects (Schadlbauer et al. 2011). Figure 7 shows the singularities of a so-called 3-RPS manipulator which is a platform that is moved by the "legs" (consisting of the three different joints: rotational, prismatic and spherical) driven by linear motors that vary the lengths of each leg.

Flexible Magnetic Nets and Iterating Algorithms

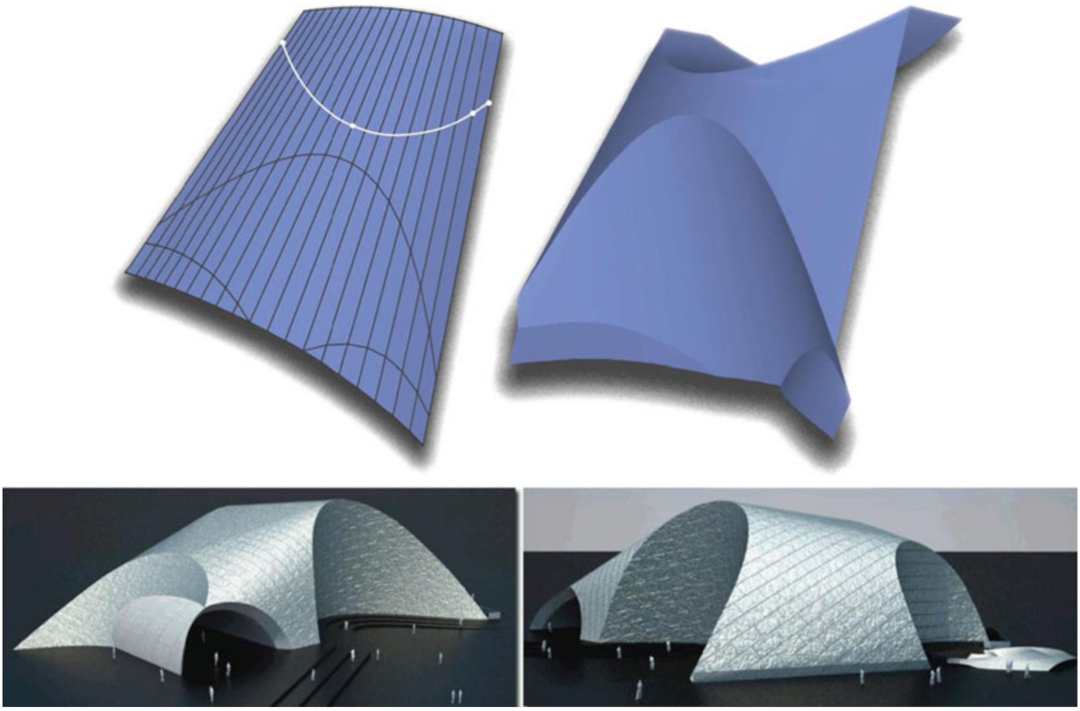
Many geometric problems do not have exact solutions, but algorithms may lead to good approximations and practically useful



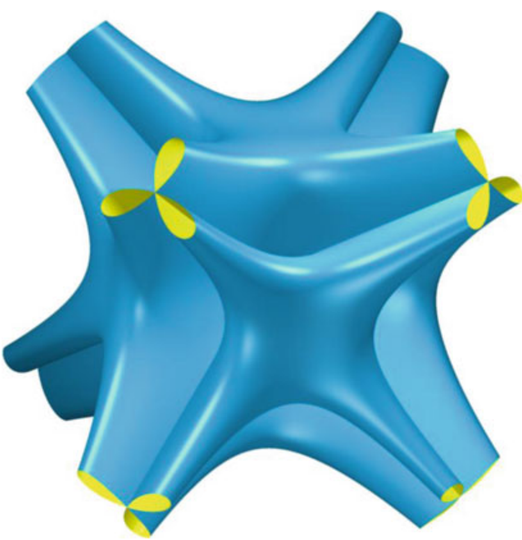
Innovations in Geometry, Fig. 4 Freeform surface entirely approximated by developable *strips* (Pottmann et al. 2008)



Innovations in Geometry, Fig. 5 "Collar surfaces" out of one piece (Glaeser and Polthier 2012)



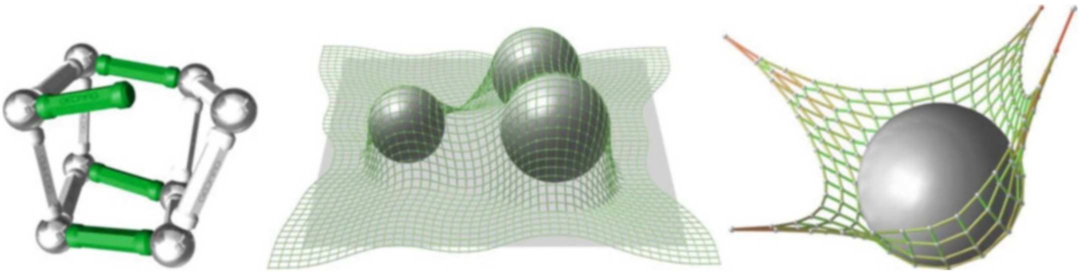
Innovations in Geometry, Fig. 6 Practical applications in design and architecture (Kilian and Flöry 2008)



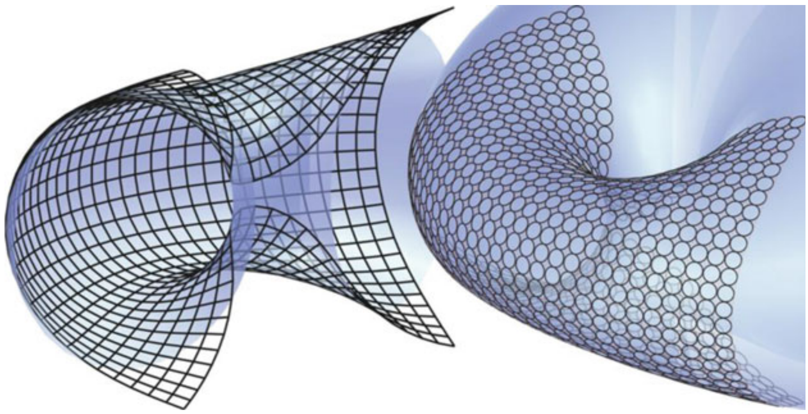
Innovations in Geometry, Fig. 7 Algebraic surface as the locus of all manipulator-singularities (Schadlbauer et al. 2011)

alternatives. A typical example is over 100 years old: The Thompson problem asks for the locus of a given number of points that are equally distributed on a sphere. Exact solutions only exist for a few special numbers (e.g., 20 points would lie on a regular dodecahedron). There are "best solutions" for all numbers, however, which can be found by various algorithms. One of these algorithms is based on magnetic repulsion: Points are considered to be magnetic and are allowed to "swim" on the surface. They push each other until a state of equilibrium is reached.

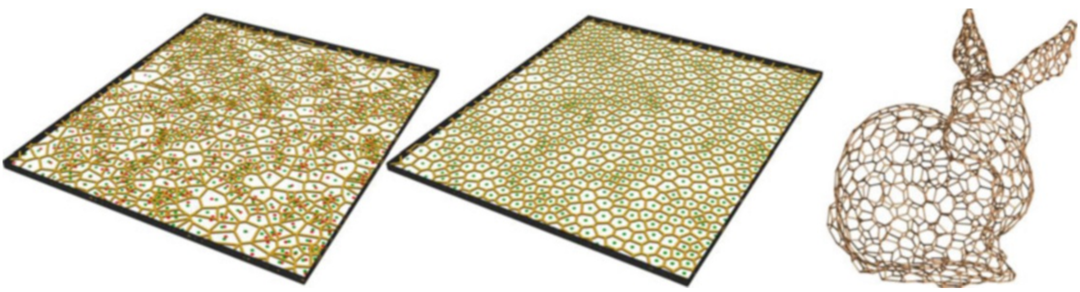
This algorithm can be extended and applied to various problems. Figure 8 illustrates the introduction of small magnetic spheres, from which four attached magnetic rods of equal length protrude. Such a flexible magnetic net can be fitted onto desired forms. In Fig. 8, the net was cast over three spheres. By means of stretching or compression of the rods – by as small an amount



Innovations in Geometry, Fig. 8 Simulation of magnetic repulsion



Innovations in Geometry, Fig. 9 Near orthogonal grid generation on surfaces (Gruber et al. 2010)

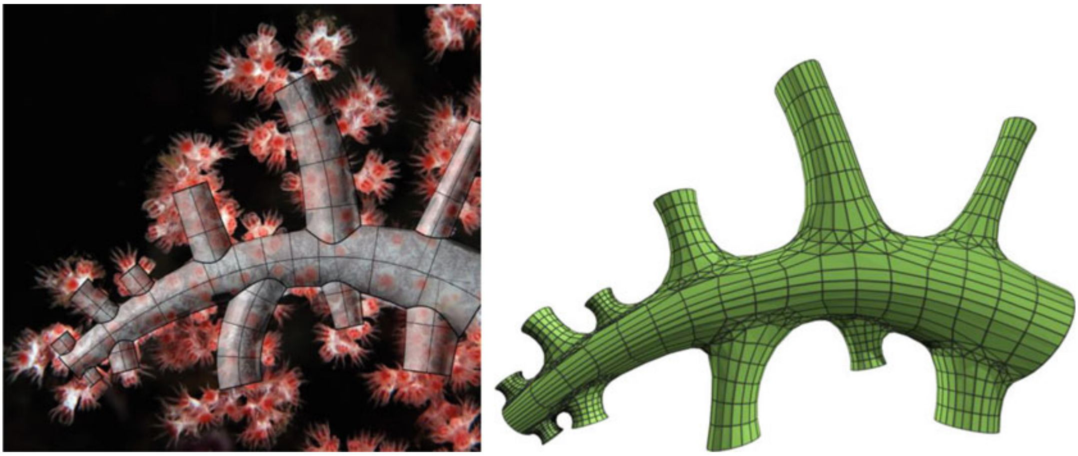


Innovations in Geometry, Fig. 10 Iterated Voronoi diagrams

as possible – the algorithm gets more practically useful for the solution of various problems, e.g., for force directed near-orthogonal grid generation on surfaces (Fig. 9). Such algorithms are iterative, i.e., small changes are made in various parameters, and the best result is taken as an input for the next step.

Comparable approaches can be applied in other situations. Figure 10, e.g., shows the generation of Voronoi-diagrams (in the plane or on surfaces) that can be improved iteratively (the area-barycenters of convex cells are the inputs for the next iteration).

Iteration of magnetic nets fitted onto geometric objects – with respect to area minimization – can also be the key for the generation of shapes that frequently appear in nature (Fig. 11).



Innovations in Geometry, Fig. 11 Iteratively minimizing the surface area of composed geometrical objects leads to organic forms

I

Conclusion and Future Directions

The computer is the main new tool of Geometry. It allows to realize otherwise hard to solve theoretical challenges. The underlying problems may be 100 years old (or even older), and large quantities of these problems have thus far remained unsolved.

Architectural Geometry has to provide construction-aware design tools that enable a completely digital work flow from design to manufacturing, especially for highly complex geometries, including animated geometry. This requires interaction of mathematicians, engineers and architects.

Innovations of and in Organizations

Kurt Mayer
REFLACT – Sustainable Consulting, Vienna, Austria

Synonyms

Innovative firm; Open innovation

Introduction

At a first glance "innovations" and "organizations" seem to be somehow contradictory phenomena.

Organizations are designed for ongoing operations. Their reason of existence is to coordinate actions and actors effectively and to strive for productivity and efficiency to make operations as profitable as possible. They have to serve their customers better than and more efficient than their competitors do. Their performance is measured by being on time and on budget and by producing products and services with a constant quality. Hence, they are always striving for specialization, repeatability, and predictability, and they are inclined to work smoothly and perfectly even.

Innovation is the ability to define and develop new products and services and to deliver them to the market. Looking at the nature of the innovation process from an organizational point of view, we have to point out first that innovation involves strong elements that cannot be planned. If "innovation concerns the search for, and the discovery, experimentation, development, imitation, and adoption of new products, new production processes and new organizational set-ups" (Dosi 1988, 222), then the dimensions of complexity, uncertainty, cumulativeness, interactivity, acting collectively, and learning play a major role in the innovation process. As a consequence the process of innovation is in clear contrast to processes of a rigidly planned implementation of well-defined action plans.

Despite this contrast it is quite obvious that organizations need innovation. Organizations that operate strictly within the bounds of their established norms and routines fail to develop. The better something works, the less excited, interested, and emotionally engaged people are. Organizations that operate strictly within the bounds of their established norms and routines get in danger to die. As a consequence the dual search for stability and exploitation on the one hand and change and innovation on the other hand poses a crucial challenge for organizations operating in the recent complex and dynamic business environment.

And as well innovation – defined as new products or services delivered to the market – usually is dependent on organizations. This is in contrast to mere inventions, which can be developed by single individuals or a group of people. The process of innovation is based on various activities of organizational creation. Different actors have to be coordinated and coupled with a wide range of activities across specialized functions, knowledge domains, and contexts of application. In the recent dynamic and complex "society of organizations" (Peter Drucker), society's problem-solving and innovation capacity rather is determined by the effectiveness and efficiency of its organizations then by individuals or groups. The processes of organizing and innovating may be seen as incompatible and mutually exclusive, but they are as well fundamentally interdependent and mutually enabling.

Against this background the following questions of (a) different perspectives to examine the relationship between organization and innovation and (b) organizational factors that influence innovation performance are focused on in this entry.

Innovation and Organizational Structure

Since the late 1950s classical organizational theory like Weber's bureaucracy or Taylor's scientific management have been challenged by the new approach of contingency theories. Classical organizational theorists like Weber, Taylor, or Chandler had based their work on the idea of universal organizational forms and the endeavor to find the "one best way to organize." In contrast contingency theories claimed that there is no best way to design organizational structures or to run a company. Rather variations in management styles and organizational structures are influenced and shaped by various aspects of the environment: the contingency factors of technology, suppliers and distributors, policy regulation, etc. Within this new theoretical context, Burns and Stalker (1961) investigated on the relationship between structure and innovation.

Mechanistic and Organic Organizational Structures

Burns and Stalker (1961) found that organizations operating in more stable environments tend to develop a more mechanistic organizational structure, while companies facing a more dynamic and uncertain environment tend to show a more organic organizational structure. Their main argument is that neither of the two types is right or wrong.

Mechanistic structures and rather rigid and hierarchical organizational patterns can be a functional and efficient structure for organizations operating in a more stable and certain environment where there is no need for quick decision-making or innovation.

On the other hand organic structures provide organizations with a more fluid set of arrangements to quickly adapt to conditions of rapid change and innovation. There, rapid communication and information sharing is necessary. Hence, departments and different functional areas need to be tightly integrated.

Building on these ideas Lawrence and Lorsch (1967) carried out a series of empirical studies in the chemistry industry. They recognized that organizations usually are not composed of one uniform structure, either mechanistic or organic. Instead mechanistic and organic structures can coexist in different subunits interacting with different demands of functional subenvironments.

Lam (2010) is pointing out that the arguments of these earlier authors developed under the theoretical umbrella of structural contingency theory had a considerable impact on both organizational theory and the provision of useful guidelines for innovation management. And they are still useful for understanding recent development in innovation and organizational change. Faced by the challenges of innovation pressures and an accelerated pace of change, we recently can better than ever observe how companies struggle to leave mechanistic patterns behind and to follow a more organic path of development. As well, the contemporary debate on hybrid organizations and ambidexterity is reflecting the most important argument of Lawrence and Lorsch. Mechanistic and organic structures can coexist within one organization and therefore strengthening the capability to deal with both revolutionary and evolutionary changes in the various technological and market environments.

Adhocracy as Organizational Archetype with High Potential for Radical Innovation

As a specialist in management theory, Henry Mintzberg (1979) aimed to prescribe effective organizational designs. Drawing on contingency theory and synthesizing much of the work on organizational structure, he argues that successful organizations develop a logical and consistent configuration of design parameters to cope with the specific challenges of their environment. As a result he concludes that organizations are likely to be dominated by one of the five pure archetypes identified he identified: simple structure, machine bureaucracy, professional bureaucracy, divisionalized form, and adhocracy. These archetypes exhibit profound differences with regard to their innovativeness (Lam 2010, 167 ff.).

Machine bureaucracy, divisionalized form, and professional bureaucracy are characterized by relatively low levels of innovativeness. The simple structure has higher innovation potential. Simple structures are characterized as being small and informal. They rely on direct control by one person, often the founding entrepreneur, who is free to searching for high-risk environments.

Adhocracy with the highest innovation potential is as well highly informal and flexible organization capable for radical innovation in a volatile environment. Distinctive traits are a highly organic structure, little formalization of behavior, low standardization of procedures, and a work organization based on specialized teams. Here it is not one single entrepreneur who searches for innovation but highly flexible and problem-solving project teams that can be quickly reconfigured in response to changes in the markets and technologies. The organizational boundaries of adhocracies are rather permeable and allowing for new ideas and knowledge from outside to come in. Adhocracies are characterized by an extensive absence of hierarchical structures. Within their areas of specialization and in coordination with coworkers, members usually have the authority for decision-making and to take actions affecting the future of the organization.

Innovation, Knowledge Creation, and Learning

In the organizational structure perspective innovation is perceived as an output of certain structural features and components of an organization. Organizations tend to shape their organizational design in line with the demands and challenges raised by the technological, competitive, and political environments they are operating in. If competitive, dynamic, and volatile environments demand for organic structures (Burns and Stalker; Lawrence and Lorsch), then innovation is an output of the structural features successful organizations are building within this context.

Another line of organizational theory is regarding innovation as process of problem-solving, knowledge building, and learning. These authors point out that innovation in the economy on the one hand and learning and knowledge building in organizations on the other hand are two sides of the same coin, since the increased speed of change confronts agents and organizations with new problems and to tackle the new problems requires new skills (Lundvall and Borras 1999). As a consequence, innovative firms select more learning-oriented employees and the market selects more change-oriented firms. Hence, the current market economy is characterized by a process of "circular cumulative causation" between innovation and learning.

These arguments reflect the fundamental shifts in the way knowledge is produced, organized, and utilized in the knowledge economy. The high rate of change and the new pressures of market competition force companies to obtain additional abilities, that is, to configure information resources in novel ways which cannot be easily imitated and replaced by competitors. Since ICTs make a vast amount of data and information available and easily accessible, the problem of information-based competitive advantages is to continually innovate and to stay one step ahead of other companies. Hence, in terms of innovation, the knowledge at the top end still seems to be insufficiently designed and hard to transfer in a routine manner that "provides the 'competitive edge' for firms which are trying to stay ahead of the pack" (Ducatel 1998, 11).

Tacit Knowledge and Organizational Knowledge Creation

Drawing on a concept of Polanyi (1958), this top end knowledge is referred to as "tacit knowledge," in contrast to "codified knowledge" or mere information. "Tacit knowledge is personal, context specific and therefore hard to formalize and communicate" (Nonaka and Takeuchi 1995, 160 f.). It refers to the observation: "We know more than we can tell" (Polanyi 1958).

Tacit knowledge has two dimensions, the "cognitive" and the "technical" elements (Nonaka and Takeuchi 1995, 60). The cognitive elements focus on "mental models" (schemata, paradigms, perspectives, beliefs, viewpoints), in which human beings create working models of the world by making and manipulating analogies in their minds. These cognitive elements, which help individuals to perceive and define their world, refer "to an individual's images of reality and visions for the future, that is, "what is" and "what ought to be." The technical elements include know-how, crafts, and skills. Both dimensions of tacit knowledge suggest that tacit knowledge defines how to use codified knowledge or even clearer: Tacit knowledge is a precondition to make use of codified knowledge.

Being "tacit" means that this knowledge is not migratory, as it is highly embedded in complex social interactions and relationships within organizations. Since tacit knowledge resides in the skills, shared experiences, and behavior of groups and individuals, it cannot be easily acquired or bought at the market place. Thus, it is different from codified knowledge, which can be obtained (through reading books, attending lectures, and accessing databases), transferred as information, and even sold in the market. Codified knowledge is accessible. Tacit knowledge, on the other hand, is rooted in practical experience and social contact. Since tacit knowledge is socially constructed knowledge, it can only be appropriated in a social context by interactivity and social interaction. It will typically have to be learned (Lundvall 1996).

The acceleration of creation processes and the use of codified knowledge via ICTs are intrinsically related to the increasing importance of tacit knowledge, which enables us to make use of information, in general, or to effectively acquire, select, and use the data and information created within a company or elsewhere. Hence, "codified and tacit knowledge are complementary and co-exist in time" (Lundvall and Borrás 1999, 33), and tacit knowledge seems to be necessary to define how to use explicit knowledge.

Having this in mind, Nonaka and Takeuchi (1995, 70 ff.) argue that only "when tacit and explicit knowledge interact (. . .) an innovation emerges." Their dynamic model of "knowledge conversion" "is anchored to a critical assumption that human knowledge is created and expanded through social interaction between tacit knowledge and explicit knowledge" (Nonaka and Takeuchi 1995, 61). According to this line of reasoning, the sources of innovation multiply "when organizations are able to establish bridges to transfer tacit into explicit knowledge, explicit into tacit knowledge, tacit into tacit, and explicit into explicit" (Castells 1996, 159).

The Knowledge-Creating Company

These collective and interactive knowledge processes imply that instrumental behavior will become mixed with "communicative rationality" where the common goal of the involved partners is to understand better what the problems are and what solutions can be developed. In this respect, interactivity, shared experiences, and learning stimulate the development and appropriation of shared beliefs and common interpretations of the social context.

Enhanced communication between (reduced) hierarchies, between departments, is intended to facilitate the "knowledge and competence puzzle" as a precondition for innovation. These strategies of social interaction are complemented by lifelong learning and HRD strategies for the whole workforce, since according to the principles of a "learning organization" (Senge 1990) "inventing knowledge is not a specialized activity.. (. . .).. it is a way of behaving in which everyone is a knowledge worker" (Nonaka and Takeuchi 1995). Guided by this line of argumentation, Nonaka and others (Nonaka 1991; Nonaka and Takeuchi 1995; Nonaka and Konno 1998) have developed the framework of a "knowledge-creating company," defining the firm as a collection of shared spaces for emerging relationships that provide a platform for advancing individual and/or collective knowledge and for generating collaborative processes that enable the transformation of this knowledge to other contexts (see the concept of "ba" developed by Nonaka (Nonaka and Konno 1998). These spaces exist in several different dimensions (Nonaka and Konno 1998):

- Physical: department within a firm, sphere of commercial influence, cooperation agreement
- Virtual: e-mail, teleconferencing
- Mental: shared experiences, professional interaction, shared ideas, and attitudes

These spaces enable the firm to become a permanent locus for the creation of dispersed knowledge.

The J-Form Organization with High Potential for Incremental Innovation

Knowledge-creating companies are commonly basing their innovation performance on knowledge embedded in organizational routines, team relationships, a shared culture, and tacit knowledge. Their knowledge strategy is emphasizing the continuous improvement of the existing and embedded knowledge. "If HP only knew what HP knows, we would be much more profitable" (former CEO Lew Platt).

In management sciences those organizations are often called "J-form" organizations referring to "Japanese type" of organizations (such as Aoki's model of the "J-firm"). The J-form of organizations tend to develop an orientation towards incremental innovation as a strategy and generally perform well in relatively mature technology fields characterized by rich possibilities of combinations and incremental improvements to existing products or components. Like adhocracy J-form organizations exhibit strong innovative capabilities; nevertheless, they differ markedly from adhocracy in terms of their knowledge configurations, their patterns of learning, and the type of innovative competences generated. J-form organizations are especially good in exploiting learning and incremental innovation, but they are not as effective in gaining knowledge from external sources and triggering radical innovation (Lam 2010).

Knowledge Management and Innovation Management

The reflections above provide the theoretical background for the extensive literature on "knowledge management" and "innovation management," which has emerged during the second half of the 1990s. Successful innovation requires the production of appropriate knowledge. In this perspective knowledge management is a complex and demanding task, aiming to gain access to fragmented knowledge domains and to organize cooperative processes, wherein the different sources of knowledge are integrated. According to Brödner et al. (1998), knowledge management has three important tasks: (a) to explicate and codify socially incorporated knowledge, (b) to connect people to these explicit knowledge bases for their effective use, and (c) to integrate the different perspectives needed for problem-solving.

However, the goal of innovation is more than production of new knowledge; it is geared towards new products or services delivered to the market. As a consequence the focus of innovation management in complementing knowledge management is on the provision of appropriate structures and spaces for managing the different phases of the innovation process. This starts with idea generation and comprises the stages of idea selection, idea evaluation, business decision, and finally the successful implementation of the idea into new products, services, processes, or business models. As a consequence a series of innovation management techniques (e.g., technology watch, patent analyses, brainstorming, lateral thinking, CAD systems, rapid prototyping) was implemented in organizations to support the process of innovation in organizations and help them in a systematic way to meet new market challenges.

Recently the innovation management approach is increasingly challenged by systemic and cybernetic perspectives on organizations. Peschl and Fundneider (2011, 44) suppose innovation management techniques to be a trial of classical managers to solve the mentioned contradiction between organization and innovation in a mechanistic way. "If innovation should be incorporated at all, it should fit into their routines and processes. In other words, their secret wish is to 'domesticate' innovation to a process, which is predictable, deterministic and scalable." Innovation management is not changing the structure or even the culture of an organization; it is rather based on the assumption that innovation can be produced or controlled like any other process.

Learning Organizations and Organizational Change

Nevertheless, throughout the 1990s and especially in the first decade of the new millennium, the debate about organizational learning got an increasing focus on deeper aspects of organizational change. In this perspective the organizational learning architecture is not restricted to the production of new knowledge and the facilitation for new products and services. Radical and sustainable learning in organizations means that the organization continuously transforms itself. Therefore, Mezias and Glynn (1993, 78) define innovation as "non-routine, significant, and discontinuous organizational change that embodies a new idea that is not consistent with the current concept of the organization's business."

Peter Senge is one of the most influential writers to promote the concept of the learning organization. Senge (1990) mentions five disciplines that characterize a learning organization: personal mastery, mental models, development of shared visions, team learning, and systemic thinking. The "fifth discipline" of systemic thinking comprises all other disciplines and is supposed to contribute to an integrated development of the other disciplines. According to Senge, people do not just learn in a learning company, it is rather the company's consistent concern to discern and to create structures that are beneficial for learning. A learning organization will foster learning at all levels, develop new and innovative processes, and continually reflect and transform itself.

Learning as Strategic Activity

Deiser (2010, 39) points out that a powerful architecture for learning and organizational change "needs to provide common spaces that instigate cross-boundary dialogue and ultimately create enabling mechanisms that foster collaboration, trust, and openness – important conditions for high-performing networks." The creation of relationship networks that emerge through integrating diverse perspectives is often a more important goal than the topical learning content. Hence, the careful and suitable design of learning processes and facilitation becomes more important than content expertise or any specialized activities of innovation management.

He further emphasizes that relevant learning happens by encountering differences. As a consequence boundaries between people, departments, or companies "are the very space where learning happens; they are the place where difference is established." The design and permanent redesign of smart and boundaries between these entities is the most crucial task of a learning architecture. As a consequence he suggests as a new strategic perspective "to design our business encounters with the world in a way that they maximize insights, and then design processes that turn the insights into strategically reflected organizational activity (Deiser 2010, 27)." This is the core of his model of a smart organization.

In a complex network society, the long-term strategic success of an organization is especially dependent on strategic partners and external stakeholders. Radically new learning rather tends to arise from interaction and feedback from those outside the company who are in a better position to create "designed spaces of irritation" and thereby shake existing perspectives and paradigms. The new innovation challenge is to develop the capabilities not only of one's own organization but of the entire network. If suppliers, customers, strategic partners, or even competitors should be integrated in this learning network, then this requires the competence of establishing external nonhierarchical relationships and arranging the collaboration of stakeholders across the value chain. Hence, the competences of sharing, collaboration, and designing spaces of collective interaction and development are the new critical competences for innovation.

Enabling Spaces for Innovation

Peschl and Fundneider (2011) develop the concepts of "enabling" and "space" as basic pillars of the innovation process in an even more explicit manner. In this perspective innovation processes cannot be managed, they just can be enabled. This implies to give up the principles of control, determining, and making and provide instead "a set of constraints or a facilitating framework supporting the processes of bringing forth new knowledge." (Peschl and Fundneider 2011, 45) Hence, an enabling space is a space supporting enabling and facilitating processes of innovation and knowledge creation. This space is designed as a multidimensional space in which architectorial/physical, social, cognitive, technological, cultural, intellectual, and other factors are considered and integrated like a composition, a piece of art (Peschl and Fundneider 2011, 49/52). As a kind of container, an enabling space is providing qualities like offering an environment of protection, of listening and observing closely, of openness, and of enabling the free flow of knowledge and of silence (52). These design qualities have to be translated and integrated into the concrete enabling space of a concrete innovation process. With respect to organizational issues, Peschl and Fundneider indicate that organizational culture is a key constraint and makes the creation of enabling spaces a real design challenge since there do not exist standard solutions or simple rules which one just has to follow in order to establish a ready-made enabling space fitting organically into the organization" (Peschl and Fundneider 2011, 53).

Conclusion and Future Directions

Even if at a first glance "innovations" and "organizations" seem to be somehow phenomena, they are fundamentally interdependent and mutually enabling. In response to environment and contingency factors, organizations develop structures, rules, norms, and processes that provide stability for complex dynamic, uncertain, and volatile processes of knowledge production, learning, and innovation. Depending on environment and contingency factors, this structural framework is looking different in various sectors or even within various departments of one organization and exhibits more or less potential for innovation. Simple organizations, adhocracies, and the J-form are three organizational forms with powerful innovative capabilities but markedly differing in terms of their knowledge configurations, their patterns of learning, and the type of innovative competences generated.

However, without the stability provided by organizations, the innovation process based on dimensions of complexity, uncertainty, cumulativeness, interactivity, acting collectively, and learning is not probable. The microlevel processes of knowledge production, knowledge conversion, and organizational learning we analyzed in part 2 of this entry all take place in spaces and environments offered and shaped by organizations. However, if organizations apply established processes of efficiency and control to the field of innovation, then the innovation process is in danger of becoming predictable, deterministic, and scalable and losing its potential. This is the criticism the approach of innovation management is confronted with.

In the first period of the twenty-first century, we are facing an increasingly complex, chaotic, and confusing environment for organizations. Increasingly unpredictable market and nonmarket conditions, a volatile and ever-changing economic landscape, a complex brew of rapidly advancing technologies and ecological challenges are creating an unchartered territory for more and more organizations.

In this environment of volatility, uncertainty and change organizations are forced to constantly and quickly change themselves and to find new viable organizational solutions. Their success is becoming more and more dependent on the ability to think in terms of organizational alternatives. Deiser (2010) pointed out that the ability to develop visionary organizational structures in dealing with customers, with partners, in connection to the organized civil society and within the company, is gaining critical importance. Especially in knowledge-intensive sectors, recent concepts like "cellular forms," "modular forms," "self-organization," "project-based networks," or "holacracy" mirror the increasing emergence of new dynamic and flexible forms of organizations with a strategic focus on entrepreneurship and innovation (Lam 2010, 170). In this new organizational context, the innovation paradigm seems to be changing as well, and the dimensions of stakeholder networks at the boundaries of the organization, of sharing, of collaborating, of enabling, and of appropriately designing multidimensional spaces for innovation become critical for success.

Innovations of Direct Democracy

Marc Bühlmann
Année Politique Suisse, Institute of Political Science, University of Bern, Bern, Switzerland

Synonyms

Direct legislation; Direct say; Initiative; Referendum

Introduction

Direct democracy is often seen as the most pure and basic form of democracy. Representative democracy allows for indirect influence of citizens voting for representatives responsible for taking political decisions. Contrarily, with direct legislation each citizen has effective and direct control over political decision making and equal power to affect decisions through binding votes. The idea of direct democracy is not new at all. The ancient Greeks still knew some sort of assemblies where decisions were made directly by those few full citizens, who were entitled to vote. In Switzerland and some of the US states, forms of direct legislation have been installed since the nineteenth century. Today, some sort of direct democratic mechanisms can be found all over the world (for overviews, see Altman 2011; Gallagher and Uleri 1996; Scarrow 2001).

Given its long heritage and the widespread use, how can direct democracy be treated as an innovation? The reasons are twofold: First, direct democracy is increasingly seen as a remedy for the problems democratic states face in the twenty-first century. The growing mistrust of citizens regarding the political elites, the declining willingness for individual political engagement, and the declining output legitimacy of representative systems are interpreted as signs of a veritable crisis of democracy. It is argued that giving the citizens more direct say – that is, enlarging their possibilities for democratic decision making and control – has the potential to foster motivation to take part in politics, to craft trust, and finally to renew democracy. In this sense, direct democracy is an innovation for representative democratic states and holds great potential for a new democratic turn. Even if direct democratic institutions can be found in many countries, citizen polls are very rare events.

Second, direct democracy has an inherent innovative potential because it enlarges the scope of political arguments. In direct democracy, it is not only the political elite but – at least theoretically – all citizens who contribute to the discussion of politics. In this sense, the more legislation is direct, the higher is the probability of new and innovative political solutions. Direct democracy allows for policy innovation and inclusion of new ideas and approaches even from minorities and outsiders.

Of course, direct democracy also has its dangers. A careful evaluation of the innovative potential of direct legislation needs a look at both the benefits as well as the dangers of direct say and control by all citizens. An appropriate juxtaposition of pros and cons must be based on theoretical as well as empirical insights. Prior to this, there must be given a proper definition of direct democracy that indeed has very different notions, features, and instruments.

Notions of Direct Democracy

Basically, direct democracy means decision making by eligible citizens as opposed to representative democracy, where decisions are taken indirectly (i.e., by representatives for whom the citizens have voted). To distinguish the existing forms of decision making by the people, and to understand their different potential for innovation, three characteristics must be clarified: activation, approval, and definition.

Activation

The first important attribute of direct democracy relates to the question: Who has the right to start a process of direct legislation and under which conditions?

First, the activation of a process of direct decision making can either be a political right for each citizen (bottom-up) or explicitly rest in the hands of the political elite (top-down). In the latter case, direct democracy takes the form of a pure public opinion poll. The government or (a part of) the parliament submits a political issue aiming at hearing the citizens' opinion on this issue, at increasing legitimation for it, or at consolidating of power. Often, this form of direct decision takes the notion of "*plebiscite*" (sometimes also "ad hoc referendum"). When the right of the activation of direct legislation is given to the citizens, this instrument can be considered either as an abrogative or rejective veto or as a citizen's proposal. The veto allows for holding a vote on whether a given law (already implemented or not) should be rejected. To avoid misunderstanding, it is only this veto-form of activation that should be denominated "referendum." The citizen's proposal grants the possibility to suggest new laws. This suggestion can either lead to a popular vote – in this case, this instrument normally is called a "citizen's initiative" – or to a more or less binding request for the elected representatives to take into consideration propositions for new laws. In Austria or in some German Bundesländer, this form takes the notion of "citizen demands" (sometimes also called "agenda initiatives").

Second, the activation of a direct decision making process depends on different legal conditions. In some countries (e.g., Switzerland, Uruguay), the renewal or modifications of the constitution must lead to a popular vote by rights, normally called "mandatory referendum" (also called regulated referendum). In other countries (e.g., Austria, France, or Spain), the representatives have the right to decide whether the people should vote on a given law or not ("ad hoc referendum"). In contrast, the launch of an "optional or facultative referendum" or a "citizen's initiative" has to fulfill conditions, normally the collection of a given amount of signatures within a given timeframe. Of course, such hurdles can be more or less high. To call for an optional referendum in Switzerland – where direct democracy is most widely used – one needs to collect 50,000 signatures (roughly 1 % of the eligible citizens) within 90 days. For a citizen's initiative, 100,000 signatures must be collected within 18 months.

Approval

The crucial feature of direct democracy is approval – whether a decision in direct legislation in the end is legally binding or not. Most often, pure plebiscites in terms of citizen opinion polls are only consultative and non-binding. Thus, even if the citizens reject a proposal, the parliament can implement it. On the other end of the scale, there are direct democratic decisions that are binding without consent of the parliament

</table>

or even against the expressed opposition of the elected representatives. Between these two extremes, there are several levels of conditions for the legal binding, mostly depending on approval quorums and participation quorums. Approval quorums ask for more than simple majorities such as super-majorities (e.g., a majority of all enrolled citizens) or double majorities (e.g., a majority of citizens plus a majority of federal states). As for participation quorums, whether a decision is binding or not depends on a minimum number of citizens participating.

Definition Power

Foremost in the case of direct democratic processes initiated by the people, one has to consider the power of definition. First, the use of a referendum or an initiative can be restricted to special cases only or be allowed for all policy fields. Second, a citizen's proposal can be more or less set out – that is, it can give more or less possibilities to the political elite to re-formulate the initial request of the initiators. In some US states and Swiss cantons, citizens are allowed to propose legislative measures (via a "statutory initiative"). The definitional power of this instrument is greater than that for a "constitutional initiative," where citizens are allowed to propose a constitutional amendment that must afterward be specified by the parliament. In some countries (such as Uruguay and Switzerland), the legislatures are allowed to make "counterproposals" against the citizen-initiated proposal. The above-mentioned "referendum" in the sense of a pure veto against a decision taken by the parliament has no definition power, because it only aims at the rejection of an existing law proposal.

The three defining elements of direct democracy are summarized in Fig. 1.

Innovations of Direct Democracy

Based on the typology in Fig. 1, considering the theoretical arguments of merits and drawbacks, and leaning on empirical findings of the advantages and dangers of direct legislation, the innovative potential of direct democracy can be estimated.

Bottom-Up Versus Top-Down

The vertical axis in Fig. 1 depicts the trigger of a process of direct legislation. The activation of direct democracy can either be top-down or bottom-up.

At first sight, innovative potential for direct legislation is greater when it is activated by citizens. At least two reasons underline this suggestion: the argument of the many and the inclusion effect of direct democracy. *First*, allowing citizens to bring in propositions for new legislation measures enlarges the scope of possible arguments and the range of political solutions. Marsilius of Padua (1967) already praised the idea of decision making by many. According to the medieval physician and philosopher, the probability that many citizens do find a better political decision than only parts of the people is high. The deliberative theory of democracy concentrates on the process of decision making and highlights the public discussion based on the mutual justification of political arguments as the essential element of democracy. *Second*, bottom-up direct legislation has an inclusive effect. Minorities – often excluded or only marginally involved in representative decision making – have the possibility to bring their specific preferences into the political arena. They can force the political elite as well as fellow citizens to think and discuss about the minorities' interests. In this sense, initiatives have an important function as a megaphone or a valve or can even help to break taboos. New, innovative, and even displeasing themes come on the agenda, and the political elite as well as the citizens are forced to argument for or against them. The innovative potential of bottom-up direct legislation lies in the inclusion and enlargement of political ideas, proposals, and arguments.

Furthermore, a citizen's right to directly take part in legislation has a system-stabilizing effect. The acceptance of laws that are directly made by citizens themselves is higher. Empirical research further shows that satisfaction with democracy and even with one's life as well as trust in political institutions and representatives is higher when there is direct democracy (for overviews on empirical findings of the impact of direct democracy, see Lupia and Matsusaka 2004; Maduz 2010). In this sense, direct democracy has the potential to innovate representative democratic systems that suffer from growing mistrust and political apathy.

Contrarily, top-down activation of direct democracy seems to have less innovative potential. Plebiscites normally only have a consultative function. The political elite quite selectively asks the citizens to legitimize a more or less disputed legislative proposal. This seems not to be innovative, neither in terms of content nor in terms of enlargement of arguments. However, enlarging the scope, one can find innovative potential in top-down activation of direct legislation, too. *First*, even consultation – compared to no direct democracy at all – holds the capability for renewal. Asking the citizens for their opinion forces the representatives to argue for or against their proposal and to explain their points of view. This can lead to a broader and probably innovative discussion on a given topic. Given the possibility of plebiscites, opposition parties could even use this instrument to force the government to take clear positions. *Second*, top-down direct democracy is not necessarily only consultative. In Switzerland, the parliament has the ability to formulate a counterproposal for a citizen's initiative. Normally, Swiss representatives absorb some requests of the citizen's proposal but reject those going too far. A counterproposal is a reformulated and attenuated form of the initial initiative. Sometimes the initiators recall their initiative when there is a counterproposal, but most of the time, both the initiative and the counterproposal are voted on. A counterproposal not only innovatively enlarges the discussion and the scope of arguments, but it presents an interesting interplay between representative and direct democracy. As such, it also can weaken a widespread criticism of direct democracy: the danger of misuse of direct democratic instruments by powerful groups aiming at promoting their own interests or constraining the power of the state (Bernhard 2012). With a counterproposal, the representatives have the chance to counter, attenuate, or enlarge one-sided proposals.

Advisory Versus Binding Decisions

The horizontal axis in the typology distinguishes binding from non-binding instruments of direct legislation. In combination with the vertical axis discussed above, the approval of a direct decision can strengthen the innovative potential with regard to contents: the motivation to find new arguments and positions is bigger and the scope of new ideas is wider when the stakes are high, regardless of whether activation is bottom-up or top-down. As for the systemic innovation, consultative plebiscites that only serve to consolidate power or that are not binding even if rejected by the people rather lead to more political disappointment of the citizenry. The very idea of direct democracy is reduced to absurdity, and the feeling that the political elite comes close to some sort of oligarchy is aggravated. However, and again, a rejection of a non-binding proposal has also some innovative potential because it cannot be completely ignored by the political elite – at least in democratic systems. If nothing else, some tiny reforms must be undertaken if the representatives want to secure their re-election.

The innovative potential of the horizontal axis should be discussed further in terms of responsibility. It is the citizens who have the final responsibility for decisions of legally binding direct legislation. As for the non-binding advisory proposals, it is the political elite who finally decide what will be done. The question of ultimate responsibility lies at the very heart of the debate between supporters and opponents of direct democracy. The former state that giving the people more direct responsibility to decide on political issues leads to higher political engagement, greater accountability and awareness of political problems, more acceptance of the democratic process, and finally even more trust in the political elite (Barber 1984). Supporters of direct democracy, thus, would state that only real direct democracy (i.e., citizen-initiated and binding law proposals) has innovative potential for widening the scope of arguments and reforming representative democracies. The critics of direct democracy are very skeptical in consideration of the capabilities of the citizens. They argue that problems of modern societies are far too complex for ordinary citizens who do not consider anything except their own interests and thus lack a sense of responsibility and accountability. Furthermore, direct democracy allows demagogues to launch populist proposals that violate human or minority rights (Schumpeter 1962). Thus, critics of direct democracy deny a responsibility of citizens. In the end, the people do not bear the consequences of their decisions.

Empirical investigation confirms neither the naïve belief in the salutary effect of direct participation that brings citizens to perfection, letting them find a Rousseauian common welfare (Rousseau 2006), nor the fear of the anarchical tyranny of powerful populist and self-interested majorities. There are hints that citizens in direct democratic systems are more politically competent and do not blindly abolish taxes or demand higher government spending. Compared with elected representatives, citizens who have the power to decide directly even seem to be more economical in spending money: the level of public debt is lower in direct democratic systems than in representative systems (Matsusaka 2005). Some empirical findings even show positive effects of direct legislation on an individual's development of civic virtues, such as political trust or efficacy (Smith and Tolbert 2004). However, there are also empirical findings that identify at least partially discriminating effects of direct democracy. Turnout at polls in Switzerland or California often is quite low. This is not a problem as such because the absentees often do not take part because they are not interested in the topic, are not concerned or feel not competent enough. The problem of this self-selection, however, is its bias: well-educated upper-class people with high income participate much more in direct legislation than do structurally disadvantaged citizens (Mendelsohn and Parkin 2001). Analysis of all polls in Switzerland further shows that the danger of direct democracy for minorities cannot be denied. Sometimes citizen's proposals collide with basic rights (Vatter 2011).

Definition Power

For some opponents of direct democracy, the notion of innovative direct democracy is a contradiction in terms. Direct democracy, rather than being innovative, severely hinders reforms and improvements. Giving citizens the possibility to veto and even cancel parliamentary legislation leads to backlogs instead of political innovation. Thus, direct democracy is seen as a brake.

The discussion on the backlog potential of direct democracy should be enlarged by the third feature of the typology in Fig. 1: the definition power. A pure referendum, as defined above, indeed only blocks a given law or legislative reform when it is adopted. This is the literal sense of such a veto- or control-instrument. However, to consider the whole idea of direct democracy as a paralyzing system would ignore some significant facts. Such a view does not account for the definition power of other instruments than the pure referendum, such as statutory or constitutional initiatives, launched by citizens. Proposals that can be more or less drafted out do indeed have a great potential for innovation. As discussed above, bottom-up induced impulses for political reforms can even break up lethargic representative systems and lead to important reforms. In this sense, direct democracy is not a brake but rather an accelerator for political change.

The degree of definition power affects the scope of the elected representatives' contribution to a specific legislation. Citizen-initiated legislation can range from a simple mandate for the representatives to create a new law to a specific proposal that must be adjusted by the parliament or even a fully set-out law that – given the acceptance by the people at the polls – must be adopted wholesale. The larger the degree of definition power of direct democratic instruments is, the less representatives will have control over the specific legislation but the greater the potential of law-giving innovation there is.

Conclusion and Future Directions

To define the innovations of direct democracy, one must clearly define what is meant by direct democracy. There are several different instruments allowing for citizens to directly join in political decision making. Thus, there is no such thing as the "direct democracy." Further, direct democratic institutions should be seen as complementary to representative democracy. There is no question of either representative or direct democracy. The distinction between direct and representative democracy is not exclusionary, but the two concepts are complementary. In fact, an enlargement of representative systems by direct democratic institutions seems to be an interesting – given the growing mistrust and apathy in established democracies, perhaps even inevitable – innovation of a democratic system. It is the complementation of representative democracy with direct forms that holds the most innovative potential for a transformation of democratic systems to semi-direct democracies.

Depending on the activation, the approval, and the definition power, the inclusion of citizens' ideas into the law-making process holds great innovative potential. As a rule of thumb, the more bottom-up the direct democratic process is organized, the more responsibility is given to the citizens in terms of approval, and the higher the degree of definition power is for citizen-initiated legislation, the greater is the potential for democratic innovation as regards content. The enlargement of the scope for different arguments, the potential of taboo breaking, and the possibility of accelerating political reform is highest when citizens are allowed to directly bring in specific law proposals.

However, there are trade-offs between the innovative potential of direct legislation and the danger of unequal and undemocratic direct decision making by citizens as well as between innovation and representative control. Direct democracy has incorporated perils such as the possible "tyranny of the majority" that harms basic rights, populist demagoguery, or discriminating demands. Such jeopardy is greater the more the responsibility for direct law making is given to the citizens. Furthermore, the more the citizens have to decide, the more the elected representatives must shift responsibility, political power, and control over the political process and output.

The challenge for established democracies in the twenty-first century is the search for a political system that gives possible solutions to these trade-offs. This should be a system that is open enough to tap the innovative potential of citizen-initiated direct legislation, but that leaves enough scope for the elected representatives to limit and control the potential dangers of direct democracy. Such a system will certainly combine elements of representative and direct democracy.

Innovation systems and individual initiative; Innovative activities, creation; Start-up and proximity relations

Introduction

The geographical proximity between science, technology, industry, and finance contributes to the emergence of innovations. Interactions are being organized through the interplay between private actors and political institutions. Today, economists (see, e.g., Acs 2001; Den Hertog et al. 2001; Feldman et al. 2005; Florida 2003) consider the regional economy as a geographical and economic platform for the organization of production and, as a consequence, as an opportunity to create new activities, goods and services, new employment, and sources of income. For almost four decades, the innovative approach based on proximity and, in particular, on the concept of the "innovative milieu" has demonstrated its pertinence as a form of modeling of decentralized economic growth and also as a source of entrepreneurship.

An analysis starting from the innovative milieu makes it possible to study the entrepreneur's economic role and function and its contribution to the innovation process. The systemic nature of the relationships that characterize an economic and social milieu (Cooke 2001) makes it possible to identify what contributes (or not) to the innovative act. Innovation and entrepreneurship (as a product of the milieu) depend to interpersonal exchanges. Are they only the result of a specific organization of economic relations? The argument here is that the systemic nature of the milieu does not exclusively relate to economic interactions but more precisely also takes into consideration the social structures that are at the origin of innovative behaviors. Moreover, institutions (states, local communities) play an important role in the organization and development of socioeconomic structures. In its turn, the innovative milieu – thanks to the relations of proximity – contributes to the entrepreneurial innovative performance through the supply of scientific, technological, and financial resources.

The first part of this entry will examine the role of synergic (spatial, organizational, and cognitive) relations – named proximity – in the innovation and entrepreneurial process. The density of these relations reinforces the capability of a local economy to generate small independent enterprises (essentially start-ups). But in the contemporary capitalism, the entrepreneur, as the owner and the manager of a small enterprise, has a specific function (second part). He is not a hero (as Schumpeter it noted), but he is a socialized entrepreneur. The former is at the origin of the development of big industries and new areas of activities; the latter is the result of the financial strategies and industrial policies of the major actors of the economy (big firms, financial institutions, central and local public administrations, etc.). In the third part, this entry will focus on the "resource potential" of the entrepreneur as a necessary condition to business creation. This potential, composed by capital, knowledge, and social relations, can give value to the entrepreneur's function. In this case, the relations of proximity, applied on the territorial level of analysis, must be characterized by the logic of collaboration, confidence, and reciprocity.

Several studies on the territorial economy based on the network analysis and the systemic relations which are developed in this case. The entrepreneur is not an actor of economic system. He is studied like a systemic relation into the network or as the result of the functioning of this network. So, the article argues to analyze how the entrepreneur builds his potential of resources in a local economy and how he uses his resources (knowledge, financial resources, social relations) to develop new relations and new economic activities.

Proximity and the Innovative Milieu

Economic Proximity and Social Relations

The concept of proximity is now widely used in both industrial economics and innovation studies (see notably Boschma 2005). A priori, proximity seems to be related to the existence of localized externalities generating phenomena of spatial concentration and regional dynamics. From this perspective, economists propose a three-dimensional approach to proximity: spatial proximity, organizational proximity, and cognitive proximity. In this approach, the issue of localization is coupled with the organizational and informational/cognitive capacity of firms.

A local economy (or a local production system) may be defined as a geographical area consisting of a set of systemic relationships among enterprises and also between enterprises, public authorities (the state), and local communities; these systemic relationships characterize the area localized for a given type of activities or final production. That economy is observed and studied as a node of productive relations which contributes to regional and local development (Uzunidis 2008).

Alfred Marshall (1919) demonstrated that the regional efficiency of such an organizational mode resides in economies in transaction costs. The concentration in a single geographical location of the main actors of the same productive system (mainly producers on one side and users on the other) not only facilitates transactions but the mutual relations of knowledge and confidence between different partners (spatial proximity). The development and accumulation of expertise will therefore create what Marshall called the "industrial atmosphere" facilitating the functioning of the local labor market. This phenomenon is related both to the workers' qualifications and experience and to the location of several enterprises in the same locality. In the meaning attributed by Marshall to the "industrial district," this environment includes a specific density of population with proven qualifications, a set of actors constituting the different links of a single production system, and finally a degree of know-how strongly resulting from acquired experience.

Before Marshall, von Thünen (1826/1850/1867/2009) in the nineteenth century underlined that the free market mechanisms are not an abstraction, but they take place in a particular territory. In this approach, the territory is defined geographically, and it is also the place where relations of proximity between individuals are developed. The von Thünen's analysis shows that the question on territory and its role for the economic dynamics is not a new phenomenon. On the other hand, Braudel (1975) had argued in the Mediterranean case that the commercial activities are developed thanks to the networks of merchant entrepreneurs.

The main characteristic is that the local organization of production is not linked to a hierarchical principle regulating an enterprise but is rather based on a principle of collaboration and cooperation between different production units. Therefore, the concept of solidarity between economic actors is of considerable importance. The local production system is mainly characterized by the proximity between productive units (individual firms, service suppliers, research centers, training institutions, etc.). The relations between these units have a variable intensity and may take on highly differentiated forms: formal or informal relations, market or nonmarket, etc. Alliances mainly relate to the flow of materials, services, labor, technologies, and knowledge. The specific nature of the activities involved in the production of new knowledge and the interactions associated with them has led economists to introduce the concept of cognitive proximity in addition to spatial-temporal proximity and organizational proximity. Cognitive proximity and knowledge exchange means the more or less formalized sharing of experiences, codes, languages, and models resulting from and facilitating the communication of information inside – and between – organizations (Nooteboom 2002; De La Mothe and Foray 2001; Foray 2003).

Proximity contributes to the coordination of the innovation process. This one, both flexible and evolutionary, imposes on the firm or on the entrepreneur the pressing need to be provided with the different types of technological and intellectual means to acquire and combine uninterrupted flows of material and immaterial resources. The "knowledge theory" applied to the company says that the ability to adapt and the efficiency of the company depends on its cognitive categories, on the interpretation codes of the information itself, and on the tacit skills and its procedures in solving the problems it encounters (Dosi et al. 1999). The scientific, technical, and industrial information as a system of knowledge (knowledge capital) which is articulated, formalized, and likely to be communicated or transferred is a means of production identifiable as such (Laperche 2007), the use of which provides innovation for the economic process and the accumulation of capital. The task of the manager or the entrepreneur consists therefore of finding the balance between managing the partnerships and developing the internal instruments of organization (see Laperche et al. 2006). To survive or grow, a company is forced to acquire new knowledge to create new competences (Penrose 1959).

Piore and Sabel (1984) integrated the proximity in a flexible system of production founded on multidirectional and horizontal relations. The dynamics of the evolution of the structures and the organization of the local system of production highlights the importance of the small enterprises. Those being more flexible and more adaptable are committed to renew the local system of production and to create new jobs since flexibility facilitates the adaptation to the new economic context. Moreover, the proximity between the large companies and the small enterprises contributes to the emergence of the innovative milieu.

Table 1 identifies the main parameters characterizing the different categories of proximity as well as the operating field and the types of stakes related to them. It is worth noting that interactions are generally multidimensional: They represent a combination of different dimensions from which a major dimension emerges. In this case, this core dimension relates to space and time.

An Innovative Milieu

Our central theoretical assumption concerning the concept of the innovative milieu, namely, the social and economic environment of a region developed over the course of history ("path dependence"), is that all innovative milieus are the product of interactions between firms, institutions, and labor. Such interactions are exclusively the result of mutual synergies (networks, partnerships, etc.) between different local agents (public or private) participating in economic and industrial development. For example, authors may refer to the different forms of cooperation between enterprises and research labs. It is firstly the surrounding socioeconomic, industrial, and scientific environment that contributes to the creation of new activities (in particular, through entrepreneurship and spin-off) and to the genesis of innovations (see also Camagni and Capello 2009). In addition, this can only develop in a "natural" form if some preconditions are respected, among which are existence at the regional level of a community of actors (enterprises, research and training centers, public administrations, professional qualifications, etc.); presence of material, human, financial, technological, and information resources in the immediate geographical neighborhood; existence of specific know-how leading to high-quality productive activity; existence of relational capital favorable to the creation of local, national, or international networks; and the existence of norms, rules, and values promoting positive behavior among economic actors.

The concept of the innovative milieu generally relates to the capacity of a local economy to generate innovations through, for example, the emergence of new enterprises. The local economy is therefore represented in the form of

Innovative Milieu as a Driving Force of Innovative Entrepreneurship, Table 1 The three categories of proximity

Proximity	Parameters	Operating field and stake
Spatial	Distance/speed	Displacement
		Flows, time
Organizational (intra- and interorganizational)	Hierarchy/market	Coordination
	Intrafirm/extrafirm	Strategy, actions, routines

a spatial system valuing all kinds of capital and merchant exchange. This spatial, economic, and social system must reduce the risks related to the uncertainty of a given investment; it triggers an innovation process that includes the creation of enterprises and the incorporation of already existing technological enterprises. International competitiveness of a territory is due to the richness of its innovative capacity (Porter 2003).

The organization of the innovative milieu is ensured by two logics: The first is related to the interaction between local actors and the second to the dynamics of the collective learning (Lundvall and Johnson 1994). Interactions contribute to organize a regional economy. They make possible to bring together local actors within a production process. The dynamics of the collective learning appears in a process where the milieu initially mobilizes resources and thereafter uses them to adapt to the change which comes from outside. The capacities of innovation are the result of the cooperation between the local actors and the use of specific resources (raw materials, capital, technology, knowledge, competencies, etc.) of the milieu. By the installation of the mechanisms of coordination, the milieu is able to ensure the balance of the cooperative relations between the local actors and internal and external competition.

Spatial, organizational, and cognitive relations of proximity form an innovative milieu. The regional anchorage of the enterprise enables it to avail itself of a pool of resources (and sometimes a market) in order to amortize the costs inherent in its investments in an economy undergoing constant change. However, this regional anchorage depends on the quality of the "pool" mentioned above, compared to the entrepreneur's expectations as regards innovation, business start-up, and consolidation. Hence, it arises the necessity for governments and local authorities to create a system organizing the resources with a view to generating multiple innovation processes taking into account the competition-cooperation behaviors between the same actors in an open economy (see, in particular, Pitelis et al. 2005). This system is a supplier of those productive resources that are capable of generating innovative entrepreneurship and also attracting other enterprises with confirmed performances in the innovation field.

The Entrepreneur's Function in the Current Stage of the Capitalism

The End of the Heroic Entrepreneur

At the core of an innovation milieu, specific attention can be paid to the creation of small enterprises. In the present economic uncertainty and following the trends to decentralization, the establishment of enterprises is supposed to solve many problems linked to the rigidities resulting from institutional interventionism. Its flexible structures enable much easier reaction to consumers' expectations. Moreover, the possible bankruptcy of an enterprise does not threaten the financial and industrial fabric of the country, region, or place. Establishing a considerable number of small firms is considered as a privileged instrument of industrial policy and national planning; financing and marketing activities seek to organize the markets and the development of technologies through alliances, mergers, agreements, and political interventions; the hope for an economic renewal is concentrated on small enterprises that are in full harmony with economic needs. A small enterprise is also a formidable machine able to enrich or destroy capital. It presents itself as a sort of carrier of values to the extent that it creates bridges for the transfer of productive resources (financial capital technologies, labor force with different qualifications, and competencies) to activities, markets, and large companies able to make profits.

Entrepreneurs have been at center of economists' concerns and public policies since the beginning of the 1980s in capitalist economies (Boutillier 2008). This fact is relatively new. Since the end of the Second World War, the paradigm of the big enterprise has prevailed. The years of growth that followed the Second World War were marked by phenomena of industrial vertical concentration and the evolution of managerial capitalism. Economy was directed by a "technostructure" and, in particular, by managers being salaried workers (Chandler 1977). Entrepreneurs, as founders-owners-managers of firms, seemed to belong to an age that had gone to the heroic period to which J. A. Schumpeter often refers. The big company imposed itself and together with it mass production and salaried employment. W. J. Baumol (1969) wrote in a famous paper that the entrepreneur had disappeared from the economic literature. For a lot of economists, the main economic actor is not the entrepreneur but the enterprise.

In Schumpeter's theory of economic evolution (Schumpeter 1935), the entrepreneur is the economic agent achieving new combinations of production factors. He is the hero of the capitalism. Five combinations must be taken into account:

1. Manufacturing of a new good, in particular, unfamiliar to consumers' circles or endowed with a new quality.
2. Introduction of a new production process that is almost unknown in the specific industrial branch; it is not imperative that it is based on a new scientific discovery, and it may also be found in the new commercial process applied to a commodity.
3. Opening of a new outlet, a market in which the specific industrial branch of a specific country has not yet been penetrated, respective of the previous of the market.
4. Acquisition of a new source of raw materials or semifinished products; again, it does not matter whether this source has to be created or already existed, has been taken into consideration, or considered inaccessible.
5. Formation of new organization, for example, creation of a monopolistic situation or sudden emergence of a monopoly: the heroic entrepreneur who creates a new industry, similar to what happened at the end of the nineteenth century (movies or electricity) or at the end of the twentieth century (electronics, computer).

In his ultimate book entitled Capitalism, Socialism and Democracy, published in 1942, Schumpeter was largely pessimistic about the future of capitalism. It was because the development of capitalism led, according to him, to the disappearance of competition. Companies were becoming bigger and bigger. In addition, these were powerful organizations and bureaucratic enterprises. Schumpeter insisted on the following idea: The entrepreneur is being replaced by an organization. Entrepreneurs are no longer responsible for innovative activities, which are now performed by teams composed of expert members who have no direct link with the market or the consumer.

The vanishing of the Schumpeter entrepreneur is a metaphor used to analyze the development of managerial capitalism, the evolution of big enterprises. In the 1960s, J. K. Galbraith (1967) pursued Schumpeter's analysis of managerial capitalism and demonstrated that the economy of capitalist-industrialized countries did not fit with the paradigm of pure and perfect competition. Six distinctive elements emerged:

1. Domination of a handful of big enterprises whose ownership is split between a myriad of shareholders, a plethora of small owners of enterprise

2. Presence of a considerable number of very small firms, however, rather marginal as regards the creation of wealth
3. Disappearance of the entrepreneur replaced by a division between the owners of capital (shareholders) and capital management (managers): the "technostructure"
4. Development of planning tools in order to minimize the uncertainty resulting from the functioning of the market
5. Presence of a plethora of small entrepreneurs who do not operate in a market characterized by pure and perfect competition but in markets dominated by big firms
6. The expansion of a huge bureaucracy related to technological and not political considerations

The Socialized Form of the Entrepreneurship

But since the 1980s, the entrepreneur, as a concept, is reappearing in economics because of the positive factors that contribute to create a propitious environment for the creation of enterprises. Economists hold the idea according to which the economic, social, and political environment facilitates the development of specific economic behaviors, as for example, entrepreneurial behavior. According to the OECD, the emergence of entrepreneurship is related to the rank it holds in the scale of values and to the intensity of incentives and support it receives. However, the beginning of the 1980s was marked by a whole set of major economic and social changes that consecrate a sort of rupture from the previous period:

1. Policy of liberalization of the economy (contestable markets theory) and the development of the financial markets: The privatization of the economy releases capital in huge quantities – new investment opportunities emerge; development of investment funds and pension funds; the aging of the population; and the withdrawal of the social state from the financing of pensions stimulated their development. The major problem was to identify new investment opportunities in a context of slow economic growth. Capital becomes impatient (Harrison and Blustone 1990).
2. Development of information and communication technologies and biotechnologies generated new investments opportunities.
3. The "garage mythology" and "the legend of the entrepreneur" prevailed. As in the early days of capitalism, an idea that was already considered outdated was revived and propagated: the heroic entrepreneur. However, one trend to forget that the knowledge the new innovative entrepreneurs used to succeed is the result of the institutional and the networking (military or civilian) scientific research.
4. The crisis of welfare state: G. Gilder (1985) argued that the welfare state generates poverty because it encourages too many people to rely on social services instead of looking for a job (since the 1970s, the public choice school and the theory of bureaucracy have strongly criticized Keynesianism). According to Gilder, only the entrepreneur is capable to fight against poverty and unemployment.
5. Increase of mass unemployment and growing insecurity of salaried employees (development of part-time employment and multiemployment): Is it the "end of work" or the beginning of the "entrepreneurial society" (Audretsch 2007)?
6. New public policy: The main question is to help unemployed workers to create their enterprises (their means of existence, their job), thanks to the emergence of an institutional environment (reduction of taxation, of administrative barriers, flexibility of labor market, etc.). For Keynesian economists in the 1960–1970s, the fundamental role of the state was to sustain demand and create markets. In fact, the main objective of J. M. Keynes was social peace and political stability. In the 1980s, the economists of endogenous growth theories (Aghion et al. 2001) explain that the state has a major role to play in order to sustain the supply and support enterprises to innovate. In this turn, innovation generates wealth and employment. Through an appropriate public policy, the state tries to facilitate the transition from the situation of job worker to that of entrepreneur or from wage earner to

entrepreneur, in short to introduce more flexibility in the labor market.

7. The big managerial enterprise with its pyramidal architecture (Sennet 2006) is no longer adapted and is compelled to change: The structure of the network enterprise is flexible and decentralized (to benefit from new information and communication technologies).
8. As regards the number of salaried workers/employees, the size of enterprises has also been reduced.
9. Since the beginning of the 1990s, entrepreneurship has become an academic discipline taught in universities. Awareness programs targeted at the youth are also elaborated upon.

Thus, economic theory has a definition of new capitalism: It is a socioeconomical organization based on private property and free market. The characteristics of the managerial capitalism were the same. The fundamental differences between new capitalism and managerial capitalism are (1) the organization decentralized of industrial production (network enterprise and enterprise networks) assisted and coordinated by the ICTs and finance, (2) development of the financial markets (which generate capital funds for investment), (3) flexibility of labor market, and (4) new role of state which is to build an institutional environment to create enterprises and jobs.

In the first decade of the twenty-first century, the economy of industrialized countries is undergoing major transformations at the scientific, technological, and productive levels. The financial crisis of 2008 is also the beginning of major changes in the productive systems. If one refers to Schumpeter's theory about entrepreneurship, this situation lays a fertile ground for innovation and for business creation (Langlois 1987; Perroux 1970; Heerjte 2006), a process that fuels the ascending phase of an economic cycle.

In this context, the entrepreneur is no longer heroic but rather socialized (Boutillier et al. 2008). He is stuck between three logics: that of the big enterprise that structures and outsourcers all or a part of its activities; that of the state striving to promote the creation of new businesses, on the one hand, to fight against unemployment and, on the other, to foster the development of innovations seen in the Schumpeterian meaning of the term (product, process, organization); and that of relations of proximity on a local (spatial) but also on a interinstitutional (networks) level. The concept of the socialized entrepreneur must be distinguished from the collective entrepreneur or even from the entrepreneurial corporation (Hagedoorn 1996) that characterizes the managerial enterprise: In fact, the socialized entrepreneur may be defined in the first place by his macroeconomic function (job creation, innovation, outsourcing of the productive and service activities of big companies, localization).

In the new capitalism, the socialized entrepreneur takes place in the networks. He is an entrepreneur sitting at the interface between two logics:

1. The logic of the big industrial and financial enterprise that seeks to stimulate the creation of enterprises in order to test new markets
2. The logic of the state that seeks by these means to fight against unemployment and promote innovation

Indeed, faced with the complexity of the innovation process, M. Castels (1996, 1997, 1998) went as far as to maintain, quite cleverly, that the fundamental unit of the economic system is no longer the entrepreneur, the family, the firm, or the state but the network composed of different organizations. Thus, this network gives birth to the new entrepreneur (Table 2).

The Entrepreneur's "Resource Potential" and the Innovative Milieu

The "Resource Potential" and the Entrepreneur's Function

The entrepreneur's individual qualities and personality undoubtedly play a major role in the decision to create or buy out a small firm. Nevertheless, the action of starting up that initiative is determined by the macrosystemic dynamics of accumulation and profit. These dynamics generate barriers as well as personal enrichment opportunities that encourage an individual to become an entrepreneur who will ultimately succeed or fail. The fact is that nobody is born an

entrepreneur but may become one through the mobilization of a potential of resources composed of capital, knowledge, and relations. Support involves capital for investments and operations, knowledge for choices and decisions, and relations for the financing, association, and selling of products.

Economists define the entrepreneur as the founder, manager, and owner of at least a part of the enterprise. In such conditions, he may also be an innovator (Say or Schumpeter analysis); however, unemployment may as well be at the origin of his decision. Nevertheless, he always remains the economic agent who bears the risk since he is, in every case, the main financial backer of his enterprise, together with his relatives. On the other hand, the entrepreneur may be defined as a set of resources. By using the concept of potential of resources of the entrepreneur, the researcher relocates the entrepreneur and his enterprise in the general logic of the capitalist system. The potential of resources is split up in the following way:

1. A set of financial resources including all the effective financial resources (own spending, family assets, heritage) or potential (access to credit, subsides, various public aids, etc.)
2. A set of knowledge including all entrepreneurs' knowledge whether they are certificate, by a diploma, or a result from professional experience: technological, organizational, economic knowledge, etc.
3. A set of social relations: personal, family, or professional relations that the entrepreneur may mobilize in order to fulfill his project. Two social relation networks may be distinguished: on the one hand, a network of institutional relations (relations with public institutions, enterprises, banks, etc.) and, on the other, a network of informal relations with relatives, family, friends, neighbors, working relations, etc.) (Granovetter 1973). In this example, these two networks develop interdependently. Thus, it is through the information given by a friend that the observer learns about the existence of a specific type of financing. However, the individual's social background plays a fundamental role because it largely determines the network of friendly or family relations (Bourdieu 1985; Coleman 1988; Putman 1995).

Innovative Milieu as a Driving Force of Innovative Entrepreneurship, Table 3 Resource potential of the entrepreneur

Resource potential	Major characteristics
Knowledge	Tacit and various types of knowledge acquired in the family context
	Scientific and technological knowledge acquired at school
	Knowledge acquired during relations with third parties (family, professional activity, etc.)
Financial resources	Own spending
	Affective inputs: parents, relatives
	Bank credit
	Institutional financial aid (e.g., direct assistance from the state)
	Financial inputs brought in by another entrepreneur
Social relations	Informal relations (family, friends, neighbors, colleagues, etc.)
	Formal relations (stat, banks, other enterprises, research centers, etc.)

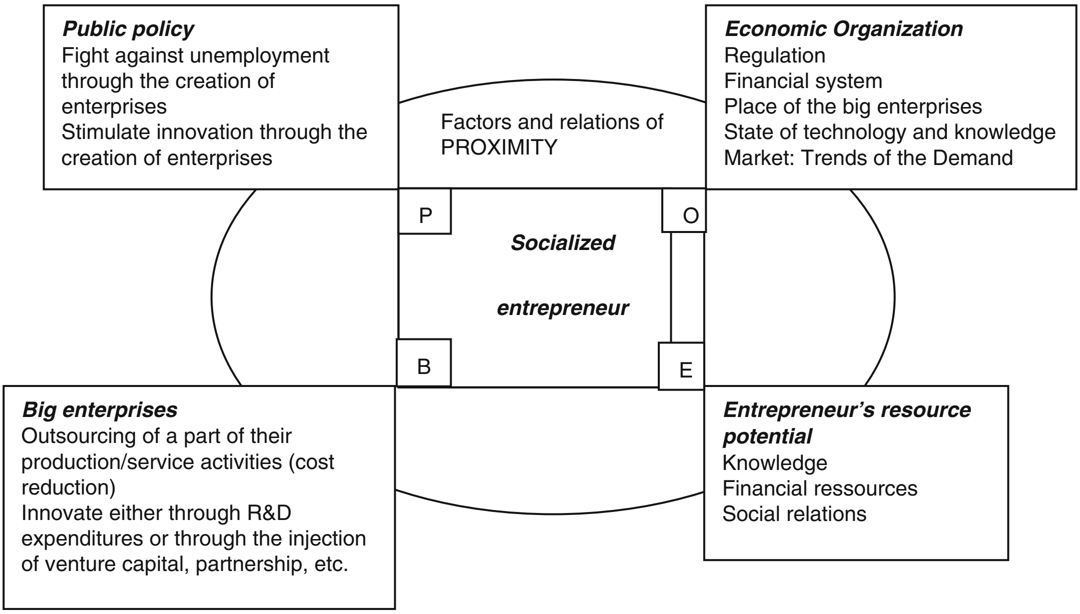
Source: Boutillier (2008), p. 80

The three components of the entrepreneur's resource potential are determined by the place he holds in the social organization chart – in spite of the increasing socialization of the economy. The elements assume a fundamental role. The family gives a taste to start a business; at the same time, it is a source of financing. This phenomenon can be observed in France, in the United States, and also in Russia where the business regulation is very new. A lot of entrepreneurs had a member of their family in business activity. In the Russian case, a lot of entrepreneurs have a member of their family in the Communist Party. It means that the Communist Party is a means to develop social relations. With the support of the family, the functions exerted by the entrepreneur draw their logic from public policies targeted at the dampening of the consequences of the crisis (employment of innovation policies) and from strategies aiming at the productive and financial reorganization of big enterprises (Table 3).

How the Relations of Proximity Increase the Resource Potential of the Entrepreneur?

The ability of the entrepreneur results from the variety and richness of the resource potential he has himself constituted. In its turn, the composition of that resource potential depends on factors that are external to the enterprise and entrepreneur. In particular, public policies of assistance for the creation of businesses (to stimulate innovation and/or to fight against unemployment) will largely determine the financial resources to which the entrepreneur will be authorized to have access in order to create his enterprise and ensure its survival. The economic and social organization has several dimensions and therefore several effects. The general level of development of knowledge and technology in the society will have an impact both on the knowledge acquired and assembled by the entrepreneur (on the basis of his education and the competences of the members of his team; activities related to economic and information watch) and the technological level of his activity. The nature of the financial system (e.g., ease or difficulty of going public, bankers' degree of "conservatism," level of development of venture capital, etc.) influences both the capacity of an individual to become an entrepreneur and the capacity of an enterprise to more or less accelerate its development.

The degree of concentration in the market, for example, the presence of big enterprises, also plays a considerable role in the dynamics of creation of small enterprises and in their type of activity (in particular subcontracting). Finally, it is necessary to underline the policy led by enterprises with a view to innovate either by their own means (R&D budget) or by implementing different types of partnership including the injection of venture capital. In conclusion, the presence and nature of the links between the "POBE" factors

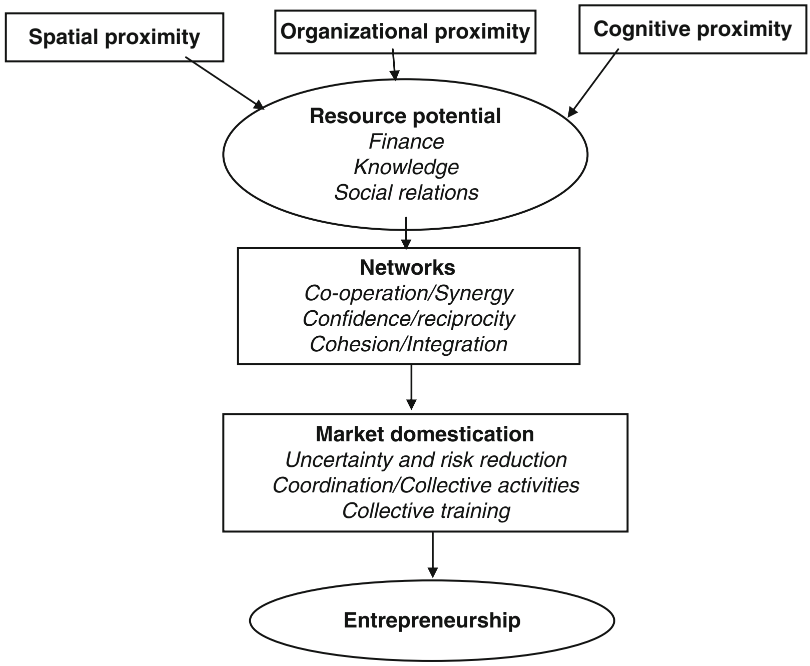


Innovative Milieu as a Driving Force of Innovative Entrepreneurship, Fig. 1 The socialized entrepreneur, the core of the organic square of business activity (Source: Authors)

(public policy, economic organization, big enterprises, entrepreneur's resource potential) lead economists to relocate the entrepreneur in his economic social, political, technological, and spatial context. This organic square provides a way to analyze the creation of enterprises at the scale of a specific local economy (Fig. 1).

The emergence of a "successful" region results from the fact that it is able to manage its own capacity to develop new products, new techniques, and new organizations. Thus, innovative milieu is the combination on a given geographical space of enterprises, training centers, and public or private research units involved in a partnership approach with the purpose of identifying synergies around common projects of an innovative nature. It combines attractiveness (agglomeration effects), diffusion (dispersion effects), and externalities: These three factors are essential for the generation and propagation of innovations. Externalities can be defined (Marshall 1891) as being positive or negative effects, which involve an activity of an economic agent outside this activity or that the agent is subjected to from outside. The most attractive for a company is to achieve, in a setting favorable to investment, substantial external savings, without having to bear the slightest cost that its activity creates for the community as a whole (pollution or various nuisances) (Krugman 1991). It is important therefore to underline that taking the enterprise will create various effects on the local community, but, in return, she will expect from the community means and opportunities to enlarge her property (assets) or where necessary to defend it.

What is favorable to an innovative entrepreneurship offering the possibility to support "network economies" is the existence of an area created, in economic and social terms, by the relations of proximity: infrastructures of transport, communication, telecommunications, education, engineering, etc.; contractual and cognitive interactions; confidence and cooperation; share same codes and business competencies, a dense network of enterprises; fiscal and financial supports and aids, etc. Figure 2 presents the links between the relations of proximity, the resource potential of the entrepreneur, and the realization of socialized



Innovative Milieu as a Driving Force of Innovative Entrepreneurship, Fig. 2 Proximity and entrepreneurship (Source: Authors)

entrepreneurship through the insertion in networks and the risk reduction.

Relations of proximity enrich the resource potential of an entrepreneur and create synergies and a large range of confidence and reciprocity links. With for consequence the reduction of the risks related to the uncertainty of a given investment (market domestication).

The entrepreneurial activities take place in a particular spatial milieu. It is in this milieu that the entrepreneur builds his potential of resources (knowledge, financial resources, and social relations). The entrepreneur develops his social relations in a particular territory, even if his objective is to develop more large-scale (and international) activities. The territory becomes a special innovative milieu by the density and the intensity of the three dimensions of the proximity: spatial, organizational, and cognitive. Enterprises (big or small) can be located in a territory for different reasons (costs reduction, demand access), and if public policy plays a nonneglect role to new business development and attractiveness, the entrepreneur, as a social agent, benefits principally from his relations to create his business. These different social relations (family, socialization, education, etc.) are also the engine of the future development of his enterprise (Ehlinger et al. 2007; Grossetti and Barthe 2008). So, economic activities are embedding (according the Polanyi's concept redefined by Granovetter) in a particular territory.

Conclusion and Future Directions

Since the 1980s, the entrepreneur has made its comeback on the forefront on the economic and political scene. In an approach combining economics and sociology, in this entry, authors tried to go deeper into the analysis of the origin of the entrepreneur's function, studying the construction of his "resource potential," that is, the set of knowledge, social relations, and financial resources gathered together by the entrepreneur in his environment. This resource potential is not stable and may be increased or reduced in different economic, political, and social contexts. According to the approach by the innovative milieu, relations of proximity reinforce the entrepreneur's potential. Business start-up becomes easier. The first meaning of physical proximity was soon supplemented by other interpretations in which the operating field of proximity (space, organization, or institution) is intertwined with the contents of the proximity relationship (information, training, knowledge, technology, etc.). The three types of proximity have made it possible to better examine the process of business creation. The systemic links between an individual and his socioeconomic environment create investment and profit opportunities. If this environment is oriented toward innovation, these opportunities will be more numerous. Thus, the innovative milieu can be studied as a major source of entrepreneurship in the current stage of the market economy.

An innovative milieu, as an innovation system, describes the relationships (scientific, technological, industrial, commercial, financial, political) between private and public institutions (enterprises, research and engineering labs, administrations, etc.). In general, the relationships consist of financial and information flows and the movement of persons. The purpose of that system is to produce innovations (new organizations, new goods and processes, new resources, new combinations of productive resources). This system facilitates business creation on the local level and contributes to define the socialized entrepreneur. This new entrepreneur is a socialized entrepreneur because he develops his activity in a particular economic environment which is structured by the business networks and by the financial, tax, and legal incentives of central or local public authorities.

In a network economy, local economies are now seeking to develop by relying on private initiatives coupled with targeted public and individual action. Investment attractiveness, the capacity to create enterprises, and the creation of jobs determine the performance of an innovative milieu. The milieu is integrated in a context resulting from the development of complex interactions between its actors. These actors and interactions constitute a system which is defined at the same time by its objectives and its composition. The analysis of the innovative milieu as a complex system leads economists and sociologists to study the whole of the local actors (enterprises, authorities, public services, etc.) in relation with the outside. Inside this system, the innovation plays a central role. The integration of the actors within the milieu contributes to the emergence of new enterprises by offering to the future entrepreneur the essential financial, relational, and cognitive resources.

Synonyms

Productive local system; Regional cluster; Regional innovation system

Introduction

Spatial economic theory was structured to the 1980s around two alternative thesis: the first one was called the thesis of convergence and the second approach was the thesis of divergence. For the convergence approach, income of production factor should tend to equalize all over the world. On the contrary, for the divergence approach, central and richest regions will keep on winning from their past advantages. But Aydalot (1986) brought to the fore a third way he called "reversal." In such a situation, the old industrialized regions face a persistent decline, whereas new regions, without tradition of industrialization but service-oriented, appear and become richer. The same phenomenon was observed in many European countries and in the

United States. This phenomenon challenged scholars because these regions developed on an endogenous basis. As far as development is concerned, advantages are never permanent. Winning regions can lose their competitive advantages if they do not keep them up, whereas losing regions can overcome their drawbacks to create new advantages.

To revitalize themselves, regions have to develop an important endogenous factor: entrepreneurship. Scholars are still debating on the concept of entrepreneurship. Today, two main approaches exist (Bruyat and Julien 2000). The first approach takes up the work of Turgot and Say and considers that any actor which creates a new activity is an entrepreneur. The second approach, following Schumpeter's work, considers that entrepreneurs are only the innovators. The entrepreneur is the individual who originates the dynamic of evolution in the economy. He detects new opportunities to make profit and creates a new organization to generate the innovation. In this sense, the entrepreneur has a non permanent status. As soon as he stops innovating, he is not still defined as an entrepreneur.

Entrepreneurship can be defined as the creation of a new organization in the economy. This new organization can be created ex nihilo; the owner-manager was not an "entrepreneur" before the creation. The new organization can also be a spin out of a large incumbent company (it is called corporate entrepreneurship) or from a university or a public research organism (academic entrepreneurship).

Innovative Milieux Produce Entrepreneurship

Maillat and Perrin (1992) define a "milieu" as "a geographic space without a strictly defined frontier which is characterized by a kind of unity that one can identify by behaviours. Different kind of actors such as firms, institutions, and public organism of research and formation... are located into the milieu, they own material and immaterial ressources that characterizes the milieu." To sum up, for these authors, milieu has three components: (1) a productive system including various and diversified activities, productive activities, and activities of service (as funding, transport, and consulting); (2) a local workforce market with a work time, which corresponds to the productive specialization of the milieu and a system of training and research that also contributes to the productive specialization; and (3) a dynamic of interaction and learning. Actors located into the milieu interact locally and create between them this structure of organization that allows the functioning of the milieu and the development of innovation. Learning facilitates the adaptation of the milieu to the change of the economic environment. It allows the evolution of the milieu and allows to replace specific resources that are the basis of the competitive advantage of a milieu because these resources differentiate this milieu from the others.

Most of work on entrepreneurship and on the ability to concretize the project of creation insists on the importance for the future owner-manager of two kinds of factors: from the microeconomic point of view personal characteristics of the owner manager and from the macroeconomic point of view the characteristics of the environment (Fisher and Nijkamp 2009).

Schumpeter is the first author that defines the owner-manager as the economic actor who has a peculiar ability to detect new opportunities. This ability is an important component of the entrepreneur's personal characteristics and competences. This competence is differentiated between individuals. Following Audretsch and Aldridge (2009), this ability is linked in an endogenous way to the production of knowledge during the innovation process. When an incumbent firm produces knowledge during its innovative activities, it faces what these authors call the "knowledge filter," i.e., to the gap between produced knowledge and knowledge useful to develop a marketable innovation. The valuation of produced knowledge and its ability to be converted into marketable innovation becomes a competence of actors. The commercial value of knowledge is a source of incertitude for actors. The entrepreneur becomes the actor that detects that some piece of knowledge could acquire a bigger commercial value and tries to exploit that perception, leaving the incumbent firm to set up a new organization. Doing so, the future entrepreneur becomes the actor that will be the transmitter of knowledge spillovers. The entrepreneur will assure the diffusion of knowledge and its concrete use into the new organization. To sum up, the process of innovation activities impulses the apparition of non-exploited opportunities and at the same moment allows the apparition of entrepreneurs. So, the process of knowledge creation generates entrepreneurs endogenously because of the existence of spillover phenomenon.

Initially, most of the works took into account a large environment; it is only recently that scholars took into account spatial environment set up the works on innovative milieux and regional systems of innovation.

To accomplish the setup of the new organization an entrepreneur should be able to mobilize a set of diversified resources. He can mobilize his own resources but also the resources that are located into the milieu. Therefore, the entrepreneur is embedded into the "organic square" of the economy (Uzunidis 2010). The composition of the potential of resources depends of the entrepreneur's own resources, of the economic organization of the milieu, of the relative place of large firms compared to sme's, and of the public policy.

The entrepreneur's resource includes his personal knowledge and diversified kind of capital, including social capital that allows him to access to the social network that he will use at the different stages of the funding process. The economic organization of the milieu is linked to the degree of concentration of the market, to the state of the scientific and technical potential that will get an influence on the technical development of firms, to the nature of the funding system and especially to its facility to grant credits to the firms, and lastly, to the kind of regulation that exists into the milieu (public regulation vs regulation by private operators). The relative importance of large firms plays a part too because it makes the setup of sme's easier or not. Besides, the existence of networks between small and large firms will also make the creation easier. Lastly, public policy can support the creation of new firms with public measure.

Innovative milieux favor entrepreneurship combining three kinds of proximities: geographic proximity (the distances between the actors located into the milieux are small), organized proximity (networks between actors located into the milieu make the milieux function), and cognitive proximity (actors share professional, organizational, and even cultural knowledge. Their interaction leads to the set up of norms of regulation shared among them.). These three kinds of proximities contribute to aliment the potential stock of resources that are available for the actors of the milieu. Besides, networks between local actors contribute to the "domestication of the market," favor the entrepreneurship reducing the risks linked to the creation, and protect new organization during the first stage of the start-up.

So, when the three kinds of proximities are present simultaneously, the dynamic of interaction inside the milieux induces entrepreneurship endogenously and leads to the development of the milieux.

Perrin (1992) studies three different milieux and demonstrates that they have a different capacity to create innovation and entrepreneurship. In the Nice area, the milieu has remained few industrialized for a long time. Firms have only adapted products that were not new to the market using new process neither. In this area, the milieu fails to become an innovative milieu. On the contrary, in the Marseille area, firms belong to medium- and high-tech sector. Firms located outside the region create spin-off located into the city. Public policy played an important part in developing the creation of varied areas of activity and by modifying the productive specialization of the enterprises moving from an industrial specialization to a service orientation. Doing so, public policy managed to attract any large firms interested by the amenities of living into the area. The third case concerns the scientific park of Sophia Antipolis. In fact, this area managed to become a milieu only on the third part of its development, after a long period without any internal interactions between local actors. Lastly, large groups perceived the interest of local interactions and modified the functioning of their plants to impulse local interaction and innovation. In the third case, large groups are the major set up of entrepreneurship creating spin-offs.

However the part played by large firms is ambivalent as far as entrepreneurship is concerned. In fact, large firms can favor new organizations, creating spin out, as they can destructure the industrial tissue of a milieu. Large firms can favor spin outs, but the local milieu will function well only if these large firms will allow local interaction between the new spin out and other organizations of the milieu. Besides, the innovative milieu will survive only as longer as the large firms are interested by local interactions and are convinced of the efficiency of local geographic spillovers. On the contrary, large firms that prevent their local plant from interacting locally will contribute to limit the development of the milieu. Large firms that are located outside of the milieu can also contribute to the malfunctioning by buying the local firms and by using them in a global and nonlocal strategy.

Influence of Entrepreneurship on Innovative Milieux: The Missing Relation

Effects of Entrepreneurship on Regional Growth and Regional Employment

Scholars have identified the relationship between entrepreneurship and regional growth and employment for a long time. But empirical studies have not validated this relationship for a long time. Fritsch (2008) surveyed a set of studies that corroborate the relationship. The entry of new firms on a market affects the competition's process. The first consequence of this entry is to challenge the market position of the competitors and conduce them to more efficiency. Then, the creative destruction process takes place and revitalizes industrial tissue. Public policies generally consider that entrepreneurship has a positive impact on regional growth and employment. Empirical studies that take into account the spatial level of the influence of entrepreneurship are very scarce and generally conducted at the regional level. However, any studies bring to the fore a striking result: setup of start-up would lead to a decline in total regional employment in rural areas and in areas where the birth rate of start-up is weak. On the contrary, the growth of regional employment would be higher in urban areas and areas where the birth rate of start-up is higher.

Networks of the Entrepreneurs During the Setup of the Start-up and During the First Years of the Ongoing Business

Empirical studies about the spatial location of the entrepreneurship's networks during the phase of the setup of the start-up are very scarce. In the pre-start-up phase, entrepreneurs mobilize their social networks. This social network includes member of entrepreneur's family, friends, and neighborhood relationships (Schutjens and Stam 2003). In the setup phase, the entrepreneur's network evolves to include organizations that focus more directly on the direct needs of the start-up as incubators, funders, and various kinds of professional advisors. The creation device support is generally local. Lastly, once the new organization has set up, its network includes customers and suppliers. Besides, the new entrepreneur should set up quickly if he wants the new start-up manage to stay on the market. But many start-ups have no networks at all after many years as Quevit and Bodson (1992) illustrate for the city of Liège. From a spatial viewpoint, the network's start-up does not evolve from local space to international. In fact, start-ups choose the spatial extent of their network directly linking it to their strategy. So, any start ups will choose a local network, whereas others choose directly a national or international network. In fact 39% of the start-up began with an extraregional network and not a local one (Schutjens and Stam 2003). Besides, this network has remained extraregional for a long time.

So, firms have some difficulties to create their milieu because networks are not necessarily established locally. That point limits the interaction dynamic. So, a start-up, even if it locates into a well-developed milieu, does not necessarily take part in the dynamic of local interactions. Doing so, it does not contribute to reinforce the milieu.

Besides, the local dimension of the network will also depend on the firm's sector. Therefore, service firms use more local networks than industrial firms. Besides, the size of the firm will influence the need of a local network. Small firms have a more local network than large firms.

Implications

One of the limits of the innovative milieu approach is the question of their border. Scholars of the GREMI's group have deliberately not defined the border, because they consider that the border must be defined in reference to the interaction systems and the existence of a local culture shared among the actors. But this open definition leads to consider various kinds of spaces as "milieux," e.g., cities, set of cities, or area defined in reference to geographic attributes. This lack of indicator often leads to some practical difficulties to identify a milieu, and the comparison between many case studies of milieu becomes difficult.

Quévit and Bodson (1992) demonstrate that external relationships are as frequent as interactions internal to the local milieu. In such situation, can someone consider that the object identified can be defined as an innovative milieu? In fact, these two authors hesitate to qualify their case as a milieu and prefer to speak of "a nascent dynamic."

The second limit of the approach is due to the fact that a well-functioning milieu is characterized by two dynamics: a dynamic of local interaction and a dynamic of learning. The learning dynamic favors the revitalization of the milieu. If the interaction dynamic has been well documented on various kinds of milieux, it is not the case for the learning dynamic. This dynamic is difficult to observe. Besides, the interaction dynamic should be local to allow the growth of the milieu. But at the same time, the milieu should open to the outside economic space if the milieu wants to remain efficient. So, actors of the milieu should establish both local interaction and external interaction to get some new ideas and sources of innovation and let the milieu renew over time. The way to link the two kinds of interaction is not often studied, whereas it is fundamental to understand how entrepreneurship appears in a milieu.

As far as public policy is concerned, two main points can be underlined. Firstly, Audretsch and Aldridge (2009) bring to the fore the endogenous development of entrepreneurship in the milieu because of knowledge spillovers. From this point of view, any public policy that encourages innovation and knowledge production will sustain entrepreneurship at the same time. Then the debate is to choose to encourage innovation of the public sector or of private organizations. As the social return of research is larger than the private one, public policies should encourage more innovation from the public sector to promote entrepreneurship.

However the experience of many countries, as far as entrepreneurship is concerned, does not corroborate this prediction. And it appears that many other factors can prevent the creation of start-ups. So, public policy has a very important part to play to protect nascent organizations and domesticate the market. Public policy should contribute to reduce the risks that new entrepreneurs take when they create their firm. Public policy still has many instruments to sustain entrepreneurship, but they are not all efficient. For example, incubators get a mitigated outcome. Besides, the financial system plays an important part too, in making the creation and the funding during the first years of the ongoing business easier or not. Public policy could intervene to sustain the funding or encourage financial system to give credit to small firms.

Secondly, public policy promotes entrepreneurship. But if its negative impacts have been brought to the fore by theory, with the well-known effect of Schumpeters' creative destruction, its concrete manifestations are not really taken into account by policies. In fact, today, there are no means of preventing the close down of firms in industries with important modification of competition regimes due to the innovators.
