Lastly, the milieu approach can lead to competition between territories. The milieu approach focuses on the endogenous ability of a territory to create factors of development. If the milieu is not able to create these factors by itself, it can try to draw them from the outside, especially firms located in other regions by a policy of grants, for example. But doing so, one milieu can grow more rapidly than another one and become a winner region, but it is at the expense of the other territory. The milieu generates a dynamic of competition between another milieu and from the macroeconomic point of view, the total effect for a country can be negative.

Conclusion and Further Direction

One of the most promising further ways of research is to conduct more work on the missing relationship: one of the influences of the entrepreneurship on innovative milieu. GREMI's group demonstrated that the set up of new entrepreneurs could have negative effects on the future evolution of the milieu. An important change in the kind of activity in which the milieu is specialized, for example, often leads to a phase of decline before a potential recover. But the recover does not appear in all the cases studied. The part played by entrepreneurs into the milieu and their impact on the evolution of the dynamic of interaction is not yet theorized.

The milieu approach remains the most interesting approach to understand endogenous development in connection with entrepreneurship. However this will be true except the different milieu search to draw competitive advantage by drawing factors and especially firms from the outside, increasing competition between territories. In fact, milieu needs the openness to the outside to grow over time, so they should develop more cooperation with other milieux to be connected to various spaces to be able to benefit from the variety of these links.

Synonyms

Entrepreneur; Inventor

The term of innovator is not specified in the economic works. Since some decades, this term has appeared in political statements or journalistic papers.

The nearest concept is entrepreneur and sometimes inventor or even growth leader. Since Cantillon, in the eighteenth century, the entrepreneur has been a man who manages its own business and takes risk. In his book "Theory of economic development" (1911), Schumpeter used this word for the "capitaines d'industrie" who innovate. So he began confusion between the two concepts of entrepreneur and innovator. Today, it appears there are two distinct words for one single concept: the nearly academic word of entrepreneur conceptualized by Schumpeter and the commonly used term of innovator.

This short study will clarify the differences between entrepreneur and innovator and will specify the characteristics and the functions of an innovator.

Definitions

Innovation

To define an innovator, one needs a clear definition of innovation, and strangely, this is not so obvious.

In this entry, an innovation is the implementation of a novel technique at the macroeconomic level, a novel tool, or a new organization in the broadest meaning of those words, in order to sustainably improve the overall economic efficiency of society as a whole.

The innovation value is the "technical rent" of the new efficiency that can be assessed as a Ricardo rent.

Innovation is the implementation of a new kind of value creation.

It should be noted that innovation is a societal phenomenon and that a social choice is required to move from the old to the new technology, organization, or process. This is a complex process that we call the "fragmentary social choice." See hereafter Section "Diffusion: The Fragmentary Social Choice".

The Innovator

The innovator is not totally an inventor or a scholar or a manager. He is not neither a "capitaine d'industrie" nor even an entrepreneur. He is a part of all and assumes the central decision-making functions in the innovation process. This complex function enables the invention (or the idea) to become an innovation through four near-simultaneous operations: financing (1), setting of technical standards (2), definition of the economic model (3), and then the first sales that confirm the previous choices (4). Thereby he initiates a process of "social choice" of innovation. He works more on the market side than on technics. A single person usually performs this complex function. Sometimes several people are needed.

The innovator is usually preceded by the inventor who has almost all the ideas, but the inventor does not know how to organize them for making them suitable for the public. Seizing the opportunity, the entrepreneur gives an industrial dimension to the innovation, follows the innovator. Sometimes, one individual supports two or three functions, mainly as an innovator and entrepreneur, and then begins the confusion between the different functions. In small-scale innovations, said incremental, this innovation function persists but in

Concepts	Kind of value creation	Recipients of value
INNOVATOR	- New kind of value, with a technical rent.	- Mainly, the society as a whole and sometimes the entrepreneur.
ENTREPRENEUR, Founder of any new company including one person company (excluding innovator)	- Value move with a new vector / often, cost cutting.	- Mainly, the founder and his company.
INTRAPRENEUR Growth leader	- Value move, but greater	- The company, and often poorly, the growth leader.
SOCIAL ENTREPRENEUR (Sometimes innovator)	- No market value but a great social value.	- The society as a whole.

Innovator, Fig. 1 Value created by entrepreneur and innovator (Source: Author)

a reduced shape, as J. Schumpeter had stressed it in 1942 (Schumpeter 1942/2008).

We have to underline that innovation is a matter of global efficiency of the society. That means that innovation may include all that has an effect on overall economic efficiency, including some laws or organizations.

Innovator and Entrepreneur

Entrepreneur is a self-ruling person with an objective of "value creation," whereas an innovator is a man who creates new kind of value.

All have a common objective of "value creation." But the nature of the value (or the quality of the opportunity) and its recipients are not the same: if there is an innovation, it is a new kind of value, with a "technical rent." Otherwise, it is only a move of the value inside the society from a recipient to another, not a creation of new kind of value. This is detailed in the Fig. 1.

The Fig. 2 shows the different kinds of innovator and entrepreneur and how these concepts are close, related, and nevertheless different.

As a consequence of the partial recovery of the two concepts of innovator and entrepreneur, we will see overlap between innovation policy and entrepreneurship policy.

Innovation Value and Innovative Company

The innovation is a new kind of increase of efficiency and therefore is the source of new kind of value creation. And the value creation is the key figure of the innovation. It is the dimension of the innovation. This concept is a kind of the technical rent which is a Ricardo rent. The greatest this innovation value, the easier it will be to beat conservatism if there is any need of it.

From an economic point of view, the innovative company is the tool of the innovator to spread the innovation value among users, makers, inventors, and himself, through the price and the business model (see Fig. 3, below).

Innovator's Ecosystem

As the innovator is a living being, he has got an ecosystem for living with resources, regulation, and other people around (see Fig. 4). The capacity of innovation is therefore dependent upon environmental factors without quantity effect, except a minimum effect as for artists. But these minima are dependent upon laws, social values, or even civilization as a whole, and even unwritten social rules.

This ecosystem approach is rather new and has been developed outside classic economics by practitioners of law and venture capital. Seen in the "Rainforest" in the references section (Hwang and Horowitt 2012).

Innovator, Fig. 3 Distribution of innovation value through prices (Source: Author)

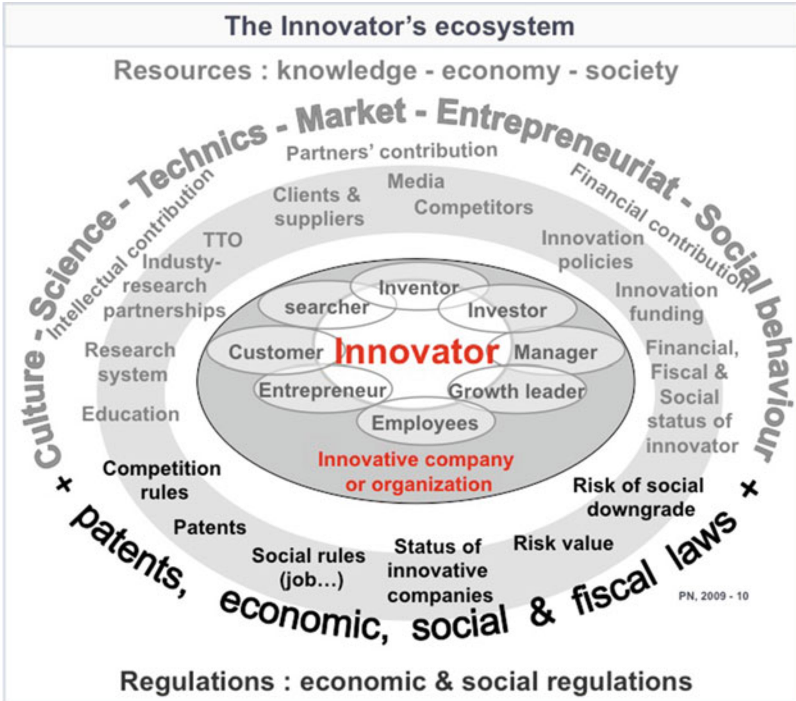
Innovators Cases

Through history, there are several examples of innovators. They may be also inventors or entrepreneurs in the same time. These examples help to understand the nature of functions and the profile of men.

Fifteenth Century: Gutenberg Created the First Innovative Company

The path of the printing invention before Gutenberg stays sketchy: some people argue that he may have got information about Chinese or even Korean tools. Nevertheless, he has to make, to finance, and to sell. History got

Innovator, Fig. 4 The innovator's ecosystem (Source: Author)



some information about the work of Gutenberg to finance and build the first printing press and complete set of movable types using metal alloy, including oil-based ink. And he did sell his product defining together the economic models of publisher and printer. At the end, he has got some big trouble with his financial partner.

He became a legend in innovation history. Please note that Gutenberg is the first innovator of the Western civilization with a name. He also is the first creator of an innovative company.

Eighteenth Century: Watt and Boulton Established the First High-Tech Venture

The story – maybe, the legend – of Watt is better known. He is not the inventor of the steam engine but (only?) an improver of the previous steam engine invented by Newcomen 60 years before (see Rolt and Allen 1997). The result was a sharp decline (75%) of coal consumption. Watt used to be an assistant at the University of Glasgow. Boulton has been the second business angel of Watt. The first one, Roebuck, went bankrupted.

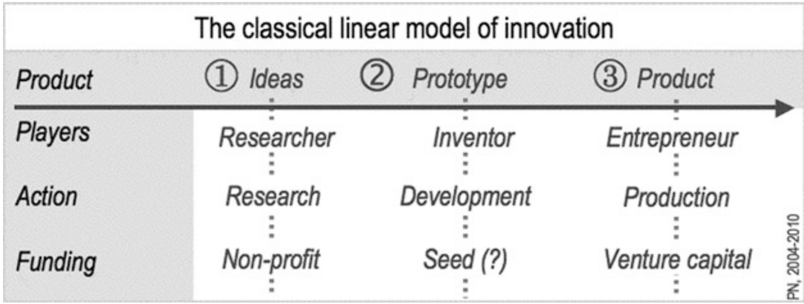
Watt has been considered as the inventor, and he was actually kind of an inventor. His partner Boulton was the main innovator. He brings the money, imagined the business model, and sold the steam machines. Nobody knows Boulton, as it is often the case for the main innovator. And nobody knows Newcomen who is the main inventor as it is also often the case for the main inventor.

Nevertheless Watt took part to the innovation by improving the technical standard of Newcomen. And for this reason, he is also an innovator.

The business model was very modern: the machines were rented (not sold), and at the beginning, the rent was half of the money saved by the leaseholder, by comparison with the Newcomen machine. Roughly, the lease ranged around 1–1.5 times the cost of the coal used by the Watt machine.

Nineteenth Century: Thomas Watson, Graham Bell, and Theodore Vail

Graham Bell is probably one of the most inventive people in the history. But few people know that he needed two more persons to reach success: an assistant (Watson) for inventing and a CEO (Vail)



Innovator, Fig. 5 The classical linear model of innovation (Source: Author)

to manage the business! Together, these three people assumed the innovator function in the Bell Company.

Twentieth Century: The Box of Malcolm Mac Lean (the "Container") Might Be the Biggest Innovation of History with Lowest Scientific Content

Malcolm Mac Lean is both a major innovator and totally unknown. He imagined the container while he was the president, owner, and driver of a "one truck" trucking company, but he developed it several years later when he became the president and owner of a shipping company. As it is explained by Levinson (2006), the Box allowed cutting cost of 90%! It is the main tool of the international trade. Without the Box, the economic development of the world would not be the same. He was an inventor, an innovator, an entrepreneur, and a "capitaine d'industrie." Although the technical side of the innovation was quite simple, the innovation was still complex due to social, legal, and business context. Perhaps the innovator function is often so complex that it requires two or three people to assume it.

Twentieth Century: Steve Wozniak and Steve Jobs

The design and the making of the first microcomputer are well known today. It required two people at least to manage this conception. One must note that neither Job nor Wozniak was CEO of the Apple Company at the beginning. There are pure innovators, but one is on the technical side and the other one on the marketing side. And there is a third one, the CEO on the management side (Gallo 2010; Isaacson 2011).

Theoretical Analysis

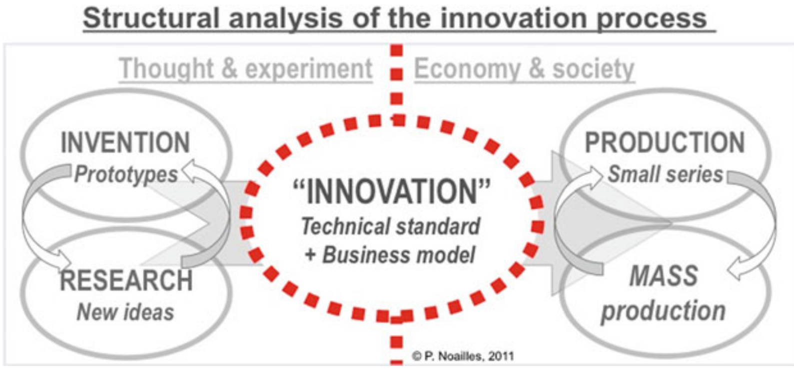
Few more details on the innovation process are needed to understand it and to specify the role of innovator.

The Process of Innovation and the Functions of Innovator

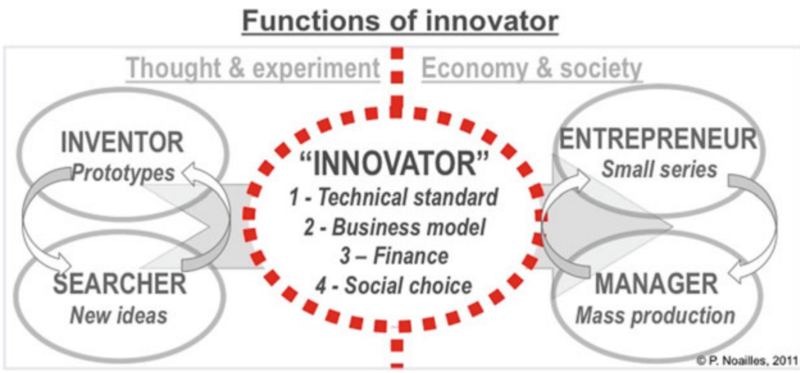
In 1911, J. Schumpeter described the innovation process for the first time. Almost always, people only memorizes a simplified diagram which can be summarized in a linear and seemingly rationale way (Fig. 5). In 1945, Vannevar Bush (inventor and director of the Office of Scientific Research and Development of President Roosevelt) has popularized this model in his report "Science, the endless frontier."

A more detailed analysis shows that there is no linear process but two kinds of complex, random, or unpredictable processes before and after the innovation, and a very complex "step" operation in the middle, named "innovation" which consists in finding in the same time the right technical standard and the good business model and then to finance and to begin to sell successfully (Fig. 6).

The history of technics often shows us that only one man holds this innovation function. We call him "Innovator" (see Fig. 7). The Innovator is the head of the innovation process: he is (or they are) the man (men) that organizes and finances the first definition of the technical standard and of the business model. Then he shows the quality of his choices by the first significant sales, thus initiating the process of fragmentary (or progressive) social choice that will transform the product "invented" into a product widely used (diffusion).



Innovator, Fig. 6 Structural (functional) analysis of innovation process (Source: Author)



Innovator, Fig. 7 The functions and the men (Source: Author)

He is not the inventor who creates and designs the object. He comes at the end of the chain of inventions. He is the man who makes the final choices, or more properly the techno-economic "arbitration" for matching the product to market. He is the man who turns ideas and prototypes into a concrete project suitable to the market and accepted by society. He is followed by the entrepreneur who expands the industrial scale of innovation. Sometimes, he is also a technician, an inventor, a marketing man, a social inventor, or an entrepreneur.

The core of innovation process with *"finance + technical standard + business model + marketing"* is a solution to a complex question. This solution is generally based on the combination of a wide range of knowledge and an extraordinary choice due to a nonrational analysis (e.g., inspired by a vision of the future). It was the case for microcomputer, later PC. The idea of IBM and other companies was a professional tool, whereas the idea of Steve Jobs, Bill Gates, and others was a home computer. The latter imagined and designed a home computer, whereas IBM designed a PC for offices. The market was the home computer concept with possibilities of professional uses. Or in other word a professional computer designed as a home computer. And more important, the business model was standard software and not specific software developments (Gundling 2000; Hargadon 2003; Wessner 2005; Christensen 2011; Goldberg et al. 2011; Cooter and Shäfer 2012).

Diffusion: The Fragmentary Social Choice

If we stay at a level of storytelling, the keywords for diffusion are the percentage of users, with a description: innovators, early adopters, early majority, late majority, laggards (Rogers 1962–2003).

If we want to go through process analysis, we may need a new concept, that is, the fragmentary social choice. This is mainly a market process.

This is a new concept and a significant part of the innovator's work. The innovator begins this process by completing the first substantial sales.

But this is just the beginning. The social choice is not over. New consumers should confirm it. During this period, the innovation (technics and economics) may be improved and sometimes significantly.

Usually, this fragmentary social choice lasts from 10 to 30 years. Among the shortest cases, there are mobile phone and compact disk, which need only few years to get a choice and 10 years to reach a high rate of diffusion over 80%. Among the longest, there is mobile steam engine for railways, which needed several decades from 1795 up to 1830 only to find the correct technical standard. The key problems are economics and technic. But as a whole, the apparent cost paid by the end user is often the main cause for delay. The real keys are the business model plus social behavior and habits.

Patent and imitation were the traditional technical keywords of the diffusion. Even if there are not the real main ones, it must be recalled that patent (invented in Venice in years 1570, to boost an imitator of Gutenberg) is often supposed to help innovators. The questions remain the existence and the length of patent. The only solid argument is history: during the last three centuries, only countries with a solid patent system were innovative.

Men and Functions, Typology of Innovators

The innovator function is different from the man (men) who assumes it. The innovator may be an entrepreneur or an inventor but also a senior corporate executive or a political leader. This typology is the first step in the way to linking man and function.

From Gods to Human People

Six thousand years ago, the ancient civilizations had imagined the "gods of innovation": the Mesopotamian Apkalus under the leadership of Enki must be seen as the distant base common to all Western technological civilizations. Closer to us, 2,000 years ago, and still more unknown, Lug dominates the Celtic pantheon, but he is on the losing side against the Romans. And that is why he has no descent. The Egyptian god Thoth and the Greek god Prometheus have a moderate significance, very far from the influence of Enki and Lug.

Now, let us go down from this pantheon toward the daily reality of innovation. Through economics and history, there are four main types of innovators. This is only a typology with overlaps between functions.

The Innovator–Entrepreneur (Sometimes Inventor)

It is the "mythical" innovator often discussed in economic literature devoted to entrepreneurship. This innovator has been characterized and named by Joseph Schumpeter as an entrepreneur. Sometimes, he is also inventor as was the case for T. Edison or even Louis Blériot. The greatest examples are Steve Jobs, Bill Gates, Thomas Edison, Henry Ford-I, Armand Peugeot, or Louis Renault.

The Lord Innovator (Who is also Often an Entrepreneur)

(Baumol et al. 2010) first used this word for history of enterprise. It refers to these gentlemen who have assumed the role of innovator during the Middle Ages and before. During the nineteenth century, there were many "lords" (rich people) who were committed to innovation from railway to water treatment. Often, they developed some key elements in the economic model as Rothschild and Pereire for French railways (Chemins de Fer du Nord et PLM, now SNCF) or Henri Siméon for the business model of water treatment in France (Compagnie Générale des Eaux, now Veolia, world leader of water treatment).

The "Intrapreneur," Growth Leader or Catalyst

The "intrapreneur" is an employee who develops new ways of working and new products as part of an existing business. He has to deal with hierarchy as well as with the market. In this field, there is no consensus on a well-defined denomination. Finally, one would add all the small players named "Kaizen." They all work on incremental innovations more than on breakthrough innovations. They are the main stakeholders of the "innovation machine" of Baumol (2002).

The Politician

The social choice is sometimes directly made by politicians, especially for the legislative innovations and for the national programs of "modernization." In these cases, the innovator will naturally be a politician. General de Gaulle in France was an archetype of this approach by launching innovative programs but focusing more on research than on innovation. His successor, Georges Pompidou, launched major innovative industrial programs (Ariane, Airbus, civil nuclear power, TGV) which are still the grounds of the industrial power in France 40 years later. Mustafa Kemal in Turkey and John Kennedy in the USA are other icons of this type of approach.

As a conclusion of this portrait gallery, we may add the copycats (Shenkar 2011), followers, and imitators who greatly help modernization, development, and even diffusion. But, of course, they are not truly innovator!

Perspectives on Economics and Sociology

The innovator is someone who not only changes economics, that is, the coefficients of the exchange board of Leontief, but even the rules of the world by finding and developing new products. This is obvious for Edison, Bell, Watt, et al. This is still almost true for small innovators (Kaïzen) who also contribute to change the economic efficiency of the world. This fact offers two prospects for development:

1. Nowadays, economics is based solely on a mathematical rationality that is expressed and summed up by the systematic search for quantitative relationships such as "cause and effect." The mathematic model is the archetype of this "school."

   The "innovator" approach proposes to fulfill the current void in innovation by introducing an element of "chance" in a world of "necessity." It deals with the everlasting question of "change" outside the rules. This question is reminiscent of the biology for the genetic mutations. Basically, it proposes that the innovator is the agent for change. He characterizes his action but does not specify causal relations.
2. The Innovator function initiates and conducts the changes of the society. This function of "innovator" seems to be the same type as that of a farmer, a warrior, or a priest detailed by Dumezil. In fact, their function is to modify the human condition.

Conclusions and Future Directions

This structuralist approach of the innovator function places the innovator at the center of the innovation process that is the Gordian knot of wealth creation. In other words, this put again the man at the center of economics, even if short-term regulation remains a mathematical science.

This approach opens three major debates on the deepening of new concepts, on innovation policies, and on rationalism and humanism.

Deepening New Concepts

All the concepts around the innovator are already known from a managerial point of view. The correlation table is rather quick to set up: the ecosystem is the environment, innovative company is often start-up company, social choice is market penetration, and breakdown of created value is business plan. But they are not the same and they have to be deepened from an economic point of view to become new economic concepts. This maybe the roadmap of innovator and innovation economic studies for the next years.

The Debates on Innovator Policy Versus Innovation Policy

This may be the most important consequence of the birth of a solid innovator concept: a new base for innovation policy.

After a long dispute over the past 20 years, it is now accepted by main *international organizations* that the key factor of development is innovation. The question remains how?

From many reports and studies on the path to success in fostering innovation and from our own experience, we can say that the following rules may avoid you the bitterest failures, but they cannot warrant any success.

Do Only Politics to Avoid the "Broken Dreams" of Traditional Innovation Policies

Through examples, Josh Lerner (2009) showed two points: in each leader regions in entrepreneurship and innovation, such as Silicon Valley, the public sector has played a significant role. However, merely every direct state intervention in the world went to failure!

This point seems to become the first part of the consensus of the policy makers around the world: be politic and not operator. Do not try to manage everything by yourselves. Stay on politics. Do influence your local leaders and establishment but do not try to manage the economy – except with public purchasing policy.

Entrepreneurship Policy is a (Major but not Unique) Part of Innovation Policy

The second part of consensus seems to be that the entrepreneurship policy is a major part of any innovation policy, meaning that innovator–entrepreneur is often the best way to transfer technology from lab to economy. Often, innovator policy is only entrepreneurship policy.

However, innovation policies have to include national innovation strategy with major projects such as the space program or the human genome program.

Take Care of innovator's Ecosystem Instead of Innovation Ecosystem

Following the innovation system during the 1990s, the current favored topic among policy makers seems to be the innovation ecosystem as a result of a systemic analysis. The word sounds well the green vocabulary but seems to be inappropriate, as the innovation is not a living animal. The right concept could be innovator ecosystem including technical, fiscal, financial rules but also social rules, including non-written rules, which may be the most important. Remember that all US states have merely the same laws, but only two small regions (Boston and Silicon valley) feature a high rate of innovation.

Tech Transfer (TT) through Start-up as a Key of Innovation Policies

At the end, the TT, by transferring ideas from laboratories to economy, is the key of the innovation capacity. But the shortest way from laboratories to the economy is not what could often be thought: from laboratories toward existing companies through tech transfer offices. On the contrary, in most cases, the shortest way is to transfer to start-up companies through people and mainly innovators.

Take Care of Local Scientific Base

On the long run, you will need a scientific base for innovation. And this scientific base needs a good education, a large university, and some large laboratories. This is the soil where innovations will grow.

Be Ambitious, Realistic

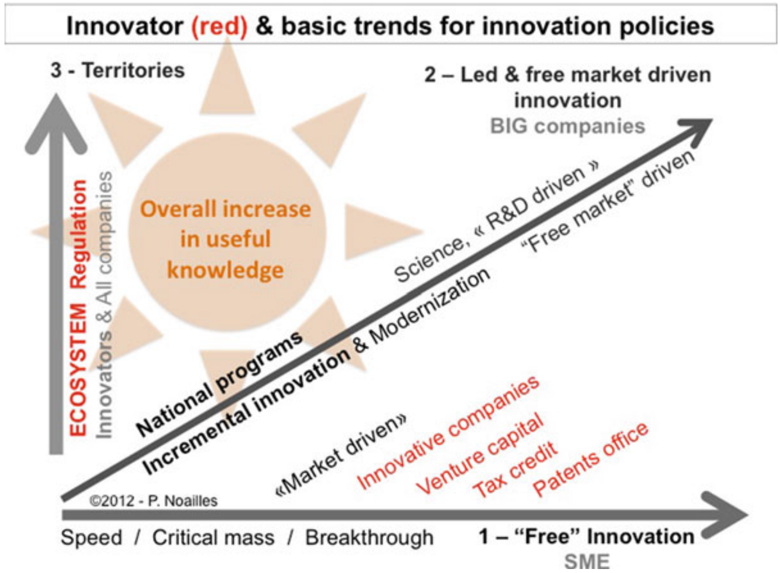
Remember that innovation is global, complex, and diverse. Innovation policies may have several levels and shapes as shown in Fig. 8.

Rationalism and Humanism

In economics, the innovator is at the center of the dispute between rationalism and humanism. Since Adam Smith, economics is mainly a matter of market (offer and demand) and organizations. On the other side, the Marxist approach ignores the market and sees only structures. Even modern statistical approach focuses on markets and sectors. The best symbol of the rationalist approach of the modern economics is the input–output matrix of Leontief. Unfortunately, this does not explain all the economic activity but only its short-term rational side due to the organization of production. On the other side (nonrationalist), we find more people than structures: this is the human side (and humanistic) of the economy. And the innovator belongs to this nonrational side.

Economics has ignored innovation for two centuries. Technology was an external factor. Until now, 50% of the growth is unexplained by

Innovator, Fig. 8 Innovation versus innovator policies (Source: Author)



rational economics. By now, scholars try to explain 50% of growth with endogenous growth based on the knowledge economy. This knowledge economy totally relies on the combination of tech transfer and the marketing capacities of people. And the idea is to find innovation factors or the best structure to increase tech transfer and marketing. Unfortunately, history shows that there is no direct or rational relationship between laboratory capacities and innovation capacities. For example, research and innovation were not linked for IBM and the home computer, for USSR globally, for the "box" which was developed without any research at all. On the rational side of economics, you only would have to put people in structures and laws to generate innovation. The main objective of this academic science is to identify innovation factors. But they do not exist.

As sociology has to take into account psychology (Moscovici 1980–1991), the "other" side of economics tries to take into account some nonrational people like innovator to overpower the complexity of the modern economy. For instance, we underline that main laws and rules are the same all over the USA and that two small territories are leaders in innovation: Silicon Valley and Road 128. Innovation relies on innovators, not only on written laws. That is why you need an ecosystem approach and not only a regulation approach. Hwang and Horowitt (2012) use the term of "rainforest" for this ecosystem. Coming back to the question of tech transfer, we have to understand that it is mainly dependent on the innovator who is nearly the obligatory go-between from knowledge to the economy. The idea of innovator policies is to find and position the right people in the right ecosystem or even to foster the right people by establishing a right ecosystem.

However, we have also to consider that at the end, conclusions of both sides may join on some decisions like education, tech transfer organizations, fiscal status. Instead of being a question of fight, the innovator could open the door between the two economics: rational and nonrational, structured and humanistic. The combination of both sides is politics. But this is still another great disputation.

Embedded agency; Paradox of agency

Introduction

The term "institutional entrepreneurship" refers to the "activities of actors who have an interest in particular institutional arrangements and who leverage resources to create new institutions or to transform existing ones" (Maguire et al. 2004, p. 657). The term is most closely associated with DiMaggio (1988, p. 14), who argued that "new institutions arise when organized actors with sufficient resources see in them an opportunity to realize interests that they value highly." These actors – institutional entrepreneurs – "create a whole new system of meaning that ties the functioning of disparate sets of institutions together" (Garud et al. 2002). Institutional entrepreneurship is therefore a concept that reintroduces agency, interests, and power into institutional analyses of organizations. It thus offers promise to researchers seeking to bridge what have come to be called the "old" and "new" institutionalisms in organizational analysis (Greenwood and Hinings 1996).

The entry begins with some observations on institutional entrepreneurship stemming from its paradoxical nature. Research on institutions has tended to emphasize how organizational processes are shaped by institutional forces that reinforce continuity and reward conformity. In contrast, the literature on entrepreneurship tends to emphasize how organizational processes and institutions themselves are shaped by creative entrepreneurial forces that bring about change. The juxtaposition of these contradictory forces into a single concept generates a promising tension – one that opens up avenues for inquiry into how processes associated with continuity and change unfold, and, how such unfolding processes can be influenced strategically. Accordingly, the entry first discusses the two core concepts underpinning the focus of this special issue, institutions and entrepreneurship, paying particular attention to how they emphasize aspects of social life that are seemingly at odds with one another. It then shows how the apparent contradictions that arise when these concepts are combined into "institutional entrepreneurship" relate to the paradox of embedded agency.

Institutions

Institutions are commonly defined as "rules, norms, and beliefs that describe reality for the organization, explaining what is and is not, what can be acted upon and what cannot" (Hoffman 1999, p. 351). As taken for granted, culturally

embedded understandings, they specify and justify social arrangements and behaviors, both formal and informal. Institutions can thus be usefully viewed as performance scripts that provide "stable designs for chronically repeated activity sequences," deviations from which are counteracted by sanctions or are costly in some manner (Jepperson 1991, p. 145).

Organizations exist in an environment of institutions that exert some degree of pressure on them; institutional environments are "characterized by the elaboration of rules and requirements to which individual organizations must conform if they are to receive support and legitimacy" (Scott 1995, p. 132). Institutions constrain behavior as a result of processes associated with three institutional pillars: the regulative, which guides action through coercion and threat of formal sanction; the normative, which guides action through norms of acceptability, morality, and ethics; and the cognitive, which guides action through the very categories and frames by which actors know and interpret their world (Scott 1995).

Institutional arrangements are fundamental to understanding organization because of the ways in which they tend to be reproduced without much reflection in practice, become taken for granted, and create path dependencies. As a result, organizational scholars, whether adopting economic, sociological, or cognitive perspectives, have traditionally focused on the critical role that institutions play in providing continuity and stability in organizational processes.

Among institutional economists, for instance, the appearance and maintenance of institutional arrangements are explained in terms of economizing on transaction costs (Coase 1937; Williamson 1985). According to this perspective, institutional arrangements function to reduce uncertainty and to mitigate opportunistic behavior such that transaction costs associated with negotiating, monitoring, and enforcing contracts between boundedly rational actors are reduced. Institutional arrangements, in turn, tend to reproduce – rather than change – existing social arrangements.

Sociological perspectives on institutional theory emphasize how institutional arrangements confer legitimacy, which is "a generalized perception or assumption that the actions of an entity are desirable, proper or appropriate within some socially constructed system of norms, values, beliefs, and definitions" (Suchman 1995, p. 574). As a result, some actions within a particular institutional field come to be seen as legitimate (Meyer and Rowan 1977) and may even be "prescribed," making it difficult for actors to deviate from them.

Literature on cognitive processes views actors as interpreters of ambiguous symbols and constructors of meaning. Thus, mutually understood schemas, mental models, frames, and rules of typification channel the sense-making activities of individuals, who are caught in webs of significance of their own making. Actors engage in organizing as a "consensually validated grammar for reducing equivocality by means of sensible interlocked behaviors," thereby translating "ongoing interdependent actions into sensible sequences that generate sensible outcomes" (Weick 1979, p. 3). With this view, institutions – shared cognitive frames – give meaning to inherently equivocal informational inputs by directing sense-making processes. Moreover, the shared nature of these cognitive frames makes it difficult to stray far from them in either thought or deed.

In sum, the institutional literature, whether it focuses on economics, sociology, or cognition, has largely focused on explaining the stability and persistence of institutions as well as isomorphic change in fields. More recently, however, there has been interest in how non-isomorphic change can be explained using an institutional lens, as well as what is nature of the "institutional work" needed to create, maintain, transform, or disrupt institutions (Lawrence and Suddaby 2006; Hardy and Maguire 2007). Associated with this has also been a emphasis on processes of contestation and struggle within and over institutional fields (Garud and Rappa 1994; Maguire and Hardy 2006), which are viewed as political arenas in which power relations are maintained or transformed (Lounsbury and Ventresca 2003).

Entrepreneurship

To understand the critical role that entrepreneurship plays in the functioning of the modern economy, one only needs to refer to insights offered by Schumpeter (1942). For Schumpeter, entrepreneurship is an engine of economic growth with the introduction of new technologies and the consequent potential for obsolescence serving to discipline firms in their struggle to survive perennial gales of creative destruction. The disruptions generated by creative destruction are exploited by individuals who are alert enough to exploit the opportunities that arise (Shane and Venkataraman 2000).

From a sociological perspective, change associated with entrepreneurship implies deviations from some norm (Garud and Karnøe 2001). Consequently, it is unlikely that entrepreneurial outcomes and processes will be readily embraced by actors committed to existing ways of doing things in a particular field. To be successful, then, entrepreneurial efforts have to gain legitimacy, an undertaking that is made more difficult as more social groups with heterogeneous interests are involved. Indeed, as novel outcomes from entrepreneurial efforts spread, more diverse social groups will be affected and possibly mobilized, and, in the process, new legitimacy battles will be spawned.

Lachmann's work (e.g., 1986) highlights the active creation rather than the mere discovery of entrepreneurial opportunities, and it is here that literature from cognitive psychology sheds light. Cognitive psychology notes that the genesis of novelty is frequently driven by "bisociation," the intermingling of seemingly unrelated ideas from different knowledge domains (Koestler 1964), and is facilitated by metaphors and analogies (Tsoukas 1991). Indeed, just as new technological artifacts may emerge from recombination of material resources, new insights may also emerge from recombination of intellectual resources, a process in which outcomes are indeterminate. As products of recombination, new ideas have to overcome problems of legitimacy that arise when categories are crossed.

Common to all these perspectives on entrepreneurship is an appreciation that the emergence of novelty is not an easy or predictable process as it is ripe with politics and ongoing negotiation. What may appear to be new and valuable to one social group may seem threatening to another. Thus, as with institutional theory, the literature on entrepreneurship has also had to come to grips with issues of agency, interests, and power, but it has approached these from the perspective of change rather than continuity.

Work on institutions has, then, traditionally focused on continuity although it increasingly acknowledges the importance of change. In contrast, the work on entrepreneurship has focused on change even as it acknowledges that change is difficult to accomplish. The juxtaposing of institutional and entrepreneurial forces into a single concept, institutional entrepreneurship, thus offers considerable promise for understanding how and why certain novel organizing solutions – new practices or new organizational forms, for example – come into existence and become well established over time.

Separately, each body of literature faces the limitations associated with the longstanding "structure-agency" debate. Privileging structure over agency leads to causally deterministic models wherein some features of the social world become reified and "structure" others, voiding agency and creativity from humans, which in the extreme are assumed to be automaton-like processors of objective information rather than interpreters of intrinsically ambiguous symbolic inputs. In assuming that structures frustrate and, in the extreme, render agency by individual actors impossible, this work explains stasis and continuity; but it is less equipped to deal with change. Theories that privilege agency, on the other hand, often promote heroic models of actors and have been criticized for being ahistorical, decontextualized, and universalistic. Moreover, by emphasizing intentionality, such theories give little attention to unintended consequences of action, which are important components of the reproduction of institutions.

Conclusions and Future Directions

Researchers from a wide range of disciplines have attempted to address these issues by offering theoretical perspectives that combine structure and agency in some form of mutuality constitutive duality. Giddens's (1984) work on "structuration" and Bourdieu's (1977) notion of "habitus" are, perhaps, the most well known (Mutch 2007). According to these researchers, structure is both the medium and outcome of social practices: Instead of being in opposition, structure and agency presuppose each other and are mutually constitutive.

Within institutional theory, this broader structure-agency debate is often referred to the paradox of embedded agency (Seo and Creed 2002). The theoretical puzzle is as follows: If actors are embedded in an institutional field and subject to regulative, normative, and cognitive processes that structure their cognitions, define their interests, and produce their identities, how are they able to envision new practices and then subsequently get others to adopt them? Dominant actors in a given field may have the power to force change but often lack the motivation, while peripheral players may have the incentive to create and champion new practices, but often lack the power to change institutions (Maguire 2007).

One answer to this puzzle lies in conceptualizing agency as being distributed within the structures that actors themselves have created (Garud and Karnøe 2003). Consequently, embedding structures do not simply generate constraints on agency but, instead, provide a platform for the unfolding of entrepreneurial activities. According to this view, actors are knowledgeable agents with a capacity to reflect and act in ways other than those prescribed by taken-for-granted social rules and technological artifacts (Garud and Karnøe 2003). Agency is "the temporally constructed engagement by actors of different structural environments – the temporal-relational contexts of action – which, through the interplay of habit, imagination, and judgment, both reproduces and transforms those structures in interactive response to the problems posed by changing historical situations" (Emirbayer and Mische 1998, p. 970). Conceptualized in this way, institutional structures do not necessarily constrain agency but, instead, may also serve as the fabric to be used for the unfolding of entrepreneurial activities.

Institutional entrepreneurship not only involves the "capacity to imagine alternative possibilities," it also requires the ability "to contextualize past habits and future projects within the contingencies of the moment" if existing institutions are to be transformed (Emirbayer and Mische 1998, p. 963). To qualify as institutional entrepreneurs, individuals must break with existing rules and practices associated with the dominant institutional logic(s) *and* institutionalize the alternative rules, practices, or logics they are championing (Garud and Karnøe 2001; Battilana 2006). Thus, strategies must be developed to embed change in fields populated by diverse organizations, many of whom are invested in, committed to, and advantaged by existing structural arrangements. It is not surprising, therefore, that institutional entrepreneurship is viewed as an intensely political process (Garud et al. 2002).

Efforts at theorizing struggles over institutional arrangements have generated interest in the linguistic and symbolic aspects of power where the focus is on the meanings that humans attribute to a situation which, in turn, influences how they act in relation to it. Lukes (1974) focused on the power of meaning when he introduced his notion of a third dimension of power (Levy and Scully 2007), an unobtrusive form of power to create particular meanings for desired outcomes (Hardy 1985). In the context of institutional theory, the relationship between power and meaning has been addressed through the concept of "translation" (Zilber 2006), which is premised on the idea that the meaning of practices is negotiated locally (Lounsbury and Crumley 2007), with practices becoming institutionalized as meanings become shared and taken for granted across the wider field (Zilber 2007). This work challenges the idea that new practices are transmitted intact and unproblematically and, instead, emphasizes negotiations "between various parties, and the reshaping of what is finally being transmitted" (Zilber 2006, p. 283).

Efforts at shaping institutions will not go uncontested, and, therefore, these attempts can easily go awry (Garud et al. 2001). Consequently, institutional entrepreneurs must be skilled actors (Perkmann and Spicer 2007) who can draw on existing cultural and linguistic materials to narrate and theorize change in ways that give other social groups reasons to cooperate (Child et al. 2007). To this end, institutional entrepreneurs use "framing" strategically (Khan et al. 2007), articulating their change projects in particular ways to "define the grievances and interests of aggrieved constituencies, diagnose causes, assign blame, provide solutions, and enable collective attribution processes to operate" (Snow and Benford 1992, p.150). Through particular frames, new practices can be justified as indispensable, valid, and appropriate. This, in turn, can help mobilize wide-ranging coalitions of diverse groups and to generate the collective action necessary to secure support for and acceptance of institutional change (Wijen and Ansari 2007).

In conclusion, research on institutional entrepreneurship remains popular, particularly because of the paradox of embedded agency, and a range of different approaches are being employed to learn more about these dynamics (see Hardy and Maguire 2008; Battilana et al. 2009; Garud et al. 2010). Future research will, however, need to tread a fine line between putting agency back into institutional analyses of organizations and unreflexively privileging heroic "entrepreneurs" (Hardy and Maguire 2008; Garud et al. 2010).

Synonyms

Entrepreneur – change agent, promoter, broker; Innovation – deviation, alteration, implemented novelty; Institution – establishment; Policy – line, program; System – arrangement

Key Concepts and Definitions

Institutional Entrepreneurship

Institutional entrepreneurs are actors who initiate changes that contribute to transformation of existing institutions and/or creating new ones (Battilana et al. 2009). Institutional entrepreneurs can be organizations or groups of organizations or individuals or groups of individuals who act as change agents. They are actors who initiate divergent changes and actively participate in the implementation of them (Battilana et al. 2009, p. 67).

The concept of institutional entrepreneurship was first introduced by Paul DiMaggio in 1988, and it is based on his observation that organized actors do not only comply with institutions but consciously aim to create institutions or to transform existing ones, and for this purpose, they mobilize resources, competences, and powers (DiMaggio 1988).

Institution

Different schools of thought define *institutions* differently. Scott's (2001) three-dimensional view cuts cross many schools. According to Scott, institutions are composed of regulative, normative, and cultural-cognitive pillars. The regulative pillar highlights institutions as constraining forces that regularize behavior. It frames individual actions and choices by rule setting, monitoring, rewarding, and sanctioning activities. The normative pillar includes values and norms that by prescription, evaluation, and obligations frame individual actions and choices. Normative pillar consists of factors that influence actors' choices and actions by informing what is preferred and/or desirable. It also informs about the standards on which existing structures are based (Scott 2001, pp. 51–54). For its part, the cultural-cognitive pillar stresses those external frameworks that shape actors' internal interpretation processes (Scott 2001, p. 57) and, therefore, demolished, renewed, and/or totally new institutions change the ways actors see, interpret, and understand themselves, their actions, and positions in wider structures (Sotarauta and Pulkkinen 2011).

Innovation System and Innovation

The dynamic and continuously expanding body of research shows how industries, firms, and the public sector actors, in their efforts to create new innovations, are embedded in national, sectoral, and/or regional *innovation systems* (Lundvall 1992; Braczyk et al. 1998; Malerba 2002) and how innovation systems are constructed on knowledge-creating and knowledge-utilizing subsystems (Autio 1998).

An innovation system consists all the relevant economic, social, political, organizational, and other institutional factors that influence the development, diffusion, and use of new knowledge (Edquist 2008, p. 5) and have an influence on individuals', firms', and organizations' learning capacity and hence on their ability to innovate (Lundvall 1992; Lundvall et al. 2002). All this is supposed to produce new creations of economic and/or societal significance, i.e., *innovations* that are widely accepted as primary sources of renewal in a global economy (e.g., Edquist 2005).

The various approaches on innovation systems stress, according to a narrow definition, "interacting private and public firms, universities, and government agencies aiming at the production of science and technology" (Niosi et al. 1993) and "networks of institutions that in interaction initiate, import, modify, and diffuse new technologies" (Freeman 1987). Additionally, according to a broader view, innovation systems consist of organizations and institutions affecting and supporting learning and innovation (not only focusing on science and technology), and thus, according to this view, innovation system embraces also such actors that earlier were not seen influencing innovation (Asheim and Gertler 2005, p. 300).

In the literature on innovation systems, such factors as intellectual property right laws; other laws; various standards; environment, safety, and ethical regulations; organization-specific rules; industry specialization and structure; governance structure; financial system; structure of the research and development; R&D investment routines; and training and competence building system as well as operational cultural factors are raised as institutions (see, e.g., Autio 1998; Braczyk et al. 1998; Edquist 2005, 2008).

Institutional entrepreneurs are here seen as those actors who consciously work to change the institutional environment to better support the many functions of an innovation system and hence creation of innovations.

Innovation Policy

In innovation studies, innovation policy is fairly generally seen as actions by public organizations that influence innovation processes (Edquist 2008). Innovation policy is usually seen to consist of explicit measures to promote the generation, diffusion, and efficient use of new products, services, and processes in markets or more widely in a society. Innovation policy often has wider objectives than those focusing only on science and technology even though it more often than not incorporates elements of these. Consequently, broad-based innovation policy may cover a wide range of initiatives that are linked to science, technology, user needs, societal demand, and education.

Recent studies emphasize that contemporary innovation policies are designed and implemented in multi-actor innovation arenas and related networks (state–region–municipality–firm–university–polytechnic) (Kuhlmann 2001; Sotarauta and Kosonen 2013). Consequently, multi-actor forms of innovation policy challenge the straightforward definitions of innovation policy that see it as something only the public sector performs alone. Innovation policy is one arena among many through which institutional entrepreneurs may work to change institutions, and on the other hand, changes in innovation policy may be a consequence of institutional changes.

Open-Ended Issues and a Selection of Main Challenges

Agency: What Actors Do to Change Institutions for Innovation?

Institutions being central in promotion of innovation following generic questions guide studies focusing on institutional entrepreneurship in the context of innovation systems: (a) how to promote institutional change for better innovation systems and, consequently, (b) how to create, demolish, and change something that is stable and a source of order and a product of emergent properties (Sotarauta and Pulkkinen 2011). Indeed, there are calls for explicit efforts to change institutions for innovation. For example, Lundvall et al. (2002, p. 255) call for deeper understanding of transformation processes of innovation systems at an institutional level. They also see that the institutions as such are not as important targets of study as the processes of institutionalization are.

Institutions by definition imply permanence and stability, and one of their key characteristics is that they are resistant to change. This kind of restrictive perspective reminds that actions deviating from what is framed as appropriate by institutions are often sanctioned, one way or another. In the literature, restrictive view has recently been actively complemented, and also the enabling role of institutions is being acknowledged (Hage and Meeus 2006). Therefore, an institution can be interpreted both as an object of change itself and as a constraining as well as an enabling and incentivizing structure for change (Soskice 1999, p. 102). Institutional approach has been criticized for its inability to explain transformation and institutional change and more generally for predicating compliance and conformity. This critique, for its part, has generated increasing interest in the role of agency in institutional change and thus also institutional entrepreneurship (Tracey et al. 2010).

Of course, in the literature that focuses on national, regional, and sectoral systems of innovation, there already are several notable examples of the efforts to understand how institutional systems affect innovation and how innovation may also affect institutional change. However, policy process and agency as well as institutional change still are black boxes for students of innovation system. Innovation systems are often treated as if they function well or transform themselves without conscious efforts to change them (Uyarra 2010). Additionally, as Uyarra (2010) also states, innovation scholars often do not peep into policy processes but assume that they progress step-by-step from analysis to policy design to implementation and action. For these reasons, institutional entrepreneurship is gaining more ground as it aims to add knowledge in how social actors work to change the institutions that govern their own activity. Indeed, it improves understanding of the ways power is exercised in these efforts and how actors strategize and mobilize tangible and intangible resources for institutional change (Garud et al. 2007).

The point of departure here is that by taking institutional entrepreneurship as a key organizing device also in studies focusing on innovation systems, an analytical leverage could be added and thus to better understand institutional change, agency, and policy processes.

Complex Social Process: What Is Going on in Innovation Systems?

DiMaggio and Powell (1991) maintain that when adopting institutional entrepreneurship as theoretical lens, institutions can be studied as outcomes of complex social processes and as products of human agency. Institutional entrepreneurship provides an analytical framework to study what various agents do in cooperation and/or competition with each other to change institutions; how they interact, relate, and evolve with wider institutional constellations; and importantly, what kinds of risks they take and what they invest personally in the change efforts. Consequently, this kind of approach highlights the importance of studying interests, legitimacy, strategy, and power (Levy and Scully 2007), while the more conventional approaches on innovation systems highlight the presence or absence of actors, institutions, and interaction patterns (Uyarra and Flanagan 2010, p. 683).

By definition, an actor needs to be intentional in action to be recognized as an institutional entrepreneur. In studies on institutional entrepreneurship, it is important to distinguish forms of institutional change that are relatively spontaneous and emergent from those that take shape with considerable strategizing, organizing, and coordination (Sotarauta and Pulkkinen 2011). This distinction may help in the efforts to understand what institutions can be shaped and how. Additionally, there is a need to ask to what extent and under what circumstances institutions can be directed. Clearly, conscious efforts to change institutions and emergent development patterns are in many ways intertwined. Intentionality of purposive change agents needs, more or less, to be adjusted to emergent properties, those being outside the reach of institutional entrepreneurs. For these reasons, it is not suggested here that there might be some kind of predestined causality between institutional entrepreneurs' actions and institutional change.

At best, institutional entrepreneurship studies are a form of process-oriented inquiry where the role of actors is fleshed out by analyzing the change processes in which the institutional structure coevolves with actors; thus, the interaction between structure and actors needs to be seen as bidirectional.

Embedded Agency: How Actors Aim to Change Something That Frames Their Own Actions?

Hall and Thelen (2009) divide the role of agency to institutional change into three main types: (a) reform (institutional change explicitly directed or endorsed by the actors), (b) defection (key actors cease behaving according to the rules and practices prescribed by a preexisting institution), and (c) reinterpretation (the actors learn new ways of thinking and consciously create new interpretations of themselves, rules as well as practices without abolishing the institution itself).

Institutional entrepreneurs may possess a formal position to attack institutional arrangements by applying above-mentioned generic strategies, but some of them may not have it. It would be tempting to assume that mayors, leading policy makers, CEOs of main firms, vice chancellors, and other authorities with formal positions would somehow automatically be institutional entrepreneurs. There is a need for both conceptual development and more fine-grained empirical analyses before it would be possible to reliably answer to the question who institutional entrepreneurs in different situations actually are (Sotarauta and Pulkkinen 2011). Of course, whoever institutional entrepreneurs are and whatever their change strategies may be, their freedom to push for institutional change is limited in situations of fragmented power and authority. Interestingly, institutional entrepreneurs are constrained by the very same institutions they aim to change, and therefore, their work is a form of "embedded agency" (see more, in Battilana 2006; Leca and Naccache 2006; Seo and Creed 2002).

A core belief underlying in the approach suggested here is the importance of understanding interactions between actors and their institutional settings. It is more or less impossible to understand institutional entrepreneurship without understanding how actors shape institutions they are embedded into and how institutions shape their actions. This calls for relational, contextual, and systemic understanding. This kind of *process and system-oriented approach locates institutional entrepreneurship not in the attributes of individuals but in the relationships connecting actors in an innovation system and institutional change*. To understand these kinds of institutional change processes, it is important to ask the following: How do institutional entrepreneurs deal with change? What kind of change strategies do they launch? What is the combination of change strategies they adopt in specific situations at specific times? How can actors innovate and renew institutional settings if the very institutional environment they wish to change determines their beliefs and actions? How do they resolve the paradoxical situation in which they aim to change those institutions that frame their very actions? How do they earn/take their positions? Who are the institutional entrepreneurs in different institutional contexts? (Sotarauta and Pulkkinen 2011).

Institutional Change: How Institutions Governing Innovation Change?

When studying institutional change, there is a danger to fall into a "radical change trap" and focus mainly on those changes that are easy to detect and observe and thus to see change as a discontinuous period between periods of stability and continuity. This kind of view on change might lead to simplified accounts on institutional entrepreneurs' roles in institutional change. It is suggested here, inspired by Streeck and Thelen (2005), that there is a need to be more sensitive to gradual transformations. Incremental changes are not only reactive and adaptive for the protection of institutional continuity, as often assumed. Accumulation of subtle, seemingly minor changes in longer periods of time can lead to considerable discontinuity that may surface beneath the apparent stability. Indeed, "creeping change" (gradual transformation) suggests that there are no optimum states but a constant search is a core in institutional change processes (Streeck and Thelen 2005) and thus also in the strategies adopted by institutional entrepreneurs. All this suggests that when studying institutional entrepreneurship, there is a need to be sensitive to continuity and discontinuity as well as incremental and abrupt changes and their combinations.

Broader View on Institutions Called for: What Are They?

In spite of the fairly generally shared understanding that institutions mediate in subtle but pervasive ways evolutionary trajectories of economies. Their specific roles in the innovation puzzle are still poorly understood and perhaps even underappreciated. While innovation system literature highlights the role of institutions, they have been conceptualized and empirically studied with fairly narrow lenses. In innovation studies, institutions are often conceptualized as rules of the game, while organizations are seen as players (e.g., Edquist 2005). Hodgson, however, argues that also an organization can be, but not always is, an institution in itself (Hodgson 2006). Some of the organizations may evolve so that they end up framing the actions and choices of other actors and thus become institutions by themselves (e.g., universities in their own countries and regions and Nokia in Finland).

All in all, the ultimate question is why and how certain institutional arrangements facilitate economic development and innovation while others seem to hinder them, and to answer this question, the fairly clear-cut distinction between institutions and organizations need to be reconsidered and the notoriously complex and context-sensitive nature of the concept appreciated. It is suggested here that institutions governing innovation systems ought to be approached as a context-specific and open empirical question. It is also suggested that by focusing on what actors actually do to change the conditions for innovation might enable us to learn more about the true nature of institutions.

Implications for Policy and Practice

Innovation policy has been stressed throughout the world as a way to renew economies and cope with challenges of globalizing world. Simultaneously, there is a growing understanding that there are no one-size-fits-all innovation systems or policies in circulation (Tödling and Trippl 2005). This suggests that institutions framing both innovation systems and policies differ significantly between many different types of regions and countries. For example, as shown by Asheim et al. (2011), even in relatively small countries like the Nordic countries, which in many ways are fairly similar to each other, innovation policies indeed differ from each other.

The Nordic countries are only one example among many how institutions mediate economic development paths and how historically rooted national institutions frame the choices of both individuals, firms, and policy makers. More explicit focus on institutional entrepreneurship might enable policy makers to better understand the nature of both institutional obstacles and ways to cross them, instead of searching for ways to adapt to latest buzzwords in global circulation. Additionally, by explicit focus on institutional entrepreneurship, it might be possible to identify the true roles of policy making in different situations, and thus, it might be possible to design more sophisticated policy approaches and policies.

Conclusions and Future Directions

The main challenge in studies aiming to understand innovation systems by an explicit view on how institutions change and on what actors do to change them is to understand the dynamics of institutional change with a microlevel analytical lens. This calls for (a) identification of institutions that are locking industries, countries, and/or regions into the past development path or slowing their transformation down; (b) analysis of the ways actors aim to demolish and/or renew these institutions; and (c) identification of strategies different actors adopt when aiming to create new institutions to support the emergence of a new development path (see also Sotarauta and Pulkkinen 2011). The concept of institutional entrepreneurship might offer a conceptual lens in these efforts by seeking for a balance between structure and actor.

Institutional entrepreneurship provides an analytical framework of how various agents aim to change institutions as well as how they interact, relate, and evolve with wider institutional constellations. Especially important for this line of study is the notion that micro-agent change leads to macro system evolution, i.e., before change at a macro level can be seen, it is taking place at many microlevels simultaneously.

Institutional entrepreneurship needs to be studied with three perspectives in mind: (a) the *process* perspective that informs a study on the dynamism of innovation systems and secures a temporally conscious approach; (b) the *network* perspective that informs about the social relationships of the actors in and beyond a innovation system; and (c) the *governance* perspective that informs about the wider systemic issues framing and molding both the actual systems and change processes as well as forms of institutional entrepreneurship.

Ultimately, to repeat and conclude, the aim of taking institutional entrepreneurship under close scrutiny is to add analytical leverage to endogenous innovation processes and systems and find a fresh lens that enables studies operating in between macro and micro issues.

The expression "knowledge-based economy" is one of the most used in the economic and managerial literature. This expression refers to the fact that, roughly since the mid-1970s, knowledge and, more broadly, intellectual capital is the most important input in the production process of the economy (as compared to other inputs such as tangible capital, land, and low-skilled labor). A tangible manifestation of the critical role of knowledge in the production process is provided by the raise of firms which are specialized in knowledge production, be it consulting companies specialized in supply chain management or quality management, technological start-up, and/or university spin-offs. The common point between those firms is that, since they produce only knowledge, they must be able to valorize it, i.e., to sell it on markets.

In other words, the prominent place of intellectual capital in the knowledge economy directly shed light on the importance of intellectual property, i.e., on the means for entrepreneurs to protect their intellectual creations. Entrepreneurs usually seek to secure their intellectual capital by relying on intellectual property rights (IPR in the following). Most used IPR are (the list is not exhaustive) patents, trade secrets, brands, copyrights, models and drawings, etc. From an entrepreneurial point of view, IPR are keys to secure intellectual capital and hence to provide incentives to continuously develop novelties and innovation. And obviously, needless to say that the more important intellectual capital in the value creation process, the more important the place granted to IPR and, most of all, the more important it is to adapt a coherent strategy to use them (Teece 2002).

The issue of intellectual property is therefore critical today in almost all inventive and creative sectors, be it in traditional industries, in art or in creative industries. In particular, since creative industries are at the intersect of art and industry (Caves 2002), the issue linked to intellectual property in those sectors is likely to be different than in more traditional sectors (and also more complex). According to Bach *et al.* (2010): "Creative industries typically include industries that focus on: Creating and exploiting intellectual property products such as music, books, film and games; or providing business-to-business creative services including advertising, public relations and direct marketing. To a large extent, these creative industries integrate artistic as well as industrial dimensions, thus narrowing the gap between the use of patents (traditionally used in industry) and copyrights (traditionally used in art)." For instance, in the case of the movie industry, the music industry or the video-game industry, to cite only some of the most famous creative sectors, firms must today be able to combine and to handle a multiplicity of IPR and a multiplicity of valorization strategies.

From a social perspective, at the era of Internet, the role of IPR is vividly debated in the economic literature (Andersen et al. 2007). In a sense, technologies of information and communication (TIC in the following) exacerbate the Arrovian dilemma between incentive and diffusion (Arrow 1962). In its seminal paper, Arrow described the problem faced by entrepreneurs who seek to sell informational goods, i.e., goods which are hardly appropriable and nonrival. He explained that no buyer would accept to pay for something that he has no clue about. Thus, sellers must disclose the information in order to be able to sell it. But as soon as they do so, buyers do not need to pay to acquire the information since they already have it. This dilemma explains why IPR are fundamental in markets for informational goods and in creative industries.

Now, with the advent of TIC, this dilemma is still made more relevant. On the one hand, it becomes more and more important to prevent imitation and to secure intellectual property since in many sectors the Internet makes it easier and easier to duplicate and to copy new creation, thus undermining the incentives of inventors and creators. But on the other hand, TIC also increase the value of the dissemination of those new creation, which reinforce the importance of a wide diffusion of new creations at a low (if not zero) cost. For instance, in the music industry, for incentives sake, it is nowadays critical to protect new songs via strong copyrights and to prevent as much as possible free download on the Internet. But on the other hand, since TIC make it possible to disseminate new songs within the economy very fast and almost for free, the value of the diffusion of new songs has also increased, which calls for a minimum of protection.

However, if on the one hand the emergence of the Internet modifies the equilibrium of IPR policies, on the other hand, it also changes firms' entrepreneurial strategies. Because it potentially generates new source of value and affects the mechanism of repartition of this value, the emergence of the Internet and improvements in TIC indeed triggers the adoption of new business models by entrepreneurial firms, often more open than more traditional ones.

The standard view of IPR focuses on their role to prevent copy and to secure monopoly power and thus to restore incentives to create. For instance, in traditional industries such as pharmaceutical or chemical industries, firms often rely on patents to protect new chemical compounds and therefore increase incentives of biotech start-ups to invest in R&D. Or, in the music sector, copyrights prevent consumers to copy new songs for free, thus increasing incentives of artists to produce new pieces of music. Here, in line with traditional thinking in management, the ability to exclude and to enjoy monopoly power is at the heart of entrepreneurs' business models.

Yet, the link between IPR and entrepreneurial strategies is not straightforward. In reality, there is a large spectrum of possible utilization of IPR and entrepreneurs might not always want to use IPR in order to exclude imitators. In particular, openness and diffusion may become interesting for firms in order to benefit network effects, to ease compatibility, or to develop business in complementary assets. Hence, the valorization of creations and inventions may not always require exclusion and full appropriation strategies. This is all the more relevant in the Internet economy, where network effects tend to be large, thus increasing the value of openness and information sharing.

Consequently, encouraged by the huge progresses of TIC, new business models have emerged recently. For instance, in software, the open-source movement demonstrates the possibility for entrepreneurs to become profitable without strong right of exclusion. Open-source software typically relies on copyleft, i.e., on a peculiar use of copyright which ensures not the exclusion but the maximal dissemination of produced lines of codes (Raymond 1999; Lerner and Tirole 2001; Dalle and Jullien 2003; Benkler 2006). Thus, in open-source communities, participants who produce lines of code cannot appropriate them and control their use. Yet, many firms do devote times and resources to contribute to open-source project although they know they will not be able to appropriate the produced software. This clearly illustrates that open business model can sometimes be profitable.

The success of open-source software has triggered many scholars to explore how and when to export this model in other sectors. In the field of arts, for instance, licenses based on creative commons' principles are now deeply rooted in the practices of many actors. Similarly, Lakhani and Panetta (2007, p. 98) explain that: "The achievements of open-source software communities have brought the distributed innovation model to general attention so that it is rapidly taking hold in industries as diverse as apparel and clothing, encyclopedias, biotechnology and pharmaceuticals, and music and entertainment."

If the example of open source is quite extreme, it suggests that, for entrepreneurs, IPR strategies based on strong exclusive rights may not be optimal. In many cases, it might pay for an innovative firm to weaken its IPR and to adopt open business model. For instance, in the case of open source, it must be noted that, technically, software "protected" by a copyleft is not automatically free. It can be sold. Yet, the copyleft means that nobody can prevent someone from distributing it for free, which seriously undermines the incentives to sell it. In practice, therefore, copylefted pieces of art are usually distributed for free.

Second, creators by opening their invention or creation do not usually abandon all their rights over it. Very often, they keep at least their name associated to their creation. It is the case, for instance, under the label of *creative commons*, which proposes some more or less permissive licences, but under which it is always very important to mention the name of the creator.

Third and more important, new business models can be designed around free and open invention and creation. For instance, in industries with strong network effect (where the value of the good largely increases with the number of users), it may pay for firms to open their technology, to favor its diffusion and wide use in order to benefit from network effects. Network effects indeed introduce the issue of standard and compatibility. And, needless to say that exclusive strategy is seldom relevant in order to favor compatibility. More generally, any times a market is multisided, the issue of openness, at least on one side of the market, must be addressed by firms who operate on those markets. It may indeed pay to offer the good for free (or almost for free) on one side of the market in order to increase the value of the good for customers on other sides, thus increasing their willingness to pay and the firm's potential of revenue.

Similarly, as illustrated by the case of software, weakening its IPR might lead to maximize sales of complementary assets (Teece 2002). Indeed, if complementary assets are exclusively controlled by the firm, providing a free good might enable entrepreneurs to increase their profits on those complementary assets. In other words, it is possible for artists not to sell directly their copylefted work but to make money out of complementary services that are combined with the open resource. This explains why, for instance, firms as Google or Amazon are strong contributors of open-source software. They do not sell the software but they combine it with assets that they hold exclusively (reputation, networks) in order to maximize their revenue.

Finally, open environment is critical in order to lever the work of creative communities. Bach et al. (2010) emphasize indeed that in creative industries, the process of creation is generally a collective effort that necessitates the interaction and coordination of a multitude of heterogeneous economic actors. Basically, Bach et al. argue that stakeholders of the creative process are talented individuals, firms, and creative communities. In particular, they stress the critical role of the latter. According to them: "the locus of creation is rooted within the diverse informal communities with which firms and individuals must somehow maintain links in order to keep introducing novelties. *Creative communities* refer here to informal groups of individuals who accept to exchange voluntarily and on a regular basis in order to create knowledge in a given field. As the knowledge-based economy expands, such communities take in charge some significant parts of the *sunk costs* associated with the process of generation or accumulation of specialized parcels of knowledge." This is, for instance, clearly the case in the video-game industry in which dominant firms must rely on the production of underground creative communities of artists (Cohendet and Simon 2007).

However, the point which is important to make here is that, with respect to IPR, creative communities have radically different needs than firms. Communities need openness and knowledge exchanges while firms need exclusion and knowledge retention. This is what Bach et al. (2010) call "the IPR dilemma in creative industries." Communities can only flourish under weak IPR. Creative projects entail integrating, cutting, and pasting, assembling creative elements dispersed among a vast array of technical and cultural activities carried out by diverse and distinct actors. Thus, in order to foster the production of novelty, firms, individuals, and communities must rely on some kind of open spaces. In particular, it is important for firms to moderate their use of exclusive IPR in order to preserve privileged links with creative communities. Lessig (2001, 2004), for instance, insists on the fact that creation is a collective process involving communities and that, for those creative communities, the issue of access is more important than the issue of incentives. According to him, creativity can hardly occur in a world of permission and the production of novelty requires the preservation of a free platform on which creators can freely draw to feed their creativity.

In order to reconcile those two opposed positions and to preserve the delicate balance between appropriation and creation, firms might therefore develop specific arrangements, which often means to behave less aggressively in order to be able to lever the work of the masses. These new strategies of intellectual property are clearly in line with all the recent literature on open innovation which stresses new innovative strategies based on user communities, crowdsourcing, etc.

Conclusion and Future Directions

In creative industries, the issue of intellectual property (and in particular intellectual property rights) and entrepreneurial strategy is critical. In many situations, it is important for new ventures to be able to prevent imitation. But, on the other hand, in some cases, it may also pay to adopt more open business models. Indeed, in creative industries, building an ongoing creative dynamics requires the preservation of a fragile equilibrium between exclusion and openness, which ensures the coevolution of individuals, firms, and a creative underground. In this sense, firms must accept to some extent new uses of IPR, in particular those based on copyleft strategies and creative commons in order to favor links with underground communities.

This discussion on the role of intellectual property and new entrepreneurial strategies is essential because it contributes to introducing new dimensions to comprehend the debate on intellectual protection in creative industries. Yet, future research will have to complete it at least with respect to two issues.

First, future research will have to improve the understanding of the business models that allows firms to exploit and use the strength of open strategies. In particular, it will be important to explore whether or not it is possible for firms to elaborate hybrid strategies in between exclusive and open access in order to reconcile their need of appropriation and of creation. If yes, under which conditions? For instance, crowdsourcing is often presented as such hybrid strategy (a mix of strong appropriability and peer production). Yet, it is well known that crowdsourcing in the case of inventive and complex activities raises many problems and is likely to work only in limited contexts (Burger-Helmchen and Pénin 2011).

Second, future research will have to understand the functioning and evolution of creative communities and their interactions with the business sphere. The dynamics of creative industries indeed strongly depends on the creation and development of local creative communities that are in charge of elaborating and diffusing the norms and rules which help to regulate the behavior of all the different actors. How those communities evolve, how they change and interact with other actors of the innovation process, is a fundamental research question that needs further investigation.

Synonyms

Creativity; Human-computer interaction; Simulacrum

The information age, we still call it. Since postwar revolutions in technology (and above all in communications, we must remember), it has become commonplace to see the world and its events as information, as data. The processes of storing, accessing, and processing information are accepted culturally as central roles of contemporary technology, the central pillar of the trio of sensing, computation, and communication that characterizes and enables technologized life. The notion of "interactivity" is one of the foundational, defining concepts of the technological age. The idea that technology can respond to, appear to adapt itself to human actions or transpose those actions to other contexts transforms the scope of behavior of both human and machine. Over a generation, two developments have brought this relationship to a point where the interface often seems transparently thin: cultural practice and the common imagination have assimilated many of the implications, and technology has become faster, smaller, adaptable, and ubiquitous. This entry will explore the shape of the liminal space within this interface.

From Ubiquitous Concepts to Ubiquitous Reality

Interaction

Interaction is inevitably one of the broadest terms within technological culture. It is used to refer to all levels and modes of causal relationship between human and machine, however, conscious, intentional, or otherwise. The idea of interaction in a social sense or in dealing with the working together of machines, systems, or models is also relevant here. Interaction generally has a social context, and the modularity or complexity of systems means that intra-system relationships are equally important. Feedback is an important component in any interactive (rather than reactive) context.

Simulation

In its simplest sense, we might seem to be dealing with machine imitation of some behavior in the material or cultural world. In fact, the design and interpretation of such systems produces potentially complex and interesting meaning-generating relationships. More fundamentally, most systems designed for any kind of interaction can be seen as embodying a model. This might take the form of a set of simple assumptions, or of a population of dynamical systems designed to model complex behavior in the material or virtual world. Most crucially, the idea of simulation suggests an act of interpretation by a subject – a designer, observer, or user. It implies that the machine-embodied system is understood as a model or parallel of another system in a material or imagined world.

Invention

Invention tends to be understood as innovative application of science or technology – a new way to do something or something new to do. Here we will use a broader definition also encompassing means of producing new knowledge or understanding and aesthetic creation.

Interaction, Simulation, and Invention: A Reflexive Relationship

Invention, Creativity, and Cognition

Theories of creativity tend to emphasize the role of interaction rather than miracle birth. Indeed, the latter – the genius moment – we would now explain in terms of the process of emergence, as will be discussed below. Most such theories suggest that invention is the product of a more or less consciously observed encounter between internally modeled spaces or behaviors. The spontaneous reflexive process of the mind's generation of maps of its own conceptual spaces is at the root of such interpretations. Creative thought can be seen as the drawing of analogy between different mental spaces within interacting constraints of similarity, structure, and purpose. More recently, researchers have proposed an evolutionary explanation; that genius typically explores a wide range of potential behaviors, often in parallel, searching for complexity, novelty, and emergent structure. These explanations have in common an understanding that invention is the fruit of interacting simulations, of material of conceptual models. The action of imagination is the projecting of this interaction onto a new plane. Such a plane may be visual, aural, or temporal, for example, or it may be a new space of possibilities with its own potentialities, constraints, and dynamics.

In this respect, simulation must be considered an integral component of consciousness; every human behavior implies a model and projection on some level, and most involve some kind of interaction with the material or social world. In dealing with technology, external models and instrumentalities come into play, and in understanding this we must bear in mind that humans are optimized for engaging with humans. Indeed, we are disposed to understand behaviors in general (from the mythological actions of the gods to those of Disney cartoon animals) as human. This tendency is fundamental to our design of and interaction with machine behaviors. Interaction thus depends on a degree of credibility, an act of faith, or investment on the part of the "user" – the subject. The three key technologies are well tried; most advances in design and production transform practicality rather than concept. It is the capacity of the potential subject – the human – to imagine themselves into new technology-mediated contexts that carry such change forward. The special property of the technologies of interaction and simulation is that they create the very reflexive environment by means of which such vision becomes possible. They are the very instruments of invention.

Contexts for Action

Interaction with models is not exclusive to computational processes, of course. Maps, tools, pen, and paper and notational systems all function as extensions of human behavior. Heidegger's example of the hammer is a much-discussed theoretical reference in this respect. More generally, cognitive functions and individual and social behavior are mediated by tools, technology, representations, and social structures. External memory, representation and devices for manipulating the material world all become part of a feedback system that incorporates not only internal and external modeling, but also projections of how things might develop – simulation. In considering the prospect of digital craft, the *symbolic* nature of digital technology is crucial. This is how it is able to relate real and virtual actions and information. It also means that every relationship is mediated by a symbolic layer; technology is a medium. The computer provides a network of representational contexts for action. The power and flexibility of these contexts lies precisely in their symbolic nature, in their capacity to map representational spaces onto one another. The symbolic layer also facilitates and requires cross-disciplinary research and creation – invention that is the product of the interaction of different areas of thought and practice.

Representation, Modeling, and Emergence

Representation itself is thus a vital issue. Interaction and simulation both rely on symbolic models of a material, virtual, or informational space. Model making depends on reducing the number of parameters (degrees of freedom) to a non-infinite number tractable in the particular technological context and representing those parameters symbolically. Explicitly or otherwise, in identifying the system to be modeled a designer constructs a quasi-autonomous model of a situated system the behavior of which has enough overlap with that of an experienced, imagined, or comprehensible system for the user to engage with it meaningfully. The art of modeling is itself one of invention, of perceiving and defining as a quasi-autonomous system with limited links to its environment one which in the material world has a potentially intractable number of such relationships. The power of such an approach lies not only in its calculability, but also in its modularity and generalizability. More complex systems can be constructed of such models, to simulate and test the nature of relationships, and patterns if behavior and interaction can be abstracted.

Representation remains at the heart, however, complex, responsive, or contingent a system appears. Any difference between information and control systems lies in their use and design, in their mode of output rather than in their abstract structure. The nature of interaction (as opposed to remote or complex control) has tended until recently to continue such an information-based understanding of human behavior. Even beyond the confines of AI research, there has been an implicit assumption that an adequately rich and navigable knowledge base could form the basis of machine behavior with which humans are content to interact. While many interactive systems still effectively work on the basis of what is known as "good old-fashioned artificial intelligence" – "top-down" models, such as expert systems – most thought on machine intelligence over the last 20 years has moved toward an embodied, situated, distributed “bottom-up” approach. Interaction thus becomes one of the primary aspects of the model to be designed and observed. Most importantly, the knowledge potentially generated or revealed by such a system is not explicitly embodied in its structure and rules. Knowledge becomes a function of time and context; it is *emergent*. Definitions of emergence vary by context (Clayton and Davies 2008), but there is a general division those of weak emergence – emergence in the eye of the beholder – and strong emergence – new structure or behavior that has a causal impact on the behavior of the system itself.

Modes of Interaction

Similarly, many issues that are often connected with interaction are inseparable from questions of what used to be referred to as human-computer interaction. The parameters of interface design for interaction are well rehearsed: mode and degree of physicality, degrees of intuitiveness or necessary learning, analogy with other objects, systems, or models, and – crucially – feedback. Research in interaction design tends to focus on the individual; the concept of *joint cognitive systems* considers at the broader interaction of social and technological systems. The more recent notion of “experience design” acknowledges the dynamic nature of the relationship. Questions of the design of physical objects have become integrated with those of interfacing. Recent work points to the important role of skill acquisition in satisfactory and engaging interaction; successful design is the product of a partnership between designer and use. The design of interaction can enable the user to navigate complexity through structure, effective communication, and a learnable, sociable interaction, but the user must also seek to understand, engage, and learn. Interaction is thus not limited to the confines of the standard personal computer interface. Indeed, many screen-based exchanges might better be classed as iteratively reactive rather than interactive.

Developments in sensing technologies and data processing have greatly enhanced the potential of interactive environments. This might take the form of sophisticated multimodal interaction, such as immersive environments, or the intelligent processing of data that embodies complex actions, such as the abstraction of human forms from visual input. In both cases, the range of interacting behavior is vastly expanded from, say, a switch or dial. With this broadened palette of range and mode of input must come a thicker layer of software mediation between subject and response. This creates richer potential for learning on the part of the system; multimodal learning is also a more intuitive process for the subject.

Prosthetic Culture

Technological evolution drives the cultural understanding of human-machine relationships to another paradigm. If subject and computer are integrated such that the subject no longer perceives a distinction, then the situation is no longer one of interaction. Instead, we are dealing with a form of prosthesis, but one that is cognitive and experiential as well as physical. Theorizing of this situation generally pursues two lines: notions of the “posthuman,” as state in which informational dynamics are no longer entirely constrained by material life, and the balancing view of human knowledge and understanding as being essentially and evolutionarily embodied. Both are vital lines to consider. The new situation will likely afford the emergence of concepts that could not form in the “raw” human situation, constructs which require the extended context for their formation. However, as with previous technological innovation – writing, communications, computing, for example – this will doubtless also add to the conceptual repertoire of raw human thought and culture. Theorists refer to such a dynamically mind-technology coupled process as *enactive systems*, within which technology becomes an integral part of human sense-making. The extension of the individual through simulation and interaction could lead to its dissolution into a dynamical pattern of evolving cultural constructs. In this reading, interaction is no longer an intentional exchange but rather an evolutionary, emergent process of continual invention in which the boundaries between individuals become dynamical and multiple.

The Crucial Role of Time

Temporality introduces an infinitely greater richness to interaction. Dynamical models represent the evolution of a system over time. They may be characterized by the mode and degree of interaction they afford:

– Autonomous systems (e.g., meteorological, social, or economic models, generative graphics or music)
– Systems that are quasi autonomous but allow or require data from outside (simple computer games, continuously evolving information systems such as finance)
– Systems that allow multiple or complex intentional relationships with the subject(s) (flight simulators, interactive performance systems)
– Systems that inhabit a real world environment (installations, immersive environments)

This might be better understood in terms of the *distribution* of interaction – the points in the cycle of imagination, design, and use at which imagination might intervene. Fully autonomous systems play an equally important part in the emergence of new modes of thought; the creative influence of concepts of chaos and complexity are obvious examples.

State variables within the system evolve over time. In a digital context, dynamical systems must be discrete time models (i.e., they proceed in steps, however small), which themselves are integrations of continuous time systems the behavior of which is represented by differential equations. In this respect, computational systems are themselves models of mathematical systems. Recursivity is an important characteristic of such systems; the state at time $t + 1$ is calculated from the state at time t on the basis of the equations of the model incorporating any changes to state variables from external sources. This property allows for relationships and feedback loops between variables that are generally the source of perceived nonlinear behavior or emergent structure – that is, behavior or structure over time that is not predictable from the initial state without running the system in time. We might posit interaction and invention in the observation of nonlinear behavior in a dynamical system. The design of modes of intervention in that system implicitly assumes a dynamical model on the part of the subject. Similarly, intervention by the subject is structurally equivalent to an evolving parameter or feedback loop within the system; the subject becomes part of the environment of a complex system, and vice versa. New knowledge and invention are two sides of the same coin. Given that no simulation can be absolute, the difference between simulation and interactive systems is largely one of design and use, of cultural convention.

Invention and Complex Systems

The modularity of modeling allows for complex simulations such as the massively multi-point calculations of contemporary weather forecasting – a vast number of interacting localized systems. It also affords the possibility of agent-based modeling, in which the global system behavior is the product of interactions between internal autonomous systems, each modifying the environment of the others. The paradigm of *Artificial Life* is based on the coevolution of such structures. Taking its cue from the "non-intelligent" design of nature, it views life as the organization of matter and explores life-as-it-could-be through the self-organization of complex systems. As a research tool, A-life models have been used to explore phenomena from the evolutionary to social to cosmological levels. They are naturally suited to the modeling of adaptive and emergent behaviors, and for the exploration of virtual worlds. The different modes of operation of A-life models and their artifacts provide a good example of how design at different levels generates different kinds of interaction and invention. A system might allow subject interaction simply in the setting of parameters before a particular system run, perhaps generating output graphically or as sound. It might permit intervention during its operation, such that the subject effectively becomes an agent participating in the evolutionary process, or it might be formed about the subject in a more complex set of relationships to effectively become an extension of the subject. Artists have also used A-life approaches to "growing" carbon-based life forms, by intervening in the genetic and environmental processes.

If, hypothetically, a simulation were absolute, that would itself transform our mode of knowledge and thus constitute invention. Baudrillard presents the canonical argument for the dangers of simulation; not by coincidence is his *Simulacra and Simulation* the book in which Neo hides his contraband in *The Matrix* (itself hollowed out to become an empty self-representation). In such an interpretation, wars are fought primarily on screen, other times and places are known through a distant lens, edited and manipulated. The here and now, represented in the same way, becomes at best undistinguishable, at worst less-than-real. In fact, of course, such factual-historical and anthropological misrepresentation is far from new; one might even interpret aspects of religious dogma as the manipulation of cosmological self-image. What is interesting is that the technologies of apparent immediacy are no more an absolute guarantee of objectivity than the mythologized reports of ancient battles, received months after the event. Baudrillard sees three levels of simulacrum: physical copy, mass production, and our present state of hyper-reality in which a reference "reality" ceases to be relevant; concepts of real and virtual dissolve. Recent theorists pursue the implications of this "desert of the real" in respect of the interpenetrations of cultural and political behaviors.

Simulation becomes simulacrum at the point when the subject no longer questions the material reality of experience. In William Gibson's novel *Neuromancer* such experience is likened to hallucination, for example. Such a metaphor points to the crucial role of consciousness. The simulacrum only really obtains when consciousness cannot or does not distinguish. Science fiction is replete with borderline cases. Yet crucial aspects of simulation function appropriately outside this state. Flight simulators present an example. Faced with an emergency, the subject's physical emotional responses reflect those of an actual situation sufficiently for the exercise to be meaningful without the pretence of "reality." The relationship with a simulation known *not* to be real is fascinating, and points to the crucial role of the relationship of the simulation with the subject – that is, the relationship is always interactive to a degree, regardless of apparent physical intervention. The simulation model of certain computer games would appear to present an authentically new paradigm – one deriving from the cultural diffusion of concepts from ecology – in that an environment has to be maintained in balance. This contrasts with the drive to imbalance of earlier games using metaphors from war (chess) or economics (*Monopoly*). Additional levels of cultural simulation can be seen in computer games that seek to recreate not the apparent reference experience but the depiction of that experience in another form – for example, wargames that simulate not the experience of war but its representation in film. This points an interesting cultural phenomenon: it seems that engagement with virtual environments relies to some extent on prior experience and conceptual models. As with film (or any other art form), interaction with virtual worlds can serve to reify preconceptions as much as to engender invention.

Interactive Aesthetics

Material and virtual realities are mixed the aesthetic concept of *critical fusion*. It has been called a "telegraphic art," an art produced by action-at-a-distance in space or time. One defining behavior of telegraphic art is its relationship with memory: rather than searching or indexing, telegraphic art can produce emergent memory or *anamnesis*. New media are by their nature programmable. Generative art produced by autonomous machine behavior might appear to stand in opposition to interactive art, an aesthetic mode in which the viewer develops an instrumental and changing relationship with the work. However, the distinction is not so clear; the process of invention is still fundamental at the stage of design (and perhaps of perception), and an interactive work based on some form of simulation or model also displays a degree of autonomous behavior. Key issues in interactive art include kind of experience, mode of engagement, phase of involvement, and viewpoint of evaluation. The engagement process can be articulated in terms of stages of adaptation, learning, anticipation, and deeper understanding. The concept of play is frequently used to understand the nature of involvement. In all cases, the machine behavior has to engage on some level with human behavior, perception, and models; it is clear that technological art must develop together with research in cognition. The close relationship between artistic and scientific research and the role of collaborative work have transformed the nature of artistic practice.

Conclusion and Future Directions

We should consider the understanding produced through simulation as a new kind of knowledge. This is another example of the reflexive nature of the situation. Both the artifacts and behaviors observed and the resultant new concepts are emergent; ontology and epistemology are in a double bind. DeLanda proposes that we see a simulated system as of a space of possibilities with a defined structure.

What simulation and interaction afford above all is an extension in complexity, contingency, and time of the reflexive process that makes us human, that is at the root of human invention. As a medium and a context for symbolic representation, simulation represents both a means for the externalization and exploration of ideas and a mirror reflecting their potential and consequences. Invention – whether of a global grand design or of a spark of personal meaning – is the product of cycles of interaction between model and subject. To return to our starting point of creativity, it is most likely to occur in a moment of perceived resonance with *another* model.

Interactive Processes in the Form of Creative Cooperation

Anne-Laure Saives[1], Robert H. Desmarteau[2] and W. David Holford[1]

Definitions

Creative cooperation: “The term creative cooperation captures the use of extensive cooperation between incumbents and new entrants initiated (‘created’) by an innovation that leads to a search for mutually complementary assets. Complementary assets such as marketing, manufacturing, and after-sale service are often needed to ensure the successful commercialization of an innovation.

Therefore, a 'complementary innovation' destroys the existing industry structure, but instead of destroying the incumbent firms with it as in the Schumpeterian model, it results in an industry structure of extensive cooperation between incumbents and new entrants firms that allows for a symbiotic coexistence in a newly defined industry" (Rothaermel 2000, p. 150).

Cooperation: Cooperation implies a relational system of organizations working together toward a common purpose. "A continuum moving from cooperation to coordination to collaboration moves generally from low to high formality" relationships between stakeholders of the system (Reilly 2001, p. 55).

Creative response: One can speak of "adaptive" responses when firms, in the face of major changes within their environments, respond by simply readjusting their existing practices. Conversely, "creative" responses (a) mobilize practices which are situated "outside of existing managerial practices" (McCraw 2007, p. 474), (b) cannot be planned or possess a nondeterministic trait, (c) depend on the specific leadership of individuals, (d) permanently change economic and social situations so as to create new environments, that is, affect the behaviors of other companies or a whole industry at large, independent of the size of the innovating firm in question.

Creative cooperation practices: Creative strategic management practices of firms (i.e., dynamic capabilities) resulting in creative cooperation and complementary innovation.

Knowledge-based economy: An economy in which knowledge and human cognition take a central role in the production process (Castells 1996; Rifkin 2000). According to Foray (2000), today's knowledge-based economy is characterized by a *marked increase* in knowledge externalities as well as by a *growth in the arena for change* (in the sense of activities dedicated toward innovation) within economic activity. During the past three decades, this new economy has imposed itself across massive investments in both production and knowledge transmission (research and development, education systems, patent acquisition and patent development systems, etc.), as well as by the advent of new information and communication technologies (Foray 2000).

Network-firm: Within the context of the knowledge-based society, organizations are comprised of internal networks, often non-hierarchical in nature, with a multitude of individuals, groups, teams, and communities which are dynamic and interconnected across formal and informal mechanisms. These organizations are, in turn, interconnected with other organizations within alliance networks and industrial, geographical, or sectorial clusters of activities. Hence, the network-firm (Sérieyx and Azoulay 1996) is particularly well adapted to a global and complex environment characterized by the interdependence and dynamism of technologies, products, or services. Such an environment calls for collaboration throughout the organization as well as around it.

Defining Creative Cooperation Through Creative Collaboration Practices

High-technology-intensive industries involve high degrees of collaborative practices whereby interfirm relationships, as well as the cooperative innovation management practices that accompany these, are constantly changing. The evolution of the biopharmaceutical industry is an emblematic case in point of how science-driven industries in this age of the knowledge-based society are continuously transforming. Here, with the acknowledged consecration on the necessity of biological sciences within the drug discovery process (Cooke 2003), biotech firms have become indispensible partners with the pharmaceutical industry. This entry aims to define and characterize these creative collaborative practices across an organizational re-reading on the concept of "creative cooperation" as proposed by Rothaermel (2000). This will be conducted in three steps: (a) a review on the notion of "creative response" to change as first explained by Schumpeter, (b) a synthetic review of the literature on contemporary "network-firms" within the knowledge society, and (c) an operational definition of "creative cooperation," and the specific management practices associated with this, based on theoretical and empirical literature covering the case of the life sciences sector.

The Disruptiveness of Practices Within an Innovating Context

Schumpeter (1942) used the term "creative destruction" to describe the now-classical idea of how innovation drives or stimulates capitalism. Furthermore, the firm's capacity to survive depends on its capacity to internalize this ability to innovate so as to render it as an organizational routine. In his 1939 work entitled *Business Cycles*, Schumpeter specifies that not all change within their environment engenders the same types of responses on the part of existing firms. He distinguishes "adaptive" responses from "creative" ones. Can these teachings on the art of change and the practice of innovation serve as a springboard toward describing and understanding the context of today's biopharmaceutical industry (and eventually, of science-driven industries in general)? An abundant literature on biotech SMEs shows how the dynamics of cooperation, via alliances and collaborations, is central within the industry's response to technological change (e.g., the advent of biological drugs) (Koput et al. 1996; Fetterhoff and Voelkel 2006). Rothaermel (2000) considers that the case for biopharmaceutical innovation does not engender a wave of "creative destruction" but rather entrains a "specific creative response" at the level of the industry's structure: "creative cooperation," as a symbiotic-like cooperation between incumbent firms (pharmaceutical companies) and new entrants (biotech companies), occurs with the ultimate aim of commercializing an innovation. Such cooperation is essentially motivated by the complementary assets and resources that can be achieved, which are necessary toward the industrialization process of life science inventions and innovations. Interfirm cooperation is, therefore, the preferred reconfiguration mechanism in response to a changing context. The following section of this entry aims toward helping us understand and decode this hybrid of "creative cooperation" at the organizational level.

A Look at the Evolution of "Creative Cooperation" Practices Within the Network Age

Throughout the past three decades, the conjugation of stakes related to the "knowledge-based economy" with those of the "network age" have helped lead toward the emergence of new organizational realities, and most notably, toward the multiplication of alliances and collaborations. More specifically, a number of authors have identified the network-firm (or the firm within a network) as the archetypal organizational form within biotech firms (Powell et al. 1996; Powell 1998; Baum et al. 2000; Cooke 2003; Patzelt and Audretsch 2008; Chiaroni et al. 2009). "Creative cooperation" inscribes itself within an emergent stream of theorization on network-firms and the open business model (Chesbrough 2006) within the age of the knowledge-based economy. As such, the specific literature on biotech sectors considers the locus of innovation to reside within both the internal and external knowledge exchanges by means of value networks (interconnectivity). This involves dealing with (a) uncertainties and risks related to the difficulties in measuring the feasibility of scientific projects in biosciences involving multiple research paths and multi-disciplines in required fundamental knowledge, (b) of creating new capacities for integrating the evermore tacit knowledge of scientific experts (or of that contained in patent portfolios and other intellectual properties) (Owen-Smith et al. 2002), and finally, (c) to forge long-term learning capacities for the transmission of knowledge developed over long periods by means of long-term partnerships (rather than by opportunistic "deals") (Pisano 2006). Along these lines, Baker (2003) argues that new distinctive capacities of biotech firms are to henceforth stem from the articulation of internal innovation capacities as well as from reticular capacities to detect knowledge which can stimulate innovation.

Toward an Operational Definition of "Creative Cooperation"

Based on a systemic and dynamic definition of the strategic firm, "creative cooperation" within the biotech sector, thus, involves at the organizational level (also refer to Table 1):

- A *creative strategy (and governance)*, which constantly re-questions the business model of the firm and the pertinence of its portfolio of products (or intellectual property), services, competencies, technologies, and relationships in regard to the evolution of its capacities (and of those of its partners) for transforming knowledge into assets (Durand et al. 2008).
- A *creative organization* which implies *organizational innovation* toward new partnership forms; toward the positioning of the firm within its value chain and value network; and toward transforming the ways of coordinating knowledge creation (scientific and technical) within networks by means of openness (e.g., Chesbrough's (2003) "*Open Innovation*"; or Leonard-Barton's (1998, p. 155) "*Fight the not-invented here syndrome*").

In the case of biotechs, at least four creative cooperation practices (or dynamic capabilities (Teece 2007)) have been mentioned within the literature of the past two decades, and were also described by managers of biotech firms in the Quebec case study (Saives and Desmarteau 2010; Bréchet et al. 2012):

1. *Thinking and acting in networks*: The building up of an open network of expertise and high-caliber experts so as to construct a credibility of developed knowledge by varying the locations of intervention where these independent experts bring forth the benefits of distanciation. In support of this thinking is Venkatraman and Subramaniam's (2002) argument that firms are just as much portfolios of relations as they are portfolios of capacities and activities, whereby factors toward their competitive advantage reside in economies of scale, of scope, and of expertise. Here, their key resources are tied to their position within a network of expertise such that the strategic unit of analysis shifts away from the firm itself toward a *network* of internal and external relations where the objective becomes a matter of profiting from intellectual capital. The strategic focus, therefore, aims toward transforming new *knowledge* into *products* or *services* across a *network of specialized entities* involved in a variety of innovating activities; and toward maintaining strong ties so as to coevolve with various sources of knowledge and ideas, such as universities, regional start-up clusters, companies providing risk capital, and other co-specialized firms (Floricel and Miller 2003, p. 50–506). For the firm itself, the issue is much less a matter of rendering its processes and routines inimitable than to ensure its *centrality* within the network. And if one were to pursue a research agenda on this theme, it should be noted that Biotech SMEs have relied heavily on networking with star scientists, star CEOs, or high-profile venture capitalists on their advisory boards in an attempt to signal the underlying quality of their competences and their business models, as well as to gain status and credibility. One possible research avenue would be to understand the comparative effectiveness of the different ways in which biotech firms attempt to gain such credibility.
2. *The construction of symbiotic and equitable partnerships* toward the valorization of joint intellectual assets of the firm throughout all stages of scientific discovery; and this, across the manifestation of an original organization of bidding-up the value of its knowledge and project portfolio. This new way of progressively negotiating payments and deposits reminds us of Kalamas et al. (2002) who predicted a shifting of contractual discussions between biotechs and pharmas toward much earlier in the discovery process on the basis that biotech firms have increased their power of negotiations as a result of maturing technical and administrative competencies. As such, biotech firms have become better negotiators for license and expertise networks by concluding business contracts that are based on a more equitable sharing of value spaced over time,

Interactive Processes in the Form of Creative Cooperation, Table 1 Operational dimensions of "creative cooperation" within the biopharmaceutical industry: a synthesis of creative cooperation practices

	Creative Cooperation Practices			
Dimensions	Thinking and acting in networks	Constructing equitable partnerships	Arbitrating in-house and outsourced activities	Engaging the academic toward the market
Strategy	Emphasizing external expertise to achieve credibility	Establishing lasting and reciprocally profitable partnerships (*New deal making*)	Systematically arbitrating all links within the logistics chain	Valorizing translational research *(from science to business)*
Organization (Structure, culture)	Establishing independent and varied governance instruments	Honesty and frankness within communication mechanisms based on long-term visions	Flexibility within all structural and cultural components (e.g., *the bidding-up of ideas*)	Proliferation of bridges (physical, cultural, cognitive) between science and the market

thus leading to more durable and reciprocal relationships. Furthermore, Chesbrough (2007) asserts that innovation practices are evermore conducted within an "open" mode whereby the arbitrage between in-house and outsourced activities is conducted by embracing more fully a partnership perspective. An example of such innovating practices (Chesbrough and Appleyard 2007) shows how pharmaceutical giant Merck finances and implements a research partnership network whereby the value and wealth created is more equitably redistributed. In short, Chesbrough's fundamental message is that the strategic evolution of innovating practices within today's organizational environments is (and must be) transcended across a reticular openness. Both biotech and large incumbent firms have come to realize that their respective skills are largely complementary and are engaged in a series of different symbiotic partnerships. Further research would be needed on documenting the best microlevel practices and interactions which facilitate successful interorganizational relationships.

3. *The systematic arbitrage between in-house and outsourced activities across every link of the value chain*, and this, as a result of a "knowledge on outsourcing" made possible across the control of pharmaceutical research and clinical production quality standards.
4. *The proliferation of bridges (physical, cultural, cognitive) between science and market* so as to better enable, track, orient, and valorize scientific creativity and invention carried out within universities. The fact that the collaboration between universities and companies is an important key toward biopharmaceutical innovation is not new within the literature on national innovation systems. However, how does one render it more effective and efficient? Pisano coined the term "translational research" as a form of research that "translates" discoveries and fundamental scientific concepts into specific product opportunities. It connects in a much more systematic fashion fundamental research with clinical tests, including activities such as the identification and validation of targets, the screening of in vitro and in vivo candidates, and certain first-stage clinical tests.

In this sense, companies build creative organizations across a prolific bridging between the fundamental and the applied. Several levers are effective toward this end, which include (1) the hiring of liaison agents or "knowledge translators" (better known as Leonard-Barton's (1998, p. 155) *boundary spanners*), often being biopharmaceutical managers that were formerly researchers or vice versa, who support and ensure a cultural proximity between actors so as to enable the translation of science and assure the proper circulation of knowledge between the academic and economic spheres, (2) multipartied cooperation toward the bringing together of science and the market, and finally (3) the proliferation of opportunities toward the creation of knowledge across numerous technology platform

I

applications within firms which also favor this science/market reconciliation.

Further research and studies, again at the micro-organizational level, could be conducted with regard to which types of bridges with academia have been the most effective toward inducing technological returns for the bridging firms; or again, on how different firms have interfaced with academia.

Conclusion and Future Directions

Creative cooperation is a new force toward the reconfiguration of innovating industries. It involves cooperative practices within the context of change and for which it possesses all the characteristics of "creative response" as defined by Schumpeter.

In today's age of open innovation, the biopharmaceutical sector is a probative example. In practice, the biopharmaceutical industry put forth creative responses to major technological changes and to increasing complexities which the life sciences have introduced within the drug discovery process. Starting from the "research workshop," a number of biotech VSE/SMEs have become partners in "creative symbiosis" with their peers, and more importantly with large pharmaceutical companies. The age of the bio-pharmacy is in full expansion whereby four creative practices have brought forward real signs of renewal within the art of cooperating, that is, of "creative cooperation": network-based credibility; equitable and symbiotic partnerships; network flexibility or arbitrage between in-house and outsourced activities; and finally, the proliferation of bridging between academia and market.

These four creative practices are based on new management principles, in part inspired by the Japanese approach (Nonaka and Takeuchi 1995) as well as more recent theory on governance. Indeed, *selective openness* (toward a network of expertise, toward commercial, production, or academic research partnerships), *complementarity and redundancy* (of information for decision-making across various governance instruments; of commercial partnerships for the proliferation of opportunities in innovation; of knowledge belonging to the committed parties involved in "translational" research), and *autonomy and equity* (of information belonging to independent experts; of control mechanisms for logistic chains; of knowledge sharing within "translational" research) seem to be the master words of future academic research and firms' practices of "creative cooperation" within the age of *open* innovation.

Multidisciplinarity; Transdisciplinarity

Introduction

This entry is based on findings obtained from a cross-sector analysis of successful interdisciplinary innovation in the UK, sponsored by NESTA, the UK National Endowment for Science, Technology and the Arts, and conducted at the Centre for Research in the Arts, Social Science and Humanities (CRASSH) at Cambridge University.

Public policy for scientific investment emphasizes the need to support interdisciplinary research. The Royal Society report (2009) "The scientific century: securing our future prosperity" is typical, recommending that science and innovation can become "better aligned with global challenges" by reforming the UK research funding and assessment to support and reward interdisciplinary work: "Connections with and between the natural sciences and the social sciences, arts and humanities will be increasingly vital for innovation" (Royal Society 2010: 40). However, documents such as these are unclear with regard to the precise processes and mechanisms, or even the personal dynamics, through which such collaborative innovation occurs.

While the notion of interdisciplinarity has gained popularity due to a general association of innovation with processes of boundary crossing, collaboration, and the integration of different kinds of knowledge in general policy literature (e.g., in the UK see Council for Science and Technology 2001; Cox 2005; HM Treasury 2004), there is scant attention paid in this literature to what interdisciplinary research might consist of in practice. In academic accounts, epistemologically grounded frameworks for identifying and categorizing interdisciplinary research have been useful for the purpose of measuring interdisciplinarity in practice (e.g., Huutoniemi et al. 2009). However, they are limited in what they can tell us about the social aspects of collaboration between people to produce knowledge (Lattuca 2002) and, importantly, the critical role of the leadership of interdisciplinary teams (Brewer 1999). There is then a need to improve understandings of the actual processes of knowledge production as they occur on a day-to-day basis in order to avoid abstracting interdisciplinarity as an index of innovation and end in itself (Strathern 2004).

Definition: Family Resemblances in Collaborative Experience

The following analysis is informed by an anthropological perspective – that forms of knowledge do not exist outside of the specific social relationships in which they are constituted and reproduced (e.g., Brown and Duguid 2000; Chaiklin and Lave 1993; Engeström 1999; Latour and Woolgar 1979). Rather than reviewing policy recommendations and epistemological accounts of interdisciplinarity (of which there are many), the objective here is to describe interdisciplinary innovation in terms of the experiences of those who are recognized as achieving it.

The scope of the analysis was determined by a reputational survey of those considered by their peers in the UK to be exemplary practitioners of interdisciplinary innovation. Several rounds of "snowball sampling" asked leading practitioners which of their peers should be considered as exemplars, eventually making contact with 473 nominees from a wide range of disciplines. A second research phase involved a series of in-depth reflective workshops, to which a sample of these exemplary practitioners was invited as "expert witnesses." This phase was phenomenological in the sense that it focused on comparing personal reports of the experience of collaboration within the context of a professional career (Blackwell et al. 2009). The survey and workshop phases were supplemented with further site visits and interviews, and informed by reflection on the work of the Crucible network for research in interdisciplinary design, which has supported participants in more than 100 interdisciplinary projects over a period of 10 years.

The goal then here is not to construct a typology of interdisciplinarity or even a catalogue of what might be considered innovative practices. Rather, the purpose is to elicit the experiential aspects of working across perceived boundaries in the production of knowledge. Participants for the study were recruited from academia, the corporate, and public sectors. Workshop transcripts and survey responses were finally analyzed by a research team that was itself interdisciplinary and cross sectoral, comprised of both academic researchers and commercial strategy consultants with backgrounds in design, social anthropology, engineering, and economics. The result has been to treat the notion of interdisciplinarity as a "family resemblance" (Wittgenstein 1958). That is, not to assume practices categorized as "interdisciplinary" necessarily share a common set of properties, but rather are characterized by overlapping similarities in appearance.

In the remainder of this entry, these similarities are discussed in order to provide an introduction to the effective practices of interdisciplinary innovation identified here.

The Importance of Individual Leadership

While this analysis confirms previous studies of interdisciplinarity that emphasize the value of teams, of collaboration between different disciplines, and the ability to cross boundaries between different kinds of knowledge (e.g., National Academies 2005), it has also highlighted the essential role of the leaders of these enterprises. The majority of individuals that were identified from the reputational survey as exemplary interdisciplinary practitioners were managers and facilitators of projects. In this respect, the importance of key individuals to innovations arising from interdisciplinary collaboration cannot be underestimated. These individuals cannot be seen simply as charismatic leaders whose authority rests on their personal qualities, although the success of the projects they led was certainly reliant on the relationships they engendered between project members. What they worked to achieve was a personal engagement with the aims and goals of the project itself. In the sense that this does not involve normative values propagated through commitment to or faith in the leader, the authority of their leadership, while not impersonal, was depersonalized.

Narrative Construction of Events

Many individuals recognized as innovative interdisciplinary practitioners share an ability to narrate their projects to different audiences in ways that spoke to the relative value placed on the enterprise by interlocutors, negotiating differing needs and demands, and communicating in different registers to a variety of stakeholders. Whether this was representing the importance of research to funders, speaking to clients, or presenting arguments for policy, these leaders framed the narrative construction of the value and benefit of project goals to best communicate their goals and ideals to a variety of audiences. To be able to inspire and motivate diverse groups of disciplinary practitioners required framing project goals in ways that could appeal to all according to their own personal values and ideals. Researchers might, for example, be involved in a project because of the relative value placed on research outcomes – whether profit or the greater good, for career advancement, or the desire to broaden one's own intellectual horizons.

For some individuals, project goals might be subordinate to their personal aims, but the broader project narrative was able to accommodate and provide direction to various modes of personal and professional engagement. Meanwhile, project leaders might have to articulate the wider societal value of a project to a research funding body, framing arguments for its value within institutional and governmental funding priorities.

Shared Values

The importance of developing a sense of shared values and commitment to the research agenda was a theme frequently emphasized by expert witnesses. In some cases, this was a long-term commitment to an ideal, as in the work of the "Equator" consortium, a 6-year technology design initiative supported across eight UK universities to cultivate a community with diverse skill sets based in fundamental, curiosity-driven research. Consortium managers sought to create an environment in which teams could work together such that individuals derived their own value from the project while working within the framework of the consortium's research agenda. Mechanisms of appraisal were not merely measures of performance but placed key emphasis on critical reflection. This was a shared process of introspection that was seen to be a vital aspect of the management of the project, an egalitarian management style that allowed for people to engage with the project on their own terms and, importantly, implied a relationship of trust between all parties.

Commercial organizations are more typically concerned with incremental innovation that builds on existing products and business models. However, the egalitarian management ethos of commercial consultancy TTP bears a remarkable resemblance to that of successful interdisciplinary academic projects. TTP does not sell interdisciplinarity to its clients – clients already have a generalist understanding of their own business and come to TTP for specialist skills, not skill in interdisciplinarity. The core business of TTP relies on their being able to "sell" currently available staff as universal specialists – specialists in any problem that might present itself. The business cards of TTP staff do not reveal any specialization but present the holder as a representative of the TTP ethos. It is therefore essential that the company be managed in an egalitarian way, emphasizing social networks, collaborative personal styles, and matrix structure rather than strict disciplinary boundaries. There is then a strong sense of individual autonomy and flexibility in bringing people together in problem-solving teams in which knowledge and expertise might be combined in an ad hoc basis.

Polestar Leadership

The director of an interdisciplinary university research center for nanophotonics had consistently found that despite shared objectives, the most exciting discoveries from his work were not those expected at the start of a project. He gave highly skilled staff the freedom to pursue questions that interested them and noted the importance of motivating such a team through shared purpose. However, the tension between this leadership "from behind," and conventional expectations of leadership by vision and example, led him to describe his management style as neither from in front or behind but rather "sideways management," developing the metaphor of the "polestar," a long-term vision or goal that served as a common motivator to which multiple ideals and values might be oriented as a desired, ultimate research outcome.

Polestar leadership extends beyond the common notions of either intellectual leadership within an established tradition or of managerial coordination of activities within a project. It entails being able to recognize opportunities for alternative outcomes and being skilled at harnessing excitement among members of a team as it arises. This approach to innovation presents a number of challenges and paradoxes for managers and research sponsors. Few organizational structures are able to accommodate radical changes in the goals of a project, and it is hard for investment decisions to be made without articulating explicit outcomes that can be evaluated in advance. Although funding review and assessment procedures often distinguish between these intellectual ("scientific") and practical ("management") aspects of a research enterprise, the leadership of an interdisciplinary enterprise is not well characterized by either. Instead, leadership is manifest in the promotion of shared values and commitment to a community who share them. That community draws in, not only those directly employed in an enterprise but a wide variety of stakeholders, sponsors, and publics. The "polestar" vision that the interdisciplinary leader promotes and exemplifies does not rely on the knowledge structures of an established field (that would be a disciplinary research project) but on the potential to develop new knowledge and practices within a community that will value them.

Unanticipated Outcomes

The most valuable innovations arising from interdisciplinary research are often not anticipated at the outset, because successful interdisciplinary outcomes involve not only new answers but also new questions. Whether in contexts of professional problem-solving or open-ended curiosity-driven research, innovations arise in ways that cannot be foreseen at the outset of a new interdisciplinary enterprise, whether assembling a commercial team or commencing a research project. Most professional disciplines, or kinds of academic knowledge, bring with them ways of approaching a problem. This often involves restating the problem in a way that is compatible with the knowledge of the discipline – for example, the problem of obesity might be described by a physicist as being essentially one of "energy balance" – the result of people consuming more calories than they expend in exercise. However, the definition of a problem in disciplinary terms immediately excludes insights of other disciplines. Obesity might alternatively be described as a problem of social structure, to be addressed by investigating the fact that it is the wealthy and powerful who are obese in some cultures, but the poor and excluded in others. Neither formulation of the problem offers any direct assistance to the other.

Questions arise from the particular values of a discipline (in the obesity example, physicists are primarily interested in closed systems, while anthropologists are primarily interested in societies). It is only after significant periods of time or with specific attention and focus that collaborators from different disciplines are able to adopt each other's values to an extent that problems can be reformulated in radically different ways. Once this has been achieved, the ecology of interdisciplinary knowledge provides the context in which newly discovered problem formulations can be developed and exploited.

Ontology Versus Epistemology

It is often suggested that the main barrier to interdisciplinary collaboration is that disciplines develop their own jargon, such that those from outside cannot understand terminology. To a somewhat trivial extent, this may be true, although most experts are well aware of the technical terms and acronyms used in their field, and are easily able to adjust their discourse when speaking to nonspecialists. However, on the basis of findings of the study, it can be seen that the main obstacle to interdisciplinary innovation is not the need to find a "translator" or to develop a shared vocabulary. On the contrary, people from different disciplines seem to talk at cross-purposes because they are trying to achieve different things. They have difficulty understanding statements not because the words are unfamiliar but because the intention presumes different core values. In this respect, the issue of commensurability can be perceived as one of the ontological grounding of particular positions and perspectives rather than misunderstanding as a consequence of epistemological differences.

Many of the expert witnesses took the opportunity to reflect on their own personal histories and compare those histories to the attributes that they valued in collaborators, students, and employees. Individuals often seem to become "imprinted" with particular disciplinary styles as a result of early life experiences, especially first professional experiences and (for academics) early experience of higher education. This is not so much a matter of specific knowledge or disciplinary vocabulary (although vocabulary remains a consideration). Rather, it is a difference in ways of thinking, manner of approaching a problem, or the way in which goals are conceived. Expert witnesses referred to this obliquely or in passing as their "home discipline" or "native discipline," somewhat as though it were a first language, perceived ethnicity, or a country of origin. The literature on interdisciplinarity tends to assume that disciplinary knowledge is explicit rather than tacit, can be imparted via formal education, and can be articulated when necessary for comparison to other disciplines. It was found that those who work in interdisciplinary contexts, including among people who themselves have moved among many disciplines, suspect that their first academic training has left permanent traces that influence their intellectual style, wherever they have subsequently found themselves. The existence of personal and tacit disciplinary styles may form a natural limit on pace of disciplinary change, which could only be generational, if it is primarily the result of early career experiences. Interdisciplinary enterprises construct new communities that are composed of individuals who share willingness to step outside the knowledge boundaries within which they are trained. It is the diversity of the individuals that provides opportunities for unanticipated insight and innovation.

The Public Value of Interdisciplinary Innovation

While there are many components of innovation, encompassing both creativity and exploitation, this cross-sector analysis clearly brought to light the diverse targets for innovative activity in different sectors, encompassing the development of products or services for commercial exploitation, curiosity-driven academic research, problem solving of various scope, and the creation of social value through specific intervention. These may be summarized as follows:

- Commercial exploitation of new ideas, technologies, and processes is a primary concern of innovation, enshrined in definitions from business and economic policy bodies. The objective is to create, develop, implement, and sell products or services. To this end, commercial innovation is likely to be purposeful and managed. The result may be incremental – a minor enhancement of an already marketed or used product, service, or process. More spectacularly, commercial innovation may be radical, characterized by a greater degree of novelty, perhaps with a capacity to disrupt previous business.
- Curiosity-driven research is most often found in the academic sector. It seeks knowledge and new insights, creating unifying theories and models that describe a new understanding of perceived phenomena. Those phenomena might be equally well in the domains of science, of humanities, of arts and creative industries, of sociology, or of politics and policy. The aim is insight, not necessarily with the intention of action or intervention.
- Problem-solving activity is directed toward identifying some new approach that solves a situated problem. Here, there may be a problem of agreed boundaries – what is the scope of the problem and what kind of solutions are expected. The objective is an explicit intervention to solve or ameliorate the problem. In this context, success can be characterized by the extent to which the problem is resolved. New knowledge or new insights are a convenient but nonessential by-product.
- The enhancement of social value is another form of innovation, whether the health of a population or the social cohesiveness of a community. Here, the development may lie in the creation of a new intervention, or it may lie in the process by which change was exercised, for example, in an artistic endeavor that engages with marginalized parts of society.

So what is the value proposition of interdisciplinarity in these examples?

In the areas of problem solving or of the commercial development of a new product, service, or process, the objectives may be tightly defined. Here, the explicit intention of interdisciplinarity is the use of different skills or analytic perspectives – to frame the problem or opportunity, to bring to bear different repositories of knowledge, and to use the insights so gained to achieve a richer solution. It is believed that interdisciplinarity increases the likelihood of a radical solution to the problem or realizing the commercial opportunity. This requires more than the simple combination of professional skills to carry out routine business (as when a nurse, an anesthetist, and a surgeon work together in an operating theater). Radical innovations combine people and skills in unexpected ways, leading to results of different kinds to those that professional training is focused on.

In academic, curiosity-driven research, there may be new insights created by the new conjunction of differing interests and perspectives. In such cases, the different disciplines combine in ways that serendipitously stimulate breakthroughs. Indeed, in the pure research area, there is increasing enthusiasm for the unpredictable novelty and potentially radical nature of the results of interdisciplinary teams. Such research can also result in breakthrough opportunities for later commercial application or as foundations for innovative cultural and social action. However, such forms of exploitation often occur at a distance or a long time after the initial research investment. In these cases, it is not usually the goals of the original research project that result in long-term benefits. Instead, it is the creation of an "ecology" within which such exploitation can happen, where there is an intellectual and skills capacity of highly trained people, and these people have experience of working within other disciplinary contexts as well as networks of contacts giving them rapid access to other disciplinary knowledge.

A key policy concern at present is how one can prioritize and evaluate research activity that is supported with public funds. It is essential that value be demonstrated to the public and that those receiving public funds be held accountable for their use of funds. However, a paradox for responsible stewardship is that, while public funds should be directed toward known outcomes of public benefit, interdisciplinary research has essentially unknown outcomes. "Safe" or "incremental" research is considered less deserving of public support, yet it continues to be prioritized by mechanisms that assess performance within established categories. In order to maintain quality of academic enquiry, it is necessary to establish mechanisms that recognize and reward determined curiosity, willingness to step outside boundaries, and reflective development of personal and community practices.

Conclusion and Recommendations

Interdisciplinary innovation is primarily a social phenomenon, associated with the processes and experiences of crossing social boundaries, rather than an epistemological phenomenon as often implied by metaphors of "cross-fertilization" or "filling gaps" in human knowledge. Social structures are certainly associated with knowledge structures – every social group acquires and organizes its own characteristic body of knowledge. However, there is no reason to believe that academic disciplines as custodians of knowledge are any different from other social groups. Individual departments within large public organizations and corporations are equally likely to acquire, structure, and preserve special bodies of knowledge within which to define relative expertise, seniority, or originality among colleagues.

The instrumental agenda for policy advocates of interdisciplinary innovation is that new problems faced by organizations may need to be addressed by using knowledge from elsewhere. Of course, many routines and conventionally applied problems also include aspects that are well-defined as requiring a variety of specialist expertise (e.g., the design of a house may involve an architect, structural engineer, quantity surveyor, construction lawyer, etc.). Problems of this kind are ubiquitous but are not regarded as being "interdisciplinary" because of their conventional nature. The term "multidisciplinary" is often suggested as a means of distinguishing between routine collaboration and the innovative problem solving associated with interdisciplinarity.

When addressing a new kind of problem – one that requires an innovative solution – it may be clear from the outset that more than one kind of knowledge will be necessary to construct a solution. However, because the appropriate relations between disciplines have not yet been formulated, it will be necessary for collaborators to cross boundaries when negotiating a solution. Furthermore, even large organizations are unlikely to accurately forecast the problems they will face in future; in which case, the formulation of responses to future problems will require knowledge resources from outside the organization boundaries. The social need for crossing boundaries in interdisciplinary innovation is therefore a natural consequence of organizational life. Interdisciplinary boundary-crossing experiences are associated with innovation because they arise from novelty and from the need to prepare for the future.

This entry focused specifically on the personal experiences of those people who have gained a reputation for effective work in interdisciplinary innovation. These findings should be seen as being complementary to studies of organizational structure and to studies of the business and economic consequences that result from innovation.

The essence of interdisciplinary innovation is the experience of teamwork, where each member encounters people with different skills and perspectives to their own. However, those different kinds of knowledge are associated with boundaries. As noted above, knowledge is maintained within organizations – usually by the group of experts who are at the core of any organization and who maintain and develop its core knowledge. In many organizations, and especially academic disciplines, recruitment, induction, and advancement within the organization are often managed in terms of the extent to which an individual has acquired its core knowledge. Within traditional career structures (and again, academic disciplines are archetypal), the ultimate benchmark of expertise is the amount of knowledge that a person might reasonably acquire in a lifetime. Organizational knowledge boundaries, whether government departments or academic disciplines, are likely to be set in accordance with the lifetime capacity of the experts at the center of the organization.

Policy rhetoric advocating interdisciplinarity often denigrates the "silo," employing a metaphor that suggests knowledge would be better released into locations where it can be applied. However, the findings do not suggest that boundaries can simply be ignored or removed. Boundaries are essential to the social construction and maintenance of expert knowledge. The challenge of interdisciplinary teamwork is to find effective ways of working across those boundaries without disrupting them. In this respect, incommensurability might be perceived potentially as an enabler or driver for interdisciplinary engagement. The aim here is the facilitation of cross-disciplinary engagement – not to establish the ultimate veracity of a particular truth, model, or account of events but to generate the possibilities for new insights via engaging with those oriented practically in and perceiving the world differently.

There are, of course, obstacles facing those who wish to work outside their established organizational boundaries. Many disciplines have grown together as social groups precisely because of a set of shared values that motivated the creation of the discipline. It takes a wide range of skills, including substantial personal leadership ability, to manage a team of people who hold different values. In order to be effective interdisciplinary innovators, the team must develop shared values and culture, probably over a period of many months, leading to years. The leader of an interdisciplinary enterprise must create conditions to enable, encourage, and inspire that process. Furthermore, the leader must be able to recruit resources sufficient to maintain the team within an inherently uncertain environment.

The most valuable outcomes from an interdisciplinary enterprise were not anticipated at the outset. This is unsurprising, because future problems, or even novel problems that cross today's boundaries, are problematic because of the way they defy description in disciplinary terms. It is in the nature of such problems that they cannot be described or characterized in established terms. The leader must therefore be able to attract resources, maintain them over a considerable period of time, and be a competent manager of uncertainty and risk, while also being a skilled enabler of serendipity – providing the capacity to recognize and profit from unexpected events.

Introduction

From the beginning the discourse on interdisciplinarity (ID) was "a discourse on innovation in knowledge production" (Weingart 2000: 30). Its basic objective has been to make science and higher education more responsive to the complexity of life-world problems and more relevant for the public good and the legitimate needs of the society. The criticism leveled in the name of ID against the disciplinary organization of the traditional universities was summarized under the oft-cited catchphrase "Communities have problems, universities departments" (CERI 1982: 127).

The term interdisciplinarity or interdisciplinary research (ID) can be defined in two distinct but intersecting ways: interdisciplinarity means either the collaboration of researchers trained in different fields of knowledge or the integration of different concepts, methods, and data from two or more different disciplines, no matter if this interdisciplinary integration is achieved by an interdisciplinary research group or by a single researcher.

However, an interdisciplinary *integration* of different knowledge fields requires at the same time new *divisions* of knowledge, since the definition of specialized topics between disciplinary knowledge fields is essential as interdisciplinary foci for any collaborative research across disciplinary boundaries (Weingart 2000: 36). The dream of an all-encompassing unity of knowledge belongs to the past, an ID integration of different knowledge claims can be reached only in a variety of local syntheses between research findings of carefully selected disciplines.

History of the Concept

The Organization for Economic Co-operation and Development (OECD) was in the 1970s one of the first organizations promoting interdisciplinarity with the aim to strengthen universities "which in the future ought not be the servant but the conscience, the analytical mind and the driving force in society" (Briggs et al. 1972: 288). Scientific research should become more relevant for the economic as well as the societal development of modern societies. It was the time of the starting discourse about "knowledge societies," which found 1973 its prominent advocate in

Daniel Bell's book "The Coming of Post-Industrial Society: A Venture in Social Forecasting" (Bell 1973).

Nevertheless, the concept of interdisciplinarity itself was from the beginning about the nuts and bolts of the day-to-day research in industrial laboratories and at universities. In contrast to the discourses on knowledge societies (Bell 1973), Mode-2 research (Gibbons et al. 1994; Nowotny et al. 2001), the Triple Helix Model (Etzkowitz and Leydesdorff 2000), and on Quadruple Helix Innovation Systems (Carayannis and Campbell 2012), the discourse on ID research does not presuppose any macro theories about societal developments or all-encompassing speculations about historical developments. Although to make a well-founded case for doing ID research, ID supporters are often relying on one of these theoretical forecasts and analyses of modern society. The concept of ID itself just asserts that for the solving of certain societal problems, researchers have to transgress disciplinary boundaries and engage in ID collaborations. The competence to engage in ID research is seen as an indispensable craft for modern societies: if someone wants to cope with the complexity of the modern world, the competence for ID research is a vital skill to be learned. Therefore, ID is basically a discourse on the how-to-do of successful disciplinary-boundaries-transcending scientific research (Arnold 2009).

As a matter of fact the term interdisciplinarity became since the 1980s a prominent key tender term in many newly established research funds aiming at more social or environmentally relevant scientific research (cf. Hackett 2000; Krull and Krull 2000). Soon ID was implemented in university curricula as well, teaching students – with an eye to their prospective field of work and to their role as responsible citizens in a modern democracy – to tackle with complex life-problems by the use of different scientific methodologies in a professional way (Kockelmans 1979; Frodeman et al. 2010: 345–403).

In 2004, the EU research Advisory Board circulated recommendations for interdisciplinarity in research (EU Research Advisory Board 2004), in 2005 the Finnish Academy of Science followed with a study promoting ID (Bruun et al. 2005), whereas in the USA the National Academy of Sciences together with the National Academy of Engineering issued a report evaluating past achievements of ID research and recommending ID as an important and successful way for innovations, stating that:

> "many of the great research triumphs are products of interdisciplinary inquiry and collaboration: discovery of the structure of DNA, magnetic resonance imaging, the Manhattan Project, laser eye surgery, radar, human genome sequencing, the 'green revolution,' and manned space flight." (Committee on Facilitating Interdisciplinary Research et al. 2005: 17)

Furthermore – as the report adds (ibidem) – many of today's "hot" research topics are interdisciplinary like nanotechnology, genomics, bioinformatics, neuroscience, conflict, and terrorism, as well as research in areas like disease prevention, economic development, social inequality, and global climate change.

Aims and Limits of Disciplinary Research

The First Obstacle for ID: The Disciplinary Organization of Science

Although the term *disciplina* was used as early as in the Middle Ages for the ordering of knowledge within universities, the invention of the modern scientific discipline (here and in that which follows including humanities and the social sciences) dates back to the nineteenth century and the invention of the modern research university in Berlin. Since then, disciplines are the basic units of differentiation within the system of science and the higher education system as well. They were established together with the emergence of modern scientific communities and the first scientific journals with their standardized ways of scientific communication with colleagues and specialized readers only. Amateur scientists, which were in the eighteenth century as educated public still an accepted part of the scientific community, became now excluded (Stichweh 1984, 1992). It was the arrival of what Thomas Kuhn later famously called "normal science." Its chief characteristic is its close alignment to approved "paradigms" (or what Kuhn later called "disciplinary matrix"), setting narrow limits for new methods and research questions:

> "Perhaps the most striking feature of the normal research problems [. . .] is how little they aim to produce major novelties, conceptual or phenomenal. [. . .] To scientists, at least, the results gained in normal research are significant because they add to the scope and precision with which the paradigm can be applied." (Kuhn 1970: 35 f.)

"Normal science" is nothing more or less than a kind of "puzzle-solving," since each paradigm identifies perplexing puzzles, suggests paths to their solution, and reassures that not scientific genius but the hard work of scientific practitioners will be sufficient for success (Kuhn 1970: 179). In other words, paradigm-led normal science is aiming at perfection, that is, incremental innovations, to find better answers to existing questions. Radical innovations, like paradigm shifts, are within the disciplinary organization of the sciences the exception and not the rule.

The Second Obstacle for ID: The Variety of Epistemic Cultures

However, it is not merely the disciplinary orientation of normal science which impedes ID collaborations. Even, should the need for an ID collaboration be acknowledged by scientists, cooperation may become difficult since different epistemic cultures are often in conflict when it comes to questions like: What are sound methods? How to measure quality, but also more subtle differences like differences in social values making day-to-day collaboration within interdisciplinary teams again and again vulnerable to conflict and fundamental misunderstandings (Arnold 2004; Becher 1993; Knorr-Cetina 1999)? Furthermore, different disciplines are often not considered as of equal rank and status within the disciplinary system:

> "[T]he interdisciplinary team is an open rather than a closed system. [. . .] Interdisciplinary teams in this respect are status systems that reflect external hierarchies and disciplinary chauvinism. [. . .] [T]he status system of a team will tend to follow the status system of the world outside the team if there is no strong alternative organization, though even a strong organization cannot eliminate status ambiguity and clashes in career goals, professional styles, and epistemologies." (Klein 1990: 127, cf. Lamont 2009)

The different disciplinary contributions by themselves, therefore, often do not add up to a coherent whole, that is, to an integrated research result, since they adhere to quite different epistemological principles or are the product of diverse research routines.

The Third Obstacle for ID: The Claims of Professional Jurisdiction

For experts (inside and outside the universities) to accept that other experts can contribute with their methods and disciplinary knowledge as much as oneself to the solution of a problem implies in the end to give up one's own disciplinary claim for exclusive professional jurisdiction over this problem field. Hence, interdisciplinary cooperation can conflict with professional aspirations to prevent competing scientific communities and professions from interfering in one's own field of expertise:

> "A jurisdictional claim made before the public is generally a claim for the legitimate control of a particular kind of work. This control means first and foremost a right to perform the work as professionals see fit. Along with the right to perform the work as it wishes, a profession normally also claims rights to exclude other workers as deemed necessary, to dominate public definitions of the tasks concerned, and indeed to impose professional definitions of the tasks on competing professions. Public jurisdiction, in short, is a claim of both social and cultural authority." (Abbott 1988: 60)

For that reason the demand for ID cooperation is seen especially by dominant disciplines and professions as infringement of their jurisdictional claims for exclusive responsibility; to admit the relevance of the expertise of other disciplines for a particular research project is like accepting a kind of defeat inevitably undermining the social and cultural authority of one's own disciplinary knowledge and expertise. The authority of jurisdictional claims is important for disciplines not least because jurisdictional claims, when acknowledged as legitimate, are directly translatable in further research funding and job opportunities on the labor market for their graduates (Turner 2000).

Innovations: Crossing Disciplinary Boundaries

Trading Zones: The Value of Multidisciplinary Perspectives

Although multidisciplinarity is not ID as such, since a multidisciplinary perspective on an issue is per definition not aiming at an ID *integration* of the different perspectives, multidisciplinarity can become an important, if only preliminary stage in the process of designing ID projects and research programs. Putting a multiplicity of disciplinary approaches together can provide a multifaceted outlook revealing the complexity of real-world problems pointing out the need for a truly interdisciplinary solution.

Peter Galison developed the concept of disciplinary "trading zones" in his attempt to describe the requirements of a difficult, but in the end successful multidisciplinary collaboration between engineers and physicists with different theoretical background in the development of particle detectors and radars (Galison 1997: 781–844; Gorman 2002). These different groups had not only to find an agreement over those objectives, the design of the particle detector had to achieve: to communicate their ideas they had to invent a common ("creole") language transcending their disciplinary idioms to explain their research programs and to share their disciplinary expertise commonly.

> "The point is that these distinct groups, with their different approaches to instruments and their characteristic forms of argumentation, can nonetheless coordinate their approaches around specific practices. [. . .] Note that here, as in any exchange, the two subcultures may altogether disagree about the implications of the equivalences established, the nature of the information exchanged, or the epistemic status of the coordination." (Galison 1997: 806)

Unlike ID, which aims at a comprehensive integration of disciplinary knowledge domains and shared epistemological models, *multidisciplinary* co-operations can differ about theories and their understanding of the collaboration, since they do not necessarily need unanimity and a common perspective.

Such "trading zones" between different scientific and societal groups are public spaces where the need for certain interdisciplinary co-operations and projects can become pressing and where innovations through brokering of ideas, methods, and theories are becoming more likely to emerge. Therefore, as Lester and Priore have argued, certain institutional and organizational arrangements to encourage this kind of brokering and trading of multidisciplinary information with the help of public domains have to be established and maintained within an innovation system. Particularly the modern research university with its diversity of scientific disciplines under one organizational roof is well-designed for this special purpose: to provide a kind of "sheltered space" that can sustain public conversations between a variety of scientific specialists and societal stakeholders:

> "To a much greater degree than in business firms, the disciplines dominate [within the university] the conversations; but the diversity of perspectives is greater than in firms because academic discussions draw in a broader range of participants [. . .]. Even accounting for the restrictive influence of the disciplines, a university, far more than a firm, is a public space." (Lester and Priore 2004: 166 f.)

These multidisciplinary public conversations within the universities (and at other places) give rise to "interpretative communities" enabling actors with different backgrounds to establish common definitions of societal problems and research questions, which are the indispensable precondition for the design of ID research programs and research co-operations.

Interactional Expertise: Communicating Across Disciplinary Boundaries

The competence necessary to build ID research co-operations within these "trading zones" is what Collins and Evans have called "interactional expertise" (in contrast to "contributory expertise"), that is, an expertise in understanding and communicating knowledge across the boundaries of disciplinary communities and specialized fields of expertise:

> "mastery of interactional expertise [. . .] is the medium of interchange within large-scale science projects, where [. . .] not everyone can be a contributor to everyone else's narrow specialism; it is, *a forteriori*, the medium of interchange in

properly *interdisciplinary*, as opposed to multidisciplinary, research." (Collins and Evans 2007: 31 f.; cf. Collins and Evans 2002)

To cooperate successfully with other disciplines it is necessary to understand their problems, methods, and results, so one can talk with members of this scientific community about their research questions and findings on a certain level of expertise without becoming a member of this community by oneself. Obtaining this level of understanding is possible only with the help of insiders, who are willing to explain their work. Cultivating interactional expertise for an interdisciplinary cooperation requires an ongoing effort to make disciplinary knowledge accessible to a wider public, in other words by participating in efforts of "popularization" which itself is usually aligned with innovation and interdisciplinarity:

> "In modern science innovation, especially radical or revolutionary innovation is regularly coupled to interdisciplinarity as a mechanism of hybridization of scientific knowledge. And popularization is often based on interdisciplinary combinations of knowledge which sometimes are audacious. Therefore, there is a significant innovation potential in popularization [. . .]. Doing popularization is [. . .] an opportunity for experimenting with a level of intellectual risk which is not readily accepted in everyday scientific practice." (Stichweh 2003: 215)

Communicating scientific knowledge successfully beyond the confines of its disciplinary community is only possible if this knowledge is placed within a wider context: its relations to other sources of knowledge – how they match or mismatch with one another – as well as its societal relevance have to be explained, helping to understand the significance of this knowledge and why it should be considered as relevant in the context of certain research questions. Furthermore, concentrating on the relevance of scientific knowledge for societal problems is an effective way to connect disciplinary expertise to the expertise of other disciplines, to relate scientific findings to everyday knowledge and to widely hold cultural beliefs – in preparation for the development of ID epistemological models.

Interdisciplinary Epistemology: The Need for ID Models

For the integration of different disciplinary knowledge fields one is in need of a theory or an epistemological model of the relations between these different knowledge claims. For example, how can someone best analyze a historical period or – more generally – the "cultural" practices of a societal group: the evidence of social sciences based on statistical numbers is different from the evidence of historical scholarship based on archival sources. And both are different from the evidence of literary and media studies based on an interpretation of a novel or a film. However, each of these knowledge domains can provide a substantial contribution for the understanding of someone's "culture." Only a combination of these different disciplinary results, governed by a theoretical model of the epistemological relations between their methods and sources, can give an interdisciplinary perspective on the distinctive cultural features of someone's way of life, that is, a detailed explanation of one's culture.

Therefore, when the French historian Fernand Braudel proposed (together with the members of the so-called Annales School) a research program aiming to show how geography and economy have shaped societies and historical events in particular, he had to integrate findings from disciplines as diverse as geography, economy, and history within a theoretical model. Since these

> "systems of explanation vary infinitely according to the temperament, calculations, and aims of those using them: simple or complex, qualitative or quantitative, static or dynamic, mechanical or statistical. [. . .] In my opinion, before establishing a common program for the social sciences, the crucial thing is to define the function and limits of models, the scope of which some undertakings seem to be in danger of enlarging inordinately." (Braudel 1980: 40)

Braudel's epistemological reflections on the different disciplinary systems of explanations made him aware of what he called the *longue durée* (the long term) in contrast to the short-term events which lie in the traditional focus of the historians. To integrate these different levels of explanations, he established his famous distinction between three levels of time: (1) the geographical time of the natural environment, where change is very slow and almost imperceptible for human actors, (2) the long-term developments of the economic, social, and cultural history, and (3) the time of the historians dominated by short-term events and the actions of individuals, including those of politicians and soldiers. Only then could Braudel begin to integrate the diverse disciplinary findings within a methodological sound historical framework, as he did, for example, in his influential *The Mediterranean and the Mediterranean World in the Age of Philip II* (1949).

Another example is an ID model developed by the interdisciplinary Birmingham School of Cultural Studies to understand innovation in the "culture industry" analyzing, as an example, the invention of the Sony Walkman. Introducing the model of the "circuit of culture" they have tried to understand the interactions between five different cultural processes: the production of goods, the consumption, different kinds of regulations, the cultural representations within mass media, and the construction of social identities. In other words, how an electronic device "is represented, what social identities are associated with it, how it is produced and consumed, and what mechanisms regulate its distribution and use." (Gay et al. 1997: 3). The ID model is necessary to combine diverse types of knowledge about an electronic device such as the Sony Walkman. Only then is it possible to understand how every product is participating in various economic, social, and cultural processes: why success and failure of an innovation are always depending on the interaction of these processes, which are often mistakenly seen as autonomous and for that reason usually analyzed by separate scientific disciplines.

A theoretical model of the ID relations between different knowledge domains helps to understand how someone can integrate different disciplinary findings in a methodological sound way.

Organizing Interdisciplinary Research Teams

Each discipline or research area has to develop and care for its own epistemic culture. Therefore, it is important, which scientific disciplines should be integrated within an interdisciplinary project. Different methods, different kinds of argumentation and evidence, as well as different social arrangements of inner-disciplinary co-operations require customized solutions for every single ID-research project (cf. Piaget et al. 1972; Piaget 1973; Becher 1993; Klein 1996; Arnold 2009). But also the host institutions can differ regarding the type of ID research that they are supporting. There are on the one hand ID institutions with changing research topics and temporary research groups, such as the German Center for Interdisciplinary Research (ZiF, *Zentrum für interdisziplinäre Forschung*, University of Bielefeld), founded in 1968 (Frodeman et al. 2010: 292 f.), or on the other hand institutions with long-lasting ID research teams institutionalized in departments staffed with both permanent and temporary researchers, such as at the Austrian Faculty for Interdisciplinary Studies (IFF, *Fakultät für interdisziplinäre Forschung und Fortbildung*, Alpen-Adria-Universität Klagenfurt), with predecessor organizations dating back to its first formation in 1979 (Arnold and Dressel 2009). In the former case ID is seen as driven by changing scientific interests, in the latter ID is organized around societal problems, which require steadfast attention over many years if they ever should be solved.

Nevertheless, there are also some characteristics, which most ID research projects have in common. For example, to create an ID research team out of a multidisciplinary group of researchers, where at least one of the research participants has to think interdisciplinarily, working deliberately on the integration of the different methods and research findings (Parthey 1999). Much time has to be designated for periodic team meetings (not least at the beginning, but during the project as well), to elaborate not only a common understanding, but also to address personal irritations and conflicts between team members face-to-face. Since learning from other disciplines is an important element of ID projects, a successful ID research process can be seen as fostering a type of societal learning, where scientists share their different knowledge and expertise aiming to create a common understanding of the problems and the solutions, with the result that every team member has to acquire and adopt this knowledge during the research process (Arnold 2009).

However, ID depends on the individual researcher's competence and personal ability to cooperate with others in ID research teams. Studies suggest that there are certain character traits which many effective ID researchers have in common like "a high degree of ego strength, a tolerance for ambiguity, considerable initiative and assertiveness, a broad education, and a sense of dissatisfaction with monodisciplinary constraints" (Klein 1990: 183).

Evaluating Interdisciplinary Research

As Heinrich Parthey showed, a good indicator for ID is the percentage of researchers within a research group who formulate their own guiding research problem in concepts spanning across disciplinary boundaries. Because thinking from an ID perspective means to formulate and justify the guiding research problem on a different theoretical level and with different theoretical concepts than the methods with which these interdisciplinary problems are approached afterward by the participating disciplines. In addition, a second important indicator for ID research is the interdisciplinary character of the methods applied to the problem: when scientists borrow methods across disciplinary boundaries, for example, by transfer of methods from other specialist fields of research (Parthey 2011). Both traits have to be encouraged within research teams and both are valuable indicators for the evaluation of the "interdisciplinarity" of an ID research project.

But one main problem in evaluating the quality of ID remains: Who is able to judge about the quality of ID research? Disciplines have their standards and their peers, but ID projects are by definition transcending disciplinary boundaries:

> "Since interdisciplinary research is a new synthesis of expertise, peers in the strong sense of the word do not exist. When new combinations of knowledge are tried in interdisciplinary projects, no one but those conducting the work are competent in all aspects of that combination." (Laudel 2006: 57)

Furthermore, empirical research suggests a bias against ID in peer review since peers tend to favor proposals belonging to their own field of study (Laudel 2006) and are falling back on traditional disciplinary standards of the disciplines involved so that in the aggregate all too often an ID research proposal has to meet more quality criteria than disciplinary proposals, increasing the likelihood of getting rejected by research funds (Lamont 2009: 208–211, Mansilla 2006: 25, Huutoniemi 2010: 312 f.).

As already said above (Sect. The First Obstacle for ID: The Disciplinary Organization of Science), paradigm-led disciplinary science is aiming at perfection, that is, incremental innovations, to find better answers to existing questions. Disciplinary evaluations, therefore, endorse those projects which are "sound" and "mature" according to the existing disciplinary standards, they are looking for inaccuracies. However, innovations are per definition not "mature" and in the beginning not "sound" (as defined by disciplinary-oriented evaluators) as well. Since competing quality standards of different disciplines are often one of the reasons why disciplines cannot agree to cooperate in a common research project, ID research has often to develop and justify its own methodological standards, which are appropriate for its special research questions and its carefully selected new research objectives.

Conclusion and Future Directions

Creating an innovation and ID-friendly research environment will remain an important objective for the near future. Since despite critics who are still claiming that ID is nothing but a passing science policy fad: as long as modern research and teaching is primarily organized within disciplinary boundaries, ID research will assert its rank as one of the most important paths to innovation. Its major aim will remain to counterbalance the conservative and inward-looking character of strictly disciplinary research organizations, of their research questions and evaluations. For that reason the distinct quality of ID has to be recognized for the funding of research and the management of research organizations as well. Traditional quality indicators like publications in disciplinary journals can contradict the very intentions of ID-research: stipulating that the results should be published in different (disciplinary) journals forces research teams at the end of their project to dissolve the already achieved level of ID knowledge integration again into its disciplinary parts. By insinuating that disciplinary audiences are the only legitimate judges about the outcomes of ID research, ID is against its principal objective treated as nothing but a loosely connected "multidisciplinary" synopsis of disciplinary research questions and findings.

Hence, the assessment of ID should not solely consist of a post hoc addition of individual expert opinions, but of the deliberate attempt to integrate different disciplinary perspectives with the help of the consolidated judgment of an ID expert group, amenable to reason and time-consuming deliberations. Only a disciplinary-boundaries-bridging group of experts is able to appreciate the specific merits of ID research such as developing new research questions and research programs beyond well-trodden disciplinary paths.

Furthermore, since ID is not only aiming for innovations but also on social relevance, combining interdisciplinary research with participatory transdisciplinary research (TD) is a highly successful method to ensure within an ID research project both the non-disciplinary character and the social relevance of the research questions. Thus, proceeding from life-world problems and integrating not only knowledge of different scientific disciplines, but in addition also non-scientific expertise as well, can be seen as one of the most promising research strategies for the future of ID.

Synonyms

Empathy; Interest and enjoyment; Motivational components of creativity

Key Concepts and Definition of Terms

Creativity is a complex construct often defined as requiring the components of both novelty and usefulness. So how can organizations and managers activate both novelty and usefulness in encouraging creativity in the workplace? Broadly defined, motivation is a set of psychological processes that directs, energizes, and sustains action (Mitchell and Daniels 2003). People may be moved to action by several different kinds of motivations. Researchers have explored the effects of extrinsic, intrinsic, and prosocial motivations on creativity often with inconsistent findings. Perhaps alone, these motivational drivers encourage a focus on only one of the two main components of creativity, but activated together, different motivations may more consistently encourage creativity through increasing both novelty and usefulness considerations.

Intrinsic Motivation

The most common definition of intrinsic motivation can be stated as a desire to expend effort based on an individual's positive reaction to the task itself, primarily founded in a personal interest in and enjoyment of the activity that is being performed (Amabile 1996; Ryan and Deci 2000). Intrinsically motivated people often find themselves lost in their driven activity for the pure enjoyment of it. The need to explore this activity often leads one to focus on new experiences with little regard for their value outside of the pleasure derived from engagement in these activities.

Prosocial Motivation

The desire to expend effort based on a concern for others is a common definition of prosocial motivation (Batson 1987; Grant 2007). The target of prosocial motivation can be a single individual, group, or other people in general. Thus, this motivation directs one to act in a way that is intended to benefit others. This focus on helping others encourages one to have an understanding of what might contribute to others needs or wants.

Perspective Taking

The cognitive process of adopting another viewpoint in an effort to understand their needs, positions, and interests is often defined as perspective taking (Parker and Axtell 2001). Trying to view a situation through another's eyes can help one recognize what that other person is thinking, feeling, or interpreting from a given scenario.

Creativity

J.P. Guilford (1897–1987) is often considered the father of modern creativity research. He defined creativity as novelty bounded by some degree of evaluation that the novelty fits the needs of the particular situation. More recently, creativity has been broadly defined as a contextually based social judgment that an idea, process, product, or person is both novel and useful (Amabile 1996). The two factors of novelty and usefulness are contextually bound in that they are essentially comparative considerations. Novelty is compared to what is currently known or done. Usefulness is estimated with respect to a need, intent, or problem.

Theoretical Background and Open-Ended Issues

Positive Motivational Influences on Creativity

Creativity can be found in almost every aspect of human endeavors from art to science, from one's personal life to business interactions. The outcomes of creative efforts are often seen as important drivers of economic value and human achievement. Yet as creativity requires some component of differentiation from what is already present or currently accepted, there is a note of risk involved with being creative. In presenting a creative product or approach, one opens oneself to failure or rejection. Thus, this type of activity is not naturally a default but requires a motivational force to counterbalance the perceived risks of being different that are so integral to being creative. Even as creativity requires some amount of novelty, it also requires a second component: usefulness. Driving one without the other may leave an effort short of achieving an improvement in creativity.

Novelty and usefulness are the two main criteria for something to be considered creative. Novelty is the extent to which something is new or unlikely to have been considered by others. Usefulness is the appropriateness or value of a thing in a given situation. If one was asked to generate a creative new product to replace glass as a car windshield, corrugated aluminum might be a novel response, as it would be different and probably unlikely to have been considered by others. However, this response would probably not be considered useful as a key need in car windshields is transparency. This idea would thus not be considered creative as it only possesses one and not both components required for creativity. Just the same, a response of clear plastic might be useful but not novel. Creativity requires the presence of both novelty and usefulness factors.

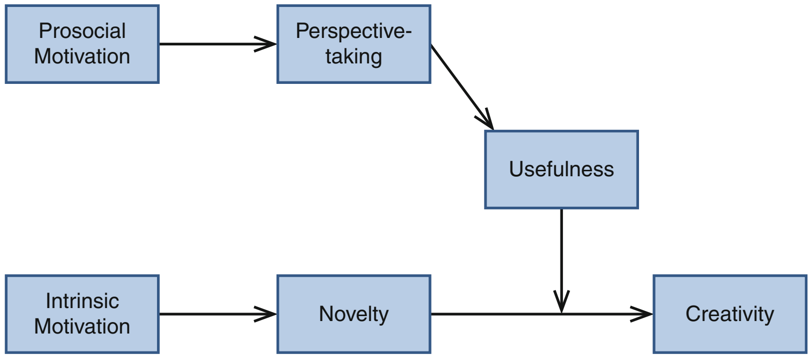
It is this dual componential nature of creativity that makes single focused approaches to driving its attainment inconsistently effectual. If one motivates a focus on novelty without consideration for usefulness, creativity may be increased via more novelty, but those gains may be offset by a loss of focus on usefulness. This could happen with a drive toward usefulness crowding out novelty, as well. To consistently motivate people to higher creative achievement, both components must be activated.

Amabile (1996) has tied intrinsic motivation to creativity as a central factor essential to developing creative ideas or products. When one is driven by intrinsic motivation, the engagement of the activity is the end, and the activity is not undertaken as a means to some external goal. Individuals so motivated experience a desire to explore their curiosities, to learn, and to continue the activity. This individually driven focus on the enjoyment of the task at hand leads to a feeling of freedom and escape from control that allows an individual to explore novel concepts. This feeling of freedom and intense immersion in an activity is well described by Mihaly Csikszentmihalyi in his book Creativity (1996).

This type of activation encourages creativity through cognitive exploration, positive affect, and persistence. On the cognitive side, the desire to learn often stimulated when one is intrinsically motivated by a task, encourages one to expand one's understanding of the activity and explore new avenues of the task. Positive affect has a similar influence on creativity in that positive affect has been linked to an increase in cognitive flexibility and a broadening of the information available to an individual. Additionally, persistence in the activity allows a longer time to explore new ideas and generate options, thus maximizing the effects of cognitive and affective benefits. This increase in flexibility and information increases the likelihood that combinations of ideas and solutions will be unique. Donald T. Campbell argued in 1960 that the more information available and the more combinations one can generate will logically lead to more novel options being developed.

When one is so engaged in an activity, the development of novelty can often be seen as an end in itself. Oftentimes, one can get so absorbed in the intrinsically motivated activity that other considerations are ignored. It is this aspect of intrinsic motivation that encourages a drive for novelty at the expense of external considerations beyond the activity. Sometimes, the results of these intrinsically motivated activities coincide with external demands. Organizational efforts at matching individual's personal interests with work duties, allowances for job crafting, or encouraging autonomy are several ways of encouraging alignment of novelty generation with organizational utility. However, these efforts may encourage a chance congruence of novelty and usefulness; they do not put a direct focus on the utility of generated ideas or solutions.

A focus on utility is often encouraged by motivation efforts imposed from external sources, particularly within organizations. Externally determined rewards for completing certain tasks or reaching milestones can be very effective at driving certain behaviors, but these rewards encourage activity in a task for an externally justified end. Often, these extrinsic motivational approaches are seen as efforts to control an individual and as such are often detrimental to intrinsic motivation and the resultant gains in novelty. This being the case, extrinsically focusing a person on an externally determined goal (usefulness to the organization) may come at the expense of novelty. If extrinsic motivation can be applied in a noncontrolling fashion, then there may be an opportunity for creative synergy between these motivational sources (see Hennessey and Amabile 2010 for a broader discussion).



Intrinsic and Prosocial Motivations, Perspective Taking, and Creativity, Fig. 1 Relations between intrinsic motivation, prosocial motivation, perspective taking, and the components of novelty and usefulness driving creativity

Creative synergy or a maximization of both novelty and usefulness can be engendered when intrinsic motivation is paired with an internal drive to be productive for others. Prosocial motivation encourages individuals to be concerned for and act in ways that contribute to the welfare of others. This is an internally generated desire and thus avoids the negative effects related to feelings of being externally compelled to engage. However, acting on a desire to help others necessitates at least an attempt at understanding of what may be helpful to them. This type of other-focused motivation may benefit creative efforts by providing a desire to focus on the usefulness of these efforts.

Being motivated to help someone may provide the intent for usefulness. Moving this intent to effective improvement in creativity requires understanding of what might be helpful to the target of one's prosocial motivation. This intent to help others encourages one to build an understanding of what might be beneficial to those one seeks to help. In this way, prosocial motivation promotes an attempt to understand issues from another's perspective. This perspective taking can help provide an external reference of what ideas or products may be ultimately useful to others.

Combining both intrinsic and prosocial motivations may be an effective way to maximize creativity. By activating increased focus on both novelty and usefulness, the motivational effects may be more powerful together than alone. This model as shown in Fig. 1 posits that intrinsic motivation influences creativity through increasing novelty and prosocial motivation influences creativity through perspective taking increasing usefulness.

Conclusion and Future Directions

This model of how motivation relates to creativity through its components of novelty and usefulness can be valuable in conceptualizing how different motivations may influence creativity to generate synergistic effects. Research in this area (Grant and Berry 2011) has supported this general model, finding a strengthening of the link between intrinsic motivation and creativity when perspective taking is encouraged through prosocial motivation. The inclusion of the novelty and usefulness components in this model is at this point theoretical. How these motivations and perspective taking exactly influence creativity efforts is an area for future exploration. Additionally, perspective taking may be engendered by different means other than prosocial motivation; thus, there are opportunities to explore the independent effects of perspective taking on usefulness and creativity.

These findings suggest that organizations might want to broaden their attempts to motivate employees for creativity through multiple avenues simultaneously to encourage a focus on both novelty and usefulness. By considering how different motivations influence creativity through the individual components of novelty and usefulness, this work attempts to explain inconsistent results often found when studying single motivations and their relation to creativity. Hopefully, this approach to expand the precision of how motivation relates to creativity can be applied to other areas of investigation into this complex concept we call creativity.

Background: Microeconomics of Novelty Creation and Problem Solving

Obviously, invention and innovation can be hardly analyzed from the usual cost/benefit perspective of economics. These processes are conjectural by their very nature:

- Because ex ante results of the search endeavor cannot reasonably be anticipated (or even expected)
- Because there is no guarantee for the social acceptance of a possible result
- Because there is the risk that an accepted result cannot be used as a source of (additional) private yield (Nelson 1959a, b, 1982)

Due to these intricacies, invention and innovation have previously been either considered as coming "out of the blue" (Kirzner 1979; Vromen 2001) or have been simply postulated as an outcome of mesopatterns in terms of paradigms, routines, and institutions (Dosi 1988; Lundvall 1992).

Notwithstanding these caveats and provisos, various attempts to conceptualize the novelty creating process from a microeconomic perspective have been made (Kline and Rosenberg 1986; Noteboom 2000; Witt 2009). The common denominator of these attempts is that these novelty creating processes have essential features which can be dealt with analytically: (a) there are boundary conditions or triggers making the occurrence of these processes highly probable; (b) these processes can be divided in different phases, each of which is characterized by specificities in terms of cognitive resources, uncertainty, and economic constraints; (c) time matters not only in terms of succession and path dependency but also in terms of feedback loops with different range; (d) multiple types of behavior are included in these processes (especially deliberation and intuition); and finally (e) their social embedding has to be taken into account (especially related to the issues of acceptability and appropriation).

The concept of problem solving initially figured out in Gestalt psychology (e.g., Wertheimer 1922) and afterward imported and specified for economic contexts by Herbert Simon (e.g., Simon 1965). According to Simon, problem solving is a cognitive device which allows bounded rational agents to make decisions in a complex environment. Simon especially proposes his approach as a more realistically conception of human (and organizational) behavior than the standard approach of economics, namely, the expected utility concept. Nevertheless, there is an ongoing controversy about the question if the former concept is suitable for analyzing novelty creating processes (including invention and innovation) in terms of the features (a–e) mentioned above. This might be partially due to the fact that the core of the problem-solving concept was developed by supposing simple problems or rather abstract themes (e.g., the "Tower of Hanoi" – problem and chess).

The Core Concept of Problem Solving and Its Restrictions

The starting point of the problem-solving procedure is the perception of a "problem." "A person is confronted with a *problem*, when he wants something and does not know immediately what series of actions he can perform to get it . . . . . To have a problem implies (at least) that certain information is given to the problem solver: information about what is desired, under what conditions, by means of what tools and operations, starting with what initial information and with access to what resources" (Newell and Simon 1972, p. 72; Cyert and March 1992, p. 121). Hence, the essential feature of a problem is a divergence between the given and the desired state of affairs. The conditions for eliminating this divergence are on one side the initial constraints of the agent (in terms of money, time, and knowledge) and on the other side the (virtual and real) transformation devices (in terms of heuristics and operators) for the given state of affairs. Yet, the applicability of these transformation devices is uncertain in that there is only a rough idea about the appropriateness of these devices.

"Problem solving" is the process of finding out a sequence of states between the initial and the desired final state under the given constraints. This process is based on a "mental representation, a mental scheme for holding information in memory and operating on it"

(Simon 1999, p. 674; Newell and Simon 1972). The elements of the mental representation are:

- An interpretation of the given situation
- A listing of the transformation devices (operators derived from heuristics) according to this interpretation
- A test and evaluation mechanism for the results of operator application.

Hence, selecting a cognitive activity under the constraint of available knowledge and the experience about the problem domain marks the starting point of the problem-solving process.

The listing of the transformation procedures within the mental representation is not complete because not all the procedures contained in the knowledge stock are activated. This would easily lead to a combinatorial explosion of transformation possibilities which, due to cognitive constraints, would have to be dealt with on a trial and error base. Therefore, the problem solver applies only a part of the available search procedures (heuristics) to reduce the size of the problem space, i.e., the space which is defined by applying all available transformation possibilities to all possible states. These heuristics might be either explicit in that they are explicable and even programmable or they might be implicit in that a given situation includes cues about what to do for the experienced problem solver.

However, only under ideal conditions problem solving will be a linear sequence of representation, operation, and realization. Normally, it will be a feedback process between the steps "operation" and "representation" as well as within the "operation" step. Furthermore, if several attempts to reach a given goal are not successful, the goal itself might be modified (in quantitative or qualitative terms).

This sketch of the seminal contribution of Simon and Newell to the analysis of the elements and process of problem solving shows that this is a pathbreaking alternative to the standard model of the deliberate decision process (a) in that it focuses an open-ended search behavior divided in the statement of the given situation, the figuring out of the problem space, and finally the solution of the problem and (b) in that it integrates the assumption of bounded rationality in terms of knowledge-dependent problem representation and in terms of limited capabilities of problem manipulation (by heuristics and operators). Due to these cognitive constraints, the process of problem solving might become sticky and path-dependent.

Nevertheless – at least in its original form – the concept has a rather narrow scope. *First*, it takes only the goal-related outcome into account which abstracts from basic abilities of the agents as well as from individual specificities. *Second*, according to the computer-oriented context in which this concept of problem solving was developed, it was mainly confined to clear cut ("well-defined") problems. This means that the goals of the agent as well as the heuristics used for reaching this goal are specified in such a way that the results of the application of these heuristics can be unambiguously evaluated with respect to their goal-reaching capability. Furthermore, it is assumed that this capability is even measurable in terms of a larger or smaller distance to the goal. *Third*, it is assumed that the definition of the problem and the finding of the problem-solving devices are two separable elements and that the problem-solving devices are merely instrumental for the problem itself. Thus, only these solution advices are varied during the problem-solving process. Taking these limitations into account, one might become skeptical about the essential difference between this problem-solving approach and the decision approach in standard economics. Furthermore, this simplistic problem-solving approach has been criticized due to its affinity to what computers can do (instead to what humans used to do; cf. Dreyfus and Dreyfus 1986).

Enhancing the Concept of Problem Solving: Ill-Defined Problems and "Creative Problem Solving"

Ill-Defined Problems and Creativity Research

Not all problems in the economic world are well defined in the sense of the standard approach of problem solving. Sometimes, even the understanding of the initial situation is not in such a way clear that it can be transformed into a mental representation. Consequently, it remains vague in which way such a situation can be influenced by any kind of operator and which goals are appropriate for it. However, even if the situation is well understood, it might be difficult to solve a problem because there are multiple incommensurable problem spaces and/or a lack of appropriate operators/heuristics making it intricate to find a sequence of reasonable operations. Finally, it is possible that the goal is not defined in a unanimous manner. These caveats are the background for admitting "ill-defined problems" (Simon 1973) and thereby broadening the scope of the concept of problem solving.

The inconveniences arising with ill-defined problems – which do normally occur in an uncertain world – change the character of the problem-solving process. *First*, it is not any longer "directed" insofar it successively reduces the gap between initial and final (goal-reaching) state; rather, it might circle around or even be regressive by broadening the gap. This is due to the lack of appropriate operators/heuristics and/or the goal ambiguity. *Second*, the instrumental role of problem-solving devices does not hold anymore if the problems are ill defined. Under this condition, heuristics and operators as emanations of the stock of knowledge are themselves influencing the way the problem is posed at every time step. Problem solving then becomes an iterative and simultaneous exploration of problems and solutions.

Solving ill-defined problems makes great demands upon the actors involved. At the core of the individual ability to look for new situations and to deal with them is the human creativity. Referring to the research on human creativity therefore helps to understand how ill-defined problems can be solved. This research has a long tradition starting when the ability to create something new is no longer considered as a divine inspiration but rather an individual capacity of the human being. However, even in the professional treatment of creativity in psychology, it took some time before single hypothesis approaches (such as the psychodynamic, associationist, and Gestaltist treatment) to this human ability have been overcome in favor of a broad treatment including all resources and processes known in modern cognitive psychology (Guilford 1950; Weisberg 2006).

The modern creativity research defines creativity as "the ability to produce work that is both novel (i.e., original, unexpected) and appropriate (i.e., useful, adaptive concerning task constraints)" (Amabile 1996; Sternberg and Lubart 1999). Hence, what is meant by creativity in the sense of modern creativity research are the individual creative traits and processes. Creativity research does not primarily deal with the wide range of tacit everyday creativity. Rather, creativity here implies that the individual creative output (product) is being assessed and accepted by the environment. Following this definition, three different – although interdependent – aspects of creativity are emphasized in the modern creativity research: the individual qualities, the process analysis, and the environment. All these aspects are relevant for solving ill-defined problems and thereby broadening the scope of the original concept of problem solving (Weisberg 2006).

- The *individual qualities* can be subdivided in knowledge and skill endowment, motivation, and personality features. For being creative, knowledge is required about the domain specificities (Weisberg 1999). This knowledge should be well organized giving the possibility for switching flexibly between different levels of generalization. Whereas this kind of knowledge is "declarative," also "procedural" knowledge is required in terms of knowing how to use available heuristics. These different levels of knowledge are accomplished by skills in terms of finding new heuristics and capabilities for recombination and association of given elements of knowledge (Chand and Runco 1992; Policastro and Gardner 1999). However, knowledge and skills are not sufficient for being creative: Additionally, a strong motivation for fulfilling a task is required. This strong motivation can either come from inside in that an individual views such an engagement as an end in itself (intrinsic motivation) or in that this motivation comes from outside following from external information or expectations without restricting the autonomy of the person under consideration (informational or enabling extrinsic motivation; Amabile 1996). Finally, some personal qualities are required for a creative activity. Among the most important ones are curiosity, the steadfastness of purpose, patience, and a fundamental willingness to bear risks (Csikszentmihalyi 1999b). Knowledge, skills, motivation, and personality are combined in two overarching features of creativity: *deliberate cognitive style* and *divergent thinking*. A deliberate cognitive style is a stable preference for using extensively deliberate (conscious) resources in sorting out the possibilities of action (Kirton 1989). Divergent thinking is a specific way to use these cognitive resources. Convergent thinking has only one direction; one conventionally correct answer is searched for. Contrary to that, divergent thinking proceeds in different directions (Guilford 1959). Hence, the approach of creative individuals to problems is original in that they are breaking with traditional formulation and solution of problems, and it is flexible in that many ideas about formulation and solution are held for a long time simultaneously in mind until a switch to one of these options occurs (Amabile 1996).

- The *process analysis* of creativity was initially heavily influenced by the idea that the creation of something new is a rather unexplainable operation in terms of rational process analysis. This gap in explanation was either filled by referring to mysterious abilities of the human genius or it was assumed that creative ideas emerge from a largely uncontrollable Darwinian process of random variation and natural selection. This gap is well documented in one of the first process models of creativity by Wallas (1946). In this model, four phases are distinguished: (a) the definition of the issue and the observation of the starting conditions in the phase of preparation, (b) then the phase of incubation in which the issue is laid aside, (c) the phase of illumination in which the new idea is born by picking up the issue after a while, and finally (d) the phase of verification. How this illumination can happen remained unexplained at that time. Furthermore, it seems dubious to separate this act of illumination from all conscious endeavors to analyze the issue. This lack of explanation was reflected in the process model of Rossman (1964). In this model, the preparation phase is composed of observation of need, analysis of need, a survey of all available information, and a formulation of all possible solutions. The incubation/illumination phases are replaced with a critical analysis of these possible solutions and a birth of the new idea out of this analysis. The last phase is analogous to Wallas (here based mainly on experimentation). How this "birth" of the new idea happens still remains mysterious. Meanwhile, these traditional conceptions have been challenged by at least two relevant approaches: On the one hand, the incubation/illumination paradox is explained as a cognitive process, relying on cognitive operations and not on mystical insights. Thereby, the features of the four-stage model are either updated (Amabile 1996; Cszikszentmihalyi 1999b) or rejected (Weisberg 1993). On the other hand, very promising endeavors have been made to propose new models to overcome the traditional perspective (Finke et al. 1992). Additionally, a lot of empirical and experimental work has been done to explain problem-solving (and problem-finding) processes (Runco and Sakamoto 1999; Lubart 2001).
- Creative operations do not happen in an empty space; they have an *environment*. This environment is relevant for the generation of a creative act as well as for the evaluation of the result of this creative act. According to the difference between the outcome of creativity (an idea, a concept, a physical product, etc.) and the creative person, the environment is seen to consist of a "domain" to which the product refers and a "field" to which the person refers (Csikszentmihalyi 1999a, b; Weisberg 2006). Unresolved problems in the domain as well as the way the experts in the

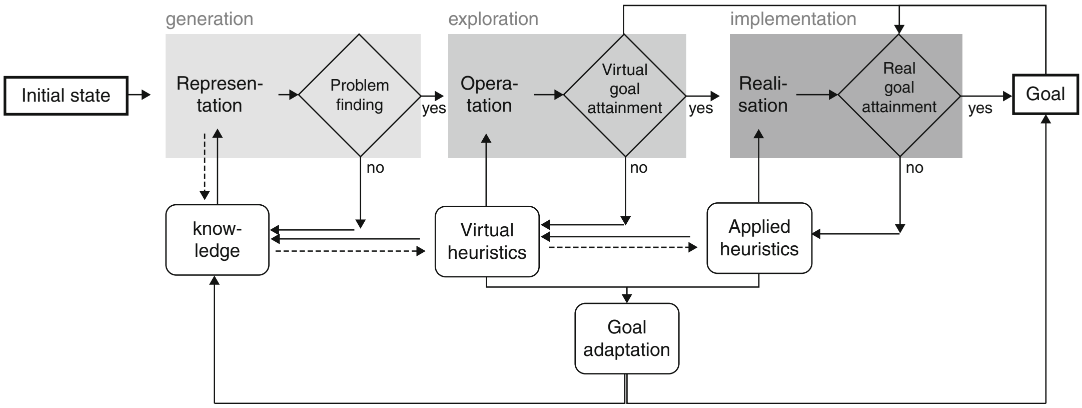
field deal with these problems determine the act of creativity: on one side, by the accessibility to the (incomplete) knowledge of the domain and, on the other side, by the degree of the open-mindedness of the experts in the field. This is related to the knowledge base and the motivation of the creative person and to the preparatory stage of the creative process mentioned above. But the domain and the field are also important "test beds" of the results of a creative act. It will become manifest how much the domain is altered by this creative result (To what degree hitherto unsolved problems are pretended to be solved?), and the experts in the field will have to evaluate this change in the domain (Is the solution accepted? How far reaching is it?).

What conclusion can be drawn from this sketch of creativity research for dealing with ill-defined problems? (a) Before problems of this kind can be solved, a creative specification of these problems in preparatory steps is necessary. (b) Unconscious illumination, imagination, and the like are not sufficient for explaining the creative process because a necessary condition for creativity is conscious endeavors. At the core of creating something new, there is a twofold process of synthesizing ideas, facts, etc., on one side and a transfer and transformation of these ideas, facts, etc., on the other side. (c) Insofar, as the solution of ill-defined problems requires acts of creativity, individual qualities as well as a creativity friendly environment are necessary for the problem-solving process. (d) Finally, the role of a variety of cognitive elements like knowledge, motivation, and memory is emphasized.

Creative Cognition and Creative Problem Solving

The separation of personal qualities, process analysis, and environmental conditions is a useful starting point for systematizing the insights of creativity research. But from the perspective of modern cognitive psychology, this separation seems arbitrary, and therefore, attempts have been undertaken to broaden the process analysis of creativity to include at least some aspects of personal qualities and environmental conditions. Such an attempt is "creative cognition," developed by T. Ward, S. Smith, and R. Finke. In this approach, a new model of the cognitive process and structure of creativity is proposed, incorporating thereby the aspects of individual qualities and – though at a different level – aspects of environment (Finke et al. 1992, 1999). The main feature of this approach to creativity is a heuristic model called "Geneplore" (Finke et al. 1992; Ward et al. 1999). According to this model, the creative process is a sequence of generative and exploratory processes (hence the name).

The *generative processes* take place in the initial phase. Here, mental manipulations of knowledge elements (retrieval, association, synthesis, transformation, transfer) lead to new mental representations, e.g., to a new interpretation of the initial situation, new (virtual) operators, new evaluation mechanisms, and/or new combinations of these elements. Such new representations may consist of discovered patterns, mental models, and the like. These results of the generative processes are not simply novel. Rather, they have some inherent ambiguity, incongruity, and divergence and therefore encourage the investigation of these results in the second phase, the *exploratory processes*. Because the problem definition is incomplete in that no definite goal is given, the applicability and usefulness of the new representations are now tested, and if necessary, the goal is adapted. What kinds of problems can be tackled with such new representations? Are new attributes of a problem at stake accessible? What kind of operators can be used to manipulate the initial context and what will be the result of such a manipulation? This can be summarized as a figuring out of appropriate virtual heuristics. Finding answers to these questions might include a modification (focus or expand) of the preinventive structures (new mental representations) which are the result of the generative process. Hence, multiple feedback cycles between generative and exploratory processes might be necessary until a useful novelty has been discovered.



Invention and Innovation as Creative Problem-Solving Activities, Fig. 1 Enhanced concept of problem solving

What kind of insights for a problem-solving process under the condition of an ill-defined problem can be gained from the creative cognition approach? Insights from creative cognition for the concept of problem solving are threefold: *First*, a specification of what is meant by "ill defined" is provided. By bringing in new cognitive devices (like mental models, analogy building, context shifting, and divergent thinking; Finke et al. 1992), it is possible to specify what generative/explorative method is used. Furthermore, the following questions can be answered: Is the "illness" of the definition due to not having a new representation or is it due to the unexplored usefulness of a new representation? Or is it due to both? *Second*, the generative processes constitute a specific determining stage of the whole problem-related process: the problem finding. This is tantamount to finding representations or heuristics by using the "Geneplore" approach. *Third*, the problem solving itself changes character in that it becomes creative. It deals with new heuristics/operators and makes of problem-solving proper a temporary operation in an overarching problem-finding/problem-solving feedback process. Given that, the focus of the core concept of problem solving (cf. section "The Core Concept of Problem Solving and Its Restrictions") can be enhanced by including the phases of generation and exploitation. Figure 1 shows the main features of such an enhanced problem-solving concept.

Applying the Problem-Solving Concept to the Microeconomics of Invention and Innovation

Invention as a Problem-Finding/Problem-Solving Activity

Invention means the creation of a conceptual novelty. It denotes the creation of an idea or a concept, waiting for being applied in a practical context. Such a new idea or concept might be based on new knowledge which is simultaneously created with the invention ("primary inventions" in the sense of Usher 1971, p. 50), or the invention is the result of new applications of a given set of knowledge ("secondary invention," Usher 1971, p. 54).

Considering invention as an act of creative problem solving means to specify the endowment of the inventor in terms of cognitive resources (cf. above section "Ill-defined Problems and Creativity Research"). A profound declarative knowledge about the domain, the ability to flexibly combine the elements of this knowledge, and knowing how to search in a given domain for new insights (procedural knowledge) is the *first* cognitive prerequisite for the creative act of invention. *Second*, the motivation for inventive activity is intrinsic in that this activity is seen (by the inventor) as an end in itself. Any environmental expectation about the result of the invention is either ignored or transformed in the inventor's individual motivation. This means that on one side there is no person who is directly forcing the inventor to follow a predetermined action pattern; on the other side, this does not exclude that the inventor has an open mind for scientific, technical, social, or economic needs in his environment. A *third* momentum of the inventor is a combination of all personal qualities which have been attributed to the creative personality (cf. section "Ill-defined Problems and Creativity Research") with a special emphasis on a deliberate cognitive style and divergent thinking.

For invention, the environment hence has the double role to be (a more or less) stimulating background and to be an evaluating context. The stimulation is given in terms of scientific, technological, social, and economic "driving forces" (i.e., strategic and/or global needs in these domains). This background for the invention process may be given by identifying "reverse salients" (Hughes 1978, pp. 172, 179), i.e., the bottlenecks of a global system development in the domains mentioned before. The focus on these reverse salients is determined (a) by education and expertise of the inventor, (b) by the prior activities of the inventor in the same or a similar domain, and (c) by anticipating some feasibility constraints in terms of funding, accessible R&D facilities and perhaps by referring to the expectation of an entrepreneur (Schumpeter 1983). The evaluation of the invention is one important function of the entrepreneur. This function can be incorporated in a special group of entrepreneurs, or it may be a temporary feature of actors, which have also other roles to play (as it is often the case in small- and medium-size firms). This entrepreneurial evaluation process of invented products may be influenced by the hostility of those vested scientific, technological, social, and economic interests for which the innovative development of the invention might be a threat (Nelson 1959a; Gilfillan 1970; Hughes 1978; Amabile 1998).

Given this background, the process of invention can be characterized (in a stylized manner) by referring to the features of an enhanced problem-solving concept: (a) it deals with ill-defined problems, (b) it includes a stage of problem finding, and (c) it solves problems in a creative manner.

ad (a): Taking "problem space," "goals," "heuristics," and "operators" as attributes of a problem definition, all these attributes can be in the state "none," "one," "multiple," and "vague." A vague problem space is given if there is a high uncertainty about the dimensions of the problem to deal with. The goals are vague if a goal is not known in a positive sense but only in a negative sense in knowing what is not intended. The heuristics and operators are vague if the appropriateness of both for any given goal is ambiguous. Then there are 4^4 possibilities to characterize the problem situation. The problem situation for an inventive activity lies somewhere between a situation which is well defined (all attributes are in the state "one") and a situation of total ignorance in which all attributes are in the state "none." The typical situation of inventive problem solving is defined, *firstly*, by a vague problem space and a vague fixing of the goals. This corresponds to the incomplete knowledge of the inventor about possible directions for transforming an initial situation and to a loose binding to the "driving forces" of the environment mentioned above. *Secondly*, heuristics are vague and possible operators are unknown (state "none") when the invention process starts. Hence, when the invention starts, the string of the attributes (problem space, goals, heuristics, and operators) is:

$$I_{\text{vent}} = \{\text{vague}, \text{vague}, \text{vague}, \text{none}\}.$$

This specific type of an ill-defined situation is called here a "strong ill-defined problem."

ad (b): Given such a strong ill-defined problem, the first stage of the inventive process is the solution of the "problem" of problem finding. This problem is coped with by the above mentioned generative processes (section "Creative Cognition and Creative Problem Solving") leading to preinventive structures in terms of a specification of the problem space, mental models about this problem space, and a discovery of new (virtual) heuristics and operators for "walking through" this problem space. Thereby, it is specified where this walk

I

could go to, i.e., hopefully the vagueness of the goals is reduced by these generative processes. Ideally, at the end of this stage of invention, at least the problem space should be specified, and a couple of heuristics (e.g., heuristics for decomposing and for recomposing a problem space) as well as operators should wait for being explored.

ad (c): In the next stage of the inventive process, the heuristics and operators are explored. In this process, a feedback to the understanding of the problem space as well as to the goals of the whole operation takes place. One way to specify such a process more closely, is to assume that the inventor may use one of the available decomposition heuristics to discern the weakest point of a problem at stake, then he/she may solve this weakness by using an heuristic of analogy to a similar (better known) problem, and finally, this abstract solution is adapted to the real-world problem by using a recomposing heuristic (Hughes 1978, p. 173).

Invention as an economic activity is confronted with strong uncertainty. This uncertainty is twofold: *Firstly*, there is no clear relationship between input and output (Arrow 1971, p. 172). Hence, there is a high risk of either not finding any new idea or concept at all or to find something which is not applicable, i.e., something that cannot be used as a source of innovation (output uncertainty). This side of the uncertainty can be expressed as the problem of determining the direction and amount of search activities. *Secondly*, if the invention is successful, there is no guarantee that those who are not willing to pay for the use of it can be successfully excluded (exclusion uncertainty). Partially, this uncertainty can be reduced by juridical protection (e.g., application for patent). Especially the output uncertainty confines the applicability of the usual economic calculation framework in terms of costs and (expected) yields. Invention takes place due to a strategic orientation because only in the long run a pay off can be expected. In the short and medium term, the output uncertainty as well as the motivational requirements for the inventors imply the paradox that inventive activities are the more successful, the more this activity is delinked from the normal organization of economic activities and from the efficiency criteria coupled with this normal organization (Nelson 1959).

To resume, dealing with invention in a (broadened) problem-solving framework has several specificities. It shows that invention consists of a sequence of knowledge-using and knowledge-generating stages and their feedbacks:

- It integrates modern creativity research by demystifying the “act of insight” in that the latter is seen as a combined effect of cognitive resources, environmental conditions, and personality features. Thus, the inventive insight is not a sudden recombination or synthesis of given elements of knowledge; rather, it is a result of a – socially shaped – process of finding, defining, and treating a problem.
- The definition of this problem is influenced by a “supply push” in terms of new knowledge and a “demand pull” in terms of global needs. Hence, there is an “. . .interplay of moving frontiers of knowledge and growing need upon the direction and likelihood of success of individual ‘acts of novelty’” (Nelson 1959, p. 107).
- Finally, in this approach, it is possible to pick up the results of those case studies related to technological inventions which are not part of the creativity research and to interpret them in a problem-solving procedure.

Innovation as a Problem-Solving Activity

Innovation means the creation of an instrumental novelty. In many cases, it is the process of applying and thereby figuring out the result of the invention process. Generally, this figuring out has to meet two requirements: The feasibility of applying the inventive idea/concept has to be shown in technical, institutional, and behavioral terms. Furthermore, a path to the marketability of this feasible application has to be demonstrated. To deal with these challenges is at the core of the entrepreneur function.

The cognitive resources involved in innovation as a specific stage in the overarching creative problem-solving process are in most parts different from the cognitive prerequisites for invention. Whereas both processes have in common that a profound knowledge of the domain is necessary (declarative knowledge), the requirement for the procedural knowledge shifts in the case of innovation toward knowing how to solve a given problem. Due to an increasing focus on applicability and solution requirements, the motivation is no more intrinsic in that the innovation is seen as an end in itself. Rather, the innovator is – at least partly – animated by strong incentives in terms of either "motivational slack" or deficits in realizing some aspiration level as regards a given goal (March 1994).

The environment of the innovator is set by the ideas/concepts "offered" by the inventor, the given solutions to past problems in terms of products, processes, organizations, and behaviors as well as the competitors. Compared with the inventor, the stimulation for the innovator coming from this environment is more visible (in case it is there), and the driving forces for his activity become less global and less far reaching. In such an environment, the innovator has his role as entrepreneur to play: After assessing the opportunities given by the products of the inventive process, he has to focus on one option and implement it as a midrange improvement of his market performance. This implies that there is some acceptance for what he is doing on the side of producers or consumers.

Compared with the process of invention, the process of innovation differs in the way it poses and solves problems: (a) It still deals with ill-defined problems, but the "illness" is weaker than in the case of invention. (b) There is no stage of problem finding anymore. (c) Solving the problems at stake requires less creativity.

ad (a): The definition of the problem is shaped by picking up the results of the invention stage. The mental representation of the problem space as well as the goals are to a certain degree specified (turning from the "vague" to the "multiple" state) by the invented option the innovator wants to implement and by the triggering market conditions for such an innovative activity. Hence, the following questions arise: What are the technical feasibility problems of a given concept? What qualities of the product innovation promise what kind of advantage in the market performance of the innovator? Additionally, the innovator has to deal with remaining uncertainties as regards heuristics and even more as regards operators. Although these heuristics and operators are to a large degree determined by the invented option, at least a multiplicity of these heuristics and operators have to be checked. Furthermore, the implementation of the invented option may necessitate to find out and experiment with unknown (sub)heuristics and unknown (sub)operators. Hence, the string of attributes (problem space, goals, heuristics, and operators) at the beginning of the innovation switches now to:

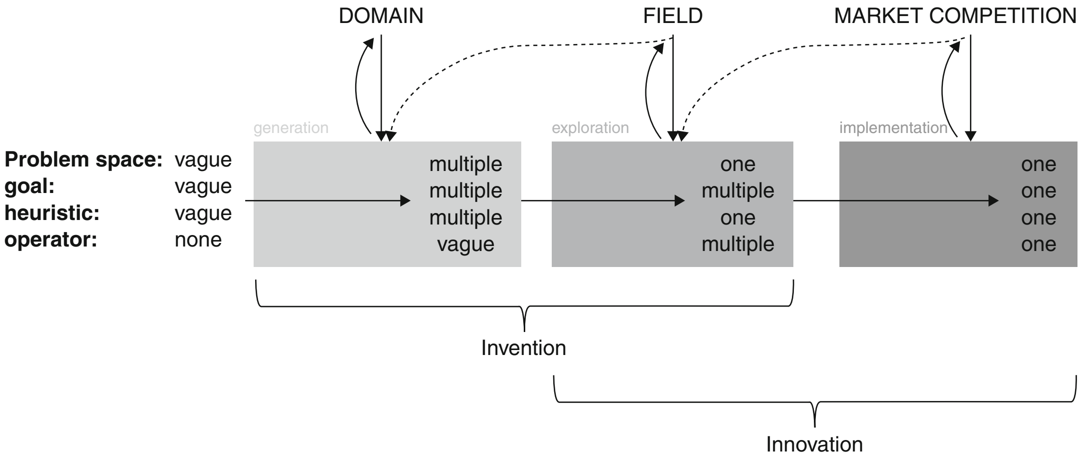
$$I_{vat} = \{\text{multiple}, \text{multiple}, \text{multiple}, \text{vague}\}.$$

This specific type of an ill-defined situation is called here "weak ill-defined problem."

ad (b): Assuming that the initial condition for the innovative process is the application of an outcome of invention for improving the economic performance and given a weak ill-defined problem, no problem finding is necessary – the finding problem is solved!

ad (c): Solving the weak ill-defined problem of innovation still requires some creative resources. Even if heuristics and operators are determined by the option picked up by the inventor, the outcomes of these transformation procedures are uncertain. For example, which of the heuristics and operators discovered during the invention process may be appropriate for generating a desired product quality? Additionally – as already mentioned – new subproblems will arise and hence a need for new subheuristics and suboperators. Exploratory processes with respect to the whole problem at stake as well as regards the subproblems are still necessary.

Compared with the invention process, the overall degree of uncertainty is reduced. Although the implementation of an idea or a concept may be a source of additional



Invention and Innovation as Creative Problem-Solving Activities, Fig. 2 Features of problem solving during invention and innovation

uncertainty, the output uncertainty is reduced because the amount and direction of the search activities are much clearer now. Contrary to that, the exclusion uncertainty is increased because competitors may use the same invented option and similar heuristics and operators. Last but not least, the great challenge for the innovator is to transpose the figuring out of the invented option into a context which is determined by normal organizational procedures and economic evaluation criteria.

The Novelty Creating Process as a Whole and Its Embeddedness

Invention and innovation are stages of the novelty creating process as a whole (which also includes the diffusion phase (Rogers 1995)). They are distinct in terms of general definition, cognitive resources, environmental conditions, process elements, and economic character. Taking into consideration these differences, the whole novelty creating process can be deciphered by referring to the dimensions of problem solving and the social embeddedness of the latter (cf. Fig. 2). This is a process in which the state of the string of the problem representation (consisting of the components problem space, goal, heuristic, and operator) changes according to a process of "generation," "exploration," and "implementation." Starting with a situation slightly better than total ignorance in which at least some rough ideas exist about problem space, goals, and possible heuristics, the generation process leads to a reduction in the search space. It identifies different dimensions of the problem space and creates a finite number of heuristics and operators. This still very large search space is further reduced in the exploration process in which ideally a unique problem space should be found (being one condition for a switch to a well-defined problem) and possible goals of the process should be specified. The task of the final implementation stage is to find unique states for all the components of the problem representation. This means there should be definite answers to the following questions: What is the novelty about? What is it good for? What are the steps from an initial situation with a problem to be solved and a final situation, where the problem is solved?

The novelty creating process is not unidirectional (cf. Fig. 1). Because it is a process of search, discovery, and learning, there are feedbacks between the successive stages of this process (Nelson 1959; Heuss 1965; Usher 1971). In terms of the suggested process analysis, this means that the findings of the exploration stage stimulate new generation activities. This may be the case, either if the exploration shows that the generative activities went in the wrong direction (substitutive feedback) or if a further specification of the invention or a complementary invention is necessary (adaptive feedback). Correspondingly, it was observed in the research about innovation that "...often an innovation is changed or modified by a user in the process of its adoption and implementation" (Rogers 1995, p. 174). In terms of the process analysis above, this is tantamount to a feedback from the implementation stage to the exploration stage. The reasons for this feedback are analogous to the feedback mentioned before.

Invention and innovation are not disjunctive stages in the novelty creating process. Rather, there is a fuzzy border between these two processes in that they overlap. The final stage of the invention process in which an idea or concept is explored thereby reducing the ambiguity of a problem representation (or discovering potential problem representations) may be the first stage of an innovation process. In this process an understanding of the invention is obtained (specifying the problem space) and the range of goals is defined to which the invention can be related.

According to the analysis of the social embeddedness of creative activities given in the systemic approach of creativity research (Csikszentmihalyi 1999a, b), these different stages of the novelty generating process are influenced by different environmental conditions. The generation phase depends on the socially available knowledge about the domain at stake (apart from the individual tacit knowledge). On the other side, this domain knowledge is influenced by the new knowledge produced during the invention process in case that this new knowledge is communicated. When the generated ideas or concepts are explored and thereby related to existing ideas and concepts in the domain (including an assessment by the people in the given domain), the influence of a "field" comes in. This is the way the inventor is affected by needs articulated in the public. Furthermore, if the field is dominated by some order parameters, there might even be an influence of the field on the direction of the generating processes of invention. As in the case of the domain, the field is influenced by the results of the inventive exploration. Finally, the implementation stage is shaped by the embedding of the innovator in the economic competition which strongly determines his goals. If a strategic deficiency in his/her competitive performance is observable for the innovator, this will have an impact on his exploration activities.

Conclusions and Future Research

The skepticism against the suitability of the concept of problem solving in the context of explaining invention and innovation can be relativized if this concept is enriched by integrating the insights of creativity research and modern cognitive psychology. Most of the generic features of novelty creating processes mentioned in section "Background: Microeconomics of Novelty Creation and Problem Solving" can be explained in such a conceptual setup:

- "Generation," "exploitation," and "implementation" can be identified as specific phases each of which combines peculiar personal, economic, and environmental conditions and gives the dimensions of problem solving different expressions.
- The successive occurrence of these phases (including path-dependence) as well as the multiranged feedback loops between them specifies the critical role of time for the novelty creating process.
- The behavior involved in such processes is not monistic; rather, it includes different modes of action especially skills, intuition, deliberation, and choice.
- Finally, the issues of acceptability and appropriation are dealt with in taking into account the "domain," the "field," and the market competition as environmental conditions.

But, by simply postulating a problem to be solved as the starting point, the boundary or trigger conditions making the occurrence of the novelty creating processes highly probable remain rather void in the concept of problem solving. To meet this explanatory requirement necessitates a broader perspective of the agency under consideration especially including the social and organizational form in which invention and innovation take place (Dosi et al. 2011; Runco 2007; Nickerson and Zenger 2004; Bijker 1987). Given this, it should be possible to elaborate the conditions favorable for the temporary passing of the agency into the ambitious and costly mode of invention/innovation (Beckenbach et al. 2012).

Invention and Modification of New Tool-Use Behavior

Synonyms

Creativity; Evolution; Material culture, emergence; Technological innovation

Introduction

The invention and modification of new tool-use behavior is the essence of technological innovation. Although tool use can be found in both humans and nonhuman animals, humans are distinguished by the variety of their tool use and their invention of new tool-use behaviors by modifying previous types. Humans are also unique in their customary use of metatools, that is, tools used to gain or modify a second (primary) tool, which is then used to achieve the goal.

Human technology has been pervaded by metatool use, from the construction of stone tools by our Oldowan ancestors of 2.5 million years ago, achieved by knapping one stone with another, to the most sophisticated computer-controlled machines consisting of some tens of thousands of components (or sometimes more) in the twenty-first century. This entry discusses the invention and modification not only of the tool itself but also of tool-use behavior, which incorporates several aspects such as technique, function, target, and so on.

Tool Use

Background and Definition

Complex tool-use behavior is a hallmark of human beings. Until Jane Goodall observed a chimpanzee at Gombe in Tanzania using a twig to extract termites from their impregnable shelter in 1960, researchers had believed that tool use was a uniquely human trait. Even now that there is accumulating evidence that nonhuman animals also demonstrate tool-use behavior, some might say that the history of the invention of tools parallels the history of humanity. It is true that there are considerable differences in the variety and complexity of tool-use behaviors between humans and nonhuman animals. The mechanism of generating these differences has recently been one of the most controversial research topics. The invention and modification of new tool-use behavior is central to this question.

Several researchers have provided definitions of tool use. One of the earliest explicit definitions, proposed by van Lawick-Goodall (1970), focused on the abstract properties of this behavior: "the use of an external object as a functional extension of mouth or beak, hand or claw, in the attainment of an immediate goal." Beck (1980) offers a more detailed definition, one that has been used widely in the animal tool-use literature: "the external employment of an unattached environmental object to alter more efficiently the form, position, or condition of another object, another organism, or the user itself when the user holds or carries the tool during or just prior to use and is responsible for the proper and effective orientation of the tool." Matsuzawa's (2001) definition is simpler and makes the point clearly: "a set of behaviors utilizing a detached object to obtain a goal that is adaptive in the biological sense."

Tool Use in Humans and Nonhuman Animals

Nonhuman animals, especially some primates, dolphins, elephants, and birds, also demonstrate tool-use behaviors. They are known to use and make tools and also to demonstrate multiple tool uses. For example, chimpanzees, which are known as the most prominent tool users besides humans, demonstrate a rich variety of tool use with divergent tool materials and techniques aimed at various targets: fishing termites and ants from a nest with a twig or a stalk, dipping for ants on the ground with a rigid wand, scooping up algae floating on a pond with a stick, drinking water with a leaf sponge, cracking open nuts with a stone hammer and an anvil (Fig. 1), clipping a leaf for a courtship display, and so on. The most complex form of tool use found in chimpanzees is the use of a wedge in cracking nuts. Chimpanzees at Bossou in Guinea have been observed to insert a third stone underneath an anvil to serve as a wedge, thereby keeping the anvil stable and flat. While almost all other examples of tool use in nonhuman animals contain only a single relationship between a single tool and a single target (level 1-type tool use), nut cracking with a hammer and an anvil entails two relationships between objects (level 2-type tool use), and three relationships can be discerned in the instances of wedge use (level 3-type tool use): (1) a chimpanzee uses a stone as a hammer to hit a nut, where (2) the nut is placed on an anvil stone, and (3) the anvil stone itself is supported by a wedge stone (Matsuzawa 2001). There is no evidence that nonhuman animals can use tools at level 4 or higher.

Besides the chimpanzees' infrequent wedge stone use, there is no clear evidence in the wild that nonhuman animals use metatools, that is, using one tool to make or gain a second (primary) tool. This is considered to be because of the animals' cognitive inability to do so. Metatool

Invention and Modification of New Tool-Use Behavior, Fig. 1 Chimpanzees' use of stone tools for cracking open nuts at Bossou in Guinea (Source: Photograph by Nogami Etsuko)

use is very cognitively demanding because the relationship between a metatool and the goal object is not direct but rather mediated via the primary tool. Another possible explanation from an ecological viewpoint is that the animal can select or manufacture the appropriate type of primary tool in the first place, and consequently there is no need to use a metatool. The lack of metatool use might be one of the restrictions preventing technological innovation and expansion in nonhuman animals.

Because tools are used extensively by both humans and wild chimpanzees, it is widely assumed that the first routine use of tools took place prior to the divergence between the two species. These early tools, however, were likely made of perishable materials such as sticks or consisted of unmodified stones that cannot be distinguished from other natural stones as tools. The first evidence of stone tool industry that can be found in fossil records dates as far back as 2.5 million years: Oldowan chopper tools. *Homo habilis*, an ancestor of *Homo sapiens*, is considered to have started manufacturing Oldowan tools. Oldowan technology is typified by what are known as "choppers." Choppers are stone cores with flakes removed from part of the surface, creating a sharpened edge that was used for cutting, chopping, and scraping.

Thereafter, humans invented numerous kinds of tools that can be used in a variety of contexts such as feeding, clothing, housing, traveling, and social interactions. After the long Stone Age, around the fourth millennium BC, humans started to use metal instead of stones as the material for their tools. In the Middle Ages and thereafter, the incorporation of new energy sources such as water, wind, heat, and nuclear power caused major technological innovations. Humans evolved an opposable thumb, which is useful in holding and manipulating tools, and our brain size increased, which led to our understanding of the physical principles and causal regularities of how tools work. These features are considered to have contributed to the invention and modification of new tool-use behaviors in humans.

Origins of Material Culture

Not only for humans but also for some nonhuman animals, especially chimpanzees (Whiten et al. 1999), recent studies have revealed geographic variations in tool-use behavior among communities. For example, chimpanzees at Bossou in Guinea crack open oil-palm nuts, whereas chimpanzees at Gombe and Mahale in Tanzania do not demonstrate such stone tool use or hammering techniques even though nuts and suitable stones are readily available at these sites. This is interpreted as evidence of material culture in these species, and it proves that tool use is not totally inherent but rather acquired by invention and modification. These cultural variations are considered to be maintained and passed on from generation to generation through social learning and transmission. This social learning and transmission mechanism enables an individual to learn a novel behavior from others; however, this cannot explain the mechanism of the emergence of the novel behavior in the first place. The mechanism of emergence, that is, invention and modification, of a new tool-use behavior is a key to understanding the origins of material culture.

Invention and Modification of New Tool-Use Behavior

"Invention" and "Modification"

In many cases, it is difficult to clearly distinguish "invention" from "modification" because these two types of change are often continuous, and the difference is merely a matter of degree. For example, de Beaune (2004) examined changes in tools in early humans and suggested that new tools were the result of combining preexisting elements rather than creations *ex nihilo* (Fig. 2). That is, changes can be seen as the "invention" or as "modification" of tools, materials worked, techniques, or other elements.

There are very few records of the invention and modification of new tool-use behavior in nonhuman animals. At Bossou in Guinea, where "ant dipping on the ground" by chimpanzees is customary, a chimpanzee was observed to demonstrate a new tool-use behavior, "ant fishing in trees," which had never been observed over the past 27 years. In 2003, a 5-year-old juvenile chimpanzee was observed to be engaged in ant fishing in trees by employing wands of similar length to those used for ant dipping on the ground, which is a customary tool-use behavior of this community (Fig. 3a). Two years later, at the age of seven, his tools for ant fishing were shorter and more suitable for capturing carpenter ants living in a tree hollow (Fig. 3b). In this process, two steps can be recognized: the first is the change of the target ants from safari ants on the ground to arboreal ants, and the second is the change in the tool length. This can be considered an example of emergence of a new tool-use behavior in which it is difficult to clarify exactly whether the new tool-use behavior was "invented" at the first or second step.

Elements that Could Have Been Newly Invented and Modified

As seen in the above example of the emergence of "ant fishing in trees" by a chimpanzee, there are several elements that could be invented or modified in the process of the emergence of a new tool-use behavior: tool shape, tool material, technique, target, function, and a combination of these.

Tool Shape: In Stone Age tool innovation, 2.5 million years ago, *Homo habilis* first made tools (Oldowan chopper tool, Fig. 4) by hitting one stone against another. About 1.5 million years ago, *Homo erectus* started to shape stone tools more carefully by flint knapping, so that they had long straight cutting edges, like a knife (Acheulean hand axe, Fig. 5). In nonhuman tool use, chimpanzees make fishing and dipping tools from natural plants by stripping off unnecessary leaves and biting off some of the plant to obtain the appropriate length. In the above example, the chimpanzee was observed to adopt tools of different length 2 years after he started to target the different ant species. Some captive corvids (*Corvus moneduloides* and *Corvus frugilegus*) are known to have invented a hook tool to retrieve an out-of-reach bucket containing a worm.

Tool Material: Nonhuman animals mainly use plant materials such as sticks and leaves. Plant tools are easily worked and shaped but are perishable and disposable. Stone tools are hard and tough but are difficult to process. Metal tools have the advantages of both plant and stone tools: they are hard, tough, and also easy to shape. The invention of metal tools stimulated the expansion of technological innovation in humans.

Technique: With the same tool, several different techniques can be employed. For example, when chimpanzees dip for safari ants with a wand tool, some chimpanzees dip for ants

with one hand and then sweep the wand directly with their lips (one-handed technique), while others hold the wand in one hand, sweep the ants with the other hand, and hastily put the mass of ants into their mouth (two-handed technique). Different efficiency levels among techniques may drive behavioral changes in tool use, although chimpanzees are known to considerably stick to an acquired technique.

Target: It is sometimes possible to use the same tool for a target that is different from its original target. For example, in the above case of the chimpanzee's invention of ant fishing in trees, the chimpanzee seemed to first apply a tool and technique originally used for dipping for ants on the ground to ants in trees. Different targets normally have different characteristics and may require tool users to modify their tools accordingly. In this case, the chimpanzee changed the length of the tool 2 years later.

Function: Early stone tools in humans are considered to have had several different functions. For example, Oldowan chopper tools, the earliest stone tools, were used to cut meat off the bone, to crush bones to eat the marrow, to crack open nuts, to skin an animal for its hide, and to fashion wood and bone into other kinds of tools. Thereafter, according to their sophistication in stone-processing techniques, early humans invented tools shaped for specific purposes, such as sharper knifelike tools.

Combination: Combinations of two or more tools sometimes generate a new tool use, enabling an individual to achieve a goal that is otherwise difficult or impossible to accomplish. Three categorical types of combinations can be considered: sequential multiple tool use (tool set), metatool use, and fusion of multiple tools of different functions. As an example of the first category, chimpanzees are known to use a tool set, that is, the sequential use of a digging tool and a dipping tool and sometimes even more (up to five different tools) for obtaining food that is difficult to access, such as termites in a hard shelter and honey in an underground hive. Wedge stone use in Bossou chimpanzees can be interpreted as metatool use (see section "Tool Use in Humans and Nonhuman Animals"). An alarm clock in our modern life is an example of the fusion of a measuring tool (clock) and a perception tool (alarm).

Mechanisms of Invention and Modification

How can the invention and modification of a new tool-use behavior be achieved? Ernst Mach (1838–1916), an Austrian physicist and philosopher, noted: "The majority of the inventions made in the early stages of civilization, including language, writing, money, and the rest, could not have been the product of deliberate methodical reflection for the simple reason that no idea of their value and significance could have been had except from their practical use." On the other hand, Thomas Edison (1847–1931), an American inventor, stated, "None of my inventions came by accident. I see a worthwhile need to be met and I make trial after trial until it comes. What it boils down to is one per cent inspiration and ninety-nine per cent perspiration."

Despite the apparently contradictory remarks by Mach and Edison, both of these suggest an important issue: when we say "a tool-use behavior is invented," we have to recognize its significance and/or necessity. As clearly described in Matsuzawa's definition (see section "Background and Definition"), a tool has to be used "to obtain a goal," and therefore it should be "adaptive in the biological sense." In other words, without any significance or necessity of use, an object cannot be a tool. For example, a stone can be a tool only for animals that are able to use the stone for a specific purpose, such as cracking open nuts. For Mahale and Gombe chimpanzees who do not demonstrate nut cracking, a stone exists as an object, but not as a tool. Consider another example. A stone anvil (or a hammer) can be broken when a chimpanzee cracks open nuts on (or with) it. The shape of the broken stone with sharp edges is similar to that of an Oldowan stone tool. The chimpanzee sometimes reuses the broken stone as a hummer (Matsuzawa 2011); however, it is not used in a newly invented way like Oldowan chopper tool by the chimpanzee, which does not notice its significance or does not have any necessity for using it in this way. In short, we can say that necessity is the mother of invention of new tool-use behavior.

In the process of the invention of a new tool-use behavior, it is possible to consider three types of mechanisms: by accident, by trial and error, and by insight.

By Accident: An individual notices that an object (or objects), whether it has already existed or has newly appeared, serves as a useful tool for solving an overt or potential problem when the individual is not aiming to invent a tool for a specific purpose.

By Trial and Error: An individual, when struggling to solve a problem, finds out a way of using an object (or objects) to reach a correct solution or satisfactory result by trying out one or more ways or means until the errors are sufficiently reduced or eliminated. In this process, at least at the first trial, the individual does not fully understand the causal relationship between the tool use and solving the problem.

By Insight: An individual, when struggling to solve a problem, finds out a way of using an object (or objects) to reach a correct solution or satisfactory result with a full understanding of the causal relationship between the tool use and solving the problem. This is achieved without learning based on trial and error.

It is difficult to clarify which of these three mechanisms takes place in each process of

Invention and Modification of New Tool-Use Behavior, Fig. 6 Invention and modification of hook tools by captive non-tool-using rooks. The rook in this photo extracted the bucket containing a worm using a piece of wire she had just bent (Source: Bird and Emery (2009))

invention and modification. This has continued to be a matter of debate. In nonhuman animals, most tool-use behaviors are considered to have been invented by accident or by trial and error. There are few reports that indicate the insightful invention of tool-use behavior in nonhuman animals. Bird and Emery (2009) reported that captive rooks, which are not tool users in the wild, spontaneously used appropriate tools and modified the tool shape to solve several problem-solving tasks (Fig. 6). In most cases, the rooks did so without trial and error. The authors suggested that this provides evidence for insight in the problem-solving abilities of rooks, referring to Thorpe's (1964) definition of insight: "sudden production of new adaptive responses not arrived at by trial behavior . . . or the solution of a problem by the sudden adaptive reorganization of experience." However, controversy remains as to whether the rooks' invention of tool-use behavior can qualify as insightful because other possibilities such as learning and shaping during previous experiments could not be excluded.

Even in humans, insightful invention is probably not as dominant as we naively suppose. The term "insightful" is often used for behaviors for which we cannot fully explain the information-processing mechanism. People often attribute their own behavior to what they perceive as insight, but in many cases, they can be shown to be wrong, whereas in others the label simply reflects ignorance of the origin of inspiration (Kacelnik 2009). In the above remarks, Thomas Edison also emphasized the trial-and-error processes of his inventions. Nevertheless, it is also true that humans can accumulate their knowledge through their own experience, by social learning, and from shared knowledge passed on from generation to generation. With this capacity, humans may invent a new tool-use behavior through analogical reasoning: new problems and their solutions are stored in their long-term memory and later, if necessary, serve as a source of analogous situations from which to draw inferences about the current one (de Beaune 2004).

Conclusion and Future Directions

In conclusion, there is no doubt that humans and some species of nonhuman animals have invented and modified a variety of tool-use behaviors and have passed them on from generation to generation. So what is the difference between humans and nonhuman animals? What enabled humans to achieve considerable technological innovations in such an evolutionarily short period? One plausible explanation is cumulative cultural evolution, which is considered to be unique in humans. Humans have a capacity to recognize that a modification of a known behavior being used by another individual is more productive or effective in obtaining results than one's own and have the flexibility to switch to this alternative behavior. This is the core of the "ratchet effect" (Tomasello 1994), whereby incremental improvements in behavior occur in succeeding generations. So far, evidence of cumulative cultural evolution in nonhuman animals remains minimal and controversial. This is probably because nonhuman animals lack some of the essential abilities such as imitation, evaluation and comparison of efficiencies, and behavioral flexibility or just because they have not experienced any necessity to achieve such an evolution in their natural environments.

At this moment, the cognitive processes that lead to the invention and modification of new tool-use behavior remain for further investigation. Since the first observation of wild chimpanzees was achieved by Jane Goodall in 1960, the study of nonhuman animals' tool use does not have a long history, and we have not accumulated enough examples of invention and modification of new tool-use behaviors. It is difficult to clarify the mechanism even in human cases and much more difficult for human cases involving fossils because it is impossible to identify the "first" appearance from fossil records. Despite these difficulties, however, investigation of the cognitive processes underlying the invention and modification of tool-use behavior is worthwhile, as it deepens our understanding of how we can reach the production of a new idea, the origins of creativity.

Invention Versus Discovery

Carlotta Piscopo and Mauro Birattari

Synonyms

Discover: Observe, Find, Unveil; Invent: Devise, Create, Innovate

The concept of discovery indicates the process of finding something that exists but that is not known or recognized yet. The concept of invention, on the other hand, indicates the process of devising something that does not exist.

The two concepts of discovery and invention form a dichotomy that portrays a central tension in epistemology. They highlight two different angles from which one can look at the relation between theory and experience.

Introduction

The relation between theory and experience has always been an issue of paramount importance in both philosophy and science. The first modern stand on this issue traces back to Francis Bacon, the father of the experimental method. According to Bacon, scientific theories are obtained directly by induction from observation: Scientific theories exist in nature and scientists limit themselves to discover them through observation. According to Bacon, science is a process that consists in a gradual and linear accumulation of truths about nature. This epistemological position can be conveniently indicated as the *discoverist* position.

The discoverist position has been challenged by a major breakthrough in physics: the refutation of classical mechanics. For more than 200 years, the Newtonian description of nature allowed scientists to obtain predictions that matched accurately empirical results both in the terrestrial and in the celestial domain. The crisis of Newton's theory came as a shock for all scientific disciplines. This shock affected also the epistemological foundations of science. In particular, the fact that classical mechanics, which had been considered for centuries as the true description of the universe, was superseded by relativistic and quantum mechanics challenged the very idea that science is about the accumulation of truths about nature.

The shift from classical to relativistic and quantum mechanics determined a major *epistemological shift*: the shift from the discoverist position to what can be named the *inventionist* position. This shift moves from the idea that science is made of truths that are discovered by induction from observation to the idea that science is about the construction of conjectures that are not obtained directly through experience and that cannot be definitively verified on the basis of experience itself. The dichotomy *inventionism/discoverism* can be used to highlight the tension between the two positions on the status of science that have characterized the scientific debate after the crisis of classical mechanics.

The Discoverist Position

The discoverist position has its roots in the ancient and medieval philosophy and relies on the idea that the ultimate structure of nature can be eventually known beneath the fallacious appearances. As already mentioned above, Bacon embodies such an epistemological position. Bacon's picture of science rests upon the idea that natural laws are obtained by induction from simple observation. Coherently, Bacon (1610) insists that the experimenter should avoid all theoretical anticipations that Bacon calls *idola*. The term *idolum* comes from the Greek *eidolon*, meaning image or phantom. Bacon uses this term to convey the idea that scientists should not observe reality through theoretical constructs: Scientists should simply stick to the data obtained from experience, which Bacon regards as completely objective and as the only source of knowledge. In the proper experimental phase, the experimenter should collect data and organize them in what he calls *tabulae*, which can be regarded as the forerunners of the contemporary databases. The experimenter should eventually derive by induction general laws from the *tabulae*. Two centuries after Bacon, John Stuart Mill (1843) further elaborated the discoverist view of science. Mill stated that induction is a necessary tool to acquire knowledge: It is the only genuine method that allows us to obtain general theories and to justify them. In a way, the discoverist view can be epitomized by the idea that science can eventually remove Schopenhauer's *veil of Maya* and reveal the truth about reality.

The idea that laws truly representing nature can be extracted simply and immediately from experimental data stands on the assumption that these laws are isomorphic to the reality to which they refer. Translated in more contemporary terms (see, e.g., Hastie et al. 2003), this assumption equates to the idea that the real system under observation belongs to the model space. This assumption is necessary if a scientific model is deemed to converge, when sufficient experimental data are available, to the real system itself.

The idea that it is possible to obtain a perfect account of nature underlies the development of modern science. Immanuel Kant's philosophy of science can be seen as the first modern attempt to articulate this idea. Though Kant cannot be seen as a discoverist thinker, he believed that the laws of natural science are indubitably correct because they are based on the a priori categories of cognition, which are applied to phenomena and to which phenomena conform perfectly. Clearly, the significant successes obtained by classical mechanics through the centuries strongly supported the conviction that the correct representation of the universe had been obtained and that science had reached the final truth.

The Crisis of Classical Mechanics and the Problem of Induction

The crisis of such a solid theory as classical mechanics undermined the key assumption on which the discoverist position rests: It undermined the idea that, on the basis of observation, it is possible to derive models that coincide with reality. The inadequacy of classical mechanics suggested that models are, at best, approximations of reality and that they remain ontologically distinct from it.

The crisis of classical mechanics revived one of the most controversial issues in epistemology: The Humean problem of induction according to which no matter how much evidence is accumulated in favor of a theory, the theory can be, at any moment, disconfirmed by further observations. The reemergence of the issues raised by Hume is testified by the fact that a significant number of critical works on induction are coeval to the crisis of the Newtonian paradigm.

In the early twentieth century, Henri Poincaré (1902) argued that scientific theories are not inductive generalizations of experience but are *conventions* that science uses because they yield to useful predictions. Just few years later, Pierre Duhem (1906) criticized Newton's contention that the theory of the universal gravitation was obtained by observation and generalized by induction. Through the well-known example of the "inductivist chicken," Bertrand Russell (1957) stressed the idea that the principle of induction cannot be either proved or disproved on the basis of experience and that it should be accepted as an a priori principle. Karl Popper (1935) firmly rejected the idea that science is characterized by the use of inductive methods. According to Popper, scientific theories are bold speculations that are not obtained by induction from experience nor are definitively verified by it. Following Kant, Popper held that scientists do not draw scientific laws from nature, but they rather apply them to nature. Yet, Popper opposed Kant's view that scientists must necessarily succeed in applying scientific laws to nature, and he insisted on the idea that scientific theories have a temporary status and that they are kept as long as they resist to the test of experience. Thomas Kuhn (1962) questioned, in his turn, the idea that science grows linearly by accumulating truths about nature, and he portrayed science as a process composed of irreconcilable steps. According to Kuhn, science is made of stipulations that the scientific community decides by agreement to use and eventually to replace with alternative ones, which typically lead to an innovative and often incompatible account of reality.

The Inventionist Position

The critical concerns raised in the twentieth century about the discoverist conception of science can be conveniently gathered under the above-mentioned heading of inventionism. Notwithstanding none of the thinkers mentioned in the preceding section, except Popper, explicitly uses the term *invention* to characterize the nature of scientific models, these thinkers share the idea that observation does not directly lead to theories and that it cannot be used to finally prove that theories correspond truly to reality.

Popper delineates the core idea of the inventionist epistemology through the thesis of the asymmetry between verification and falsification. With this thesis, Popper subverts the inductivist presumption that there is a positive relation between observation and theory: He puts forward the idea that the relation is rather in the *negative*. Though scientific theories can never be definitively verified by empirical observation, they can be definitively falsified by it. Coherently, Popper characterizes scientific theories as inventions of the human mind rather than as discoveries of the ontological properties of nature. It should be noted that, in this respect, the title "The Logic of Scientific Discovery" of the English translation of the original German "Logic der Forschung" appears contradictory and seems to suggest the opposite idea. Yet, at a closer look, there is no contradiction between Popper's inventionist view and the original title of the book as *Forschung* means literally *research* rather than *discovery*.

By delineating a composite inventionist and falsificationist conception of science, Popper aimed at forsaking the then mainstream logical positivist stance according to which *verifiability* is what distinguishes science from metaphysics. Popper's argumentation is that, since scientific statements cannot be definitively verified by induction from experience, verifiability cannot be used as a solid criterion to demarcate science from metaphysics. Popper found in the possibility of being tested, and potentially falsified by experience, the appropriate criterion of demarcation between scientific and metaphysical statements. Following Poincaré (1902), Popper considered the *predictive adequacy*, rather than the *ontological adequacy*, as the criterion to be used to justify a scientific theory. The predictive adequacy can be assessed on the basis of empirical tests and therefore pertains to science. On the contrary, assessing the ontological adequacy or, in other terms, the adherence to reality goes beyond the limits of the empirical method and therefore concerns metaphysics. A contemporary formulation of the idea that science should limit itself to what can be empirically assessed is Van Fraassen's *constructive empiricism* (1980). Constructive empiricism rests upon the assumption that the goal of science is to obtain theories that are empirically adequate and not to discover the truth about the unobservable aspects of nature.

By drawing a clear line of demarcation between science and metaphysics, Popper wished to preclude metaphysics from playing a role in the justification of empirical theories. Yet, Popper admitted that some speculative ideas, and he cited the example of ancient Greek atomism, had been of value for science as they have been subsequently turned into scientific theories. In acknowledging the value of metaphysics, Popper echoed Whitehead's idea that modern science owes much to metaphysics. As stressed by Whitehead (1926), science eventually rests upon the faith into the deterministic order of nature that should be seen as the reinterpretation of the medieval belief in a rational God. In particular, it can be noticed that classical mechanics relies upon the idea of an "intelligent and powerful Being" that is ultimately responsible of the order of nature (Newton 1713). Further, it can be observed that Leibnizian mechanics supposes that the world that an observer experiences is nothing but the one that God chooses as the best among many possible others (Leibniz 1710). Through the *principle of least action*, this idea carries on to the Euler-Lagrange theory, to the Hamilton-Jacobi theory, and ultimately to all contemporary formulations of classical mechanics (Lanczos 1986). Nevertheless, as far as Popper reasoning is concerned, the idea is that scientific theories should be justified only on the basis of their predictive ability. As explicitly argued by Popper (1963), metaphysical assumptions, like the one of the perfect adherence to reality, can drive scientists toward interesting research directions. Yet, the theories that are devised along these research directions are to be regarded as conjectures that can be justified only on the basis of the fact that they lead to reliable predictions.

By arguing that science does not rest upon truths derived by induction from experience but rather on bold conjectures that precede observation and that are then checked against it, Popper claimed that he had skipped the problem of induction. Yet, by emphasizing the inventionist character of science, Popper raised a central epistemological issue: the *objectivity* of science. Indeed, stating that science invents laws *about nature* and does not discover laws *in nature* amounts to abandon the idea that scientific knowledge is obtained from, and justified on the basis of the observation of, a reality that exists independently from our mental representations. Popper (1935) provided an answer to this issue by introducing the idea of the *intersubjectivity* of science: Though scientific theories are inventions, they are not arbitrary because the predictions derived from them are "intersubjectively tested" by the scientific community according to well-defined experimental protocols.

The very idea that science is about prediction rather than about the discovery of final truths traces back to concerns raised in the late nineteenth century. This idea is paramount to Mach's epistemology. Before the crisis of classical mechanics, Mach (1883) developed an *instrumentalist* conception of science according to which scientific theories have not to be intended as referring to real entities. According to Mach, scientific theories are rather useful instruments for making predictions. Mach's epistemology, in its turn, may be traced back (Popper 1953) to the one of Berkeley (1710). With his composite empiricist-instrumentalist position, Berkeley anticipated Mach in delineating the idea that scientific theories are justified by their practical utility and in denying that science can discover the intimate nature of reality.

The instrumentalist view of science remained marginal until the end of the nineteenth century. It became mainstream in the early twentieth century, as it appeared the adequate epistemological background for the then-newborn paradigms of relativistic and quantum mechanics. The discussion that confronted Niels Bohr (1949) to Albert Einstein on the interpretation of quantum mechanics shows that the Berkeleian and Machian views of science deeply influenced the epochal turning point that characterizes physics in the twentieth century. Although Einstein is typically presented as an advocate of a realist interpretation of the quantum theory, he agreed with the inventionist thinkers that scientists do not draw from observation theories that correspond perfectly to reality. As put by Einstein (1949), reality "is mentally constructed," and the constructs that are used by scientists to account for the sensory experiences must not be regarded, as Kant did, "as unalterable (conditioned by the nature of understanding) but as (in the logical sense) free conventions": These conventions are justified by their ability to provide a "logical representation" of sensory experiences.

Contemporary Incarnations of the Discoverist Position and the Current Debate

Notwithstanding the idea that science is about discovering the truth has undergone serious criticisms in the first half of the twentieth century, starting from the 1960s, a discoverist stream of thinking reemerged in the literature. This stream of thinking goes under the name of *scientific realism* (Smart 1963; Boyd 1973; Putnam 1975). This new version of the discoverist view revised significantly the notion of truth. Notwithstanding it considers truth as the final goal of science, it acknowledges that science cannot deliver absolute truths. This fundamental change of view emerged from the fact that the notion of truth was replaced by the notion of *truthlikeness* (Oddie 1986; Niiniluoto 1987). The idea behind this revised notion of truth is that science does not state absolute truths but only approximates truths by eliminating false theories and by devising more accurate descriptions of reality.

The notion of truthlikeness is formulated and analyzed within the *similarity approach* (Oddie 1986; Niiniluoto 1987) where it is adopted to provide an explanation of the predictive success of scientific theories. Scientific realists acknowledge, in line with the inventionist view, that scientific theories are selected on the basis of their predictive success. Yet, they claim that it is necessary to recur to the notion of truthlikeness in order to both decide which theory to select among competing ones that are equally predictively successful and to explain why the selected theory is more successful than its rivals: Through the so-called *no miracle argument* (Putnam 1975), a number of realist thinkers argued that the amazing success of science would be miraculous if scientific theories were not, at least approximately, true of the world.

The scientific realist strategy to move from an absolute to a softened conception of truth is motivated by the need to respond to the issue of falsification. Yet, accepting that science is about approximating truth rather than discovering it constitutes a breakthrough in the scientific realist epistemology. It heads the realist epistemology toward an *asymptotic discoverist* conception of truth. This asymptotic conception amounts to renounce the key realist assumption that scientific theories correspond to reality. It nonetheless implies the hope that eventually, and possibly in infinite time, theories converge to truth.

The realist attempt to revive the notion of truth has been seriously challenged in the 1980s by Larry Laudan (1981). Laudan questioned the very idea that the predictive success of a theory is an indication of the fact that the theory is a true account of reality. Laudan pointed out that the history of science indicates that the empirical success of scientific theories does not guarantee either their genuine reference to reality or their truthlikeness. Classical mechanics is a representative example in this sense. Recently, it has been argued that the reasons why the notion of truthlikeness has been perceived as unsatisfactory are related to the double role that this notion plays in the similarity approach: Using Kant terminology, Piscopo and Birattari (2010) clarified that the dissatisfaction derives from the fact that the notion of truthlikeness plays a *constitutive role* in the selection of empirical theories while it should play only a *regulative role* in their conception. Within the similarity approach, truthlikeness performs, on the one hand, the regulative function of a stimulus to continuously search for a more complete account of reality. On the other hand, it plays a regulative role while deciding which theory to select among competing ones: The conclusive criterion for preferring a theory to a rival one is the better correspondence to reality.

The problematic issue with the regulative use of the notion of truthlikeness is that the crisis of classical mechanics has definitively ruled out the idea that a scientific theory can be shown to truly correspond to reality. It is therefore hard to see how the criterion of truthlikeness can act as a regulative principle for the selection and the justification of scientific theories.

Notwithstanding the challenge posed by the crisis of classical mechanics to the idea that science is about discovering the truth, there is nowadays a propension in epistemology toward a discoverist position as it is testified by the reemergence of realist perspectives. This propension has a deep motivation. It should be seen as an attempt to preserve the objectivity of science: It is aimed at defending the idea that there is a reality independent from the observer and that this reality can eventually be discovered through observation.

At a closer look, the tension between the discoverist and the inventionist views of science is not a prerogative of epistemology. This tension emerges, for instance, clearly in the artificial intelligence and machine learning field that goes under the name of *knowledge discovery in databases*. As its name suggests, the field of knowledge discovery in databases rests upon the idea that it is possible to build programs that can discover general laws from data sets. The expert system BACON.1 (Langley et al. 1987) is a milestone in machine learning and should be regarded as a realization of the inductivist and discoverist idea. As it is made clear by its name, the assumption behind the implementation of BACON.1 is that this system is built to *extract* theories *from* nature rather to *construct* theories *about* nature. In other words, the very assumption that is made is that since BACON.1 does not devise theories but discovers them in nature, these theories are necessarily a true representation of nature itself.

It must be noted, yet, that though the discoverist view has pervaded the machine learning field for decades, some sectors of the community seem to have eventually switched to an inventionist position. In particular, nonparametric statistical methods such as bootstrap (Efron and Tibshirani 1993) and cross-validation (Stone 1974) do not rest on the hypothesis that the real system under observation belongs to the model space: If the system does not belong to the model space, the learned model cannot coincide with the system itself, and therefore, no discovery is possible. In such a case, the learned model can be at best an approximation of the system. The learned model can be therefore considered only as a useful invention.

Concerning the possibility of building inductive machines, just few years before BACON.1 was built, Popper raised doubts about the idea that a machine could discover scientific laws by induction from simple observation:

> [. . .] *we may consider the idea of building an inductive machine. Placed in a "simplified world" (for example, one of sequences of coloured counters), such a machine may through repetition "learn", or even formulate, laws of succession which hold in "its" world. If such a machine can be constructed (and I have no doubt that it can) then, it might be argued, my theory* [here Popper means the theory that science does not rely on induction] *must be wrong; for if a machine is capable of performing inductions on the basis of repetition, there can be no logical reasons preventing us from doing the same. The argument sounds convincing, but it is mistaken. In constructing an induction machines we, the architects of the machine, must decide* a priori *what constitutes its "world"; what things are to be taken as similar or equal; and what* kind *of "laws" we wish the machine to "discover" in "its" world. In other words we must build into the machine a framework determining what is relevant or interesting in its world: the machine will have its "inborn" selection principles. The problems of similarity will have been solved for it by its makers who thus have interpreted the "world" for the machine*. (Popper 1963)

Conclusions and Future Directions

A tension between the *discoverist* and the *inventionist* views can be seen both in science and in epistemology. The discoverist view is motivated by the need to preserve the objectivity of science, but this view has to deal with the problem of induction. The inventionist view skips the problem of induction, but it has to renounce the idea that scientific knowledge has an objective character.

The tension between the discoverist and the inventionist views appears unavoidable in future discussions about the nature of science. On the one hand, the discoverist view responds to the philosophical concern of ensuring that science is not an artifice but a rational and objective enterprise. On the other hand, the inventionist view is enforced by the pragmatic acknowledgement that even the best confirmed theories are simply conjectures that can be eventually abandoned and substituted by alternative ones that are expected, in their turn, to face the same destiny as their predecessors.

Further research is needed in order to solve the above-mentioned tension. Popper's falsificationist view and the related conception that science does not produce truths but rather builds intersubjectively testable theories appears to be a viable solution: Falsificationism describes scientific theories as not arbitrary though it accounts for their fallible character.

Introduction

How people invent? Famous scientists and engineers sharing their memories, as well as psychologists studying the creativity process, describe similar situations: An individual facing a difficult problem is mentally exploring various approaches, persistently trying and rejecting ideas until the right one comes. Psychologists call this process trial-and-error method (T&EM).

T&EM has a great history. It was used to create first stone knives, bows, guns, windmills, building, ships, and almost everything we can see around. Some results are astonishing: Polynesian catamarans, old Chinese, Norwegian, or Russian boats are practically perfect. Each element has the best shape. However, archeological research has shown that even 500 years ago, these vessels were rather far from perfect. One hundred years after another of repeating practically the same shapes, the builders yet were introducing slight changes into design. Some of them were unsuccessful, causing fatal accidents, and have been forgotten; the others, successful ones, were becoming a standard. It was a long evolutionary way similar to the evolution of life with similar consequences including fatalities and victims.

With the acceleration of technological evolution, T&EM became less and less acceptable as a method of design. It is absolutely unreasonable today to build thousands of samples to select the best design of a modern aircraft or a steam machine. Engineering science has stepped in offering various means, allowing identifying the best design with the help of scientific research, calculations, modeling, computer simulations, etc. As a result, engineering design today is rather systematic, structured, and well-controlled process, while searching for new ideas is still lacking all these necessary features.

In the typical creative process, people start from exploring apparent conventional solutions, usually governed by their *psychological inertia* slowly moving to the area of "wild" ideas. After hundreds of unsuccessful attempts, luck becomes a king: Someone occasionally can notice a café-maker in the room and wonder if steam could help to solve the problem.

The T&EM effectiveness depends on how difficult the problem is. It could be measured by a number of trials that have to be made to guarantee successful results. This number can vary within wide range – from dozens for simple problems to hundreds of thousand for difficult ones. T&EM is rather sufficient for the problems that do not require more than 10–20 trials; however, for difficult problems that require out-of-the-box thinking, it leads to an unacceptable waste of time and efforts.

In addition to low efficiency, T&EM contributes in poor problem statements. Often a problem is stated in occasional and incorrect format with a lot of unnecessary information while needed information is absent.

Until recently, the T&EM deficiency has been compensated via increasing number of people working on the same difficult problem. At the same time, since the mid-1950s, it had become obvious that even the most adequate utilization of human resources could not satisfy the required pace of invention production. Accelerating technological evolution demanded simple and affordable creative methods. So, the demand has originated the supply. To date, over hundred of various creative techniques and methods are available with different efficiency, area of application, and practical importance (Higgins 1994). At the same time, because it seemed fairly obvious that creativity was a product of the human brain, the main approach to creativity was focused on attempts to enhance the creative process by facilitating an individual's mental processes, that is, *psychology-based approach* to creativity. In summary, these efforts were aimed at the following:

- Unleashing natural creativity and eliminating mental blocks
- Stimulation and mobilization of resources helpful for generating ideas by a group or individual

Later, a fundamentally different, knowledge-*based approach* has been introduced including various analytical steps aiming to manage (organize, restructure, etc.) and utilize available internal knowledge and experience; eventually this approach led to utilization of specially developed and structured external knowledge (innovation knowledge bases).

The basic advantages of the innovation knowledge-base techniques are the following:

- Accumulation of the best practices in creative problem solving is possible.
- Proved knowledge can be assessed.
- Results are repeatable and do not depend on personal (psychological) issues.

The most significant result of the knowledge-based approach is the Theory of Inventive Problem Solving (TRIZ – a Russian acronym for the Theory of Inventive Problem Solving, pronounced as "trees" (Altshuller 1984).

TRIZ Origination and Early Discoveries

TRIZ was founded by Genrich Altshuller, who was born in former Soviet Union in 1926. He has made his first invention at age of 14 and was later educated as a mechanical and chemical engineer.

He also has a military education as a pilot. In 1946, he was employed as a patent agent in Soviet navy with the main responsibilities to assist inventors in filing their patents. However, because of his background, he was frequently approached by engineers stragling with difficult problems. While trying to help them, Altshuller began questioning if a certain systematic or even scientific approach to innovation is possible. After conducting preliminary studies in this area, he decided to embark on his own quest to develop such approach.

While traditional studies on creativity were focusing on psychological aspects of the innovation process, Altshuller chose studying thousands of patents looking for common threads, repetitive trends, and patterns related to innovation activities. The early results of this research brought discovery of *patterns of inventions* (inventive principles) and *patterns of technological evolution*. Other results included *definition of an inventive problem* and *levels of invention*.

In the history of TRIZ, two distinct periods could be identified: *classical TRIZ* and *contemporary TRIZ* characterized as follows:

Classical TRIZ	TRIZ as it underwent development led by Genrich Altshuller in the former Soviet Union (from the mid-1940s to the mid-1980s).
Contemporary TRIZ. Phase 1	TRIZ during *perestroika* in the former Soviet Union, when first commercial application started (from the mid-1980s to the early 1990s).
Contemporary TRIZ. Phase 2	TRIZ as it penetrated the Western world (beginning in the early 1990s to present).

TRIZ Fundamentals

Among the basic discoveries of TRIZ, the most important are:

- Any technical system develops according to certain patterns.
- The patterns of evolution for different systems have much in common.
- The patterns of evolution can be unveiled through researching the evolutionary history of a system (for the area of technology, this evolutionary history is contained in the patent library and other sources of technical information).
- Via application of these patterns, one could accelerate the evolution of that system to its next generation.
- Based on these discovered patterns of evolution, universal methods for searching for new ideas can be developed.

Patterns of Invention

Altshuller's analysis of patents showed that the same fundamental solutions had been used over and over again for different problems, often separated by many years.

Invention #1. Sweet Pepper Canning Method

To prepare green peppers for canning, the stalk and seeds must be removed. This is done manually in the kitchen, but automating the process for large-scale production is difficult because the pods are nonuniform in shape and size.

The following method was invented to core green peppers: The peppers are placed in an air-tight container, in which the pressure is gradually increased to 8 atm. The pods shrink and, as they do so, fracture at the weakest point, where the stalk joins the pepper. Compressed air penetrates the pepper at the fractures, and the pressure inside and outside the pepper eventually equalizes. The pressure in the container is then quickly reduced, causing the pepper to burst at its weakest point (which has been further weakened by fractures). The top is "ejected" from the rest of the pepper, taking the seeds with it.

Invention #2. Husking Sunflower Seeds

One method of husking sunflower seeds is to load them into a bunker, increase the pressure inside the bunker, and then decrease the pressure sharply. The air that penetrates the husks under high pressure expands as the pressure drops, thereby splitting the husks.

Invention #3. Filter Cleaning Method

A filter used to treat fine-grained sand consists of a tube whose walls are coated with a porous, felt-like material. When air passes through the tube, the sand particles are trapped in the pores. Cleaning such a filter is difficult.

The filter can be cleaned by exposing it to a pressure of 5–10 atm and then quickly dropping the pressure to normal. The sudden change in pressure forces air out of the pores, along with the sand. The sand particles are carried to the surface, where they can be easily removed.

Invention #4. Splitting Imperfect Crystals

When manufacturing tools made of artificial diamonds, crystals that contain fractures cannot be used. Splitting the crystals at the fracture yields useable diamonds, but efforts to do so often produce new fractures.

As an alternative, the crystals can be placed in a thick-walled, air-tight vessel. The pressure in the vessel is increased to several thousand atmospheres and then quickly returned to normal. This sudden change in pressure causes the air in the fractures to break the crystals.

Invention #5. Producing Sugar Powder

A technique similar to those described above is employed, at much lower pressure, to break sugar crystals into powder.

The inventions above span different areas of technology and appear at different times, yet they are clearly similar. Moreover, the problems addressed by these inventions are similar. Undoubtedly, had the later inventors known of the earlier solutions, their problem-solving tasks would have been straightforward. Unfortunately, the barriers that exist between different industries made this practically impossible.

We can imagine that a problem solver trying to devise a way to remove the shells from walnuts will know (or be able to find out) how sunflower seeds are shelled, and solving the problem will therefore be relatively simple. Let's imagine, however, that this solution did not yet exist in the food industry. In this case, it is very unlikely that our problem solver will look for a solution in the metallurgy or diamond production industries, and he therefore will be unable to apply a "ready-made" solution and instead must spend time and money reinventing it.

Altshuller realized that knowledge about inventions could be extracted, compiled, and generalized so that it would be useful to inventors in any technological domain. For example, all five of the above inventions can be described as follows:

Problem: Breaking Apart an Object *Solution:* Apply a gradually increasing pressure for some period of time, and then abruptly drop the pressure. The pressure differential will create an "explosion" that breaks the object apart.

This generalized knowledge can be organized and made available so that, when faced with a problem, an inventor needs to only match the problem with the generalized problem, then refer to the corresponding solution(s).

In this way, TRIZ provides problem solvers with access to the most effective solutions over a broad range of industries, based on the accumulated innovative experience of inventors throughout history. In TRIZ, these generalized solutions are called *inventive principles*.

Patterns of Technological Evolution

The first set of patterns of technological evolution was distributed by Altshuller among TRIZ schools in the mid-1970s. This seven-page manuscript became the most valuable component of TRIZ and established the foundation for TRIZ as a science.

The set of patterns included three groups named after the laws of theoretical mechanics as follows (Altshuller 1984):

Group 1 – Statics – determines the beginning of a system's life cycle, including:

1. Completeness of an engineered system
2. Energy flow in an engineered system
3. Harmonization of the synchronization rhythms or parts in an engineered system

Group 2 – Kinematics – determines the general evolution of a system, including:

4. Increasing ideality of an engineered system
5. Nonuniform evolution of subsystems comprising an engineered system
6. Transition to the overall system

Group 3 – Dynamics – reflects evolution in contemporary conditions involving certain physical and technical factors, including:

7. Transition from macro- to microlevel in an engineered system
8. Increasing substance-field involvement

Later, various modifications to the set above were introduced, including numerous lines of evolution (more detail step-by-step descriptions of evolution within the patterns).

Contradictions

One of Altshuller's key findings was that *nearly all great inventions* (*except serendipitous discoveries or inventions resulting from accidents or mistakes*) *are the result of the resolution of one or more contradictions* (*paradoxes*). This common thread – the relationship between contradictions and inventions – provided invaluable insight about problem solving that had previously been unavailable (Altshuller 1984).

A ***contradiction*** exists when attempts to improve one feature of a system cause another feature to degrade.

Altshuller identified two types of contradictions. The first is called a *technical contradiction*. A technical contradiction exists when an improvement to one characteristic of a system is associated with the deterioration of another characteristic. Indeed, engineers often talk in terms of such "dilemmas":

- If we add more functional capabilities to this machine, it will become more complicated and difficult to maintain.
- By increasing the speed of our process, we end up with more errors.

The second, more fundamental type is called a *physical contradiction*, when a characteristic must exist in two opposite states:

- A pen tip should be sharp to draw legible lines but blunt to avoid tearing the paper.
- Aircraft landing gear is necessary for landing but is undesirable during flight.

The conventional way to deal with a contradiction is to look for a compromise or trade-off. Revealed in the patent fund, however, are many examples of solutions that resolve contradictions. This means that *methods for satisfying contradictory requirements exist and can be applied.*

The discovery of the relationship between contradictions and inventions led to significant findings that were soon to simplify the process of solving inventive problems. Altshuller realized that the key to attacking an inventive problem was to reveal the contradiction that lies at its core. For recognized and formulated contradictions, tools for their resolution were created.

Ideality and Inventive Resources

Another Altshuller's important fundamental discovery was that *as technological systems evolve, they become more ideal*. By his definition, a completely ideal system would just perform its function without having side effects, cost, or any other undesired factors. Further, he concluded that all these negative factors that make the system less ideal are associated not with its function but rather with the system that performs this function. Based on this conclusion, *in an ideal system, the function is performed without the existence of the system* (Altshuller 1999). Accordingly, the best solution to a problem will be the one closest to the ideation ultimate result (IUR) that could be defined as follows:

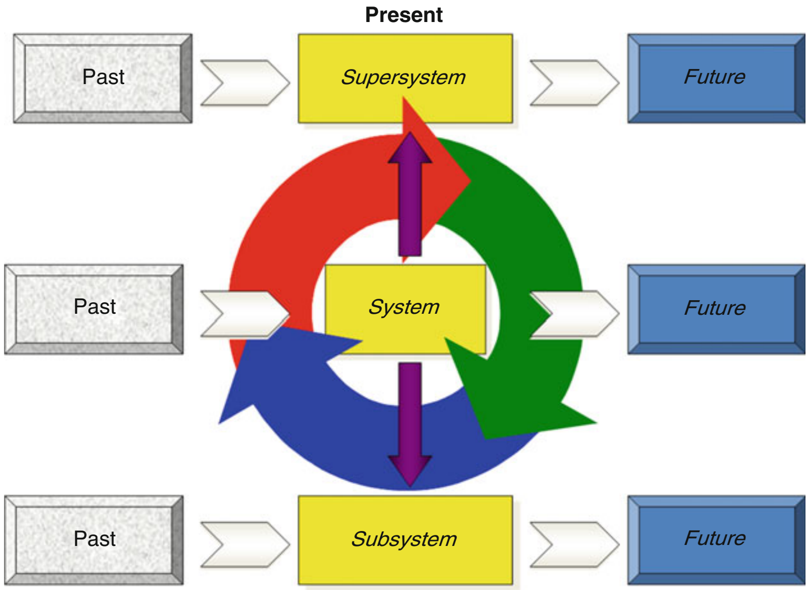
- Produces the desired improvement
- Does not make the system more complex and/or costlier
- Does not cause any side effects/consequent problems

These statements are obviously extreme and are never actually attainable, yet it is important to keep them in mind as we look for inventive solutions to difficult problems.

In real systems, *ideality* for a given system can be defined as the ratio of the sum of its useful features (benefits) to the sum of harmful (or undesired) factors. Given that, the way to increase system's ideality could be one of the following (or both):

- Increasing system benefits
- Reducing harmful factors

The general approach to achieving near-ideal solutions is using *inventive resources*. An inventive resource can be defined as an attribute of a system or its surroundings that could be utilized for system



Inventive Problem Solving (TRIZ), Theory, Fig. 1 9-screen model of creative thinking (Altshuller 1984; Ideation International 1995)

improvement instead of introducing (adding) external means. These attributes could be:

- Any substance or anything made of a substance (including waste) that is available in the system or its environment
- An energy reserve, free time, unoccupied space, information, etc.
- The functional and technological ability to perform additional functions, including properties of substances as well as physical, chemical, geometric, and other effects

Example

At egg farms, instead of using special devices for date stamping, workers use gloves with date-stamp on one of the fingers. The eggs get stamped as they are placed by workers into cartons.

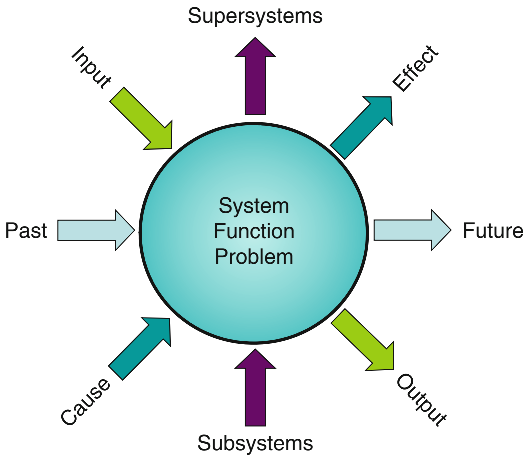
System Approach

Typically, when a problem arises in a system (or in its certain part, for this matter), problem solvers try to solve the problem by focusing on the *system*. But experienced inventors think differently. They understand that the system elements and the elements of the close environment are interconnected; because of that, changes in one part of the system produce sequential changes (both positive and negative) to other parts of the system and its environment. Given that, they simultaneously think about the system, the supersystem, and all associated subsystems and how they could be useful in problem resolution. For example, the system "airplane" is a part of the supersystem "transportation." Switching from the "airplane" to "transportation" changes our point of view for how to deal with a problem associated with an airplane.

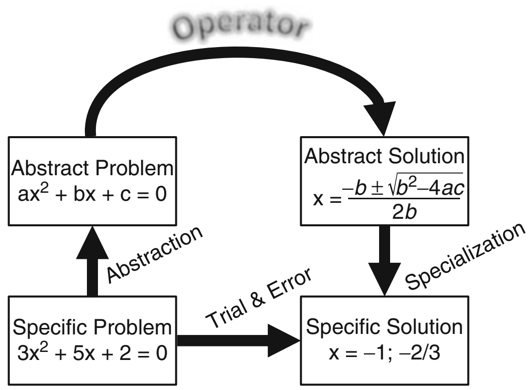
Example

If we are looking for ways to reduce the time it takes to fly from Los Angeles to Tokyo, and we are targeting a system called "airplane," then our focus for solving the problem would be centered on making the airplane move faster. On the other hand, if we focused on the supersystem "business trip," we might consider *all* aspects associated with moving a person through the entire process, from the time he/she leaves the house until he/she arrives at the desired destination. This more expansive look at the problem now includes driving, parking, ticketing, security check-ups, baggage handling, entering and exiting the plane, directional signage in the terminal, and so forth.

Altshuller suggested that the thinking process of the most talented natural inventors could be illustrated with the diagram shown below (Fig. 1).



Inventive Problem Solving (TRIZ), Theory, Fig. 2 8-angle system approach (Ideation International 2004)



Inventive Problem Solving (TRIZ), Theory, Fig. 3 Principle of solution by abstraction applied to quadratic equation (Ideation International 1995)

Because thinking about numerous aspects of the situation is extremely hard for normal human being, he recommended transforming this complex picture in a linear sequence of "boxes," allowing considering one direction at a time.

Later, the schematic above was convoluted in two axes, system axis and time axis, and two additional axes were introduced, suggesting eight angles to the problem situation (Fig. 2).

Main Approach to Inventive Problem Solving

Humans possess an innate approach to problem solving: When faced with a problem we do not know how to solve, we try to think of a similar, *analogous* problem for which we know a solution. Then, with this known solution in mind, we try to devise an analogous solution to the problem we are trying to solve. The chances that we will succeed using this approach are determined by:

- Our knowledge of problems with known solutions, accumulated through education and experience. This knowledge is needed to make the analogical "leap" from our new problem to the analogous problem.
- Our ability to devise a solution to a new problem from the analogous solution.

If one's experience and/or ability to see analogies is limited, principle of abstraction can help (Fig. 3).

The example above is a well-established approach in math. TRIZ suggests that the same approach could be applied to inventive problem solving (Fig. 4).

Similar to math, each transition described above is supported with well-defined tools (Fig. 5).

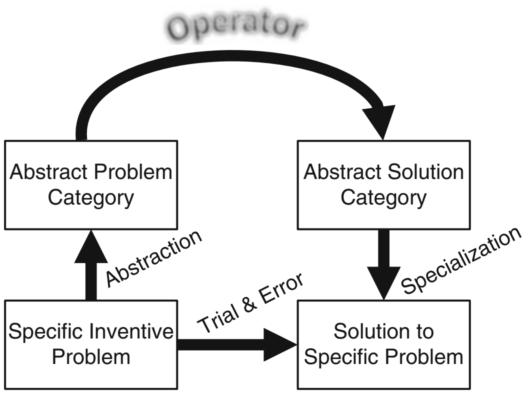
TRIZ Way of Thinking Versus Conventional Thinking

The main concepts of TRIZ, especially ideality, resources, contradictions, and system approach, constitute TRIZ way of thinking, which is different from conventional thinking of the majority of human individuals. The Table 1 below shows the difference.

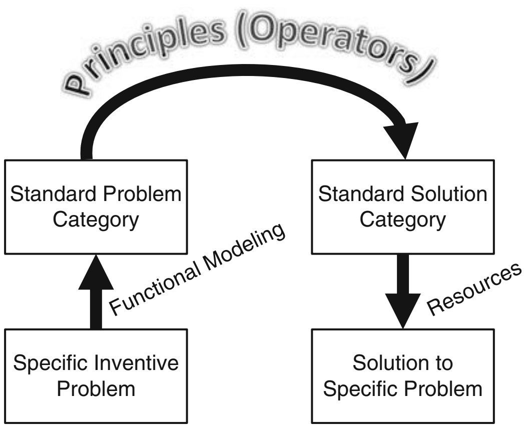
Simple algorithms and several well-formulated recommendations can help master TRIZ way of thinking, making it an inherent part of an individual's mentality.

TRIZ Tools

TRIZ tools for systematic innovation include *analytical tools* that help understand if it is necessary to reformulate the problem and



Inventive Problem Solving (TRIZ), Theory, Fig. 4 Principle of solution by abstraction applied to inventive problems (Kaplan 1996)



Inventive Problem Solving (TRIZ), Theory, Fig. 5 How TRIZ works (Ideation International 2004)

knowledge-based tools that represent the best innovation and problem-solving practices extracted from patents and other sources of information.

Analytical Tools

Analytical tools of classical TRIZ include:

- Algorithm for Inventive Problem Solving (ARIZ)
- Substance-Field Analysis

Later, two additional analytical tools have been developed to ensure complete support of all steps in the problem-solving process, including problem definition and formulation (Terninko et al. 1998):

- Innovation Situation Questionnaire®
- Problem Formulator®

ARIZ

ARIZ (Russian acronym for the *Algorithm of Inventive Problem Solving*) is an analytical tool organized as a set of sequential steps helping reveal contradictions and create a set of models of the problem that serve as pointers to apply appropriate knowledge-base tools. The first version of ARIZ was introduced by G. Altshuller in 1959. Since then, numerous modifications have been developed based on feedback and suggestions provided by TRIZ theoreticians and numerous TRIZ practitioners. The last standard version introduced by Altshuller was ARIZ-85C (1985) including over 60 steps. Since then, several modifications have been compiled by various TRIZ providers (mostly simplifications), but none of them has become a standard.

Substance-Field (SF) Analysis

Substance-Field (SF) Analysis is an analytical tool introduced by G. Altshuller in the mid-1970s with the following assumptions (Altshuller 1984; Terninko et al. 1998):

- The minimal model of a functioning technological system includes two objects or substances interacting through a field or force (energy).
- The system can be graphically modeled by a triangle relating the substances and the field.
- Depending on completeness of the given model (all three elements are present or some are missing) or the nature of interaction (useful or harmful), certain standard solutions are recommended.

The Innovation Situation Questionnaire®

(Innovation Situation Questionnaire®, Problem Formulator®, and Directed Evolution® are trademarks of Ideation International Inc.)

The Innovation Situation Questionnaire (ISQ) is a set of questions helping collect and organize available knowledge about a problem situation for the purpose of supporting the problem-

Inventive Problem Solving (TRIZ), Theory, Table 1 TRIZ way of thinking versus conventional thinking

Concept	Conventional thinking (attitude)	TRIZ thinking (attitude)
Ideality	Looking for incremental obviously feasible solutions	Envisioning the most desirable solution in assumption that anything is possible and, once it is envisioned, looking to realize it or the closest possible
Resources	Means for system improvement should be brought from the outside. To add a function or a feature, one should introduce additional element, energy, money, etc.	First, look for an unused resource (internal or from the close environment) that can perform an additional function or provide an additional feature
Contradiction	Avoiding; when confronted, looking for a trade-off or a compromise	Understanding that any difficult situation has an underlined contradiction. Formulating (verbalizing) this contradiction(s) and applying appropriate operators for its resolution
System approach	Limiting solution space within the area in which a problem has occurred	Understanding that elements of the given system and its environment are interconnected; changes in one part of the system produce sequential changes (both positive and negative) to other parts of the system and its environment; every problem should be considered as a problem situation with multiple angles to address the issue

solving process (Terninko et al. 1998; Kaplan 1996). Although typically subject matter experts for a given system know their system well, this knowledge is usually focused on performance and/or production. While this is helpful and even necessary, knowledge of this type can produce strong psychological inertia factors that hinder the creative process. ISQ questions have been carefully selected based on extensive TRIZ experience of leading TRIZ specialists; as a result, they help look into the problem situation from TRIZ point of view and allow for generating the first inventive ideas.

Problem Formulator®

The Problem Formulator is an analytical tool for transferring knowledge about a particular problem situation from the user's mind into a comprehensive set of Directions for Innovation (problem statements) (Terninko et al. 1998). Problem Formulation process included two steps:

- Building a diagram (visual model) that describes the problem (innovation) situation in terms of cause-effect relationships
- Converting the diagram into an exhaustive set of Directions for Innovation

Each computer-generated Direction for Innovation serves as a "pointer" to a relevant portion of the knowledge base.

Knowledge-Based Tools

Besides patterns/lines of evolution, knowledge-based tools of classical TRIZ include (Altshuller 1984):

- 40 Principles and Contradiction Matrix
- Separation Principles
- The System of (76) Standard Solutions
- Selected Innovation Examples
- Effects (Phenomena)

Historically, various TRIZ knowledge-based tools were developed with the expectation that older tools would eventually be replaced or absorbed by more advanced and effective tools (Zlotin 1999). As a result, by 1980s many TRIZ schools practically stopped teaching the 40 Innovation Principles providing only brief information about this tool and instead put emphasis on the System of (76) Standard Solutions. However, later it became apparent that excluding the 40 Innovation Principles from a practitioner's "toolbox" had a negative impact on one's practical problem-solving abilities, primarily due to the fact that the older tool had its own advantages, like simplicity. Also, several very effective recommendations from the 40 Innovation Principles were not included in the System of Standard Solutions (e.g., "transformation of harm into a benefit"). On the other hand, tools multiplicity led to duplication and confusion which tool to use in various practical cases.

Later attempts to resolve the issues above and to further enhancement of TRIZ knowledge-based tools went in two main directions (Zlotin et al. 2010):

- Development of an integrated operational knowledge-based tool (System of Operators) that included all recommendations contained in the 40 Innovation Principles, System of Standard Solutions, Utilization of Resources, etc. This new system allowed working with any problem model known in TRIZ: technical contradictions, physical contradictions, substance-field models, etc.
- Development of simplified sets of principles (operators).

TRIZ Applications

The first TRIZ application (reflected in the name of the methodology) – solving inventive problems in technological areas. However, inventive problem solving (IPS) is only one of the existing innovation needs. To address all needs and develop a complete innovation and problem-solving platform, the following steps have been taken:

1. Identifying all needs related to problem solving and innovation and development of a comprehensive set of applications that will address these needs.
2. Development of computer-aided processes for each application.

This approach resulted in the development of the following additional applications supported by the family of TRIZ-based software (TRIZSoft®) (Zlotin et al. 2010):

- *Anticipatory failure determination* (*AFD*) – proactive process for analyzing, predicting, and eliminating failures in systems, products, and processes
- *Directed evolution*® (*DE*) – predicting next generations of products, services, and technologies via inventing them and developing a comprehensive set of scenarios describing future generations of a system
- *Control* (*Management*) *of Intellectual Property* (*CIP*) – evaluation and enhancement of intellectual property (IP) related to proprietary technologies, inventions, patents, and patent portfolios

Furthermore, contemporary TRIZ possesses tools and processes developed for addressing various issues beyond technology, including problem solving and innovation in areas of business, management, logistics, organizational development, social aspects, and more (Zlotin et al. 2000). Together with inventive problem solving (IPS), the applications above could be considered as contemporary *office of innovation*.

TRIZ Education

Learning how to apply TRIZ concepts and tools takes time. In various ways, TRIZ could be counterintuitive to many people. Psychological inertia, fear of contradictions, lack of open mind, and other reasons make it difficult to learn and accept TRIZ concepts for adult professionals often overwhelmed with their everyday tasks.

Original typical TRIZ courses developed during the era without computers and support from academia were rather long (at least 240 h). The long learning curve was necessitated by the large amount of knowledge that must be acquired from various sources and through substantial practice before becoming a self-sufficient practitioner. Over the years, TRIZ has accumulated many tools of various degrees of complexity, yet there were no clear rules as to which tools should be applied to a particular practical case. Typical TRIZ knowledge included numerous examples and illustrations (learned from instructors and accumulated from one's own experience) and other (mostly tacit) knowledge about how to successfully utilize TRIZ methods and tools. There was no doubt that this issue could become a serious obstacle in wide dissemination of TRIZ.

TRIZ for Professionals

Since the mid-1980s, the need to accelerate TRIZ learning for professionals became quite critical. One (rather obvious) way was to simplify TRIZ learning via focusing on the easy-to-learn TRIZ concepts. Unfortunately, the downside of this approach was substantial reducing of TRIZ problem-solving power. The other approach was development of TRIZ-based software tools. This approach also could be realized in two ways – (a) computerization of existing TRIZ tools and (b) restructuring TRIZ knowledge, making it more suitable for computerization (and thus more effective) (Zlotin et al. 2010).

Today, various TRIZ courses are offered (with or without software) for professionals, from 4–8-h orientations to extended ones. The most cost-efficient proved to be 3–5-day workshops during which the participants learn TRIZ fundamentals and use TRIZ software to simultaneously work on their project. The best results are achieved when these workshops are followed with coaching/mentoring for 30–60 days to ensure successful completion of the project.

At the same time, short TRIZ courses (even with the utilization of software helping achieve good practical results) cannot accomplish one very important objective – development of TRIZ mentality necessary to become a TRIZ professional (similar to the fact that one cannot learn math in a 3-day workshop to become an engineer). Naturally, it should be different if the main TRIZ concepts were learned at early age, like math.

TRIZ for Students and Children

Given the main difficulties with teaching TRIZ to professionals, it became obvious that most of the difficulties could be overcome if TRIZ were taught to college students and even school children of various ages. The first attempts to engage children audiences were made in 1970s in the Soviet Union, when G. Altshuller had a special page in the all-union paper, publishing basic TRIZ concepts and holding a contest for them to participate. Later, Altshuller summarized this 10-year experience in one of his books (Altshuller 1996). Since then, various TRIZ courses have been taught to school children and even in kindergartens.

Since the mid-1990s, some elements of TRIZ have been taught at various colleges and universities in USA and other countries. Lately, fully credited courses for undergraduate students and for continuous education have been offered.

Conclusion and Further Directions

Over 65 years of TRIZ development could be illustrated below (Fig. 6).

Started from revolutionary discoveries, it has resulted in creation of numerous tools and applications to satisfy all innovation needs and problem solving in practically all areas of human activities (Figs. 7 and 8).

The benefits from learning TRIZ for an individual are quite obvious – one can become a strong critical thinker, innovator, and problem solver.

For an enterprise, the main benefits of TRIZ utilization could be illustrated as shown below (Fig. 9).

When a project manager is about to start a project (starting point), he/she has to analyze possible directions and make a decision which way to go. Typically, the options to consider are few; theoretically, an exhaustive set of all possible options could have many more; however, it may take decades to find all of them if one relies on gradual accumulation of practical knowledge. Therefore, the manager has to make a “forced” decision within reasonable time in the situation of insufficient knowledge relying on his/her intuition, “gut feeling,” etc. Utilization of TRIZ with its powerful analytical tools and extensive knowledge base that accumulated the best innovation practices could significantly shrink this time – a typical problem-solving project can take 4–8 weeks.

The majority of more or less successful techniques introduced to the industry in the twentieth

century (value engineering, quality function deployment, lean manufacturing, six sigma, etc.) have a weak link – luck of tools to produce creative solutions. Because the latter is the strongest point of TRIZ, it makes it greatly compatible with practically all other techniques and methods for quality improvement and cost reduction.

At the same time, TRIZ is neither a magic wand nor a silver bullet. If one would like to "calculate" the result of implementing TRIZ within an enterprise, the formula could look as follows (Fig. 10).

From the formula above, one can see that if such critical factors like subject knowledge, personal capability, motivation, and/or management support is missing, the overall results will be zero (with or without TRIZ). However, if all these necessary components are in place, TRIZ could be a tremendous multiplication of efforts and acceleration factor to the innovation process.

Inventive Problem Solving (TRIZ), Theory, Fig. 9 Accelerating innovation with TRIZ: more solutions, better, and faster (Ideation International 2001)

In spite of 65 years of development, research, and utilization and close to 5 M of search results on Google, TRIZ is still a very young science and technology. The strongest challenges are:

- Absence of Industrial Standards. Many companies tried some TRIZ products, services, and/or education from various providers with inconsistent results. While power of TRIZ methodology is quite visible to technical people, it is not so for the top executives who are focusing on bottom line rather than on technical issues. Although innovation has become a "buzz" word for the twentieth century, very few companies have the strategy and culture to embrace it and unleash its full potential. Because of many organizational and cultural factors affecting TRIZ implementation (see Fig. 9 above), there are not enough success stories to start TRIZ "tornado."
- Lack of Academic Research. Although being created using empirical approach, TRIZ was built as a science, with assumptions, definitions, and fundamental knowledge (patterns of evolution); however, during "Russian period" of TRIZ (1946–1992), most of the TRIZ research was done by individual enthusiasts, without sponsors or academia involvement. Even today, serious TRIZ studies are limited. Few commercial companies are

Inventive Problem Solving (TRIZ), Theory, Fig. 11 Evolution of TRIZ applications (Ideation International 2001)

more focused on sales and marketing strategies than research.

- Lack of Benchmark. Although there is a lot of offering of TRIZ products, services, and education on the market, potential clients have a hard time to evaluate the supply. As a result, certain negative experiences hinder wide TRIZ dissemination.

From the future direction's point of view, there are several aspects of TRIZ further evolution. As a methodology, it has gone through several transformations as follows:

- Way of thinking
- Set of tools
- Set of processes
- Complete system (office of innovation)

From application's point of view, TRIZ evolution could be considered as follows (Fig. 11):

Given the above, further directions in TRIZ development should be as follows:

- Theoretical base of TRIZ (TRIZ as a science)
  - Axiomatic foundation of TRIZ
  - Revised and extended system of patterns/lines of evolution
- Development of new and enhancing existing tools and applications, including productivity software tools
- Continue expanding TRIZ in new areas, for example:
  - Validation and enhancement of intellectual property
  - Solving scientific problems
  - TRIZ for nontechnical systems (business, management, politics, marketing, etc.).
- Integrating TRIZ with other creative techniques and business, quality, and knowledge management systems like six sigma, stage gate, etc.

At the same time, TRIZ has far overgrown its name. Solving inventive problems was a strong necessity of industrial era. There is still room for further development, including honing analytical tools, upgrading and extending knowledge base, finding new applications, etc. However, today, a problem in a certain system can be compared to a sickness; problem solving is equal to looking for a cure. This health care analogy shows us a better way – healthy lifestyle allowing avoiding problems in the first place. Similarly, the next step in evolution of TRIZ is transition to directed (managed, guided) evolution of technology and beyond that will eventually allow any individual or entity to be able to plan and control their destiny, including formulating goals and timely unveiling (anticipating) and solving problems that could arise on the way to a destination.

Inventive Resources

Boris Zlotin and Alla Zusman
Ideation International Inc., Farmington Hills, MI, USA

Synonyms

Substance-field resources

Definition

An inventive resource can be defined as:

- Any substance or anything made of a substance (including waste) that is available in the system or its environment
- An energy reserve, free time, unoccupied space, information, etc.
- The functional and technological ability to perform additional functions, including properties of substances as well as physical, chemical, geometric, and other effects

The term "resources" is widely used within many contexts to refer to natural resources, financial resources, human resources, etc. In TRIZ, the creative utilization of the resources available in a system to increase the system's *ideality* is a cornerstone of *inventive problem solving*.

The concept was introduced in 1982 by Vladimir Petrov in the form of *excessiveness in technological systems* that could be utilized to increase the system's ideality. In 1985, Genrich Altshuller introduced "substance-field resources" as a component of the *Algorithm for Inventive Problem Solving* (*ARIZ*). These resources were grouped based on accessibility (internal, external, and from the supersystem(s)), readiness for utilization (readily available and derived (modified readily available resources) and cost (free, inexpensive, cheap). Later, this concept was expanded to include other types of resources such as functions, information, space, and time (Zlotin, Visnepolschi, Zusman). Other types of resources suggested were *differential resources* (Vertkin), resources produced by differing attributes or parameters; *change resources* (Royzen), resources produced by a change to the system; and *super-effect* (Gerasimov, Litvin), an additional benefit resulting from innovation that often goes unrecognized.

Until recently, the utilization of physical, chemical, geometric, and other *effects* has been regarded in TRIZ as another way to increase a system's ideality, as these effects often permit the substitution of a relatively complex system with a much simpler one. However, because an effect can be defined as a predictable (i.e., predetermined or statistical) response to a specific influence based on certain properties of participating elements and these properties (e.g., substance properties) can themselves be considered resources, one can suggest that the utilization of effects is yet another type of resource.

The concept of inventive resources is closely connected with a system emergence and its evolution along an *S-curve*. Typically, there are plenty of resources in the system in the beginning; fast growth is associated with intensive consumption of available resources; the amount of remaining resources is becoming scarce in the vicinity of maturity; the system's decline starts when initial resources are practically exhausted.

An abundance or lack of resources in the existing system can determine the success of problem solving; one can find multiple acceptable solutions in the system rich with resources. On the contrary, finding a solution to a problem in a system with nearly exhausted resources always represents a serious challenge; in certain cases, the solution could be provided only by transition to the next generation of the given system (new S-curve). In other words, certain resources should exist to enable invention. At the same time, every invention creates new resources that could be utilized for its further development and new applications (super-effect).

The most important issue associated with inventive resources is that they are usually unobvious or hidden (the easily apparent resources having already been utilized). A significant step in the formalization of the concept of resources and their utilization was the creation of checklists of typical resources (both readily available and derived) embedded in various TRIZ software products.

Inventive Thinking Skills, Development

Alexander Sokol, Edgar Lasevich, Renata Jonina and Marija Dobrovolska-Stoian
Thinking Approach Group (TA Group),
Riga, Latvia

Synonyms

Teaching problem solving; Teaching thinking; Thinking skills, development

Background

Development of inventive thinking skills should be considered in the context of the so-called thinking skills approaches. Although hardly anyone disputes the need for teaching thinking, the actual approaches and programs can vary significantly as there are different theories and pedagogical traditions that underlie them. When analyzing the situation in the field of teaching thinking, it is useful to distinguish between specific programs for teaching this or that aspect of thinking, approaches to teaching thinking, and theoretical frameworks which constitute the basis for various approaches.

Teaching Thinking

Programs

There are numerous programs for teaching thinking. Traditionally, they can be divided into two types: stand-alone and infusion. The former offers a general training in this or that aspect of thinking as a separate subject in the curriculum, while the latter offers thinking instruction as an integrated part of a subject matter course. Thinking programs are usually developed within some approach to teaching thinking: numerous programs for teaching elements of critical thinking (Baumfield et al. 2004), programs developed within Teaching for Understanding approach (Wiske 1998), a large variety of developmental education programs (Davydov 1996), and many others. When such programs are developed by the authors of approaches or people close to them, they tend to become the programs – the ones mostly known and quoted, for example, Feurstein's (1990) Instrumental Enrichment program, de Bono's (de Bono 1973–1975) CORT Lessons, Lipman's (1985) (Lipman et al. 1984) novels and accompanying manuals, etc. As a result, they may often be situated somewhere between programs and approaches, as more specific programs can be developed on their basis when adapting them to peculiarities of a particular situation.

Approaches

While most programs are primarily aimed at solving a local problem, approaches are developed to solve a much more global problem. Contribution to solving this problem is the reason for the development of the approach. An approach should also follow a certain theoretical framework(s). Due to various reasons, approaches can be developed with a different degree of precision – compare, for instance, a very elaborate description of Teaching for Understanding approach developed within the Project Zero and rather general and fragmented data on educational approach to teaching lateral thinking developed by Edward de Bono. An approach gives a possibility to develop various programs for teaching thinking. Lipman's Philosophy for Children, Elkonyn and Davydov's Developmental Education, and what is known as the Montessori Method are examples of approaches. It is necessary to mention that in time, some approaches develop to a degree when just a name remains and there already exist many, often quite different smaller approaches developed within the umbrella one. Critical thinking is the most well-known example.

Theoretical Frameworks

Theoretical framework is a theory, or a set of theories, which constitutes the basis of a given approach. This theory should not necessarily be a pedagogical theory – it can come from a different field of studies. Moreover, the theory should not be pedagogical in most cases, as the scope of problems it is supposed to solve should lie beyond the field of education. For instance, formal and informal logic are the underlying basis of critical thinking approaches to teaching thinking, while dialectical logic (Ilyenkov 1984) and a number of theories developed by Russian psychologists (Leontyev 1974; Vygotsky 1982) constitute the basis for developmental education approach. Note that the understanding of a framework proposed here places some widely quoted "theories" of thinking, Baron's (1987) theory of intelligence, or Sternberg's theory of rationality (Sternberg 1985) to the group of approaches.

Development of Inventive Thinking Skills in Approaches to Teaching Thinking

Inventive thinking skills are required to effectively solve nontypical (creative) problems in various domains avoiding a large number of trials and errors, where nontypical problem is the one for which no solution exists or is not known to the problem solver (Sokol et al. 2008). Thus, education for inventive thinking should aim at helping one acquire skills for coping with the new and the unknown. It is often assumed that this aim is catered for by widely spread thinking skills approaches such as critical thinking, Teaching for Understanding, Philosophy for Children, etc. As indicated in the next section, despite numerous useful features of the approaches, their main focus is different from what is required for the development of inventive thinking skills.

Critical Thinking

General Description

Critical thinking is an umbrella term for quite a few different approaches. The content of a critical thinking skills instruction is not so easy to identify as practically each more or less distinguished author has come with his/her list of critical thinking skills. Paul describes 35 dimensions of critical thought (Paul et al. 1990). Facione (1990: 13) proposes six groups of critical thinking skills: interpretation, analysis, evaluation, inference, explanation, self-regulation, and two groups of dispositions, approaches to life and living in general and approaches to specific issues, questions, or problems. Robert Ennis (2002) suggests three main dispositions: (1) Care that their beliefs be true and that their decisions be justified, that is, care to "get it right" to the extent possible; (2) care to present a position honestly and clearly, theirs as well as others'; and (3) care about the dignity and worth of every person (a correlative disposition) and 15 abilities.

Critical thinking approaches stand out from the rest of approaches due to the most developed assessment tradition. In addition to a number of various critical thinking tests developed largely in the United States, there is an A and AS Level Thinking Skills exam administered by the University of Cambridge International Examinations where critical thinking takes a major role. Yet the range of skills tested appears fairly limited and includes largely various aspects of mathematical problem solving.

Aims and Theoretical Basis

Aims of critical thinking–based courses can be formulated on the basis of definitions of critical thinking. Ennis (1997) defines critical thinking as "reasonable reflective thinking that is focused on deciding what to believe or do." Bailin (1998: 3) says that critical thinking should be conceptualized in terms of things necessary for making reasoned judgments. Paul (Scriven and Paul undated) says that "critical thinking is the intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered from, or generated by, observation, experience, reflection, reasoning, or communication, as a guide to belief and action."

Ennis's definition leads to a very general aim that might sound as follows: educate a learner who is able to think reasonably and reflectively and as a result make decisions on what to believe or do. A part about reasonable thinking would probably be the aim if formulated by Bailin's followers while Paul's approach would be generally the same but giving a more explicit understanding of "reasonable and reflective."

Constructivism is the educational theory that lies at the basis of critical thinking. At the same time, it is necessary to note that due to a large number of various kinds of critical thinking currently taught around the world, the degree of constructivism in this or that approach may differ. Even working with materials that presuppose a constructivist approach, the teacher may often keep very close to the traditional teacher-centered model of teaching. This can often be seen in language classrooms when the teacher exemplifies a classical authoritative pedagogy using a "communicative" course book. Yet, if it is teaching for critical thinking rather than teaching critical thinking, it is a constructivism approach that is essential for successful learning.

Conclusions

Instruments of critical thinking work best when applied to dealing with today's knowledge. They can be extremely useful for analysis, evaluation, and interpretation of this knowledge, making inferences and explaining, but they have not been created for dealing with situations when no knowledge is available. Critical thinking is a tool for today and to a lesser degree a tool for tomorrow. Its focus is not so much on solving inventive problems (and thus developing inventive thinking) as finding a place in the ocean of solutions, as Ennis puts it, "deciding what to believe or do."

Teaching for Understanding

General Description

The authors of the approach distinguish between knowledge, skills, and understanding. Knowledge is seen as "information on tap." Skills are "routine performances on tap." "Understanding is the ability to think and act flexibly with what one knows' (Wiske 1998: 40) and is recognized through flexible performance criterion (Wiske 1998: 42). It is stressed that the performance view of understanding should not be seen as just attaining a representation, a matter of "getting it." "Developing understanding should be thought of as attaining a repertoire of complex performances. Attaining understanding is less like acquiring something and more like learning to act flexibly" (Wiske 1998: 52).

There are four guiding questions underlying Teaching for Understanding Framework (TfU):

- What topics are worth understanding?
- What about these topics needs to be understood?
- How can we foster understanding?
- How can we tell what students understand? (Wiske 1998: 61–62)

These four questions are the basis for four elements of the TfU: generative topics, understanding goals, performances of understanding, and ongoing assessment. The authors speak about four dimensions of the TfU: knowledge, methods, purposes, and forms. The authors also describe the features that characterize the master level of understanding (Wiske 1998: 199–200).

Although it is not explicitly stated, a list of dispositions proposed by Perkins et al. (1993: 7–8) can also be considered a part of TfU-based syllabus. It would mean that there are seven main dispositions that are aimed to be developed in the TfU classrooms: to be broad and adventurous toward sustained intellectual curiosity, to clarify and seek understanding, to be planful and strategic, to be intellectually careful, to seek and evaluate reasons, and to be metacognitive.

Aim and Theoretical Basis

The view that "what students learn needs to be internalized, able to be used in many different circumstances in and out of classrooms, serving as a base for ongoing and extended learning, always alive with possibilities" can be considered the aim of the TfU framework (Wiske 1998: 13).

As well as with most thinking approaches, the theoretical basis of the TfU framework is constructivism, or as Perkins puts it, a brand of constructivism that might be called performance constructivism because of its emphasis on building learners' repertoire of understanding performances more than on cultivating the construction of representations (Wiske 1998: 57). The difference, according to the authors, lies in what gets constructed: representations or performance capability. "Learning a topic with understanding is not so much constructing a representation to fit the topic as developing a flexible performance capability around the topic" (Wiske 1998: 55).

Conclusions

Generative topics that lie at the heart of the approach are based on today's understanding. Thus, they cannot be either new or unknown. The same holds true about methods and forms. TfU is grounded in what we see as good performance today rather than what will be a good performance tomorrow. It is useful for the development of various thinking skills; however, it is not designed for working with inventive thinking skills.

Philosophy for Children

General Description

Although Philosophy for Children is sometimes seen as a critical thinking approach, its author Mathew Lipman (2003) says that critical thinking is only a part of the program. According to Lipman, there are deficiencies of critical thinking programs that "doomed it from the start" (Lipman 2003: 5–6). Philosophy for Children is offered as an alternative educational approach to improvement of thinking in schools. Its curriculum "is composed of novels for the students and manuals for the teachers. The novels are age-differentiated, and they aim to stimulate in children patterns of questioning and discussion that are first modelled by the fictional characters in the novels and subsequently continued, by internalization and appropriation, by the live children in the classroom, as they talk about what they have learned" (Lipman 2003: 156). Children are learning to become the community of inquiry which is seen as the only fully appropriate pedagogy for improvement of thinking (Lipman 2003: 5). "The community of inquiry wants to build a system of thought" (Lipman 2003: 103). In Lipman's novels, fictional characters serve as role models to children. Children are expected to gradually internalize the behavior of the characters (Lipman 2003: 102) and then demonstrate a similar behavior in the classroom.

Aim and Theoretical Basis

Philosophy for Children is aimed to develop three dimensions of thinking: critical, creative, and caring which collectively produce multidimensional thinking (Lipman 2003: 197). The ultimate aim of the program is to provide education for "an inquiry-driven society" (Lipman 2003: 204). Thus, the aim of the program may be formulated as follows: educate a learner who is able and wishes to think in a multidimensional way and is a part of "an inquiry driven society."

It is not surprising that Philosophy for Children is also based on the constructivist tradition in education. At the same time, Lipman's constructivism is much closer to the Russian school of psychology and it shares many commonalities with such an approach as developing education (Davydov 1996) which is largely based on the Vygotskian Cultural-Historical theory (Vygotsky 1982). At the same time, it is necessary to note that a number of important differences exist between the two approaches, such as different conceptualization of thinking, various objects of study, models of educational process, etc. (see Margolis (1996) for more details).

Conclusions

Constructive (creative thinking) and value (caring thinking) dimensions are important in the context of the development of inventive thinking. At the same time, the focus in the program is more on "protective" tools rather than "constructing" tools, as critical component seems to prevail over the other two. This is also reflected in the role given to the formal logic in the process of development of thinking skills. For the development of inventive thinking, Philosophy for Children novels should contain characters that face and resolve nonstandard (creative) problems rather than deal with the typical ones.

Specific Approaches to the Development of Inventive Thinking

An effective approach for teaching thinking should be based on a sound theory. The drawback of most current approaches and programs lies in the absence of a theory for inventive thinking that would underlie them (Baron 1993: 191; McGuinness and Nisbet 1991: 176; Moseley et al. 2004: 24). At present, the only widely recognized theory dealing with the inventive thinking is the Theory of Inventive Problem Solving (TRIZ) (Altshuller 1979). A number of simplified versions of TRIZ (e.g., SIT, ASIT, USIT) and its modifications (e.g., OTSM-TRIZ, ATRIZ) also underlie approaches to the development of inventive thinking.

Problem-Centered Education

Problem-centered education (PCE) (Nesterenko and Belova 2010) comprises interdisciplinary tools that allow to structure and transform information with the aim of analyzing and solving problems in various fields. Its basis is the General Theory of Powerful Thinking based on the Theory of Inventive Problem Solving (OTSM-TRIZ) (Khomenko and Ashtiani 2007).

The system of PCE didactic tools includes a system of models and procedures for organization of inquiry-based research activity of students. The system of models includes information and contextual blocks. The former comprises three levels of models for different types of descriptions of objects studied: the empirical description for mastering ways of researching and describing objects via their features, the systemic description where objects are considered as systems with a specific function, and the problem description where both material and immaterial objects are considered through the demands set to them by people. The levels are organized in such a way that each consecutive level is based on the previous one. The latter block allows to consider objects in three different "worlds": the real world, the world of images, and the fantasy world.

The PCE didactic tools include training for introducing and acquisition of thinking models, tasks construction sets, and diagnostic materials. Models are interdisciplinary and are applicable across subjects. Models are the basis for the procedures that provide for the organization of the inquiry-based research activity of learners. Among others, the procedures include research based on the bank of objects aimed at finding patters and developing rules, research based on the system operator that helps learners pose questions and develop a systemic description of an object, problem solving procedures that contain contradictions of various levels of complexity, etc.

Thoughtivity for Kids

Khomenko and Sidorchuk coined the term "thoughtivity" for the approach for the development of inventive thinking of children starting from the age of 3 (Khomenko and Sidorchuk 2006). The approach is the result of almost 20 years of research and approbation in over 30 kindergartens. There are three underlying principles: nonlinearity of teaching and learning, the use of both hemispheres in the learning process, and the demonstration of the way of thinking by the adult. The principles are implemented through three technologies: the Analogous Solution Technology aimed at helping children acquire the skills for solving problems by analogy, the Contradiction Technology aimed at helping children see and formulate contradictions that underlie problems, and the Algorithm of Inventive Problem Solving (ARIZ) Technology aimed at helping children acquire a sequence of steps for dealing with inventive problems. All technologies are implemented with children through specifically designed tasks and games supported by very detailed teacher guides.

The Thinking Approach to Language Teaching and Learning

The thinking approach to language teaching and learning (TA) (Sokol 2008) is aimed at an integrated development of language and thinking skills of learners. Initially developed for teaching English, the TA is now used for many other languages: German, Russian, Latvian, Chinese, etc. OTSM-TRIZ is the underlying theory of the TA. Any TA course is an infusion thinking course as learners are developing inventive thinking skills while mastering their language skills. TA offers a modular structure that is based on the five technologies that underlie the approach:

- The Self-Study Technology aimed at educating the learner who wishes and is ready to take full responsibility for his/her learning and knows how to make learning a success
- The Creative Grammar Technology aimed at learning to see language as a system
- The Text Technology aimed at learning to see language as a means used for solving problems
- The Yes-No Technology aimed learning to see how various problem-solving models work in a system
- The Research Technology aimed at providing learning with the possibility for transfer of knowledge and skills (Sokol et al. 2008)

The TA technologies offer systems of tasks to learners. Learners' work on tasks is organized through three steps: challenging their current knowledge and getting them to build algorithms for dealing with a task and organizing their reflection. These are referred to as the thinking task framework. The work through the framework allows to expand the TA to other disciplines as reflected in latest projects developed by the proponents (see www.ta-teachers.eu).

Some Other Important Concepts

Thinking Curriculum/Meta-curriculum

The thinking curriculum is often seen as a meta-curriculum that constitutes the foundation for various subject curricula. It offers learners most general skills and models that can be later employed for acquisition of specific disciplines. Thus, the thinking curriculum becomes the driving force for the integration of different subjects.

Importance of (Inventive) Thinking Dispositions

Although the word skills is widely used for teaching thinking approaches, most researchers agree that skills alone are not enough for any practical learning outcome. It is essential that learners also develop dispositions to support the skills. In the context of inventive thinking, it means that one is not only able to cope with nontypical (creative) problems but is disposed to do it. When inventive thinking dispositions are developed, one deliberately searches for the unknown and tries to reveal the contradictions underlying each problematic situation. The dispositional aspect is very important for any initiative aimed at the development of inventive thinking skills.

Infusion Versus Stand-Alone Courses

Thinking skills instruction can be brought to learners either as a stand-alone or as an infusion course. The former option is still used a lot in many approaches; however, researchers tend to agree (Perkins 2002; Swartz and Parks 1994) that the latter option is more effective. In addition to the actual thinking skills instruction, an infusion approach establishes a connection with a discipline, thus allowing for an integration of a thinking skills instruction in the subject matter. It should be noted, however, that infusion courses place significantly higher requirements on teachers and, therefore, are more difficult to administer.

Open-Ended Issues

Materials/Books for Teaching (Inventive) Thinking

Most educational contexts presuppose the existence of textbooks for any subject offered to learners. Apparently, this makes the administration of courses easier for both learners and teachers. However, from the learning point of view, an availability of a textbook is not necessarily an advantage. This is especially so in the case of teaching inventive thinking, where the focus should always be on nontypical issues, while a textbook by definition presents a collection of typical solutions to well-known problems.

Teacher Education for Teaching (Inventive) Thinking

Traditionally, teacher training provides teachers with effective ways of conceptualizing the subject matter and mechanisms of successfully bringing it to students. No matter how modern the approach to either of this could be, from the point of view of inventive thinking, it is still dealing with a typical solution rather than facing the unknown. It is arguable whether the teacher who avoids facing the uncertainty can help learners develop the kind of thinking required for coping with ambiguity. It means that teachers themselves need to have developed dispositions for inventive thinking in order to be able to help their learners in the process. This puts serious implications for the process of teacher education.

Assessment in Teaching (Inventive) Thinking

Assessment is an essential component of any learning. Teaching for inventive thinking is no exception, and any approach to developing it should offer specific criteria on the difference between powerful and poor thinking when dealing with the unknown. However, this very same issue brings to a trap: if learners are aware of what exactly they are expected to do, it has become a typical problem that does not require any inventive thinking approach. This means, in turn, that assessment has stopped being assessment for learning.

Conclusions and Future Directions

It is widely accepted that inventive thinking skills can and should be improved. It is done best through integrating a thinking skills instruction into various disciplines. For achieving better results, the process should start as early as possible. Although programs may seem easier to adopt, one needs to start from the theory and approaches if aiming at a long-term innovation. TRIZ and its further developments appear the most effective theories for educational approaches, dealing with the development of inventive thinking. All materials for teaching thinking should be dynamic and "finalized" by teachers and learners involved in the actual learning process. Assessment for thinking should be developed and integrated in the normative education documents. Systemic approach to teacher education is essential: teachers who teach for thinking should be required to think.

Synonyms

Creative destruction; Growth and development; Modernization

A variety of factors will cause changes in an economy. Among the most important are growth and development. These involve the introduction of innovations into the economy – such as new products, productive techniques, or technology. These special factors were analyzed by economist Joseph A. Schumpeter who became known for his contributions to economic theory in the area of innovation and entrepreneurship. This entry introduces Schumpeter's philosophy as well as his theoretical construct of creative destruction. He is often credited for starting modern growth theory that is based on the inevitable by-product of the process of development and innovation. Schumpeter's description of the innovation process and its diffusion continues to be characteristic in the contemporary knowledge- and technologically driven global economy (Carayannis and Ziemnowicz 2007).

Entrepreneurial Innovation and Economic Change and Development

Schumpeter's Early Theory

Schumpeter pioneered the idea that entrepreneurial innovation was central to economic change and development. Schumpeter's first theory about the role of the entrepreneur was presented in 1911 when he authored the book about the evolution of economies while he was a professor of economics and government at the University of Czernowitz. The book was translated from German as "The Theory of Economic Development" in 1934. Schumpeter's primary focus on the role of the entrepreneur or businessperson was in contrast to that held by most Keynesian or pre-Keynesian theorists.

Schumpeter reflected on the business-cycle volatility of the 1890s and concluded that capitalist economics grow in the long run. His view of Walrasian-style equilibrium analysis was empirically inadequate and too static to explain economic growth. The passive, price-taking approach with continual economic equilibrium did not reflect real-world behavior. Schumpeter noted the continual process of change in real economies and markets. He postulated that in a dynamic economy, there must be an assumption that a force exists within such an economy that can account for change and development. Schumpeter argued that this force is embodied in the entrepreneur. He defined entrepreneurship as "the carrying out of new combinations"

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8, © Springer Science+Business Media LLC 2013

(Schumpeter [1911] 1934, p. 66). Schumpeter's entrepreneur was "the agent of innovation," and he described them as "the pivot on which everything turns." He wrote that an entrepreneur does not invent but rather innovates. He explained that the quality of the entrepreneurial activities determines the speed of capital growth and whether this growth would involve innovation and change.

This was in contrast to David Ricardo's approach that described the productive functions in an economy as one of the three English socio-economic classes at the turn of the nineteenth century: labor from the working class, land from the aristocracy, and capital from the merchant class. The entrepreneurial function was identified with the capitalist or with the manager. The entrepreneurial function was simply identified with the roles performed by the capitalist, or the manager (McCraw 2007). Expanding this approach, Robert Solow's mid-twentieth-century growth theory called for the use of three options: more labor, more capital, or more capital per worker, to achieve economic growth. However, this concept still did not include and explain the role of innovation within the economy. On the other hand, Schumpeter introduced the hypothesis of entrepreneurial innovation as the primary factor that propels capitalist economies upward. He explained that it is the entrepreneur who creates innovation and further pointed out that innovation is not only invention. Schumpeter's entrepreneurs were driven by numerous factors such as competition to improve their organization, incorporate technology, and even take advantage of financial opportunities; they created change and did not behave according to traditional economic equilibrium theories. Schumpeter described: "in capitalist reality as distinguished from its textbook picture, it is not [textbook]... competition which counts but the competition from the new commodity, the new technology, the new source of supply, the new type of organization (the largest-scale unit of control for instance)–competition which commands a decisive cost or quality advantage and which strikes not at the margins of the profits and the outputs of the existing firms but at their foundations and their very lives" (Schumpeter, Capitalism, Socialism and Democracy, 1942, p. 82).

Schumpeter thus identified innovation as the critical dimension of economic change. He elaborated his theory to describe the process of innovation and also distinguished five types of innovation: (1) new production processes, (2) new products, (3) new materials or resources, (4) new markets, as well as (5) new forms of organizations (Schumpeter [1911] 1934, p. 66). As such, he also broke new ground in the field of innovation management. Schumpeter went further to describe diffusion of innovation or the process over time of acceptance or absorption of it within an economic system. Without innovation, no diffusion can take place; correspondingly, without diffusion, an innovation remains a singular isolated event. Diffusion is thus complementary in Schumpeter's theory. He suggested that innovation without diffusion would not lead to economic development (Brouwer 1991, p. 58).

Schumpeter described that the entrepreneurs who initiate, create, and adopt innovations generally gain profits. The entrepreneur's original innovation produces increasing profits for them. Others attempt to replicate the success of the innovator by coping the innovation. Depending on the resources available and entrepreneurial capability, diffusion can be rapid or slow. Schumpeter thus postulated that this process and transforming innovations, as well as their diffusion, will lead to waves of economic change that affect the entire economic system.

However, Schumpeter pointed out that the entrepreneur is not primarily motivated by the prospect of gain but also something else: "the dream and the will to found a private kingdom," "the will to conquer," as well as "the joy of creating" (Schumpeter [1911] 1934, p. 93). This is another way of describing the pleasures gained from being an agent of change as a result of the entrepreneur's innovative capabilities. Schumpeter explained that change in an economy is a function of innovation and entrepreneurial activities.

Schumpeter's Later Theory

Schumpeter presented a further elaboration of his ideas after studying how the capitalist system is affected by market innovations. This contribution came in 1942, during the Second World War, in the book "Capitalism, Socialism and Democracy."

Schumpeter's analysis came on the heels of the Great Depression when the defense of democracy and the structure of future economic systems – capitalism or socialism – were in question. He described the process where "the opening up of new markets, foreign or domestic, and the organizational development... illustrate the same process of industrial mutation, that incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one." This was a process that Schumpeter described as "creative destruction." He continued to argue that innovation by the entrepreneur leads to waves of "creative destruction" as numerous innovations cause existing stock of ideas, skills, technologies, and equipment to become obsolete. Schumpeter's core concept was not "how capitalism administers existing structures, . . . [but] how it creates and destroys them."

Schumpeter's seminal term of "creative destruction" came into existence late in his career, but it succinctly summarizes the theory of economic evolution that he held throughout his life. He had experienced a continuum of economic change during his career: from first-hand knowledge of entrepreneurial firms in turn-of-the-century Vienna to the large bureaucratic corporations during the 1930s and 1940s in the United States. He observed the innovations introduced by enterprises in the economy as "industrial mutation" that "incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one" (Schumpeter 1942, p. 83). Schumpeter's creative destruction theory is based on the process of modernization, the continuous progress implemented by individual entrepreneurs and corporate business managers working in a dynamic economy that bring about an improved standard of living for everyone. He stated that change is the only constant in the evolution of capitalist economies but that the rate of change is not constant. Schumpeter forewarned that capitalist economies do not evolve smoothly but discontinuously. He described the disruptive innovation process occurring at "irregularly regular" intervals.

After analyzing the capitalist model of the economy, Schumpeter tried to identify which companies would be in a better position to innovate. He developed the theory that a company's ability to innovate was mainly connected to its size. Initially he defended that small companies should be in a better position due to their flexibility, while large companies might get trapped in bureaucratic structures. Schumpeter now described that economic growth and technical progress is achieved by the enlargement of firms and the destruction of competition, not through the "invisible hand" of free competition. His theory was that large companies compete not strictly in price but in achieving successful innovations. In contrast to entrepreneurs and smaller firms, large corporations have better resources and more market power. Schumpeter explained that this type of competition proved to be more effective for achieving economic progress than the traditional approach through price competition.

Schumpeter's theory assumed that innovation-originated market power could provide more effective results than pure price competition. He described that technological innovation often creates temporary monopolies that produce excessive profits. This was driven by competition of the type that Schumpeter called product innovations. Schumpeter argued that this profit disequilibrium would be eliminated by the introduction of rivals and imitators. He explained that just as competition drives innovation, it also brings about "swarms" of imitators that want to capture the excessive profits and simply copy their rival's innovation. This process attracts investment and provides a boom in the marketplace. However, with more alternatives and supplies in the marketplace, the original innovator's profit advantage is eliminated as prices drop. Schumpeter explained that the market sector becomes less attractive, and investors leave until the next disruptive innovation is introduced, meaning the cycle restarts.

The "Creative Destruction" Process of Innovation

According to Schumpeter, the innovational process revolutionizes the economic structure from within, relentlessly destroying the old one while continually creating a new one. The process of creative destruction is the essential attribute of capitalism (Schumpeter 1942, p. 83), and Schumpeter described, “the history of capitalism is studded with violent bursts and catastrophes” (Schumpeter 1939) where “a perennial gale of creative destruction” is blowing (Swedberg 1991, p. 157). It is significant that Schumpeter’s hero is not the competitive market but the creative daring entrepreneur (Schumpeter 1934). Creative destruction triggers entrepreneurship, and entrepreneurs produce benefits that permeate the free-enterprise system. Schumpeter describes this economic growth as the consequence of entrepreneurs bringing knowledge that is qualitatively new to the existing economic system (Langlois 1991, p. 5). Entrepreneurs are therefore the dominant force for change, and their primary weapon is their energy in action (Bauer 1997). They induce change by putting together existing elements in new combinations.

The strategic stimulus to economic development, in Schumpeter’s (1934) analysis, is innovation: it may be a commercial or industrial application of something new, such as a new product, process, or method of production, but it may also manifest itself as new markets or sources of supply, as well as new forms of commercial business or financial organization. Entrepreneurs are change agents who challenge the status quo and create the new by destroying the old (Foster and Kaplan 2001). Schumpeter also extended and reoriented economic principles from the prevailing assumptions established during the 1920s and 1930s. His ideas concerning structural economic change evolved from classical economic theories, but he extended the fixed-structure theory of economic development.

Nevertheless, Schumpeter argued that the temporary monopolies provided the incentive necessary for corporations to develop new products and processes. Schumpeter now enhanced his theory that change in an economy is not only a function of innovation and entrepreneurial activities motivated by profit but also because of market power. Schumpeter explained that the results of these changes form what are known as “business cycles.” Even though economic activity may recede, one of Schumpeter’s arguments supporting the enduring strength of capitalism relates to the notion of creative destruction (Schumpeter 1934). He states that the competitive market is the key to the success of capitalism. In the real world of economic theory, the economy is always changing: new firms start up, old ones die out, new technologies are introduced, and old ones fade away.

Schumpeter’s change in his view of innovation came late in his career, and his discussion of innovation theory was a marginal part of his work. Innovation theory is thus derived only from his analysis of the different economic and social systems and because Schumpeter provided no empirical foundation for this perspective. Moreover, there is no strong evidence to support Schumpeter’s relationship between the size of a company and its ability to innovate. Nevertheless, Schumpeter’s ideas provide an important insight that when innovation is viewed as “creative destruction” that creates waves in dynamic economies and markets, then those who grasp discontinuities faster will reap benefits. This is because of the diffusion process whereby new methods of production are generalized throughout the economy reaching equilibrium prices, thus eroding the extra profits that were captured by the innovators and even the first followers, while late adopters run the risk of being driven out of the market. Schumpeter stated, “the problem that is usually visualized is how capitalism administers existing structures, whereas the relevant problem is how it creates and destroy them” (Schumpeter (1942), p. 86). Managers on the forefront of the restructuring of markets and early followers will be rewarded, while late adopters may be driven out of business.

Competition compels the various agents in an economy to innovate as well as to imitate. More contemporary “endogenous growth” theories build on Schumpeter’s idea as they describe technical change deriving from the profit-motivated research and development (R&D) corporate expenditures. Even more recently, it has been a fashion to focus on the “supply side” of innovation by being democratic in encouraging innovation and have everyone in an organization work on developing the next “big” idea. This approach has been institutionalized at numerous companies such as 3M and Google (The Economist 2010). This provides many ideas that require an evaluation system evaluated to identify the best innovations. Another way of promoting Schumpeter's ideas is to focus on closing the gap between the ideas and their implementation. This assists in making incremental improvements to existing products and processes but is less likely to produce breakthrough innovations as called by Schumpeter. Nevertheless, the entrepreneurial function will never become obsolete because as ever higher standards of living are achieved; wants automatically expand. Schumpeter was ahead of his time by identifying leisure goods as emerging economic wants (Schumpeter 1942).

Schumpeter took on the classical "static" mainstream economic doctrines and developed an innovative "dynamic" perspective, thus establishing the distinction between static and dynamic economic analysis. Schumpeter built upon the works of Smith, Ricardo, and Marx, but he introduced a dynamic theory that focused on understanding why economic systems change. However, he rejected Marx's violent revolutionary predictions about capitalism by examining factors outside normal quantitative analysis. He viewed different theoretical perspectives from other disciplines as complementary rather than competitive, able to coexist and enrich understanding of social phenomena (Schumpeter 1934). He thus took real-world examples and incorporated them into his economic theory. Schumpeter believed there were both internal and external factors that could make a cycle of change occur in an economy. This recognition is the key to his theory of entrepreneurship, which is at the core of "creative destruction" (Dahms 1995, p. 4).

Conclusion and Future Directions

Schumpeter's creative destruction philosophy is the rule, rather than the exception: organizations survive by focusing on what will allow them to be, and stay, one step ahead of the competition. Schumpeter observed how businesses conduct their operations and influence the quality of human lives and wrote that innovation was the preeminent mechanism by which individuals could rise and survive in competitive capitalism (Brouwer 1991, p. 18). Without innovation, business survival and success are unattainable. The contemporary environment abounds in disruptive (as opposed to sustaining) technologies, as well as discontinuous (as opposed to continuous) innovation. The latter type of innovation is significant because of the many attempts to determine the extent to which discontinuous innovations can be "managed" and how organizations can try to predict and leverage the emergence of disruptive technologies. Schumpeter's ideas are important because central to today's highly competitive global business environment is individual and organizational capacity for higher-order learning, as well as the ability to manage the stock and flow of specialized knowledge.

Schumpeter recognized that transformations within the economy were the key agents for innovation and economic development. He also identified change as the core factor for organizational survival. Obstacles to this creative process constrain growth, yet, managers often strive for business stability, making adaptation to changing situations difficult. Schumpeter also described economic evolution as altering the normal circular flow of demand, production, and consumption, demonstrating that moving away from the economic equilibrium can cause changes that generate new waves of opportunity. He regarded the introduction of innovation into economic activity as the destruction of existing arrangements. Advances in the contemporary knowledge-based global economy have resulted primarily from entrepreneurship and innovation – exactly as Schumpeter envisioned – and his ideas help explain how a climate of continuous change and potential improvement can create economic opportunity. Economic growth often brings rewards, but innovation can also create hardship for some because of the resulting upheaval. Innovation is frequently thus both the hero and the villain, because it impinges on every economic level in society. His ideas about innovation and its diffusion continue to be the foundation supporting the contemporary knowledge- and technologically driven global economy.

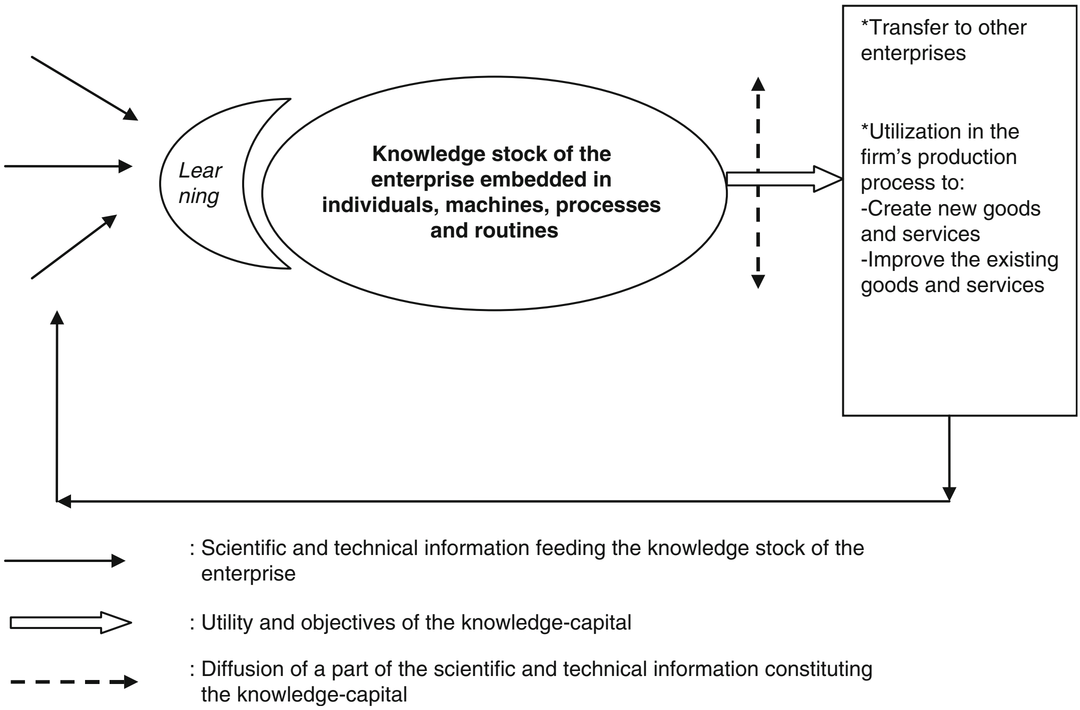
Entrepreneurship in open innovation systems; Innovative businesses; Innovator, competencies

To innovate, firms constitute an innovation potential, which we call "knowledge capital." It is made of knowledge produced by the firm itself or through cooperation. Innovation networks are thus built, where enterprises of various sizes and institutions – whether public or private (universities, research laboratories) – work together. But, what is the place of small businesses in these networks developed by larger companies? This entry begins with a definition of the concept of knowledge capital. It then presents the evolution of its formation and focuses on the place, assets, and limits for small businesses to participating to such innovation networks.

Knowledge Capital: Definition

We can define the "knowledge capital" as the set of scientific and technical knowledge and information produced, acquired, combined, and systematized by one or several firms for productive purposes. "Knowledge capital" (see Fig. 1) refers to the accumulated knowledge of one or several linked firms (embedded in the individuals – know-how – machines, technologies, and routines of the enterprise), which is continuously enriched by information flows and which is used in the production process or more globally in the value creation process. Thus, it is a dynamic concept – a process – that defines the knowledge accumulated by one or several firms and continuously enriched and combined in different ways, and eventually used or commercialized. This productive aim – the creation of value – is the main characteristic, which turns knowledge into "capital."

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,



Knowledge Capital and Small Businesses, Fig. 1 The "knowledge capital"

A firm may use its "knowledge capital" in a value creation process by:

– Simply selling this knowledge base to another enterprise (e.g., the selling of a computer program). Thus, the "knowledge capital" (embodied in the software) is transferred to another enterprise, which can use it in its production process.
– Using this "knowledge capital" in its own production process. In this case, the "knowledge capital" can be considered as a means to produce or to improve goods and services and as a tool for reducing the production process completion time.

Evolution in the Formation of the Knowledge Capital: Toward Open Innovation

The management of innovation activities by the firm has been changing over time. The first R&D laboratories were developed within big companies at the end of the nineteenth century and at the beginning of the twentieth century (Liebig in Germany, General Electric in the United States) and then became a major component of their organization. During the twentieth century, the innovation activities of firms were supported by the States which in OECD countries accounted for more than 70 % of GERD (gross domestic expenditures on R&D) up to the end of the 1970s (30 % on average today). The innovation model was qualified as "linear": the R&D steps were achieved successively and at different places (basic research was achieved in universities and in research centers, applied research and technological development within enterprises).

In the early 1980s, when the mass production and consumption model reached its limits, innovation has become the engine of competition between firms implementing global strategies. First, the globalization of firms' strategies did not imply research laboratories, in order to reduce the risks of information and know-how outflows. The variety of intellectual property rights regimes also

reinforced the risks of appropriation by competitors of their knowledge capital. In the current knowledge-based economy, information and communication technology facilitates the global exchanges of information and the codification of information widens to large parts of the knowledge. Intellectual property rights were harmonized and reinforced at the global scale, thus creating trust for investors. These are important reasons explaining that firms do not only locate abroad production and sale units but also research laboratories which have various aims, from the adaptation of goods produced by the home company to the complete local conception of goods which will be delivered globally. This period is also characterized by the development of the "open innovation paradigm" which means that "valuable ideas can come from inside or outside the company and can go to market from inside or outside the company as well" (Chesbrough 2003, p. 47). According to the author, the development of this model is linked to several changes: a growing mobility of high skilled workers, the growing presence of venture companies, new possibilities offered to market internal ideas, and the increasing capabilities of external suppliers. In this model of "open innovation," the creation of knowledge and the whole innovation process proceeds through feedbacks between R&D, design, production, and commercialization. In this chain-linked model, the genesis of innovation results from systemic links between knowledge and the market. The open innovation strategies put forward the growing importance of networks, within which the knowledge capital is built.

The tendency toward the collective constitution of knowledge capital is gaining ground in the context of the economic crisis (Laperche et al. 2011). As a matter fact, collaborative research gives the possibility for firms to reduce the cost and risk of innovation development. At the same time, it opens new opportunities for them to renew their supply, finding new technological paths and thus opening new markets. Companies collaborate at all stages of the innovation process (from design to the development of new goods and services) and with multiple partners. The objectives are diverse; we list them in Table 1.

Place of Small Businesses and Forms of Cooperation

Small businesses are traditionally less active than the big companies in innovative activity, in the production of internal resources, and in the access to external ones. In Europe, 9.5 % of innovative SMEs cooperate with other partners. Cooperation is higher in the leading innovative countries (Denmark, Finland, Germany, Sweden, Switzerland, United Kingdom) than in other countries (European Commission 2010). Open innovation is also more implemented within high-tech SMEs, such as biotechnology companies. For them, commercializing their technologies is one of their core competencies and provides a means of rapid growth. When SMEs cooperate with other firms or institutions, they privilege flexible forms, and their main aims are to access markets and to improve their products marketing, even if access to new knowledge is also a stated objective. Cooperation, especially in small companies, necessitates a similarity of skills (or low cognitive distance) and absorption capabilities.

If we focus more specifically on the relationship between small and large companies, we should put forward the contribution of small businesses in the constitution of their knowledge capital. Innovative small firms play a key role in the networks. Indeed, by making use of specialized high-performance small businesses in their areas, groups have access to technology outside their usual fields of research and can integrate within their knowledge capital particularly innovative technologies and complementary skills. Cooperation with small businesses also allows them to produce at a lower cost by increasing the speed of development.

One of the main forms of relations between small and large firms in innovative activity is that of investment in start-ups through venture capital. Corporate venture has soared in the United States during the 1990s and has spread in Europe before being held back by the bursting of the bubble of the net economy in 2001: many of these investments were oriented toward the achievement financial gain. They still exist today and investors' objectives are various: big corporations when investing in small businesses look for financial gain but also aim to develop at a lower cost and with fewer risks new technologies or seek to consolidate the group's activities (through, for example, the dissemination of a standard). This can be done through the acquisition on the start-up at the end of the financing period. In that case, the development cost of the acquired firm (and of its technology) has been shared between several investors. Or it may also be achieved through the signature of partnership agreements (including licensing). In other words, for groups, investment in venture capital fits into their financial and technological strategy.

Relations between groups and small innovative companies can also take pure partnership forms. Currently, some of these partnership programs are initiated by companies themselves. Big companies have been induced to concentrate on their core business, which by the way increased outsourcing strategies. Many small companies are thus the outcome of these outsourcing strategies. Spin-offs are an example of such strategy. But the relationship between the parent company and the small business often continues, through partnership agreements.

Partnership agreements may also be signed in the framework of national or international research program, or within clusters. As a matter of fact, in industrial countries, industrial policy has shifted from reducing costs of production to the increase of managerial know-how and the intensification of links between firms. Such cooperation may concern SMEs notably through local production systems but also the relations between SMEs, large companies, and public research. Then, it is through research programs at national and European levels or through clusters that SMEs are encouraged to work with large groups.

Assets and Limits of the Integration of SMEs in Corporations' Knowledge Capital

For an SME, taking part to the innovation strategy of a larger company may be an essential support for their technological product of process development, as a small business may benefit from the financial, technological, and marketing support of the big company. Taking part to an innovation network is thus a powerful mean to be profitable and even sometimes to survive.

But this type of collaboration may be difficult because of the unequal and asymmetrical power relation between the two partners. In case of conflicts, for example, dealing with intellectual property rights of products developed in common, the smaller business may be disadvantaged, due to its weak resources. The cognitive distance between small and big companies may also hinder the learning processes and be counterproductive.

Finally, cooperation sometimes leads to the acquisition of the small business by the corporation. In that case of course, that means the disappearance of the small unit. The integration of the small business within the bigger one may also lead to a lower creativity due to the different habits and routines of the two organizations. Even if the small company is not taken over by the bigger one, this kind of problem may appear if the small business loses the freedom of its managerial choices.

Conclusion and Future Directions

Strengthening the knowledge capital of large companies is more and more achieved by the multiplication of scientific and technical collaborations with all the actors of innovation. The strategy of open innovation is most often initiated by large companies because of the limited resources of small businesses and as a result of their low absorption capacity. Relations between small and large companies can be a "win-win" strategy when the small business provides specific expertise to the large company which in turn facilitates the development and dissemination of the technology. These relationships may also be hampered by an imbalance of power between the two organizations.

Governments seek to facilitate relationships between small businesses and large companies, especially through the cluster policy, implemented all over the world. Support should also take into account the need to strengthen the negotiating capacity of small businesses. It may be enhanced by an easier access to scientific, technical, and financial resources, by building of specific managerial capabilities but also by an easier access to intellectual property rights.

The business environment is rapidly becoming a global marketplace characterized by fierce competition, increasing consumer demands, and the need for value-added products and services. In order to survive in such an environment, firms need to have the capacity to differentiate themselves from others. Access to or the creation of new knowledge can help firms to master this challenge. New knowledge alone or in combination with established knowledge provides the fundamental basis for continuous improvements of the firms´ processes, products, and services. In addition, it might also represent the basis for radical innovation.

Given the IT advancements, firms regardless of size or industry, can make a niche for themselves in today's business environment. Yet, these firms are characterized by entrepreneurial individuals who are interested in changing existing structures and in delivering new products to the market. These products are the outcome of the entrepreneurial firms´ capacity to exploit new knowledge. As entrepreneurial firms are crucial contributors to economic growth and employment, it is important to understand the link between knowledge creation (as promoter of change) and entrepreneurship (as the notion of change).

The intention of the following sections is to link the concepts of knowledge creation and entrepreneurship. It starts with a discussion of each of the concepts separately. This is followed by a section intended to merge the two concepts and an overview of the current understanding of the association between the concepts. The entry concludes with a brief summary and a list of possible research questions that may inform more research activities in this area.

Knowledge Creation

The concept of knowledge creation refers to ways which focus on the construction of new knowledge. Knowledge creation in companies can be supported by, for instance, giving organizational members' time to experiment. Knowledge is not only internally produced, but external knowledge sources need to be considered as well. Given the natural limitations, smaller firms are often forced to make use of the latter (Egbu et al. 2005).

The knowledge management process can be divided into capturing or documenting knowledge, packing (cleaning, formatting, and indexing) knowledge for reuse, distributing knowledge, and reusing knowledge. In all of these steps, new knowledge and opportunities may emerge when individuals and groups sense problems in the process.

Knowledge creations have been measured as a process, output, and outcome (Mitchell and Boyle 2010). The process perspective assesses the steps or activities undertaken to create new knowledge, such as the uses of metaphors to externalize knowledge. As an output, knowledge creation is measured in terms of an immediate product of the knowledge creation process, usually reflecting a significant enrichment of existing knowledge, such as a representation of a spoken idea. Knowledge creation as an outcome is measured in terms of a value-adding object, for instance, new service, changed routine or product prototype. Here, the link with innovation and learning is quite prevalent.

Former research has shown that new knowledge can emerge by accident (e.g., the discovery of penicillin) or by deliberate discovery by following a gap in the literature. New knowledge can, further, generally emerge from new ideas or by emergent internal or external needs. Often, new ideas are transferred to the organizations via suppliers, professional bodies, consultants, or research literature (external influences) or they stem from internal creativity and inventions. New knowledge also originates from needs and pressures from customers, competition, legislation, and so on (external forces), or they originate from perceived problems and opportunities perceived by the staff and managers of organizations (Sparrow 2005).

Knowledge creation is closely linked to learning. Learning in organizations, for example, could happen through error detection. This would comprise a proper diagnosis of the error´s cause, and its correction so that organizations can learn from experience and implement suitable actions that are intended to avoid a repetition of these errors. "Often this leads to identifying a need that requires new knowledge to be created to answer the need" (Allard 2003, p. 375). A shared place is considered important for knowledge creation as well. According to Nonaka et al. (2002), Ba provides a platform for advancing individual and/or collective knowledge. Knowledge resides in Ba and is intangible. The interaction between tacit and explicit knowledge via socialization, externalization, combination, and internalization leads to the creation of new knowledge. Finally, organizational culture can facilitate or strain knowledge creation. Hence, culture characterized by a high degree of change and flexibility will have more positive effects on knowledge creation than cultures characterized by stability and formalization.

Entrepreneurship

According to Bridge et al. (2003), there is no generally accepted definition of the term "entrepreneurship." These authors discuss a narrow definition and a broader definition of entrepreneurship. According to the former, entrepreneurship is equal to starting a business, being in a business and growing and developing a business. The broader definition has a stronger orientation to the aspect of change, underlining the involvement of innovative attributes and behavior. Adopting the latter, for Bruyat and Julien (2000) entrepreneurship encompasses "a process of change, emergence and creation" (p. 173). This includes the creation of new value (i.e., an innovation and/or a new venture) and, at the same time, the change and development of individuals. Bruyat and Julien (2000) further argue that entrepreneurship by definition is primarily given in the founding stage. In the period of growth and establishment, innovative behavior is often replaced by managing the firm.

Knowledge Creation and Entrepreneurship

Regardless of whether a narrow or a broad definition of entrepreneurship is applied, both definitions indicate the relevance of entrepreneurial firms to have the capacity to create (new) knowledge. Assuming that entrepreneurship in its purest form is mainly given in the founding stage, many of those young firms may face resource constraints which hamper them from expanding the firm's knowledge base. In addition, in many of those young firms, the owner-managers take on a central position. In such an environment it is not uncommon that the processes of business planning and decision making are limited to only those individuals. This centrality also signifies that these people are particularly responsible for the recognition of the benefits related to knowledge management and knowledge creation, respectively, to support the firm's operations. As in the founding stage day-to-day business operations specifically require close attention, this may often result in situations where insufficient time is available for strategic issues, of which planning the future knowledge need is one aspect.

As resources are scarce in young entrepreneurial firms, new knowledge is likely to result from secondary data (e.g., trade journals, sector research, conferences, and professional magazines) or from personal contacts. In addition, as systematic knowledge search and creation is more expensive compared to informal meetings with suppliers, customers, or other stakeholders, it is likely that the latter will be favored by those firms as a source to new knowledge.

Yet, knowledge creation is not limited to young entrepreneurial firms, the more established entrepreneurial firms also need to find ways to continuously enlarge their knowledge stock.

Current Understanding of Knowledge Creation and Entrepreneurship

A literature review conducted by the authors of this piece of work suggested that so far rather few empirical observations are available (Edvardsson and Durst 2012). The main findings of the investigated studies centered around three topics:

Learning, networks, and tools as facilitator of knowledge creation, as well as description the process of knowledge creation.

Beginning with learning Cegarra-Navarro and Dewhurst (2006), for instance, looked into the aspects of learning and unlearning and their effects on the creation of Intellectual capital in the Spanish optometry industry in their study. Their findings demonstrated the importance of a firm's approach to facilitate unlearning prior the creation of relational capital. In a similar manner, a study on the high-tech SMEs industry in France came to the conclusions that knowledge management dynamic capabilities – internal and external learning competence – acted as a mediating and enhancing effect on innovation performance of the studied firms (Alegre et al. 2011). A research on Malaysian SMEs also shows that learning culture and people management skills (T-shaped skills) had a positive relation with the knowledge creation process. The knowledge creation process had, in turn, a positive relationship with organizational creativity (the creation of valuable, new product, service, idea, procedure, or process) that enhanced organizational performance (Soon and Zainol 2011).

Regarding the role of networks, a UK study (Hughes et al. 2009) showed how smaller firms engage in networks in order to obtain access to new knowledge. Much valued input, according to the studied firms, came from accountants, then the Internet, third by asking employees, suppliers, and eventually customers. Other sources, such as professional and academic institutions, were regarded as less beneficial. On the other hand, information overload and time constraints represent obstacles to knowledge creation (Egbu et al. 2005). The study also emphasized that knowledge creation should be accompanied by knowledge retention; particularly the latter seems to be a real challenge for firms. Another UK study (Chen et al. 2006) showed that the majority of SMEs considered both social and electronic networks as important sources of obtaining critical knowledge. Social networks seemed to be slightly preferred to electronic networks. Critical external knowledge is mainly seen in the areas of customers, competitors, suppliers, emerging market trends, and best practices/effective processes.

Concerning KM tools, the study by Ambrosine and Bowman (2008) illustrated the usefulness of applying causal mapping to help a firm (in the given case a consulting firm) uncover its tacit knowledge and to make explicit what it should try to replicate within the organization to sustain its success. By continuously asking the consultants on what they were doing the individuals themselves were able to identify aspects of their job they had not been recognized before. Hari et al. (2005) developed a knowledge capture awareness tool that is intended to help firms to implement and pursue a systematic knowledge capture strategy.

It was further found that most of the reviewed studies looked at knowledge creation as a process; the outcome and output of the knowledge creation and its impact on innovation represent under-researched fields.

Conclusion and Future Directions

Even though there is an apparent clear link between knowledge creation and entrepreneurship, current research provides only little understanding of how knowledge is actually created in entrepreneurial firms. Given the meaning of knowledge to firms, it is important to expand the current body of knowledge in this area as it may contribute to firms' competitiveness and survivability. Questions of interest might be: How do entrepreneurial firms identify the need for new knowledge? What are the factors initiating the need for new knowledge? How do entrepreneurial firms identify the type of new knowledge needed? What fosters or prevents knowledge creation? How can the process of knowledge creation be measured? How can entrepreneurial firms measure the impact/output of knowledge creation? How can they institutionalize the process of knowledge creation? This brief list of questions, which is by no means exhaustive, signals the huge potential this research area is offering; thus researchers are highly encouraged to make their contributions.

> A man educated at the expense of much labor and time to any of those employments which require extraordinary dexterity and skill, may be compared to one of those expensive machines.
> Adam Smith (1776/2009, p. 62–3)

In spite of the insistence of Adam Smith, modern society and its economic systems were, until recently, understood primarily in terms of tangible assets (or property: land, equipment, structures that house the equipment, and inventories) and (manual) labor. Labor and property (capital) have had a long association in social, economic, and political theory. Work is seen as property and as a source of emerging property. Adam Smith (1776/2009, p. 586) explains, "Land and capital stock are the two original sources of all revenue both private and public. Capital stock pays the wages of productive labour, whether employed in agriculture, manufacturing, or commerce. The management of those two original sources of revenue belongs to two different sets of people; the proprietors of land, and the owners or employers of capital stock."

In the Marxist tradition, capital is objectified and encapsulated labor. On the basis of these attributes, individuals and groups were able to, or were constrained to, define their membership in society. In modern societies while the traditional features of labor and property certainly have not disappeared entirely, the new principle of "knowledge" has been added. To some extent, this challenges and transforms property and labor as the constitutive mechanisms of society and economic activity. This entry, therefore, focuses primarily on the new role of labor and property in the *knowledge-based economy* generating added economic value within the broader context of modern society as a *knowledge society*. This entry is less concerned with exclusivity as the distinguishing attribute of property or with the extent to which only labor may be viewed as a source of value. More so, it is concerned with the ways in which *novel* knowledge, defined as a capacity to act and as a capacity that primarily accounts for growth accomplishment in modern societies, is generated in knowledge-based economies through innovation.

Knowledge Societies

Different theoretical typologies of society are based on what are seen as their core principles. The core principles symbolize the constitutive mechanisms of societies, and their displacement by new core principles represents social change. Thus, *bourgeois society* was originally a society of owners. Later, it became a "laboring society" (*Arbeitsgesellschaft*), and it is now transforming into a *knowledge society*. It is doubtful that it is possible to precisely date the emergence or decline of a particular type of society. Daniel Bell (1973a, p. 346) argues, for example, even though he points out that it really is foolhardy to give precise dates to social processes, that the "symbolic" onset of the *postindustrial society* can be traced to the period since the end of World War II. It was during this era that a new consciousness of time and social change began to emerge. In contrast, Fred Block and Larry Hirschhorn (1979, p. 368) state that the 1920s mark the emergence of the new productive forces typical for postindustrial society (namely, information, knowledge, science, and technology), and in particular, the period when they began to make a decisive difference in production. In the 1920s, at least in the United States, the input of labor, time, and capital was constant or had begun to decrease, while output had begun to rise. Be that as it may, in modern society, as these observers concur, "knowledge" has become – in economic terms – the crucial source of (added) value.

The reason for analyzing the knowledge structure in modern society stems from the heightened social significance of knowledge in society more broadly and not only within the economic system, and this heightened significance is the result of the tremendous increase in the overall fund of knowledge and the historically unique-enhanced knowledgeability of its members. Of course, shared knowledge has always had a function in social life. In fact, one could speak justifiably of an anthropological constant: human action is knowledge based. This applies of course to economic life as well, as many political economists have recognized. Social *groups* and social roles of all types depend on and are mediated by knowledge. Similarly, power, productivity, competitive advantages, and economic success have frequently been based on advantages in knowledge, not only on physical strength. And, last but not least, societal reproduction is not merely physical reproduction but, in the case of humans, always cultural, that is, reproduction of knowledge.

In retrospect, one is therefore able to describe a variety of ancient societies as knowledge societies. For example, ancient Israel was a society structured by its religious-legalistic knowledge of the Torah. Ancient Egypt was a society in which religious, astronomical, and agrarian knowledge served as the organizing principle and the basis of authority. Similarly, historians such as Margaret Jacob and Larry Stewart (2004) have argued that the key explanatory variable accounting for the material and technological dominance of the West during the age of the early and the mature industrial society is the development of "useful and reliable" knowledge.

Contemporary society may be described as a knowledge society based on the extensive penetration of all its spheres of life and institutions by all forms of knowledge, especially scientific and technical knowledge. Knowledge societies arise not as the result of simple, one-dimensional processes of social change. Though modern developments in communication and transportation technology have brought people closer together, regions, cities, and villages are still by and large isolated from each other. The world may be opening up, and the circulation of fashions, goods, and people becoming more intense, but differing convictions as to what is "sacred" still create insurmountable barriers to communication. The meanings of such concepts as "time" and "place" are undergoing transformation, but borders separating people continue to be objects of intense respect and even celebration. Though fascinated by globalization, we also live in an age obsessed by identity and ethnicity. The trend toward the global "simultaneity" of events is accompanied by a territorialization of sensibilities and a regionalization of conflicts.

The Knowledge-Based Economy

The foundation for the transformation of modern societies into knowledge societies is to a significant extent based on systemic changes in the structure of their economies. The source of value-adding activities increasingly relies on knowledge. For the production of goods and services, with the exception of the most standardized forms, factors other than "the amount of labor time or the amount of physical capital become increasingly central" (Block 1985, p. 95) to the economy of advanced societies. Knowledge constitutes both input and output. The output of knowledge-based economies involves to a significant extent the increase in the knowledge intensity of its products and in efforts to achieve higher knowledge intensity of goods through intense support of innovation. Inputs in the knowledge-based economy consist to a significant extent of knowledge. The forces of production in the knowledge-based economy are less concentrated, and production is more likely nonmarket based, and public goods take on a greater role.

The dynamism of the global economy is no longer only driven by trade in conventional, durable commodities such as wheat, oil, cars, and steel but rather by traffic in *monetary* products such as currencies, stocks, bonds, and increasingly derivatives of the former. In addition, in knowledge-based economies, the flow of symbolic commodities of a *nonmonetary* nature or meaning are, for example, data ("sets of numbers"), technological trajectories, statistics, fashion regimes, programs, product marketing, as well as the growing flow of information within and across national boundaries, which attain a growing importance. The transformation of the structures of the modern economy by knowledge as a productive force constitutes the "material" basis and one of the justifications for designating advanced modern society as a knowledge society.

Although knowledge has only been defined explicitly as problematic in a minority of social and economic theories, it was always considered to be a determinant of social and economic order within the context of some of the core social theories. Marxist theories of society, for example, have always assigned decisive importance to the forces or means of production for societal development based on the assumption that man's mastery over nature is the foundation of production and wealth. As a result, general knowledge and science become a direct though not independent force of production. More recent Marxist theories, especially through the notion of the scientific-technological revolution developed by Radovan Richta and others, have analyzed scientific and technical knowledge as the principal motor of change. Max Weber's seminal inquiry into the unique features of Western civilization stresses the pervasive use of reason to secure the methodical efficiency of social action. The source of rational action and therefore of rationalization is found in particular intellectual devices.

Raymond Aron's theory of *industrial society*, which encompasses both socialist and capitalist forms of economic organization, stresses the extent to which science and technology shape the social organization of productive activities and, consequently, other forms of life in society. More recent theories of *postindustrial society* and similar efforts to forecast the course of social evolution in industrial society, in particular the efforts of Daniel Bell, have elevated theoretical knowledge to the axial principle of society. That is, codified theoretical knowledge becomes, as Bell (1979, p. 164) describes it, "the director of social change." In the economy, instrumental knowledge replaces labor as the source of added value. The strata of the producers of scientific and technological knowledge therefore become the key agency and actors of future social and economic development. Bell recognizes, of course, that every society has been dependent on knowledge. But very rarely, he stresses with emphasis, has this been theoretical knowledge. It is the "codification of theoretical knowledge that now becomes the source of advances and change in society" (Bell 1973b, p. 25), and only in the last half century have we seen "a fusion of science and engineering" (Bell 1979, p. 164) that has transformed the nature of technology itself. The accent in postindustrial society is evidently on the *instrumental mode of rational action*.

In the context of Bell's theory of postindustrial society and of theoretical concepts that resonate with his theory of modern society, knowledge – and the groups of individuals which acquire influence and control with knowledge – tend to be conceptualized rather narrowly as exemplifying the status of objective scientific knowledge and what Bell calls "intellectual technology" (see Bell 1979, p. 167). That is, the producers of knowledge claims in the natural and the social sciences generate more and more axiomatically structured assertions that employ formal languages as their medium of communication and are thereby increasingly distanced from empiricism (cp. Bell 1973b, p. 25), becoming embedded in "automatic machines" or computers. Paradoxically, perhaps, there is a general tendency in these theories of society to overestimate the "rationality" and the practical efficacy of "objective" or "reality-congruent" technical-scientific or formal knowledge.

Theories of modern society often display too much deference toward orthodox theories of science and therefore lack sufficient detail and scope in their conceptualizations of: the "knowledge" supplied; the embeddedness of the fabrication of knowledge; the reasons for the societal demand for more and more knowledge; the ways in which knowledge travels; the rapidly expanding groups of individuals in society who, in one of many ways, live off knowledge; the many forms of knowledge which are considered as pragmatically useful; and the various effects which knowledge may have on social relations.

In *Great Transformation*, Karl Polanyi (1944/1978) drew on Jeremy Bentham's notion of "social engineering" to argue that the science of organizations more than technological developments contributed to industrialization and economic growth. In his terms, "the main intellectual impetus of the Industrial Revolution were discoveries in the sociological field, not the technical inventions" (Polanyi 1944/1978, p. 167). Of course, both components, technology as an applied science of engineering on the one hand and the science of meaningful interactions between machines, humans, and organizations on the other, could be described as two sides of the same knowledge-based economical coin. Among those who also contributed to the idea of a knowledge-based economy, one needs to count Gunnar Myrdal (1957), who emphasized that the *growth rates* of industries whose cores are based on knowledge and knowledge work tend to be higher than those based on muscle and machinery. The same conclusion appears to apply to the sur*vival rate* of firms who innovate in contrast to businesses that fail to engage in innovation.

The theory of the knowledge-based economy and its political importance has been tightly interwoven with the policy activities and goals of the *Organization of Economic Cooperation and Development* (OECD) since the early 1960s and later the *European Union*. The OECD was formed in 1961 with the explicit mandate to base economic policies closer on the sciences. The OECD followed Raymond Ewell's lead, who in 1955 carried out one of the first quantitative studies that demonstrated a correlation between investment in research and developments and productivity. Among its core programmatic points were to coordinate member countries' policies of technological and scientific development, to transcend national boundaries, and to move member countries toward knowledge-based economies through coordinated research and development programs. The OECD activity resulted in the *Frascati Manual*, which features indicators for the observation and the comparison of scientific and technological achievement of countries. These indicators remain relevant to contemporary debates.

Innovation

In the knowledge-based economy, knowledge is not only a vital economic asset but also the main source for innovation, and innovation is the primary foundation for economic growth and survival. However, by definition innovation in the knowledge-based economy cannot mean the mere *reproduction* of knowledge. The plain reproduction of existing capacities for action that have been commodified is the routine business of economic conduct. Nonroutine conduct or innovation, as conceived here, is embedded in *novel capacities of action*. Novel capacities to act as ways of conceiving problems differently tend to destabilize the economic and social order, as Schumpeter's notion of creative destruction suggests. What are the foundations for the possibility of novel capacities of action and therefore for interpreting problems in a different light?

First of all, the creation/innovation of novel knowledge claims can only mean a *displacement* of knowledge on hand. Second, innovation therefore incorporates and refers to available knowledge (and relies on resources such as the available means of communication), such as, for example, knowledge on the intellectual commons, but it also transcends knowledge on hand. Third, specific social and cognitive conditions are conducive for the displacement of knowledge in place. Fourth, the entry costs to innovative activity have been lowered in the knowledge-based economy though they remain high in many fields of economic activity. The remainder of this entry focuses on the conditions that provide for the foundations for innovation in the sense of a displacement of meaning, a displacement of metaphors, rather than on different forms of knowledge and modes of innovation or the impact of innovative economic activities on regions and urban areas.

On principal, knowledge per se is not productive in and of itself. Building on Francis Bacon's famous dictum (*scientia est potentia*), knowledge may best be defined as a capacity for action. Knowledge can remain unused or even used for irrational purposes. The erroneous idea that scientific knowledge and technology bestows its own practical realization, regardless of side effects, remains a widespread conviction. Knowledge can only be realized through work in specific social contexts, a material underpinning, and a certain infrastructure just like the production of surplus is only achieved through work.

Conclusion and Future Directions

Certain cognitive competencies, which constitute the concept of knowledgeability, are crucial for precipitating creativity, invention, and innovation, and for sustaining entrepreneurship under the conditions of the knowledge economy. Representing an element of the cultural dimension identified in Carayannis and Campbell's (2011, p. 338) quintuple helix of innovation, knowledgeability refers to a bundle of competencies that have enabling capacities. The first two competencies, (a) the ability to generate novel and persuasive ideas through metaphorical displacement and (b) the faculty to engage in multiple viewpoints, speak to the requisite cognitive orientations for producing and realizing creative and inventive ideas. The second set of competencies, (c) the authority to speak and (d) the ability to mobilize defiance, refers to cognitive capacities associated with the ability to exercise agency and self-determination in a social context. The final three competencies, (e) the capacity to exploit discretion, (f) the facility to organize protection, and (g) the capacity of avoidance, represent a bridge between the processes of creative and inventive thinking to the ability to enact, protect, and cultivate these ideas in an entrepreneurial context.

These cognitive competences not only tend to be more common in knowledge-based economies but operate as a mental prerequisite for creativity, innovation, innovative processes; for conceiving of problems in a different sense; for fueling entrepreneurship; and for sustaining the comparative advantage of nations. Future research should investigate what specific orientations, cognitive competencies, and characteristics individuals must command in order to be innovative or to take innovative ideas from her environment on board, taking for granted of course that institutions provide important conditions for the possibility of innovations.

The stress on cognitive competencies or knowledgeability is not merely reiterating the much more common observation about the growing importance of a highly educated or skilled labor force in modern economies and in innovation regimes. In fact, this entry offers a rival hypothesis, namely, that the cognitive capacities enhancing innovativeness – although associated with formal education and years of education – are not only among the core foundations for innovation but also among the foundations for educational achievement, human capital, and entrepreneurship. As such, this entry represents a contribution to the sociology of innovation in distinction to the now dominant economic theory of innovation.

Synonyms

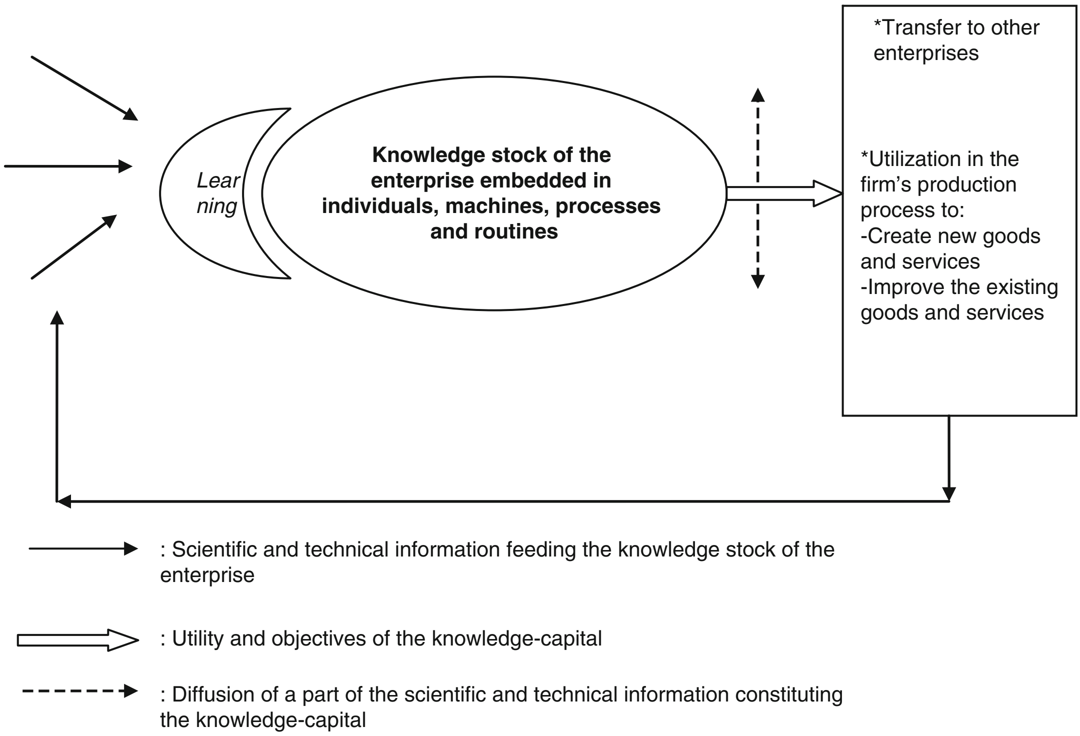
Information and knowledge stock; Innovation potential; Innovation strategy

Innovation means the development and dissemination of new combinations of production factors and takes the form of technological development (products, processes, and services), new markets, and new organizations. It has become the main engine of competition between enterprises at the global level. Innovation is also considered as the source of growth and competitiveness of regions and countries.

Innovation does not just happen. It is the result of costly and risky investments made by different kinds of organizations and institutions and of complex strategies of formation and protection of resources aimed to taking part to this process. In this entry, we focus on the firms' strategy to innovate and put forward a central element – the knowledge-capital – onto which firms focus to maintain and reinforce their capability to innovate.

The knowledge-capital is a set of information and knowledge produced and gathered by the enterprise in order to innovate. It is the backbone of their permanent innovation strategy.

The concept of knowledge-capital is very useful to study the innovation strategies of firms. How does the firm collect information on markets? With which kind of institutions does the firm cooperate (big and small firms, research centers, universities)? How does the firm learn and transform information into knowledge and routines? For what purposes? How does the firm



Knowledge-Capital and Innovation, Fig. 1 The "knowledge-capital". (Source: Laperche 2007; Laperche et al. 2008, 2011)

protect its knowledge-capital (role of intellectual property rights, of secrets, and lead time)? Knowledge-capital appears as a useful concept to study in depth all these current issues.

Definition of the Knowledge-Capital

We can define the knowledge-capital as the set of scientific and technical knowledge and information produced, acquired, combined, and systematized by one or several firms for productive purposes. Knowledge-capital (see Fig. 1) refers to the accumulated knowledge of one or several linked firms (embedded in the individuals – know-how – machines, technologies, and routines of the enterprise), which is continuously enriched by information flows and which is used in the production process or more globally in the value creation process. Thus, it is a dynamic concept – a process – that defines the knowledge accumulated by one or several firms and continuously enriched and combined in different ways and eventually used or commercialized. This productive aim – the creation of value – is the main characteristic, which turns knowledge into "capital."

The information collected on markets (through intelligence strategy, through the access to patent information, through the purchase of technology and the signature of license contracts...) is integrated into the knowledge stock through learning processes which are basic in the transformation of information (flow) into knowledge (stock). The use of the knowledge stock depends on market and production opportunities and on the degree of maturity of the developed technologies.

A firm may use its knowledge-capital in a value creation process by:

- Simply selling this knowledge base to another enterprise (e.g., the selling of a computer program). Thus, the knowledge-capital (embodied in the software) is transferred to another enterprise, which can use it in its production process.

- Using this knowledge-capital in its own production process. In this case, the knowledge-capital can be considered as a means to produce or to improve goods and services and as a tool for reducing the production process completion time.

Theoretical Roots of the Knowledge-Capital

Theoretically, the notion of knowledge-capital is based on the definitions and/or on the economic developments of three key concepts/notions: knowledge, firm, and capital. The economic analysis of knowledge has changed over the time. Neoclassical economists first considered technical progress as exogenous and knowledge as a public good, notably characterized by its nonappropriability. As for technical progress, the firm has also long been considered as a "black box" and did not very much catch the contemporary economists' eyes.

After the Second World War, the firm has become a *complete* object of study, place of production of new knowledge (Penrose 1959), and symbol of modern capitalism (Galbraith 1967). The interest that arose from the work of Schumpeter (1950, 1983) on the role of innovation in the economic dynamism but also from Solow's work (1957) on the residual technical progress and economic growth gave birth to new analysis aiming at explaining the origin of innovation and of knowledge. The evolutionist theory and the resource-based approaches stress the learning processes that are at the origin of the firm's own technological trajectories and put forward the double nature of knowledge, codified and tacit, which makes its appropriability possible (almost in part) (Nelson and Winter 1982; Dosi et al. 2000). The new growth theories have taken account of those new developments and associate to public intervention, the market as a place of allocation and appropriation (intellectual property rights, routines) of fundamental resources to growth.

The most recent developments insist on the role of external knowledge and notably on the way firms capture external information in its environment (which explain the key role of proximity and interactions) and to transform it in the enterprise's own knowledge. Knowledge production and innovation are thus considered as collective processes and are built within complex networks of cooperation (Laperche et al. 2008, 2010).

The notion of knowledge-capital is built on these main evolutions in the analysis of knowledge and firm. But it does not forget the crucial contributions of early authors.

The developments of the classical economists already stressed the collective nature of production and of innovation. Smith (1976) considered the technical and social division of labor as means to increase the productive and innovative power of labor. Say (1996) analyzed the links between the scientist, the entrepreneur, and the worker. Marx (1977) showed how production is based on the combined workforce – appropriated by capital – of the collective of workers. The notion of knowledge-capital also borrows from the classical economists their dynamic conception of capital. In this approach, capital is not only a stock of resources available for production; it is a process that indicates the constant renewal and the productive use of this stock. To sum up, knowledge-capital is fed by modern or more ancient approaches of knowledge creation, coordination, and diffusion.

Knowledge-capital also aims to integrate the value creation process (which can take, for instance, the form of the production and diffusion of a new machine). This determines the integration of information in the knowledge stock, the combination of information and knowledge, the codification of tacit knowledge, and the diffusion of knowledge. With this particular focus on the aim – the value creation process – we also reintegrate in the analysis the tensions linked to the relations of power existing between firms of different size and strength and that particularly occur, as studied below, in the current context of constitution and protection of the knowledge-capital.

The Formation of the Knowledge-Capital

The process of knowledge creation is today the result of a node of partnerships between the (more or less independent) units of a networked firm, other networked firms, and other institutions (universities, research labs, and start-ups). This collective process is usually referred to as the "open innovation paradigm," which means that "valuable ideas can come from inside or outside the company and can go to market from inside or outside the company as well" (Chesbrough 2003, p. 43). According to this author, the open innovation paradigm has tended to replace the earlier paradigm of closed innovation since the end of the twentieth century. The logic of the closed innovation paradigm was an internally focused logic where companies financed, generated, developed, built, and marketed their inventions. It corresponded to the linear model of innovation that was prevailing all along the twentieth century and where innovation resulted from a succession of separated steps (in time but also institutionally) from scientific development to the diffusion of new products and services. This model began to be undermined at the end of the twentieth century due to a conjunction of factors such as the growing mobility of high-skilled workers, the growing presence of private ventures companies, the new possibilities offered to market internal ideas, and the increasing capabilities of external suppliers. The economic context where innovation performance is the engine of competition and where profitability imperatives constrain the investment policy of firms is also an important factor explaining the growing importance of collaboration in the formation of the knowledge-capital. In this new model, knowledge creation and the whole innovation process proceed by feedback between R&D, design, manufacturing, and marketing services. In this chain-linked model of innovation, the genesis of innovation results from the systemic linkages between knowledge and the market. Open innovation strategies put forward the growing importance of networks, considered as knowledge factories and boosters. This is within these networks that firms now build their knowledge-capital.

The formation of this knowledge-capital is today achieved on a global scale. This can be assessed by the growing importance of international R&D partnerships between firms, patents and technology flows, and globalization of R&D. Moreover, firms are increasingly developing their knowledge bases thanks to the innovation networks into which they are involved.

Knowledge-Capital and Innovation, Table 1 Means of formation of the knowledge-capital

In-house means	External means
Investment in human resources	*Equity relations*
Investment in and management of R&D and means of production (tangible and intangible)	Joint venture
	Purchase of innovative enterprise
	Nonequity relations
	Contracts (including licensing) with other (industrial and service) firms
	Contracts (including licensing and hiring of short-term researchers) with institutions: e.g., university research labs
	More informal contacts

As a matter of fact, the formation of the enterprise's knowledge-capital implies the gathering of different types of inputs, that is, human resources (researchers and engineers), tangible resources (machines and tools), and intangible ones (patents, software, information, methodologies, and protocols). The enterprise has to produce and appropriate scientific and technical knowledge in order to expand the knowledge base it has already accumulated. Different means – that is, usually complementary in knowledge-based and innovative firms – are used: in-house (or internal) means (investment and management of human resources, R&D, and tangible and intangible resources) and external means. External means can be divided in two categories: equity relations (e.g., joint venture) and nonequity relations (contracts with firms and other institutions and more informal contacts) (see Table 1).

The purpose of all these strategies is to reduce the cost, risk, and length of technical progress and hence increase the short-term return on investment in the scientific and technical fields. This purpose is all the more important since the complexity of technological development increases. This implies a collective process of innovation that gives the possibility to innovate quicker and with less risk. Due to the profitability imperative, the big enterprise develops external means of formation of the knowledge base, which are both less risky and less costly. This does not mean, however, that the firm does not make in-house investments any more, as this kind of investment is crucial to understanding and absorbing the scientific and technical development achieved by other institutions on their own base and to define an architecture to organize the many parts of the new system.

As the knowledge-capital is the central tool of firms' competitiveness, the issue of its protection, as a whole and in its parts, is also crucial.

The Protection of the Knowledge-Capital and the Roles of Intellectual Property Rights (IPRs)

IPRs include industrial property rights: patents, trademarks, industrial models, and the protection of trade secrets. They also include copyright protection. The patent is a temporary monopoly (which lasts 20 years) given to an inventor, as an acknowledgement of the invention, whether a product or a process in all fields of technology, provided that it is new, involves an inventive step and is capable of industrial application. A trademark protects words, names, symbols, sounds, or colors that distinguish goods and services from those manufactured or sold by others and indicate the source of goods. Trademarks, unlike patents, can be renewed forever as long as they are being used in commerce. A design patent may be granted to anyone who invents a new, original, and ornamental design for an article of manufacture. Trade secret laws protect individuals and businesses against the misappropriation of trade secrets by improper means. Copyrights protect works of authorship, such as writings, music, and works of art that have been tangibly expressed.

The many works dealing with the functions of intellectual property rights in enterprises give us the possibility to draw up a list of the main aims that encourage firms to use them (Table 2).

Knowledge-Capital and Innovation, Table 2 The reasons of the resort to intellectual property rights (in particular to patents)

Protection against imitation (copy dissuasion and/or lawsuits in case of counterfeiting)
Incentive to invest in R&D by making investments profitable (production and commercialization of protected products and/or signature of license agreements)
Negotiation means (in partnerships and/or with financing institutions)
Image/reputation of the enterprise
Assessment of internal performance/valuation of the enterprise
Blocking competitors/reinforcement of entry barriers

Well studied in the literature, they may main be summed up in three main roles: a defensive/incentive role, an offensive role, and a coordination role. The defensive/incentive role refers to the possibility given to firms owning IPRs to recoup the investments incurred to develop new goods and services thanks to these temporary monopolies and to defend their ownership in courts in case of infringement. The offensive role mainly refers to the fact that IPRs may be by themselves a source of value (through licenses) and may block competitors and reinforce entry barriers. Another role is gaining ground, which we call a “coordination role” (including the impact of IPRs in negotiation and in the reputation of the enterprise) (Laperche 2011). IPRs play an important role in the coordination of activities as they may clarify the relationship and thus reduce the transaction costs between all the partners that take part to the formation of a firm's knowledge-capital. The ownership of trademarks, for example, (and this also goes for patented inventions or designs) acts as a signal of the quality of the central firm or potential suppliers' products and services. In other words, trademarks may increase the reputation of the central firm and of potential suppliers that would be chosen thanks to the IPRs they own. In the case of subcontracting and in franchising contracts, licenses allow the different units to use the patented invention or the protected trademark or design usually owned by the central firm. Licenses are usually considered to be responsible for productive efficiency: they facilitate the efficient diffusion of proprietary products, they let others use the intellectual property rights as inputs to innovation (research tools), and they resolve blocking situation and enable the development of complementary inventions. IPRs allow the diffusion of technology within the enterprise and gives incentives for the production of specific assets. In the case of R&D partnerships, where specific assets are jointly built (co-contracting or contracts between the central firm and a research lab for example), shared patents reduce the possibility of opportunist behavior ("holdup" situations) between the co-contractors.

The coordination function of IPRs (reduction of transactions costs) and their role of incentives (for the creation of new knowledge) appear to be linked. The incentives offered by IPRs are usually explained by the temporary monopoly associated to their possession, which increases the profitability (or its assessment) of investments. However, in the networked enterprise, the incentives associated to IPRs are also linked to their impact on the coordination of activities. As a matter of fact, IPRs clarify the relationships between the co-contractors (coordination) and thus, by reducing transaction costs, give incentives to the collective building of knowledge-capital, by protecting the tangible and intangible elements that constitute it. In the networked enterprise, the coordination role of IPRs is linked to their more traditional defensive/incentive roles. The temporary monopoly conferred by industrial property rights gives the possibility to go to courts in case of infringement. IPRs thus secure merchant relations and give an incentive to joint investment efforts and to the internal transfer of technology. Within the networked enterprise, IPRs are a tool used by firms to replace the control based on the ownership of tangible assets by a control based on the ownership of intangible assets. The coordination function is also visible through the relationships with investors. IPRs give a value to R&D investments, in a context where profitability has become an imperative. Filing and holding patents transform potential inventions in valuable assets, which can give confidence to investors and shareholders concerning the profitability of the firm's investments.

However, if we come back to the first role assigned to IPRs (defensive/incentive), some limits have been put forward. For instance, patents spread too much information and are costly (direct and indirect costs). Strong patents increase the cost of innovation (notably in network activities) due the cost of cross-licensing agreements. Copyright protection implies the capacity to provide proof of being the first creator. To reduce the limits of IPRs, enterprises use joint tools of protection; in other words, they built a portfolio of protection tools, notably associating secrecy and lead time. This leads us to the offensive role of IPRs within innovation networks.

The innovation strategies of networked firms lead to a blurred distinction between the networked enterprise and the innovation network to which it belongs. As a matter of fact, the formation of the knowledge-capital implies contractual relations between the central firm and units and partners. The partners may be small and medium enterprises specialized in technological fields, but they may also be big enterprises and competitors of the networked firm as a whole. These kinds of alliances are meant to share the cost of development of new products and processes and to reduce the time needed for their conception. These alliances often lead to an important number of patents that can be owned separately by the different partners or be shared.

Whatever the chosen solution, the development of a new technique leads to an important number of patents, which can block the use or even the final production by a subcontractor that would have to sign too many and costly licenses. The number of infringements and litigations also increases. Some legal solutions are proposed to conciliate the incentives to innovate and the dissemination of knowledge, such as compulsory licensing, nonexclusive licenses, and modifying the duration and the breadth of patents. But another type of solution to these restrictions has been found in the way firms manage their industrial property rights. This is the case of patent pool that can be defined as the aggregation of intellectual property rights which are the subject of cross-licensing, whether they are transferred directly by patentee to licensee or through some medium, such as a joint venture, set up specifically to administer the patent pool. Patent pooling is not new and was often regarded as a threat to competition (notably in the USA under antitrust laws). However, since the beginning of the 1980s, patent pools have been considered as having significant procompetitive effects when they integrate complementary technologies, reduce transaction costs, clear blocking positions, avoid costly infringement litigation, and promote the dissemination of knowledge. The procompetitive effects of IPRs are thus clearly related to their coordination function.

Patent pooling is often studied in relation to its procompetitive effects, but it also plays an important role in the definition of the position of the firm within its network. As a matter of fact, patent pooling, even in the case when complementary technologies are involved, supports the idea of a growing private and oligopolistic appropriation of the knowledge-capital. Even if the formation of knowledge-capital depends on interdependent relations between increasing numbers of institutions (big firms, small businesses, research labs, etc.), only a few firms appropriate the return of their investment, thanks to the patents they own separately and/or collectively and that they license to each other. The other members of the innovation network (the users, clients, suppliers, subcontractors, etc.) who are not the owners of the technology have to pay a license fee to use the technology and/or to produce the products and services that derive from this technology. This is true, even if they have participated, in more or less easily observable ways (competencies, consulting, informal exchanges of information, etc.) in the formation of the knowledge-capital from which the licensed technology or set of technologies emerges. What is important here is that the practice of patent pooling, notably resulting from ex ante cooperation processes, contributes toward defining the position of firms (their hierarchy) within the networks. The members of the patent pool – the ones that own the separate or shared patents – are the leaders of the networks.

Thanks to the power conferred by the ownership of intellectual property rights, they build entry barriers protecting the highest level of networks (the leaders). These protected leaders can also keep their advance over competitors, by reinvesting the rents they receive from the commercialization of licenses in R&D processes meant to develop the next generations of technology. This strategy clearly shows the offensive role of IPRs within innovation networks, that is, to say their role in the definition of the position of firms within the network(s) to which they belong.

Conclusion and Future Directions

To understand the genesis of innovation, it is important to focus on the firms' strategy of formation and protection of their knowledge-capital. Collaboration is central: the networked firm develops collaborative strategies with other firms and institutions to be able to maintain its ability to innovate continuously. IPRs have important roles to play in the processes of formation and protection of the knowledge-capital. IPRs appear as the coordination device of the networked enterprise. This coordination role is associated with the more traditional incentive/defensive and offensive roles of IPRs. In the networked enterprise leading open innovation strategies, we consider that the coordination function (reduction of transaction costs, reputation, and resolution of blocking situation) contributes to increase the incentives to develop innovation and give confidence to partners for sharing the costs incurred in the formation of the firm's knowledge-capital. We also showed that the specific use of IPRs as a coordination mechanism is integrated in the leadership strategies of big networked firms. They contribute to the definition of each firm's position within its innovation network and to an oligopolistic appropriation of the knowledge-capital, basis of future innovations.

Original Concept

Through the analysis of numerous inventions during the development of the *Theory of Inventive Problem Solving (TRIZ)*, *Genrich Altshuller* discovered that different inventions involved

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8, © Springer Science+Business Media LLC 2013

different levels of creativity. It therefore seemed likely that different tools and techniques would be required to create a variety of inventions. (Clearly, the invention of a pencil with built-in eraser differed greatly from the invention of the steam engine.) In the late 1960s, Altshuller defined various levels for inventive problems related to (Altshuller 1999):

- The number of trial and error attempts required to guarantee a solution of a certain level
- The scale of change imposed on the original system

According to Altshuller, inventive problems can be divided into five levels, as shown below (Table 1):

It can be seen that the number of mental trials that must be entertained to guarantee a satisfactory solution grows dramatically as the level increases. In fact, for high-level inventions, the number of trials is so high (in the thousands) that there is no guarantee that a solution can be found at all; thus there is no control over the innovation process.

Example: Edison, who was known for his persistence (it took tens of thousands of trials to find a material suitable for use as a light bulb filament) was unable to build a nuclear motor using trial and error; inventions of this level are based on scientific discovery, and the necessary discovery (nuclear theory and neutron multiplication when a nucleus is divided) had not yet occurred.

In the course of his research, Altshuller conducted statistical analysis of inventions granted between 1965 and 1969 over 14 patent classes (former Russian patent classification). The results showed the following distribution among the five levels:

Level 1 – 32 %
Level 2 – 45 %
Level 3 – 18 %
Level 4 < 4 %
Level 5 < 1 %

Apparently, the inventions of high levels are rare given the amount of trials typically necessary to obtain them.

For each stage in the typical problem-solving process, Altshuller identified specific criteria to help identify the level of a particular invention. According to Altshuller, the typical invention stages included:

- Choosing the task
- Choosing the search concept
- Gathering data
- Searching for an idea

Levels of Invention, Table 1 Levels of Inventions: Description

Level	Description	Typical number of trials	Example
1	Smallest inventions produced by methods well known within the specialty. No contradictions have been resolved	Up to 10	Using modular design to facilitate easy repair of a complex device
2	Minor improvements to an existing system. Contradictions are resolved using methods known within the industry	Up to 100	Bifocal glasses
3	Fundamental improvements to an existing system within the same paradigm. Contradictions are resolved using methods known outside the industry but within the same domain of knowledge (mechanics, chemistry, etc.)	Up to 1,000	Automated transmission
4	A new generation of a system that entails a new operating principle for performing the system's primary functions (paradigm shift). Contradictions are resolved using methods known outside the relevant domain of knowledge	Up to 100,000	Jet aircraft
5	Pioneering invention typically based on a new scientific discovery	Over 100,000	Laser, radio

Levels of Invention, Fig. 1 Suggested new distribution of inventions among the levels (Zlotin and Zusman 2004)

- Finding the idea
- Practical implementation

Altshuller regarded the discovery of levels of invention as a very important step in the development of TRIZ as a pure engineering science (i.e., a science based on the statistical research of patents and other sources of technical information). He also used his findings to emphasize the fact that high-level inventions were always the main focus of TRIZ, and that TRIZ was the only way to control the process of high-level innovation, as it reduced (and possibly eliminated) the number of blind trials required. At the same time, however, the concept of levels of invention has not provided any specific instruments facilitating practical invention and/or problem-solving processes.

Further Development of the Original Concept

Distribution of Inventions Among the Levels

Work with inventions of various levels conducted by the authors and their associates between 1982 and 1985 suggested that the distribution of inventions among the levels as defined above should be close to the Gaussian (normal) distribution curve, as shown below (Fig. 1).

The difference between the Gaussian distribution and Altshuller's numbers (in Altshuller's research there were fewer inventions at level 1 than level 2, which does not comply with the normal distribution) can be explained as follows:

- Level 1 inventions often go unpatented, for various reasons, for example:
  - Local importance and limited value of the invention
  - Unwillingness to disclose the invention to competitors
  - Preference for treating low-level inventions as useful suggestions
- Inventions of level 1 are likely to be rejected by patent examiners for insufficient novelty.

Solving a Problem at Different Levels

The level is assigned to an invention rather than to a problem as many problems can be solved at different levels, depending on the available *resources* of the system and the imposed limitations to system change. Table 2 below shows the results of a project aimed at reducing the vibration of an electrical generator for a specific transport scenario, and describes typical solutions found at different levels.

Given the above, it is clear that levels should be attributed to the inventions (solutions) rather than the problems. For practical purposes, however, it is convenient to rank inventive problems as well. To resolve this issue, it was suggested that the level of a problem be determined according to the *acceptable* solution level. In the above case, a level 1 solution was satisfactory and the problem was ranked accordingly.

The discovery that a problem can have solutions at different levels was an important argument in the discussion of what the primary focus of TRIZ should be – providing a single,

Levels of Invention, Table 2 Solving a problem at different levels of invention

Level of invention	Technical solution	Drawback
0	Install generator on rubber pads to absorb vibration	Vibration at certain frequencies not effectively addressed
1	Use multilayer pads of different materials, with the thickness of each layer calculated to better reduce vibration in the given range	Does not address haphazard impacts
2	Introduce pneumatic cylinders with feedback-based control mechanisms to adjust cylinder pressure according to the magnitude and direction of haphazard impacts	Space around generator is limited; solution is expensive
3	Position the generator on strong permanent magnets with electromagnetic windings. Winding current can be changed to dampen vibration	System has high inertia; strong electromagnetic field dissipation
4	Replace generator with a device that can generate electrical energy without rotating parts, which cause vibration (e.g., by using isotopic elements – a brand new direction at the time of the project)	System is too new; costly research and testing required
5	Not considered for this project	

Level 0 denotes conventional noninventive solutions (Zlotin and Zusman 2004)

ideal (or closest to ideal) solution, or providing an array of solutions at different levels of ideality (and inventiveness) from which the ones that best fit the particular situations and requirements can be selected. Apparently, low-level inventions are better suited to short-term goals (such as reducing the cost of an existing product) while high-level inventions are better suited to long-term strategies (e.g., ideas for next-generation products).

"Relativity Principle" for Levels of Invention

Estimating the level of an invention can be considerably influenced by the area, current state, and overall level of technology. For example, Archimedes' screw for the water supply in Ancient Greece can be classified as a level 5 invention for the time; about a 1,000 years ago, a screw attaching a visor to a knight's helmet would rank between levels 4 and 5; today, using a screw to fix two parts together is not considered an invention at all.

The opposite effect – where the level of invention increases over time – can have much more important consequences. This can be illustrated with the history of the following invention:

In 1840, a lamp that burned whale oil in a specially shaped glass was invented. This remained a "small" invention until 1855, when kerosene was invented. Kerosene had the following benefits:

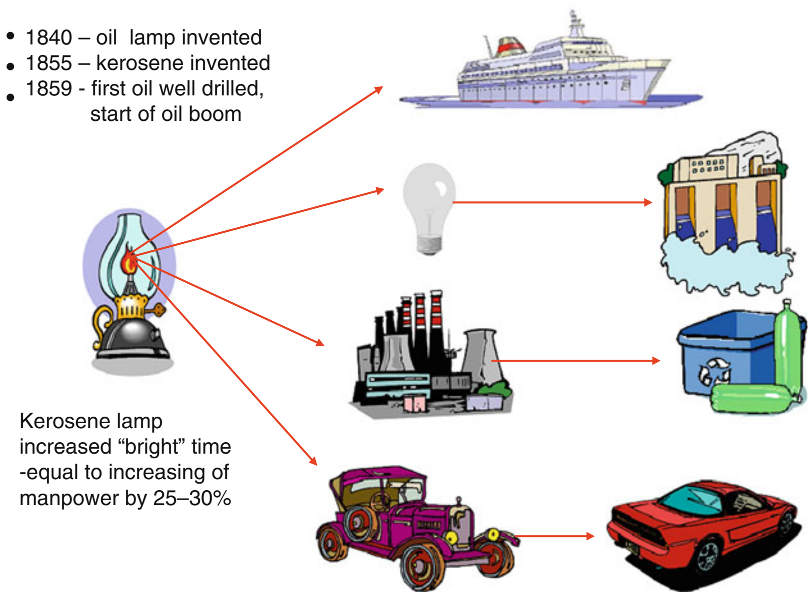
- It produced a pleasant, bright white light
- It burned without creating smoke
- It was safe (kerosene lamps were not explosive like other gas lamps).

The invention of the kerosene lamp abruptly increased the demand for oil which, at the time, was available only from oil pits. To satisfy the growing demand, exploration and new oil production methods were necessary; in 1859 the first successful oil drill launched the oil boom.

The introduction of a bright, inexpensive, and safe source of light allowed for a longer work day, night shifts, and more time for reading, education, entertainment, etc. The need for good illumination activated by the invention of the kerosene lamp stimulated the development of electrical power and of the electrical industry in general.

The mass production of kerosene created a problem, however: What could be done with the by-products, such as gasoline, that were unusable for illumination purposes because they were explosive, or heavy oil components with complex hydrocarbons? Ultimately, these by-products offered inexpensive fuel for the growing automotive

Levels of Invention, Fig. 2 “Marketing Tornado” originated by the kerosene lamp invention (Zlotin and Zusman 2004)



industry, as well as a rich source of raw material for the emerging chemical industry.

At the same time, the utilization of oil fuel instead of coal eliminated the most serious drawbacks to the expanding military and civil fleets (steam boat engines that burned coal required a lot of stoking).

The kerosene lamp (Fig. 2 above) serves as a good illustration for how a modest invention activated an avalanche (“invention tornado”) of industrial evolution. Other illustrations are the invention of typography, gun powder, hay production, the cotton gin, etc.

Levels of Invention, Implementation Strategy, and Return on Investment (ROI)

The main concepts and approaches in TRIZ were developed on the basis of statistical research of patent literature, and thus always lacked details about how the inventions were implemented. Common sense suggests that the implementation time for high-level inventions is typically long, mainly due to the lack of necessary knowledge and the research required for gaining that knowledge. Another reason is the high psychological barrier associated with a paradigm shift. At the same time, the analysis of information other than patents (including anecdotal knowledge about how particular inventions were implemented), shows that another important reason for delays in implementation is the number of problems that must be solved to ensure success.

Typically, the implementation of a level 4 invention cannot occur unless a number of level 3 inventions have been made (i.e., to solve secondary or so-called consequent problems). In turn, each level 3 invention might require a number of level 2 inventions, etc., ultimately entailing the solution of many conventional engineering problems.

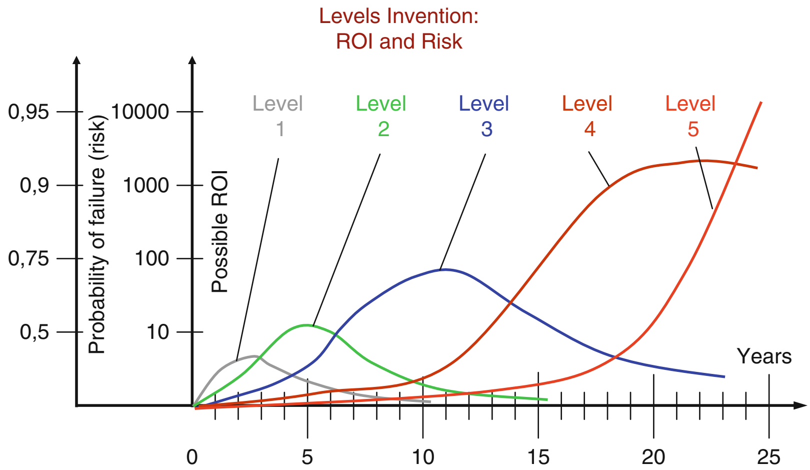
Given the above, an effective implementation strategy should include the timely identification and resolution of consequent problems at all levels. Failure to do so can result in long delays in implementation.

It is important to note, however, that consequent problems should not be more difficult to solve than the original problem.

The consideration that every higher level invention contributes multifold in the number of lower lever inventions with each level down can provide another (additional) explanation of huge difference between the number of inventions of high and low levels.

Implementation time and actual return on investment (ROI) are significantly dependent on the level of the invention. The first idea for an invention often

Levels of Invention, Fig. 3 Levels of inventions, ROI and Risks (Zlotin and Zusman 2004)



emerges when there is no practical means to realize it. For example, the first theoretically possible laser was described by Einstein in 1913. In 1948, the Russian scientist V. Fabricant patented the idea of a coherent light source (the term "laser" came later), but could not get enough financing to build a working device. In the early 1950s, Towns in the USA and Basov and Prochorov in Russia almost simultaneously built the first maser – a gas device operating in the radio frequency range (later all three shared the Nobel Prize for their achievement). At that time, however, there was no practical application for the new invention. Not until 1959, when R. Gould (a disciple of Towns) successfully built the first solid laser based on a ruby crystal, did the practical application of lasers actually begin. Still, it took another 20 years until lasers were widely applied in consumer electronics and significant profit was generated.

In recent times, the acceleration of scientific and technological progress has significantly reduced the implementation time required for large inventions – but not enough. The typical correlation between implementation time, ROI, and risk for inventions of different levels is shown in the Fig. 3 below.

Apparently, none of the levels is optimal; each has its advantages and disadvantages:

- Low-level inventions are typically fast and easy to implement and the risk is low; however, they do not provide a competitive edge or significant ROI.
- High-level inventions can provide a competitive edge and high ROI but require substantial and long-term effort before beginning to pay off, making them very risky.

Below one can see a number of strategies that can help "harmonize" the invention output.

Strategies for Low-Level Inventions

As mentioned earlier, low-level inventions have never been the primary focus of TRIZ, yet their importance and value can grow enormously. The rich resources that arose with the invention of the kerosene lamp (that eventually resulted in a "tornado") went unnoticed for a long time, delaying the recognition of the invention's value. The studies of US and European patents show that underestimating an invention's value often results in patents that cover no more than 10–15 % of the newly created opportunities. Such patents provide limited protection and can disclose more than they protect, serving as invitations for potential competitors to capitalize on strong, original ideas. To avoid this situation, it is crucial to unveil, in a timely fashion, newly emerged resources, for example, by conducting Directed Evolution® (Directed Evolution is a registered Trademark of Ideation International Inc.) paying special attention to new areas of application (Zlotin and Zusman 2001).

Example: The evaluation of an optical film intended for use in gift wrapping resulted in the identification of a new area of application – home interior (following the last boom in housing).

Given the above, new possibilities discovered for a low-level invention can increase its overall value (and ROI) while maintaining advantages such as short implementation time (at least for the first area of application), low initial investment, and relatively low risk.

Strategies for High-Level Inventions

The main problems associated with implementing high-level inventions are long implementation time, expensive R&D, and high risk. In these cases, it is critical to review the entire technology and its evolutionary resources (Zlotin et al. 2005), paying special attention to:

- Identifying partial low-level inventions and applications associated with the given high-level technology, especially those that can be quickly and inexpensively implemented.
- Identifying secondary (consequent) problems at lower levels, which must be solved to ensure successful implementation.
- Timely unveiling and resolving potential problems that could delay or complicate the implementation, for example, by conducting *Anticipatory Failure Determination* (AFD).

Some of the recommendations suggested for increasing the value of low-level inventions, such as searching for new applications or linking to "tornados," are applicable for high-level inventions as well.

Conclusion and Further Directions

1. Aside from its theoretical importance, the concept of levels of invention is valuable in terms of practical application. For different levels, different problem-solving and intellectual property strategies can be recommended.
2. The level of an invention can be identified using a set of criteria, detailed descriptions and illustrations of which are embedded in software.
3. Further research could be done in the directions of increasing precision and possibly quantifying the levels of innovation.

Introduction

The spheres of creativity, invention, innovation, and entrepreneurship are strictly related with the life and performance of organizations. Companies have to be creative, inventive, innovative, and entrepreneurial if they want to be competitive and prosperous on the modern market (Carayannis and Chanaron 2007). Due to the variety of products and services offered by the business entities in most industry sectors, it is mainly knowledge of gloCal (global and local) character (Carayannis and von Zedtwitz 2005) that makes the company outstanding among similar organizations and enhances its market attractiveness. Although companies have to search continuously for innovations and the spirit of entrepreneurship (Drucker 2006), determining the competitiveness of modern economies (Welfens et al. 1999), because they operate in the multilevel systems of knowledge (Carayannis and Campbell 2006), in several of them, immediate results and profits are valued more than both the long-term learning and the time-consuming dissemination of novel thoughts and ideas (Moore 2010). Additionally, although knowledge is an indispensable part of company performance, being created and represented in routines, practices, cultures, and relationships (Badaracco 1991; Lemon and Sahota 2004), its importance is not taken into account in many organizations. The other considerable issue is the alternating nature of knowledge since the characteristics of cognition and instruction have changed with the flow of time. In the past, geographical distance was one main factor shaping human relations, also the ones responsible for creation and invention, whereas nowadays, common interests determine the individuals' choices of joining groups (McPherson et al. 2001). Thus, modern innovation networks are created by people who may represent different cultures and it is the diversity of innovative environments that determine their success (Baker 2009; Thatcher and Brown 2010), since heterogeneous information flows increase the probability that the incoming data is related to the already known information (Cohen and Levinthal 1990) or they provide novel solutions to existing problems. Additionally,

> *the competitiveness and superiority of a knowledge system is highly determined by its adaptive capacity to combine and integrate different knowledge and innovation modes* via *co-evolution, co-specialisation and competition knowledge stock and flow dynamics* (Carayannis and Campbell 2009: 223).

Thus, knowledge isolation influences the economy in a negative way, whereas the openness for new cultures and domains increases the innovative potential and stimulates the absorption of new innovation-oriented stakeholders. The mentioned diversity demands, among others, advanced linguistic skills to create and disseminate knowledge in a culturally and linguistically diversified setting.

It should also be remembered that knowledge is not what is only visible in words and numbers, but it may be also tacit, not written down, not easy to observe, unrecognizable, and hard to categorize and describe (Nonaka and Takeuchi 1995). Thus, it is language that enhances or hinders the creation and usage of knowledge since the proper selection of linguistic tools may help understand novel ideas and thoughts, especially the ones that are difficult to be perceived, named, and disseminated. The diversity of ideas and thoughts should also concern the hierarchical dimension of organizations. Taking into account the type of communication to be used, the leaders should follow the rules of "social poetics" (Shotter and Cunliffe 2002), stressing the dialogue between supervisors and subordinates. In the case of CI2E (*creativity, invention, innovation, and entrepreneurship*) networks in organizations, social poetics deals with the mutual input in and for idea creation and maintenance, in discussing some innovative issues within the organization, with all the workers, customers, and other people related to the performance of organizations. The notion of diversified stakeholders, which is related to the concept of "heterophily" that can be understood as the dissimilarity between interlocutors in terms of (for example) education, gender, beliefs, and social status, and "homophily" that is perceived as homogeneity among participants in discourse as far as their individual features are concerned (Rogers 1995), shapes organizational communication that focuses on structuring and maintaining an organization that is creative, innovative, inventive, and entrepreneurial. Linguistic heterogeneity emphasizes the communicative aspect of CI2E. The linguistic heterogeneity of the studied domains is related to input heterogeneity, process heterogeneity, and output heterogeneity. Input heterogeneity refers to the diversity of factors shaping economic activity, such as land, labor, capital, entrepreneurship. On the other hand, process heterogeneity relates to the differences in using the inputs. The third aspect, namely, the output heterogeneity, concerns (among others) such issues as number and size of firms, company performance, and market concentration (Carayannis 2008). Taking into account the mentioned aspects, that is, the heterogeneous input, process, and output, the languages of CI2E will be to some degree homogeneous, but possess also important heterogeneous features. Each of them has different heterogeneous inputs, processes, and outputs and, consequently, expresses a different linguistic heterogeneity. Thus, the language of CI2E should be homophilous and heterophilous at the same time; it should possess homophilous characters since only common communication tools allow for efficient and quick communication, using linguistic tools that are understood and used by both encoders and decoders of messages. At the same time, they should have heterophilous elements since only diversity allows for the variety of perspectives and the magnitude of available solutions (Bielenia-Grajewska 2012b).

Moreover, nowadays, society experiences an era of hyperconsumption, with people consuming many goods, in different places and at different times (Lipovetsky 2011), being bombarded by changing media images, techno-images, finance-images, and idea-images (Appadurai 2005) that they cannot "digest" themselves. Taking into account the mentioned situation, the direct dialogue would be more and more impossible. Thus, the future is in the hands of various types of connectors, translators, net-creators, whose tasks are to build relations and transfer information (Szlendak 2010). Taking into account the mentioned feature, it can be stated that such a role can be played by modern organizations. For example, employees can be the mediators, communicators, and translators of innovations. The last feature can be understood as translating the language of innovation for potential stakeholders, by presenting innovations in such a way as to make them clear and easily applicable (Bielenia-Grajewska 2011). Referring to the mentioned characteristics of language, in the coming sections it will be discussed, how language determines the sphere of CI2E.

CI2E and Linguistic Issues

The relation between CI2E and language is mutual. First of all, language allows for information flows between various domains (specialized disciplines) of knowledge. Thus, it offers to those, who are looking and searching for data, several diversified sources of information that can be selected according to one's needs and preferences (Bielenia-Grajewska 2012a). Secondly, it is the language understood in the broad sense, with its written and spoken mode, with its formal and informal style that allows for effective CI2E knowledge creation and knowledge communication. Thirdly, since creativity, invention, innovation, and entrepreneurship aim at creating something new or innovative, the role of language, among others, is to name new ideas and their products. Moreover, the activities of creating, inventing, innovating, or entrepreneurship rely on some sources during the act of constructing some novelty, with linguistic resources being one of them. Simultaneously, language mirrors the state of art in each of the studied domains.

Thus, observing the communicative sphere of creativity, invention, innovation, or entrepreneurship informs readers or listeners about the level of technological or economic advancement of the studied domain. To add, language is an important part of branding since the chosen name for the merchandise determines the success or failure of service or products related to CI2E. At the same time, all the components shape the language as such since they determine the need for communication and the creation of new terms and concepts. Moreover, the popularity and usage of the newly coined words and phrases mirror the successes and failures of each CI2E domain. Thus, the advancement of CI2E determines the development of lexicons and, at the same time, language influences the level and characteristics of CI2E. Since communication not only allows for the exchange of services and goods, but also for ideas and thoughts (Bennett 1998), those not in possession of advanced linguistic skills have lower chances of participating thoroughly in innovation networks since they may have problems with articulating their ideas. Thus, the process of creation, invention, innovation as well as commercializing novel products or services is determined by linguistic factors. The mentioned barriers may result from the linguistic characteristics of the organizational lingo such as linguistic policies as well as the low communicative skills of broadly understood stakeholders, related to their psychological features and social skills.

Moreover, language is an indispensable element of corporate allostasis. Allostasis, being originally a biological term, denotes the organisms' ability to adopt to new conditions by means of hormones and mediators (Karatsoreos and McEwen 2010). Consequently, corporate allostasis is related to all the actions necessary for the company to react to the changes in its environment. Communication, especially the language itself, constitutes a very powerful element of corporate allostasis since it allows the organizations to react to any alternation and impose necessary actions. Proper dialogue proves to be especially important in the times of risk and crisis when the organizations have to communicate with diversified stakeholders (Bielenia-Grajewska 2012c).

Furthermore, all the issues related to the linguistic side of company performance can be treated as an important element of company capital. Thus, the term *company linguistic identity capital* can be used to show how much can be achieved by creating and exercising effective company linguistic identity (Bielenia-Grajewska 2012d). In the case of the studied concept CI2E, company linguistic capital is shaped by various systems, such as political, social, cultural, and economic ones, and the creative, inventive, innovative, and entrepreneurial nature of the organization itself.

Relations Between CI2E and Language from a Systemic Perspective

As far as the methodology is concerned, the postmodernistic studies are taken into account by concentrating on the systemic approach (the open system perspective), which allows to study each of the mentioned domains as a separate system to some degree, but at the same time to concentrate on the relation between various domains. Moreover, these systems are dynamic, responding both to the inner and outer factors (e.g., Balestri 2005; Becker 1997; Johnson et al. 1964; Teubner 1984). For example, innovations do not exist in a vacuum and they do not concern exclusively one product, service, or idea, but they are determined by the relations between political, economic, and social systems (Küppers and Pyka 2002). Looking at the issue from the perspective of the Quadruple Helix, four helices determine the innovation system: academia/universities, industry/business, state/government, and media and culture-based public relations as well as civil society (Carayannis and Campbell 2009). The mentioned discussion can be also conducted with the use of the Quintuple Helix approach, by taking into account the role of social ecology (Carayannis and Campbell 2012). In addition, it should be stressed that the systemic nature can be observed at both the microsphere and macrosphere. Taking a larger perspective, every innovation network can be understood as a subcomponent of a larger innovation network (Carayannis and Campbell 2012). Applying the micro-point-of-view and the internal-systemic-environment, it is reasonable to take the notion of creativity into account that is directly connected with the interaction of three elements: a culture of symbolic rules, a person who introduces the novelty in the symbolic sphere, and a group of experts who understand and accept the innovation (Csíkszentmihályi 1996). The same can be observed with other notions of CI2E since they all require the presence of three indispensable elements: the initiator, the receivers, and the environment they function within.

Additionally, the application of systems theory is also useful, because the cooperation of subsystems may lead to synergic results (Kerzner 2009). Thus, the existence of various systems within the domain of CI2E is also the source for the uniqueness of the concept as such as well as its constituting domains. Moreover, as Luhman states: In every system, there is a main element that undergoes constant reproduction to maintain the fundamental functions of the system. In the case of social systems, it is communication that is the main determinant (Ramage and Shipp 2009), with language shaping and maintaining the organizational ecosystem. Thus, in the next section, the attention focuses on selected linguistic characteristics and features of CI2E to show the general patterns of the language that shape creativity, invention, innovation, and entrepreneurship.

CI2E Domains from a Systemic Linguistic Perspective

The characteristics discussed here are representative not only for the studied domain itself, but due to the interrelation of the spheres belonging to CI2E, they determine the shape of the other disciplines constituting a CI2E system. The main feature related to the growing importance of CI2E in the modern economy is related to the growing popularity of these concepts, also for everyday life. For example, in the twentieth century, creativity is not only referred to as being the characteristics of art or literature, but it is also employed to denote the novelty of everyday human activities (Mueller 2010). Thus, creativity can also be discussed when one's everyday actions are observed. One of the examples related to creativity is its linguistic dimension. Creativity expresses a relationship to language, since people are capable of constructing their own sentences, the ones they have never heard before but created themselves (Kintsch 2010; Runco 2007). Since language can serve as an identity marker (Scollon and Wong Scollon 2001), the sentences coined by individuals mirror their characteristics, education, preferences, social background, etc. The same can be discussed in the case of organizations. Apart from the *compositional creativity* that is connected with creating new products or services in carefully planned processes, modern organizations also use *improvisational creativity* when they have to face emergent crisis or risk situations (Fisher and Amabile 2009). The mentioned improvisational creativity also concerns the linguistic dimension of organizational performance. Unexpected corporate events may require using not only the well-known strategies, but also trying to create novel communication solutions to address the appearing problems. Since creativity has to be accepted by the social environment (Mueller 2010), it has to be communicated in a way that is understood by every receiver. Thus, such linguistic tools have to be selected that allow for quick and efficient corporate dialogue. The power of language in relation to creativity is related to the fact that creativity gives the individual not only the fulfillment, but also leads to results that will influence future actions (Csíkszentmihályi 1996). Thus, looking at the issue from the process perspective, the way that language is used in the course of creation will determine the success or failure of products or services in the future. For example, the mistakes made during the creation process resulting from communication problems determine the later stages of product or service implementation and acceptance.

Language also influences the domains of invention and innovation. Invention and innovation are terms that are often confused in the literature.

> *Invention is the discovery of a new product or process, whereas innovation is the process through which inventions and new ideas become a business or operational reality* (Needle 2004: 355).

In invention, the idea of repetition is common; when something proves useful, adding a feature or an element might be a good solution (Weber 1996). The same can be applied in the case of communication. When a linguistic strategy is efficient, it is likely to be used further with some modifications. The act of invention is strongly connected with language since

> *one invents with language or with other symbol systems, which are socially created and shared by members of discourse communities* (LeFevre 1987: 34).

As far as innovation is concerned, the role of both, individual and group characteristics, determine the creation and maintenance of innovation. According to social constructivist approaches, group interactions determine how an individual perceives oneself and the world and one's approach to innovation. Moreover, groups may create anti-innovative identities that may hinder future innovations (King and Anderson 2002). To add, since language may be also the element of divide, the role of Innovation Diplomacy is to eliminate the linguistic distance and enhance the initiatives aiming at increasing the potential of markets and investors (Carayannis and Campbell 2012). It should also be stressed that linguistic issues depend on the type of innovation models. Consequently, the model of linear innovation modes is different from the model of nonlinear innovation modes, also from a communication perspective (Carayannis and Campbell 2009). One of the factors shaping both the individual as well as the social approach to innovation is language. Thus, one's linguistic identity may serve as pro- or anti-innovation factor and, consequently, hinder or enhance innovation acceptance and dissemination.

The sphere of entrepreneurship is also determined by linguistic factors, with language being the tool of creating and maintaining competitive advantage. Moreover, entrepreneurial discourse supports novel products and services since their conception and formation draw stakeholders' attention to the unique features of the offered merchandise.

Metaphors in CI2E Discourse

Among others, linguistic symbolism plays a crucial role in the CI2E communication. Thus, linguistic rituals, figurative language, metaphors, and storytelling are an important part of CI2E. Taking into account figurative creativity (Kövecses 2005), one of the most visible examples of human cognitive ability is the ability to create, use, and understand metaphors. Metaphor creativity is not exclusive for literature, but can be found in various contexts and uses (Semino and Steen 2010). For example, metaphors are used in professional communication since they make the dialogue quicker and more efficient (Bielenia-Grajewska 2009). One of the reasons for the popularity of metaphors in different types of communication is the fact that metaphors themselves have some elements of creativity, innovation, invention, and entrepreneurship embedded in themselves. First of all, metaphors, by using well-known and novel domains, allow to show similarities and differences between objects (Olds 1992) and offer an indefinite number of interpretations (Schon 1969). Metaphors enhance the understanding of novel concepts by using well-known domains (Brown 1994; Reeves 2005), since they are able to verbalize novel ideas (Kurth 1999), especially when the available linguistic resources are not sufficient (Lakoff and Turner 1989). Secondly, people create metaphors when they have difficulty in using literal language to express their feelings or send some information (Gibbs 1999). Thus, a metaphor is not a decorative element only, but it is related strictly to individuals' cognition (Deignan 2005; Vega Moreno 2007). Consequently, the way one creates metaphors depends on the way he or she perceives the reality. In the case of corporate discourse, the way one coins and uses metaphors depends on both the individual personae and group identity.

The other reason for the popularity of metaphorical names is the fact that they are remembered easier than standard expressions (Espunya and Zabalbeascoa 2003), and they allow the receivers to see and perceive something from a different perspective (Cacciari 1998). However, their characteristics may also lead to some problems with their understanding since

> *metaphors must be approached and understood as if they were true at the same time that we are aware they are fictious-created and artificial* (Spicer and Alvesson 2011: 35).

It should be also stated that the relation (relationship) between CI2E and metaphors is mutual. As has been presented above, the way metaphors are used shapes the way CI2E is perceived by various stakeholders. At the same time, the level of CI2E and its characteristics influence the usage of metaphors since people construct metaphors about concepts they know better (Edwards and Clevenger 1990). For example, it could be argued that the term and concept of the "Quadruple Helix" innovation system (Carayannis and Campbell 2012) has also some metaphorical qualities in the support of explaining the dynamics of knowledge production and innovation application in the knowledge society, knowledge economy, and knowledge democracy. Metaphors are also important at the individual level of CI2E since it allows persons with leadership quality to show their future vision as to persuade social actors into their ideas (Vincent 2012). However, metaphors may also entrap those who use them. Although a short-term rhetorical success can be achieved by using a metaphor, it can turn out that the action that was pictured by metaphors as strong and efficient is not that powerful in reality (Burkholder and Henry 2009).

Despite the circumstance that metaphors can be found in all languages belonging to the sphere of CI2E, it is the language of entrepreneurship that is abundant in figurative language. Since

> *entrepreneurship is a dynamic process of vision, change, and creation that requires an application of energy and passion toward the creation and implementation of new ideas and creative solutions* (Kuratko 2009: 21),

it also involves the linguistic creativity in creating and implementing novel thoughts and achievements. It should be stressed that metaphors also have been changing since leadership is evolving. For example, in the past, the metaphors of commander and controller were used that stressed the mechanistic and structural aspect of leadership, whereas nowadays metaphors such as designer, coach, covenant-maker, maestro, steward, and moral-exemplar are popular (Bogue 2010). Moreover, the used metaphor mirrors one's leadership style. For example, the leadership person who uses the metaphor of a family to describe his or her team exercises a different management style than the one who describes his or her subordinates as the "ant colony" (McLeod 2012). Another way of looking at entrepreneurship is through the prism of an orchestra metaphor, with the conductor being

> *responsible for bringing out the artistic talents and gifts of each symphony member, while the musicians work together to blend and harmonize the music* (Komives et al. 2007, p. 32).

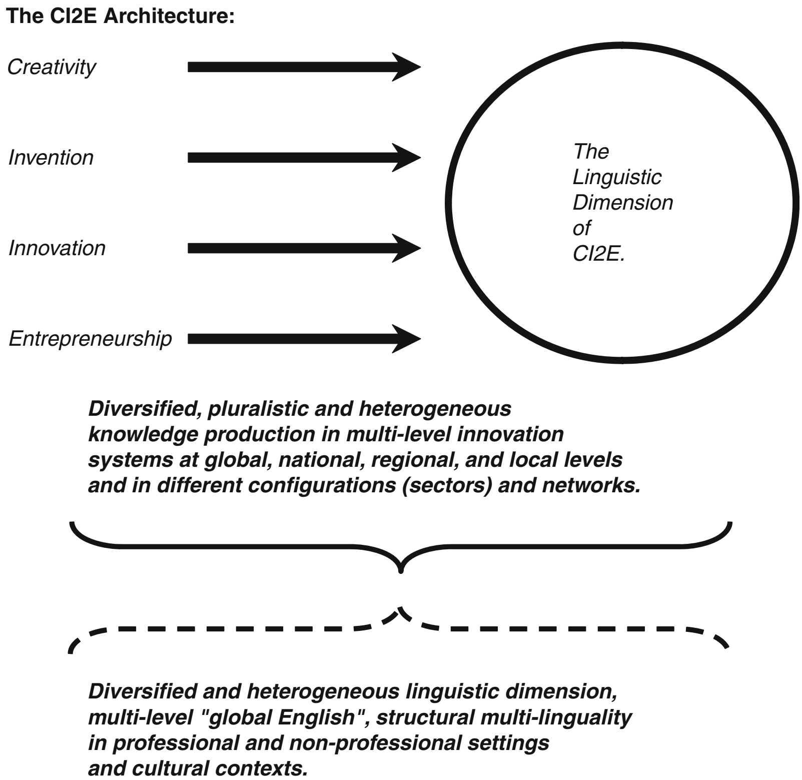
The difficulties and complexities of entrepreneurship are also being presented by metaphors.

For example, the metaphor of journey is utilized to exemplify such features such as complexity, having some obstacles and problems in the process of realization (Dodd 2002). The job of managing can be compared, for example, to navigating the ship, with a map and a compass in hands (D'Egidio 2003). Furthermore, complexity (and stages) may be exemplified in the metaphor of building as well as the metaphor of raising a child (Dodd 2002). Since entrepreneurship is also connected with fighting for a good position on the competitive market, it is occasionally pictured by using the metaphor of "war" (Dodd 2002; Lumby and English 2010). Another area of metaphorization in organization is cognition. Thus, the metaphors of learning, brain, and knowledge are used and are being employed (Henry 2001).

Conclusion and Future Directions

As has been discussed, the language of CI2E (*creativity, invention, innovation, and entrepreneurship*) has several distinct features that determine the communication with different stakeholders that should be understood broadly. However, one should remember that each domain within the CI2E sphere has its own distinctive features. One of the reasons is the function of the domain itself which determines the linguistic sphere of its performance. Thus, each system within CI2E relies on carefully selected linguistic devices to describe the domain. For example, the degree and type of linguistic symbolism vary, taking into account different communicators, audiences, and purposes. At the same time, the language used by each system is not the same since it is shaped by different relations between the subsystems, both within the CI2E sphere and with other outer systems.

Is there a language of creativity, invention, innovation, and entrepreneurship? The analysis presented here suggests that the CI2E architecture of knowledge production and innovation systems (innovation application) also finds an expression in a linguistic dimension of CI2E. The linguistic dimension of CI2E should make creativity, invention, innovation, and entrepreneurship visible. However, more importantly, it would also have to be asked: *What is the proper language of creativity, invention, innovation, and entrepreneurship*, to be creative and innovative, to support knowledge production and innovation application? The more diversified, pluralistic, and heterogeneous knowledge production evolves in advanced economies, societies, and democracies, and in multilevel arrangements of innovation systems (Carayannis and Campbell 2012: 21, 32–35), the more diversified and heterogeneous also the linguistic dimension of CI2E should develop. *Between CI2E knowledge production and the linguistic dimension of CI2E, there are several interlinkages and cross-references, even suggesting a coevolution.* There can be advances in CI2E knowledge production and in CI2E language. Furthermore, language shapes culture. Kuhlmann, for example, uses the term and expression of the "innovation culture" (Kuhlmann 2001: 958). Language of innovation may also cross-relate with a culture of innovation. *Is nonlinear innovation coupled to a nonlinear language of innovation?* In addition, multilevel innovation systems in gloCal (global and local) settings require also the formation and evolution of a global language so that there can be global communication in world-wide systems of knowledge production and innovation. There exists already the concept of "English as a global language" (Crystal 2012). In several contexts, this actually implies diversified forms of bi-linguality or multi-linguality, where English is the language for professional communication, being accompanied by other languages for regional, local, and personal communication. Multi-linguality may add to "creative knowledge environments" (on CKEs, see Hemlin et al. 2004). Multilevel innovation systems, operating at the same time at global, national, regional, and local levels and in different (also different sectoral) configurations, require a structure of a "multilevel expression of global English," where professional English as well as professional and nonprofessional other languages coexist. Global English is a social expression of and in knowledge production, and can be enhanced by IT (perhaps also by artificial intelligence) in the future. Global English



Linguistic Dimension of Creativity, Invention, Innovation, and Entrepreneurship, Fig. 1 The co-evolution of the linguistic dimension of CI2E and the CI2E of knowledge production and innovation systems

integrates knowledge production and innovation globally in context of multilevel innovation systems and systematically introduces and amplifies multi-linguality in culture. Advances in the linguistic dimension of CI2E should be related to advances in CI2E knowledge production and innovation systems (see Fig. 1).

Synonyms

Family enterprise investment

Introduction

Entrepreneurial finance includes both equity and loans. The equity aspect includes personal savings, family and friends, business angels, venture capitalists, and the public equity market. The caption "love money" relates to the financing of a business by family and friends. Love money can be defined as money or capital given by family or friends for business start-up. The basis of giving money is based on the relationship that exists between the two parties. Family can include parents, siblings, as well as uncles and other members of the extended family.

The first recorded use of the term love money found was by the Canadian House of Commons Report of the Standing Committee on Industry (Ottawa: Parliamentary Publications Directorate, October 1994) on p. 44: "The term 'love money' refers to capital advanced by the entrepreneur of the SME (including personal loans secured by personal property of the entrepreneur such cars and houses), family, friends and neighbours" (cited by Lefton 1998 in footnote 2). Over time, the founder's own capital seems to have escaped the definition, and love money is now considered to include money invested in business by family and friends.

Other Related Concepts

Sweat Equity: It is the free services provided by cofounders, often before the enterprise starts, for which no remuneration is provided. The value of the entrepreneurial project is of course more than the value of the sweat equity, which is just one part of the total project value. However, sweat equity may continue at future stages of the enterprise. The use of family labor in microenterprises and family supervision or managers in small and medium companies is well documented (Thankur 1999). However, the love of family and friends required to build up an enterprise often goes beyond offering labor or supervision and includes offering money.

Transactional Sex: The term "love money" can conjure up ideas of transactional sex, perhaps because love may include sex. It may also include gifts to sexual partners not amounting to transactions, such as accepted social practices in some countries where it is the duty of boyfriends to offer money gifts for love to their girlfriends (Poulin 2007). It is clarified that even if such gifts could occasionally be used for entrepreneurship, this entry does not look into this area.

Angel Investors (Also Known as Business Angels): Angel investors are wealthy individuals who invest in risky projects of entrepreneurs in the early stages and often provide advice and social contacts. Their motives are largely economic although noneconomic motives may play a part (Riding 2008). It is clarified that the accepted notion of business angels excludes those belonging to family and friends (Ramadani 2009).

Reasons for Love Money

There are a number of reasons people would take money from family and friends to help finance their businesses. These include lower transaction costs, greater control over the business, desire to retain profits, too many strings attached to outside money, access to family resources, and failure to raise money from outside sources (Steier 2003).

The lower transaction costs are related to agency theory. The hiring of professional managers requires monitoring, and this imposes costs. If family members invest money, the trust which has already been built up allows for a reduction in monitoring costs.

The advantages of investing in family businesses include alignment of long-term interests of the family, lower monitoring costs, selfless rationalities inherent in family, and loyalty to the family. The disadvantages include conflict in private life affecting business, opportunities to engage in inefficient or slack behavior (free riding), limited talents of family members (compared to professional managers), and families have limits to growth if they rely only on supervision by family members (Steier 2003 cites Pollak 1985). This may lead to repaying family loans even if loans to all others are waived in bankruptcy.

Sociological and Anthropological Roots of Love Money

Consumption and Social Interaction

Love money has also been associated with the consumption of goods and services, most notably by Miller (2001). Consumption for Miller is a process where family members both seek to influence each other and create familial solidarity. This connection between social relations and economic transactions according to Zelizer (2005) is insufficiently understood partly due to the disciplinary tensions between economics and sociology. Drawing on the work of Biggart and Castanias (2001), Zelizer explores the "interplay" between economic exchange and social relations and highlights how social relations can predate economic exchange and therefore "can facilitate exchange", as well as acting as a means of managing risks (p. 337). This suggests that love money investment is a function of strong social bonds between family members owing to the concept that strong social relationships are important.

Social interactions do more than alter economic exchanges, they change the nature of the money itself. Zelizer (2005) details how household incomes are earmarked depending on both their source and use. For example, prostitutes will spend their earnings on drugs, drinks, and clothes, while simultaneously carefully guarding to ensure any family expenditure comes from income earned outside of prostitution. A similar process occurs in household production with members matching "meaningful relations with appropriate economic transactions and media" (2005, p. 242). Zelizer's concept of earmarking suggests a weakness in the existing literature on love money: we do not know enough about how money for investment is created, negotiated, and identified or the ongoing discussions after the decision has been made. Although Riding has helped provide an indication of the scale of the investment made and the respective failure rate, we still do not know, for example, whether the investing party simply lost their money due to business practices, or whether they wanted to withdraw it at an inopportune moment in the firm's development, or indeed whether intra-family disputes about the investment were the causal factor.

International Usage

Daphne Berdahl's (1999) study of an East German village demonstrated the bond between love money and personal relations. In a state where goods and services were difficult to access, both money and barter were used as a means to maintain relationships. It was the strength and breadth of these connections that enabled household members to access comparatively preferential treatment, but without gifts, barter and bribing relationships could not be used to access the informal economy.

Section 2: The Economics of Love Money Investments

The love money investors may be passive investors or active investors. The distinction is that active investors take part in the operations of the business in which they have invested. In a study in Canada, it was found that 29% are passive and 71% are active, and it was estimated that passive investors make losses 62% of the times while active investors make losses only 47% of the time (Riding 2008). Nevertheless, the size of the love money investor market is thrice the size of the business angel market which, in turn, is estimated to be twice the size of the formal venture capital market (Riding 2008). Earlier research indicates that for the 15 countries providing data, the informal market is 1.6 times the venture capital market, and almost half the market for informal investments is provided by family and over a third by neighbors and colleagues (Bygrave et al. 2003). Irrespective of the country differences and difficulties in estimation, this topic is clearly very important for entrepreneurs and researchers.

The motivations of family members investing in family businesses are twofold: one is the economic motive of earning money and the second is the nurturing motive of helping the family member grow (Steier 2003).

The governance and control mechanisms of family businesses therefore find a mix of market mechanisms (price), relational mechanisms (trust, altruism), and hierarchical elements (administration) (Steier 2003).

Drivers of Love Money Investment

Szerb et al. (2007) divide the informal investors in four components. They define classic love money as family with no ownership experience while they consider family with experience as kin money. Similarly, outsiders with no ownership experience are distinguished from business angels (who have ownership experience). They find that what drives informal investments of all four categories is personal context (knowing the entrepreneur, seeing the opportunity, skills, and fear of failure) rather than macroeconomic factors (economic development, start-up costs, taxation, education). Classic love money and nonowners help out in times of crisis, while kin money is more active in periods of growth. In developed countries, outside investment is more forthcoming. Foreign direct investment is negatively correlated with kin money.

Implications

There is little evidence about the extent of love money investment in SMEs, though work by Allan Riding (2005) for the Canadian government suggests that it stands at 11 billion Canadian dollars, which is three times the investment made by business angels. However, Riding found there was minimal evidence that love money investment was an effective means to capitalize new firms. When he produced further research in 2008, he found that not only do business angels secure better returns but that family and friends' investments perform dismally. Perhaps an explanation for the poor performance of love money, especially given that the financial cost of raising love money capital is likely to be cheaper than business angels, was contained in Schulze et al. (2001) who showed how owner-managers of small firms often create perverse agency problems, such as not hiring the best staff and being slow to react to market changes because of lack of independent investor demands. Equally, owner-investors allow nonpecuniary factors to shape their judgment, or they overinvest causing their children to free ride. Despite this, Kang (2000) points out that family investors can be more patient and wait longer for an economic return. According to Schulze et al. (2001), this is insufficient and suggests family firms should incorporate internal control mechanisms to minimize the possibility of the problems outlined above.

There are a number of difficulties that come into play in relation to love money.

Is It a Gift or an Investment?

If a parent provides love money to one child's enterprise, and the parent dies, is the money given a loan or investment, or is it a gift? Depending on the treatment, the succession rights of this child versus other inheritors would change (Steier 2003).

What Is a Fair Return on the Investment?

If the enterprise is successful and the entrepreneur repays the loan to his family, how should they decide on equity and in-kind help (sweat equity)? For example, some relatives may have provided a free place to stay; others may have spent time building morale. No matter how much the entrepreneur pays them for this, there may be unclear notions of expected returns (Steier 2003).

How to Get Informal Investors to Register

In many countries, investment can be sought from registered investors. Informal investors, such as love money investors and business angels, may not even be aware that they have to be registered (Riding 2008).

Involvement of Unsophisticated Investors

It is also possible that unsophisticated investors may provide less useful advice and unnecessary constraints that impede the business performance (Riding 2008).

Conclusions and Future Research Directions

Overall, we know that love money exists and that family and friends invest in business enterprises. We also know that the informal entrepreneurial investments are greater than other more formalized systems such as business angels or even venture capital. What remains uncertain is the breakdown between those who invest for altruistic reasons and those who invest for return on investment. Comparisons between love money and other form of business enterprise investment would provide useful insight into entrepreneurial finance.

Synonyms

Low- to mid-tech SMEs; Low-R&D-intensity entrepreneurship; Low-tech small firms; Non-research-intensive entrepreneurship

Definition and Issues at Stake

The Organisation for Economic Co-operation and Development (OECD) classifies a high-technology industry as one in which the level of research and development (R&D) intensity (a measure of the proportion of annual turnover invested in R&D) is greater than 5 %. By contrast, low-tech firms have an R&D intensity of less than 3 %, while mid-tech firms have an R&D intensity of between 3 and 5 % (Bender et al. 2005; Hirsch-Kreinsen et al. 2008). A large proportion of industries are low to mid tech, including motor vehicle manufacturing, pharmaceuticals, aerospace and electronics industries, food processing, printing, furniture manufacturing, household appliances, and plastics (Hirsch-Kreinsen et al. 2006). The vast majority of small firms all around the world are active in low- to mid-tech industries.

From the Literature

Previous findings suggest that significant differences exist between the low-R&D firms and their high-R&D counterparts in relation to the number and type of innovations generated and how such firms manage the process of commercialization (Mazzarol et al. 2011).

As small firms are different from large firms in the way they operate and are managed (Welsh and White 1981; Gibb and Scott 1985; D'Amboise and Muldowney 1988; Julien 1993; Torrès 1997), it is not surprising to find that they have different approaches to their innovation processes. Limited scale and resources encourage small firms to adopt more informal processes for organizing their activities, utilizing personal ties and social networks, and taking advice from nontraditional sources such as friends who are also in business (see ▶ Network and Entrepreneurship and ▶ Partnerships and Entrepreneurship (Vol Entrepreneurship)). This seems particularly true in low-to mid-tech sectors.

Studies of small to medium enterprise (SME) manufacturing firms suggest that innovation is a necessary but not sufficient prerequisite for competitive performance (Liao and Rice 2010). Such SMEs appear to gain from having clear innovation strategies and formal structures for commercialization (see ▶ Innovation Opportunities and Business Start-up; Terziovski 2010). Yet differences appear to exist between low-tech firms and those with higher levels of investment in R&D. The mid- to high-tech manufacturers seem to get more benefit from R&D investment that is directed toward product development, while the low-tech firms get benefits from investment in product development process innovations (see ▶ Product Innovation, Process Innovation). These are innovations relating not to the creation of new products but of processes (e.g., computer-aided design (CAD) systems) that can assist them to produce their existing products more flexibly and faster (Raymond and St-Pierre 2010).

Importance and Issues at Stake

Despite the relative importance of low- to mid-tech firms, much of the focus of government policy within what is often called the national innovation system (NIS) (see ▶ National Innovation Systems (NIS); Lundvall 2007) is upon high-tech industries or what has been referred to as "the Silicon Valley business model" (see ▶ Business Model; Cohen 2010; OECD 2010). While much of the traditional work on innovation has focused on technological R&D-driven inventions, and this type of work continues to be prioritized by government R&D investment policies, there has been increasing recognition that innovation needs to be considered with a much wider lens (see, e.g., Godet et al. 2010). More and more studies show that the traditional high-tech "Silicon Valley" venture capital-funded business model is not the only approach adopted by small firms seeking to innovate and many small innovative firms are growing without major external funding (see ▶ Venture Capital and Small Business; Maskell 1998; Von Tunzelmann and Acha 2006). Results on this matter are an important finding as they signal the importance of other models of innovation for small firms. Indeed, there is a strong case for "ordinary SMEs" to innovate with more modest, self-funded innovations and still make a sound contribution to the national economy.

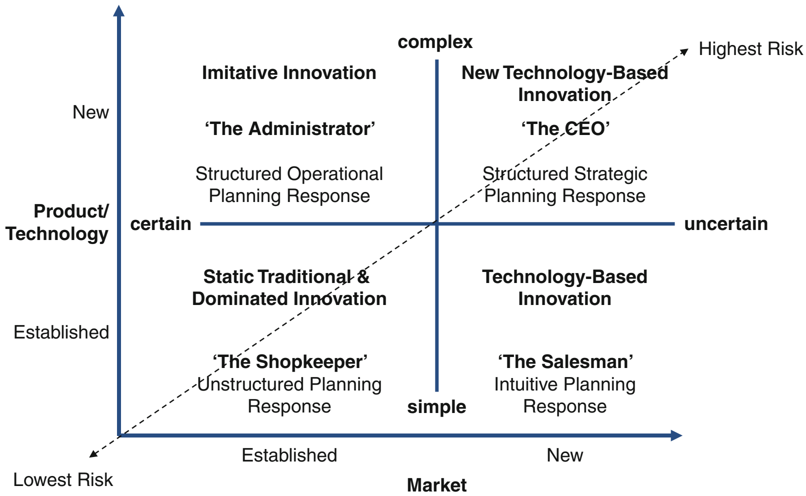
What is important from both research and policy perspectives is that significant innovations can occur throughout the value chain and may involve collaboration with other parties. This is particularly relevant for innovation processes in small firms. The ability of many small firms to successfully engage in innovation and commercialization is often restricted by their lack of resources, weak or unsystematic marketing and management competencies, and inadequate use of appropriate third-party advisors (Adams 1982; Vermeulen 2005). Yet findings demonstrate that small firms can be active innovators (see ▶ Innovator) in spite of their limited scale and resources.

High- and Low-R&D-Intensity SMEs: Organizational Configuration for Innovation

Tidd (2001) observed that despite several decades of research into the management of innovation, there remained no clear or consistent findings or even a coherent set of advice for managers. He proposed a matrix model comprising four quadrants that were defined by the two primary dimensions of uncertainty and complexity. The four organizational structures (see ▶ Entrepreneurial Organizations) that emerged from this framework were:

- *Differentiated* (low uncertainty and low complexity): The key competitive advantage comes from product and service differentiation, marketing competence, and the formation of a structure that is focused on product or market divisions.
- *Innovative* (high uncertainty and low complexity): Here the key competencies required are scientific or technological in nature, and organizational structure is likely to be functional.
- *Networked* (low uncertainty and high complexity): This requires competence in project management and organizational structure focusing on professional skills and knowledge.
- *Complex* (high uncertainty and high complexity): This requires a range of competencies as well as adaptive learning.

Mazzarol and Reboud (2009) developed this complexity–uncertainty trade-off into a model of strategic innovation management which is illustrated in Fig. 1. As shown in the figure, there are four strategic planning responses depending on



Low-Tech Entrepreneurship, Fig. 1 A model of strategic innovation management (Source: Mazzarol and Reboud 2009)

the uncertainty found within the market and the level of complexity found within the product technology. Simple innovations with low levels of complexity that are being commercialized within markets that are stable and certain are what have been referred to as static traditional or dominated (Rizzoni 1991). This type of planning response is what Mazzarol and Reboud (2009) refer to as "the shopkeeper" and is one that involves a relatively unstructured planning response with low levels of formality.

By contrast, the high-risk, disruptive innovation that is associated with new technologies requires a structured strategic planning response, or what is described as "the chief executive officer (CEO)." In situations in which the technology is already well established but the market environment is uncertain require the planning response of "the salesman," which is typically that of a less formal, more intuitive approach, while the new technological innovation that requires high levels of complexity in its development, but is to be commercialized into a market that is certain, requires the planning response described as that of "the administrator." This is formal and structured, but of an operational not a strategic nature (Mazzarol and Reboud 2009).

This model proposes that there is an interrelationship between the type of innovation that is being commercialized, the nature of its target market environment, and the type of planning response that is optimal for these conditions. It is consistent with the framework proposed by Tidd (2001), and, as discussed below, it provides a conceptual basis for understanding the notion of low-tech entrepreneurship.

The Issue of Innovation Measure

Noting that although innovation is supposed to take several forms (including organization innovation, e.g., see the Oslo Manuel (OECD 2005)), it is almost always measured based on product innovation only; other authors (e.g., Raymond and St-Pierre 2010) propose to encompass other forms of innovation like process innovation. As they state: "*While having been the object of numerous studies, the link between R&D activities and innovation in SMEs still requires clarification and further understanding*." They argue that taking into account process innovation, even not giving a perfect picture of all innovative activities in a firm, improves the view of the amount of innovation produced by SMEs (see ▶ Measuring Organizational Climate for Creativity and Innovation).

Studying creative industries, where lots of SMEs are highly innovative, Lindman, Scozzi, and Otero-Neira (2008) give also elements indicating a high level of non-technological innovation in small firms especially based on innovations in design.

Another proposition aiming at capturing other forms of innovation carried out by small firms is proposed by Teixeira, Santos, and Oliveira Brochado (2008). They analyze collaboration based on R&D between small firms and show that lots of SMEs in low-tech sectors develop relationships based on R&D and innovation. It gives also a view that proximity (both geographic and cultural) has a strong influence on the level of formalization and sophistication of the R&D involved in such partnerships.

Size and R&D Intensity and Consequences on Management and Strategy

In a study of innovation practices within small firms from eleven OECD countries, a size effect was found in relation to R&D intensity (Mazzarol and Reboud 2011). Micro and small firms were identified as having higher R&D intensity ratios than their medium to large counterparts. This suggests that as the business matures, it is more likely to focus on consolidation of existing products within established markets than trying to launch new products into new markets. Funding for innovation was in this case largely derived from retained profits with little interest shown in equity financing. However, equity financing and venture capital were more likely to be of interest to firms with high R&D intensity. Compared with their low-R&D-intensive counterparts, the high-R&D-intensive businesses were more likely to feel that the generation of new products and innovations were a major focus for their firm. They were also more likely to involve customers in the development of the innovation and to have a formal new product development (NPD) process in place. Such firms were likely to be focused in their NPD process on technological product innovations as a primary area of attention, followed by market development innovations as a secondary priority. By contrast, the low-R&D-intensive firms were more likely to be engaged in the development of technological process innovations. This finding is consistent with the research of Raymond and St-Pierre (2010) who examined manufacturing firms.

While these high-R&D-intensive firms were found across all industry sectors and throughout all the countries from which the study was drawn, it was more likely to find them in nontraditional industries such as Information and Communication Technologies (ICT) or biotech rather than manufacturing, services, or retailing. However, it is not suggested that R&D intensity, and with it innovation management formality, is restricted only to these more “high-tech” sectors. These findings are consistent with those of Covin and Prescott (1990) who found that low-tech product innovators differed from their high-tech counterparts in terms of their structure, market orientation, and need for external financing. High-tech firms were more focused on building their market share and had a greater need for external financing. As found by Terziovski (2010), formalization in the innovation management process and the organizational structure associated with it is likely to be rewarded with superior performance.

Managerial Competence

In high-tech fields such as biotech, there is a need for senior management teams to comprise a balance between scientific, technical areas and financial and marketing skills (Sardana and Scott-Kemmis 2010). However, while such a balance of competencies is clearly valuable in all industries, it may be less common in micro firms in low-tech sectors (Maskell 1998).

Nonetheless the success of new ventures in low-tech sectors can rely heavily on the capacity of adaption and anticipation of their managers (Evers 2011; see ► Entrepreneurial Capability and Leadership).

Effectuation Style Decision Making

Several studies provide evidence to support the decision-making principles used by entrepreneurs in situations of uncertainty called effectuation Sarasvathy (2001); Read and Sarasvathy (2005). Small low-tech firms are engaged in a view of the future where they were seeking support and precommitments from customers. The basis for taking action toward the commercialization of these innovations is often intuitive.

This is also true when seeking to internationalize their activity (Andersson 2011).

This suggests managers of small innovative firms demonstrate a willingness to take on new innovation and its unexpected outcomes. Furthermore, as discussed by Gibb and Scott (1985), the strategic awareness and personal commitment of the managers are vital for small firms to achieve their objectives for product and market development.

Conclusion and Future Directions

A Lower Public Support

Due to a number of reasons, from the difficulties of measuring innovation to the lower visibility of more incremental innovation, low-tech entrepreneurship and the innovative activity of low-tech SMEs are often underestimated. Even if a huge part of the economic activity is carried out by small low-tech firms all over the world, high-tech ventures are more visible and more supported by governments. Studying the situation in Austria, Radauer and Streicher (2007) note, for example, "*that Low-Tech SMEs are actually more innovative than commonly thought and that supporting these industries might yield positive effects. The Austrian innovation system is diversified, yet programmes that aim at low to mid tech (LMT) innovations are scarce*" (p. 247).

The Importance of the SME Ordinaire

Few taxonomy have focused on innovation within small firms. Rizzoni (1991) offered six types, and, as discussed above, Tidd (2001) and Mazzarol and Reboud (2009) have offered four types. Jones-Evans (1995) sought to classify entrepreneurs from technology-based firms into four types known as "researcher," "producer," "user," and "producer" with some subcategories. Autio and Lumme (1998) also proposed a four-part typology for new technology-based firms that included (a) "application," (b) "market," (c) "technology," and (d) "paradigm" innovators.

However, this does not address innovation directly. Although there is the classification of low-, mid-, and high-tech firms based on the proportion of annual turnover invested in R&D, it remains linked to technology-based ventures.

More and more studies suggest that there is a high level of innovation activity taking place among small firms that may not be gazelles or associated with traditional high-technology sectors. As a benchmark of innovation activity, the level of "R&D intensity" is a potentially better measure for differentiating firms, although to classify high- and low-R&D-intensity firms into high or low technology was not strictly correct. It seems therefore that more work needs to be done to develop a robust and universally applicable taxonomy for small firms engaged in innovation. A first attempt in that direction would be to use a two-part taxonomy in which firms are classified into what could be described as "*SME Ordinaire*" and "*SME Entrepreneuriale*." The first group comprises the vast majority of small firms that are capable of innovation but not necessarily strongly focused on growth or engaged in high technology. They do not conform to the "Silicon Valley business model" that has captured so much attention in recent decades. The second group is more the "growth-focused, venture capital-seeking business" that is likely to be, although not necessarily, technology-based.

These two types of firm should not be viewed as two ultimate choices. They are not mutually exclusive constructs. It is more appropriate to view them as the end points of a continuum and perhaps to be strategic choices that an entrepreneur or small business owner–manager can select from at given points in time. For example, as Mazzarol and Reboud (2009) suggest that the choice of a "shopkeeper," "salesman," "administrator," or "CEO" strategic planning response is contingent on the level of uncertainty and complexity facing the firm's management team and the type of innovation they are seeking to commercialize. In the early years after establishment, it is to be expected that a firm might be quite entrepreneurial as it seeks to find its market niche. However, once it matures and enjoys stability, the focus may return toward the *SME Ordinaire* behavior. More work is needed to fully develop this understanding, but it is clear that there must be greater recognition of the *SME Ordinaire* within academic and policy circles.

Introduction

What is the genesis of mathematics? What mechanisms govern the acts of mathematical discovery, invention, and creativity?

> The genesis of mathematical creation is a problem which should intensely interest the psychologist. It is the activity in which the human mind seems to take the least from the outside world, in which it acts or seems to act only of itself and on itself, so that in studying the procedure of geometric thought we may hope to reach what is most essential in man's mind. (Poincaré 1952)

There are two theories regarding the origins of mathematics (Hersh 1997). The first theory, attributed to Plato, states that mathematics exists independent of man's involvement in the field. As such, mathematical knowledge is "discovered," much in the same way knowledge about the natural world is discovered. The second theory, referred to as the "formalist theory," poses that mathematics is a construct of mankind, a product of human thinking. In this case, new knowledge in mathematics is "invented," much like new technology is invented. Although some mathematicians cling to one or the other of these theories as being the truth concerning the nature of mathematics and its origins, many find a middle ground that combines attributes of both. To see how these two extremes, along with the middle ground play out in practical terms, consider the example of the infinitude of prime numbers. A platonist would argue that the prime numbers existed independent and prior to us and that they existed in infinitude. Humans merely discovered them. A formalist would argue that prime numbers exist because they were defined as such. One possible middle ground between these two views is that the numbers themselves were invented (or defined) but the property that some numbers are prime was discovered, as was the fact that there is an infinite number of prime numbers. That is, mathematics is created by humans but does not bend to the will of humans (Stewart 2006).

This example highlights how it might be possible to draw a distinction between the usage of *invented* and *discovered*. In an attempt to draw further distinction, it can be suggested that mathematics is *invented* when someone deliberately and willfully creates something new, even if it is only new to that one individual. On the other hand, mathematics is *discovered* if by some mechanism a mathematical property emerges out of some already existing mathematical object (numeric, algebraic, geometric, or otherwise). So, for example, Napier invented logarithms, while Fermat discovered the theorem that bears his name. However, when definitions (which are invented) and properties (which are discovered) become conflated, this distinction becomes convoluted. Hadamard (1945) offers an anecdote that nicely explains this conflation.

> Such distinction has proved less evident than appears at first glance. Toricelli has observed that when one inverts a closed tube on the mercury trough, the mercury ascends to a certain determined height: this is a discovery; but, in doing this, he has invented the barometer; and there are plenty of examples of scientific results which are just as much discoveries as inventions. Franklin's invention of the lightning rod is hardly different from his discovery of the electric nature of thunder. (p. xvii)

Hadamard goes on to state that because of this inability to make a clear distinction between discovery and invention, he will not concern himself with it and will, instead, treat them equally. Furthermore, he states that the "psychological conditions are quite the same for both cases" (p. xvii). For these very same reasons, the phenomena of discovery and invention will be treated here without distinction.

A further conflation that the above example (and, indeed, the first paragraphs) exemplifies is the role of *creativity* within the phenomena of discovery and invention. As will be seen in the pages to come, creativity is an aspect of discovery and invention that is often indistinguishable and inseparable from either discovery or invention. As such, these terms will be used interchangeably throughout this entry but at some points will be treated in isolation.

History

In 1902, the first half of what eventually came to be a 30-question survey was published in the pages of *L'Enseignement Mathématique*, the journal of the French Mathematical Society. Édouard Claparède and Théodore Flournoy, two French psychologists, who were deeply interested in the topics of mathematical discovery, creativity, and invention, authored the survey. Their hope was that a widespread appeal to mathematicians at large would incite enough responses for them to begin to formulate some theories about this topic. The first half of the survey centered on the reasons for becoming a mathematician (family history, educational influences, social environment, etc.), attitudes about everyday life, and hobbies. This was eventually followed up, in 1904, by the publication of the second half of the survey pertaining, in particular, to mental images during periods of creative work. The responses were sorted according to nationality and published in 1908.

During this same period, Henri Poincaré (1854–1912), one of the most noteworthy mathematicians of the time, had already laid much of the groundwork for his own pursuit of this same topic and in 1908 gave a presentation to the French Psychological Society in Paris entitled *L'Invention mathématique* – often mistranslated to Mathematical Creativity (c.f. Poincaré 1952). At the time of the presentation, Poincaré stated that he was aware of Claparède and Flournoy's work, as well as their results, but expressed that they would only confirm his own findings. This presentation, as well as the essay it spawned, stands to this day as one of the most insightful and thorough treatments of the topic of mathematical discovery, creativity, and invention.

> Just at this time, I left Caen, where I was living, to go on a geological excursion under the auspices of the School of Mines. The incident of the travel made me forget my mathematical work. Having reached Coutances, we entered an omnibus to go some place or other. At the moment when I put my foot on the step, the idea came to me, without anything in my former thoughts seeming to have paved the way for it, that the transformations I had used to define the Fuschian functions were identical with those of non-Euclidean geometry. I did not verify the idea; I should not have had the time, as, upon taking my seat in the omnibus, I went on with the conversation already commenced, but I felt a perfect certainty. On my return to Caen, for conscience' sake, I verified the results at my leisure. (Poincaré 1952)

So powerful was his presentation, and so deep were his insights into his acts of invention and discovery that it could be said that he not so much described the characteristics of mathematical creativity, as defined them. From that point forth, mathematical creativity, or even creativity in general, has not been discussed seriously without mention of Poincaré's name.

Inspired by this presentation, Jacques Hadamard (1865–1963), a contemporary and a friend of Poincaré's, began his own empirical investigation into this fascinating phenomenon. Hadamard had been critical of Claparède and Flournoy's work in that they had not adequately treated the topic on two fronts. As exhaustive as the survey appeared to be, Hadamard felt that it failed to ask some key questions – the most important of which was with regard to the reason for failures in the creation of mathematics. This seemingly innocuous oversight, however, led directly to his second and "most important criticism" (Hadamard 1945). He felt that only "first-rate men would dare to speak of" (p. 10) such failures. So, inspired by his good friend Poincaré's treatment of the subject, Hadamard retooled the survey and gave it to friends of his for consideration – mathematicians such as Henri

Poincaré and Albert Einstein, whose prominence were beyond reproach. Ironically, the new survey did not contain any questions that explicitly dealt with failure. In 1943, Hadamard gave a series of lectures on mathematical invention at the École Libre des Hautes Études in New York City. These talks were subsequently published as *The Psychology of Mathematical Invention in the Mathematical Field* [51].

Hadamard's classic work treats the subject of invention at the crossroads of mathematics and psychology. It provides not only an entertaining look at the eccentric nature of mathematicians and their rituals but also outlines the beliefs of mid-twentieth-century mathematicians about the means by which they arrive at new mathematics. It is an extensive exploration and extended argument for the existence of unconscious mental processes. In essence, Hadamard took the ideas that Poincaré had posed and, borrowing a conceptual framework for the characterization of the creative process from the Gestaltists of the time (Wallas 1926), turned them into a stage theory. This theory still stands as the most viable and reasonable description of the process of mathematical invention.

Defining Discovery and Invention

The phenomena of mathematical discovery and invention, although marked by sudden illumination, actually consist of four separate stages stretched out over time, of which illumination is but one stage. These stages are initiation, incubation, illumination, and verification (Hadamard 1945). The first of these stages, the *initiation* phase, consists of deliberate and conscious work. This would constitute a person's voluntary, and seemingly fruitless, engagement with a problem and be characterized by an attempt to solve the problem by trolling through a repertoire of past experiences. This is an important part of the inventive process because it creates the tension of unresolved effort that sets up the conditions necessary for the ensuing emotional release at the moment of illumination (Hadamard 1945; Poincaré 1952).

Following the initiation stage, the solver, unable to come up with a solution, stops working on the problem at a conscious level and begins to work on it at an unconscious level (Hadamard 1945; Poincaré 1952). This is referred to as the *incubation* stage of the inventive process and can last anywhere from several minutes to several years. After the period of incubation, a rapid coming to mind of a solution, referred to as *illumination*, may occur. This is accompanied by a feeling of certainty and positive emotions (Poincaré 1952). Although the processes of incubation and illumination are shrouded behind the veil of the unconscious, there are a number of things that can be deduced about them. First and foremost is the fact that unconscious work does, indeed, occur. Poincaré (1952), as well as Hadamard (1945), used the very real experience of illumination, a phenomenon that cannot be denied, as evidence of unconscious work, the fruits of which appear in the flash of illumination. No other theory seems viable in explaining the sudden appearance of solution during a walk, a shower, a conversation, upon waking, or at the instance of turning the conscious mind back to the problem after a period of rest (Poincaré 1952). Also deducible is that unconscious work is inextricably linked to the conscious and intentional effort that precedes it.

> There is another remark to be made about the conditions of this unconscious work: it is possible, and of a certainty it is only fruitful, if it is on the one hand preceded and on the other hand followed by a period of conscious work. These sudden inspirations never happen except after some days of voluntary effort which has appeared absolutely fruitless and whence nothing good seems to have come . . .. (Poincaré 1952)

Hence, the fruitless efforts of the initiation phase are only seemingly so. They not only set up the aforementioned tension responsible for the emotional release at the time of illumination but also create the conditions necessary for the process to enter into the incubation phase.

Illumination is the manifestation of a bridging that occurs between the unconscious mind and the conscious mind (Poincaré 1952), a coming to (conscious) mind of an idea or solution. What brings the idea forward to consciousness is unclear, however. There are theories of the aesthetic qualities of the idea, effective surprise/shock of recognition, fluency of processing, or breaking functional fixedness. For reasons of brevity, this entry will only expand on the first of these.

Poincaré proposed that ideas that were stimulated during initiation remained stimulated during incubation. However, freed from the constraints of conscious thought and deliberate calculation, these ideas would begin to come together in rapid and random unions so that "their mutual impacts may produce new combinations" (Poincaré 1952). These new combinations, or ideas, would then be evaluated for viability using an aesthetic sieve, which allows through to the conscious mind only the "right combinations" (Poincaré 1952). It is important to note, however, that good or aesthetic does not necessarily mean correct. Correctness is evaluated during the *verification* stage.

The purpose of verification is not only to check for correctness. It is also a method by which the solver reengages with the problem at the level of details. That is, during the unconscious work, the problem is engaged with at the level of ideas and concepts. During verification, the solver can examine these ideas in closer details. Poincaré succinctly describes both of these purposes.

> As for the calculations, themselves, they must be made in the second period of conscious work, that which follows the inspiration, that in which one verifies the results of this inspiration and deduces their consequences. (Poincaré 1952)

Aside from presenting this aforementioned theory on invention, Hadamard also engaged in a far-reaching discussion on a number of interesting, and sometimes quirky, aspects of invention and discovery that he had culled from the results of his empirical study as well as from pertinent literature. This discussion was nicely summarized by James Newman (2000) in his commentary on the elusiveness of invention.

> The celebrated phrenologist Gall said mathematical ability showed itself in a bump on the head, the location of which he specified. The psychologist Souriau, we are told, maintained that invention occurs by "pure chance", a valuable theory. It is often suggested that creative ideas are conjured up in "mathematical dreams", but this attractive hypothesis has not been verified. Hadamard reports that mathematicians were asked whether "noises" or "meteorological circumstances" helped or hindered research [. . .] Claude Bernard, the great physiologist, said that in order to invent "one must think aside". Hadamard says this is a profound insight he also considers whether scientific invention may perhaps be improved by standing or sitting or by taking two baths in a row. Helmholtz and Poincaré worked sitting at a table; Hadamard's practice is to pace the room ("Legs are the wheels of thought", said Emile Angier); the chemist J. Teeple was the two-bath man. (p. 2039)

Given the formalist nature of mathematics discussed earlier, it should be mentioned that invention and discovery are not "part of the theories of logical forms" (Dewey 1938). They are extralogical. That is, discovery and invention are not representative of the lockstep logic and deductive reasoning that mathematics is often presumed to embody. Invention and discovery are part of a cohort of extralogical processes that includes creativity, intuition, and imagination.

Approaches to Creativity

The four stages of mathematical discovery and invention described above and characterized in Hadamard's seminal work were not original to Hadamard. A psychologist by the name of Wallas (1926) used the same characterization to describe the general creative process about 20 years prior to Hadamard's work. Because of this close relationship between the three phenomena (invention, discovery, and creativity), the body of literature on creativity is one that cannot be ignored. Aside from offering a variety of examples of invention and discovery, this literature also contributes to the construction of a better understanding of the phenomena through three distinct academic discourses: the focus on product, process, and person. This is not to say that there exist only three discourses but rather that this entry focuses on only three discourses. A brief synopsis of each of these discourses follows.

"Creativity" is a term that can be used both loosely and precisely. That is, while there exists a common usage of the term, there also exists a tradition of academic discourse on the subject. A common usage of "creative" refers to a process or a person whose products are original, novel, unusual, or even abnormal (Csikszentmihalyi 1996). In such a usage, creativity is assessed on the basis of the external and observable products of the process, the process by which the product comes to be or on the character traits of the person doing the "creating." Each of these usages is the roots of the discourses that we present here, the first of which concerns products.

Consider a mother who states that her daughter is creative because she drew an original picture. The basis of such a statement can lie either in the fact that the picture is unlike any the mother has ever seen or unlike any her daughter has ever drawn before. This mother is assessing creativity on the basis of what her daughter has produced. However, the standards that form the basis of her assessment are neither consistent nor stringent. There does not exist a universal agreement as to what she is comparing the picture to (pictures by other children or other pictures by the same child). Likewise, there is no standard by which the actual quality of the picture is measured. The academic discourse that concerns assessment of products, on the other hand, is both consistent and stringent (Csikszentmihalyi 1996). This discourse concerns itself more with a fifth, and as yet unmentioned, stage of the creative process: *elaboration*. Elaboration is where inspiration becomes perspiration (Csikszentmihalyi 1996). It is the act of turning a good idea into a finished product, and the finished product is ultimately what determines the "creativity" of the process that spawned it; that is, it cannot be a creative process if nothing is created. In particular, this discourse demands that the product be assessed against other products within its field, by the members of that field, to determine if it is original and useful. If it is, then the product is deemed to be creative. Note that such a use of assessment of end product pays very little attention to the actual process that brings this product forth.

The second discourse to be discussed concerns the creative process. The literature pertaining to this can be separated into two categories, a prescriptive discussion of the creativity process and a descriptive discussion of the creativity process. Although both of these discussions have their roots in the four stages that Wallas (1926) proposed makes up the creative process, they make use of these stages in very different ways. The prescriptive discussion of the creative process is primarily focused on the first of the four stages, *initiation*, and is best summarized as a *cause-and-effect* discussion of creativity, where the thinking processes during the initiation stage are the *cause* and the creative outcome is the *effect* (Ghiselin 1952). Some of the literature claims that the seeds of creativity lie in being able to think about a problem or situation analogically. Other literature claims that utilizing specific thinking tools such as imagination, empathy, and embodiment will lead to creative products. In all of these cases, the underlying theory is that the eventual presentation of a creative idea will be precipitated by the conscious and deliberate efforts during the initiation stage. On the other hand, the literature pertaining to a descriptive discussion of the creative process is inclusive of all four stages (Kneller 1965; Koestler 1964). For example, Csikszentmihalyi (1996), in his work on "flow," attends to each of the stages, with much attention paid to the fluid area between conscious and unconscious work, or initiation and incubation. His claim is that the creative process is intimately connected to the enjoyment that exists during times of sincere and consuming engagement with a situation, the conditions of which he describes in great detail.

The third, and final, discourse on creativity pertains to the person. This discourse is dominated by two distinct characteristics: habit and genius. Habit has to do with the personal habits as well as the habits of mind of people that have been deemed to be creative. However, creative people are most easily identified through their reputation for genius. Consequently, this discourse is often dominated by the analyses of the habits of geniuses as is seen in the work of Ghiselin (1952), Koestler (1964), and Kneller (1965) who draw on historical personalities such as Albert Einstein, Henri Poincaré, Vincent Van Gogh, D. H. Lawrence, Samuel Taylor Coleridge, Igor Stravinsky, and Wolfgang Amadeus Mozart, to name a few. The result of this sort of treatment is that creative acts are viewed as rare mental feats, which are produced by extraordinary individuals who use extraordinary thought processes.

These different discourses on creativity can be summed up in a tension between absolutist and relativist perspectives on creativity. An absolutist perspective assumes that creative processes are the domain of genius and are present only as precursors to the creation of remarkably useful and universally novel products. The relativist perspective, on the other hand, allows for every individual to have moments of creativity that may, or may not, result in the creation of a product that may, or may not, be either useful or novel.

> Between the work of a student who tries to solve a problem in geometry or algebra and a work of invention, one can say there is only a difference of degree. (Hadamard 1945)

Conclusion and Future Directions

Mathematical discovery, invention, and creativity are remarkably complex concepts which are intricately woven together. Having said this, they are also self-defining. That is, one knows when one has been creative, made a discovery, or invented something even if it is difficult to explain these phenomena to the uninitiated.

Different Ways of Measuring Creativity

About a decade ago, the National Center on the Gifted and Talented identified more than 100 techniques to assess creativity (Treffinger et al. 2002), and Cropley (2000) reminded that a list of at least 255 creativity tests can be filled. Indeed, a variety of instruments and procedures have been devised to evaluate creativity. This stresses the need to organize conceptually the different ways in which creativity can be measured.

Creativity is assessed either as an *actual* behavior or disposition or as a *potential* skill or attitude. In the former case, evaluators analyze and judge an artifact that was produced or a behavior that was held, which are allegedly creative in their own nature; alternatively, evaluators require evaluated individuals to do so by themselves. In the latter case, evaluators ask the evaluated people to do something which is not creative in itself but which can be conceived as an indirect index of the level of creativity, that is, assumed those people can actually express in other relevant situations.

Furthermore, creativity can be measured with respect either to the *cognitive* processes, which are involved, or to the *personality* traits, which are associated to it. In the first case, the ability to perform mental operations, which are meant as activated during the generation of a creative outcome, is assessed. In the second case, the goal is to evaluate to what extent a person shares the features, which are conceived as characteristics of prototypical creative individuals.

Measuring Potential Creativity: Cognitive Processes

The creative potential is usually assessed through tests requiring people to perform relatively simple tasks, which have been invented to activate the basic mental operations involved in more complex situations where creativity is needed. Hence, such tests can be categorized according to the specific operations they imply, which in turn depend on the underlying theoretical framework.

The conception that creativity concerns primarily the production of abundant and diverse ideas was stressed by the factorialistic perspective, which prompted the construction of different tasks in which individuals are asked to give many responses starting from a given stimulus. Performance is evaluated according to the richness of the thinking flow and the ability to follow new directions in order to achieve uncommon outcomes. The divergent generation of original ideas can be measured by the *Creativity Tests for Children*, the test consisting in the completion of schematic pictures included in *Creativity Assessment Packet* and the *Torrance Tests of Creative Thinking* (TTCT), which is currently the most frequently employed psychometric tool to assess creativity. Also, a set of tasks devised specifically by Wallach and Kogan for young children in the 1960s is grounded on the assumption that creativity depends on the ability to produce many differentiated and original ideas.

According to associationism, creative ideas are achieved through the unusual combination of known ideas. Already Vygotsky in the 1930s claimed that creative activity consists of the recombination of information already known or previously acquired. In the 1960s, Mednick argued that creativity can be identified by the ability to connect ideas which are semantically distant from each other. The *Remote Association Test* (RAT) was constructed to measure such ability: it requires to complete a series of three words with a fourth word which can be associated to each of the three given terms. To do so, the respondents must find words, which have a weak, uncommon association with the given terms.

Finally, what is commonly meant by "creativity" refers to what Gestalt psychologists called "productive thinking," which allows individuals to identify new properties of the given elements and to conceive and use them in new roles or perspectives. Such skills can be measured by means of instruments as the *Purdue Elementary Problem-Solving Inventory*, which requires finding problems, asking questions, analyzing situations, formulating hypotheses, and drawing conclusions by changing the mental perspective. Also the *Test of Creative Thinking* (TCT) is based on Gestalt psychology grounds, such as the tenet that creativity needs to break mental boundaries in order to consider situation from a different point of view and to restructure it. Similarly, the *Creative Reasoning Test* (CRT) is based on riddles whose solution requires overcoming fixation on the usual meaning of the given elements.

Recently, the attempts to construct new tests were inspired by the need to integrate the different mental operations involved in creativity. This was the case of the tests elaborated by Antonietti and coworkers (see Antonietti et al. 2011), which tried to assess jointly the three main mental operations mentioned above. For instance, the *Widening-Connecting-Reorganizing* (WCR) test, consisting of two versions (multiple-choice questions and open questions), includes visual – such as images of objects, geometrical figures, or scenes – and verbal stimuli, ranging from the presentation of single words to hypothetical questions. In the *Widening* subtest of the multiple-choice version, the respondent is asked to choose one answer among alternatives, which varies according to the degree of originality. In the *Connecting* subtest, the respondents are asked to choose, given a list of words or images ranging from common to rare associates, the elements that they would relate to the given situation and to justify the choice. In the *Reorganizing* subtest, the respondents, faced with a hypothetical situation, are asked to choose one answer among alternatives, which vary gradually from obvious to unusual consequences.

As a second case of the tendency mentioned above, we can make reference to the *Evaluation of Potential for Creativity* (EPoC) (Lubart et al. 2011). EPoC measures different processes involved in creativity in different domains. More precisely, EPoC allows evaluators to assess both divergent-exploratory and convergent-integrated modes of thinking. The divergent-exploratory mode consists in expanding the range of ideas. The convergent-integrative mode consists in combining elements in new ways. EPoC includes two alternative forms. Each form is composed of eight subtests covering two domains (verbal and graphic). In the divergent-exploratory subtests, respondents are asked to generate many ideas with reference to a given stimulus. The convergent-integrative subtests require an integrated and finalized composition of elements.

Measuring Potential Creativity: Personality Traits

If some researchers view creativity entirely as a cognitive process, others see it as a set of personality traits. Within this approach, personality inventories, self-report adjective checklists, biographical surveys, interest and attitude measures, and interviews are all methods used to assess the creative person.

Among personality inventories, the *Gough's Adjective Check List* is strictly focused on creative personality. Specifically, it identifies 30 adjectives that reliably differentiate more from less creative people; 18 of those adjectives are positively related to creativity (capable, clever, confident, egotistical, humorous, individualistic, informal, insightful, intelligent, interests wide, inventive, original, reflective, resourceful, self-confident, sexy, snobbish, and unconventional). Other instruments are worth mentioning: the *Barron-Welsh Art Scale* and the *Creative Perception Inventory* require individuals to endorse personality traits associated to creative personality.

Other two self-report tools measure creativity as a factor included in the wide personality assessment. This is the case of the *Myers-Briggs Type*

Indicator and the *NEO Five-Factor Personality Inventory*. The first one is a self-report measure to assess individuals' preferences for different types of information processing. It rates individuals on four dimensions by presenting 300 forced-choice items: introversion-extraversion, intuitive-sensing, thinking-feeling, and perceiving-judging. The creativity index, which can be computed through the Myers-Briggs Type Indicator, is a pattern among the four dimensions closely associated with creativity. An introverted, intuitive, thoughtful, and perceiving person may be more likely to be a creative individual. The *NEO Five-Factor Personality Inventory* broadens the three factor models of personality (based on neuroticism, extraversion, and openness to experience) to other two factors (conscientiousness and agreeableness). This self-report personality inventory includes bipolar adjective pairs asking respondents to rate themselves on a nine-step scale. The factor structure underlying this inventory has impressive validity across cultures, life span, and gender.

Within personality assessments, projective tests are also used to measure creative personality within a psychodynamic approach by assessing unconscious motivations and needs that may energize creative behavior. The basic assumption of projective tests is that participants' responses to vague stimuli will tend to portray personality style. The most used projective tests used in creativity assessment are the *Rorschach Inkblot Test* and the *Thematic Apperception Test* (TAT). The first consists of ten cards, each containing an inkblot. Five cards are black or gray and five are colored. Respondents have to report what they see or what might be represented by the inkblot, one at a time. Although all scoring systems require considerable training and practice, generally more original responses are interpreted as reflecting more creativity and productivity, and people can feel more comfortable in expressing their personal view. The TAT has been developed to measure creativity, and it has been showed that it can be successfully employed to evoke the motive to create.

Among creative personality measures, personality inventories are more structured than projective tests, which rely on qualitative interpretation for meaning and, even with the most rigorous scoring systems, can reach only modest reliability and validity.

Measuring Actual Creativity

Explicit definitions and theories of creativity do not ever access the wealth of information inherent in accomplishments in creative fields. For this reason, Plucker and Runco (1998) suggested that, when people engage in creative activity, "their thoughts and actions are guided by personal definitions of creativity and beliefs about how to foster and evaluate creativity that may be very different from the theories developed by creativity experts" (p. 37).

The *Creative Activities Checklist*, suitable for use with children in Grades 5–8, is based on this ground. The test simply asks participants to indicate how frequently they have participated in recent times in real-life activities in six areas: literature, music, drama, arts, crafts, and science. A similar but more recent assessment is represented by the *Creative Achievement Questionnaire* (CAQ), which measures creative accomplishments in ten domains: visual arts, music, dance, architectural design, creative writing, humor, inventions, scientific discovery, theater and film, and culinary art. Only people with significant achievements in at least one domain receive high scores on the CAQ. Two further instruments are worth mentioning. The *Creative Experiences Questionnaire* (CEQ) allows evaluators to assess how frequently an individual is prone to fantasy. The *Emotional Creativity Inventory* (ECI) measures the actual capacity to experience and expresses original and relevant combinations of emotions, meant as an expression of the richness of a person's emotional life. Individuals scoring high in this inventory know and apply a variety of regulation strategies as well as experience more complex emotions.

Another method of measuring creative achievement is the use of expert ratings as a criterion for eminence. Five professors of architecture, for example, were asked by McKinnon to nominate the living architects who had had the most influence on the field. Using this method, information on creativity was collected during open-ended interviews with nominees. Other authors used biographical inventories to measure creativity, also if they do not focus exclusively on creativity. The two best known instruments of this kind are the *Biographical Inventory* and Taylor's *Alpha Biographical Inventory* (ABI). They include 165 and 300 items, respectively, some of them in multiple-choice format, some requiring the selection of alternatives, and some open-ended. Specifically, the scale of the Schaefer and Anastasi's *Biographical Inventory* focuses on factual information and concerns five areas: family background, intellectual and cultural orientation, motivation – pervasive and continuing enthusiasm, breadth of interest, and drive toward novelty and diversity.

A recent developed inventory is the *Biographical Inventory of Creative Behaviors* (BICB), a 34-item scale assessing everyday creativity across a broad range of domains, such as arts, crafts, and creative writing but also covering social creativity, such as leadership, coaching, and mentorship.

Interesting is the focus on creative self-concepts proposed by the *Creativity Domain Questionnaire* (CDQ) (Kaufman 2006), which measures people's beliefs about their level of creativity in different domains. Self-beliefs about creativity play a critical role in many high stakes decisions, because people use their beliefs about their traits, preferences, and abilities when choosing hobbies, careers, friends, and relationship partners. The *Revised Creativity Domain Questionnaire* (CDQ-R) (Kaufman et al. 2009) includes 21 items, which form four factors: drama, mathematics/science, arts, and interaction. Each item is completed on a six-point scale, and the four domain scores can be averaged to obtain a global creativity score.

Another interesting interpretation of creativity in act is that proposed by Csikszentmihalyi. The author, looking at different individuals who had produced works that were publicly acknowledged as creative and who had all affected their culture in some important ways, concluded that the major distinguishing characteristic of creative people is the capacity to experience "flow." Flow is conceptualized as the balance between opportunities of action (challenges) and personal abilities (skills) and the experience of timelessness and oneness with activity in which one is engaged. Several methods have been developed to measure the flow state, including semi-structured interviews, questionnaires, and the *Experience Sampling Method* (ESM). According to Nakamura and Csikszentmihalyi (2002), the semi-structured interview is the approach of choice in studies directed toward rich, integrated description, whereas paper-and-pencil measures, such as the *Flow Questionnaire*, are more appropriate when the goal is not to identify but instead to measure dimension of the flow experience and/or differences in its occurrence across contexts or individuals. ESM is the most widely used approach for measuring flow, and it is not limited by reliance on retrospective evaluation. In ESM, subjects are paged periodically and asked to fill out questionnaires describing the moment at which they are paged. Within this approach, flow represents a good indicator of creative people.

Conclusions and Future Directions

Given the many methods of assessing creativity, what is the most useful approach? First, one must consider the reason for the assessment (Lopez and Snyder 2003), according to the domain, such as education, counseling, job placement, or others and the age of the evaluated individuals. Secondly, a solution to overcome limits related to the complex concept of creativity could be that of considering the multiplicity of measures as indicative of viable, dynamic, creative field. Houtz and Krug (1995) suggested that "multiple instruments and methods permit flexibility and adaptability to new problems and situations, maximum theory development, and application to real-world problems" (p. 273).

The psychology of creativity ought to be open to innovative approaches to assessment and one less obvious reason is that it will accelerate the growth of evidence in creativity assessment (Silvia et al. 2011) as is already achieved in other fields (Plucker and Makel 2010).

Measuring Organizational Climate for Creativity and Innovation

Igor N. Dubina
Economic Information Systems, Altai State University, Barnaul, Russia

Synonyms

Creative climate; Innovative climate; Innovativeness; Innovativity; Work environment

Definition

Organizational climate is a relatively stable set of physical, social-psychological, administrative, and economic factors characterizing the conditions for work and influencing on employees' professional activities within an organization domain.

Introduction

The alteration of a company's work environment for creativity represents the most important way to develop employees' creativity and to manage this process. For maintenance of the "continuous creativity" strategy, it is necessary to create a favorable organizational and psychological climate for creativity, not only for "creative employees" (such as inventors, managers, and engineers), but also for all workers. For example, Japanese firms support and accumulate not only inventions but any "fine" ideas ("secondary innovations") as well. These secondary innovations are the main source of competitiveness since they promote constant production update, cost reduction, and quality improvement. The aggregated effect of secondary innovations often is greater than that of a few giant ideas because modern business depends on a continuous flow of ideas.

Improving the organizational climate for creativity and innovation can promote effective problem-solving in a company, and often increases a company's productivity and competitiveness. Therefore, optimizing the work environment for creativity to achieve maximum effectiveness with limited investment can be considered as one of the key elements of creativity management. The creative environment depends on many different factors such as management structure, leadership style, workplace conditions, and available resources. In the literature, there are many recommendations for improving the work environment for creativity and innovation, such as how to motivate employees to be more creative and how to eliminate different blocks against creativity. But improving an organizational climate also requires some assessment methods and measurement instrument to evaluate improvement efforts. The conception of ► Creativity Management Optimization supposes that interventions for improving the environment for creativity are directed to the most appropriate areas and in the most appropriate amounts.

Main Terms and Definitions

The literature refers to the metaphorical term "creative climate" to describe socio-psychological conditions for creativity (the fourth P – Press – in the ► 4P Creativity Model), paralleling meteorological conditions ("warm," "cold," "storm," "calm") and attributes of the work environment. Researchers, applying this term, pay attention mostly to psychological and sociological aspects of creativity development. Usually, they do not take into account some organizational, economic, and management mechanisms for creativity management. For a firm, it is very important not only to have a creative climate but also to use the creativity of their employees effectively.

The term "creative climate" refers to the "inner" environment in which new ideas are being generated and supported. This, however, does not necessarily consider any *practical* results of creativity development. On the other hand, the special term "innovativeness" frequently has been used for characterizing how innovative a company is. In contrast to the "creative climate," innovativeness emphasizes the intensity and results of a firm's innovative activity more than conditions for creativity.

This terminology reflects the fact that an organizational climate for creativity and the climate for innovation are not the same, although both characteristics correlate closely and even overlap. For example, using CCQ, Isaksen and Kaufmann (1990) demonstrate that more innovative and commercially successful companies express a more creative organizational climate. King (1995) provides another example: a study of four subunits of a large chemical company revealed that the subunit, whose climate was most favorable toward creativity, was not most successful in terms of innovation. "The most innovative division showed characteristics generally found to inhibit individual creativity; conflict, disharmony, and lack of trust" (King 1995, p. 85). Ekval (1996) suggests that some characteristics of creative climate may be favorable to incremental innovation, small step improvements of the existing products and processes, but they may be hampering for radical innovation, and vice versa.

Dubina (2005) proposed to combine the above terms and introduced the term of "innovativity" as an organizational capability for actualizing employees' creativity and shaping it into practical tangible results. *Innovativity* integrates creative and innovative aspects of the work environment in an organization. This suggests a complex index, underscoring a firm's dependence on innovations, its sensitivity to changes, the conditions for the promotion of new ideas, and the support, encouragement, and realization of creative initiatives of the employees.

Factors, Methods, and Instruments

Several approaches to assess the work environment for creativity and innovation have been developed recently, including the following methods and instruments:

- Assessing the Climate for Creativity (KEYS), originally called the Work Environment Survey (Amabile 1996; Amabile et al. 1999)

- Creative Climate Questionnaire (CCQ), originally called the Climate for Innovation Questionnaire (Ekvall 1996, 1999)
- Situational Outlook Questionnaire (SOQ), an English version of the CCQ (Isaksen et al. 1999)
- Team Climate Inventory (TCI) (Anderson and West 1996)
- Siegel Scale of Support for Innovation (SSSI) (Siegel and Kaemmerer 1978)
- The Art of Innovation (AI) (Michaelides 2007)

These instruments often are used to measure how conductive work environments are for employees' creativity. The critical analysis, carried out in Mathisen and Einarsen (2004), revealed a number of ways for improving these instruments, including the selection of evaluated factors, scale development, and a more emphasis on impeding factors. Despite various organizational characteristics measured by the instruments, it seems possible to specify several major characteristics or climate categories.

Challenge refers to the emotional involvement of the members of the organization in its operations and goals, when the members find satisfaction in their jobs (CCQ, SOQ). Similarly, the KEYS instrument measures *Challenging Work* as a source of motivation.

Freedom involves the independence or autonomy that organizational members can exert, when completing tasks or developing ideas. This dimension was identified in the CCQ, SOQ, AI, and KEYS. Similarly, the SSSI identifies *Ownership* as the feeling of control that organizational members obtain, when creating, developing, and executing ideas.

Idea support is the extent to which ideas are treated in a constructive and positive way (CCQ, SOQ). Similarly, the KEYS includes a *Supervisory Encouragement* dimension that refers to a supervisor, who serves as a good work model, values and supports ideas of employees. The SSSI links *Leadership* to support and other organizational aspects such as distribution of power, development of ideas, and personal development. The TCI defines *Support for Innovation* as the expectation, approval, and practical support given to teams.

Trust/openness refers to emotional safety in relationships (CCQ, SOQ). Similarly, *Participative Safety* is being described in the TCI as the extent to which the environment is nonthreatening for organizational members to present and develop ideas. The KEYS mentions trust and openness under the *Work Group Supports* dimension.

Dynamism/liveliness is described in the CCQ and SOQ as the eventfulness of life in the organization, the frequency of organizational changes. The SSSI addresses a dimension called *Continuous Development*, which involves continuous organizational changes in which deep-seated assumptions, goals, and problem-solving approaches are questioned.

Playfulness/humor is defined as a spontaneous and relaxed atmosphere in the organization (CCQ, SOQ, AI).

The category *Debates* refers to the occurrence of encounters between view points, ideas, opinions, and experiences (CCQ, SOQ). The KEYS mentions constructive challenge under the *Work Group Supports* dimension. The TCI identifies a *Norms for Diversity* dimension, where few behaviors are considered as deviant, as an openness for diversity.

Conflict refers to the presence of emotional and personal tensions (in contrast to conflicts between ideas) in the organization. This is the only negative factor in CCQ. Similarly, the KEYS mentions internal strife and destructive competitions as organizational impediments. The TCI cites nonthreatening environment as means to create participative safety.

Risk taking is defined as a tolerance for uncertainty and ambiguity (CCQ, SOQ, AI). Risk taking is also mentioned as an aspect of *Organizational Encouragement* in KEYS.

Idea time is being described in the CCQ and SOQ as the amount of time people can use for developing and elaborating new ideas. The KEYS identifies extreme time pressure, under the *Workload Pressure* dimension, as an obstacle for creativity and the development of ideas.

Organizational encouragement involves the company-wide system that promotes creativity by a fair evaluation of ideas, risk taking, reward and recognition of creativity, and an active flow of ideas. The antithesis of organizational encouragement includes formal management structures and bureaucracy (KEYS).

Sufficient resources includes the availability of money, tools, materials, information, and the assistance of organizational members in developing and executing their ideas facilities (KEYS).

Task orientation involves the extent to which team members commonly agree and commit themselves to task quality and excellence, when interconnected with the group's vision and methods to evaluate results (TCI). Similarly, the KEYS includes shared commitments to projects as a part of the *Work Group Supports* definition.

Vision is the degree to which the group's vision and goals are clearly defined and reachable (TCI). Shared vision is listed under the *Organizational Encouragement* dimension in the KEYS. Similarly, *Consistency* is being described in the SSSI as a steadiness of processes and desired products to preclude organizational member deviation from project objectives.

These instruments are well described and analyzed in the literature and widely used in practice. Despite some imperfections (Mathisen and Einarsen 2004), they may be very helpful for managers and consultants in assessing the effect of creative climate improvement efforts and identifying relative strengths and weaknesses within and between work groups.

The mentioned approaches to assess a creative climate do not directly include factors of organizing and controlling creativity. As an attempt to improve existing instruments, Dubina (2006) suggested an approach to quantitative assessment of the work environment for creativity. In his model, the work environment for creativity is represented by the organizational creative capacity (OCC) that is measured by three groups of parameters such as:

- Supporting, facilitating, and developing employee creativity
- Encouraging and fostering employee creativity
- Organizing, directing, focusing, and monitoring employee creativity

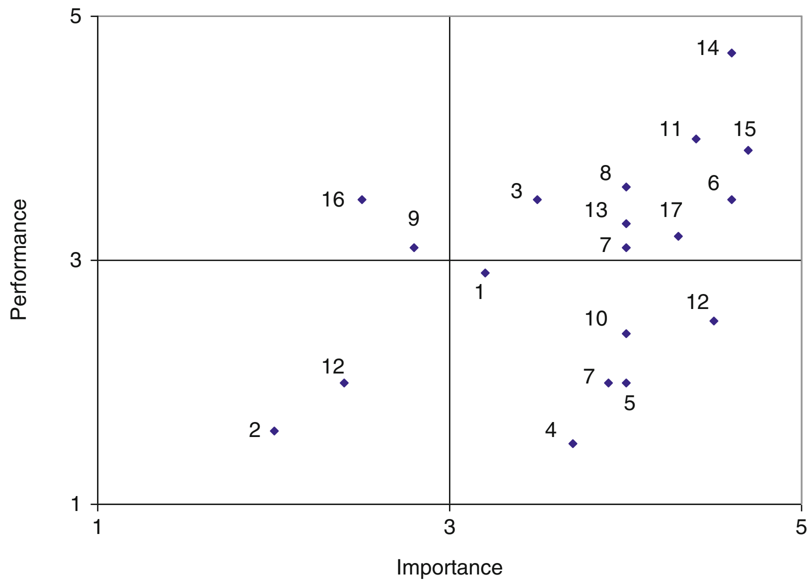
These parameters are characterized with indicators such as:

- A company's sensitivity to new ideas, tolerance for uncertainty and mistakes, risk taking, workplace conditions, granting time and resources for creativity, cooperation stimulation, freedom and flexible conditions for work, information exchange, available resources, and creativity trainings
- Cultivating intrinsic motivation and financial and nonfinancial stimulation
- Creativity and/or innovation strategy development, employee participation in decision-making, creativity hazard control, coordination of employee interests and the company goals, and creative leadership

To collect attitude data for assessing climate indicators, a Likert scale is usually applied, so appropriate mathematical and statistical methods should be used for processing the results obtained with such a scale for undertaking correct quantitative analysis. There are also other problems and inconveniences with using such instruments. All of them are based on a set of questions (usually, 50–150 items) and the categories (or factors) of an organizational climate are evaluated on the basis of replies to these questions. The questionnaires often take considerable time to complete. Usually, it also takes much time to analyze data, while sometimes a manager needs just a quick evaluation of a climate. Finally, it is not so easy to modify an existing instrument to use in another cultural context. The development of the SOQ is an example. It is an English version of the CCQ, and it is based on the same climate model and consists of as many items as the CCQ. But actually, they are different instruments since a "direct" and literal translation is impossible because of linguistic and cultural realities. The translation of questionnaire items results in a new instrument. According to the theory of measurement, changing any item of a questionnaire may change the indexes of measurement reliability and validity. Therefore, multifold testing is required for a "translated" measurement instrument.

All of these factors were a rationale to develop a simpler instrument which can be based on direct

Measuring Organizational Climate for Creativity and Innovation, Fig. 1 Estimates for climate factors in Improvement Priority Matrix (Source: The author's own work)



evaluation of climate categories (Dubina and Umpleby 2011). Seventeen key factors that contribute to the generation of new ideas and their successful implementation as projects in organizations are evaluated:

1. Safety for suggesting new ideas
2. Supervisory tolerance for risk and uncertainty
3. Employees' freedom/autonomy in decision-making
4. Sufficient resources provided for elaborating new projects
5. Sufficient time provided for employees' work on new projects
6. Challenging work
7. Supervisory encouragement to work cooperatively on new projects
8. Organizational openness to new ideas
9. Effectiveness of team work
10. Trust in the workgroup
11. An effective system for recognizing new ideas in an organization
12. Producing new ideas for trying new opportunities for business, not only for current product development
13. Supervisory positive acceptance of employees' creative suggestions
14. Supervisory encouragement of employees' creative approach to doing work
15. Fair rewards for creative suggestions
16. Dynamism of an organization and its openness to changes
17. Effectiveness of creativity and innovation activities

Employees evaluate these factors with two 5 point scales: importance scale (from 1 that is unimportant to 5 that is extremely important) and performance scale (from 1 that is very poor to 5 that is excellent). The averaged estimates for each factor are used as coordinates in a diagram with the importance – performance axes and four quadrants (Improvement Priority Matrix) (Fig. 1).

The factors of greatest interest for improvement are those that fall in the southeast quadrant defined by high importance and low performance. Those climate factors are considered the highest priority elements for an organization and need to be improved most of all. A ratio of importance to performance (IPR) was also calculated to increase the accuracy of climate assessment: $IPR = I/P$. The higher the IPR, the higher the priority a factor has.

An advantage of this approach to climate assessment is making allowance for the importance (or "weight") of each climate factor for an organization. Traditional approaches usually do not take item or factor "weights" into account.

The method is rather easy for respondents to understand. Applying this approach, it is possible to very quickly (up to 7–10 min) assess an organizational climate and get a clear "snapshot" of it. This method may be used independently or in a complementary way for assessing climate with the existing approaches in order to gain additional information about the work environment for creativity and innovation.

Conclusion and Future Directions

Measuring an organizational climate can help to identify necessary directions and amounts for interventions for improving the climate. The measurement of the climate characteristics can help to answer the following questions: How well does the climate fit the tasks or purposes of the organization? What structures may help promoting employees' creativity and better match the needs of the organization? The assessment of the work environment may direct interventions to the most appropriate areas, and in the appropriate amounts, to improve organizational performance.

Some organizational characteristics and climate dimensions are differently perceived by people with different creative styles. In other words, some types of people view their work environment as favorable to creativity, while other types of people perceive the same environment as less favorable. In particular, *Adaptors* and *Innovators* (see ▶ Creative Styles) prefer and need different climates for their creativity to flourish. Contemplating these differences may also be useful for managers, who need to learn applying different approaches for different members of the same group. Such an understanding can help organizations to better leverage their human recourses in order to get the maximum effect from employee creativity.

More studies are required to investigate the relative influence of different environment factors on work performance. Therefore, the correlation of environment factors with indicators of work performance represents one prospective possibility for future research. For this purpose, the development of usable and reliable quantitative methods and tools for auditing and diagnosing the work environment for creativity is necessary to make an organization's creative and innovative activities more effective.

The methods and measurement instruments for measuring an organizational climate can help to design an optimal organizational structure to facilitate, develop, encourage, and induce the appropriate aspects of creative performance needed for effectiveness. Repeated use of these methods, about every 6 months or a year, can provide an optimal strategy for managing employees' creativity more systematically, methodically, and relevantly to the specificity of an organization, its goals, and resources.

Synonyms

Internal models; Working models of invention

Key Concepts and Definition of Terms

Invention, as defined by Webster's Dictionary, is a device, contrivance, or process originated after a period of extensive study and experimentation. Generally, it is argued that invention is something that is novel and useful.

A mental model is a construct of cognitive science that refers to beliefs and ideas that intelligent systems consciously construct from their experiences. Mental models control thoughts and actions; they create the expectation of certain results of thought experiments and give meaning to objects and events of the world. Although mental models provide some internal stability in a continuously changing world, they also blind their users to facts and ideas that challenge or defy deeply held beliefs. By nature, mental models are fuzzy and incomplete. Moreover, they are highly idiosyncratic, i.e., everyone develops mental models that differ completely or in detail from everyone else's with regard to the same object to be understood.

Theoretical Background and Open-Ended Issues

This entry is based on the presumption that creative invention necessarily and sufficiently presupposes the construction and use of mental models. It is assumed that it is common practice for inventors to use mental models as sets of heuristics to develop their projects. Accordingly, a mental model can also be defined as the ideas and concepts an inventor has about an invention. Mental models are often dynamic prototypes an inventor can run in the mind's eye. Their decisive advantage is that they allow an inventor to radically reconstruct previous knowledge about various domains to help to solve a complex problem. In other words, mental models for invention are often based on analogies between different domains. This can be illustrated through the example of the telephone. Its inventor Alexander Bell had expertise in human anatomy that he used in developing a mental model of the telephone (Gorman and Carlson 1990). Another example is provided by Thomas Edison, who made a career out of taking parts from one invention and fitting them together with a different invention to produce a third one. Edison's use of mental models also demonstrates one of the problems of using such techniques. When Edison was trying to develop the kinetoscope, he was hampered by having the same mental model for motion pictures as he did for the phonograph. He saw the kinetoscope as a single-use device, and in the end, he was compelled to discard his mental model of a "phonograph with pictures" (Carlson and Gorman 1990). This is an example of the observation that a mental model can also make one blind to facts and ideas that challenge or defy deeply held beliefs.

How Mental Models Work in General

The idea of mental models is based on the assumption that an individual who intends to provide a rational explanation for something or to invent something new must develop practicable methods in order to generate adequate explanations from his knowledge of the world and his limited information processing capacity: Thus, the individual constructs a *model* that both integrates the relevant knowledge and meets the requirements of the situation to be mastered cognitively. The idea that mental models play a significant role in complex problem solving and discovery has a long tradition in the twentieth century psychology and epistemology in which various roots can be distinguished. However, it was Craik (1943) who introduced the idea of *internal models* to epistemology with the notion of a working model. This model "works" when it is within the realm of the subject's knowledge as well as the explanatory need with regard to the concrete situation to be mastered cognitively. A similar conception of internal models has been adapted by numerous psychologists who were concerned with the investigation of people's operation of complex technical or physical systems (see, e.g., Hacker 1977; Veldhuyzen and Stassen 1977).

According to mental model theory, individuals create internal representations in order to understand and explain individual experiences and events (Johnson-Laird 1989). Individuals also make sense of a new, unusual, or complex phenomenon by creating and using mental models (Seel 1991, 2001). Thus, a mental model is an internal, subjectively plausible, ad hoc construction for explaining a phenomenon of the world or inventing something that did not exist before.

According to Rumelhart, Smolensky, McClelland, and Hinton (1986), people have three essential abilities for processing information and acting successfully in various environments. First of all, people are very good at *pattern matching*. They are obviously able to quickly "settle" on an interpretation of any input pattern. This ability is central to perceiving, remembering, and comprehending. It is probably ***the*** essential component of most cognitive behavior – and it is based on the activation and instantiation of schemas. Second, people are very good at *modeling* their worlds due to their ability to anticipate new states of affairs resulting from actions in the world or from an event they might observe. Both pattern matching and modeling are grounded on building up expectations by "internalizing" experiences and are crucial for making inferences (Seel 1991). Third, people are good at *manipulating* their environments. This can be considered as a version of man-the-tool-user, which is perhaps the crucial skill for building a culture. Especially important here is the ability to manipulate the environment and to create artifacts as external representations which can be manipulated in simple ways to obtain answers to very difficult and abstract problems. As people gain experience with the world created by their actions, they internalize their experiences with external representations to develop mental models.

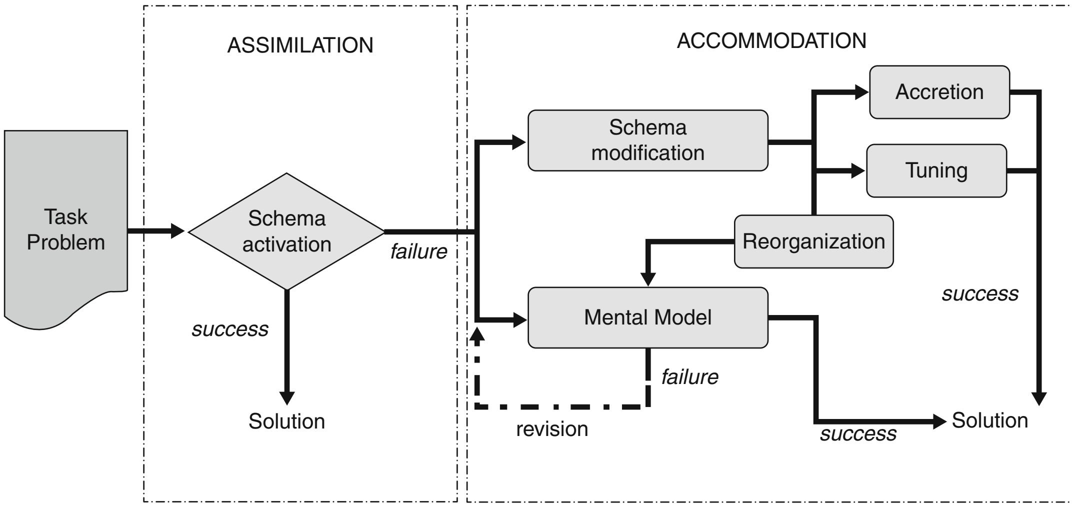
In order to explain these basic capabilities of intelligent systems, Rumelhart et al. (1986) divide the cognitive system into two modules or sets of units. One module – called an *interpretation network* – is concerned with producing appropriate responses to any input from the external world, while the other module is concerned with constructing a *model of the world* and producing an interpretation of "*what would happen if we did that*" with a particular external representation. The modeling part of the cognitive architecture is concerned with generating expectations about changes to the world that may result from imagining an external representation and operating on it. The interpretation network receives input from the world and reaches a relaxed mental state by producing relevant cognitive responses, whereas the "model of the world" predicts how the input would change in accordance with these responses.

Mental models constitute the fundamental basis for developing "models of the world," discussed here in accordance with Rumelhart et al. (1986), and they may serve as *models for reasoning* as well as *models for understanding and invention* (Seel 1991). In both cases, mental models are constructed to meet the specific requirements of situations and tasks the subject is faced with for which the activation and/or modification of a schema fails. While a schema is a slot-filler structure, a mental model contains a set of assumptions that must be justified by observations. This justification of assumptions is closely connected to a *reduction to absurdity* (Seel 1991), which is a process of testing continuously whether a model can be replaced with a better model. As long as this is not possible, the model is considered suitable.

Models for understanding and invention have their starting point in the tentative integration of relevant simple structures or even single bits of domain-specific knowledge step by step into the coherent design of a working model in order to meet the requirements of the task to be accomplished. Johnson-Laird (1983) considers this process of a stepwise enrichment of models as a "fleshing out" that also refers to the learning-dependent progression of mental models. Mental models for understanding represent the structure of world knowledge because they are generated to structure it and not to reproduce or copy a given external structure. Models for understanding and invention correspond to pragmatic conceptions of modeling. They can be externalized by means of particular symbol systems and generate subjective plausibility with regard to complex phenomena to be understood and explained. However, in contrast to the pragmatic approach of modeling, proponents of the mental model theory agree on the point that mental models are cognitive artifacts which correspond only more or less to the external world since people can also construct pure *thought models* which bear no direct correspondence to the external world but rather only to world knowledge. This corresponds to the idea of coherence epistemology (Seel 1991). In general, models for understanding and invention have the following characteristics: (a) They are incomplete and constantly evolving, (b) they are usually not an accurate representation of a phenomenon but typically may contain errors and contradictions, (c) they are parsimonious and provide simplified explanations of complex phenomena, and (d) they often contain measures of uncertainty about their validity that allow them to be used even if incorrect.

When People Must Construct Mental Models . . .

In the cognitive architecture provided by Rumelhart et al. (1986), schemas and mental models are considered as two basic mechanisms



Mental Models and Creative Invention, Fig. 1 Cognitive functions of assimilation and accommodation (Seel et al. 2009)

of cognition. The observation that creativity was considered to be closely related to the formation of new schemas of thinking in the literature of the 1960s (e.g., Guilford 1967) raises the question as to whether the construct mental model is necessary to explain human creativity.

Clearly, the construction of mental models presupposes semantic knowledge that is – according to cognitive psychology – organized by schemas. Schemas are considered as building blocks of cognition (Rumelhart 1980) and, in consequence, also as building blocks of mental models. In recent decades, schemas have emerged as a central theoretical construct of cognitive psychology, and schema theory has enriched the psychological knowledge about information processing, logical reasoning, and problem solving (Rumelhart 1980; Rumelhart et al. 1986). In cognitive psychology, a schema is conceptualized as a unit of mental representation in which the conceptual structures, relations, and processes of a particular semantic phenomenon of the world are organized as slot-filler structures that run automatically when triggered by input information that fits with the default values of a schema.

The cognitive architecture proposed by Rumelhart et al. corresponds to a great extent to Piaget's genetic epistemology and its basic mechanisms of assimilation and accommodation. Actually, assimilation is dependent on the availability and activation of cognitive schemas, which regulate the incorporation of new information into cognitive structures that can be addressed and activated through the default values of a schema. However, if a schema does not fit immediately with the requirements of a new task it can be adjusted to meet the new requirements by means of *accretion, tuning, or reorganization* (Seel 1991). This modification of a schema is a central part of accommodation. If and only if accretion, tuning, or reorganization of preexisting schemata is not successful, accommodation advances to the construction of a mental model (see Fig. 1).

In the rare case that no schema is available or can be activated, an immediate construction of a mental model may occur. In this case, an individual constructs a mental model which collects and integrates the relevant *bits of semantic knowledge* into a coherent structure step by step in order to meet the requirements of a phenomenon to be explained. Both "fleshing out" and "reduction to absurdity" are necessary for the completion of a mental model, which runs as a preliminary working model for invention. Mental models, like heuristics in general, often become apparent when the problem solver encounters a kind of resistance to the explanation of something. For example, an expert who solves a particular class of problems automatically by triggering schemas may have to struggle to find a solution to a novel problem and may be forced to develop a mental model. Indeed, creative invention necessitates the construction and improvement of a mental model.

Mental Models for Inventions

Creativity is often placed on a level with spontaneity, but creative invention is usually not the result of spontaneous ideas but rather the end-point of a long-term cognitive confrontation with a complex problem. First of all, invention is "hard work," and second, *necessity is the mother of invention*. Third, mental models provide the "frame" for an invention by constraining proto-inventions to an applicable product, which is generally considered as both sufficiently new and useful. The use of the prefix "proto" indicates a precondition or an early stage of development of a solution to a problem. According to mental model theory, inventors develop tentative mental models of the problem in order to generate proto-inventions through design heuristics. In mental model theory, this is called "reduction to absurdity," which refers to a continuous process of testing and revising a mental model and the resulting proto-invention. A small number of design heuristics can generate an abundance of proto-inventions, but a really successful invention will be rare.

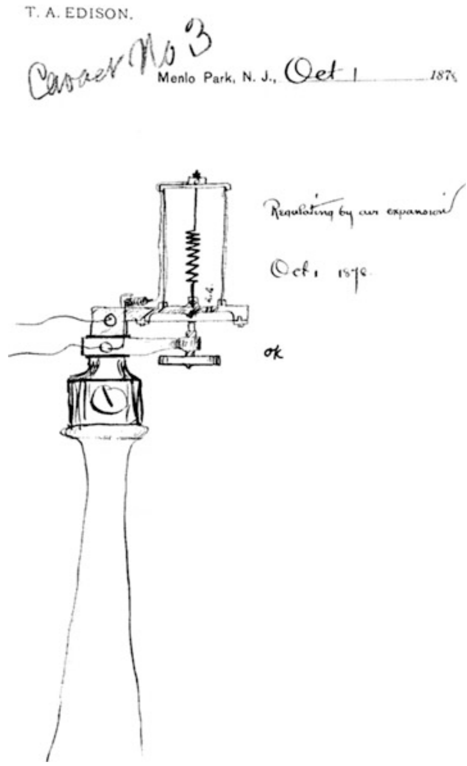
One can increase the probability of constructing an effective mental model for creative invention by developing analogy models that are built on what is known and can be transferred successfully to a new problem. The person creating a model for a proto-invention constructs an initial solution model by selecting only a few attributes from a known base domain and then mapping them to the target domain. This can be illustrated by an example provided by Holyoak and Thagard (1995, p. 33): "Our knowledge of water provides us with a kind of internal model of how it moves. Similarly, our knowledge of sound provides us with a kind of model of how sound is transmitted through the air. Each of these mental models links an internal representation to external reality. But when we consider the analogy between water waves and sound propagation, we are trying to build an isomorphism between two internal models. Implicitly, we are acting as if our model of water waves can be used to modify and improve our model of sound."

If this process of building an isomorphism between two mental models leads immediately to an acceptable *conclusion by analogy*, the procedure will be finished. But in the case of creative inventions, this situation should arise relatively infrequently since usually it is not easy to construct a mental model to explain an unknown phenomenon on the basis of previous experiences with similar phenomena within another domain. However, if the construction of a mental model is successful, it may serve four major functions: (1) Models aid in the *simplification* of an investigation to particular and relevant phenomena in a closed domain. (2) Models aid in the *envisioning* (or visualization) of a complex structure or system. (3) Models aid in the *construction of an analogy,* which helps to identify the structure of an unknown domain with the help of the structure of a known domain. In this way, a well-known explanation (e.g., Rutherford's atomic model) can be mapped onto a phenomenon to be explained (e.g., quantum mechanisms). Such models are called *analogy models*. (4) Finally, models may aid in the *simulation* of the processes of a system. This occurs when an individual interacts with the objects involved in a situation in order to manipulate them mentally in such a way that the cognitive operations simulate specific transformations of these objects that may occur in real-life situations. These *simulation models* operate as thought experiments that produce qualitative inferences with respect to the situation to be mastered.

Naturally, there is a substantial lack of empirical research on the role of mental models for great inventions that cannot be forced by experimental treatments. However, one can find some good case descriptions of great inventions in the literature (e.g., Brockman 2000) that demonstrate how inventors construct mental models by engaging in analogical reasoning and performing "thought simulations" and then rule out unpromising designs and follow up on promising ones. A nice example of this "thought simulation" by means of a mental model that can be found in the literature is Oatley's (2011) essay about Shakespeare's invention of the theatre. Other good accounts of the role of mental models for inventions refer to Thomas Edison (1847–1931), with a particular emphasis on the cognitive processes involved in Edison's creative inventions (Carlson and Gorman 1990; Gorman and Carlson 1990). With regard to the invention of the light bulb, one can state that Edison began his efforts to solve the problem by creating a regulating system that kept a platinum filament between the incandescent and melting temperatures. This phase of operating exclusively in the design space of regulated platinum filament bulbs lasted some months (Fig. 2).

In the following phase (January 1879 to October 1879), Edison adopted a strategy of functional decomposition of the complex problem when he discovered that gasses boil out of a platinum filament raised to incandescence and damaged the wire. He now explored how different filaments changed due to high temperatures generated by a blowtorch. During the next months (up to December 1879) Edison developed the first practical high-resistance carbon bulbs. It took Edison nearly 1 year to invent the light bulb, and the invention process was associated with cognitive processes that are characteristic of the construction and revision of a mental model. First, he referred to his broad knowledge of mechanisms to develop self-regulating bulbs, but these efforts at finding an analogy model were not successful, not until he broke down the functional relationship of the complex problem into its constituent parts and employed a kind of "beam search" at various phases.

Beam search is a heuristic search which optimizes a best-first search in order to reduce memory requirements as well as to organize partial solutions to a problem in accordance with a heuristic which aims at predicting how close a particular solution is to a successful overall solution. In terms of mental model theory, beam search corresponds largely to a reduction to



Mental Models and Creative Invention, Fig. 2 Edison's first design of a light bulb (1878)

absurdity of model candidates. Beam search uses a breadth-first search strategy to generate all possible consequences of a current model and sort them in increasing order of heuristic cost.

The effectiveness of mental models and related heuristics (such as beam search) can also be demonstrated by referring to other great inventors, such as Nikola Tesla (1856–1943) who "electrified the world." In his autography (Johnston 1983), Tesla reports that he relied heavily on his capability of visualization and mental simulation for inventions. More specifically, he informs us about his creative inventions by using a kind of mental model:

> My method is different. I do not rush into actual work. When I get an idea I start at once building it up in my imagination. I change the construction, make improvements and operate the device in my mind. It is absolutely immaterial to me whether I run my turbine in thought or test it in my shop. I even note if it is out of balance. There is no difference whatever, the results are the same.

> In this way I am able to rapidly develop and perfect a conception without touching anything. When I have gone so far as to embody in the invention every possible improvement I can think of and see no fault anywhere, I put into concrete form this final product of my brain. Invariably my device works as I conceived that it should, and the experiment comes out exactly as I planned it. In twenty years there has not been a single exception. .... The incessant mental exertion developed my powers of observation and enabled me to discover a truth of great importance. (Tesla 1919; retrieved from http://www.tfcbooks.com/tesla/my_inventions.htm#I.%20My%20Early%20Life)

Conclusion and Future Directions

Since its introduction into the literature in the 1980s, the concept of mental model has played an increasing role in science education literature. Franco et al. (1999), for instance, discuss the relationships between external representations, mental models, and ideational realizations by referring to scientists' and inventors' mental models as working devices for creative inventions. Innovation and creative inventions are inherently very complex phenomena and subject to manifold cognitive and social requirements. As the evidence grows that there is a close link between invention and mental models (and their basic functions), there is no doubt that there is a need for theoretical and practical advances in the understanding of how mental models work in making inventions. This chapter discussed key aspects of creative invention and mental models, including definition issues of some basic constructs which underscore the need for a cognitive perspective. The review and discussion of mental models and creative invention reveals not only numerous advances but also substantial research questions that require more complex and comprehensive approaches than the previous case studies to be found in the literature (Calabrese-Barton 1998).

The chapter concludes with a reference to a promising project – the "invention curriculum" proposed by Sharif and San (2001) – which is designed to enable students to be creative in their thinking, innovative, and inventive. Students are enabled to create artifacts by applying a design process, starting with problem identification and idea formulation and continuing with prototype building and evaluation. The results of this UNESCO project show great promise for the training of discovery learning in the classroom.

Merits of Aesthetics in Realm of Science

Vuk Uskoković
Therapeutic Micro and Nanotechnology Laboratory, Department of Bioengineering and Therapeutic Sciences, University of California, San Francisco, CA, USA

Introduction

Some may say that an image is worth thousands of words. This short discourse begins with two of them posed side by side, a scientific and an artistic one (Fig. 1). On the left, one could see a scanning electron micrograph of parallel monolayers of electrospun collagen fibers which resemble the pattern of the sky on the legendary Van Gogh's painting, Starry Night shown on the right. The similarity in the pattern between a scientific and an artistic image may prompt us to look deeper into their more fundamental commonalities. Finding those within their methodological roots rather than explicating the surface ones will be the subject of the following discourse. For when found at the roots, homologies on the surface could be recognized and fostered with ease. Therefore, the first steps in the discourse that follows will correspond to opening the views on physical phenomena in general. This would also turn out to be equal to plunging deep into the foundations of the eye that sees the world.

Teaching: The Pragmatic Principles of the Philosophy of Co-creation

Perceivable outlines of the physical reality are neither solipsistic nor objective but could be rather seen as falling into the category of intersubjective phenomenalism. From Heisenberg's uncertainty principle and the measurement problem to the findings of the constructivist school of cognitive science, empirical signs are everywhere that the subject co-defines the properties of the perceived reality as much as the latter is determined by its

Merits of Aesthetics in Realm of Science, Fig. 1 A scanning electron micrograph of self-assembled collagen fibers on glass (*left*) and Vincent Van Gogh's Starry Night (*right*). Reproduced with the permission from the Museum of Modern Arts, New York, NY

objective propensities. The author's fastidious blending of subjective creative effects in the perception of reality and those that are undeniably common and thus partially objective has yielded the philosophy of co-creation articulated on previous occasions (Uskoković 2009b, c, 2012).

The co-creational thesis dictates that every experience is the product of the impressions of the world as it is as well as of the subject's own, inner creativity defined by his biological nature in the current stage of evolution and by intentions, aspirations, emotions, and other psychological attributes of the mind. Every detail of the perceived reality is thus partially drawn by the cognitive subject himself, and, as such, it hides the essence of the subject's own being as much as it outlines the features of the "real" world, the beauty of which is independent and only "in touch" with the subject. Or, as Arthur Eddington summed this up, "All through the physical world runs that unknown content which must surely be the stuff of our consciousness; here is a hint of aspects deep within the world of physics and yet unattainable by the methods of physics" (Schuller 1980). At the very end of one, the so-called measuring apparatus pole in this co-creational dialogue in which the experiential reality is being drawn the deepest values of the human mind could be recognized, whereas at the other, the so-called measured system end, the creative intelligence hidden behind the veil of the physical reality, nameable as Nature, Creator, or God, could be foreshadowed.

Philosophically meticulous exploration of experiential details can thus naturally lead the explorer to recognize in them the reflections of both the hidden ontological aspects of the origins of the physical reality and of one's own intrinsic nature, including all the prejudgments, anticipations, and values nourished from within. "Nature always wears the colors of the spirit" (Emerson 1836), Emerson proclaimed, and his viewpoint becomes readily understandable upon knowing that any perception always reflects both how the subject is and how the world, independently of the subject, is. Either of the two alone, without being intermingled with the other, cannot be made knowable. Both of these creative poles are imperceptible per se, comparable to the sound of one hand clapping from the popular Zen koan. Only in pair can they produce something perceptible; the very question of whether the sensual information comes from one or the other pole then becomes meaningless.

Since they arise in the co-creational dialogue between the human mind and Nature, all scientific models and relationships are partly human inventions aside from constituting literal discoveries. All products of scientific measurements arise from the interaction between the measured systems and the measurement devices, whereby the latter include the observer's mind and all the presuppositions with which one approaches the measurements. All of these assumptions about the object of one's study become inconspicuously reflected in the final measurement outcomes. All the properties and qualities that scientists and experimenters ascribe to the worldly objects should thus be considered as attributes since they are partly objective but partly defined by their subjective nature as observers. The world perceived by the observer is thus the world of one's experience first and foremost, albeit the fact that the latter still possesses solid objective traits which enable humans to share experiences, including objects and insights. Therefore, one could consider scientific imagery not as truthful, realistic, and universal reflections of an objective world identical for all observers, but as partly subjective and metaphorical in nature, a product of individual and social imagination as much as an objective reflection of the world per se. In view of this, products of scientific creativity partly serve the pragmatic purpose of enlightening human experiences instead of discovering the one and only truthful nature of the physical reality.

As the co-creational thesis suggests, the element of discovering and the one of inventing are, in fact, inextricably entwined, as much as the roles of the subject and the object are equally involved in defining the features of the object in the subject's eyes. Beauty lies in the object itself, but it is also partly in the eyes of beholder, as some might say. An immediate consequence of this phenomenal insight is that all the efforts in the scientific arena have the ultimate purpose of enlightening the world of other people's experiences, and the greater the shine of love in one, the more open the road to extraordinary scientific discoveries will lie ahead. The more one loves and respects humanity and fellow earthlings, the greater the drive will be in one to diligently explore the mysterious seas of scientific knowledge and eventually come up with lustrous pearls of wonderful insights. Besides, the feeling is that common sense wisdom too blossoms most efficiently from the stems of selfless care for weak and fragile creatures of the world, which all humans ultimately are and which could be therefore seen as an incessant fuel for the flights of human imagination and creativity toward stars. Hence, as in the Tai-Chi-Tu symbol, knowledge can be found in the center of the spinning of the vortex of love, whereas love can be seen standing at the foundation of the incessantly rising towers of human knowledge.

To sum up, scientific imagery is not truthful and universal; it is rather a result of imagination and inventiveness of the human mind. As such, it is only one of countless potential ways of describing the reality. Genuinely metaphorical in nature, it can be seen as arising from the same, pragmatic roots of the human tree of knowledge from which arts originated, only later, on the surface, branching out to its special avenues and approaches. Consequently, it comes as no surprise that the nature of human thinking, both scientific and nonscientific, is analogical, metaphoric as much it is logical and analytical in its nature. As such, it is unequivocally inspired by the artistic eye for natural phenomena.

When asked about the sources of inspiration for developing his theory of relativity, Albert Einstein said, "The theory of relativity occurred to me by intuition, and music is the driving force behind this intuition. My parents had me study violin from the time I was six. My new discovery is the result of musical perception" (Schuller 1980). On another occasion, Einstein alludes to the complementariness of science and arts by claiming that "both music and scientific research are nourished by the same source of longing, and they complement one another in the release they offer" (Wilczek and Devine 1988). Many extraordinary scientists would agree that aesthetic sensibility presents a core of exceptionally inventive exhibitions of the powers of the brain and that love and compassion could thus be considered as the essence of rationality and intellect. Numerous scientists were in love with poetry and music and intensively played an instrument or two, from Pythagoras to Werner Heisenberg to Richard Feynman to Enrico Fermi. At the end of his Critique of Pure Reason, Immanuel Kant noticed how "two things still fill my mind with ever increasing wonder and awe... the starry heavens above me and the moral law within me" (Kant 1781). Not only may his division of the ultimate mystery of being to two elementary poles be correlated with the aforementioned metaphysical poles – the essences of mind and Nature – that in their co-creational interaction give rise to the spiritual and physical evolution of life and matter, but it is apparent that the two resulting aspects of human creativity – the productivity evident in the world outside and an artistic, aesthetically sublime and profoundly compassionate heart cultivated within – always go hand in hand and can be thus considered as one and the same (Wilkinson 1979).

Application: Science and Art Are One and the Same

The most important, although often not readily recognizable, discovery of the empiric approach to scientific method was the "discovery" of the very method of arrival at scientific discoveries (Whitehead 1925). Adopting the programmatic method of reaching novel discoveries, however, resulted in gradual distancing of human aspirations, passions, the sense of sacred intimacy with Nature, and, more than anything, love of science and Nature away from the subjects of science and lab benches. Slowly, over time, the romantic charm of doing science has been put asleep and at this point in time, witnessed is a rise in the way of doing science that has not existed before. Namely, it seems as if scientific research is about to fully transform itself into an entrepreneurial activity that can follow practically any prototypical self-profiting business model. Management and administrative skills have thus become equally or even more important for conducting the scientific "business" successfully than embracing the physical phenomena studied with a whole lot of devotion and passion. Scientists are wrongly taught that the larger the amount of funding for a given research, the more significant outcomes will result. Despite the fact that the blue-sky research (Braben 2004), disconnected from immediate gains and applications and focused on basic scientific aspects solely, was shown to be the most fruitful one from the perspective of the advancement of human knowledge and technologies throughout the history, funds are nowadays primarily given to scientific projects focused on short-term goals. Yet, every gardener knows that what grows fast in his field is most probably nothing but weed, whereas all the fruitful trees require time to yield their first fruits and even more to grow to their full size and capacity. Arts are no exception to this either. Conducted with the desire to comply with commercial demands, they similarly transform to mainstream movements, with a little of artistic value, and as such, luckily, do not stand impressed for a very long time in the collective mind of humanity.

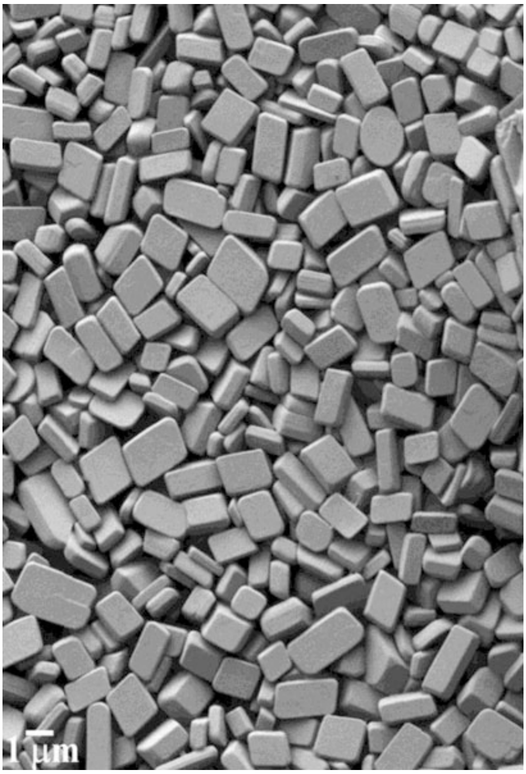
This age has consequently produced scientific minds that contrast Galileo, Leonardo, and other romantic figures that were risking their lives in fighting for truth and norms of timeless beauty against the intellectual repression of the establishment. Ours is the time pervaded with scientists that present their results by wishing to satisfy merely their funders and other reward holders, disregarding the precious connections with the wells of inspiration residing within their own minds, ending up suffocating the romantic charms of doing science, inherently tied to paradigm-shifting originality that borders nonconformist dissent, and becoming inert and uninspiring slaves of academic authorities. The mainstream scientist has thus become more obsessed with securing one's own academic recognition, tenure, and, increasingly, exorbitant salaries and social benefits more than with altruistically subduing the spell of Nature to the spirit of science. Instead of passionately searching for "truth" through the genuine dialogue between the human mind and Nature that all sciences represent, scientific activities have thereby begun to resemble any other business in which the creative force behind the production of goods is made passively subservient to demands of other people.

While depriving the modern scientific practice of the renaissance charm and profound, alchemical enthusiasm that used to endow scientific endeavors in the past, the majority of scientists have lost faith in the importance of nourishing gorgeous beliefs and aspirations as something that should underline each research effort. Yet, we could argue that truly significant scientific discoveries would hardly ever be made by one unless one's whole being starts living for their sake. The hypothesis that could be put forward at this point is that unless scientific conceptualizations and experimentations are pervaded with silent prayers radiating from the scientist's heart, the overall successfulness of the implemented methodologies will be, more or less, predestined for failure. Luckily, however, even when one cannot readily recognize the sources of love and care for the beings of the world behind the appearances of one's knowledge, they exist, deeply hidden like the roots of a tree, which is why even when it seems as if one carries out one's daily tasks absentmindedly, without any lovingness underneath one's breath, beneficial results may still miraculously appear in front of one.

The solution to this problem seems to lie not in rebuilding the artistic bases of scientific practice, but in illuminating them since they already exist in place, though most of the time unrecognized and ignored, the task much simpler than their recreation. By reinstating awareness of the artistic nature of scientific endeavors and bringing back the wholehearted passion for doing science, scientists may restore some of the personality traits and preferences that typified scientists and philosophers of the romantic era. For example, the love of science underlying scientific inquiry and practice has gone hand in hand with the interdisciplinary orientations of scientists. Leonardo, Galileo, Paracelsus, Goethe, or, more recently, Gregory Bateson, who were all combining, crisscrossing, and mutually fertilizing many areas of human inquiry and creativity, may be historical examples of scientists with exceptional interdisciplinary inclinations (Capra 2007). For when one loves something and cares about it, one naturally tends to look at it from a wide array of perspectives so as to enrich one's knowledge thereof and ensure its sustainability. The blind spot effect can also demonstrate how staring for too long at any particular system from a fixed stance makes one blind to many of its qualities. Interdisciplinary inquiry thus tends to pay off as constant changes of perspectives do not suffocate, but rather foster one's abilities to penetrate and comprehensively examine the investigated systems.

Another thing entailed by this romantic charm is a belief that one could do incredible things with a fistful of resources. Without these beliefs that stood behind many groundbreaking discoveries in science, including quantum theory and theory of relativity, no brave and "crazy" paradigms that turn the actual scientific outlooks upside-down could be arrived at. Just as exorbitant expenditures on health care have failed to increase life expectancy beyond certain levels (Garber and Skinner 2008), so has fosterage of ever more experimentation had little effect on boosting scientific excellence (Hollingsworth et al. 2008). The psychosomatic roots of human health and imaginative roots of scientific discovery are rather immune to attempts to enhance them guided by the simple norm "the more, the better," and looking back at the history of science can make one realize that most of the groundbreaking discoveries came out of little or no investment at all (Hollingsworth 2007). No wonder therefore that some of the most exciting scientific findings (Ball 2006), from penicillin to solar cells to Big Bang, were derived partly serendipitously (Roberts 1989). If the blueprints used for planning scientific or any other quests for meaning in life were drawn with a perfect precision, without leaving any space for an inflow of accidental, random effects, the prospect of paths projected toward discovery and innovation would seem vain. But a mind that holds on to logical concepts and guidelines and is yet open to absorb sudden and unpredictable signs arising on the research paths is the one suited for making remarkable discoveries. For the balance between analytical orderliness and dreamy voyaging to stars sets conditions for all types of progress in life. In other words, scientific conduct is inherently imaginative, spontaneous, and artistic and as such resists any attempts to confine it within a set of fixed instructions.

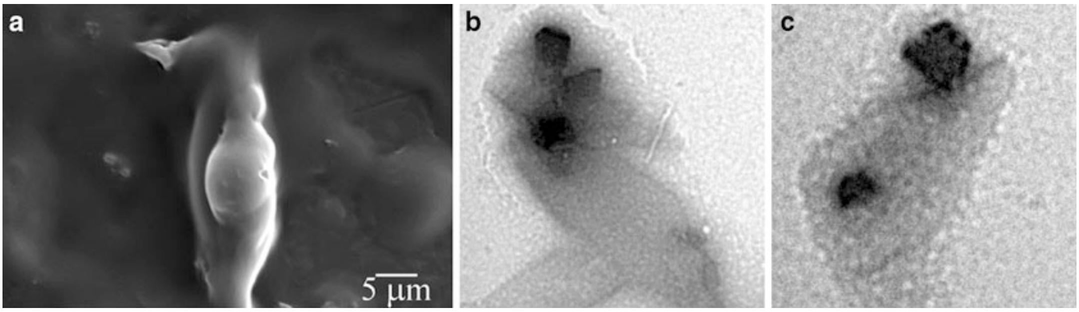
Serendipity, voted the most popular English word toward the turn of the century, derives its name after a Persian princess who had a natural gift for making extraordinary discoveries quite by accident (Uskoković 2010b), and if one's wish is to bring this elusive princess onto one's side, so to say, one better lets beautiful, lifesaving visions and emotions emanate from the depths of one's mind. For when tapping in the dark along innumerable possible sets of boundary conditions that could yield a desired product is required in the research realm, listening to the voice of intuition tapping on one's shoulder, often pointing at metaphorical signs in the everyday life that may be relevant for the given research, is of immense benefit. Indeed, then, embarked on a research voyage aimed at producing stable dispersions of cholesterol particles (Fig. 2; Uskoković and Matijević 2007), enormous amounts of time were spent outside, walking next to Raquette



Merits of Aesthetics in Realm of Science, Fig. 2 Monodisperse particles of cholesterol obtained by creatively traveling along parallel rails, one of which was emotive serendipity and the other one of which was epistemic clarity

River, caressing trees, climbing their branches, and rolling back against their bark in an eruption of pastorally amiable emotions. At the same time, a wish was constantly nourished to attain the aim and that never for the sake of advancing in career, but selflessly, for the sake of bringing forth discoveries that would benefit humanity. For unless steps in science or anything one engages one's creativity in are not made with a silent prayer radiating from the depths of one's heart, singing melodies that engrain a wish to bring beauty and salvation to the creatures of the world, whatever one does will not live up to the immense potentials that all human beings hold within. Poetically and prayerfully, therefore, even though one spends time diving for pearls in the sea of science, the kingdom where knowledge and reason occupy much higher place on the hierarchy of values compared to emotions and intuitions, one's actions are to be conceived and conducted in accordance with the simple guideline given by Blaise Pascal in his Pensées, "Heart. Instinct. Principles" (Pascal 1669), in no other order than this. It is with sadness in eyes that one could then observe the lifeless and passionless processions of modern professionals inertly following the streams of beliefs that any form of emotional involvement is a distraction rather than a motivation and drive essential for their endeavors in life to succeed. For since pragmatic purposefulness stands at the root of all sciences, neglecting to cultivate altruistic, warmhearted feelings during even the most routine lab bench work means going against the grain of genuine scientific creativeness, predisposing the resulting scientific edifices to be erected on inherently unstable, shaky foundations.

In that sense, an aesthetic eye can be said to be as important in navigating voyages toward discovery in the scientific realm as obedience to analytical principles that dominate the given field. To further illustrate this, three aesthetically pleasing images that possess scientific meanings too are displayed. In Fig. 3a, one could see a penguin-shaped deposit of amelogenin on the surface of fluorapatite/silica glass-ceramic, showing mineral formation associated with the penguin's "heart." Aside from an aesthetic appeal of the image, it possesses an intricate scientific message too by demonstrating that the nucleation and crystal growth of apatite in the presence of amelogenin, the main protein of the developing enamel matrix, starts from the amelogenin layers deposited on top of apatite surface, thus yielding vital insights into the mechanism by which amelogenesis in vivo proceeds (Uskoković et al. 2011b). The same parallel scientific and artistic meaningfulness could be ascribed to the transmission electron micrographs in Fig. 3b-c, where one could recognize an amelogenin cloud surrounding a few apatite particles akin to a supermodel doing a catwalk (Fig. 3b) and a cheerful hailer (Fig. 3c). Aside from their aesthetic appeal, these images demonstrate thorough binding of amelogenin to apatite particles (Uskoković et al. 2011a). Finally, getting back to the similarity in the wavy navy blue pattern in



Merits of Aesthetics in Realm of Science, Fig. 3 Scanning electron micrographs of calcium phosphate nucleating from within an amelogenin layer deposited on top of a fluorapatite/glass substrate (**a**) and 100 × 100 nm transmission electron micrographs of hydroxyapatite particles suspended inside of an amelogenin matrix (**b**, **c**)

Fig. 1a and b suggests not only that aesthetic appeal can assist scientists in their research but that there are hopes that scientific tools and imagery will be increasingly utilized in future in attempts to enrich and improve the fineness of artistic expression in numerous artistic genres and schools. To illustrate the immense potentiality of the envisioned encounter of sciences and arts, a starting point could be the Arts and Technology program conceived by the Los Angeles County Museum of Art in the late 1960s, whereby pairing scientists and artists around common projects resulted in numerous productive mutual fertilizations of ideas. Half a century later, an experimental project called Great Arts for Great Science is being developed at CERN with the aim to bring scientists and artists together under its umbrella and set up a platform for enhancing mutual understanding and communication between the two, starting from the assumption that "science has an emotional impact," whereas "art micro-influences people's perceptions and ways of approaching things" (Feder 2011). The effects of one such communication were probably most striking in the case of collaboration between the Californian painter, Robert Irwin, and the NASA physicist, Ed Wortz, of which Irwin said the following: "The biggest product of the Art and Technology thing is the effect we had on each other. I radically changed Ed's life, and he radically changed mine" (Weschler 2009). Experimentation in sensory deprivation in which they engaged through this common project propelled Irwin in the direction of more profound understanding and explication of the philosophy of perception, aside from mere artistic expression, while Wortz, who until that time had virtually no interest in art, eventually left his research in physics to become a gestalt psychotherapist at Los Angeles Buddhist Meditation Center.

Conclusions and Future Directions

The metaphoric nature of all human knowledge brings together scientific and artistic expressions under the same pragmatic umbrella. To realize that reaching for love and care stands at the root of all communications, scientific and artistic alike, is to reveal aesthetic foundations of all the diverse types of human inquiry about the place our being occupies in the cosmic scheme of things. Individual branches of the tree of human knowledge are to be naturally ramified in the course of its evolution, but cultivating a sense of unity supported by that fact that all these branches sap the underground waters from a common stem presents an equally important challenge. And this common stem stands for nothing other than aspirations of love and care for the fellow earthlings and life as a whole, animate and inanimate alike. It is them that could be hypothesized to act as the fundamental wheels of scientific creativity.

Scientists should be more widely inspired to write about and recognize the metaphoric meanings of relationships and imagery present in their sciences rather than ashamedly pushing them aside and indulging in unnaturally dull presentations of their paths to discovery (Uskoković 2009a). This would help interrelate their scientific thinking with real-life observations all until a feedback between the two is established. The real-life insights could then inspire one's scientific quests and vice versa. By explicating the importance of creative qualities forged through appreciation of human arts for productive and innovative scientific conduct, as well as by enhancing the impressiveness of artistic expressions by utilizing the scientific eye to the world, many benefits for both sciences and arts could be reached. In such a way, lights on the importance of bridges that extend between more aesthetic fields of human inquiry about the nature of reality, including theology (Uskoković 2010c) and arts (Uskoković 2010a), and empirical sciences, traditionally dominated by the merits of analytical reasoning, would be shed.

The artist dormant in every human spirit tells that without great passions and wholeheartedness, strivings to grasp the physical reality and bring it on to the side of humanity, so to say, will be futile. The rational thinker, on the other hand, tells that without analytical clarity and disciplined consistency, the artistic endeavors would appear chaotic and ungraspable. What may be called for then is bringing scientists and artists of the modern day face to face and appealing on them to imitate each other, all until a balance is reached. The former, constrained by the rigid norms of logic and ratio, unable to let go and follow the voice of their heart, and the latter, carelessly, without solid bases of analytical thinking, uncontrollably flying around in their flights of fancy, would be transformed for better. By mirroring each other, scientists may end up opening their hearts and filling them up with vivid imaginations which would then be included in guiding their day-to-day professional activities and decisions in the lab. For to be a truly inspiring scientist, one needs to feed the thirst of one's philosophical and artistic senses and to constantly question the meaning of it all, alongside devoting his studying efforts to aims that surmount the narrow confines of his ego. As for the artists, this would instill analytical order and discipline into the nihilistic chaos and frequent fruitlessness of their mindsets. Needless to say, both would prosper. For art is meant to serve the purpose of glorifying both the human spirit and the world, of awakening love and wonder in human eyes, and pointing at immaculate traces of beauty that reality abounds with. In return, such feeding of creative potentials of human beings through arts and deifying the world by artistic means goes back to produce ever more wonderful scientific and technological creations which are then to ignite the artistic sense of wonder in humans in this endless feedback cycle during which human spirit enriches the world that enriches human spirit. With each spin of this wheel whereon science and arts are intimately conjoined, human spirits become ever more elated and the world ever more inspiring and fulfilling.

To sum up, the message for the stereotypical scientist of the modern times is that the qualities of bright intellect alone, without the support of the shining grace of human heart underneath, would never be able reach enduring solutions to the problems of life lying ahead. This is why, prior to engaging in any scientifically creative endeavor, it is necessary to look back first through the eyes caring to build the foundations of the embraced research approaches in the light of love and passion, and only then look forward, in the direction of the new coasts of knowledge and epistemic treasures that crave to be discovered, peeking at us gleefully from beyond the horizon. "I like the view but I enjoy sitting with my back turned to it," Gertrude Stein said once, offering a thought that neatly reflects what tedious conformists that inhabit the academic hallways of the modern day may merely see as a sympathetic quirkiness in the way of doing science of one who has held on to the hereby advocated balance between analyticity and artfulness. For with one such fanciful descent into the foundations of the eye that sees the world did this discourse begin, and the streaming of humanity toward horizons of enlightening futuristic insights and discoveries will be inevitably conditioned by the human willingness and ability to descend to the deepest foundations of experience every now and then and lightly sweep the dust of human ignorance collected over time on the antique pillars found thereon, on which the world is sustained.

Acknowledgment Transmission electron micrographs were obtained during the author's work performed at the National Center for Electron Microscopy, which is supported by the Office of Science, Office of Basic Energy Sciences of the US Department of Energy under Contract No. DE-AC02-05CH11231 (#1375).

Synonyms

Cognitive mechanism; Figure of speech; Likeness

Introduction

Contemporary theories define "metaphors" as devices that aid in structuring our thoughts. Metaphors influence how we perceive the world, classify experiences, and guide our reasoning. These tools can help *reflect*, *understand*, and *solve a problem* from new and unconventional perspectives. For these reasons, metaphors play a critical role in the "design" domain, where they not only contribute to *organize design thinking*, but also have the potential to enhance "creativity." Another characteristic is that they allow designers to think unconventionally and encourage the application of original ideas to design problems. The use of metaphors is well documented in the design literature despite not many empirical studies were carried out in order to analyze the contribution of metaphors to design and to design creativity in particular. In this entry, the relations of metaphors and design creativity, and their implications to practice and education are discussed.

The Notion of "Metaphor" in "Problem Solving" and the Generation of "New Concepts"

Metaphors

Numerous definitions have been given for *metaphor*. This notion is defined as a figure of speech where a word or phrase literally signifying one type of object or idea is used in place of another to imply a likeness between them. Metaphors allow reflecting on a *concept* by considering other concepts that are either weakly related or not related at all. Metaphors can also help comprehend an *experience* in regard to another experience. For example, the metaphor "falling into a sea of love" suggests the existence of infinite love. In language, metaphors can be recognized by the preposition "as" or the verb "is" (e.g., "each person *is* a whole world" or "a city *as* a jungle").

Metaphors are generally used as linguistic devices in daily communication (e.g., Lakoff and Johnson 1980), but can be also found in a diversity of domains such as science, engineering, art, literature, design, and education.

One of the most well-known contemporary theories of metaphor was proposed by Lakoff and Johnson (1980) and by Lakoff (1993). This theory considers metaphors as cognitive tools that enable to categorize human experiences according to a *conceptual system*. Accordingly, metaphors influence how people understand, think, perceive, and organize concepts and experiences in their minds. When a metaphor is incorporated into our conceptual system, it may change our perception of a particular situation and provide a new understanding.

Metaphors can be classified into verbal and figural:

- *Verbal metaphors* – are concerned with abstract ideas and concepts generally represented by text or speech.
- *Visual metaphors* – concepts are represented by visual displays, such as drawings and photographs, and are of particular importance for the design domain.

Metaphorical Reasoning

Metaphorical reasoning is defined as the *cognitive act* that enables a description of an object or event, real or imagined, using concepts that cannot be applied to the object or event in a conventional way. The vague nature of metaphors enables a unique type of reasoning that permits exploring unknown ideas and to establish novel relations with other unrelated ideas. Basically, metaphorical reasoning refers to the identification of previously overlooked or unnoticed *similarities* between two apparently unrelated *ideas*. In many cases, such ideas belong to different fields that are *distant* one from another, like, for example, architecture and literature. By means of metaphorical reasoning, it is possible to establish a comparison between two ideas that have some characteristics in common, but at the same time they differ in others.

Metaphors and Problem Solving

Metaphors are viewed by cognitive psychologists and linguistics as efficient *heuristics* aiding in *problem solving*. Problem solving is referred to the area of cognitive psychology that studies the thought processes involved in solving problems. As *cognitive strategies*, metaphors enable problem solvers to enlarge the universe of possible solutions, affecting the way they perceive and structure knowledge in their minds when dealing with a problem. Therefore, the power of metaphors is essential to reflect, understand, and solve a problem from new and unconventional perspectives.

The use of metaphors in problem solving is characterized by the following steps, proposed by Gentner et al. (2001):

- *Retrieval and interpretation of metaphorical concepts* – one or more unfamiliar concepts are identified and retrieved from remote metaphorical sources and are interpreted and represented through a number of principles. In this first step, potential relationships with the problem at hand are generally not obvious to the problem solver.
- *Mapping of relationships* – it consists in establishing a system of correspondences or relations between the metaphorical source and the problem at hand, enabling a novel understanding of the situation.
- *Transference of relationships* – the system of relationships obtained from a metaphorical source is transferred to the problem at hand, and a novel concept is applied and developed as a problem solution.

Metaphors are especially useful in problem-solving tasks such as design, where the production of creative solutions is a most important and critical aspect.

Metaphors and the Generation of New Concepts

Another virtue of metaphors is the generation of *innovative concepts*. The creation of novel and innovative concepts is related to how individuals *interpret* and *structure* their *experiences*. Perceiving and structuring an experience from an unfamiliar point of view can contribute to the transformation of conventional and familiar concepts and to the reinterpretation of a situation in terms of *transformed* and unfamiliar concepts. Transformed concepts are defined as extensions of old and known concepts that have been modified, and therefore they embrace new views of a known situation.

The metaphor "a city is a kind of living organism" illustrates the transformation of the traditional concept of "city." The meaning of "a kind of living organism" and its projection on the idea of "city" will very much depend on how the metaphor is interpreted and applied to the novel situation. However, the notion of living organism is not associated to any organism in particular, but instead to a group of concepts that can be subjectively related to it. Thus, the relationships established in a metaphor can be seen as the result of the transformation of concepts influenced by personal experience as well as by individual expectations.

"Design" by "Metaphor"

Design

The notion of *design* is generally referred to as a drawing or a plan created to illustrate the appearance and function of an artifact, big as a building or small as a microchip, before it is made. The *act of design* not only allows elaborating the form of an object, but also to *plan* and *direct actions* to foresee how the object will look and behave. Primarily, to design is about the manipulation of form, function, aesthetics, and materials of an artifact, and in domains such as architecture, it is also concerned with the treatment of light, space, and environment. The design of an artifact needs to satisfy goal specifications, a number of constraints, and a set of requirements. The design activity extends to a variety of areas such as industrial, engineering, architectural, graphic, and textile design.

Design Problems

A characteristic of *design problems* is that they are *ill-defined* (also called *wicked problems*), and as such they are difficult to formulate (Goel 1995). These singular problems are complex, unstructured, and undetermined. A basic difference with *well-defined* problems is that these type of problems lack:

- *Completely specified initial conditions* – when problem solving begins, the starting state of the design process is ambiguous and controversial.
- *Means for transforming initial conditions* – problems cannot be totally solved through the use of automatic operators, or by the application of algorithms since they are nonroutine, meaning that they differ from one to the other. Therefore, solving an ill-defined problem involves searching a large number of potential unique solutions.
- *Completely defined goals* – the end state, or the target be reached, is unclear and ill-specified.

Due to the nonroutine, unclear, and ambiguous nature of the design problems, it is difficult to know beforehand what type of information will lead to a successful solution. It is also difficult to know how the design outcome will look like. For all these reasons, design problems embrace the generation of *creative* and *unpredictable solutions*.

Design Process

From the late 1970s, design problem solving started to be viewed as a nonroutine and unique activity strongly based on individual experience and innovative thinking (Dorst and Cross 2001). Since then, many studies have been conducted to gain insight into the nature of the design process. A main focus was set on the individual thoughts, intentions, and goals of the designer, which are fundamental to not only structure and represent design problems, but also to guide the design process.

According to Schon (1985), the design process can be characterized by a *cyclical interaction* between the *reflective designer* and a permanently evolving design situation. In his view, the design process can be described as *reflection-in-action*, which is the result of an iterative search cycle where the designer is involved in a *reflective conversation* with the design situation. The main phases of the reflection-in-action approach are:

- Identification of relevant aspects of a design situation
- Definition and representation of the design problem according to personal interpretations and experiences of the designer
- Performing design actions to find a viable solution
- Reflecting on the design outcomes

Understanding the design process as reflection-in-action is very helpful in the early stages of the design process, where design alternatives can be manipulated and transformed as the interpretation and representation of the design problem evolves.

Using Metaphors in Design Problem Solving

Designers use different types of aids to deal with design problem solving, such as references, typologies, design principles, analogies, and metaphors. Instead of attempting to solve problems through known design solutions, the use of metaphors enables to *reflect* on the ill-defined nature of design problems from the beginning of the design process. In this way, metaphors assist in converting ill-structured design situations into *manageable problems*.

Metaphorical Reasoning and Design Creativity: Consequences for Practice and Education, Fig. 1 The Lloyds Bank building, London, 1985 by architect Richard Rogers, depicting the use of the verbal metaphor "form follows function." (**a**) Frontal view of main façade. (**b**) Lateral view of main façade

Despite designers are not always conscious of the role played by metaphors, they often use them as primary aids to:

- Clarify design ideas and organize design thinking
- Structure undetermined design situations
- Characterize, represent, and redefine designs anew
- Limit the large number of potential design solutions

However, establishing metaphorical relations with design problems is a most difficult step of the process. This is achieved through an iterative process, which develops progressively as designers become more acquainted with the design situation (Casakin 2011).

The strength of metaphor in design problem solving also resides in its vagueness and *ambiguity*, since without being anything in particular, it can be many things simultaneously. From a design perspective, ambiguity is what differentiates between:

- *Literal use of a metaphor* – an identical copy of an object that served as a metaphorical source
- *Using a metaphor through personal interpretation* – as a tool for restructuring a design situation by reflecting and elucidating on the object used as a metaphorical source

The ambiguous nature of metaphors allows to move beyond constraints imposed by conventional design, explore unfamiliar alternatives, and gain broader understanding of previously unforeseen design aspects.

The Use of Verbal and Visual Metaphors in Design

There is a vast collection of examples reporting the use of *verbal* and *visual metaphors* in the design literature. In the architectural domain, metaphors influenced entire generations of designers. For example, in his book "Complexity and Contradiction," the architect Robert Venturi refers to the verbal metaphor "less is a bore" to "promote richness and ambiguity over unity and clarity" and "contradiction and redundancy over harmony and simplicity." The Lloyds Bank building by the celebrated architect Richard Rogers illustrates the use of the verbal metaphor "form follows function." Accordingly, the external appearance of the building is the outcome of the exposition of the building's internal uses such as staircases, lifts, and pipes (see Fig. 1a, b).

Antoni Gaudi's formal explorations on fantastic organically inspired designs illustrate an example of the use of visual metaphors evoking the presence of natural patterns. His architecture transcends mere functionality to create extremely innovative motives, forms, structures, and spaces that are sensitive to a poetic view of reality. The Catalan architect incorporates into his designs principles adopted from nature, such as

Metaphorical Reasoning and Design Creativity: Consequences for Practice and Education, Fig. 2 Casa La Pedrera, Barcelona, 1905 by architect Antoni Gaudi, depicting the use of visual metaphors taken from nature such as organic forms and growing patterns. (**a**) Facade. (**b**) View from the terrace

organic curves and growth patterns, using a method technically known as organic construction. Typical examples of breathtaking creations bringing to light underlying principles behind Gaudı's designs are Park Guel and Casa La Pedrera (see Fig. 2a, b). Another example is the Heinz Galinski School by Zvi Hecker, who also became interested in organic and complex forms. Hecker uses the visual metaphor of "an open book" to design a singular learning environment represented by a series of twisted spaces organized by a radial system. The idea of an open book allowed the design of a singular school in which private irregular places surrounding a central patio open to panoramic views to the city. As a result, an unusual experience of endless and surprising smashed spaces is generated.

"Creativity" and "Design"

Creativity

Creativity refers to a fascinating and stimulating human ability that goes beyond daily and routine thinking and doing. Numerous definitions have been given for the notion of creativity, for example, the ability to restructure known concepts to make uncommon inventions. According to Csikszentmihalyi (1997), creativity is related to the ability to perceive reality from unconventional viewpoints, communicate original thoughts, explore unusual alternatives, and make valuable discoveries. Creativity is associated with unusual or statistically infrequent things that are also remarkable and valuable. This notion is also concerned with the application of cognitive processes related to *innovative problem solving* that can lead to the generation of remarkable and helpful solutions.

Assessment of Creativity

A key subject in the creativity literature deals with the problem of how creativity can be assessed. When creativity is put into practice to assess individual performance, it is typically defined by four main factors proposed by Guilford (1981):

- *Fluency*: total number of relevant responses
- *Flexibility*: different categories of relevant responses
- *Elaboration*: amount of detail in the responses
- *Originality*: statistical rarity of the responses

Self-assessment of Creativity

Self-assessment of creativity is defined as the manner that people *evaluate* their *own creativity*. In the early 1970s, a diversity of tests of creativity were conceived to assess an individual's self-perception of creativity. Studies conducted in different domains such as writing, statistics, and psychology showed that the way people assess their own creativity affect their thinking. For example, high self-assessment of creativity was shown to improve the enthusiasm and devotion to work.

Creativity in Design

Creativity is a most important characteristic of the design activity. *Design creativity* refers to the design acts necessary to produce useful but also novel and valuable outcomes. A characteristic of creative design problems is that they are nonroutine and innovative, and thus cannot be solved by retrieving prior knowledge. Design creativity refers to the exploration of unfamiliar information and the development of new ideas that conduct innovative solutions. This requires restructuring and a shift in the perception of the design problem anew.

Most research on design creativity focused on the grounding of creativity, the personality of the designer, the design process, and on the promotion of creativity, such as the development and application of models, methods and strategies for enhancing, or supporting creative design outcomes. Other studies centered on the personal motivations leading to the generation of creative acts, but only few of them centered on the assessment of design creativity (e.g., Casakin and Kreitler 2008).

Assessment of Design Creativity

In the design domain, the *assessment of design creativity* is an important but poorly acknowledged subject. In most cases, design creativity is evaluated as an all-inclusive assessment sustained by the agreement or common understanding shared by experts of the field. It is quite frequent that the evaluation of creativity in design is not based on objective parameters, or on well-defined criteria, and thus it remains biased and fuzzy. When design creativity is assessed by expert knowledge based on objective criteria, originality is seen as the most dominant factor, followed by fluency and flexibility. Elaboration, however, is considered a weak factor (Kreitler and Casakin 2009).

Self-assessment of Design Creativity

Self-assessment of design creativity refers to the way that designers *evaluate* their *own creativity*. The capability of designers to explore and find out new knowledge is assumed to depend to a large extent on the manner they perceive and assess their own designs. However, the validity of self-perceived creativity as a measure of design creativity depends on how their understanding of the design process is affected by their:

- Knowledge
- Skills
- Experiences
- Emotions
- Attitudes
- Goals
- Motivations

Despite some have questioned the validity of self-assessment of creativity, learning from self-assessment has important implications for design practice and design education. Understanding the manner that designers, and design students in particular, assess their own designs plays a crucial role in knowing how to support and assist them through the process.

"Metaphors" and "Design Creativity": The "Design Studio"

Metaphors and Creative Design

Metaphors are ideal to support and enhance *design creativity*. One of the reasons is that creative design is characterized by the exploration of a vast number of alternatives, most of which extend besides known and familiar solutions. Another reason is that metaphors help enhance creativity by encouraging reflection on design problems anew (Schon 1985).

Metaphorical reasoning also enables stressing some aspects of the design problem while momentarily ignoring specific constraints that can be detrimental to develop design creativity. The use of metaphors allows designers to think *unconventionally* as they support the application of new ideas to familiar design problems. Changing from one metaphor to another strongly affects how designers understand and represent a design situation. Therefore, different metaphors can potentially lead to a large number of diverse and creative problem redefinitions. Interpreting and representing a problem through the use of metaphors contributes to a more prolific exploration of innovative and creative candidate design solutions.

Creative Design and the Design Studio

The acquisition and development of theoretical and practical professional knowledge is a major aim of *educational programs* in departments of design. A large part of the educational process takes place in the *design studio*. The design studio is defined as the most important educational environment where students acquire skills, integrate theoretical with practical knowledge, while they enhance their expertise and competence, and develop their judgment progressively. The design studio is also the place where students imagine, plan, and develop innovative artifacts. It is in this educational environment where the use of metaphors can contribute to enhance the creativity of the students.

The Design Studio Pedagogy and Creativity

The traditional *design studio pedagogy* is based on two main *educational approaches* dealing with:

- *Learning-by-doing* – refers to the transference of experience from teachers to students, mainly in a *listening* and *doing* way. During "one-to-one" training sessions, students develop their designs in a *trial-and-error* manner, while teachers criticize the projects and make recommendations to improve their achievements. A main shortage of this educational approach resides on the dependency established by the students with their teachers, in particular at the beginning of the career, which can be detrimental to the development of individual design creativity.
- *Precedent-based reasoning* – in this educational method, students are exposed to a collection of selected *projects*, such as artifacts and buildings designed by master designers that are in some ways similar to the design problem at hand. Through this pedagogical approach, students learn a series of design issues that are supposed to help them deal with the problem. However, a disadvantage of this approach is the frequent lack of capacity and skills to identify and retrieve critical knowledge from the design examples and transfer it to the design situation. Thus, most cases, students blindly copy existing projects, resulting in uncreative design outcomes.

Despite the shortages and disadvantages of the above educational approaches, they are fully adopted in most design studios around the world.

Metaphors in the Design Studio and Their Contribution to Creativity

The use of metaphors in the design studio constitutes an *alternative pedagogical approach* to the traditional design studio methodologies (Casakin 2011). Metaphors are proposed as an unconventional educational method that helps students develop their project according to their own views and beliefs. An advantage of this approach is that it sensibly reduces dependence ties established with studio teachers and the inability to deal with imposed design precedents.

The use of metaphors in the studio showed to have a positive effect on promoting creativity with regard to three main components:

- *The design student* – endows with meaningful personal experiences to improve their learning and creative skills
- *The design process* – contributes to identification of design goals, clarification and definition of design situations, exploration of remote domains not associated with the design problem, and restructuring design situations from scratch, a stage considered critical in creative design problem solving
- *The design outcome* – enhances originality, innovation, and elaboration of the design product

Conclusions and Future Directions

Metaphors were showed to be powerful cognitive strategies that assist in problem-solving tasks demanding creative skills such as design. Metaphors affect how designers reflect, understand, and solve a problem from novel viewpoints. Perceiving a design situation from unfamiliar perspectives can contribute to the restructuring of design thinking, which is particularly helpful in the early stages of the process.

The use of metaphors has important implications for both design practice and design education. The application of these tools in real practice can contribute to think unconventionally and avoid or reduce reutilizing familiar design schemas and existing solutions. The variety of concepts retrieved from different metaphors can guide the designer to a large number of problem interpretations and eventually to generate more innovative design products. Besides this, metaphors showed to play an important role in the design studio and to enhance the creativity of students. Future intervention programs should consider the adoption of metaphor use in the design studio as a genuine alternative to existing pedagogical approaches.

Method for Creating Wisdom from Knowledge

Michihiko Esaki
Wisdom Management Research, DTCN International Incorporation, Gifu City, Japan

Synonyms

Abductive, deductive, and inductive thinking; Bridging knowledge management to wisdom management; Creative thinking; Decision making and judgment; Optimization; Problem solving by wisdom; Project management; Research and development; Wisdom management methodology

Background of Methodology

To think, take action, and get results in a complex problem and task realization, it is necessary to know where to start and what is the end result.

The "Method for Creating Wisdom from Knowledge" published in 2009 is the most comprehensive and universal method in the world at present (2013).

The development of this methodology started with the writing of the Japanese paper "A Method of Decision Making for Management" using information of difference in 1976 and the English version in 1977 for the 4th International Conference on Production Research (Tokyo, Japan). Since then, there have been many applications leading up to its full development.

For example, in 1979 and 1985, it was successful in the creation of the Design to Cost procedure http://dtcn-wisdom.jp/1979-Design-to-cost-procedure-WashDC.pdf which led to the further development of the Method for Changing Knowledge to Wisdom (1999–2010). As a result, the English version of the Method for Creating Wisdom from Knowledge was presented in 2010. The entire contents of this methodology has been put on the public domain from September 2011 (http://dtcn-wisdom.jp/00001-E-wisdom%20book.pdf) and can be utilized by anyone around the world in order to "Save the Earth, create and satisfy customers."

The entire contents include Problem solving by wisdom, Method for creating wisdom for task realization, and Wisdom Management Methodology.

Each method can be downloaded from: http://dtcn-wisdom.jp/00001-E-problem-solving.pdf http://dtcn-wisdom.jp/00001-E-wisdom%20book.pdf http://dtcn-wisdom.jp/00001-E-wisdom-managent.pdf

The "Method for Creating Wisdom from Knowledge" consists of the componential method stage, way of thinking, and the elements of methods, as shown in Fig. 1.

Explanation 1: Relationship of the Purpose and Measure

The starting stage is ⓪, which is the stage in chaos (Fig. 1). This is the Measure.

The upper most purpose is to realize "Save the earth, create customers, and satisfy customers" as shown in ①. The upper first level purpose is "to get results of the upper level purpose, i.e., customers' satisfaction and safety"②.

The upper second level purpose is "to secure the minimum profit required for the above-mentioned purpose including risk cost" ③.

In order to do the above, it is necessary to have the mindset of ④ and ⑤ and the component method of ⑥ to ⑭ in Fig. 1. Figure 1 must be read from top to down while repeating, "in order to do XX, it is necessary to do YY."

Explanation 2: Explanation of Each Mindset of the Components and Methods

④ Decision mechanism by information of difference.

⑤ Exact usage of the questions: "In order to do what, how to go about doing it" and "Why,"

i.e., "In order to do . . ., how to do . . .?" This question is directed to the future and creates wisdom (for the future). However, the question "Why?" arrives at a dead end (refer to above URLs).

⑥ Switch "Problems" to "Tasks," but when it is a task to begin with, do not make the switch.

In the case of problem solving, the first step is to think about the cause of the problem. However, in the case of the task, the first step is to think about the purpose or upper purpose of the task.

To combine this thinking style, it is necessary to switch "Problems" to "Tasks," but when it is a task to begin with, do not make the switch.

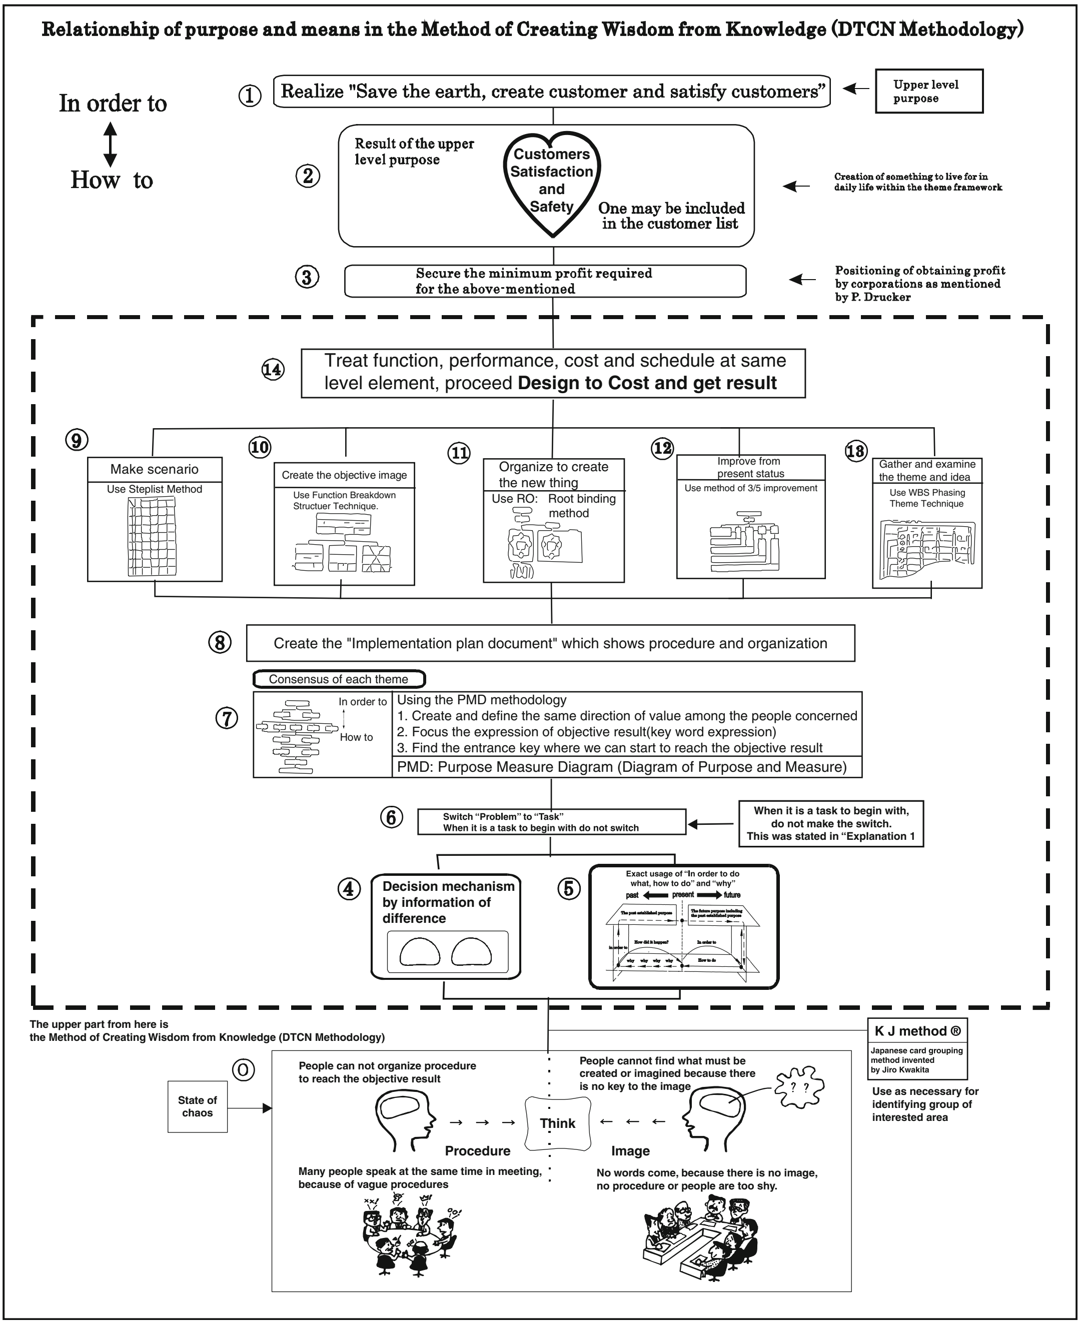
⑦ Use the PMD (Purpose Measure Diagram) method to grasp the Direction of Will and the "Main Keyword," for decision making and judgment under the mechanism of theory of decision and judgment mechanism using information of difference (presented in Japanese in 1976 and in English in 1977).

This method can effectively be used for abduction (hypothesis) and deduction thinking simultaneously by having the direction of Will and its "Main Keyword" for success.

⑧ Create the implementation plan document to effectively use the component methods of ⑨, ⑩, ⑪, ⑫, ⑬, ⑭.

⑨ Use the Steplist method to create a faultless inductive/deductive approach thinking and actions for each phased procedure of thinking, actions, decision, and judgment.

This model comes from the Japanese rice cooking process for tasty eating catered to the customers' requirements. This model also includes well-controlled quality assurance and quality



Method for Creating Wisdom from Knowledge, Fig. 1 The relationship of the Purpose Measure component in the Method for Creating Wisdom from Knowledge which can lead to the Wisdom Management Methodology

management mechanisms. This is referred to as exact and faultless phased project management procedures.

⑩ Use FBS (function Breakdown Structure) technique for creating structure of things or systems and their operations. This method integrates and creates effective and efficient structured Things and System WBS (Work Breakdown Structure) and their operation.

Method for Creating Wisdom from Knowledge, Table 1 Relationship of Knowledge, Will, Wisdom, and "New Knowledge by result of wisdom" Michihiko Esaki 2000/9/17、Rev4 2011-3-17. (Note) An introductory chapter to the Method for Creating Knowledge from Wisdom can be found at http://dtcn-wisdom.jp/00001-R3E1.pdf

Have Knowledge of "Knowledge to Wisdom"	Feed back	1	Have Knowledge: If one has the knowledge of the Method for Creating Wisdom from Knowledge, whether consciously or unconsciously, people can proceed to action rows 2 to 4 faultlessly.		Have Knowledge indicates having the following 2 information: 1. Have information on cause-effect relationship. To have knowledge means that if something is done, a certain result can be expected (For example, having knowledge that if the light switch is turned on, the light bulb will shine.) 2. Have information on the existence. Information on the existence of 'things' or 'information'. (ex.1) Information that a building exists somewhere. (ex.2) Information that the following "Information on wisdom" exists	Method of acquiring knowledge	Have knowledge through experience	Experience gained through experience, have sensory knowledge. (ex.) To know how to ride a bicycle. (characteristics) To unconsciously know the cause-effect relationship.
							Have knowledge through studying.	To have knowledge in the narrow sense obtained through reading and hearing.
							To Analyze http://dtcn-wisdom.jp/00001-E-analysis.pdf	For things that have already occurred, clarify ① what are the Will (of people, nature's laws or Will), ② what is the input and output relationship and ③ whether the results have come out.
		2	Have Will	A	Have wants, needs and seeds	Wants means to have the desire or wish to do something. Needs means to have the demand to want something that is realizable. Seeds indicates having the seed or means that a thing can be used for something. Having one or more of these things is acceptable.		
				B	Organizing the Will (Organize in the Direction of Will and the Main Keyword).	In order to realize any one or the combination of the above wants, needs and seeds one will have to grasp the Main Keyword and the Entrance Keyword, which will realize the Main Keyword and show where to start, by asking oneself "In brief, how to do it?", "In brief, to do what?" (The PMD (Purpose Measure Diagram) is very effective in organizing this. In addition, by grasping the Main and Entrance Keywords, the mechanism of decision making and judgment through Information of Difference will be able to be used to realize it.)		
		3	Have Wisdom	A	Have procedure in order to realize the following	1. Based on 1., information relating to a "Faultless Phased procedure", which shows how to realize the desired results, will be created. (example) Information relating to a Faultless-Phased procedure such as "In order to brighten a dark room, a lighter will be used to find the light switch on the wall so that it may be turned on." (The Steplist method is very effective in creating this procedure.)		
				B	Have the structural component of things or systems of the desired results	2. Information concerning the mechanism and components of 'things or systems' are created so that one may understand what 'things or systems' are needed in order to realize it. (ex.) Information relating to the mechanism of things need to be on hand or must be created so that one may know what kind of reinforcements are necessary to design a house capable of withstanding an earthquake with a magnitude of 7. (The FBS (Function Breakdown Structure) method is very effective in creating an optimized structural component.)		
		4	Have new knowledge as a result of using wisdom			By being able to explain to others the above wisdom, this wisdom then changes into 'new knowledge'. Then, it can be passed on to others as knowledge.		

By returning the result which has the new information of 4. back to "Have knowledge" of 1., it can be used to create new wisdom by the newly created "Wisdom Engine"

⑪ Use the RO (Root Organizing) method to organize new things and systems in conventional organizations.

⑫ Use the 3–5 improvement method for defining the temporary, middle, and final stages.

⑬ Use the WBS phasing theme technique to "pick up" the theme/idea for all lifecycle stages to prevent undesirable results in operation.

⑭ If you want to proceed with the Design To Cost procedure, you can proceed by using the above-mentioned methodology which has the cost and schedule elements in it.

Explanation 2: How to Proceed with Wisdom Management

1. Add the knowledge of Method for Creating Wisdom from Knowledge to conventional knowledge or management knowledge. Then, it will be in the wisdom management domain.
2. In order to have wisdom, it is only necessary to have the direction of Will and the Main Keyword to accomplish it.
3. In order to have the direction of Will and the Main Keyword in it, it is necessary to use the PMD (Purpose Measure Diagram) method which shows the direction of Will and Main Keyword (Fig. 1, ⑦).
4. The PMD is created with cards using Verb and Noun expressions with minimum adverbs and/or adjectives. These expressions will answer what is going to be done and what is necessary to be done under the Task or theme/subject in the order of "In order to do . . ., how to do . . ." This sequence will be repeated from top to down on paper in visible form. Thus, these expressions can be adjusted on paper in visible form among the people concerned for task realization.
5. For example, Knowledge consists of the following:
   (a) Information of the existence of things.
   (b) The process, i.e., if we drop a glass as a process, we shall have broken glass with sharp edges as the result. This is knowledge.
6. If we want to have broken glass with sharp edges, this is Will.

In order to realize the Will, it is necessary to drop the glass from a sufficient height for the process. We will get broken glass with sharp edges as the result. This is wisdom.

Explanation 3: How to Attain the Complete Wisdom Management Cycle

Have Knowledge as shown in Table 1 and use it effectively for the purpose of wisdom management.

Conclusion and Future Directions

As problem solving becomes a part of task realization, finding the solution can be simplified. This methodology also clarifies one's upper purpose (ulterior motives included) and constrains one to implement plans honestly or in light of others' monitoring. The uppermost purpose of this methodology should always be to give all people stability and safety and/or to save the Earth. I hope that in the future, the knowledge of this methodology will be taught to students before entering society in order to contribute to world peace.

(Note) This wisdom from knowledge methodology basically comes from my oldest article and book found in Reference Esaki, (1977a), (1977b), Esaki (1979) New Thinking and Procedure of Design-to-Cost by Steplist Management Thinking, 1979 Washington, D.C., and Esaki (2002) Advanced project management methodology with the method for changing knowledge to wisdom in wisdom management era.

Microcredit

Introduction

Microfinance is the provision of financial services to the poor and the financially excluded. These financial services include credit, savings, insurance, remittances, and guarantees, among others. As a result, an associated vocabulary includes microcredit, microsavings, microinsurance, microremittances, and microguarantees.

The major common problem of providing all these services to the poor is that the transaction size is very small. As a result, any processing cost, or transaction cost, becomes a high percentage of the transaction amount. This makes the product very expensive for commercial banks and formal financial institutions to provide these services to the poor, who, therefore, remain excluded. A second common problem is that the poor lack not only financial capital but are often socially excluded and lack bridges to rich people. A third common problem is that they are often uneducated, even illiterate, and excluded from technological innovations.

To solve these problems, microfinance institutions (MFIs) have created social innovations which permit them to offer financial products which were not viable commercially (Armendàriz and Morduch 2010; Couchoro 2011). Seeing the success of MFIs, commercial financial institutions are also downscaling to profit from the vast market at the bottom of the pyramid. All of these are trying to use advanced technologies such as management information systems, mobile banking, and online financing to increase their outreach (Ashta 2011).

One possible solution for the poor to rise from poverty is to become microentrepreneurs and take charge of their own fate.

Although microfinance can include personal finance as well as entrepreneurial finance, in this entry we will restrict ourselves to features of microfinance impacting entrepreneurship. We will focus largely on microcredit because it is the most developed form of microfinance, but today, it is being increasingly realized that other financial products are more necessary for the poor than microcredit.

Microcredit and Entrepreneurship

What Is Microcredit?

In underdeveloped countries, the vast majority of the population has no access to the banking system, whether in rural or in urban areas. The absence of appropriate formal financial services had long led the people to the informal financial sector. At best, they use Rotating Savings and Credit Associations (ROSCAs), a traditional practice of mobilizing savings, brilliant but sometimes very risky (and reserved for the middle class, the one having the capacity to save), and at worst, they are entrenched with the usurious moneylender, with very prohibitive interest rates. In the 1990s, it was estimated that 90% of adult African population was excluded from financial services compared to 85% for Brazil (Gentil and Servet 2002).

Microcredit is an innovative strategy which aims to fight effectively against credit exclusion. It aims towards a minimal equality in the access to credit by allowing people excluded from the traditional financial system to take loans for creating their own jobs. It can be defined as any loan initiative intended to create income-generating activities, focused on microentrepreneurs with no access to traditional bank lending. It aims to fight against poverty.

The Microfinance Information eXchange (MIX) 2010 statistics show that gross loans portfolio and the average loan are different from one region to another (Table 1).

Owing to low transaction sizes, and because of the relatively high processing costs, the microfinance institutions (MFI) apply an interest rate generally higher than that of the banking sector. Regulators do try, in some countries, to control this, but the ceiling varies over time. For example, in the particular case of countries of the West African Monetary Zone (Couchoro 2010) with centralised laws on usury for all financial institutions operating in the area, "a usury ceiling" not exceeding twice the discount rate of the central bank (i.e., 17% per year) was initially decreed. The MFIs have since obtained a waiver; the central bank has revised the law on usury. Today, there are two ceilings: one for commercial banks (18%) and the other for MFIs (27%).

Microfinance and Entrepreneurship, Table 1 Microcredit institutions loans statistics

Regions	Gross loan portfolio (billions of $)	Average loan ($)
Africa	4.6	371.9
Latin America and the Caribbean	22.9	1,024.4
South Asia	8.4	144.0
East Asia and the Pacific	21.2	305.6
Eastern Europe and Central Asia	8.3	1,687.8

Evolution of Microcredit

Microcredit is staged today as a global movement, part of a globalization process, and is considered as an excellent indicator of economic, social, and cultural opportunities, "an important lever for change, contributing to local development . . ." (Gentil and Servet 2002).

The number of customers has more than doubled from 2003 to 2011 (Table 2). Table 3 provides the geographical distribution of microfinance.

Microcredit Model

Microcredit consists generally of short-term loans with repayments that occur as soon as the loan is disbursed. Repayment is either weekly or monthly.

In order to reduce default risk and to avoid excluding candidates to credit, microcredit program sets up an innovative mechanism in the financial world: group lending based on joint guarantee. Apart from group lending, there are other mechanisms such as progressive lending, local management, compulsory savings, and training in the management of income-generating activities. Group lending consists of granting credit to a group whose members are chosen freely and are responsible for the repayment of all the loans to the group. If one member fails, the

others are forced her to honor the commitment; otherwise, they are the ones who pay back in her place. Progressive lending is to provide credit in tranches whose amount increases as the previous loan tranches are repaid. Future loans are provided only if the previous loan has been repaid.

Microcredit and Entrepreneurial Opportunities

Development actors want to show the potential of poor people to take entrepreneurial initiatives. Through microcredit, they want to highlight the ability of the poor to create their own business, doing their own jobs, if they are freed from the constraint of self-financing their projects. Microcredit is for the masses excluded from the conventional financial system, sometimes subject to the whims of suppliers and the dependence on moneylenders, with a hope to enable them to develop a wide range of productive activities, thus generating income, and in turn, improve their living conditions and social status.

Microcredit is characterized by a strategy based primarily on a participatory process. This process requires the active involvement of all actors in society, especially the borrowers, towards the objectives of fighting against poverty. Through this approach, the poor will find the opportunity to influence policies that affect their lives. The philosophy of microcredit is that the beneficiaries should not be passive actors in the fight against poverty (which makes them assisted) but rather active actors, responsible for improving their living conditions. Undoubtedly, it has the characteristics of participation and empowerment that are radically different from assistantship.

However, the scope of microcredit is limited to the ability of beneficiaries to enhance the resources that are available to them. Microcredit should not give the impression that everyone is able to create, manage, and develop her own business.

Other Microfinance Products and Entrepreneurship

Microsavings and Entrepreneurship

"Saving is where financial services begin and end" (Rutherford 2001). Microsavings are the small amounts of money saved by poor people with financial institutions, mostly microfinance institutions (MFIs). They serve two main purposes. Firstly, they provide a source of lump-sum cash in case of future events, that is, emergencies, start-up business capital, and major life cycle events, and secondly, they support daily consumption needs of the poor people (Mersland and Eggen 2007).

MFIs have the development objective of employment creation to facilitate growth of enterprises along with poverty reduction. As financial service providers, MFIs on one hand provide loans to accelerate growth of existing enterprises and facilitate creation of new enterprises while, on the other hand, give the entrepreneurs access to secure places for savings. Among the poorest of the poor, the most important element of microfinance is not lending but providing savings opportunities (Collins et al. 2010). Such savings can be quite useful in the lives of the poor people, as once a large amount is accumulated together, this can finance acquisition of assets, construction of houses, and more importantly starting up community-based enterprises.

Stuart Rutherford (1999) describes three basic ways people can covert a flow of savings into a lump sum: “saving up,” “saving down,” and “saving through.” Saving up is mentioned as small accumulation of money till it reaches a lump sum; saving down refers to loans, where people save in the form of making the repayments of the loans; and savings through is either through insurance or some other group based system where the poor people may get access to a lump sum at the time it is needed through a series of small savings. All three systems are important to promote entrepreneurial activities as financing the entrepreneurship needs of the poor clients is on the top of the list of financial services provided by MFIs, as this smoothens the client’s income, thus help building a sustainable livelihood (Tavanti 2010).

Empirical evidence also suggests that poor people use saving products more than they use credit. Opportunity International Bank of Malawi has 45,000 borrowers and 250,000 savers, Equity Bank in Kenya has 715,000 borrowers and 4 million depositors, and Grameen Bank has over $1.4 billion in deposits, which is 145% of its outstanding loan portfolio of $965 million (Maes and Reed 2012). In a study on Bangladesh, it is found that there are 27.8 million depositors and about 20.6 million borrowers in a sample of 28 MFIs and that 26 of these 28 Bangladeshi MFIs have more depositors than borrowers (Khan and Ashta 2012). The excessive use of microcredit may have led to overleveraged microenterprises and perhaps suicides by microentrepreneurs owing to the creation of stress in the relationship between the credit agent who needs to show a 100% recovery and the borrower who cannot always ensure this (Ashta et al. 2011). It was suggested that microsavings may be one way to balance the relationship between the MFI and the borrower so that the agent is not only giving loans to the client but also receiving deposits from him and cannot therefore alienate him.

Microequity

Another way to balance the stress of over-leveraged entrepreneurs would be to use microequity which lowers downside risk (Ashta et al. 2012).

Although individual microequity is difficult to document, because it often hides in the informal love money market, there are isolated movements which indicate that microangels exist and that they often band together in clubs to provide both equity and advice to small enterprises. In France, for example, since 1983, these microangels have been getting together and forming clubs called CIGALES in which each contributes between 7.50 Euros per month to 450 Euros per month depending on how micro he or she is. Once the combined savings of the club is large enough, they finance projects which require equity of as little as 1,000 Euros to projects where many clubs may get together to invest 25,000 Euros.

They believe in proximity and provide advice and mentoring to the entrepreneur. However, if the mentor is unable to answer the question, he uses the combined human capital of the entire club to get an answer. And if they cannot, the members use their network to find people who can help the entrepreneurs. Finally, once a CIGALES club is associated with a project, a strong signal is given to other financiers, including banks, that the project is good, and therefore loans also come in where otherwise bankers feared to tread.

Microequity takes away the downside risk of putting their money in the risky enterprise since the microangels will not ask for money back if the enterprise is a failure, and it thus removes downside risk and the effect of loss aversion (Quattlebaum 1988; Tversky and Kahneman 1991; Ashta and Otto 2011).

Microinsurance and Entrepreneurship

The first noted search for microinsurance is a paper by Dror and Jacquier (1999). However, insurance for the poor as mutual protection was the foundation of many insurance countries in the nineteenth century (Churchill 2007). A notable publication is an edited publication by Churchill (2006).

Microinsurance is insurance for the poor which is characterized by low premiums and low caps. Microinsurance may be either directly related to entrepreneurship or indirectly related.

Examples of direct relationship with entrepreneurship include property risks such as crop insurance, cattle/livestock insurance, theft/fire insurance, and insurance for natural disasters. The reasoning is that when a farmer has insurance against downside risk, he is inclined to be more risk seeking which can pull him out of poverty. For example, if he is insured against crop failure, he can use innovative cropping strategies which may have higher yields.

Examples of indirect relationship with entrepreneurship include health and accident insurance (illness, injury, disabilities). Often, if a poor entrepreneur falls ill, he is unable to work and repay loans. As a result, his business collapses. If health insurance kicks in, he is able to survive during this critical period and continue repaying his loans. Research suggests that households that are insured against hospitalization and accidental death have less diversified income portfolios (Kwon 2010). This focus on a core business may improve profits.

No centralized agency maintains public access documents for microinsurance. A survey in Africa (Matul et al. 2009) estimated that there were 14.7 million poor people insured in Africa, 56% of who are in South Africa. The most used insurance product was credit life insurance, that is, an insurance which repays the debt if the insured dies.

Microinsurance may be delivered directly by insurance companies, but is often packaged in ways by which it can be delivered by microfinance institutions, which are directly in contact with microborrowers. Some microinsurance programs are community-based mutualization of risk but suffer from low coverage.

Two preconditions for commercial microinsurance firms to successfully sell directly to the poor are to understand how the poor are different and have different needs and to educate the poor on the use of insurance (Churchill 2007).

A study of 600 MFIs indicated that MFIs' willingness to offer microinsurance is positively correlated to a rise in the financial expense ratio, loan repayments in arrears, years of operation, number of borrowers, woman borrower ratio, life insurance penetration ratio, and family size. In contrast, it is negatively correlated with their loan asset ratio, bad loan write-off ratio or average loan size in comparison to GNI per capita (Kwon 2010).

Microremittances and Entrepreneurship

Human beings migrate since the beginning of civilization. People migrate for food and security, searching better employment opportunities, and income security. Today, migration does not take place only to change the destiny of the migrating people but also to improve the livelihood conditions of families staying back in the home countries. This is done through remittances, which channel the migrants' income. In 2005, the worldwide officially recorded remittances were US $ 232 billion. Of this, the developing countries received US$167 billion, which was more than twice the level of development aid from all sources (Global Economic Prospects 2006).

Remittance is the surplus portion of earnings sent back by the expatriate community from the country of employment to the home country. Over the years, remittance has emerged as an important source of external development finance (Hasan 2006). Remittance has significant impact at household level. This impact of remittances partially depends on the characteristics of the migrants and the recipients, that is, whether they constitute the rural poor, or the more educated sectors of the population generally residing in urban areas (Hasan 2006).

Remittances are cited as making up around 60–70% of recipient poor households' total income (De Bruyn and Kuddus 2005). Investment in health and education is valuable for long-term economic growth and poverty reduction. Studies have found that migrant families invested more in these areas (Murshid et al. 2002). While such investment works as indirect contributor towards developing entrepreneurial skill, remittance acts as an enabler to develop human capital as well as direct investment in enterprise. The money sent by migrants to their families facilitates investment in both productive and consumption goods, which otherwise would not have been possible due the nature of large cash involvement in such initiatives (Yang 2008).

Microguarantees and Entrepreneurship

In developed countries, mutual guarantee associations or government-backed public institutions guarantee part of banks' loans to entrepreneurs (De Gobbi 2003). This reassures the bank because often entrepreneurs are able to pay back a large part of the loan, even if they are not successful in total reimbursement. The European Association of Mutual Guarantee Societies has 34 members providing guarantees for 1.9 million small and medium enterprises (Source: aecm.org, 2009 statistics). However, although such guaranteeing institutions are cropping up in developing countries, they do not have the required outreach among the poor.

Guarantees are closely related to microcredit. Part of the reason microentrepreneurs, especially poor ones, are not able to get loans is that they do not have collateral. Microfinance has used social solidarity guarantees to overcome this problem: if one of the borrowers cannot pay, someone else from the group would not get a loan or someone else from the group must pay (De Gobbi 2003).

Of course, microentrepreneurs can also get guarantees from people who do have collateral. But very often, poor people lack the bridging social capital to meet richer people who would be willing to put their assets at risk for helping out the poor.

Today, thanks to technology, we see the development of websites such as UnitedProsperity.org which take cash from someone in a rich country which then serves as cash collateral for a bank loan to a MFI in a poor country and from the MFI to a poor entrepreneur, thus extending the ability of the MFI to give loans to poor people.

Conclusion/Future Directions

Microfinance is both evolving as a social institution as well as utilizing new technologies such as cloud computing information systems, mobile banking, and online financing of microfinance institutions for the development of its outreach (Ashta 2011). Many of the financial services being targeted to the poor, including microsavings, microinsurance, remittances, and transfer payments from the government to the poor payments, are based on innovative institutional creation. All of these represent areas for future research.

Microfirms

Michel Marchesnay
ERFI, Université de Montpellier, Montpelier, France

Synonyms

Angels investors; Craft trade; Craftsmanship; Cyber entrepreneurship; Developing countries; Entrepreneur; Female entrepreneur; Incubators; National culture; Networks; Proximity; Self entrepreneurship; Services; Small business; Small business firms; Smaller firms; Social entrepreneurship; Social responsibility; SOHO; Start-up

The word "microfirm" is both a recent neologism and a generic concept. It refers to the so-called smallest business firms, that is, those tiny size firms theoretically governed (managed and/or owned) by one person. However, the *world* of microfirms reveals itself to be highly heterogeneous. As well as the small shops or stalls in African markets, it comprises also highly skilled "SOHOs" (small organization, home office) working at a worldwide level!

In spite of the fact that microfirms are undoubtedly the most numerous of business entities in the world, they are mostly ignored by economic theories. The "entrepreneurship wave," since the last quarter of the twentieth century, is primarily based on the start-up of very small businesses (one or two people), mostly in craft or services activities, from low-tech to high-tech businesses. Moreover, the recent interest in "sustainable development" has underlined the socioeconomic and even political impact of "eco-entrepreneurial" microfirms.

Contrary to their organizational simplicity, researchers have found extreme complexity in both internal and external relationships of microfirms. Thus, more than with the general model, and following P-A Julien (1998), they suggest a list of criteria, leading to a pragmatic classification. The main criteria are the following ones:

- Registered or not
- Number and kind of employees (family, community, salaried)
- Activity sector
- Working at home or not
- Tangible and intangible assets or not
- Identity of the entrepreneur: age, gender, community membership, level of education and training, goals, and vision

Obviously, the turnover and the number of employees is the most frequently inaccurate. However, empirical studies suggest a "ceiling" of seven people, showing that beyond that size, organizational problems, specific to bigger firms (task differentiation and individual integration), arise (Pearson et al. 2006).

By combining the two famous definitions of the entrepreneur, respectively, by Richard Cantillon (mid-eighteenth century) and Frank Knight (mid-twentieth century), the entrepreneur, viewed as an ideal type, may be loosely defined as "everybody earning an uncertain income in a risky business" (Schumpeter 1952). Thus, it logically includes, according Mark Casson's opinion (1982), "immoral" activities, as seen below.

Nowadays, entrepreneurship research is faced with two contrasting figures of the "microentrepreneur." The first one will be specified as the microentrepreneur "by force," suffering from a low or mediocre social legitimacy and economic competitiveness. The second one will be entitled microentrepreneur "by choice," based on the search for both higher social status and economic performance.

The Microfirms "By Force"

"By force" means that those people are more or less constrained to adopt the status of entrepreneur, as defined supra. They would generally have preferred to be recruited, ever as salaried workers, possibly in a big concern, or as civil servants. However, it matters to make a sharp distinction between the "poor workers," proletarian, and the "supported entrepreneurs," pertaining to the lower class. The status of "craft entrepreneur" may be seen as a way to have access to the middle class.

1. *Survival microentrepreneurs* are poor, with unstable jobs. Their business is unregistered and too often located in the underground economy, precarious, unsafe, and risky businesses, including criminal activities (such as illegal drug dealers). They earn a low revenue, just enough to survive and help their family. Those proletarian microentrepreneurs proliferate in megalopolis (illegal immigration). In spite of their contribution to their own family, and even of some prestige among their native community, they suffer from a far lower social status. Moreover, as shown in the cast system, in many underdeveloped countries, the poorest are often debtors vis à vis usurers, actually working in a kind of slavery.

A Case of a "Survival Microentrepreneur"

Mohamed sells illegally smuggled cigarettes on the street, in a "tough neighborhood" (Barbès) located on the Paris East Side. Born in Algeria, unemployed, he decided to come illegally to France. He sells each packet for 3 euros, and earns around 400 euros per month. He says that "it is not a 'genius' for work, but I searched for a job on the markets, on the construction sites, but nothing!" To one passerby, he whispers, "Marlboro, Marlboro. . ." and concludes the deal. An accomplice comes to pick up the carton hidden in an iron column of the elevated railway. "Today, it's OK, but sometimes I sell nothing all the day."

2. *Supported microentrepreneurs* aim to get a higher rank in the social hierarchy and to benefit from a higher legitimacy. During the early 1960s, the Johnson administration undertook a program, called "The New Frontier," designed to help minorities and poor communities. Consequently, the SBA (Small Business Act) started, in charge of the promotion and learning of start-up microfirms. During the 1970s, the worldwide rise of unemployment, mainly due to the manufacturing crisis, entailed an enlargement of the entrepreneurship programs to the whole set of unemployed peoples, firstly in the Northern America, and secondly in Europe (e.g., the European Small Business Act, voted by the European Parliament). Today, a lot of public, associative, and private organizations offer a large span of free and paid supports.

The Case of "Self-Employed" Entrepreneurs

Governments, in developed countries, promote the so-called self-entrepreneurship by offering tax exemptions and easier registration. They intend to support part-time workers and retired people and to induce them to earn a (legally) complementary income by undertaking registered "small jobs." For instance, one retired person explains that "his pension being insufficient, he earns around 400 euros per month with home activities of repairing, assembling, masonry, tiling, and so on." Another one (an ex-cook) says he "earns 20 euros per hour doing plumbing and electrical work." A third one explains that he cannot decently live with a pension of 1,000 euros per month, and, consequently, put advertisements in the local newspapers ("Retired, well equipped, can do small jobs in your home or garden for 15 euros/hour"). However, a lot of registered "self-employed entrepreneurs" declare no annual revenue (two thirds or around five hundred thousand registered "auto-entrepreneurs" in France).

During the last decades of the twentieth century, such supporting programs for the "disabled" or communities expanded to underdeveloped countries or areas. These programs are mostly administered by nongovernmental organizations, mostly depending on the various programs of the Organization of the United Nations or the World Bank. Besides these official incentives, there are also private ones, supported by foundations and sponsorship, for example, Bill Gates and DANONE, who promote "supported microfirms."

The Case of Grameen Bank

The Grameen Bank experiment with microcredit for the poorest people in Bangladesh, undertaken by the Nobel Peace Prize winner, Muhammad Yunus, is the best known case of this kind of support. Pr. Yunus thought indeed that the multilateral institutions "are unable to understand that the poor may be entrepreneurs and create employment." The Grameen Bank lends money for inexpensive investments (a sew machine, a bike, tools, etc.) at a low interest rate (compared to the practiced loan sharks in underdeveloped countries). Furthermore, the Grameen Bank has enlarged its credit loans to all types of small businesses and to other countries (India, etc.). It must be noted that the rate of payback by entrepreneurs (primarily women) was very high, until the last years. However, the Grameen Bank and Yunus recently encountered troubles from their government and critics in the media, partly due to the ambiguity between the initial "social business" and the current more classical "banking business."

3. *Community microfirms* are supported by a group of people, linked by ethnic values, issued from, or living in the same territory (ISBJ 2011). For instance, the community, or the "enlarged family," will help a teenager to acquire some experience in a given activity, knowing that, most often, each community is specialized in a given activity (ethnic restaurant or café owner, mason, grocer, etc.). Similarly, the "tontine" system aims to allow and dispatch credits inside a community (e.g., inside an African village). Each saver, in turn, will benefit from a loan designed to acquire a business asset (tool, machine, commercial premises, etc.).

   A lot of ethnic communities, everywhere in the world, benefit from a high spirit of enterprise, an "innate" propensity to create their own businesses. Those communities most often originate from difficult regions (mountain, desert, island, etc.) or from lower social classes so that they emigrate toward more munificent places or countries. Being often religious and austere, they work hard, in order to get both economic comfort and social appreciation, and send money to their family or village, hoping to retire in their native place.
4. *Family microfirms* are owned and managed by the family members. Family governance in western societies is primarily limited to the

nuclear family, consisting of parents and children. The family members primarily intend to maintain the independence of their shared patrimony and avoid borrowing and "external" associates. Those family microfirms flourish in local, stable markets, for instance, in food and retail trades. Some of them, named "Enokians," may even survive over several generations so that the family chief acquires a social promotion, becoming an influential person in the village, town, region, etc., for instance, in the town council or the chamber of commerce. Most often, such "survivor" microfirms expand and become bigger concerns.

A Case of "Family Group of Microfirms"

For several generations, this family has been embedded in a residential suburb of an expanding town. They designed to buy out the nearby bakeries, closing either for failure or retirement. The family now possesses the majority of the bakeries in the neighborhood. In order to benefit from economies of scale, they centralized the bread making in a one baker's oven. Each bakery is managed by a family member, in charge of adapting the business model to the local customers. This strategy may be observed also in community firms.

5. *Craft microfirms* are defined as the business units where the entrepreneurial competence is primarily based on both technical and practical learning and secondarily on mastering the professional customs in the craft activity. The origins of the craft manufacturing system are linked to the birth of the cities, during the early stages of the urban civilizations. Each craft activity is structured by two hierarchical institutions:
   - Firstly, the socioeconomic status is linked to the estimated value of the craftwork. Since early times, lower status is attributed to the activities dealing with dirty, unsafe, insecure, and/or polluting and raw materials, such as carcass, hide, dye, earth, cast iron, etc. Those activities are rejected in suburbs, or desert places, and such craftsmen are affiliated to the lower classes (or casts in underdeveloped countries). The higher craft works (and consequently craftsmen) are luxury goods, needing high skill, long training, expansive matters, and so on. Concerning the intermediate level, the French classification, for instance, registers more than 150 official craft activities in manufacturing and service units below ten employees. As members of the middle class, the social status of craftsmen may evolve from the highest (one prestigious chef managing a famous restaurant) to the lower (one pizza maker working out of his van).
   - Secondly, inside the craft microfirm, the work is shared between the master, the journeyman, and the apprentice. The master – the entrepreneur – has acquired a high degree of experience and technical skill in his job, usually vouched for by a diploma. The journeyman has a narrower field of professional competence and know-how. The apprentice has to acquire a practical experience (learning by doing). This three-tiered organization may be observed everywhere, in all countries and communities and in all historical eras, for instance, during the Roman Empire or the Middle Age in Europe.

Consequently, the craftsmen are embedded, and even officially registered, in institutions named "corporations" or "guilds." Their activity is mostly limited to proximate markets and moreover implies a tight networking with suppliers, clients, and colleagues. They are increasingly highly specialized and skilled. Moreover, the most entrepreneurial or "eldest" (family) artisans are embedded in public, professional, or private institutions. They benefit from a social promotion and get the status of *notable*, that is, of influential and recognized person on his territory.

The Microfirms "By Choice"

The "new capitalism," following on the industrial and manufacturing one, is based on service activities and intangible (intellectual) assets. Consequently, it entails the explosion of new ventures and micro-sized units in various service sectors. This is true for several reasons:

- The big manufacturing corporations outsource a whole set of functions and activities not essential for their core competence or too specialized – a niche market, according to Tilton-Penrose (1957, Chapter 3).
- The higher education system has enhanced the learning level at the master and Ph.D. degrees. More generally, the student skills have accrued, including a better knowledge of the enterprise world during their studies.
- The emerging needs at a worldwide level are primarily centered on services activities, such as health care (especially for disabled and eldest peoples), ecology and sustainable development (for developing countries or areas), agronomic research, new energies, training and consulting, and so on.

However, it is advisable to make some distinctions between these "willingly" microfirms. The main criterion is based both on the required skill and the role of innovation. It entails a classification made of "expert," "adaptive," "innovative," and "creative" microfirms.

1. *Expert microfirms* include the whole set of knowledge-based activities. It mainly refers to the private professions in free markets. The key competence of entrepreneurs, associates, or assistants is primarily based on the mastering of a discipline – most often validated by a diploma. Examples include lawyer, chartered accountant, real estate expert, NTIC engineer, doctor, expert in logistics, and, more generally, the freelance entrepreneur. Empirical researchers underline several distinctions:
   - According to a distinction between proximate and outside strategy, the search for proximity implies a deep embeddedness in the local milieu, in order to promote loyalty (e.g., a general practitioner). The alternative strategy conversely implies to "open his/her mind" on the global market, in order to scan all the events in relation to the field of expertise (e.g., a specialist in international finance).
   - Those activities are based on the production of intangible services, implying an economic and legal distinction between the services "of doing," legally compelled to obtain a definite result (e.g., a bridge for an engineer), and the services "of advising" (e.g., a doctor), just implying advice and suggestions.
   - The management of those microfirms may be individual or collective. The governance is collective, when the core competence is made of a "basket of skills," for instance, in the case of complex projects, or in order to spread overhead costs (receptionist, offices, machines, etc.) between several members, as inside a group law or consulting firm.
2. *Adaptive innovation in microfirms* occurs when they implement "new" technologies (processes), products (goods and/or services), markets (needs, places, people), or organizations. However, empirical studies reveal that the microentrepreneur gives an extensive meaning to the word "innovation." He/she usually refers to any "change" or "improvement" happened or achieved inside his/her business. Thus, there must be made a distinction between three kinds of "change": flexibility, adaptability and creativity.
   - The simplest change implies some flexibility, when the entrepreneur decides to stop the processing or delivering of some product, to terminate a contract with a supplier or a retailer, to fire or recruit an employee, and so on. The change is declared highly flexible when its "withdrawal cost" is weak (no compensations or redundancy payments, for instance). It is usually assumed that very small firms are more flexible than bigger ones due to a lesser amount of irreversible, inflexible assets. However, they are submitted to the "magnifying effect" of such decisions: in a three-person firm, a lay off of one member entails a manpower cutback of one third!

A Case of Flexible Craft Strategy

This couple lived and worked in Paris, respectively, employed as a pastry cook in a prestigious palace and a bank employee. They decided to move to a town in southern France where they bought a bakery from a retired couple. The husband intended to promote the supply of high-quality (and expensive) pastries, his distinctive craft skill. But his wife observed that the clients were demanding a larger choice and higher-quality breads. So the couple gave up "luxury" pastries and enlarged the supply of breads, with the support of a nearby miller of ecological flour. The "flexibility cost" was indeed more psychological than monetary, the profit margin being higher in bread than in pastry. After a few years, they decided to sharply change their strategy: they sold their business, in order to start a less tiring business (a fast food shop).

- Adaptability is defined as the ability to modify one or several parts of one business; to create new processes, products, or markets; and to recruit people. Inquiries confirm that microentrepreneurs mostly equate "adaptation" with "innovation." This may be partly explained by the fact that the ideas for new ventures are primarily based on imitation of "fashionable" or "cheap" businesses. Consequently, with easy entrance (and exit) from the markets, there is cutthroat competition. But the main reason for adaptation is that microentrepreneurs usually practice an incremental decision-making process, a succession of daily "microdecisions," what Henry Mintzberg (1973) describes as "emergent strategies," as opposed to the "deliberate" ones. More recently, Richard Sennett (2008) envisages, namely, in microfirms, the emergent process as a pragmatic ("craft") one, where the practical learning of the way to implementing one decision steadily modifies the way of thinking and gives rise to new ideas. For sake of simplicity, handbooks on entrepreneurship assume any venturing project as starting from an "innovative idea."

A Case of Adaptive Craft Strategy

This couple started, with two part-time employees, a business of confectionery sweets, inspired by a local recipe. The start-up period strengthened these new entrepreneurs in their project due to the high level of satisfaction expressed by the former clients. In particular, the sweets were offered to conference participants, as a welcome gift, with pretty packaging including a hand-tied ribbon. During an informal talk with the employees, it appeared that to tie the ribbon took too much time, and that this packaging was too costly. The two entrepreneurs adapted the product concept; the new packaging is less attractive, but cheaper. Doing so, they enlarged their market vision, and seized new opportunities, by getting orders from big retailing.

3. The *innovative process* of microfirms induces entrepreneurs to find and implement new ideas inside their business. The increasing propensity in the "neo-management" of big concerns is to outsource to small highly specialized businesses. This contributes to the emergence of "singular" (unique, peculiar) microfirms. The so-called resources-competences based approach has pointed out the role of idiosyncratic (original, unique) resources, defined as inimitable, nontradeable, rare, protected, and valuable. The best known cases of such "singular" strategies are seen in nurseries, incubators, innovation centers, clusters, and so on. But, more generally, the prevailing entrepreneurial skill is the ability to seize opportunities to implement an innovating concern, even in mature markets.

A Case of "Singular" Microfirms

Eurosign is a young microfirm (three employees) working in a very small village located in the south of France. The firm is well known in the world as one of the leaders in the technology of magnetized badges. It exports in Europe and to the USA. After 3 years of research, they have implemented a device designed to easily raise manhole covers. Designed for sewer, water channels, telecommunications, etc., big public and private concerns have already ordered the device because it reduces work-related injuries. Faced with increasing orders, the entrepreneur decided to replace the Swedish subcontractor with a local workshop of 300 square meters, built with the financial support of the regional council. He plans to sell 1,000 covers during the first year, and to double each year, in order to get a turnover multiplied by five in 2 years.

4. The *creative work microfirms* adopt a deliberate process, knowing that their professional skill is the search for innovative "ideas," "concepts," "products," "processes," and the supply of their own "creative energy." The "bundle" of creative microentrepreneurs is located in leisure, arts, and performance activities, as, for instance, art painters, designers, couturiers, rockers, graphics or game boy designer, and so on.

- The span of art and crafts activities goes from decorative objects (more or less artistic) to musical instruments (as the string instruments makers). These microfirms may be supported by state or local institutions, for instance, to implement a craft cluster.
- Fine arts, architecture, and design activities are primarily based on microfirms and freelance entrepreneurs. Those microentrepreneurs, called SOHO (small organization, home office) frequently work at home, even in remote and quiet places, in order to preserve their peace of mind and enhance their creative skills. However, they remain strongly embedded in external and even worldwide networks, including all types of stakeholders (colleagues, clients, art galleries, and so on). These new entrepreneurs are called "lifestyle entrepreneurs." They may be both locally embedded (the will to "take children to school") and be connected to global networks (the need to "start a Visio – conference with anybody anywhere on the Planet"). As artists, or experts, they have to promote their own creativity and originality to acquire a personal, unique ("singular") style.
- Performance activities have hugely expanded with the postmodern "entertainment society." They include not only actors, musicians, scriptwriters, directors, conductors, etc., but also the whole set of technicians working with a precarious status of "freelance," of casual workers.
- The world of communication and publishing (*lato sensu*, including releases, translators, etc.) is made up of a host of microfirms employing one or a few members microfirms. Concerning the novelists and writers, those are mostly registered, ever as "auto-entrepreneurs," or occupy a full- or part-time job.

A Case of "Creative (and SOHO) Microentrepreneurs"

These two 30-year-old men live and work in their apartment, located in the heart of the "historical center" of a southern French town. The furniture is all covered with a lot of mangas and Japanese objects. Here is the office of the young publishing microfirm, owned and managed by both editors and cotenants. During one year, they matured their project (concept, market, business plan), based on the edition of mangas targeted for young and mature adults, on the theme of fight games. They prospect in Korea and Japan, in order to buy license rights, in spite of their ignorance of Korean and Japanese languages. Indeed, they base their opinions on the illustrations, techniques, and reputation of the authors. Doing so, they take risks, but their first "baby" was successful, and the three succeeding ones have "found their public." They intend later to publish mangas written by French, or targeted for women, at a rate of seven new publications per year. But one of those two microentrepreneurs says: "Yeah, but now we have to do the real planning."

Conclusion and Future Directions

As for insects, the word "microfirms" refers to a world made of myriads of yet undiscovered kinds. Researchers on entrepreneurship have to increasingly take into account the high diversity of the worldwide population of "people with uncertain earnings," as defined by Cantillon, including unsighted ones.

Mode 1, Mode 2, and Innovation

Michael Gibbons
SPRU (Science Policy Research Unit), University of Sussex, Brighton, UK

Introduction

It is too easily forgotten that it is only since World War II, that science – in the form of basic research – was taken up by the universities, transforming them into the major players in the forward march of science that they are today. In the beginning, it was through the persuasive efforts of Vannevar Bush and others that government in America and elsewhere decided to back universities as the prime sites for the research that would underpin technological innovation (Bush 1945, Etzkowitz and Leyersdorff 2000). As a result, universities and their research and training functions gradually moved to the foreground as the key institutions to supply the knowledge and manpower to drive economic progress. However, the establishment of research in universities took science in a specific direction, that is, down a route that would lead to the development of the academic disciplines and the administrative and financial structures to support it. The disciplinary structure of science is now dominant in universities globally, and it guides the development of most research activity in mathematics and physics, chemistry and biology, economics and sociology, and even linguistics and literature.

In part, *The New Production of Knowledge* was a response to this development. In that volume, clarification by contrast was used to distinguish the characteristics of discipline-based research (Mode 1) from those of an emergent mode (Mode 2). A subsequent publication, *Re-thinking Science*, built on the notion of

Mode 2 but went more widely and deeply into the history and sociology of knowledge production, exploring some distinctive features of new social developments in what was termed an emerging Mode 2 society (Gibbons et al. 1994; Nowotny et al. 2001).

Mode 1 and Mode 2 Forms of Knowledge Production

As configurations for the production of knowledge, Mode 1 and Mode 2 are differentiated as follows. In Mode 1, problems are set and solved in a context governed by the interests of specific academic communities. By contrast, Mode 2 knowledge production is carried out in a context of application. The context of application should not be thought of as applied science because as yet there is no science to be applied in that context. Mode 1 is discipline-based while Mode 2 is transdisciplinary. The latter draws knowledge from a range of sources and integrates them in frameworks which help to identify and formulate the key research questions to be addressed. Strictly speaking, it is neither multidisciplinary nor interdisciplinary because the knowledge elements that enter Mode 2 draw on sources beyond those of any set of disciplines.

Each mode manifests different organizational characteristics. Mode 1 is hierarchical and tends to preserve its form while Mode 2 forms are heterarchical and transient. Even a superficial consideration of the operation of the disciplinary structure of science would reveal a hierarchy not only of disciplines with the mathematics and physics usually at the top but also of personnel with its professors, associate and assistant professors, postgraduate fellows, and doctoral students. Such distinctions tend to be blurred in Mode 2, in part because not all participants in knowledge production came from universities. Some might have come from government laboratories, some from industry, and others from social action groups and concerned citizens, perhaps with no particular scientific training at all. In Mode 2, all have something to contribute to the formation of a research agenda.

Equally, while the disciplines tend to develop by dividing into more and more specialisms and subspecialisms that reproduce similar organizational structures, Mode 2 configurations and their collaborations are many and varied and continue only so long as the problem in hand requires them. Afterward, Mode 2 forms might dissolve or perhaps be reconstituted around another problem with a different array of participants and organizational structure. Finally, each mode employs a different type of quality control. In contrast with Mode 2, Mode 1 scientists are accountable to one another and their discipline. In Mode 2, peer review continues to operate but accountability is more broadly based socially. Mode 2 is reflexive and absorbs knowledge inputs from many sources on a continuous basis, adjusting its organizational structure as appropriate. In summary, in contrast with Mode 1, Mode 2 involves a more temporary and heterogeneous set of practitioners, collaborating on problems identified in specific, localized contexts. Among its vehicles are research centers of various kinds.

Research centers that support the development of Mode 1 research have been in existence for many years. They can be found in universities, industry, and government laboratories. Now the genre is being extended to Mode 2 research, the characteristics of which have been outlined above. These centers are organized to adopt, adapt, and integrate knowledge from many different sources, including science, to attain a variety of scientific, technological, social, and economic objectives. They are free-standing, time-limited organizations with most staff employed on contracts. Many are funded by government in collaboration with industry, charitable institutions, and wealthy individuals. Because of the flexibility they offer, research centers are becoming a preferred mode for funding organizations. As institutions with sound reputations for pursuing independent inquiry, research centers are increasingly found in universities.

Research Centers and Socially Robust Knowledge

There is an important difference between Mode 1 research that is carried out in typical university laboratories and the Mode 2 knowledge being produced in research centers. In Mode 1, academic scientists are seeking breakthroughs in fundamental science. Much of this research is guided by the paradigms of normal science that were described some years ago by Thomas Kuhn (1996). Paradigms are relatively stable frameworks of inquiry which direct researchers down certain lines of inquiry while, for the time being, eschewing others. Day to day, they are, in effect, testing the limits and robustness of particular paradigms. In contrast, and keeping in mind this entry's focus on industrial innovation, researchers operating in Mode 2-type research centers could be said to be searching for *stable technological paradigms* that can guide technological development by individual companies (Dosi 1982). In typical Mode 2 style, research centers draw together a range of knowledge resources, including some that will forward some Mode 1 research agendas. That is one reason why many academic scientists are attracted research centers, not infrequently on a part-time basis.

In these centers, researchers from a range of backgrounds come together to seek stable technological paradigms. Here, too, in the early stages, search is characterized by a broad range of activities and the context is open to movement, in and out, of a range of participants. Indeed, a number of research centers may be established in a particular technological domain because at the outset it is unclear which of the many possible paths will yield the sought-for stability while also being pregnant with possibilities for further development. In this phase, a time-limited research center is an ideal organizational form for companies to work together with others, sharing resources until a stable paradigm emerges.

A stable paradigm is one not only capable of technological development but is also flexible enough to accommodate a wide range of economic, social, and political constraints. Thus, it was argued in *Re-thinking Science* that research centers can be in search of socially robust knowledge. In Mode 1, scientific authority operates through internal peer review. In Mode 2, peer review is more broadly based and authority becomes much more closely linked to concrete practices, their results, and impacts. Knowledge will be tested not only in the "idealized" experimental configurations of the laboratory but in a variety of local circumstances. In Mode 2, the methods that yield the reliable scientific knowledge of the disciplines continue to operate, but they are augmented to accommodate the particular context. Constant awareness of possible implications keeps inquiry open to broad range of inputs. In this way, context sensitivity changes the ways in which problems are conceived and prioritized and inquiry organized. In the process, reliable knowledge is transformed into socially robust knowledge (Nowotny et al., 2001 p. 116).

In sum, the difference between scientific and technological paradigms is not simply a relabeling of the, now traditional, distinction between pure and applied science. Rather, in Mode 2, research is molded by a broader context than Mode 1. The more strongly contextualized a scientific field or a research domain is, the more it is likely to produce socially robust knowledge.

Transaction Spaces and Contact Languages

In the more open, porous society described in *Re-Thinking Science*, new "spaces" house diverse forms of inquiry. Research centers, for example, provide organizational frameworks in which still tentative, and as yet inadequately institutionalized, interactions can take place. However, these interactions are far from being random encounters. They are the sources from which emerge the "trading zones" described by Galison in his analysis of the history of nuclear physics (Galison 1997).

From the perspective being developed here, trading can give rise to the emergence of *contact languages*, rather like "pidgin" English (e.g., Creole in the southern USA). As a means of communication, contact languages are inevitably undeveloped but, unless they "work," trading ceases. In this manner, the physicists, experimentalists, and engineers described in Galison's research were not engaged in translating from one language to another as they pieced together their microwave circuits, nor were they producing "neutral" observation sentences that some philosophers of science have suggested occur. Rather, they were working out a powerful, locally understood, language to coordinate their actions. Despite obvious limitations, some kind of understanding and exchange does occur in such situations. In *Re-thinking Science*, the metaphor of the trading zone was extended and generalized beyond interactions among scientific subcultures to wider exchanges that take place across knowledge boundaries, more generally. To accommodate this more broadly, in this entry, trading zones were relabeled as transaction spaces.

The notion of a trading zone sheds considerable light on the internal dynamics of knowledge generation in Mode 2. Perhaps here may be discerned an analytical framework to guide policy makers and others in understanding the internal dynamics of the innovation process, a process that moves from an initially inchoate situation involving many "languages" to the contact languages of stable technological paradigms. Within this view can be readily discerned the problem of trying to introduce other factors, such as cost or health and safety considerations, into a technological paradigm that is approaching stability. Policy makers should note that it is simply very difficult to add another language – say, environmental or cost implications – to a functioning contact language that has already been developed. This is why, in the generation of stable technological paradigms, inputs from a variety of sources are necessary from the beginning. Galison has shown that transaction spaces and contact languages can emerge quite naturally in the scientific subcultures of Mode 1. Why ever should they not also appear in the more complex environments of Mode 2 knowledge production? In fact, the emergence of contact languages could become an empirical litmus test for the success or otherwise of any collaboration.

Links to Other Forms of Analysis

The question naturally arises about the relationship of Mode 2 forms of knowledge production to other analyses. For example, the Triple Helix adds to the conventional interaction of the scientific and industrial estates an "overlay" of government policy making. It is incontestable that the economic development of a country depends upon a mutually supportive relationship between these three sets of actors. However, in articulating the notion of the Triple Helix, the authors argue that Mode 2 actually preceded Mode 1 in that networks of informal communications have, in fact, been the normal mode of the operation of science from its inception. Within this framework, Mode 1 is a later, and perhaps transitory, system of knowledge production, the transition being characterized by the movement from Mode 1 to a Triple Helix structure (Etzkowitz and Leydesdorff 2000).

As presented herein, Mode 2 possesses a number of characteristics, not just the reemergence in the twentieth century of nineteenth-century informal networks of scientists and industrialists. In *Re-thinking Science*, Mode 2 forms of knowledge production were seen to be the knowledge dimension of an emerging Mode 2 society. It is the open nature of this society and its correlate, the open systems of knowledge production, that are driving changes in the Mode 1 forms of knowledge production by drawing knowledge producers into the construction and execution of research agendas not only governments but users of many different stripes. It is doubtful if these forms of interaction in their current abundance and diversity were present in the eighteenth or nineteenth centuries. Societies were simply not yet in a form – open enough – to support diverse social and economic groups in the articulation of their demands or to accommodate them in the production of knowledge.

In contrast to the Triple Helix, Mode 3 offers a more comprehensive analysis of contemporary knowledge production. Mode 3 draws heavily on the concepts of systems theory (Carayannis and Campbell 2009). As is typical of this genre, the analysis is focused on the relations between high level political, economic, and social structures. The perennial challenge for system-based theories has been to explain a system's dynamics in concrete cases, not least to be able to draw out potential implications for policy. One attempt to do this has been adumbrated in terms of the notion of "articulation systems" – subsystems which mediate between different, higher order, systems. This approach goes some way to demonstrating how higher order systems interact with one another through the medium of articulation systems. With these, one begins to understand how large complex systems might interact with one another (Dalitz et al. 2012).

The dynamics of the interactions between Mode 2 knowledge production and its conjugate, Mode 2 society, can be conceived as providing some of the elements of an articulation system. This can be seen, for example, in terms of the role played by contact languages and trading zones in explaining how the multiple cultures involved in knowledge production can find a common working language that allow diverse interests to work together productively in the production of socially robust knowledge. The work of Dalitz and his colleagues may provide some common ground that might be able to link Mode 2, Triple Helix, and Mode 3 approaches.

Knowledge Production and Innovation Policy

The question that now needs to be addressed is the relevance of knowledge, whether Mode 1 or Mode 2, to innovation. In the current context, innovation has referred, somewhat narrowly, to the role that science and technology play in innovation in an industrial economy. The linear, or pipeline, model of innovation which regards discoveries in basic science as its source is still dominant among many researchers and some government policy makers. As has noted already, the publicly funded research, particularly university research, organized in Mode 1 forms, is regarded as essential to guarantee the generation of the knowledge and ideas to underpin the flow of innovations required for survival in the global economy.

A recent and robust example of this belief can be found in J. R. Cole's magisterial treatment of the growth of the American universities (Cole 2009). That growth is linked, in part, to the expansion of science in the universities that here has been labeled Mode 1 science. Cole argues that this research has provided the underpinnings for a stream of innovations. To provide some evidential support of this view and to drive the point home, Cole has produced a 152-page summary of some of these discoveries. The policy implications are simple: funding more science will inevitably lead to more innovation. However, the role of basic science in innovation, presented below, offers an explanation of why the pipeline view of innovation might be an oversimplification.

Transferring Science to Industry in Mode 1

To support the movement of basic science into the economy, both universities and government research laboratories have, for many years, operated technology transfer offices. Indeed, in the USA, the Bayh-Dole Act has recently increased the importance of patenting and licensing activities by granting to them ownership of intellectual property arising from publicly funded research that is carried out in their laboratories (Boettinger and Bennet 2006). The hope, then as now, is that protecting and then selling this intellectual property would not only provide a flow of new ideas to support innovation in industry but also provide the universities and government laboratories with an income stream. To some extent, in setting up distinct in-house R&D facilities, companies, too, work with a similar model. In each case, the linear model of innovation is operative.

The difficulty is that transfer mechanisms in which research is first carried out, protected, and then transferred requires that discrete elements of "knowledge" move across established boundaries, from one culture to another, say, from a laboratory to a product development team. Even if the laboratory and the product team are in the same company, the research and the development cultures will be different. As noted above, the appropriation of knowledge produced in one culture by another will be retarded due to the lack of an appropriate contact language.

Innovation in Mode 2

In Mode 2, knowledge is generated in a variety of organizational forms, may involve many participants, and may be located anywhere. In this mode, the principal end-users are involved from the outset. To say the least of it, early involvement by users is crucial to the development of contact languages and has the potential to reduce, if not eliminate, the traditional boundary-crossing difficulties mentioned above. Typically, in this mode of knowledge production, participants remain as long as it is useful and, when they leave, they can take with them what they regard as important for them. Traditional forms of intellectual property protection remain important but they tend to be pursued by firms after they leave the collaboration as each uses its own resources to protect that knowledge which is central to its own particular development of a particular paradigm.

Industrialists know from experience that stable technological paradigms will require inputs from many sources among which more science is only one. Integrating these perspectives into coherent research programs is what research centers, operating in Mode 2, are trying to do. By involving different interests, research centers can be sites for the generation of the socially robust knowledge that industrialists know must underpin any new product or process. In the current socioeconomic context, the production of socially robust knowledge is an imperative for companies for the simple reason that it can be a colossal cost for a firm to embark upon its expansion of a new technological paradigm only to find that it falls at the first hurdle, to discover late on that in fact the paradigm is not stable and that the collaboration has failed to produced socially robust knowledge.

Clearly, there is a tension between Mode 1 and Mode 2 in terms of the optimum way for government policy to support innovation. As has been indicated, Mode 1 has become associated with a linear model of innovation that relies on continuing and substantial funding of research as well as relatively primitive forms of knowledge transfer. However, Mode 1 is both expansive and expensive. It has expanded mainly in universities not only in the physical and biological sciences but the social sciences and the humanities as well. It has been clear for some time that this mode of knowledge production cannot go on expanding because there are simply not sufficient resources to support it. Moreover, Mode 2 forms of knowledge production as carried out in research centers has become popular with companies because it allows them to become involved in a process which requires a greater range of knowledge than any of them can possess singly. National funding agencies are also supportive of research centers because they provide a way to maintain some growth in the academic science base by spreading the financial burden through research centers that are partly funded by industry, foundations, and wealthy individuals. In current environment of intensifying global competition, Mode 2 forms can provide both governments and industry with more effective and cost-efficient ways to invest in innovation.

Conclusion and Future Directions

The Shape of Things to Come?

Technological paradigms perform a similar function in Mode 2 as Thomas Kuhn's scientific paradigms do in Mode 1. Once discovered and judged stable, researchers in industry, many of whom will have worked in the research center, take over and try to develop that paradigm in firm-specific ways. Much the same approach is taken by academic researchers as they strive to determine the limits of a particular scientific paradigm. In a similar manner, industrial firms use their own resources to exploit to the full the technocommercial potential of a paradigm, once its robustness begins to look promising. As scientific paradigms reach their limits, scientists continue to make small adjustments and theoretical and experimental refinements. In a similar manner, as technological paradigms approach their limits, incremental innovation dominates so that it often seems that latest versions of a product line, whether motor cars, washing machines, or computers, differ only marginally in color, design, and technical specification. For both, it is time to begin the hunt for another scientific or stable technological paradigm.

It may be helpful, therefore, to draw attention to an isomorphism between Mode 1 and Mode 2 and the model of innovation appropriate to each. As regards innovation, Mode 1 uses a linear model; Mode 2, a model of open innovation, as described, for example, by Chesbrough (Chesbrough et al. 2006). In this case, the isomorphism would be: Mode 1 is to the linear model as Mode 2 is to open model. But, as has been seen, linear and open models of innovation draw upon different knowledge production configurations in pursuit of innovation; the former is carried by the disciplines, the latter more open entities, that is, by transdisciplinary research centers. Thus, the single level isomorphism might be expanded as follows: the linear model is to Mode 1 as the open model is to Mode 2, as a university (or industrial) laboratory is to a research center, as reliable knowledge is to socially robust knowledge. Each mode has its particular take on the role of knowledge in technological innovation.

Finally, research centers of various kinds are finding homes in universities. Presidents value the prestige and resources that they bring while academics and some graduate students value the opportunities presented by the challenging environment of a research center, free from the administrative and teaching duties of normal university life. This development cannot leave the universities unchanged. Indeed, the research culture of centers may already be modifying the social function of universities not, it need hardly be repeated, by them becoming institutions for applied research but rather homes for the production of socially robust knowledge. To the extent that research centers do become located in, or associated with, universities, they can threaten to destabilize current Mode 1 forms of knowledge production. Indeed, some have argued that this tension has reached the point where it is driving fundamental change in the nature of universities.

In this respect, the distinguished American scholar Randolph Bourne pointed many years ago that, "the issues of the modern university are not those of private property but of public welfare," and that "irresponsible control by a board of amateur notables is no longer adequate for the effective scientific and technological *laboratories for the community* that universities are becoming." (Cole, op.cit. p. 352). Laboratories for community are fast becoming a primary function of universities, and research centers are their principal mode of knowledge production. To be sure, Bourne has grasped the ethos-changing nature the research centers have as the homes of laboratories for the community. To establish new research centers, support their development, and finesse the closure of older ones, and, most of all, to ensure the integrity of the research carried out within their institutions constitute a – if not the – principal challenge facing the academic leadership of universities in the future.

Such is the power of innovation but, as always, it cuts two ways. The demand for innovation not only provides the stimuli for the creation of new knowledge but it also alters the frameworks within which that knowledge is produced. Bourne was certainly correct when he observed that universities need to be "reimagined" if they are to meet the challenge of becoming laboratories for community. Perhaps the burgeoning of research centers will provide the catalyst to ignite that process.

Links to Other Entries in the Encyclopedia

Creativity Although this entry does not deal directly with C*reativity*, it is a key element of the performance Mode 2 organizations, particularly in the research centers elaborated herein. Likewise, research in the *Gestalt* and *Paradigm* entries will bring further specification to the internal evolution of stable technological paradigms. All three headings will add to the understanding of the inner working of Mode 2 research.

Invention Managing Creativity, particularly in research centers, is a key challenge in the emergence of technological paradigms which are one of the key objectives of research centers in Mode 2. *Managing Invention and Innovation* will provide insight into how research centers evolve toward larger, more formal organizations that are required as paradigms become stable. Entries under this heading will provide more detailed analysis of these aspects as innovation moves closer to the market place.

Innovation This aspect of the entry touches many diverse aspects of the organization of innovation that are developed more fully under the *Networks, Open innovation, and Triple Helix* entries. Further useful insights can be found in the entries under *Pasteur's Quadrant* and *Quadruple and Quintuple Helix*. As far as *R&D* is concerned, this entry suggests that the development of stable technological paradigms requires more open, porous, and flexible forms of research organizations and calls into question the function of a distinct research and development function within companies. The entries under *Paradigms* should be consulted for their contribution to a fuller understanding of stable technological paradigms. Entries under *Transdisciplinarity* will expand on this aspect of Mode 2 which is not much developed here beyond a brief description. These entries should help to clarify the distinction between trans-, and inter-, and multidisciplinary research. *Incremental Innovation* is relevant to the later stages in the development of a stable technological paradigm as a more formal organization is put in place to fine-tune technological possibilities to market conditions.

Conceptual Point of Departure for Mode 3 Knowledge Production in Quadruple Helix Innovation Systems

Universities, or higher education institutions (HEIs) in more general, have three main functions: teaching and education, research (research and experimental development, R&D), and the so-called third mission activities, for example, innovation (Campbell and Carayannis 2013, p. 5). University research, in a traditional understanding, focuses on basic research, often framed within a matrix of academic disciplines, and without a particular interest in the practical use of knowledge and innovation. This model of university-based knowledge production also is being called "Mode 1" of knowledge production (Gibbons et al. 1994). Mode 1 is also compatible with the linear model of innovation, which is often being referred to Vannevar Bush (1945). The linear model of innovation asserts that first there is basic research in university context. Gradually, this university research will diffuse out into society and the economy. It is then the economy and the firms that pick up the lines of university research, and develop these further into knowledge application and innovation, for the purpose of creating economic and commercial success in the markets outside of the higher education system. Within the frame of linear innovation, there is a sequential first-then relationship between basic research (knowledge production) and innovation (knowledge application).

The Mode-1-based understanding of knowledge production has been challenged by the new concept of "Mode 2" of knowledge production, which was developed and proposed by Michael Gibbons et al. (1994, pp. 3–8, 167). Mode 2 emphasizes a knowledge application and a knowledge-based problem-solving that involves and encourages the following principles: "knowledge produced in the context of application"; "transdisciplinarity"; "heterogeneity and organizational diversity"; "social accountability and reflexivity"; and "quality control" (see furthermore Nowotny et al. 2001, 2003 and 2006). Key in this setting is the focus on a knowledge production in contexts of application. Mode 2 expresses and encourages clear references to innovation and innovation models. The linear model of innovation also has become challenged by nonlinear models of innovation, which are interested in drawing more direct connections between knowledge production and knowledge application, where basic research and innovation are being coupled together not in a first-then, but in an "as well as" and "parallel" (parallelized) relationship (Campbell and Carayannis 2012). Mode 2 appears also to be compatible with nonlinear innovation and its ramifications.

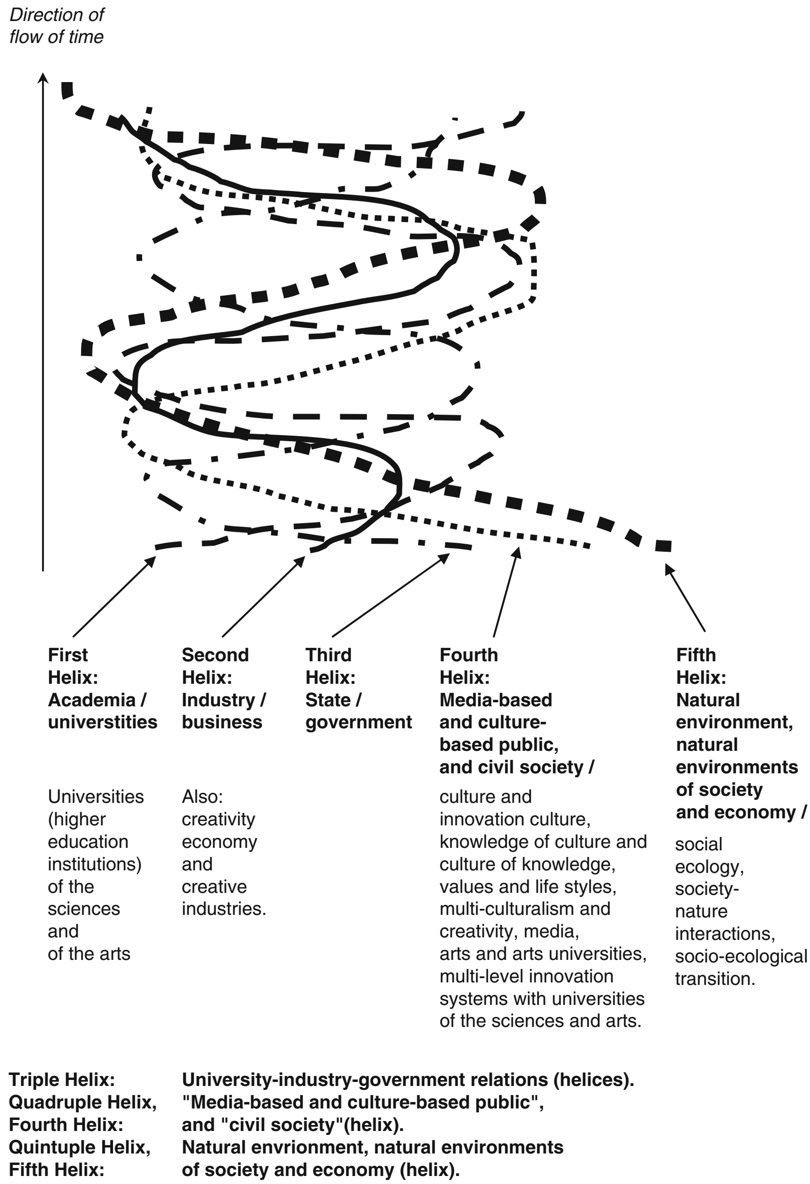
The Triple Helix model of knowledge, innovation, and university-industry-government relations, which was introduced and invited by

Henry Etzkowitz and Loet Leydesdorff (2000, pp. 111–112), asserts a basic core model for knowledge production and innovation, where three "helices" intertwine, thereby creating a national innovation system. As the three helices are being identified the following systems or sectors: academia (universities), industry (business), and state (government). Etzkowitz and Leydesdorff refer to "university-industry-government relations" and networks, putting a particular emphasis on "trilateral networks and hybrid organizations," where those helices overlap in a hybrid fashion. Etzkowitz and Leydesdorff (2000, p. 118) also explain, how, in their view, the Triple Helix model relates to Mode 2: The "Triple Helix overlay provides a model at the level of social structure for the explanation of Mode 2 as an historically emerging structure for the production of scientific knowledge, and its relation to Mode 1." More recently, Leydesdorff (2012) also introduced the notion of "N-Tuple of Helices."

The Conceptual Definition of Mode 3 Knowledge Production, Quadruple and Quintuple Helix Innovation Systems

Mode 1 and Mode 2 may be characterized as "knowledge paradigms" that underlie the knowledge production (to a certain extent also the knowledge application) of higher education institutions and university systems. Success or quality, in accordance with Mode 1, may be defined as: "*academic excellence, which is a comprehensive explanation of the world* (*and of society*) *on the basis of 'basic principles' or 'first principles', as is being judged by knowledge producer communities (academic communities structured according to a disciplinary framed peer review system)*". Consequently, success and quality, in accordance with Mode 2, can be defined as: "*problem-solving, which is a useful (efficient, effective) problem-solving for the world (and for society), as is being judged by knowledge producer and knowledge user communities*" (Campbell and Carayannis 2013, p. 32). A Mode 3 university, higher education institution or higher education system, would represent a type of organization or system that seeks creative ways of combining and integrating different principles of knowledge production and knowledge application (e.g., Mode 1 and Mode 2), thereby encouraging diversity and heterogeneity, thereby also creating creative and innovative organizational contexts for research and innovation. Mode 3 encourages the formation of "creative knowledge environments" (Hemlin et al. 2004). "Mode 3 universities," Mode 3 higher education institutions and systems, are prepared to perform "basic research in the context of application" (Campbell and Carayannis 2013, p. 34). This has furthermore qualities of nonlinear innovation. Governance of higher education and governance in higher education must also be sensitive, whether a higher education institution operates on the basis of Mode 1, Mode 2, or a combination of these in Mode 3. The concept of "epistemic governance" emphasizes that the underlying knowledge paradigms of knowledge production and knowledge application are being addressed by quality assurance and quality enhancement strategies, policies, and measures (Campbell and Carayannis 2013).

Emphasizing again a more systemic perspective for the Mode 3 knowledge production, a focused conceptual definition may be as follows (Carayannis and Campbell 2012, p. 49): Mode 3 ". . . allows and emphasizes the co-existence and co-evolution of different knowledge and innovation paradigms. In fact, a key hypothesis is: *The competitiveness and superiority of a knowledge system or the degree of advanced development of a knowledge system are highly determined by their adaptive capacity to combine and integrate different knowledge and innovation modes via co-evolution, co-specialization and co-opetition knowledge stock and flow dynamics*" (see Carayannis and Campbell 2009; on "Co-Opetition," see Brandenburger and Nalebuff 1997). Analogies are being drawn and a coevolution is being suggested between diversity and heterogeneity in advanced knowledge society and knowledge economy, and political pluralism in democracy (knowledge democracy), and the quality of a democracy. The "Democracy of

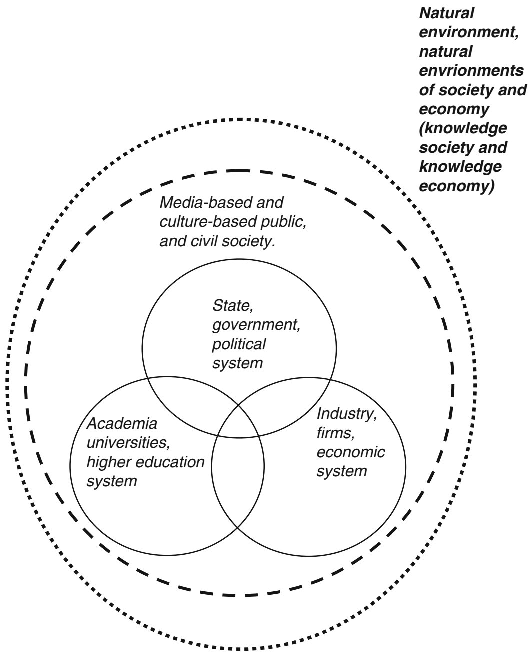


Mode 3 Knowledge Production in Quadruple Helix Innovation Systems: Quintuple Helix and Social Ecology, Fig. 1 The Quadruple and Quintuple Helix innovation systems Source: Authors' own conceptualization (Based on Etzkowitz and Leydesdorff (2000, p. 112), Carayannis and Campbell (2009, p. 207; 2012, p. 14), and Danilda et al. (2009))

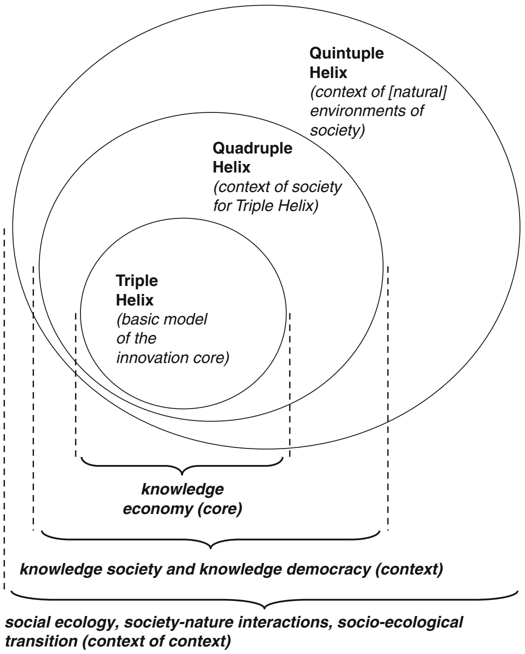
Knowledge" refers to this overlapping relationship. As is being asserted: "The *Democracy of Knowledge*, as a concept and metaphor, highlights and underscores parallel processes between political pluralism in advanced democracy, and knowledge and innovation heterogeneity and diversity in advanced economy and society. Here, we may observe a hybrid overlapping between the *knowledge economy, knowledge society and knowledge democracy*" (Carayannis and Campbell 2012, p. 55). The "Democracy of Knowledge," therefore, is further reaching then the earlier idea of the "Republic of Science" (Michael Polanyi 1962).

The main focus of the Triple Helix innovation model concentrates on university-industry-government relations (Etzkowitz and Leydesdorff 2000). In that respect, Triple Helix represents a basic model or a core model for knowledge production and innovation application. The models of the Quadruple Helix and Quintuple Helix innovation systems are designed to comprehend already and to refer to an extended complexity in knowledge production and knowledge application (innovation); thus, the analytical architecture of these models is broader conceptualized. To use metaphoric terms, the Quadruple Helix embeds and contextualizes the Triple Helix, while the Quintuple Helix embeds and contextualizes the Quadruple Helix (and Triple Helix). The Quadruple Helix adds as a fourth helix the "media-based and culture-based public" and "civil society" (Carayannis and Campbell 2009 and 2012, p. 14; see also Danilda et al. 2009). The Quintuple Helix innovation model even is more comprehensive in its analytical and explanatory stretch and approach, adding furthermore the fifth helix (and perspective) of the "natural environments of society" (Carayannis and Campbell 2010, p. 62) (see Figs. 1 and 2).

The Triple Helix is explicit by acknowledging the importance of higher education for innovation. However, it could be argued that the Triple Helix sees knowledge production and innovation in relation to economy; thus, the Triple Helix models the economy and economic activity. In that sense, the Triple Helix frames the knowledge economy. The Quadruple Helix brings in the additional perspective of society and of knowledge society. The Quadruple-Helix-innovation-system understanding emphasizes that sustainable development of and in economy (knowledge economy) requires that there is a coevolution of knowledge economy and knowledge society. The Quadruple Helix even encourages the perspectives of the knowledge society, and of knowledge democracy, for supporting, promoting, advancing, and excelling knowledge production (research) and knowledge application (innovation). Furthermore, the Quadruple Helix is also explicit that not only universities (higher education institutions) of the sciences, but also universities (higher education institutions) of the arts should be regarded as decisive and determining institutions for advancing next-stage innovation systems: The interdisciplinary and transdisciplinary connecting of sciences and arts creates crucial and creative combinations for promoting and supporting innovation; here, in fact, lies one of the keys for future success. The concept and term of "social ecology" refers to "society-nature interactions" between "human society" and the "material world" (see, e.g., Fischer-Kowalski and Haberl 2007). The European Commission (2009) identified the necessary socio-ecological transition of economy and society as one of the great next-phase challenges, but also as an opportunity, for the further progress and advancement of knowledge economy and knowledge society. The Quintuple Helix refers to this socio-ecological transition of society, economy, and democracy; the Quintuple Helix innovation system is therefore ecologically sensitive. Quintuple Helix bases its understanding of knowledge production (research) and knowledge application (innovation) on social ecology (see Fig. 3). Environmental issues (such as global warming) represent issues of concern and survival for humanity and human civilization. But the Quintuple Helix translates environmental and ecological issues of concern also in potential opportunities, by identifying them as possible drivers for future knowledge production and innovation (Carayannis et al. 2012). This, finally, defines also opportunities



Mode 3 Knowledge Production in Quadruple Helix Innovation Systems: Quintuple Helix and Social Ecology, Fig. 2 The Quintuple Helix (five-helix model) innovation system (Source: Authors' own conceptualization based on Carayannis and Campell (2010, p. 62))



Mode 3 Knowledge Production in Quadruple Helix Innovation Systems: Quintuple Helix and Social Ecology, Fig. 3 The Quadruple and Quintuple Helix innovation systems in relation to society, economy, democracy, and social ecology (Source: Authors' own conceptualization based on Carayannis et al. (2012, p. 4))

for the knowledge economy. "*The Quintuple Helix supports here the formation of a win-win situation between ecology, knowledge and innovation, creating synergies between economy, society and democracy*" (Carayannis et al. 2012, p. 1).

Conclusion and Future Directions

The terms and concepts of Mode 3 and Quadruple Helix were first introduced to international academic debate by Carayannis and Campbell (2006 and 2009), and were later developed further (Carayannis and Campbell 2012). The same applies to the Quintuple Helix (Carayannis and Campbell 2010). Further ramifications of Mode 3 knowledge production in Quadruple Helix and Quintuple Helix innovation systems are:

1. *Multilevel innovation systems, the global and the local (GloCal)*: Lundvall was pivotal in introducing the concept of the "national innovation system." Lundvall (1992, pp. 1, 3) explicitly acknowledges that national innovation systems are challenged in permanence (but are also extended) by regional as well as global innovation systems. Here, Kuhlmann (2001, pp. 960–961) could be paraphrased and the assertion that as long as nation-states and nation state-based political systems exist, it is plausible to use the concept of the national innovation system. More comprehensive in its analytical architecture than the national innovation system is the concept of the "multilevel innovation system" (Carayannis and Campbell 2012, pp. 32–35). In a spatial understanding, multilevel innovation systems compare the national with the subnational (regional, local), but also with the transnational and global levels (see, e.g., Kaiser and Prange 2004; furthermore, see Pfeffer 2012). However, it is also important to extend multilevel-innovation-systems to the challenges and potential benefits and opportunities of a nonspatial meaning and understanding: "Therefore, multi-level systems of knowledge as well as multi-level systems of innovation are based on spatial and non-spatial axes. A further advantage of this multi-level systems architecture is that it results in a more accurate and closer-to-reality description of processes of globalization and gloCalization" (Carayannis and Campbell 2012, p. 35).
2. *Linear and nonlinear innovation*: Knowledge application and innovation are being challenged and driven out of an interest of combining and integrating linear and nonlinear innovation. Key to here are a diversity, heterogeneity, and pluralism of different knowledge and innovation modes, and their linking together via an architecture of coevolving networks. Firms, universities, and other organizations can engage (at the same) in varying and multiple technology life cycles at different levels of maturity. Another way "how to think nonlinear innovation" is being suggested by the concept of cross-employment (Campbell 2011). As a form and type of multi-employment, cross-employment emphasizes that the same individual person may be

employed by two (or more) organizations, where one organization could be located closer to knowledge production, and the other to knowledge application (innovation): are those organizations also rooted in different sectors, then cross-employment acts also as a trans-sectoral networking (Campbell and Caraynnis 2013, pp. 65, 68). What results is a "Mode 3 Innovation Ecosystem": "This parallel as well as sequentially time-lagged unfolding of technology life cycles also expresses characteristics of Mode 2 and of nonlinear innovation, because organizations (firms and universities) often must develop strategies of simultaneously cross-linking different technology life cycles. Universities and firms (commercial and academic firms) must balance the nontriviality of a fluid pluralism of technology life cycles" (Carayannis and Campbell 2012, p. 37; see furthermore Dubina et al. 2012). The relationship between networks, cooperation, and competition ("Co-Opetition") represents a challenge and sensitive issue, and allows for different creative answers and organizational representations and manifestations.

3. *Twenty-first century Fractal Research, Education and Innovation Ecosystem (FREIE)*: Here, the understanding of FREIE is: "This is *a multilayered, multimodal, multinodal, and multilateral system*, encompassing mutually complementary and reinforcing innovation networks and knowledge clusters consisting of human and intellectual capital, shaped by social capital and underpinned by financial capital" (Carayannis and Campbell 2012, p. 3).
4. *Linear and nonlinear innovation, and the causality of if-then and if-if relations*: The hybrid overlapping of linear innovation and nonlinear innovation displays also possible ramifications and draws associations to models of causality and their remodeling. "We can speculate, whether this parallel integration of linearity and nonlinearity not also encourages a new approach of paralleling in our theorizing and viewing of causality: *in epistemic (epistemological) terms, the so-called if-then relationships could be complemented by (a thinking in) 'if-if' relations*" (Carayannis and Campbell 2012, p. 24; see also Campbell 2009, p. 123).

Model for Managing Intangibility of Organizational Creativity: Management Innovation Index

Ralph Kerle
The Creative Leadership Forum, Willoughby, Australia

Synonyms

Benchmarking; Change management; Creative behaviors; Creative ecology; Creative leadership; Innovation; Innovation process; Management innovation; Measurement; Organizational culture; Organizational development; Statistics; Strategic innovation; Strategy

Executive Summary

This entry explores the organizational dilemma of intangibility in innovation and the consequences of ignoring it, proposes a case for a systems thinking approach to organizational creativity, reviews the emergence of organizational economics as a new field of research for analyzing intangibility in organizations, and offers a model for benchmarking and measuring organizational creativity, a prime resource for success for an organization or business in the twenty-first century.

Introduction

The Organizational Dilemmas of Intangibility and Creativity

In *How To Measure Anything – Finding the Value of Intangibles in Business*, author Douglas W. Hubbard, a former management consultant with Coopers and Lybrand, describes the tension he felt as a member of the organization's steering committee at which they were charged with accepting or rejecting new business investment proposals. The proposed investments ranged from IT to new product research and development and from major real estate development to advertising campaigns. What concerned Hubbard was the regular rejection of "soft" proposals. Proposals that contained language such as "reduced strategic risk" or "premium brand positioning" simply because they "were considered immeasurable."

As Hubbard states, "It wasn't as if the idea was being rejected because the person proposing it hadn't measured the benefit (a valid objection to a proposal): rather it was believed that the benefit couldn't be measured – ever. Consequently some of the most important strategic proposals were being over looked in favor of minor cost-saving ideas simply because everyone knew how to measure some things and didn't know how to measure others. Equally disturbing, many major investments were approved with no basis for measuring whether they worked at all (Hubbard 2007a).

In this statement, Hubbard is highlighting the fact that most companies see organizational creativity as being tactical. We have a problem, let us call a meeting and come up with as many ideas as possible to solve it. Yet if organizations base their strategic innovation on ideation then the records show they do so at their own peril. Generating lots of ideas without first understanding the organization's economic resources, constraints, and behaviors can result in a substantial waste of time with no apparent outcome, confirming the often negative experience of organizational creativity. "Just another idea workshop," "nothing came out of the last one," "they never follow through," and "a complete waste of time" appear regularly in the anecdotal responses to research collected from Management Innovation Index (The Management Innovation Index www.managementinnovation.net) surveys on innovation effectiveness.

The chief information officer of one of Australia's leading telecommunications companies recalls the expensive construction and application of an online suggestion box that was initially overloaded with ideas. The organization's management had not anticipated this response and had no real management processes or mechanisms in place to respond to the deluge. Time-poor as most senior managers are meant that decisions were deferred on how to deal with the ideas, and in many instances, no response was offered at all. Quickly, the ideas stopped coming, and the expensive online system now sits idly and unused on managers' browsers.

Worse, still, is the selection of the wrong idea to invest in, sending an organization or product on the path to oblivion with the resulting financial catastrophe.

Google's failed Google Wave project is one example.

The Rasmussen brothers, developers of the highly successful Google Maps app, convinced Google management that they could repeat their successful efforts – this time in communications. Their initial idea was vague and tactical in construct – a new communications model that embraced all previous forms of digital communications – and overhyped from the very first press release announcing the project (Google Wave: A Complete Guide. http://mashable.com/2009/05/28/google-wave-guide/). Here was an opportunity in Google's mind to catch-up and dominate in the social media market, not properly serviced by Twitter and Facebook and cluttered with a myriad of hopeful start-ups, using the power of their existing platform.

With an initial investment of $20million, Google Wave was hardly rudimentary prototyping. The company commenced by engaging 60 software engineers and general staff, housing them in an expensive new set of offices. Google Wave was launched officially in May 2009 and was dead by August 2010 because it was based on a badly articulated idea, imbued with nothing more than unbridled optimism – this team had been successful in the past, naturally it would be successful again!

You only have to search the web to read the comments from users to discover how badly Google Wave failed (Google Wave: A Case Study on Why Interactive Design Matters http://joannejacobs.net/?p=1818).

Most revealing is the press conference (TechCrunch. Schmidt Talks Wave's Death – We Celebrate Our Failures. August 2010 http://techcrunch.com/2010/08/04/google-wave-eric-schmidt/). Google CEO Dr. Eric Schmidt gave concerning, in part, Google's new product development process. When questioned about how it worked, he gave a far from convincing display appearing uncomfortable and tense at times in describing a rudimentary prototyping process steeped in tactical thinking lacking any strategic foresight. "When launching a new product, we wait to see how well it is initially adopted, followed by the tracking of the correlation between the number of initial launch adopters and the number of new user uptakes on the second iteration of the product to determine whether the product is going to work or not," he summed up.

Harvard Assistant Professor Karim R. Lakhani in his article "Google Wave Decision Shows Strong Innovation Management" (http://blogs.hbr.org/hbsfaculty/2010/08/google-wave-decision-shows-str.html) argues that as companies get bigger their latitude for employees to be creative meaningfully is often unfortunately drowned by more rigid management structures, philosophies, and protocols. These more rigid management structures and philosophies act as impediments to creativity rather than the facilitation of it, clouding and confusing important aspects of data gathering, sense making, and ultimately decision making.

Lakhani captures the unsurfaced apprehension leaders of the twenty-first century organizations now face and will start to face more frequently. Their deep concern in the new era of information and knowledge overload is how to facilitate meaningful creative thinking around the intangibility of services and organizational processes while seeking to coordinate and mitigate their risks successfully across a multitude of organizational systems, strategic alliances, and stakeholders to produce successful innovation.

Coincidentally, Google Australia reported a loss of $3.08 million in its accounts for the 2010 calendar year.

The Case for a Systems Thinking Approach to Organizational Creativity

Identifying organizational creativity, though, as a concept is highly problematic.

Metaphorically, an organization is a humanist environment driven by a series of cumulative behaviors. Subconscious in their formation, the cumulative behaviors, like the brain and creativity itself, are constrained by a system that supports and directs it for the benefit of the organization's existence.

These cumulative behaviors need to be identified and defined in order to enable meaningful measurements to model the system of creativity operating in an organization. In addition, if the measurements are to have any value, they need to be economically and behaviorally cogent in context and reflective of the organization as a whole. The ultimate test being whether through measuring organizational creativity, the organization will obtain a better knowledge of how it can become a more efficient, productive, and successful innovator, the driving force behind all successful organizations.

It may seem odd that the first clues in finding solutions to these quandaries do not come from a humanities discipline where you might expect a discussion on creativity to reside but from the total quality movement (TQM) and, in particular, work pioneered by the American author, statistician, and management consultant Dr W. Edward Deming during the post–World War II industrial expansion of Japan.

Largely unrecognized in his native US until much later in life, Deming died in 1993 the same year his most celebrated book, The New Economics for Industry, Government, Education, was published – a lifetime's work condensed into a management philosophy grounded in systems theory.

The underlying principle of Deming's theory, which he called a system of profound knowledge, (The 14 principles of the Deming System of Profound Knowledge http://en.wikipedia.org/wiki/W._Edwards_Deming#The_Deming_System_of_Profound_Knowledge) is that a system cannot understand itself and "any transformation (in it) requires an outside view – a lens – that I (he) call a system of profound knowledge. A map of theory by which to understand the organizations we work in."

Each organization, according to Deming, is composed of a connection of interrelated processes and people which make up the system's components. The success of all managers and workers within the system is dependent on the leaders' capability to orchestrate the delicate balance of each component for optimization of the entire system.

An essential element of Deming's theory was what he called *The Appreciation of a System* (http://en.wikipedia.org/wiki/W._Edwards_Deming). This "involved understanding how interactions (i.e., feedback) between the elements of a system result in internal restrictions that force the system to behave as a single organism that automatically seeks a steady state" (The Definition of A Steady State http://en.wikipedia.org/wiki/Steady_state). It is this steady state that determines the output of the system rather than the individual elements. Thus, it is the structure of the organization rather than the employees, alone, which hold the key to improving the quality of output (http://www.improvementandinnovation.com/features/articles/link-between-demings-theory-profound-knowledge-and-systems-thinking).

However, if the system's basic components are creative behaviors, notoriously chaotic, risky, uncertain, uncontrollable, intractable and intangible, how can we observe and describe how these human frailties combine to influence and cohere to produce a steady state of organization with a quality output?

While Deming was starting out on his journey of systematizing industrial production in Japan post–World War II, American sociologist C Wright Mills was expressing his concern about the potential of the corporation to dehumanize work.

In his book White Collar: The American Middle Class (1951) he contended that bureaucracies were now developing in a way that "overwhelmed the individual city worker, robbing him or her of all independent thought and turning him into a sort of a robot that is oppressed but cheerful. He or she gets a salary, but becomes alienated from the world because of his or her inability to affect or change it."

For Wright Mills, who was constantly trying to reconcile the individual and society, the ideal corporate environment was one in which "the labourer with a sense of craft becomes engaged in the work in and for itself; the satisfactions of working are their own reward, the details of daily labor are connected in the worker's mind to the end product; the worker can control his or her own actions at work; skills develop within the work process; work is connected with the freedom to experiment; finally family, community, and politics are measured by the standard of inner satisfaction, coherence and experiment in craft labour. . .."

This was a radical view at the time but could be the basic advertising copy for an employee job description for those wishing to join today's information, knowledge, and technological industries.

Sixty years hence, Wright Mills description of the idealized environment in which an individual's creative endeavors can be recognized, expressed, and encouraged is emerging as a vital consideration in the development and success of the twenty-first century organizations.

Important to Wright Mill's thinking is the notion of experimentation in the work context and its importance to the worker's identity.

Creativity is only ever understood through imagination (the what if) and experimentation (how), states that in turn are driven by a loop of practice, implementation and perception, and the conversations that occur around the perceptions of the genesis of the practice.

Through this process, the sense of craft associated with an individual's work endeavors develops along with his/her understanding of their practice and abilities.

The lasting legacy of Wright Mill's work is that it describes the humanity and value individuals are seeking to bring to their work in organizations in the twenty-first century with the resulting personal freedom that gives them, and the organizations or networks, within in which they work. The lasting legacy of Deming's philosophy is that it has been able to build an important connection between the mechanistic and logico-rationalism of the world of systems thinking and the human aspect of management.

But wait!! A prominent voice from the ghosts of the Industrial Age is questioning our hypothesis. Lord Kelso, British physicist and member of the House of Lords, 1824–1827, booms out almost sarcastically from the floor of the chamber. "When you can measure what you are speaking about and express it in numbers you know something about it. But when you cannot express it in numbers, your knowledge is a meager and unsatisfactory kind; it may be the beginning of knowledge, but you have scarcely in your thoughts advanced to the state of science, my friends" (Hubbard 2007b).

The Emerging Influence of Organizational Economics in Business

In the 1970s and 1980s, a new breed of economists began to realize the neoclassic view of economic theory based on the rules of a market economy was ignoring an essential component – the "black box" of production, i.e., the firm in which the capital and labor came together to produce the outputs for the market. With the rediscovery of Nobel Prize winning economist Robert Coase's article "The Nature of the Firm" (Coasce 1937), economists began to devise new analytical tools around concepts such as agency theory, transaction cost economics, and game theory to develop "a collection of ideas and models, with the potential to be integrated, to guide managerial activity, and to inform organization theory and behaviors."

These new analytical tools initially focused on issues such as information asymmetrics (the study of decisions in transactions where one party has more or better information than the other), opportunism, and behavioral constraints as opposed to the tools of traditional organizational studies, with their sociological biases, focusing on behavioral norms such as power and trust.

This new approach with its reliance on econometrics and theory building as opposed to the familiar mode of generalizing from empirical evidence and systemic data analysis was warmly welcomed by managerial theorists, who were not unfamiliar with economics and the use of formal mathematical modeling to explain economic theory and were suffering criticism about their one-dimensional focus on theory and the use of case studies to support the theory.

What began to emerge at the turn of the twenty-first century were organizational economists aided by the numbers contained in these new analytics, joining with their managerial theorists and organizational studies colleagues with their empirical studies to inform business directly in more meaningful ways.

Suddenly, business leaders found themselves able to engage with economists, examining the tasks of motivating and coordinating human activity; exploring the nature and effect of efficiencies; the processes of creating, sharing, and exploiting knowledge; designing incentives; constructing intellectual property rights and ways of disseminating; and processing information that structured productive processes and activities – all matters with the potential of adding substantially to an organization's bottom line, in this new era of valuing and commercializing the intangibles of knowledge and information.

Given this context, could it be possible, then, to use this new thinking in organizational economics and apply it to benchmark and measure the cumulative management innovation behaviors that drive an organization and, in the process, locate Deming's steady state of equilibrium from which a leader can begin to meaningfully reflect on and manage the intangibility of organizational creativity to drive sustainability, growth, and success?

A Methodology for Benchmarking and Measuring the Intangibility of Organizational Creativity

In a very practical way, the impact of creativity in an organization affects its success. Yet, creativity in any organizational system is fuzzy – intangible. Rather like a theatrical production, organizational creativity is the sum of all the inputs involved in the organization's system with the outputs being the organization in performance.

A method for modeling organizational creativity, the Management Innovation Index ™ (the MIX) has been developed to enable organizations to map, benchmark, and measure their management innovation performance in the process giving a tangibility to the organization's creative fuzziness.

Management innovation is made up of two elements – the creative inputs produced by the employees and the organizational sociology which supports or impedes the flow of their creative inputs.

Creative inputs in an organization evolve from a moment in time when a single thought manifested, picked up by a person who did not initiate the thought, coalesces into a concrete idea. Once this occurs, the idea has a life of its own and begins a never-ending journey that is dependent for its survival and acceptance on its flow within the system.

To ensure the idea is given a good chance to germinate regardless of its intrinsic merit, managers seek clarity around four elements of ideation:

- Purpose – I know why I am working on this idea and it has a chance of being developed within the system.
- Motivation – I am committed, passionate, ready to take a risk, go the extra mile to make new things happen. There is a flow in my work environment that means I am not impeded and I am supported, recognized, and rewarded for my ideas.
- Orientation – I am empowered to develop my own ideas. I know who to work with to advance them. I recognize where the constraints are around my ability to advance

them. I am OK with that and know how to resolve it.
- Implementation – My ideas will get implemented in some form or another.

A survey containing a series of questions administered across all levels of the organization enables sufficient raw data to be collected to grade managers' perceptions of these elements and using Deming's concept, to obtain an appreciation of the system and its feedback mechanisms.

The second element – the organizational sociology – seeks to discover the managers' cumulative perception of how the environment in which they operate influences the way they think and apply their creativity.

To observe this phenomenon, the MIX, again using data collected from the survey, benchmarks the organization's management innovation behaviors seeking to observe any biases in patterns that may strengthen or weaken the organization's overall strategic innovation capabilities.

The management innovation components benchmarked are as follows:
- The organization's culture and environment and its managers' skills in envisioning, leadership, communication, and reflection
- The organization's strategic leadership and thinking styles and its managers knowledge and understanding of the concepts of emergence, design, collaboration, and analysis
- The organization's practices in strategic implementation and its managers experience, skills, and techniques around strategic and tactical ideation
- The cumulative beliefs and traits of the organization's leaders and managers associated with their creative thinking styles and practices

The quantitative analysis, the mapping of the organization's creativity flows and the benchmarking of the management innovation behaviors, is supported by qualitative analysis through the collection of a series of anecdotal responses to questions around managers' current creativity and innovation experiences in the work place.

The results are compiled into a Management Innovation Assessment Report containing a series of management innovation benchmarks against the organization's culture, environment, strategy, strategic implementation, and cumulative management creative capabilities. Independent specialist innovation experts offer assessment and recommendations based on the benchmarks, the outcome being a simulation of Deming's map of profound knowledge, a lens – in this instance – onto the organization's creativity.

In this way, the MIX makes visible the organization's "steady state" of creativity. Once the steady state has been benchmarked, senior leaders have tangible evidence from which they can make informed strategic and tactical decisions about the future development and direction of the organization's innovation goals and objectives.

In a comprehensive interview on the MIX's strengths and weaknesses as an analytic, Harvey Wade, Manager of Strategic Innovation, Allianz UK, said "The way the collected data and details were interpreted and presented meant that it gave Allianz real numbers and measures, assisting them to re-enforce what they felt intuitively. The importance for the innovation team, though, was in obtaining real measures with genuine rigor as it represented the views of over 150 people across the business that gave meaning to their intuition. For example, its qualitative data revealed a blockage in middle management and the reasons for the blockage that had not been clear before.

The most important point of difference for the Management Innovation Index as a form of measurement was its clear perspective on the strategic dynamics of organizational creativity. Whilst it did recommend the use of tools and methodologies, like other providers, it was distinctly not the Management Assessment Report's main focus.

What the Management Innovation Index did was put innovation into a proposition that enabled focus" (The Creative Leadership Forum 2011).

How well this focus is understood, interpreted, and supported by senior leaders defines the organization's capacity to be creative, to change, to adapt, to produce, and to manage a system of continual creative inputs, the source of the organization's innovation – its growth and success.

The biggest challenge for leaders once the intangibles of organizational creativity have been benchmarked and measured is how to communicate and emphasize its strategic and tactical importance against all the other processes and forms of measurement in which the organization is currently engaged.

Do not expect creativity in an organization, if the lead indicators are driven by employee engagement and/or behavioral thinking style surveys.

These diagnostics impede the empowerment of managers to think differently – the lifeblood of creativity – and emphasize conformity – the coffin for creativity.

Conclusion and Future Directions

As the world becomes globalized and as a consequence market and economic conditions change even more rapidly, the twenty-first century organizations will need to have the internal management skills and knowledge capabilities to move in and out of markets rapidly to compete and survive.

The emphases on market competitiveness will no longer simple reside in the clichéd marketing slogan of "identifying and satisfying customer needs." Rather the competitive edge will focus on researching and defining problems that need to be solved. Resolving problems requires creative thinking and behaviors. Importantly, resolving problems creates business opportunities. Allianz UK's innovation team promotes the notion organizationally "When there is a problem and there is a solution, there is an idea." Those leaders that are able to harness and develop their organization's unique creative capabilities in a strategic manner to solve problems will gain competitive advantage in the twenty-first century.

The Management Innovation Index™, a way of modeling an organization's creativity, makes tangible the flow of creativity within the organization and benchmarks management innovation behaviors that drive the flow. Among other aspects, the MIX enables a leader to assess the organization's management innovation behaviors that present the best opportunity for strategic and tactical development in line with the organization's goals and objectives, reveals the organization's inherent creative strengths and weaknesses across all levels of management, and informs the leader as to where the impediments to the organization's creativity specifically occur.

With the knowledge obtained through this process, a leader has data and a set of numbers from which to commence making informed decisions about the future strategic direction of the organization.

Managers and teams have a clear sense of what they need to do to develop their creative practice contextually to facilitate meaningful contributions to the growth and success of the organization overall. Mills Wright's notion of the workplace as a social environment in which managers are openly applauded for being creative rather than conforming to policies and procedures, enhances the managers' personal skills, dignity, and well-being. Organizational and executive development can focus on alleviating creative blockages impeding the organization's "steady (and now continual) state" of innovation, while deliberately and incidentally developing creative leadership, skills and behaviors across the organization.

The MIT Sloan Management Research Report of Fall 2010 "Analytics: The New Path to Value" (IBM 2010) revealed senior executives now want businesses to run on data driven decisions. They want scenarios and simulations that provide them with immediate guidance on what best actions to take both when change and disruption occur and when planning the future.

Jeremy Trott, Head of Innovation, Allianz UK leads the way in that practice when he says "With the Management Innovation Assessment Report, the outcome of the MIX, we have enough information to really concentrate on shaping our strategic innovation plan over the next two or three months, that will drive the success of the business for the next five years!"

So when a leader asks about the value of creativity and says show me the numbers, there can now be a meaningful and tangible response.

Model of Dialectical Learning

Jeffrey G. Woods
School of Business, University of Indianapolis, Indianapolis, IN, USA

Synonyms

Cognitive conflict; Dialectical inquiry; Knowledge creation; Synthesis

The Philosophical Foundation of Dialectical Learning

Dialectical inquiry (DI) is an intellectual discourse that originated with the work of nineteenth-century philosopher G.W.F. Hegel (2010). Hegel contended that a higher level of understanding and insight could be achieved by creating the two most diametrically opposed viewpoints or explanations to a given situation or problem. Two opposing views (a thesis and antithesis) are developed in order to create direct conflict between two parties. Following a structured debate, a new collective view is pursued, forming a synthesis. The differing parties base their positions on identical databases. Points of view are influenced by underlying assumptions, value systems, and cognitive abilities (Boerner et al. 2003; Scott 2011). The Hegelian dialectic or the Hegelian inquiring system is the foundation of many of our political and legal processes (Van Gigch 1978). Hegel's philosophy has been a historic approach to problem-solving and an effective technique for clarifying opposing viewpoints.

More generally, DI is a creative problem-solving technique that requires an integration of previously dissociated ideas or facts for the purpose of gaining a deeper understanding of a problem or situation. An important implication of using the DI technique is the learning that occurs. As many management scholars have pointed out, learning occurs within the framework of dialectical processes (Nonaka 1994; Argyris 1999; Scott 2011).

Using Dialectical Inquiry in Strategic Management Applications

Research on the use of the DI technique began 40 years ago and was designed to improve corporate strategic decision-making, planning, and policy determination. An initial study was conducted by Mason (1969).

Mason (1969) developed and applied DI for the purpose of examining the assumptions of strategic planners in a "debate group" context. Two debate groups are involved in using the DI method. One group represents the thesis while the other group

M

forms the antithesis. Mason suggested two criteria that DI should be able to discover in the planning process: (1) it should expose the underlying assumptions of a proposed plan so that management can reconsider them, and (2) it should suggest new and more relevant assumptions upon which the planning process can proceed. Mason believed that once management is made aware of these assumptions, it can reconsider or reformulate them. According to Mason:

> The principle theme of dialectical advise is that management learns about the fundamental assumptions of its planning problem and comes to understand them by observing the conflict between the plan and the counter-plan and their attendant world views. The vehicle for including this reflection is a structured debate. The structured debate consists of the most forceful presentation possible of the two most opposing plans, given the constraint that each side must interpret, in its entirety, the same organizational data bank. Following a statement of the problem, the structured debate begins with the advocate of the plan stating his world view or model of the situation. The advocate of the counter-plan does likewise. Then, as each item of data is introduced, it is interpreted by the opposing advocates to demonstrate that it can be interpreted as supportable evidence of their plan and negative evidence for their opponent's plan. This process continues until the data bank is exhausted.... Hegel's theory leads us to predict that the manager – observer of the conflict – will integrate and form a new and expanded world view (the synthesis). The synthesis includes exposing hidden assumptions and develops a new conceptualization of the planning problem the organization faces (1969, p. B408).

In Mason's (1969) initial field study, where he implemented the DI technique in a strategic planning exercise, one executive observed, "The two well-developed points of view pull you both ways at the same time. It becomes the vehicle for amalgamating the best plan of action you know how to develop." This result lent support to the formation of a synthesis using the DI technique.

The Dialectical Learning Process

Mason's research missed the critical theoretical link between the use of DI as a learning method and how this method activates the dialectical learning process. Activation of the dialectical learning process creates cognitive conflict for strategic decision-makers enabling them to create new knowledge from the growing insights that are discovered as a result of dialectical learning (Nonaka 1994; Davenport and Prusak 1998). Previously dissociated ideas and facts merge to create the best plan of action or decision. Dialectical learning increases strategic decision-makers' learning capacity, creating a greater number of strategic options (Boerner et al. 2003; Alajmi 2010; Scott 2011).

Dialectical inquiry activates the dialectical learning process using what in DI is referred to as debate groups who juxtapose information that has alternative interpretations of meaning. Conflicting information creates cognitive conflict in the learner/observer of the process. This learning process requires an assimilation or convergence of the conflicting information. The result of integrating conflicting information generates cognitive conflict creating new knowledge enabling strategic decision-makers to update their knowledge base. This learning process creates a new conceptualization of the problem (synthesis), leading to improved decision-making and strategic performance (Boerner et al. 2003; Scott 2011).

Because the use of DI has a potentially significant impact on improved decision-making, a more detailed explanation of how it affects strategic decision-makers' learning process is needed. This is because the use of DI and its impact on dialectical learning is particularly relevant to strategic decision-makers since their decisions will have an impact on an organization's long-term performance. Therefore, a better understanding of how DI can assist decision-makers in strategic management practices is highly valuable to learning organizations (Scott 2011; Mills 2011).

The aim of dialectical learning is to critically analyze new ideas by linking them to previous knowledge so a deeper understanding of problems can result. A structured debate format using the DI method is highly desirable because it provides opportunities for tangible learning experiences that can become a formalized part of an organization's strategic decision-making process. Strategic decision-makers can develop greater insights pertaining to problems when opposing ideas are formally debated rather than being ignored. It is important that learning occurs during the strategic decision-making process and not only after decisions are made. Strategic decision-makers who participate in the dialectical learning process develop insights and learn from using the DI method by observing debate group interaction. Therefore, in the context of dialectical learning, organizational members who comprise the debate groups become the agents for the transfer of learning (Argyris and Schön 1978).

A Model of Dialectical Learning

The model of dialectical learning focuses on individual learning. In the context of using the DI method, the use of debate groups serves as the learning source while the strategic decision-maker is the learning recipient. Ultimately, improving the knowledge base of key decision-makers is expected to result in improved organizational performance (Simon 1991).

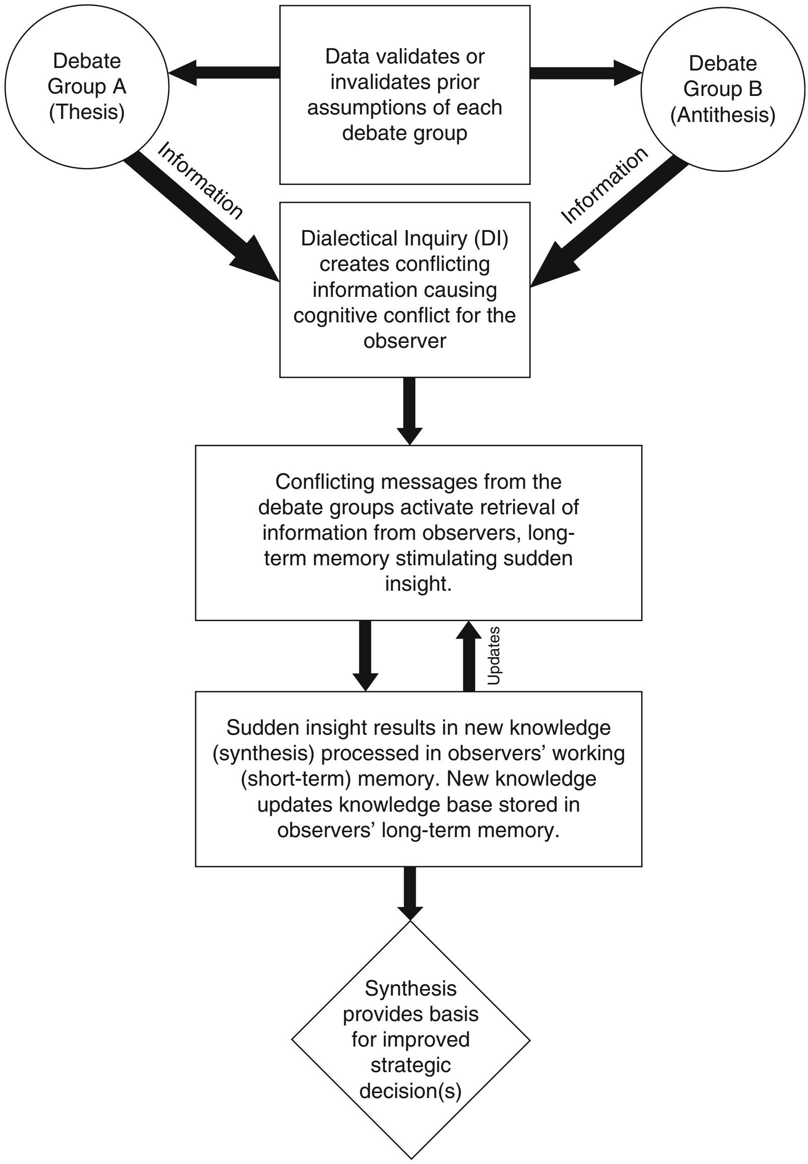
Many management scholars have pointed out that prior experiments using DI do not capture the richness of learning, the group processes at work, and their significance (Mitroff 1982). Gaining a better understanding of the dialectical learning process of strategic decision-makers would help shed light on the effectiveness of DI as a learning technique.

Dialectical inquiry may be viewed as a "trigger strategy" in the sense that opposing viewpoints create cognitive conflict providing a trigger or catalyst for dialectical learning to take place. Observing conflicting information generates the cognitive conflict needed for stimulating the dialectical learning processes of decision-makers for the purpose of producing systematic knowledge.

Dialectical inquiry creates cognitive conflict providing the stimulus for learning to occur. The structured debate groups serve as the learning source. Assumptions are determined from the content of the plan or exercise and each group's collective experience. These assumptions or prior beliefs may be viewed as the foundation of each group's initial position (Boerner et al. 2003). The initial position each group takes composes the thesis for one group and the antithesis for the other. Each debate group will interpret identical data to support its collective position. Data which can be qualitative or quantitative are the raw material provided to each debate group and, in their simplest form, are "discrete, objective facts about events" (Davenport and Prusak 1998). Data by themselves are not very useful for each debate group until they are put into context (Davenport and Prusak 1998). Ultimately, data validate or invalidate each debate group's assumptions, creating conflicting information observed by decision-makers (Scott 2011). David and Foray (2003) define information as structured and formatted data that remain passive and inert until used by those with the knowledge needed for interpretation and processing. Here, knowledge is defined as true and justified beliefs acquired empirically (Nonaka 1994). It is actively constructed in the human mind and is the most strategically important resource an organization possesses (Grant 1996).

Debate groups produce a flow of conflicting messages causing cognitive conflict in strategic decision-makers (Nonaka 1994). This learning stimulus activates the cognitive learning processes of the decision-maker accessing his knowledge base stored in long-term memory. If the problem is ill structured (a common occurrence in strategic planning), reliance on the resources of long-term memory can be extensive (Simon 1991). Thinking and learning occur in the observer/decision-maker's working (short-term) memory. Prior knowledge stored in long-term memory provides a context for synthesizing conflicting information transmitted from debate groups' interaction. The new knowledge created in the working memory updates the knowledge base in the strategic decision-maker's long-term memory (Derry 1996).

For DI to be an effective learning strategy, it should create enough cognitive conflict in the



Model of Dialectical Learning, Fig. 1 A model of dialectical learning
Source: Woods (2012)

strategic decision-maker to foster the retrieval of information from long-term memory helping to stimulate sudden insight. This new insight alters the whole character of the problem and transforms it into one that can be solved more creatively. The strategic options generated from dialectical learning are a function of the strategic decision-maker's learning capacity (Boerner et al. 2003; Alajmi 2010; Scott 2011). Figure 1 illustrates and summarizes the model of dialectical learning.

Implications of Dialectical Learning for Research and Practice: The Role of Cognitive Conflict

Strategic decision-makers must understand the process of dialectical learning in order to successfully implement DI as a formal part of their organization's strategic decision-making process. Their understanding of the dialectical learning process will enable them more easily to explain the benefits of this learning process to debate group members. The benefits of creating cognitive conflict for strategic decision-makers, i.e., knowledge creation, must be explicitly linked to improved strategic performance and the achievement of organizational goals.

The application of the DI method of learning to the dialectical learning process in strategic decision-making can be an intellectually satisfying endeavor for strategic decision-makers. Though DI has the ability to generate new knowledge critical for improving strategic performance, it has not been widely adopted. This is unfortunate as strategic decision-makers who collect extensive information before making strategic decisions will have more accurate perceptions of environmental conditions which have been shown to relate to improved organizational performance (Bourgeois 1985). Further, Burgelman (1991) has argued that creating an atmosphere where strategic ideas can be freely championed and fully contested by anyone with relevant information may be a key factor in generating viable organizational strategies. Organizations have the power to influence the success of strategic decisions through the processes they use to make key decisions (Dean and Sharfman 1996). It is likely that the dialectical learning process has been underappreciated because DI requires the use of conflict to serve as a catalyst for learning. If organizations perceive conflict as something to avoid in strategic decision-making, the benefits of implementing DI will never be realized. Avoiding conflict could potentially reinforce the status quo. One major problem is that organizations may confuse cognitive conflict with affective conflict. Cognitive conflict is task oriented. This type of conflict should be encouraged because it can enhance organizational performance (Amason 1996). Cognitive conflict must be viewed as the fuel that drives learning and enables innovative strategic solutions. It is an energy source for strategic decision-makers creating opportunities for growth and change (Andrade et al. 2008).

Affective conflict is personalized disagreement and can be destructive (Amason 1996). It is critical that debate group members understand their role in DI so as to minimize any affective conflict that could result during debate group interaction. Therefore, before experimenting with DI, there are some emotional aspects of information generation between debate groups that must be considered. These aspects of the dialectical learning process need to be considered an important part of a proposed research design. Dialectical inquiry can be an emotional experience for some members of debate groups, so it is worth discussing this limitation.

The effective use of opposition or contradiction by individuals is related to psychological health and creativity (Williams 1983). Observing the dialectical process is a form of higher-level (deep) learning involving a substantial amount of cognitive effort on the part of the strategic decision-maker. However, if DI creates affective conflict between some members of debate groups, dysfunctional behaviors could result (Fiol and Lyles 1985). Cognitive conflict can improve strategic decision-making, but affective conflict may weaken the ability of debate groups to work in the future. In order for groups to effectively debate in ways that promote respect, consideration, and understanding while incorporating other people's perspectives, it would seem that a great deal of maturity would be required. Debate group members need to be able to support their position while preserving their working relationships (Tjosvold et al. 1981; Nonaka 1994).

There are at least six potentially negative outcomes of conflict as it relates to debate- group interaction (Schmidt 1974):

1. Some people will feel defeated and demeaned.
2. Distance between people could increase.
3. A climate of distrust and suspicion could develop.
4. People and departments that need to cooperate may only look after their own narrow interests.
5. Resistance – active or passive – could develop where teamwork is needed.
6. Some people may feel left out because of the turmoil.

Clearly, because of these limitations, the implementation of DI as a structured source of learning for strategic decision-makers would require training. When a learning intervention is managed skillfully, Tjosvold et al. (1981) found that conflict in decision-making can have constructive consequences. Their study found that conflict can be used to facilitate the exchange of information when participants become skilled at disagreeing while confirming each other's competence and expressing acceptance of each other as a person.

Conclusion and Future Directions

The learning implications of DI provide the critical link between debate group interaction and the achievement of a synthesis in strategic decision-making. Conflicting information associated with debate groups' contradictory positions creates cognitive conflict in the strategic decision-maker which is a necessary component of dialectical learning. The implication is that information cannot be completely understood unless juxtaposed against alternative poles of meaning used to support the assumptions of each debate group (Slife 1983). It may be difficult to conceptualize many ideas needed to solve problems and make strategic decisions without an opposite interpretation of meaning.

The complexities associated with dialectical learning will call for some innovative research designs. Interdisciplinary researchers should collaborate to further develop this research area.

It is also hoped that practitioners will view dialectical learning as a powerful strategic decision-making model they can use to improve the quality of strategic decisions. The implementation of the DI learning technique will require extensive training and careful selection of debate group members. This training must focus on how DI can be used to improve organizational performance while minimizing any potential dysfunctional behavior between debate groups resulting from affective conflict. Because organizations learn through their members, DI is an important learning method for activating the dialectical learning process of strategic decision-makers for the purpose of improving organizational performance.

Key Concepts and Definition of Terms

A model is characterized by representing objects, phenomena, or processes of the world. Stachowiak (1973) introduces three key features of models: imaging feature, reduction feature, and pragmatic feature. Creativity can be defined quantitatively or qualitatively and has three directions of impact (Hanke et al. 2011): the creative product, the creative process, and the creative person. In general, creativity is referred to the creation of novel and useful artifacts (Mumford 2003). Models for creative inventions are representations of the world that are novel, i.e., different from already existing representations, and originate after an iterative model-building process.

Theoretical Background

Taking into account that creative inventions are understood as artifacts that are new as well as useful and are created by a divergent way of thinking, this requires an iterative process of model building (Ifenthaler and Seel 2011). According to mental model theory (Seel 1991), this process is characterized by creating, revising, and testing models of inventions. First, a model of an invention is regarded as an image or representation of the novel idea which may also function as a model itself (Stachowiak 1973). Second, a model of an invention is regarded as a reduction of the novel idea, i.e., it does not include all attributes of the represented original invention, but such that are relevant for the inventor (Stachowiak 1973). Third, a model of an invention is regarded as pragmatic, i.e., if they are not explicitly conjugated with the original invention.

Accordingly, creative inventions are guided by explanatory mental models designed with a specific end in mind. The inventor explores these internal models by developing hypotheses and then varying input parameters to investigate how well his or her conjectures align with the models. More generally, creative invention presupposes that people actively construct meaningful representations, such as coherent *mental models*, that represent and communicate subjective experiences, ideas, thoughts, and feelings. By means of such representations, an individual is also able to simulate real actions in imagination (in the sense of thought experiments) in order to create an invention (Seel 2003). In this context, mental models fulfill several functions (Seel et al. 2009): (1) They guide the comprehension of the invention as well as the concrete operations with it; (2) they allow the invention's states to be explained; and (3) they allow predictions about the invention's behavior and the effects of intervention in the invention to be derived (Greeno 1989).

Creative invention requires iterative steps of hypothesis testing as well as an increased time for constructing *appropriate* mental models. However, the generation of hypotheses within a creative invention process is a challenging task (de Jong and van Joolingen 1998). Insufficient prior knowledge could also lead to incorrect and insufficient hypothesis statements (de Jong and van Joolingen 1998). Learners' prior knowledge becomes evident through their preconceptions and naive theories. These preconceptions are not isolated units but rather parts of conceptual structures which provide a sensible and coherent comprehension of the world. Therefore, preconceptions are not easy to modify or to change if a subject is convinced of their plausibility (see Smith et al. 1993). Overall, the development and successful application of a mental model often requires quite a lot of time and mental effort due to basic processes of analogical reasoning or internal simulations.

According to Jonassen (1999; Jonassen and Cho 2008), this mental effort may be reduced and the conceptual understanding may be facilitated through mindtools (computer-based modeling tools), because these tools enable the externalization of the internal simulation processes. Besides computer-based modeling and simulation tools for the *construction* of externalized models of inventions, there are also tools which focus on the *exploration* of the underlying model of an invention (Clariana and Strobel 2008). This second type of computer-based modeling tools for the exploration of underlying models of inventions may be differentiated further into (1) black-box and (2) glass-box systems. In a *black-box simulation*, all computations are hidden from the user. Such systems include adjustable parameters and a large variety of process visualizations which become available after the actual action of the simulation is completed. On the other hand, *glass-box simulations* expose the underlying mathematical and logical simulation model. This can be realized by revealing the underlying equations, connections, and interdependencies between variables and changing variables, parameters, or equations (see Murray et al. 2001).

Conclusion and Future Directions

Imagine you want to create an ultracompact espresso maker for on the road. First, you would create a model of such a kitchen appliance by using your existing knowledge on espresso makers. Your prior knowledge on espresso makers will enable a simulation of various components which constitute the ultracompact espresso maker for on the road. Specific elements of the appliance will be revised through iterative simulation processes. Using a computer-based modeling tool for externalizing the internal simulation process might take off your cognitive effort and might highlight specific problems when designing your creative invention. Accordingly, creative inventions might be more successful when using tools for externalization. This hypothesis might be tested in future research on models for creative inventions.

Multi-level Systems of Innovation

The Institutional Embeddedness of Innovation Across Multiple Levels

A multilevel system of innovation (MLSI) describes a configuration that is characterized by the distribution of resources, competences, and institutions needed for the generation of innovations across different territorial and sectoral levels.

Since the mid-1980s, several authors (e.g., Freeman 1992; Lundvall 1992; Nelson 1993) have developed the concept of the "National System of Innovation" (NSI) in order to study the interrelations between technological development and the institutional embeddedness of innovative organizations. Lundvall proposed several basic indicators, which should mirror country-specific differences in national innovation systems. The focus on national systems, he claims, "reflects the fact that national economies differ regarding the structure of the production system and regarding the general institutional set-up" (Lundvall 1992, p. 13). The internal organization of firms, the interfirm relationships, the role of the public sector, the institutional set-up of the financial sector, as well as the intensity and the organization of research and development should reflect national idiosyncrasies.

Since the early 1990s, this approach has been diversified by studies that recognized the evolution of autonomous systems of innovation at the local, the regional, the European, and even the global level (e.g., Borras 2003; Cooke 2002; Mytelka 2000). Whereas a first group of scholars stressed the importance of local institutions and networks, transfer mechanisms, regional labor markets, as well as specific sociocultural environments, a second group pointed to the internationalization of markets, technologies, and corporate activities as well as the ongoing Europeanization of public policies. Consequently, tensions for NSIs arise both from globalization and regionalization resulting first of all from increasing cross-border technological alliances of multinational enterprises (Nelson 1993). Additionally, international science, innovation, and diffusion networks turn nationally based systems of innovation into open systems (Galli and Teubal 1997).

Arguments in favor of the existence of European or global systems of innovation refer mainly to two developments: first, the effects of national policies are diminishing due to the increase of transnationally organized technologies and businesses; second, a growing number of policy areas are coordinated by the European Union or other regional integration agreements. For some authors, the establishment of postnational institutions in the area of the science infrastructure, such as European science funding, innovation and technology transfer, and European programs for

*Views expressed in this paper are purely personal and do not reflect the position of the European Commission.

education and training are clear signs to believe in a European innovation system (e.g., Caracostas and Soete 1997).

Much attention has been paid to the concept of regional or local innovation systems (e.g., Cooke 2002; De la Mothe and Paquet 1998). Cooke (2002) has argued that the national innovation system cannot function well without regional innovation systems “in respect of the enterprise and innovation support infrastructure, specialized human capital, leading edge basic and applied research and the varieties of network relationships that function most effectively in the relatively close proximity of regional clusters.” As it is obvious that regions within a national innovation system often develop quite differently, one can conclude that specific regional or local characteristics and structural patterns exist which have a deep impact on the competitiveness of regions.

However, these concepts largely fail to show in how far the totality of NSI elements has been established on the international, European, or regional level and to what extent they are still embedded in national systems of innovation or exist separately from them. They also called the dominance of national institutions into question as they emphasized the growing importance of institutional arrangements below and beyond the nation-state level.

In contrast, the concept of multilevel systems of innovation is based on the identification of those features within a national system of innovation that have been territorially reconfigured along European/international lines or regional/local lines. Since reconfiguration processes take course in both territorial directions, beneath and above the nation-state, the growing meaning of the regional as well as the international level can be thoroughly explained. Consequently, the MLIS approach focuses on the dynamics of the reconfiguration of NSIs, rather than just describing autonomous innovation systems on one specific territorial level. Moreover, despite processes of internationalization and regionalization, the MLSI concept does not neglect the meaning of the national environment for the generation of innovation continues to be important. National patterns of economic specialization remain. This means that national systems of innovation significantly vary, for example, according to the direction of public science and technology policies, the distribution and the success of public R&D financing, the technological orientation of industrial research, and the level of the enterprises’ technological development.

Theoretical Sources of the Concept

The MLSI concept integrates two different social science theories, namely, the multilevel governance approach, which became quite prominent in European integration research, and systemic innovation concepts, which have been developed since the end of the 1980s in innovation-related economic research.

The systems of innovation approach detected that innovative activities of enterprises do not only depend upon intrafirm organizational capacities but are fundamentally shaped by the organization’s institutional environment as well as through specific technological or scientific patterns in which innovation processes are embedded. Thus, national or regional differences in technological performance can be attributed, at least to a significant extent, to variations in the institutional environment. Studies about systems of innovation usually referred either to one specific “territorial level” (e.g., “national systems of innovation,” “regional systems of innovation,” “European system of innovation”) or to one specific technology or industrial branch (“sectoral systems of innovation”). Due to processes of political decentralization, economic globalization, and paradigmatic changes in certain technological field, however, the borders of such systems have become blurred, as more and more of its functions (e.g., financing, regulation, policies) can be located across various territorial and sectoral levels. As a result of these dynamics, innovation systems at a specific territorial or sectoral level have undergone a process of reconfiguration conceived as a process that generates new modes of coordination and new constellations of actors among established or new organizations.

In view of the territorial dimension, this process has become most prevalent within the

European Union, which has emerged since the early 1980s as a key player in the field of innovation, research, and development as well as education. In Europe, many related public policies became part of a multilevel governance system, which is characterized by institutional incentives or framework conditions provided by various actors that share responsibilities across territorial levels. The concept was first introduced in the early 1990s and provided an innovative explanation for the progress of integration in Europe which was conceived as a polity creating process in which authority and policy-making influence are shared across multiple levels of government (Hooghe and Marks 2001). Considering the research on multilevel governance, a multilevel system of innovation is characterized by three institutional peculiarities: (1) actors at different territorial levels share decision-making competencies, (2) actors and decision-making arenas are not ordered hierarchically as in traditional intergovernmental relations, and (3) actors rely mostly on consensual or nonmajoritarian decision-making rules.

With regard to the sectoral dimension, systemic reconfigurations have taken place as a consequence of paradigmatic shifts in an increasing number of technological fields. The most relevant dynamic that led to the emergence of so-called science-based industries (biotechnology, nanotechnology, multimedia, etc.) has been the dramatic change of basic scientific concepts, methods, and procedures that forced many traditional industries to reorganize their innovation processes. While the generation of innovations increasingly depends on the integration and absorption of transsectoral knowledge, many of the most successful innovations in recent decades were developed at the "borders" of traditional sectors.

Implications of the Multilevel Perspective for Theory and Practice

Understanding the dynamics within multilevel systems of innovation requires a thorough analysis of those indicators that have been developed in the literature to describe the characteristics of NSIs: regulation, public technology and innovation policies, the research and education systems, the financial system, and corporate activities (Kaiser and Prange 2004).

With regard to the first variable, a MLSI would mean that market and product regulation in different technology areas would become more and more organized across various territorial levels. Such development might lead to supplementing or even replacing the national level at least in terms of the framework for setting harmonized regulations. Public technology and innovation policies mirror regional, national, and international public policy programs, their importance with regard to financial resources, and the openness of programs for third parties. New public innovation policy initiatives are often crucial for a technological catching-up process. Those initiatives might not only originate from the national but also from the regional and European level. In relation to research and education systems, a MLSI would see territorial reconfigurations, for example, through reforms in the higher education system, global university networks, or patenting. A reconfiguration would especially be triggered through science-based industries where the research and education systems play a significant role both for the provision of qualified personnel and for the commercialization of scientific knowledge. Finally, corporate activities should range from the local to the international as in the pharmaceutical biotechnology sector, for example, small- and medium-sized research companies are heavily engaged in partnerships and alliances with local knowledge providers and national as well as international pharmaceutical companies. While some activities might, at least partly, depend upon the local innovation milieu, others, however, – such as R&D and trade in high- and medium-high-technology intensive products – are to an ever-growing degree internationalized.

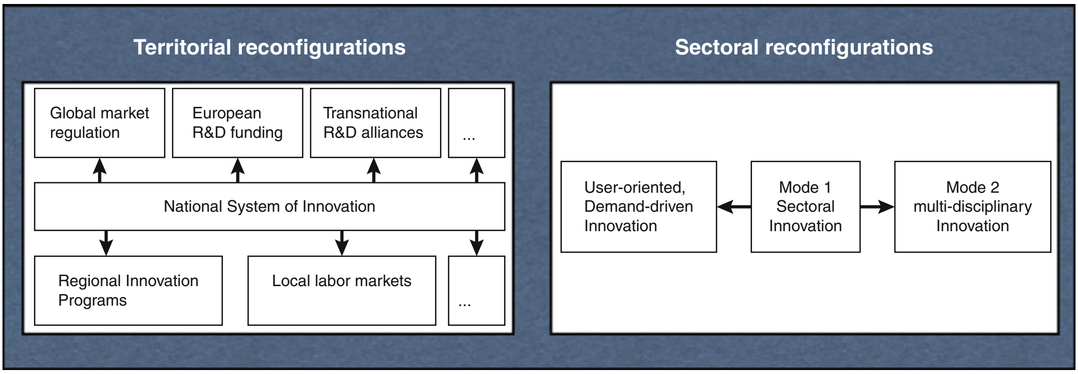
In MLSIs, some of those functions described above become part of a multilevel governance system in which institutional incentives and framework conditions are provided by various actors who share responsibilities across territorial levels. By proposing such a multilevel approach, the concept bridges the gap between innovation system approaches that analytically focus on one specific territorial level only. The MLSI concept does, however, not deny that the national institutional framework is still important even in federalized or decentralized countries, in which subnational regions and localities do not only provide incentives or create framework conditions autonomously, but also in a coordinated manner with the national and the international level. Europeanization has an important impact on the institutional environment in which innovative actors are embedded. Especially, systemic functions such as regulation, public R&D financing, and public innovation policies are increasingly integrated into a European multilevel governance system, while the financial or the research and education systems still reflect mainly national and regional patterns of specialization.

In turn, however, this also means that a more coordinated – or even integrated – multilevel innovation system is likely to increase tensions between actors who mainly interacted within national borders. At least for three reasons, the European Research Area is quite a good example of the contradictions such a multilevel setting may produce (Kaiser and Prange 2005):

1. As long as elements of an innovation system are mostly in the competence of regional or national administrations (e.g., research and education policies), it is quite unlikely that more integrated (or stronger coordination) efforts at European level are successful, especially since regions with legislative and budgetary powers are generally quite reluctant to further centralize policies and competences.
2. The significant variations of institutional settings, of innovative performances, of industrial structures, and of patterns of technological specialization in Europe restrict "policy transfer" and "policy diffusion" through a process of mutual learning to a very limited number of areas in which regions or member states share similarities.
3. Even if innovation policy coordination abstains from centralization, a more coordinated European research and innovation policy is unlikely if coordination efforts intervene into the competition of actors. Member states consider R&D expenditures as critical investments enhancing the competitive position of companies that offer employment opportunities in the member state.

The multilevel innovation system approach also provides for explanations of the dynamics that have emerged in specific innovation-related institutional arrangements. The triple-helix configuration of academia, industry, and government (Etzkowitz and Leydesdorff 2000), for example, has become subject to various forms of transitions, exactly because of the asynchrony in which these organizations engaged in processes of regionalization and internationalization. Long-term stable relations between governments and (formerly public) infrastructural companies in the telecommunications or energy sector have dissolved as a consequence of global market liberalization processes. Traditional R&D collaborations between firms and universities lost importance when especially multinational companies established research centers in the leading innovation hotspots around the globe.

In terms of the sectoral dimension, the concept of the "mode 2 knowledge production" (Gibbons et al. 1994) pointed to the increasing importance of multidisciplinary and "context-driven research" which is focused on problem solving instead of technological advancement along disciplinary trajectories. As such, mode 2 knowledge production supports the steady growth of interorganizational relations, the diversification of knowledge sources and the partial redefinition of institutional arrangements for the exchange of knowledge. A good example of current sectoral reconfigurations therefore is the parallel existence of different "knowledge regimes" within the same industrial sector where, as in the pharmaceutical industry, the protection of knowledge through patenting is crucial for the generation of profits from innovations while, at the beginning of the innovation process, an "open innovation" environment seems to provide the best conditions for the accumulation of promising new drug candidates. Sectoral reconfigurations also emerged from a new understanding of the role of the customer for innovations. While the linear model of innovation took customers' benefits from and customers' interest in innovations more or less for granted, more recent concepts highlight the role



Multi-level Systems of Innovation, Fig. 1 Logics of reconfiguration of innovation systems and the emergence of the multilevel innovation system (Source: Authors)

of demand-driven innovation processes. Moreover, it is not only that customer orientation changes the logic of innovation processes, it also establishes a new institutional understanding of the framework conditions under which the generation of innovations is most dynamic. In this respect, the lead-market concept gained attention both in scientific discourses as well as within the innovation policy community as a framework for the understanding of why innovations emerged first and were dynamically absorbed by users and customers within specific institutional settings.

In sum, the MLSI concept opens up an empirical as well as a theoretical perspective. Empirically, it helps to disclose the changing logics of innovation systems by tracing back the reconfiguration of established systemic variables both in territorial and sectoral perspectives. It helps to understand when and why multilevel innovation systems appear revealing that the reconfiguration of national innovation systems is closely connected to transformation processes of national political systems while the reconfiguration of sectoral innovation systems is related to new modes of knowledge production and a novel perspective of the role of users and customers for the generation of innovations (see Fig. 1).

Conclusion and Future Directions

Taking both the territorial and the sectoral dimensions into account, the concept of the multilevel system of innovation provides an analytical grid for the analysis of systemic reconfigurations and the institutional consequences, which arise as a result of these reconfigurations. The multilevel perspective allows for the recognition of various coordination problems that exist if actors have to decide on resources and action across territorial and sectoral borders. A multilevel system of innovation does not fully replace the existing institutional frameworks, but it adds another layer to an established system with highly persistent actor constellations and modes of coordination.

The emergence of a multilevel system, therefore, inevitably increases the complexity of the innovation process and thus produces both new opportunities and obstacles for actors involved in the generation of innovations. In order to better understand the consequences of increasing complexity, the concept of the multilevel system of innovation explicitly applies an empirical governance perspective, taking into account both the effectiveness of the novel rule- and decision-making structures that have been established among innovative actors as well as the changing institutional environment in which these actors are embedded.

The Idea of Novelty and Creativity Sciences

This entry introduces (1) the novelty and creativity sciences (creativity, invention, innovation, design, composing, business venturing, and others), (2) the idea of multiple models of each, (3) with example multiple models (meta-models) of creativity and innovation, and (4) more detailed models than are usual (here, a 64-item model of the most creative process known – natural selection). The model of creativity models that this entry presents is the most comprehensive and detailed such model yet published, at the time of this writing – a prior article on 42 models and book on 60 exist (Greene 2001, 2005). This entry also presents four size scales (compared with **levels of invention** in this *Encyclopedia)* as contexts around and under creativity and novelty sciences: excellence sciences (scale 1), some of which are novelty and creativity sciences (scale 2), one of which is creativity (scale 3), 120 models of which are presented here, and another of which is innovation (scale 3), [54 models of which are presented here. Finally, 64 dynamics of one of those 54 innovation models (scale 4) of the single most creative process known, natural selection, are presented].

Rather than summarizing the other creativity models in this *Encyclopedia*, this entry presents an intellectual tradition, centered on developing large diverse repertoires of models, and tools specially invented to support the development and use of such repertoires. One such tool,

Multiple Models of Creativity, Fig. 1 The Novelty & Creativity Sciences

a proposed replacement for prose itself, is presented at this entry's end (the model, from Michod, of 64 natural selection dynamics).

Academia educates creator-designer practitioners into a tradition of one right-y model, righter than all others. The multiple models tradition in this entry contradicts those practices and their academic source. In the history of science (Eamon 1996) European worldwide collecting produced collections categorized in museums that later scholars "explained" via causal models. Modern journals refuse categorical models (and the size of article they require). This entry attempts to open up the following: (1) multiple novelty and creativity sciences and (2) multiple models of each of them, (3) highly detailed such models – as new contexts and frontiers for practice and theory. The costs of our mania for single right-y models and benefits of switching to repertoires of diverse models are included here. Figure 1 shows one pattern among the novelty and creativity sciences (also see ► Creativity from Design and Innovation Perspectives).

Tools for Non-narrow: Thinking, Professions, Academe, and Outcomes

Herbert Simon wrote that exponential increase in knowledge volume meant professions, disciplines, theories, and professional people were, relative to the totality of that knowledge, becoming smaller and smaller fractions, with severe effects, namely, that *all* our major problems fell in the cracks between our increasingly narrow persons, professionals, and disciplines (Simon 1996). System science failed as a solution (Bartanlanffry 1969). Total quality worked better – horizontal processes replacing vertical ones, continuous improvement replacing giant innovation leaps, kansei engineering of delight quality frontiers of customer imaginings of future requirements, and statistical measures replacing management by rank opinion (Greene 1993; Lillrank and Kano 1989; Ishikawa 1991; Cole 1995, 1999). Lately, systems engineering has arisen as design of systems of systems (Maeno et al. 2010; plus ► Creativity and Systems Thinking in this *Encyclopedia*). From these "binding" other fields or meta-fields, tools for handling plural diverse models have arisen (Greene 2010; Nakano 2011).

Structural cognition (Zwicky 1969, Kintsch 1998; van Dijk 1997, Meyer 1982) is another meta-field that addresses this issue of ever narrower people and professions in a world where problems are wider and wider. Where ordinary science seeks one right-y model, structural cognition identifies diverse repertoires of models that explain a phenomena, with each model in each repertoire of models compensating for weaknesses of the other models. In doing this, structural cognition sees itself as midway between Asian causality

(10,000 bee stings to move an elephant) and Western causality (find the one tipping point in a system where slight inputs have huge outcomes). Both aim at predictive capability – but one seeks a single model, while the other seeks diverse well-balanced repertoires of models.

Structural cognition tools are especially suited to crowd-source and swarm intelligence arrangements on the web. The tools encourage application of blends of diverse models, enabling:

1. More comprehensive coverage of a phenomenon
2. More diverse aspects of a phenomenon distinguished from each other
3. More detail handled at the same time as more comprehensiveness is achieved
4. More accurate and localized diagnosis, assessment, and strategic direction done
5. More adaptive alternative responses and ways to go at crisis points
6. More common ground possibilities for reducing first apparent conflicts/differences

A Creativity Theory Support of Many Diverse Detailed Creativity Models

Torrance (Torrance 1974) in his famous work to measure creativity chose three mental capabilities:

1. Fluency – the total number of interpretable, meaningful, and relevant ideas generated in response to a stimulus
2. Originality – the statistical rarity of the responses generated
3. Elaboration – the amount of detail in responses generated

We might, then, ask these three traits of our models of creativity: (1) How many models do we have and use? (2) How rare are these models? How diverse from each other are they? (3) What is the level of detail of elaboration of each model? *Creative modeling of creativity*, it would seem, would involve us in having (1) many, (2) diverse, and (3) highly detailed models, not single right-y models of great abstraction lacking detail and specificity. This little exercise makes us clear that academia's aim for "rightness" of model gets in the way of "creativity" of model. Perhaps, mono-theism drifts into mono-theory-ism, culturally.

The Idea of a Novelty and Creativity Sciences School

Colleges and corporations today split the novelty and creativity sciences into different departments, centers, sites, and degree programs. No journals reach all creativity sciences. Therefore, each novelty and creativity science is being learned, studied, presented, and applied on its own, for the most part. What might improve was they all studied, taught, applied together. That is the concept behind creating a novelty and creativity sciences school (and research center).

The few initial experiments in this direction – primarily at De Tao Masters Academy in China and Keio in Japan – show these results:

- Intense formats – Nine creativity and novelty sciences taught in one 18-day period via 2 consecutive days per course (so interactions among them are intense).
- The graduate student insight – Students *get,* after initial frustration of their habit of seeking one rightest model, the insight that *no one model* is powerful, unbiased, comprehensive, or accurate enough to be trusted.
- Discovery of mental hiding places – Instead of all teams depending on "brainstorms" and all individuals depending on "insights" (see ► Brainstorming and Invention and ► Role of Intuition in Creativity), dozens of particular new ways for new ideas to enter life and work are found (social design automata, stratified responding, and others).
- What one novelty-creativity science teaches others – We ask designers to invent, and they find "over-specification" a problem; we ask inventors to design, and they find "under-specification" a problem – each develops wider new approaches, stretched by experiencing someone else's ways.

Multiple Models of Creativity, Fig. 2 54 Excellence Sciences

Multiple Models from the Practitioner's Point of View

Industry CEOs find two great weaknesses in single right-y models: one, it is too risky to assume that "our" present consultant-academic's model is *the* right one and all others are wrong; two, the best most statistically valid single right-y models, when fully, expensively, and sincerely applied by competent private sector organizations, produce laughably tiny improvements in creativity. A recent Harvard (Amabile, 2009) article reported copying a Japanese hit product 8 years later as the *creative* result from changing 40+ environment variables to create a "creative" and "innovative" environment (see ▶ Measurement of Creativity). Delayed copying is not a robust useful result. Single models however right-y are usually useless or very nearly so.

Six Meta-Models

Below, four levels of repertoires of models (meta-models) are presented, without discussion – 54 excellence sciences (Fig. 2),

The 18 novelty and creativity sciences
Creativity generates novelty which generates selves, knowledge, discovery, invention, and exploration

Multiple Models of Creativity, Fig. 3 The 18 Novelty & Creativity Sciences

many of which are 18 novelty and creativity sciences (Fig. 3), two of which are 120 models of creativity (Fig. 4), and 54 models of innovation (Fig. 5), one of the innovation models being 64 dynamics of natural selection (Fig. 6). This demonstrates both vertical and horizontal dimensions of the structural cognition program of tools for thinking as broadly as our problems without losing specificity and application power. All the models come from 8,000+ people from 41 nations and 63 professions interviewed over a 6-year period, the resulting capability models linked to nearest match theories from 4,000 research books on novelty and creativity sciences. At first redoing Plato by asking high performers in many fields who were top in their field and how they got to the top, produced 54 excellence sciences in the below table, many of which were novelty and creativity sciences. The same data also defined capabilities of highly creative people, great innovators, great designers, and for the other sciences. Total quality and AI software techniques generated interview & questionnaire items (Giarrantano and Riley 2004; Ericcson and Simon 1993; Laguna and Marklund 2004; Hammer and Champy 2003).

Meta-Model One: 54 Excellence Sciences, Some of Which Are Novelty and Creativity Sciences Too

Meta-Model Two: 18 Novelty and Creativity Sciences

Figure 3 presents 18 novelty and creativity sciences in rough order, showing top level relations among them. Creativity is the root of them all because it is what generates novelty into them all. The structure of the table below suggests:

1. That evolution goes on in all novelty sciences and that narration and other liberal-social arts of each novelty science derive from evolution dynamics in each
2. That multiple models of creativity apply to all other novelty sciences
3. That selves and knowledge together capture the levels novelty sciences apply to

120 models of creativity **from 150 creators, 8000 eminent people, & 4000 books and research articles** **People from 63 diverse professions and 41 nations were sources below** [A book of detailed models for 60 of the models below is available from scribd.com] Academic models that correspond with each empirical model below are noted in each box This model of models is the basis of a 4-semester course at KEIO SDM in creativity models **Source De Tao Masters Academy Creativity & Novelty Sciences Studio Plan, 2012)**			
The comprehensive first 60 models Each model below purports to explain ALL of creativity Note: a book on all below was published (Greene 2000)		The partial second 60 models Each model below purports to explain some kinds of creativity Note: the below are being tracked closely for eventual generality	
The socialities of creating	**The mentalities of creating**	**Brain management**	**Mind extensions outside brains**
Catalog	**Experiment**	**Seek exception**	**Entool mental operators**
Recommendations create creative life (by making interior & exterior room, and embracing paradox enough to enable mental travel), accumulate subcreations till they become creation machine; your creative life uses your creation machine to create **Gardner, Simonton, Sternberg, Root-Bernstein**	Solution culture creators articulate to themselves their chosen field as a failure culture; then they reverse all dimensions that characterize that failure culture to invent a solution culture, which they then apply to realize aims the field has failed thus far to attain. **Jonathan Feinstein, Greene, Marx, Arendt**	Everyman scientists, hypotheticality (BAYES) creators become aware of limitations and tendencies in how they view the world (what they notice and miss); they consciously seek frameworks for getting beyond those limits in self and others; they develop exquisitely precise and unusual hypotheses, then invent ways to test them; artists do science. **Bayes, Judea Pearl, Bunge, Sloman, Eamon**	Decentralize intuitions each group and era has its own characteristic intuitions, which creators notice and reverse or change; when central control by leaders is assumed, creators imagine many actors self-organizing without central exchanges and specially designated leaders; **Resnick, Papert, Minsky, MacDermott**
Traits creators vary via being ingenue, problem seeking, violating bounds, bricolage, then they combine ideas via metaphor, abstraction, indexing, and multiple worlds mappings, then they select combines via finding saturated fields, countering intuitions, articulating, applying aesthetic rules. **Guilford, Sternberg**	Policy by experiment creators take all that exists as hypotheses not established truths; they play around with, experiment with what now is, including present trends and thoughts; they structure work not to make systems work but to learn from whether they work or not, how the universe functions. **Deanna Kuhn (us as intuitive scientists)**	Endish means creators embed ends they aim for in the means they use to seek those ends, so that trying for goals, incrementally actualizes them; they liberate themselves from past ways, then in no man's land seek out other ones liberated from the same realities, with some of whom they dream dreams of a replacement for old ways. **Mao Tse Tung, Joseph Campbell**	Change mind map topology creators assimilate ideas into models and arrangements on paper or in their minds, but they take another step and transfer whole models of ideas from one geometry type to another, viewing the same set of ideas from diverse frameworks **Herman Hesse, T.S. Eliot, Foucault, Parsons**

Multiple Models of Creativity, Fig. 4 (continued)

Question finding creators find vital tipping point questions via finding gaps (reverse trends, depersonalize, undo successes, expand models), via finding points of high leverage (fully represent, socially index, seek intersections, change models), via changing representations of situations (change: measures, scales, causes/effects, models), via changing logic (relate, imply, unify, cross domains) **Einstein and Infeld 1938, Runco**	Creation events creators turn distributed sloppy unorganized latent processes of thinking into intense, events, either of two ways, by tweaking in parallel several emerging processes and getting them to interrelate, or by getting the right parties together in the right context and roles. **Greene**	Extreme concentrations creators do normal thoughts, feelings, and actions but continue them to ridiculous extremes which cause them to attract great attention and change frameworks and expectations of others, being declared "creative." **Arnold Ludwig**	Bridge competing nets creators just do social work in this model: they put networks of people and thought into contact that before were not at all in contact, and by how much contact, where, of what sort, creators create a particular flow of ideas. **Ron Burt, Gladwell**
Darwinian systems creators vary, combine, select, and cause idea reproduction across persons, creative works, fields, and domains (so persons, works, fields, and domains all 4 can either foster or hinder creativity, by supporting or hindering the 4 functions: vary combine, select, reproduce) **Finke (pre-inventive forms)**	Fractal model expansion creators map all that is known and tried about some idea or topic in highly organized and regular diagrams, so nothing already tried is omitted or distorted; then they regularize these maps to make what is vital and what is peripheral visually self-evident; finally, they expand the dimensionality of the diagram on all size scale, so they imagine new items associated with each past item. **Abbott**	Idea farming creators plant in minds, their own and collaborators' possible new ideas, then nurture them in various ways, letting them compete as they grow, till some of them tower over the others as more interesting or powerful or unusual; that means creators multitask among diverse ideas planted. **Edison, Kurzweil**	Avatar worlds creators in imagination or using new media see themselves or their favored ideas in alternative worlds relating in ways not of this world to other ideas and persons; exploring new contexts around and relationships with ideas in these other imagined world contexts, reveals aspects of ideas, combinations of ideas,. **Dashavatara, Chip Morningstar**
Combined thought types creators create by combining 16 distinct types of thought: getting inputs via empathy, doubt, observation, and pattern recognization, abstracting by associating, arranging, playing with, and representing ideas; grounding ideas by abstracting from cases, concretize idea in cases, extracting from routine, and creating new routines from ideas; outputting creative works by generation of—images, analogies, syntheses, and causal models. **Root-Bernstein**	Social automata, This is creating by tuning interactions of populations of entities, varying their connectedness, diversity, depth of contact, neighborhood size, till creations emerge. **Greene, Scott Page, Gilbert, Melanie Mitchell, Wolfram**	Use/make across scales creators attend to and act on smaller and larger size scales of space and time than others, **Root-Bernstein, Margulis (and Sagan spouse, she small, he large scale)**	Meta-creation = recursive innovation creators study how other creators create and modify their own ways of creating competitively based on those observations; this includes making a science out of things other creators treat as arts. **Flavell, Demetriou**
Garbage can creators establish and notice 4 cycles: new tools enable new thoughts inventing newer tools; successful works change self/other expectations making more boldness making more success and two other cycles. **Amabile, Baer & Kaufman**	Create by balancing creators map all the dynamics of an area on polar dimensions, often many at a time, and notice what poles are now emphasized and aimed for and which are slighted or missed; **Greene**	Synchronic diachronics creators study the past, map its sequences of innovation, express those as movement along abstract dimensions, then create new things by adding other dimensions, going to extremes not done thus far on past dimensions, and interpolating between	Interface evolution most interfaces and bodies of knowledge, most teaching and explanation are organized by past categories and fit new things into those layers of accumulated past context; creators create new interfaces re-contexting all we know **Liskov, Norman, Talcott Parsons**

Multiple Models of Creativity, Fig. 4 (continued)

		items of past dimensions; Altshuler did this to patents to invent the TRIZ system. **Altshuller**	
Blend	System	Japanese Aesthetics	Repetition power, software
Culture mix many perhaps all creations are done, without anything creative happening as far as the creator is concerned-the creator simply operates in another culture doing what is perfectly easy and normal in his or her own culture, but those in the culture around him are amazed declaring the results "creative"-**Holyoak & Thagard, Koestler, Richard Florida, Gordon**	Nonlinear system creators set up systems of ideas, persons, works, groups, domains that involve many things interacting, they create and tweak parameters of those populations and their interactions, or they set them up to reflect on and tune themselves; the world outside of creators is such populations of things interacting nonlinearly, and the world inside each creator's head is also such a population of things interacting **Par Bak, Gladwell, Cowan, Casti, Kaufmann**	Deliberate imprefection create to make world world not to make world mind or mind world; AWARE (ah-ness of things, empathy toward things, sensitivity to impermanence of things, MUJO (impermanence of things), WABI, SABI appreciation of emptiness) **Sen, Rikyu, Okakura**	Isolate function from means modules encapsulation; creating modules is a constant in all forms of creation-isolating the behavior or effect we want from how it is produced; this allows, encourages exaptation and bricolage. **Mitchell & Plotkin (existential types, modules)**
Discipline mix creators often perhaps always are ones who come from one domain to handle issues in another domain-here too they can be creative without trying hard or doing anything that is not easy and natural to them, in their original domain; **Koestler, (Heilman, Nadeau, & Beversdorf, 2000)**	Darwinian the most creative single process in the universe is the one that created life, and us, humans, that is natural selection; common images of natural selection are nearly 100% wrong; correct models, include collecting neutral traits libraries till some are found adaptive when environment shift substantially, **Simonton, Melanie Mitchell, Dawkins**	Beauty of belonging & not belonging is created by showing the inness of outs, and the outness of ins; seijaku (lost in one's thought but more lost in reality, in a scene), IKI (a clear, stylish manner and blunt, unwavering directness), fukinsei (unbalanced, nonsymmetry, datsuzo (freedom from habit, tradition; koukou (the majesty transmitted from past greats by withered remnants) **Donald Keene, Saito Yuriko**	Reuse & specialize taking something and its effects and behaviors and relationships and making larger or smaller, faster or slower versions of it-v **Dahl & Nygaard (simula)**
Tuning creating is a tuning operation of finding precise delicate mid-value along poles of opposite value-too much of X and too little of X and you get not creativity, but some mid-value causes creativity-this is the inverse U function of creativity. **Sternberg**	System effects creators seek unplanned emergent delayed distributed system effects, inventing by building ways to deliberately provoke and benefit from them. **Schelling**	Hide what you show indicate not express, hint not display; ushin (discrimination, exquisite distinction), shibui (beauty that appears only when gazes linger); yabo (the ugliness of the court of Louis ! 4th in France-the ugliness of directness, opposite of IKI), jo-ha-kyu (slow, break, sudden), EN **Haga Koshiro, Tadao Ando**	Exapt: reuse in new contexts every new thing every creator invents can recombine with all past things, some of which combinations will themselves be creative: especially when deployed in distant remote unlikely new contexts and environments **Levi-Strauss, Root-Bernstein**
Paradox door creators seek out anomalies, paradoxes, contradictions, things that are not working-they struggle to make sense of them and have to let go of their own selves and	Surprise creators surprise others after surprising themselves and their own minds, via liberating from what all consider essential, combining with others thusly liberated, to invent	Presence of nothing creates by minimal wordless suggestion miyabi (things polished so anything vulgar is removed); yugen (dim, deep, mysterious; fully recall from slight hint of	Code inventing code creators that create things that create, that combine, that fuse, that split, that invent, multiply their variation, combination, selection. They make

Multiple Models of Creativity, Fig. 4 (continued)

attitudes and educations into new views in order to handle them-paradoxes et al. are doorways to getting beyond what is in oneself. **Michael Parsons, Kegan, Marianne Lewis**	replacements that need protecting from established old ideas-forces **Arendt, Rollo May, Wildavsky, Fiske**	of things), honshitsu (the felt not thought essence of things), **David Oden, Onishi Yoshinori**	themselves more creative. Creators deploy initiative and creating/designing from their own selves into embeddings in what they create, so what they create creates. **Shannon, von Neuman, Turing, Kaufmann**
Scale blend creators use or invent new tools to expose phenomena on new size scales, larger or smaller-they track results on other scales-trying to invent an all scale result or theory that explains or generates the two-scale and single-scale results. **Root-Bernstein**	Adjacent beyond the universe itself invented natural selection the most creative process we know- so do/can humans create the same way the universe creates? Each new creative work combines with all prior ones making exponentially more combines-a self-scaffolding process. **Kaufmann, Boden**	Subworlding living your fantasies in order to invent bridges ukiyo (the fantasy only world, of pure unhindered human desires), anime (the sudden decisive make of a feeling in a reader by one stroke), otaku (the culture of narrow development from self out not social constraints in); cosplay (putting on lives via putting on clothes) **Nobuyuki Takahashi, Shimokawa Oten, Seitaro Kitayama**	Operate on prior results Similarly, recursion power: creators who apply operations not to similar inputs but to the results of that or other operations, extremeize, catapult beyond norms and expectations = create. **Turing, Von Neuman**
Idea marketing creators market ideas and possible solutions to their own minds, and use creative works to market ideas to their own field of people, and market that to the history. **Palombo, Noice & Noice**	Population automaton creators set up populations of things interacting nonlinearly whose interactions they tune, till better than planned results/patterns emerge, on four levels: thoughts, solutions/works, creators, domains interacting thusly. Each level has its own generator of paradoxesnegation, hubris, feedbacks, focus from parallel engagements Duncan Watts, Svyantek & Brown, Gavriel Salomon	Subspaces create sacred secular spaces where the essential nothingness of things is unobstructed. sakura (the dependable annual transience of things), sado (a special exceptional world within our world where rank and crude exaggeration have no play), muge (the ultimate beauty of full meaning no longer blocked by ego, and worldly shallownesses) **Bodhidarma(Bloodstream sermon), Gautama Buddha (flower sermon), Huike, Huineng, Myoan Eisai**	Operate on structures of data creators who apply operators whether physical, emotive, or cognitive not to single items but to ordered patterns of such items, multiply effects in variety, scale, and scope and may end up creating as a result. **N. Wirth**
Group	**Purity**	**Sense extrema**	**Democratize media**
Community of ideas creators put together ideas into community dynamics, among those ideas- associations, conferences, arguments, taxonomies, processes, sequences, events, fusings, branchings, and many more; they control these idea community dynamics via meta-cognition operators. Minsky, Hewitt, Montuori & Purser	Subcreations creators, before they make their big famous works accumulate lots of tiny inventions of tool, facility, aim, inspiration, link that grow and interact till a huge final creation emerges J. R. R. Tolkien, L. Konzack (games)	Constraint acceptance creators study and organize constraints, seeing how others overcame similar ones and finding new constraints to add to force unseen-before answers. Jon Elster	Customers as own suppliers-APPS-creating is making customers the makers not mere consumers; it is making things that turn everyone alive into a designer, producer, performer, creator; creating is inventing pre-inventive subcreations that users use to become invention. Jobs

Multiple Models of Creativity, Fig. 4 (continued)

System model creators are not all that create in this model-creation comes from a creator person interacting with creative works (past, present, and imagined future), with creative people in a field, and with the knowledge of his or her chosen domain; more than that creators interact in and across fields, creative works interact, creative fields of people interact, and creative domains of knowledge interact; so people, works, groups of people, and idea domains can foster or hinder creativity **Csikzentmihalyi, Feldman; Styhre & Sundgren**	Productivity creativity is a side-effect of immense productivity in this model; one of the first battles any creator has and wins is the battle for free time often won by personal inventions to free up time for creating; statistics show that the historically most famous creators are often even usually the most productive too. **Simonton, Wishbow 1988 (poets 5 years prep), Hayes 1970 (painters-6 years prep)**	Map past dimensions creators create by mapping all past creations and inventing unique frameworks for ordering and interpreting them; creating is simply an operation on all past creations, understood and represented very abstractly, revealing dimensions in their evolution never noticed before. **Ritchey, Zwicky**	Customers as own supplier-info wiki creators create shared spaces where ordinary people in crowds can design and invent what formerly was designed and invented by central elites; creators invent tools that allow entire populations to create, tools that make readily fusable and usable the diversities of mass populations; **Jimmy Wales, Malone**
Social computation creativity in this model is a computational process among a group of people; one way to see this is as a complex flow of parallel intersecting steams of small events/meetings where people meet people, ideas meet ideas, funders meet people, with some events spawning, shutting down, and coordinating other events, **King and Anderson, Payne, Montuori & Purser**	Performance creativity is ideas performing in this model, at first performing inside a mind for your own self, then for imagined competitors, imagined heroes of your own field in past and future, failed ideas perform in your mind for you to see patterns among them that hint at solutions; possible works perform in your mind; **Sawyer, Stanislavski, Stella Adler, Lee Strasberg**	Vacuum power this is Lao Tsu's style of painting in ancient China-painting spaces not objects, breaking perfections-symmetries-balances deliberately; creation is pure negation in this model-it is non participation in the habits, views, and enthusiasms of a field or tradition; **Ando, Lao Tsu, Merleau-Ponty, Marx**	Customers as own suppliers-things creators invent things that serve as tools and devices that encourage and enable ordinary people to create; this involves changing all products and services in this world so that their final form and next version comes from how people use them **MIT Fab Labs, Malone, Toffler**
Social movement creators find whistle points, where slight inputs change entire systems, then they design seeds that release the forces in such whistle points in a society or profession and manage via public and private dialog tactics what emerges from the movement that results; **Thomas Kuhn (paradigms), Christensen**	Influence creating is a social process of amazing a group of people via usual influence mechanisms, context setting, and selling avenues; varied types of person combine to create/influence a field-pioneers, translators, scholars, tinkerers, network hubs, glib salespersons, **Kuhn, Eamon**	Isolate senses by seeing along one sense only you lose habitual constraints from other senses and see aspects of reality not noticed before; it is Einstein seeing the speed of light as a final speed limit in the universe (as Maxwell in 1882 suggested) and working out what that one seeing changes (it changes all of physics it turns out). **Ramachandran, Suzuki, Zeami**	Customers as publishers creators invent media by which all ordinary people can perform for others, can compose for others, can invent for others, can entertain others; creators spread creating from central elites to entire populations; **John Milton Aeropagitica 1644**
Space share creativity emerges when a certain intensity of sharing of intellectual space happens, in analogy to nuclear fusion happening when particle interactions are "confined" enough for a certain density of interaction energy to be reached, causing central elements, stripped of peripheral ones, to fuse. **Segel, Schrage, Perkins, Zwicky, Gruber & Wallace**	Investing creating is investing in idea streams in this model; you create by managing a portfolio of interests, some of which you develop into ideas and actions; you invest interest, research, imagination, tool invention, collaboration, and more; **Runco and Rubenson (psychoeconomic model), Sternberg and Lubart, Hayak, Penrose**	Inner/outer reversals this going out and finding that changes what you notice inside and going in and finding that opens out new outsides to understanding-is the method of all creating, in this model; creating is going in to make new outs and going out to make new inside models and ideas and ways **Joseph Campbell, Jung**	Social doers creators make devices works and tools that enable groups to see and do what formerly only individuals saw and did; creating is taking the heroics out of creating by accumulating mass population steps and insights into stunning inventions; **MIT Fab Labs, Malone, Toffler**

Multiple Models of Creativity, Fig. 4 (continued)

Participatory art & design you create by liberating people, ideas, devices, or the world from central controls and mass media messages controlled by central elites; creation is making audiences into performers, and reversing message flows. **Shina Minoo**	Info design creators create by operating on information-representing information, modifying info types (causal, qualitative, etc.) and info topologies (logic, hierarchies, networks, etc.) **Shriver, Tufte**	Observe self others creators merely observe more and differently in this model; they pay more attention and high quality attention to things not attended to before; creating is watching without getting sucked into as others are-it is highly detached comprehensive reflective watching. **Carravagio, Brad Blanton**	Parallel media universe creating is a set of tools that liberate all from boring jobs and work and into full time creating-6 billion TV producers, virtual work worlds, creators entool every last person alive till everyone is creating all the time for each other; **Toffler (de-massifications)**
Social	**Self**	**Brain adjustment**	**World mixes**
Mass solving creating is always the gradual deployment of a particular kind of mental protocol-a solving process-across a large population from whose variety innovation possibilities arise as the common process spreads; you can imagine Newton, Leibnitz, and others exchanging letters and bits and steps of that eventual solving process spreading among them **Ohno, Kano**	Courage creators have a drive for truth that thrusts them into intense encounters with reality aspects poorly explained by current systems and knowledge, and creators practice courage of reaching beyond normal beliefs to raw phenomena, for truth. **Rollo May, Betty Cannon, Tillich**	UN-index creators see raw reality by shutting down the outer cortex of the brain which usually indexes what we see so we see, tiny fractions of what our senses get, and we see only meaningful entities not raw inputs: certain autistic people lack the index around brains and directly access raw sensory inputs-these become savants, **Mark Batey; Ken Heilman; Alan Snyder**	Raising not programming creators do not specify correct procedures but instead create entities and tools that themselves learn the world and how to operate it and by doing it anew without human attributes, discover or invent, design or make creative outcomes humans would miss; you create by not creating but by making things that interact to themselves create in this model. **Rodney Brooks, Minsky**
Process deployment creativity is the spread of other or any protocols (not just solving ones) in this model. The variety of what you spread the protocol over generates the variations from which the group selects influenced by steps in the protocol they all share. **Kano, Akai**	Anxiety channel creators unleash anxieties of existence normally hidden from, fled from and use that energy to see their chosen fields deeply and newly, **Rollo May, Kegan, Betty Cannon, Joseph Campbell, Tillich**	Shut modules monks who shut down in meditation the brain module for being in one's own body, fly. Creation is what you get when you work on something with key parts of your-self and mind shut down. That is why people report semi conscious states of mind as fostering creation the most. **Davidson & Dalai Lama**	Manage population emergences designing populations of intelligent interacting agents from whose interactions emerge, unplanned, designs is how you create in this model; creating and designing and inventing are operations to tune the interactions of intelligent populations-whether software, robots, or people-in this model; **Casti, Cowan, Holland, Kaufmann**
Optimize ideal flow creativity comes from designing work, processes, and systems so that energy flows only in intended directions, so that the ratio of that energy over side effects is optimized, and so that it is optimized over a linear function of values not single point values, so results can be tuned without loss of generality; Einstein designed all of physics optimized around the speed of light as an ultimate **Genichi Taguchi, Collcutt**	Extend self development creating is something every human does-creating their own self-but only a rare few reject the self they inherited and replace parts with better things of their own invention or choosing (educated people); creators are people who extend this process from creating a self themselves to making the self they create a creative self, **MacKinnon 1961**	Watch mind Some meditation regimes involve sitting and merely watching your own mind at work; months or years of this result in despair of ever reaching insight or happiness while led around by your own mind; despair at your own mind leads to practice bypassing its signals and categories-this leads to immense creativity **Davidson & Dalai Llama, Rex Jung; Ken Heilman; Alan Snyder**	Prosthetics the Borg in Star Trek II are what this model is about-adding machinery into brains that allow new sensations never in biology before and the opposite adding bio stuff inside brains similarly-all creating is just extending mind operators with tools outside of brains in this model. **E. E. Smith(lensman, 1933), Project Pitman at Los Alamos**

Multiple Models of Creativity, Fig. 4 (continued)

Meta-cognition creativity comes from deft changing of approach, aim, method, what is noticed throughout the creator process of creating, due to this dual-being in but not of their process of creating. **Flavell, Fisher, Shimamura; J. Feinstein**	Interest ecstasy creators create interest in things no one else is interested in-they invest their intense beam of woven interests in tipping point places where slight inputs can have huge outcome effects; **Csikzent-mihalyi, Ypma; Jonathan Feinstein**	Input extrema creativity comes from exploring to find the extremes of what each sense and cognitive facility can handle-the lowest possible light visible, the most complex possible pattern to imagine. **Ramachandran**	Smart dust creating is distributing over the entire universe communicating thinking imagining entities or extensions of human such functions till human mentality and all that exist think, feel, see, imagine, make together. **Pister**
Social connectionism creators get ideas in frame contexts (idea solids = every idea a defined fixed place), by getting them into intense interacting; those frames are stripped off, so ideas flow between frames (liquid phase), till ideas form a frame less gas, till the ideas lose peripheral contexts/ associations to become an idea plasma, coalescing into entirely new frames = creation; **J. S. Brown, Duguid, Lave, Wegner**	Career invent creating is merely inventing your own career rather than moving along a career path invented by someone else; they do this for the career that individual ideas have, that individual traits inside creative works have, that creative works have, that creators have, that people have; **Klar et al, Ghiselin**	De-conceptualize creators do what we all do except they refuse the categories we all use-they categorize anew from zero in all matters of interest; **Zeami, Rikkyu, Lao Tsu; Ken Heilman; Alan Snyder**	Brain amplifiers machines inside or around brains that amplify what they can do or react to = all in culture and all in civilization; creating is amplifying this or that operator in brains, with social, intellectual, cultural, physical tools and systems; all of civilization is such a tool in this model **Simon Hooper (cyberware)**
Demystification creators demystify-that is all; that means they recover powers given to aspects of the world while growing up; assumptions made, limits on alternative ways imagined, filters, so we miss parts of reality, hidden selfish motives and interests behind public services and boons, **Illych, Foucault**	Performance creativity creators set up nine performances: ideas in minds, traits in works, works in fields-those 3 repeated in 3 levels: in the creator's own mind, others enacting the creator's ideas as performance, and third, audiences experiencing these three; when all 9 performances happen at once, creativity occurs, and the secular is made doorway to the divine; **Alice Isen, Mattis, Poincare; Sawyer (improv)**	Jiggle (add noise) creators jiggle mental frameworks and reality dynamics, inducing noise and random-ness to unseat concepts and phenomena from their habitual contexts and settings; this resembles super-renormalization group operators in physics. **Ramachandran, Remy Lestienne**	Informated places & times creators are a history-long process of taking the all from everywhere and making it applicable in each local time and place; **Zuboff, Altman & Sivo(Loopt)**
Knowledge evolution	**Mind**	**Scale extrema**	**Radical subcreations**
Dialectics creation is a generational process in all fields-the younger people to overthrow the dominant old people, go back to what was conquered and subsequently belittled in the past, resurrecting those ideas in new contexts to dislodge established ideas and powers in their chosen field. **Marx, Hegel, Abbott**	Insight alternating deta-chment and engagement on more and more abstract representations of what does not work results in accumulating a failure index, the inversion of which specifies what even-tual solution has to be like till creation suddenly occurs as sheer insight. The despair doorway is opened by losing hope that who you now are, how you now think, will ever solve this X-*then* a pattern in your failures shows solution. **Wallace Guilford Hadamard;**	Extend substrates you create by standardizing new substrates so that hundreds can study and combine them and learn from each others' experiences (bio fab copying wafer fab); you create by inventing substrates that many can use instead of just a few. **Langton (alife)**	Structural cognition tools (cognitive list limit expansion) creators learn to apply ordinary mental operators to many times more ideas at a time than others-they invent tools for enabling them to do this and do their thinking, designing, solving work at many times the per time unit of productivity of others. **Entwhistle, Pask, Kintsch, van Dijk, Meyer, Flowers & Flowers**

Multiple Models of Creativity, Fig. 4 (continued)

Compilation cycle you create by compiling knowledge from one model to another, from one level of aggregation to another, from one level of explicitness to another, from one level of consciousness/ unconsciousness to another-such changes of format and form reveal gaps and patterns hithertofore unnoticed = creations **Nonaka and Takeuchi**	Cognitive operator extremes creators apply normal mental operators to ideas but at extreme levels and degrees; the scale, force, agility, unconventionality, bias, expression, packing of mental operators can all be carried to extremes; **Weisberg**	Tackle impossibles you create by tackling impossibles-ending death-knowing that steps in such bold directions will, by being outside of all extant realistic contexts surprise, amaze and perhaps, be powerful creations in some other context than the context that generated them **Kawasaki, Jobs, Kurzweil**	Radical increases in social indexing creators notice that all current ways and societies operate with people knowing and using tiny fractions of the needs, interests, and capabilities of people around them-and they pioneer tools that expand how many of the needs, interests, and capabilities of those around them, people can notice, remember, and use; **Thomas Vander Wal (web tags)**
Relocating idea ecosystems transplanting whole sets of inter related ideas from one idea ecosystem to entirely different ones and making analogous and new links with the ideas in that context results in creation. **Fauconnier & Turner (conceptual blending), Thomas Ward**	Making sense by observing critically and skeptically human systems of belief, expecting many of them and much of them to be built on sand, creators by spotting the ones of weak foundation find towers of illusion and delusion to puncture with single well-placed actions and works-creating is puncturing perpetual human towers of self-supporting delusion **Drazin**	Extend doer scale new technologies and substrates change the cost and expense in money, attention, effort, resources, and time of doing certain functions-creators are those who organize people to operate at new speeds and size scales based on these capabilities **Jeff Howe (crowdsourcing), Beni and Wang (swarm)**	Culture penetration as insight process creators penetrate the culture of eras, fields, theories, problems-that is, the same alternating of detachment with engagement on successively more abstract representations of that culture that all insight processes are and that is the same gradual accumulation of failures that when abstractly indexed specify what a solution must be like, more and more till a solution is suddenly found **Bohannan(anthro)**
Idea waves sets of ideas pass in 8-year periods across all fields, finding great creative applications in some and no creative applications in others; creators are people who first notice such waves and who deploy their idea contents to appropriate parts/problems of their domain; **Huczinsky**	Percept invent creators invent new ways to perceive and new things to perceive-they create and invent by seeing what no one else sees-they do this by varying frameworks, levels of detail, associations, and other things that allow them to see realities no one else sees, **Tomasello, Wittgenstein, Merleau-Ponty**	Invent new humans creators see and solve the future now-so they use stem cells and DNA knowledge to design new forms of human body for when we all have to live on the moons of jupiter after our sun expands to red giant size; creators operate under bold constraints others will not face for generations; **Kurzweil**	Social structural automata creators set up automata like protocol processes, among existing groups and structures and events in their field or society-till creations appear. **Epstein & Axtell, Prietula & Carla**
Fractal recurrence victor ideas incorporate loser ideas as components till later generations of youth revive them to overthrow old dominant ideas; creators learn these idea dynamics in their field and with great timing lead one or more of the forces that produce such repeated idea patterns. **Abbott**	Experience realization creators make a hero story for themselves and their culture: they launch fields on the hero journey of going beyond past ways into no man's land, fighting monsters till they realize the monsters come from inside them, then they come back to their field bearing magic powers from self transformation; **Einstein, Picasso**	Extend target scale creators take all we have and imagine them a million times bigger, a million times smaller, a million times faster, a million times slower-they wonder what we "get" if things are done at other scales and speeds; the US military is paying for bird sized autonomous flying devices then insect sized ones, then bacteria sized ones-intelligent dusts, for example; **Hayes et al 1987 writers**	Revolutionize older media creators examine the oldest most assumed and used media and from entirely current and future perspectives redo reinvent them-so all the basics of thinking, feeling, and acting are revolutionized-creators replace prose, replace meetings, replace discussions, replace feelings **Eamon, McLuhan, Negroponte, Maeda**

Multiple Models of Creativity, Fig. 4 (continued)

Simple programs creators invent the smallest, simplest, fewest interacting components to generate all the complexity of some phenomenon in their field they create by controlling, predicting, modeling the most with the least. **Wolfram, Klahr(machine inventing)**	Substrate update the world is an ever faster series of new substrates for doing basic functions better faster cheaper easier and for doing functions never possible in history before-creators are those who are first to redo a key function of their field on new substrates and the first to discover entirely new field functions made possible by such recently installed new substrates. **Isse Miyaki, Stephane Leducs, Arber Nathans & Smith (nobel)**	The calculus move finite elements, renormalization groups, cellular systems, grid computing, cloud computing-all these are breaking something into millions of simple pieces and accumulating calculations simple for each piece into complex bigger scale shapes impossible to calculate directly-all creating is calculus of a sort; **Leibnitz, Newton, Hrennikoff & Courant; (finite element); Ernst Stueckelberg and Andre Petermann in 1953**	Stratify responding creators slow down and separate each within-the-mind layer of reacting-what do we notice; what feeling does each noticing evoke, what association does each feeling evoke; what framework comes with each noticing and how does it determine how the noticing makes us feel; what new framings are conceivable, possible, optimal, inventable; and what new noticings, feelings, framings, meanings do they generate-creators refeel the world **Freud, Betty Cannon, Husserl, Ellis & Beck, Ken Heilman; Alan Snyder**

(from Greene 2011 and De Tao Master's Academy 2011)

Multiple Models of Creativity, Fig. 4 120 Models of Creativity (from Greene 2011 and De Tao Master's Academy 2011)

4. That experiment and discovery, art and invention, and expression and exploration capture what is applied to those levels (each of those pairs expressed via multiple models of creativity involved in them)
5. That eight novelty sciences (creativity, evolution in, story-comedy-history-philosophy of, selves, knowledge, experiment and discovery, art and invention, expression and exploration) somehow support and apply to 12 other novelty sciences (educatedness, careers, creating others, systems, cultures, quality, innovation, ventures, design, composing, fashion, performing)
6. That it is *all* about novelty in the end – each novelty science is about bringing the new into our world
7. That each novelty science differs from others in having a sort of basic direction:
   (a) Tries – in the experimenting and discovery involved in innovation and venture building
   (b) Builds – in the art and inventing involved when people design and compose
   (c) Roles – in the expressing and exploring of self and other involved in fashion and performance
   (d) Formats – in the flows of knowledge in systems, cultures, and quality achievement
   (e) Persons – making and made in educatedness, careering, and leadership

Meta-Model Three: 120 Models of Creativity

The table below presents 120 models of creativity. These came from three sources: 150 eminent creators in 63 professions and 41 nations, 8,000 eminent people similarly distributed, and 4,000 books and research articles on creativity from academics.

There have been some meta-models of creativity model types: (Harnad 2006) method, memory, magic, and mutation types of creativity theories and (Styhre and Sundgren 2005) 4P creativity model types – process, person, product, and place (see ▶ Four Ps of Creativity). However, the model below of 120 creativity models is the only published model, derived from empiric data from creators, yet with nearest match academic models indicated for each, this comprehensive and detailed. Remember each of the models named below, in its full form, printed elsewhere, has 20–60 well-ordered components (Greene 2006).

54 models of innovation How people make creations impact society and real human needs & situations Academic models that correspond to the empirical ones below are indicated in each box Note: a version of the below just as detailed as the one for 120 creativity models exists but it is not presented in this entry for reasons of space This model of models is the basis for a four-semester course at KEIO SDM on models of innovation Source De Tao Masters Academy Creativity & Novelty Sciences Studio Plan, 2012)					
Future present fight		**Idea socialities**		**Idea Ecosystems**	
Catastrophe spotting	**Pattern spotting**	**Trend riding**	**Social Physics**	**Living innovations**	**Idea farms**
Abstraction	**Inversions**	**Inhabit the future**	**Code changing action factors**	**Educatization**	**Silicon Valley clusters**
Disruption missing competitor caused disruption-Christensen	Success fails core bribes firm to ignore periphery = future-Bower	Career step moving one's career forward not by competing for established fixed positions and roles but by inventing the entirely new-Greene	Ride knowledge dynamics using knowledge dynamics, dialectics, pole-swings, loser enbeds-Abbott	Go out = go in globals invade locals, locals invade globals = all locals global-Jun & Wright	Automate invention-nurture circuits among in-process projects, power of absurd concentration; many tries, many fails = many invents-Edison
Search search in possibility spaces-Perkins	Valley inside Silicon Valley introject (inside you)-Nevens & Lee	Sell passion venture as enthusiasm package & presentation-selling motivation-Kawasaki	Movement successive successor-contexting social movements-elch at GE	Self build angst educativeness burden of daily life+self-build= flee to what fled from (authority)-Giddens	Valley-flows of ideas, people, funds, techs seeking home to love them + tiny, fast, smart, adaptive coalitions of specialties-JSBrown
Customer inventors democritize innovation= empower lead customers-Hipple	Success riding niches finding/ riding niches-Greene	Trust banks ethnic-immigrant trust-bank ventures-Granovetter	Social revolution social revolution via liberty, free invents, public happiness, historic dream, conserve novelty-Arendt	Demassify demasify=global standard items make locals globally diverse make institutions not fit-Toffler	Venture-anti-big, anti-East, from zero = new ways with new techs; anti-passive, anti-money-Greene, Jobs,
Sociality	**Social cognition**	**Co-evolution**	**Co-adaptation**	**Social grammar**	**Natural selection**
Practice geography social life of info-Brown & Duguid	Unorganize innovating = de-organizing-Sutton	Fit type menu info ecosystem device species prolifera-tion Davenport & Huber	Investment culture culture of development: reliable near future-Grondana	Resocialize social relation type mixes: share, rank, reciprocate, price-Fiske	Recursions-natural selection systems within natural selection organisms-exaptations-Michod
Network inventor net not individual hero-Hargadon	Spread one home run insight mental practices of inventors-Schwartz	Tap global diversity open business, invention outsourcing-Ches bough	Culture farms culture farming-raising ecosystems of evolving cultures-Darwin, Boyd & Richerson	Leverage diversities use diversities: un-see un-do, balance in space in time diffce type/task type-Greene, Page	Levels-evolve repertoires of neutral traits, till envt. change makes some vital; evolve levels not fitnesses-Kimura
Follow problems across radical innovation=mix frame, anomaly, tool, crisis research; patron research mixed with cllent research=combine artists, scientists, designers, engineers-Steffik	Re-see past from future invent by managing mental models-Wind & Crook	Producer customers media microcosmization = all consume all produce in all media -Jenkins	Miscopying orthogonal copying in new context = invention-Westney, Roehner, Syme	Attract creative elite tech, talent, tolerance = attract creative elites- city-fy as insight process-Florida	Soft-hard levels-egg computer, DNA program, junk DNA control statements, wrapping modules; behavior to software, firmware, hardware-compile unchanged to hardware-Gould, Dawkins

Multiple Models of Creativity, Fig. 5 (continued)

Non linear dynamics	Emergence	Wave catching	Universal inventivity	Non linearity	Interface media reinvent
New ways aims tech at once tech life histories, firms fail by adding new means to old ways/aims-Wheelwright	Position in societal enthusiasms society lust-Lienhard	Not enough idea homes maximize creations without maximizing failures = R&D, finding fits, trashing non-fits-Matheson	Tweak con-nectedness till take-off self organizing criticality-manage social automata till critical points-Bak, Gladwell	Other scale side-effects unplanned order emerges = goods from bads (Mandeville) bads from goods (Schelling)-Krugman	Replace prose ractal page formats replace prose-see count, names, order at a glance, read and write structures-Greene

Multiple Models of Creativity, Fig. 5 54 Models of Innovation (from Greene 2011 and De Tao Master's Academy 2011)

Meta-Model Four: 54 Models of Innovation

Another novelty science is innovation. Plural models of it can be obtained from both academics and from innovation practitioners, as described above.

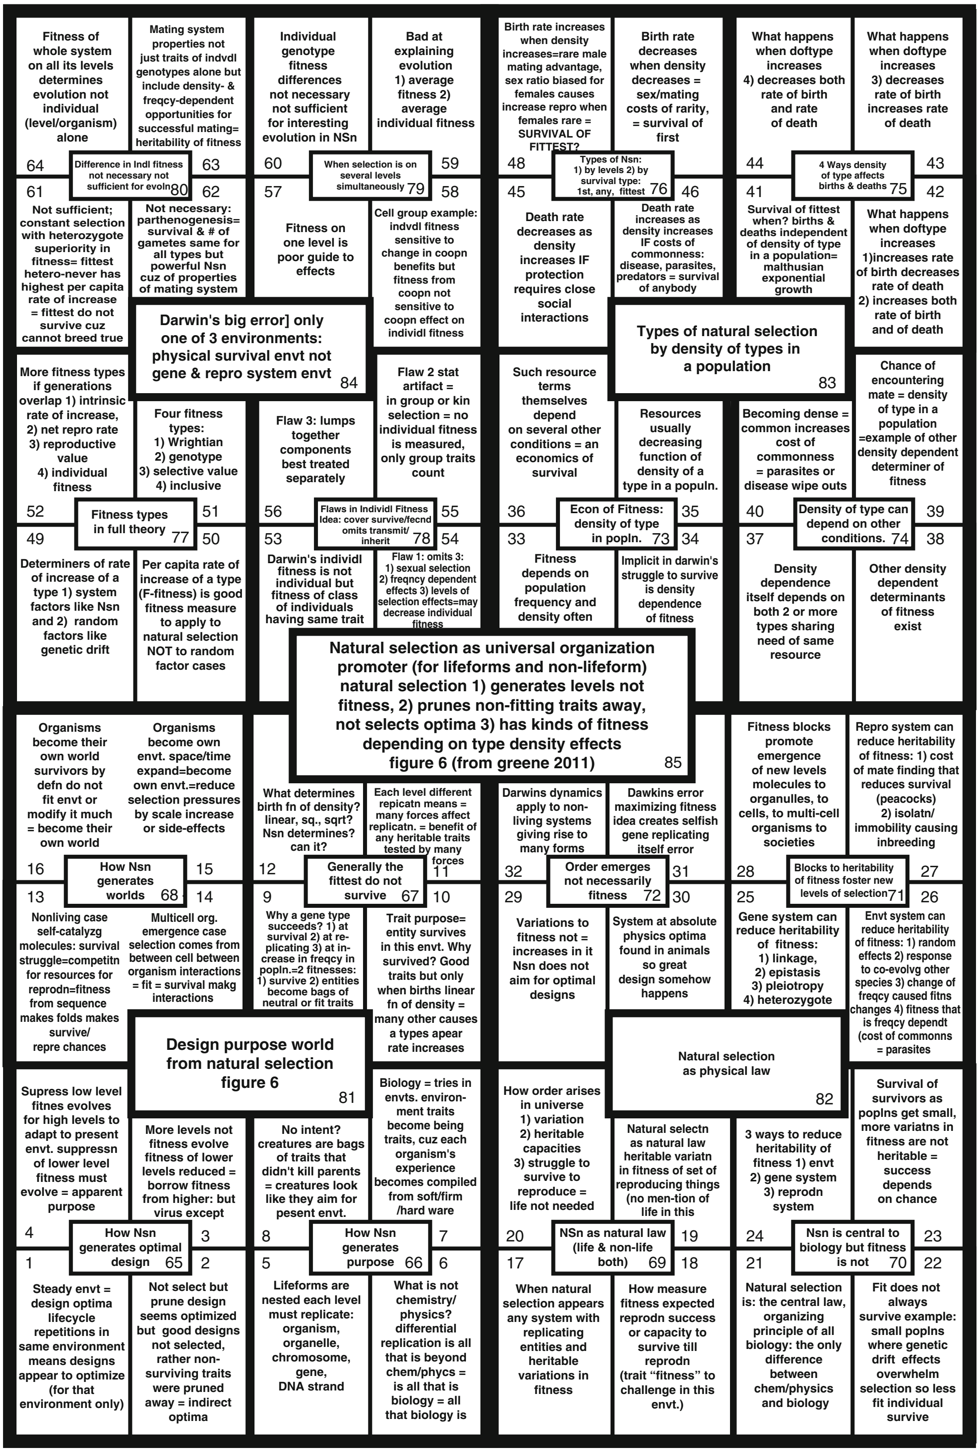
Meta-Model Five: A Comprehensive Version of One of the 120 Creativity Models – Natural Selection

The case for including in this entry a model of Darwinian natural selection is easy to make – it is the most creative single process known in the universe – the process that invented life itself, and then went on to invent all the life forms that we know of, including ourselves. The model here comes mostly from Michod (Michod 2000) with enhancements from others (Crutchfield and Schuste 2003; Nowak 2006; Page 2008).

Meta-Model Six: A Replacement for Prose Itself – Fractal Page Formats

The natural selection model just described above and presented here is two things: one, a summary of one-fourth of Michod's overall model of natural selection dynamics, and two, a demonstration of a viable replacement for prose itself. One structural cognition tool, for handling plural models, is a replacement for prose called fractal page formats. *Why does prose need replacing?* First, it is a very old interface, virtually unchanged for 8000 years. Second, it hides the structuring of its points, so elaborate encoding and decoding are needed. *Third, it lacks apparent visual scaling to* handle the drill down drill up expand-breadth focus-narrowly operators we all do on the Web. In research terms, it hides the count, naming, and ordering of its point contents. The natural selection model here makes visually evident in an instant the count (how many points), the names of points, and their principle of ordering. It bridges Web and older media nicely.

Replacing prose with fractal page formats, meetings with scientific rules of order, discussions with stratified respondings, brainstorms with social design automata, and classes and work processes with mass workshop events are



Multiple Models of Creativity, Fig. 6 Natural Selection As Universal Organization Promoter five basic interfaces of daily life that can be changed *to use and handle plural models not single right-y models*.

Conclusion and Future Directions

The webization of all industry expands who does things and what they do. Perhaps our mania for single right-y models is a relict of our tools, precomputer eras, and habits of mind. Now that everyone has several computers at hand, handling plural diverse evolving models can be managed practically, making our mania for top, elite, static, highest *ones* go away.

Some future research directions coming easily from this entry's plural diverse model perspective might be in order before closing. The items below are expatiated at some length in other publications (Greene 1993, 1999, 2003, 2006, 2007, 2009, 2010, 2011; Brown and Duguid 2005; Page 2008; Kenney 2000; Flavell 1976; Taura and Nagai 2010):

1. **Process singularities** Singularities in design process may be where two or more models of creativity conflict.
2. **Apply omitted models** Groups favor some models omitting others, so using omitteds may improve creativity greatly.
3. **Evolve among models** Particular designers, creators, and innovators may learn and prefer some creativity models early in their career and evolve into others at later phases – Why and which ones?
4. **Find best models** People and groups who create using some models may end up more creative than creators who use other creativity models.
5. **More models more creativity?** Organizations that support and use more models of creativity may get more creative outcomes than organizations that support and use fewer models.
6. **Model conflicts** Conflicts in long-term projects and creative collaborations may come from different parties and professions in them habituated to different models of creation.
7. **Meta-creativity powers** People who study which creativity models they use may, after that study, become more creative.
8. **Model diversity powers** People who are exposed to more diverse creativity models that they do not now use may, after that exposure, become more creative.
9. **Model trade-offs** *Models of creativity may be in negative trade-off relations to each other so that supporting or doing one more may hinder doing others – environment supports for doing one may shut down many others, hence reduce total creativity levels in a person or organization*. The mania for single right-y models of creativity, thereby, may harm creativity in practice more than they help it.

These are some research directions with strong implications for creative practice that come from the plural diverse models of creativity perspective of this entry. Notice that quite a few models (Kenney 2000; Brown and Duguid 2005) of Silicon Valley dynamics (see here ▶ Social Psychology of Creativity) mention the number, diversity, depth, detail of models of innovation, design, creating that come together, interact, blend, and evolve new forms there (so this entry *may* constitute how to generate replications of Silicon Valley to some extent [51]). Note that a new kind of university, funded by leaders in China, based on the plural models approach in this entry is being built as this is being written (compare with **Higher Education and Innovation**).

Dr. Deming, (Deming 2000) the quality guru, said to make one problem go away permanently, one had to throw 5 solutions at each of 5 root causes for each of 5 root problems equals 125 changes installed to fix anything. Maybe creating, designing, innovating, etc., are similar; single right-y models may be fun and easy to think about and test but have little impact compared to balanced repertoires of diverse models deployed wisely in particular cases.

National learning systems; National production systems; National science systems; Regional innovation systems; Sectoral innovation systems; Social innovation systems; Technological innovation systems; Triple helics; Varieties of capitalism

Key Concept and Definitions of Terms

Basic Ideas

The notion of an "innovation system" builds on the observation that in the modern economy, innovations are not rare acts of individual creativity, but ubiquitous and the outcome of interaction among individuals and organizations. It views innovation as processes over time rather than as isolated events, which can be uniquely dated. The notion of an innovation system usually also includes the idea of ongoing innovation as being rooted in different kinds of "learning relationships" between users and producers, between people with different type of competences, between different departments in the firms, and so on. Learning is always, in some sense, interactive and, hence, innovation is "systemic."

In markets where new products are introduced, users and producers need to communicate in other ways than by sending price signals to each other, in order for producers to discover new user needs and for users to get qualitative information about new products. Durable user-producer relationships are frequent and important. But they are only one of several examples of relationships, which affect innovation in a modern economy. Other examples are network relations, partnership relations, R&D collaboration, long-term relations between firms and financial institutes, long-term relations between firms and universities, etc. Within organizations, the interaction between departments (production, R&D, sales, etc.) is fundamental for the outcome of innovation processes.

Learning possibilities are not evenly distributed over the economy but differ between sectors. Innovation is therefore deeply affected by the structural composition (especially the specialization pattern) of the economy. Learning is also crucially influenced by the institutional framework of the economy. Institutions are here defined as the laws, regulations, norms, and

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,

practices, which shape patterns of behavior and determine how people, firms, and organizations relate and interact with each other. To the extent that learning is interactive, institutions thus partly determine learning and innovation.

Broad and Narrow Interpretations

On this background, innovation systems have been defined as including all parts and aspects of the economic structure and the institutional setup, which affect learning and innovation. The essence of the notion of a system of innovation is that the innovation performance of an economy depends not only on the capabilities of its individual firms but also on how they interact with each other and with the public sector and the financial sector. This is the notion of an innovation system in the broad sense. One reason for using such a broad definition is that it makes it possible to establish a link from innovation to economic growth.

There is, however, also a narrower conceptualization of innovation systems, which focuses especially on innovation in science-based activities in high-technology sectors under the assumption that these are especially important for the innovation performance of the economy as a whole. Another related delimitation is to focus on specific types of production and define sectoral or technological systems of innovation like the innovation system of the automobile industry, pharmaceuticals, financial services, and so on. In the following, we will concentrate on the broad version of the notion of innovation systems and on geographical or territorial delimitations rather than referring to specific sectors.

In this entry, the focus is on national innovation systems. Both sector composition and institutional setup differ across countries. This puts national stamps on innovation processes and makes national innovation system important. Further, most relevant public policies (research, education, labor market, social policy, and economic policy) operate at the national level.

But the analysis of national innovation systems must take into account that innovation systems of different geographical scale coexist and that the relevance of a particular scale is determined by the problem to be addressed. For example, the impact of national investments in R&D will affect the capacity to absorb scientific knowledge from abroad.

Theoretical Background and Open-Ended Issues

The Recent History of the Concept

The notion of a national innovation system was introduced in the 1980s to emphasize the interdependence between technical and institutional change. More specifically, it emerged as a reaction to the long crisis in the world economy, which started in the beginning of the 1970s and lasted well into the 1980s. The crisis was characterized by widespread balance of payments disequilibria, low growth rates and high rates of unemployment, and inflation.

This particular combination of macroeconomic problems puzzled mainstream economists. The inability to convincingly explain the crisis and show a way out of it stimulated the development of the notion of national innovation systems. National strategies for increasing competitiveness through reducing wages or through devaluation of the currency turned out to be ineffective. It became evident that to understand differences in national economic performance between countries, it is necessary to understand how it is rooted in innovation. The relations and interactions that feed learning and innovation come into focus (Freeman 1981).

Sharif (2006) has traced the roots of the concept national innovation system by interviewing those who developed and launched the concept. It is clear from his analysis that scholars such as Freeman and Lundvall intended the concept to help establish a different kind of basis for economic policy other than the advice coming out of neoclassical macroeconomics.

The Concept of National Innovation Systems May Be Used in Different Ways

The notion of innovation systems has been used in two complementary ways. First, it serves as a practical tool for both researchers and policy makers. It helps them to form a systematic overview of the actors and processes of innovation and the means and ends of innovation policy at the country level. The broad conceptualization of national systems of innovation covers both incremental and radical innovation and gives more attention to the role of learning processes than US-based innovation research focused upon science-based innovation.

Second, the national system of innovation may be used as a heuristic concept and focusing device. In this case, it is situated within a specific (evolutionary) theoretical approach used to study modern market economies, with a shift of attention away from resource allocation toward resource creation through learning and innovation. This draws attention to the existence of different types of knowledge, experience based as well as science based, and the different forms of learning, which creates and diffuses them.

Used in these ways, both as a practical tool and as a focusing device, the national system of innovation has become a useful notion. It introduced a new trend in the literature on innovation. Earlier, the focus was on the level of the firm. It also gave a different perspective on national science and technology policies other than "the linear model" where investments in science are assumed automatically to result in technical innovation. It offered a more holistic and systemic approach, which emphasizes the interactions between firms, organizations, and policy makers.

The concept has been criticized for being too broad and imprecise (Edquist 2005) and as being an unsound mix of analysis and political rhetoric (Miettinen 2002). Lundvall (1992/2010) responds to this criticism and recognizes serious weaknesses in the way the concept has been used.

Roots in the History of Economic Theory

Even if the concept of national innovation system mainly was developed in the 1970s and 1980s, its theoretical roots go far back in the history of economic thought. Basic ideas behind the concept go back to the nineteenth century and Friedrich List (1789–1846). His concept "national systems of production" took into account national institutions related to education and training as well as infrastructures such as networks for transportation of both people and goods. More generally, innovation as an economic activity was given more attention by classical economists than in modern neoclassical economics.

Adam Smith (1723–1790) discussed, for example, how improvements of machinery came about in very different, both experience-based and science-based ways, and Karl Marx (1818–1883) made new technologies and technical change (which he called "development of the productive forces") into driving forces in the development of the economy and society. Later, Alfred Marshall (1842–1924) linked innovation to the institutional setup of the economy as a whole as well as to management competences in the individual firms.

But it is Joseph Schumpeter (1883–1950) who is generally regarded as the founder of modern innovation theory. He saw innovation as the major force behind economic development and discussed the role of both individual entrepreneurs and R&D departments in large firms. But the analysis of national innovation systems transcends Schumpeter's perspective in important respects. While his analysis was biased in giving attention only to the supply side, the system's perspective takes into account the demand side and the interaction between supply (producers) and demand (users).

The modern literature about national innovation systems was above all developed by three scholars: Freeman (1987), Lundvall (1992/2010), and Nelson (1993). Following these contributions, there has been a very fast and wide diffusion of the concept. This has coincided with a general increase in the interest in innovation. The holistic and systemic characteristics of the national innovation systems literature have drawn attention to the role of innovation not only in the field of economics but also in other disciplines such as planning and development, geography and environment, and public administration.

Challenges

The main challenge for the research about national innovation systems is to contribute to a better understanding of learning, capability building and innovation as the main forces behind economic growth and development. Quite generally, to take the interactive and systemic character of innovation into account is a way to broaden the understanding of the process. To proceed with this approach requires a better understanding of the dynamics of the knowledge-based economy (or perhaps better, the learning economy). How do different factors interact in development, and more specifically, how can different kinds of learning be combined?

A promising research topic is to distinguish between innovation processes at the level of the firm on the basis of the "learning mode." It is possible to draw a distinction between learning processes where codified, science-based knowledge plays a major role and others that come out of processes dominated by practical experience with strong elements of tacit knowledge. Empirical data indicate that firms, which have combined these two modes, are more innovative than other firms (Jensen et al. 2007).

A second challenge is to get a better understanding of how the organization of work affects innovation. There is a clear correlation between having traits of being a "learning organization" (e.g., job rotation, interdisciplinary work groups, integration of functions, problem solving on the job, degree of freedom for the worker to organize his work, and close interaction with customers) and innovation performance. Since work organization differs significantly across countries, this is a central topic within national innovation systems research.

A third challenge is to improve the understanding of welfare and inequality in society. A capability-based approach to welfare as developed by Amartya Sen implies that it is not what we can buy or own that constitutes welfare but rather what we can do, that is, our capabilities. The learning capability is the most dynamic of the human capabilities, and it is conditioned by national institutions, including the prevailing forms of work organization. Learning has both instrumental value (it supports innovation and productivity growth) and substantive value. Therefore, an uneven access to learning and competence improvement is a central dimension of inequality. This dimension of the national innovation system deeply affects the distribution of welfare.

A fourth challenge is to contribute to a better understanding of the situated character of knowledge and learning. Within national innovation systems, regional and urban systems of innovation play a key role in determining national economic performance. Urbanization and economic growth are inextricably linked. Those countries that experience economic growth also tend to urbanize quickly, and those urbanizing faster typically experience higher rates of economic growth. Innovative cities are crucial parts of national innovation systems, and the interactions between the regional and national levels are important for both regional and national growth and development. Research on the creativity and innovativeness of cities would have to analyze the topics of distance, density, and diversity, and the interactions between them.

Finally, the innovation system research shares with other parts of innovation studies a certain bias to regard innovation as progress. There is a need to develop the analysis of innovation systems to capture situations where the institutional setup or power structure gives rise to innovations that do not respond to the needs of users or to the need of society. Empirical studies show that not all innovation activities end up with attractive solutions for users or for society as a whole. Many of them fail for technological reasons, while others fail because they do not respond to user needs. Some constellations of user-producer relationships and institutional settings may lead to unsatisfactory paths of innovation. Such forms of "system failure" may require government intervention and can only be addressed by institutional reform.

Implications for Theory, Policy, and Practice

Economic Growth Theory

The evidence is overwhelming that the most important driving force behind the increase in production and income over the past few centuries has been the advance of technical and organizational knowledge. Given that innovation is about how new knowledge is introduced into the economy, it is obvious that to understand economic growth, we need to understand innovation.

The mainstream theory of economic growth has shown an increasing interest for technical change and has moved away from treating it as an exogenous factor toward making it endogenous in its models. But it has not accepted the notion of national innovation systems.

This reflects that the theoretical foundation for national innovation systems is quite different from the one used by neoclassical economics. This is certainly true both for the neoclassical focus upon rational behavior and for its use of equilibrium analysis. The assumption of rational behavior cannot be applied since you cannot foresee the outcome of the innovation process. If you could, it would not be an innovation. Equilibrium analysis, central for standard economics, is incompatible with the elementary insight that innovation is ubiquitous and continuous in capitalism.

Theory of Economic Development

The notion of national innovation systems has made more impact on development theory than on growth theory. Development scholars have found it easy to take onboard the holistic, broad approach of national innovation systems thinking, in which also, everyday innovation in low- and medium-tech sectors play important roles.

This may to some extent be explained by a common theoretical heritage. While the concept of national innovation systems was developed mainly in the North, some of the most important elements actually came from the literature on development problems in the South. The importance of institutions, the accumulation of knowledge, and the interdependence between sectors, which are important aspects of national innovation systems, have been recurrent themes in development theory.

It has been necessary to adapt the concept national innovation system from the North to the South. From the beginning, it referred to relatively strong and diversified systems with adequate institutional and infrastructural foundations of the process of innovation. When applied to the South, the focus has shifted to policies and strategies for building and improving innovation systems, creating interactive learning spaces, bringing in new actors (like NGOs, farmers, small family businesses, intermediaries, and so on), changing the role of universities, strengthening cooperation between the formal and the informal sector, taking sustainability issues onboard, etc. (Arocena and Sutz 2000).

Innovation Policy

In the 1990s, a wide diffusion of the concept of national innovation systems took place among policy makers. At the beginning of the 2000s, most OECD countries had adopted the notion to help in the design of innovation policy. This has only partly been successful. There is still a bias in the favor of supporting science and R&D, often delimited to specific selected sectors or technology areas (ICT, biotechnology, nanotechnology, etc.) in the hope that the introduction and diffusion of new knowledge in the economy, that is, innovation, will follow more or less automatically. The combination of innovation system analysis with neoclassical economics in organizations such as OECD and the World Bank has contributed to this narrow and biased use of the concept.

The broad version of national innovation system with attention also to incremental and experience-based innovation in low- and medium-tech activities has not reached policy makers to the same extent. There is also a bias in policy making in favor of stronger intellectual property rights. This is not founded in a national innovation system approach – at least not in the broad version of the concept in which the importance of the tacit aspects of knowledge as well as the many difficulties with treating knowledge as a simple commodity are recognized.

Policy Learning

The national innovation system approach makes it clear that also policy making may be regarded as a process of learning and innovation. Policy learning related to innovation policy may support the development of the innovation capability of the economy by forming visions about it as an environment for innovation and development and forming the value premises of innovation policy.

An important aspect in this context is the development of new concepts, data, and theories of innovation and systems of innovation and the role of innovation in growth and development. To move the focus in economic policy away from the traditional preoccupation with short-term allocation of given resources and stabilization of the economy toward long-term processes of learning and innovation would be an important improvement of the policy agenda in most countries.

Policy learning may also focus on institution building to stimulate regional and local experiments in policy areas, which are in need of reform, and to develop methods to evaluate the outcomes of such experiments that take into account learning effects. Institution building, which supports the production and reproduction of human and social capital and which diffuses international, regional, and local “good practices” in a given field, is another basic topic in policy learning.

Economic growth and structural change call for ongoing policy learning, which focuses on building competencies and skills in all parts of society and on integrating perspectives and strategies from different policy areas.

Conclusions and Future Directions

The modern version of the notion of national innovation systems was quickly accepted quite broadly among scholars and policy makers, first in the North and now increasingly also in the South (Lundvall et al. 2009). This reflected a need to introduce and develop new perspectives on the long-run process of growth and development.

Both as a heuristic concept and as a practical tool for researchers and policy makers, national innovation system approaches emphasize the importance of learning, competence building, and innovation, and the interactive, systemic character these processes. To continue in this direction is a major challenge for research as well as policy making.

One important challenge for the future is to draw the wider implications of the understanding of the national economy as an innovation system for economic theory and economic policy. This was the original intention among those who launched the concept 30 years ago. But it has not yet happened. While policy makers refer to the concept, they are reluctant to draw the full implications. Here, the dominance of neoclassical economics constitutes a barrier.

Another major challenge comes from the process of globalization. There is a growing need for international and transnational innovation cooperation. How can national innovation systems be transformed so that they respond to global problems of poverty, global warming, and uneven population growth?

Definition

Creativity has traditionally been defined as the ability to respond adaptively to the needs for new approaches and new products, or as the ability to bring something new and valuable into existence purposefully. The modern concept of creativity emerged in the Renaissance and has expanded and changed in the last few decades. Postmodern scholars have problematized such basic concepts as originality and "the author" or creative person. The rise in networked information technology has led to an increased awareness of collaborative and networked creative processes. In the sciences, the machine/clockwork view of the universe was unable to account for creativity. Today, it is being challenged by a view in which creativity is increasingly viewed as intrinsic to the very nature of the universe and an emphasis on interactions and emergence rather than essentialism and an exclusive focus on the individual. A new emphasis on "everyday, everywhere, everyone" and "networked" creativity is shifting the focus from creativity as a phenomenon confined to the rare individual genius to one that also includes collaborative creativity in everyday life, with implications that are only beginning to be explored.

Theoretical and Historical Background

In the West, the concept of creativity as we know it today emerged in the Renaissance. The emergence of creativity coincided with the birth of humanism and individualism. It blossomed with the genius myth of Romanticism in the late eighteenth century. Until the 1980s, research on creativity in the West was situated mostly in psychology and focused primarily on what were known as the three Ps: person, process, and product (Runco 2007). In the romantic mythology underlying this atomistic, individualistic view, the creative person was mostly a lone, often eccentric, genius. The unit of analysis was almost exclusively the exceptional or "eminent" individual.

The "how" of creativity consequently occurred exclusively "inside" this individual, the creative person. The classic image of the creative process was of a light bulb going on over the creator's head during the "Eureka" moment. The creative process was viewed as a solitary one, initially with mystical or divine sources, and then increasingly associated with unusual mental states and psychopathology. The "what" or creative product was associated with "big bang," earthshaking insights, and products (Montuori and Purser 1999; Runco 2004, 2007).

In the dominant PPP model, the "who" of creativity could therefore by definition only be an individual person. Groups, organizations, cultures, and relationships were popularly depicted as representatives of conformity and compliance and mostly viewed as potential obstacles for the creative person. The implications of this individualistic/atomistic model for creativity are considerable. Interventions to foster creativity based on this model are directed toward developing cognitive capacities, most popularly through processes like "lateral thinking." Little or no attention paid to the role of relationships, organizational systems and structures, rewards, obstacles, and other environmental factors (Montuori and Purser 1999).

In the academic research, almost exclusively in the discipline of psychology, these "social" dimensions were generally ignored until the mid-1980s, when a critique of individualism within psychology was coupled with an emerging interest creativity in organizations. The individualist approach to creativity, and indeed the very concept of creativity itself, has been challenged by postmodern scholars who have problematized the role and nature of the "author" and the possibility of originality (Kearney 1988, 1999; Pope 2005). Postmodern scholars argue that the concepts of self, originality, and "creativity" are all socially constructed, and women and people of color are noticeably absent from the discourse of creativity. Likewise, the notion of the creative genius has been constructed and manipulated for commercial ends in order to make a product look more exceptional and desirable because it was made by a "genius." Genius is nothing more than a label placed on certain people for marketing reasons.

Creativity, Modernity, and the Machine

Creativity has had a peculiar role in the modern world. Creative artists and scientists were praised and even idolized and mythologized (e.g., van Gogh, Picasso, Einstein, Feynman). The phenomenon itself was not well understood and could not be accounted for in the prevailing paradigm. The modern scientific worldview was based on a Newtonian/Cartesian machine or clockwork metaphor in which the world was fundamentally objective, rational, linear, deterministic, and orderly. Creativity was associated with subjective experience, with the irrationality of mystical insight and inspiration and a breakdown in order. It was therefore viewed as closely aligned with disorder, whether social or personal (revolution, mental illness). Creativity was viewed as contingent and subjective, not as a lawful, orderly, and objective phenomenon worthy of scientific study. Creativity also appeared to be fundamentally antiauthoritarian because it disrupted the established order and stood for novelty, change, and individual expression. Romanticism, on the other hand, celebrated and mythologized creativity and imagination through literature, poetry, and the arts. Consequently for 200 years, the discourse of creativity was dominated by romantic images of inspiration, exceptional individuals, struggles against the oppressive forces of society and "the system," and artistic *Sturm und Drang*. If it was accepted that creativity in the arts was deeply subjective and mysterious process, this view of a disorderly process and self-absorbed artistic "creatives" made creativity very suspect in the (allegedly) orderly and efficiency-oriented world of organizations.

At the beginning of the twentieth century, in the business world, efforts were made to use the latest science to design and run efficient organizations. This was the so-called scientific management of Frederick Taylor (1856–1915). Scientific management captured the essence of the machine metaphor applied to organizations with "command and control" management. This included putting power and discretion in the hands of the manager, away from personal initiative and work groups, using "scientific principles" to replace the judgment of the workers, and the assumption that individual tasks are best performed in the greatest possible isolation because when men work in "gangs," as Taylor called them, their performance is lowered.

Organizations combined the machine metaphor of scientific management with traditional authoritarian, hierarchical structures and top-down control. The stress was on order and a system of division of labor closely tied to the notion of "divide and rule," with the manager in a command and control role to ensure that the system is enforced. This kind of authoritarian management with a rigidly hierarchical organization was designed to actively suppress any form of deviation from the rules, any personal initiative, and any collaboration. It was therefore also designed to eliminate anything that we might call creativity because creativity involves novelty and deviation from the norm.

The machine metaphor foundation of scientific management has particular implications for creativity, since the machine itself is not creative: it is the product of an external creator. Science could explain the workings of the machine but not of the creator – it could not account for novelty. God was outside or beyond the world. The creative force behind an organization (the inventor or entrepreneur figure like Edwin Land of Polaroid) developed the organization to make his or her vision a reality but was by his very nature outside or beyond to day-to-day workings of the organization. In society, creative individuals in the arts and sciences were outsiders, often considered to be close to madness: the self-destructive artist, the mad professor. These cultural images militated against the acceptance of creativity in organizations because they always presented creativity as an external phenomenon, not intrinsic to the system in question.

Creative individuals did not fit into machine organizations. In business, they were either successful entrepreneurs, who had started a company, or "creative types" that were hired out of necessity in R&D labs, marketing, advertising, and so on. Their approach was considered disordered, unreliable, eccentric, and regarded with some suspicion. With a rapidly changing interconnected world and with new developments in science such as chaos and complexity theories, the machine metaphor would seem to be outdated (Peat 2002). But in fact even though it has been severely challenged, it is still a dominant underlying metaphor, and many of the obstacles to creativity can be traced to deep-seated assumptions about the nature of organizational practices originating in the authoritarian machine model because the "well-oiled machine" and "command and control" are still the driving image and metaphor of what an organization and management should ideally look like, particularly during recessions and financial difficulty (Amabile 2010; Pfeffer and Vega 1999; Pope 2005).

Characteristics of Creativity

Creativity is associated with such personality characteristics as independence of judgment, preference for complexity, and tolerance for ambiguity (Barron 1968; Runco 2007). The characteristics point to an openness toward opportunity and alternatives rather than a desire to conform and superimpose existing interpretive frameworks. The characteristics associated with creativity are contrasted with preference for simplicity, conformity, either/or thinking, and rigidity. Intrinsic motivation is a key factor in creativity (Amabile 1996). Intrinsic means "from within." Intrinsic motivation means that we are moved from within to do something. The intrinsically motivating factors can include fascination for the subject, enjoyment while performing the task, or a feeling of accomplishment. Intrinsically motivated people enjoy what they do, and they do so because they find the task itself rewarding. Extrinsic motivation is motivation that comes from external sources rather than the pleasure of the task itself. Financial incentives and social approval are examples of extrinsic motivation. Extrinsically motivated individuals perform a task because there is an external reward attached to it. The task itself is not what they enjoy; it is the reward (financial or otherwise) that provides the appeal.

Paradox is a recurring characteristic of creativity at all levels of granularity (Montuori 2011b). It can be found in research on creative individuals, creative groups, and in the creative process. The term is used most frequently to refer to two characteristics that are usually not found together, are contrary to received opinion, or even considered contradictory.

Highly creative individuals have paradoxical qualities. For instance, they can be both energetic and quiet, smart and naïve, playful and disciplined, extroverted and introverted, rebellious, and conservative, and they escape rigid gender stereotyping. Most dramatically, perhaps, it has been suggested that they are both "crazier" and "saner," scoring higher on measures of psychopathology but also on measures of mental health (Barron 1995; Csikszentmihalyi 1996; Hampden-Turner 1999).

Research on creative groups in R&D has indicated that successful researchers are both more autonomous and more collaborative, engage in both basic and applied research, and are focused but also avoid narrow specialization. As with the paradoxical characteristics of individuals, we find that whereas conventionally these terms are mutually exclusive, in the case of creativity, they seem to be connected (Pelz 1967; Pelz and Andrews 1976).

The creative process involves both divergence and convergence, idea generation and idea selection, and being open and being critical (Runco 2007). The ability to entertain what on the surface appear to be opposing thoughts or concepts seems central to creative thinking. In fact, many creative insights and breakthroughs in the arts and sciences have been attributed to this ability, sometimes called "Janusian thinking" (Rothenberg 1979). The term for this form of paradoxical thinking is taken from the image of the Greek god, Janus, who has two faces looking in opposite directions. It is characterized by the capacity to entertain two opposite or contradictory ideas, holding each to be valid or true simultaneously. Creative individuals utilize this form of cognition that transcends ordinary logic, resulting in resolutions to complex problems that are novel and original. Such formulations are often creative because of this capacity for embracing opposites; two conditions that appear initially to be mutually exclusive or antithetical can be held in tension, and can lead to a breakthrough or insight (Arlin 1990; Yan and Arlin 1999).

Cybernetics offers a different way of thinking about paradoxical phenomena in creativity (Hampden-Turner 1999; Montuori 2011b). A static logic of either/or is replaced by a fluid process of ongoing navigation between two terms that are normally framed as contradictory. Paradoxical characteristics therefore reflect a cybernetic relationship that involves a both/and logic, whereby the terms can alternate at different times, as with introversion/extroversion, rebelliousness/conservatism, or divergence/convergence.

Environments that Support Creativity

Some environments promote creativity; others can inhibit it. Authoritarian systems were not designed to foster creativity. On the contrary, the focus was on conformity and predictability, and the main metaphor for an organization was the machine. Considerable changes have occurred in more than 100 years since Frederick Taylor articulated his model of "scientific management," but it is telling that it has only been in the last 2 decades that there has been any sustained research into environments that foster creativity and creativity in the workplace (Amabile 1983; Montuori and Purser 1999; Purser and Montuori 1999). The environments that favor creativity turn out to be diametrically opposed to authoritarian environments because, among other things, they promote independence of judgment, problem finding, and flatter organizational structures. The characteristics of creative environments are often paradoxical or "cybernetic" as they involve navigating between "creative tensions" such as being too challenging or too boring, specialization and a broad outlook, autonomy and the need for respect and approval, personal satisfaction and organizational needs, and so on.

If tasks are not challenging enough, they are not likely to elicit intrinsic motivation and creative thinking. On the other hand, too much challenge can result in people feeling overwhelmed and in "over their heads," creating a high level of anxiety that inhibits the capacity for creative thought. Csikzentmihalyi (1997) has identified the "flow state," a condition of high performance that is just challenging enough to push the person beyond their comfort zone but not far enough that they are overwhelmed by anxiety. The original research on flow state was with individuals, and recent research has suggested that particularly high-performing groups may also experience a collective flow state (Sawyer 2003, 2008). An important element in enhancing creativity in organizations is to match peoples' interests and skills with the right assignments. A good match requires knowledge about the parties involved and the nature of the assignment. The jazz big-band leader Duke Ellington is said to have made sure he even knew how his musicians played poker. He wanted to know all about them in order to be able to match them with solos in the right songs. That way he could write music that reflected the musicians' passion and ability and find a fit between individuals and the larger whole.

Creative environments do not stress overspecialization. They give freedom to move around in several disciplines and knowledge bases. Many innovative new ideas come from individuals who are not overspecialized and bring in information or ways of approaching problems from other disciplines or areas of research. Creative individuals tend to be autonomous and nonconforming, but this does not mean they do not care at all what others think of them. They do want to work in an environment in which they are appreciated and respected by their peers. It is a disincentive for them not to know how they are being assessed by their peers and not having any way of gauging how their own contribution is being received. Knowing that one's views will not be ignored and be given a serious hearing also helps to build an environment supportive of creativity.

Environments where the fear of failure is high and where failure is strongly penalized inhibit creativity (Berns 2010). Fear of failure inhibits risk taking, and with it, the likelihood that something new and creative will be uttered, let alone tried out. Environments that support creativity provide "champions" for creative ideas – whether they come from teams or individuals – that provide external support and advocacy and help them navigate the organizational bureaucracy.

Micromanagement is not conducive to creative environments and creative work. Amabile (1998) usefully differentiates between tasks that are algorithmic, and tasks that are heuristic. Algorithmic tasks involve specific, preestablished steps that have to be followed very closely, with one right way to do things, and there is no room for creativity. Heuristic tasks involve clear expectations but also considerable autonomy in how the task is to be performed, are much more likely to lead to creativity.

Creativity involves periods of relative isolation, meditation, and reflection. Along with freedom from external constraints, creative individuals often need the time to be alone with their creative process and not be interrupted. This is not to say that they do not also need time for vigorous exchanges and interactions. The creative process requires both isolation and interaction and environments that permit both those "moments" in the process (Runco 2007).

Environments that support creativity encourage creative dissent (Catmull 2008). They allow for vigorous exchanges of ideas, challenging assumptions, and discourage conformity. Creative individuals may not, and often do not, fully share the goals and interests of higher management. What sets them apart is that they are open to listening and will take direction, if they know they are also being listened to and respected for their opinions. At the same time, in order to support creativity, it is also important to be able to allow ideas to emerge and not attack them and test them before they are fully formed. Creative ideas may initially seem bizarre or wrongheaded.

The Future of Creativity

There are strong indications that in the twenty-first century, the discourse and practices of creativity itself may be changing (Montuori 2011a; Pachucki et al. 2010). The emerging research on and practices of creativity can be summarized as proposing that:

(a) Creativity is the fundamental nature of the universe, the process of creation itself, rather the spark of an occasional (C)creator, and is therefore a basic "everyday, everyone, everywhere" human capacity.

(b) Creativity is a networked, ecological, and relational process rather than an isolated phenomenon.

(c) Creativity is paradoxical; in the characteristics of the creative person, process, product, and environment are found seemingly incompatible terms: creativity requires *both* order and disorder, rigor and imagination, hard work and play, idea generation and idea selection, times of introspection and solitude, and times of interaction and exchange.

(d) Creativity is an emergent, "bottom-up" process arising out of interactions of a given system and therefore unpredictable.

From the modern individualistic focus oriented to "eminent" or uncontroversial creatives producing exceptional products (Einstein, Picasso, etc.), there has been a shift toward a more collaborative, "everyday," ecological understanding and practice of creativity. The focus is on generative interactions in a variety of mundane or everyday activities and contexts, rather than the individual lone genius working on a major contribution. Millennial college students associate creativity with everyday activities and with social interaction (Pachucki et al. 2010).

Many of the most interesting social innovations of the last 20 years or so have been about networking, participation, and grassroots efforts. These innovations are connected to the emergence of the Internet, of social media, and of a networked society. YouTube, Etsy, Facebook, Wikipedia, WebMD, Lord of Warcraft, farmer's markets, artisanal foods and the Slow Food Movement, MySpace, blogs, vlogs, Twitter, Britain's Got Talent, independent music labels and movies, GarageBand, DIY culture including DIY education, Yelp, TripAdvisor, Craigslist, Dancing with the Stars, American Idol, and reality television are all examples of new forms of expression and networked organizations that involve a much greater degree of grassroots participation than before. The traditional role of the critic, the artist, the record label, the audience, the reader, the novelist, the journalist, the photo reporter, and the newspaper is all being supplemented (and in some cases seriously threatened) by this ability individuals have to connect, participate, and even create. The traditional top-down, one-way communication from author to reader, from performer to audience, from star to public, from producer to consumer, and from leader to follower is changing with the emergence of a participatory culture (Jenkins 2009). Phenomena such as the Arab Spring and Occupy Wall Street are examples of social movements that have used a form of "swarm," or networked creativity (Montuori in press). Aided by social media and a focus on collaborative processes, they have developed new and unusual solutions to address the problems faced by social activist protesters in getting their message across.

The implications of these emerging views of creativity are considerable. "Everyday, everywhere, everyone" creativity points to the possibility of a much more widely distributed creativity throughout organizations and society. Creativity is no longer limited to a few clearly defined areas, such as the development of new products. It can be brought to bear on simple human interactions, work processes, and other areas where it was formerly not valorized. One emerging concern is that this "democratization" of creativity will lead to a "cult of the amateur," where quality and criteria will be lost (Keen 2008).

The new, contextual, and collaborative approach to creativity by the younger generation is matched in the research by a new research interest in the social dimensions of creativity. There is a move away from an essentialist view of creativity to one that is relational and contextual. Organizations that focus on innovation and adaptation to rapid change are increasingly flatter and less hierarchical. They also require more initiative from individuals, ability to make decisions and respond to unforeseen situations. The connection between creativity and improvisation is also an area of emerging research. The root of the term improvisation is the Latin term "improvisus" or unforeseen: improvisation is the ability to respond to, as well as generate, the unforeseen (Montuori 2003).

Conclusions and Further Directions

Creativity is a complex phenomenon with substantially changing discourse and practices. The initial focus on exceptional eminent individuals is being challenged by a more distributed, collaborative understanding of creativity. New complexity and network-oriented approach show great promise in the development of new conceptualizations of creativity that can accurately describe these new forms of creativity. In industries where innovation is essential, latter, less hierarchical and more adaptive organizations will be required, and creativity will be a key resource.

Definitions

Social Capital

Social capital refers to the understanding and measuring of the influence of social relationships on social agents and, broadly, the firm's economic performance.

Entrepreneurship

Entrepreneurship is an activity involving the discovery, evaluation, and exploitation of business opportunities in order to introduce new goods and services, new organizational structures, markets, processes, and materials using resources that may not have existed before.

Network

A network is a twofold system (an exchange system tied in with a technical infrastructure). It is not a hierarchy per se but a structure of exchange and flow as well as a representation common to heterogeneous organizations interconnected through space).

Background and Discussion

To address the connections between "network" and "entrepreneurship," one needs to begin with the focus on social capital. With regard to social capital, the prevalence given to exchanges is a common trait to these two notions, an aspect that may establish lasting relationships and helps understand what entrepreneurship is about. Another source of social capital may stem from benefits related to the possession of information insofar as the potential asymmetry it tends to generate, its preservation and exchange builds relationships and entrepreneurial opportunities alike. A third source comes from social norms, which condition individuals' behavior and thereby make them predictable and even reliable, building an environment favorable to entrepreneurship.

The analytical framework of networks provides a heuristic for examining the relational structures around entrepreneurship, as in clusters, for example. By extension, the network can be considered as a tool for structuring configurations likely to create social capital (Ferrary and Pesqueux 2011).

The focus on the notion of intellectual capital (or human capital), along with social capital (as represented by institutions, including those of knowledge societies) furthers the reference to networks by contrast to the two other forms of "capital" established by the World Bank (natural capital, e.g., ecological footprint, manufactured or techno-economic capital, e.g., the firm and/or "traditional" processes) – and despite consistent emphasis on the interplay between these forms and these capitals being contributing factors to the birth and development of entrepreneurship.

Two major trends refer to the notion of social capital (Ponthieux 2006), one that refers to the individual as the instigator of the construction of this type of capital and one that refers to the notion as an institutional attribute:

– The first perspective was founded by J. Coleman (1988) who draws on economic behavior, the pursuit of individual interest and exchanges based on rational calculations prone to establishing lasting relationships that ultimately become institutionalized.
– The second perspective is the one singled out by the World Bank. While the individual-based perspective refers to the notion of obligations and expectations in social relationships or even the capacity of a "well-positioned" individual to possess and acquire specific information and knowledge, a third form exists, namely, social norms, which make social behavior predictable. The first trend of the macro-social perspective refers to network sociology and the socially anchored nature of any action, hence the importance of the position one holds and the frequency of relationships with other social agents. The intermediate position – resulting from weak ties between two agent groups – is one that generates human and social capital. Another form of social network is the struggle to preserve (or reach) a beneficial position, as preservation is easier than access due to the "favored" category's "cultural" knowledge of the rules of the social game (see Bourdieu's definition: a network of social connections available to an individual or a group, which may translate into friendships, kinship, or knowledge in key fields – 1970; 1979; 1989). This network consists of investments but also legacies. The social area is then considered as a field of power between agents with different types of social capital struggling to define its important features, and that is the power and right to define or at least influence the rules of the social game. By contrast, R. Putnam (1993, 2001) emphasizes the importance of intermediate institutions in how they build the social mesh and contribute to the economic performance of an area. Thus, human capital and social capital tie in implicitly with a geographic area, which anchors the activity of these intermediate institutions. A possible criticism of this view is that it tends to homogenize the relationships developing with intermediate institutions regardless of their nature: an outreach agency becomes essentially the same as a NGO, a football club, or a union in the sense that the concept of trust is linked to social capital almost irrespective of the sources of that trust. In fact, the importance of cooperative behavior is held to be the significant factor in possessing social capital.

Building on this reference to social capital, M. Granovetter (1985), Granovetter and Swedberg (1992) proposes an alternative to the rational and selfish individual of standard microeconomics as well as the oversocialized man of structuralism: one given position, partly predefined itself, presupposes the construction of a social network around the individual. Based on this assumption, Granovetter examines strong ties (in fact, the smallest proportion,) and weak ties (shared belonging to social networks) and highlights "structural holes" and the privileged place some individuals may hold in retrieving or circulating (or not or poorly) information that others do not have.

To discuss networks is to stress the importance of the reference to an organizational mode from an understanding and predictive perspective. The notion of network, in its technical dimension, has gained legitimacy in the technological field through the "improvements" it contributes to social agents' formal decision and coordination processes. Information and communication technologies as well as the Internet are the two technical figures grounding its technological and scientific legitimacy.

Historically, the concept of network does not originate from technologies or any reference to biological or social structures. It grows out of the notion of net (weaving – popular referent). It was originally used in a medical and metaphorical sense from the mid-nineteenth century and conceived of as "any object." The notion then emerges as a median figure in between the organic and telecommunications, providing a metaphor for entering a twofold system of flow and stability. The notion of network has been used extensively since the 1970s, particularly in industrial economics, with regard to industrial organization and technological cooperation. The early 1980s saw a plethora of engineering science research on infrastructure networks (in particular computer networks, telecommunication networks, road networks, and transportation networks), which cemented its characterization as a technical, social, and economic system. In the 1990s, other studies addressed the issue of interactions. By the mid-1990s, studies started to bridge the gap between these two contributions.

On Networks

As a technical representation, the network reveals a structure through an image of several interconnected lines and raises the issue of "point to point" optimization, in other words the issue of efficient management – achieving optimal outcomes locally – and how to manage a system (e.g., joint development of railroad and telecommunication networks).

Network organization gives rise to a figure that addresses simultaneously the oneness and distinctiveness of the organization model involved, as it is both a kind of structure and a system within an organic representation. It provides a representation of the technical principle of interconnection (the technical existence of networks requires addressing its organization and management).

The reference to a network is built around three tightly interlocked foundations: the fact that it is a technological object, the fantasies it appeals to, and the language entailed in order to build a metaphor that serves as both description and utopia.

On an epistemological level, the network consists of three dimensions, most often mixed up and conducive to movement from one field to another: a cognitive dimension (the network as concept), a symbolic dimension, and a rational dimension (the network as methodology). Network organization emerges as the organizational model deriving from cybernetics and network computing and it has incorporated a technical "reality" provided by network computing. Here the emphasis is on the symbolic, organizational, and technical topic of interconnection.

Network organization is recognized as a "new" form of organization that raises the question of management along four guidelines: structural consistency, which addresses the heterogeneity of the makeup of these structures; external consistency, which addresses partnership (coordination of activities among partner organizations); internal consistency, which addresses autonomy; and consistency of value systems, which addresses cohesion.

Firms and Networks

The first network dimension faced by corporate management pertains to the very nature of certain economic activities. Several industries consist of network companies. For example, postal, phone, electric, gas, railroad, computer, or water distribution networks are enabled by their own economic models and management constraints. As N. Currien (1992) notes, network companies have an economic intermediation function. One characteristic of network companies is that the density of units and the quality of physical links (e.g., connections between postal hubs, electrical lines between power plants and consumers, etc.) that connect them together determine the firm's economic performance. One managerial issue for network companies is that they are often firms handling workflows that cannot be stored and processed in a regulated fashion. The other issue related to the systemic dimension of network activities is the necessary continuity that compels firms to ensure sustained interconnection of the network's units. Network companies are impacted by the necessary compatibility and interconnectedness of their constituent units. This requires standardized infrastructures.

On a macroeconomic level, the distinctive features of network activities may justify the existence of monopoly positions. Network companies are quintessentially prone to "natural monopoly" as monopolistic situations help optimize economies of scale by leveraging decreasing returns. Network companies thus have specific operation procedures and competitiveness factors that influence the management practices of these intrinsically reticular structures.

In the field of industrial organization, enterprise networks are perceived as a source of competitiveness and competitive advantage to firms that are part of the network, as their competitiveness is equated with the capacity to make an impact within a myriad of values made up by economic partners. The development of strategic networks through alliances, partnerships, or long-term contracts offers them a gateway to information, resources, markets, and technologies. The importance of the reticular structure may spring from the organizational strategies of firms that are refocusing on their core competencies, which may cause them to outsource all their peripheral activities. In this instance, the strategy can no longer be viewed as a rational move of adjustment to the market but as a framework that guides the development and acquisition of resources. The organization is considered as a portfolio of competencies. Its management aims to handle these strategic competencies and bring to fruition the redeployment of necessary competencies to capture new opportunities and rearrange the portfolio of "product-market" activities by anticipating changes in the environment.

By figuring out how similar and complementary the firms of one same network, two types of networks can be identified based on their degree of systemic interconnectedness (Ferrary and Pesqueux 2004):

– Enterprise networks characterized by the low systemic interconnectedness of their members because they consist of similar units with few complementarities and poor operational interaction. The units are autonomous and their performance does not depend on their interaction with other units. In this case, the disappearance of one entity of the network has little impact on the others' performance and the network's overall. One example is bank agency networks or franchise networks (fast food, hair salons, clothing stores, etc.) where the closing of one unit does not hurt others' efficiency. This form optimizes economies of scale to improve the network's "competitiveness-price" ratio rather than economies of quality entailed by interaction between the network's firms.
– Enterprise networks characterized by the high systemic interconnectedness of their members because they consist of firms with different, complementary and interconnected competencies. The disappearance of one member of the network immediately affects the other's efficiency and the entire network's. One example is a network of independent law firms with various specialties (if one of them leaves the network, say the expert on labor law, the quality of supply of the entire network takes a toll instantly because the network can no longer provide this competence to its clients). Similarly, in an industrial cluster, the absence of one competence (e.g., "training" in universities, "research" in laboratories, or "financing" in banks) is detrimental to the efficiency of the other actors of the network (as firms will face recruitment and financing issues) and thus the overall momentum. These networks with high systemic interconnectedness draw their competitive advantage from the optimized complementarities of the network's own firms and the quality of their interaction to improve competitiveness.

Such networks include enterprise networks structured around one central firm in order to optimize learning effects, as in the car industry, formal enterprise networks in order to optimize network effects, as in air companies' alliance networks, and informal enterprise networks, as in industrial districts.

However, it is important to stress the irreducible human dimension of enterprise networks usually underpinned by social networks. These are groups of individuals whose frequent economic interactions and extensive social relations can dispel relational uncertainty by discriminating accurately between dishonest and honest members. The first characteristic of these networks is that the information sought after by members moves very rapidly and reputation effects arise rapidly as well, leading to information asymmetry between members and nonmembers of the network. The second one is that solidarity exists between the members of the network, and this should be taken into account when interacting with any of them because interacting with a member of the network is conducive to interacting indirectly with all members. These characteristics will alter the nature of the exchange. The social appreciation of the risk implies that the commercial exchange should no longer be understood as an in-the-moment relation, strictly professional and individual, but as a sustainable relation mediated by an informal and personal dimension between the contracting parties, requiring at least indirectly, relations with all the members of the social group. While social ties play a major role in information flow and firms' capacity to quickly tap complementary resources, jumpstarting potential social ties enhances the process further and builds new complementarities. A priori belonging to the network guarantees that accessible competencies will build up. The network will interfere as an ex post selection system that accepts or refuses the presence of new members as potential resources. Aspects such as resource complementarity, geographic proximity of members, and duration of the social relation of exchange are critical.

As M. Granovetter suggests, inter-individual interactions translate into macro-social phenomena that symmetrically reflect back on individuals and small groups, in a context where the existence of the community is conditional on strong social ties. Weak ties enable information flow because they are less dense, less emotional, and less frequent. Virtual ties confirm the network's potential since members of a social network benefit from social capital and can trigger off virtual ties when needed. The social mesh is thus shaped by the existence of holes defined by R. Burt (1992) as "structural." A structural hole is defined as the gap between nonredundant contacts and entails the existence of strategic positions in social networks. An individual in between two communities will be better off in the sense that they will be able to communicate information and connect with the members of those communities.

Conclusion and Future Directions

Networks enable social learning (first future direction), generate reputation effects (second future direction), and changes (third future direction) in optimization expectations even if it is limited by the "unsubstitutability" of the possessor of social capital, alters the power relationship between employee and employer, and the authoritarian response it entails from the top management.

The Multi-Level Dimension of Interfirm Networks

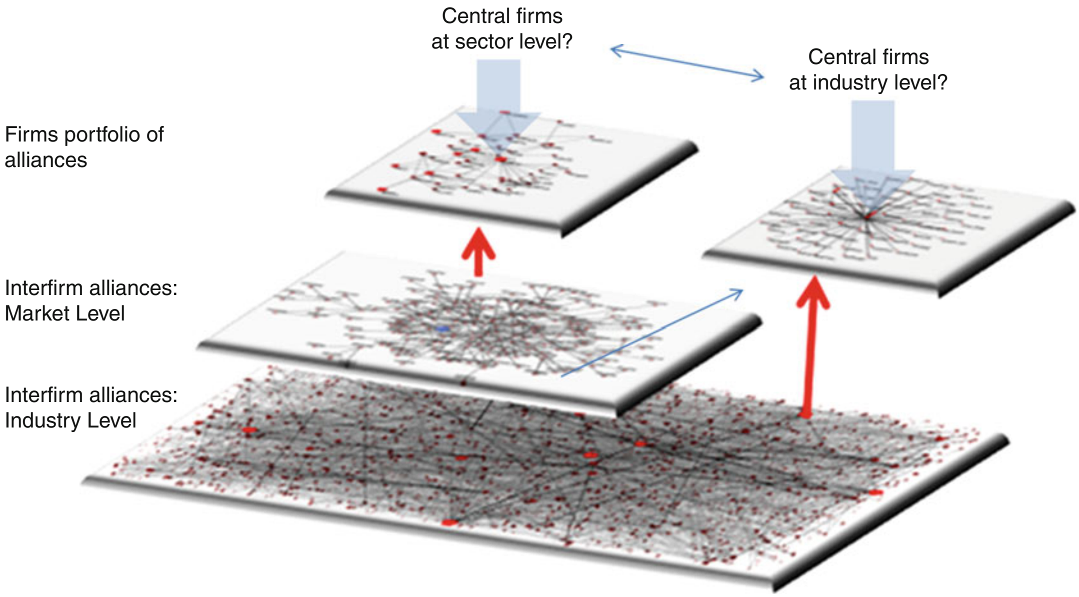
Interfirm alliances are formed today constantly across organizational boundaries. This move of firms toward open and networked systems has culminated in complex webs of international alliances. Terms such as the networked firm or the virtual organization or the open business models are now used to describe an organizational form containing a network of firms. The fact that there is scope for managerial choices has been demonstrated by Patel and Pavitt (1997). They reflect different objectives and designs made by different managers in the face of complexity and uncertainty, differences in the rate, and directions of these exchanges also obviously affecting outcomes. Management thus involves the ability to build temporary alliance portfolios created by global competition and sustained, often radical, innovation and to address the different industry segments the firm wants or needs to compete in. How a firm draws boundaries within global and complex interfirm networks to implement a growth strategy will affect its business performance and at the same time highlight the company rationale to invest in resources. Understanding network structures at firm, specific market, and industry levels and their reciprocally structuring effects should help managers devise strategies for the sustained dynamic building of effective firm alliance portfolios across international and organizational boundaries.

Though the multilevel dimension of networks is intrinsic to their analysis (Lazega et al. 2008), few scholars have addressed the complicated question of the integration of different levels of analysis in which an actor's capital is situated (Breiger 1974; Fararo and Doreian 1984; Hedström et al. 2000; Lazega et al. 2008). Moreover, analyses of structural change in real-world networks are still scarce. Figure 1 visualizes the value added by looking at the multilevel dimension of interlocked interfirm networks.

This contribution aims to seek an understanding of network dynamics at industry and market segment level and of how key entrepreneurial and large incumbent firms cope with or influence the stability or instability of the different network layers they are enmeshed in.

In this chapter, the *k*-core decomposition is used as a network analysis tool particularly adapted to emphasize the hierarchical properties and temporal variations in network structures that are not captured by other topological measures (Alvarez-Hamelin et al. 2008). The *k*-core decomposition (Seidman 1983; Batagelj and Zaversnik 2002) consists in identifying particular subsets of the network, called *k*-cores, each one obtained by a recursive pruning strategy. It therefore provides a probe that allows focusing on the network's regions of increasing centrality and connectedness properties as more central cores are more strongly connected.

The biopharmaceutical industry is an appropriate setting for this analysis as this industry is one of the most alliance-intensive.



Networking Entrepreneurship, Fig. 1 Multilevel network analysis. Nodes in this figure are firms and links between nodes are transactions. The lower network map represents interfirm alliances in a whole industry while the intermediate network, extracted from the lower one, represents the alliance network in one of the industry market segment. Central players, or hubs, and their alliance portfolios can be pulled out from one or the other level (as pointed by arrows; one at each level in the figure as examples) for analysis of their alliance strategy. Analysts can thus rapidly assess and compare firms' alliance portfolios at all levels and determine whether central players at industry – and market – level are the same and the incumbency of their structural position. A dynamic network analysis will reveal the relative stability of the different global structures (Sources: Proprietary database of alliances for the pharmaceutical industry (Gay 2010). VisuGraph software (Gay and Loubier 2009) is used for network visualization)

The innermost *k*-core structure of the industry can be characterized as it evolves, here from 2000 to 2007, and compared with the *k*-core structure obtained in one of its major sector, the antibody sector, for the same time period. This analysis shows that the *k*-core structure is extremely different at industry and sector level and that the *k*-core decomposition tool is able to clearly characterize variations in network structures and hierarchies across time at each level. This study moreover demonstrates that the different network layers evolve differently and have different levels of stability. It also emphasizes the challenges of managing entrepreneurial firms, while large incumbent firms may systematically and somewhat "passively" gain dominant positions.

Alliances and Networks as the Defining Industry Trend

The number of alliances has dramatically increased worldwide over the last decade, shifting the fundamental competitive paradigm in markets from firm-to-firm competition to more alliance-based boundary spanning, competition and strategy (Newman and Chaharbaghi 1996; Hitt et al. 1998; Holmberg and Cummings 2009). Analysts (e.g., Datamonitor) have reported recently that transactions may now account for 16–25% of median company value and more than 40% of market value for almost one-quarter of companies, while Booz-Allen and Hamilton estimate that more than one-third of the revenues of the top 2000 US and European companies come from alliances. Prominent firms such as IBM, Pfizer, and Eli Lilly generally find themselves in hundreds of alliances clearly shifting the attention from issues regarding the management of individual transactions to issues regarding the management of evolving huge portfolios of alliances. Indeed, Pfizer reviewed in 2005 only over 400 licensing or acquisition opportunities. Procter & Gamble claims that the strategy of leveraging on other assets produces more than 35% of the company's innovations and billions of dollars in revenue (Huston and Sakkab 2006).

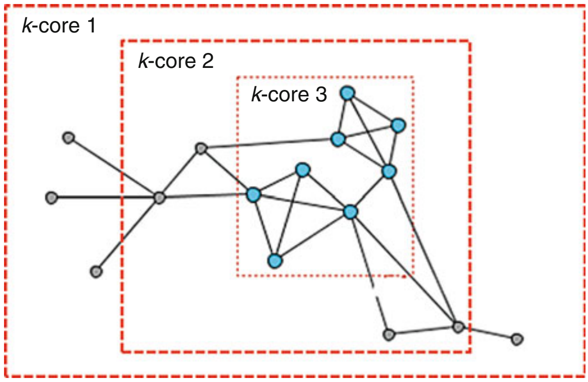
Research on the evolution of interorganizational networks suggests that networks become ever more self-reproducing and centralized, as more and more dense webs of relationships are developed among firms (Chung et al. 2000; Gulati 1995; Gulati and Gargiulo 1999; Powell et al. 1996; Walker et al. 1997). In other studies, locally embedded firms are globally connected by a handful of "shortcuts," the network being then structured as a "small world" (Baum et al. 2003; Watts and Strogatz 1998). Shortcut formation is thought to be another possible route to network change. These studies however do not help address questions of how network structures might change more significantly.

Importantly, many studies have highlighted that interfirm network structure could significantly alter performance outcomes such as growth in diverse industries (Nooteboom 1992; Hagedoorn 1993; Powell et al. 1996; Rowley et al. 2000; Ahuja 2000; Owen-Smith and Powell 2004). Soh and Roberts (2003) also suggested that the evolution of interorganizational networks is interdependent on the technical subfields they were created to control. Orsenigo et al. (2001) demonstrated the importance of technological determinants of the structural evolution of alliance networks in the pharmaceutical industry. They showed that one technological wave led to consecutive others and was induced by technical breakthroughs led by the entry of new firms acting as specialized technology "originators." However, it is not clear in extant research how innovative firms that are less endowed and socially embedded than big incumbent companies can have central positions in new markets as established firms appear to be more socially embedded than entrepreneurial firms (Katila et al. 2008). Khana, Gulati, and Nohria (1998) also introduced the concept of a firm's relative scope or ratio of the scope of the alliance to the total sets of markets in which the firm is active. They highlight that the extent of market overlap in activities between partners and with the alliance should be considered an important determinant of the likely behavior of partners.

If, as Burt (1992) argues, "something about the structure of the player's network and the location of the player's contacts in the social structure of the arena creates a competitive advantage in getting higher rates of return on investment," different categories of actors at different levels may need to call upon different networking strategies. Interestingly, Ozcan and Eisenhardt (2009) have very recently proposed that incumbent firms could possibly essentially rely on the deterministic account of interdependence and embeddedness (Gulati and Gargiulo 1999) and be successful in stable industries, while strategic action was necessary for entrants in nascent or rapidly changing markets.

Network Analysis

Previous studies in the biotech or health sector have concentrated mostly on alliances formed before 1998. This work focuses on more recent underlying topologies which are the result of profound technological and business transformations led by biotechnology in the pharmaceutical industry since 2000, following the sequencing of the human genome. Biotechnology drugs can broadly be grouped into four categories: recombinant protein therapeutics, monoclonal antibodies, nucleic acid therapeutics, and therapeutic vaccines. Recombinant protein therapeutics and monoclonal antibodies form two major market segments set to generate about 95% of total biotech sales from 2004 to 2010 (Datamonitor).



Networking Entrepreneurship, Fig. 2 Sketch of the k-core decomposition for a small graph. Each *closed line* contains the set of nodes belonging to a given k-core. Larger values of k clearly correspond to nodes with larger degree as well as more central position in the network's structure. Each decomposition step thus peels the network leaving connected the inner part of it

Both firms' transactional activities in the pharmaceutical industry and in one of its major subnetworks, the antibody market, are examined here.

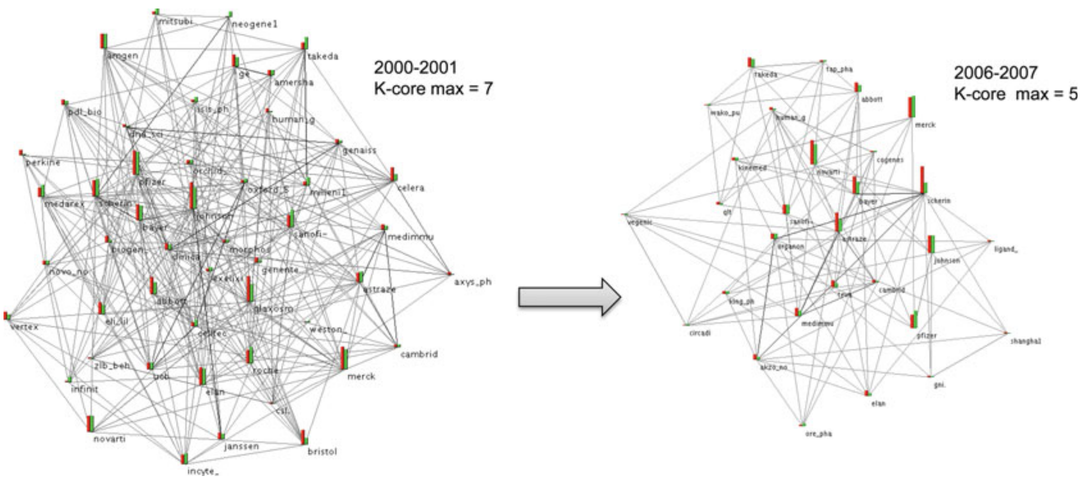
A unique collaborative agreement dataset was used for this purpose (Gay 2010). This dataset was compiled by querying specialized internet sites (leading sources for news releases and regulatory filings from companies throughout the world such as Business Wire and PRNewswire, as well as companies' Internet site) for alliances made in the pharmaceutical industry in the years 2000–2007. The data sample contains 4,755 firms worldwide with 1974, 1740, 1624, and 1,740 firms being involved in the whole industry in 2000–2001, 2002–2003, 2004–2005, and 2006–2007, respectively, and 102, 128, 300, and 370 firms being involved in the antibody sector alone for the same time periods.

VisuGraph network display software was also used for the representation of network evolving structures (Gay and Loubier 2009). Firms in this study are nodes, and the links that connect them are the alliances, or legal binding agreements. Centrality measures the importance of a node in a network. The simplest of centrality measures is degree centrality, also called node degree. The degree k of a node in a network is the number of links connecting it with other nodes. The k-core decomposition consists of a recursive pruning of the least connected organizations that allows disentangling the hierarchical structure of interfirm networks by progressively focusing on their central cores. Different subsets of the network, called k-cores, are obtained by this recursive removal of all organizations of degree, or number of alliances, smaller than k, until the degree of all remaining organizations is larger than or equal to k. Larger values of "coreness" clearly correspond to organizations with larger degree and more central position in the network structure. The core of maximum order is referred to as the main core or the highest k-core of the graph (Fig. 2).

Temporal Variations of Network Structures

The fact that the pharmaceutical industry and the antibody sector have a power law, i.e., hub-dominated, distribution of firms has already been published elsewhere (Powell et al. 2005; Gay and Dousset 2005). A multilevel study allows examining how the pharmaceutical industry is structured by its hubs and how the two types of actors that define this industry, small innovative biotech firms and large pharmaceutical incumbents, influence it or its market segments, taking a major one as an example.

The network maps obtained at various time points between 2000 and 2007 are considered here.



Networking Entrepreneurship, Fig. 3 *k*-core analysis of the pharmaceutical industry from 2000–2001 to 2006–2007. The nodes/histograms are firms, their height being proportional to the number of transactions that the company makes (the *red* and *green bars* account for the transactions made in 2000 and 2001, respectively, for the *left figure* and 2006 and 2007 for the *right figure*). Central players or hubs on the left (2000–2001) are major pharmaceutical companies (Astrazeneca, Pfizer, Schering, Bayer, GlaxoSmithkline, Novartis, Roche, Sanofi-Aventis, Abbott, Merck, Johnson and Johnson, Takeda, GE-Healthcare, Bristol-Myers) followed by biotechs which brought breakthrough technologies to the industry such as Genentech, Amgen, Biogen, Protein Design Labs, Cambridge Antibody Technology, Medimmune, Millennium, Human Genome Sciences, Vertex, Celera, Celltech, Medarex, and Morphosys. Fewer hubs are present in the right figure (2006–2007) and now include essentially major pharmaceutical companies (Astrazeneca consolidating its biologics portfolio in Medimmune and Cambridge Antibody Technology acquired in 2007, Pfizer, Bayer-Schering which purchased Organon International, the drug unit of Netherlands-based Akzo Nobel in 2007, Abbott, Sanofi-Aventis, Merck, Takeda, and Novartis) (Sources: Proprietary database of alliances for the pharmaceutical industry (Gay 2010). VisuGraph software (Gay and Loubier 2009) is used for network visualization)

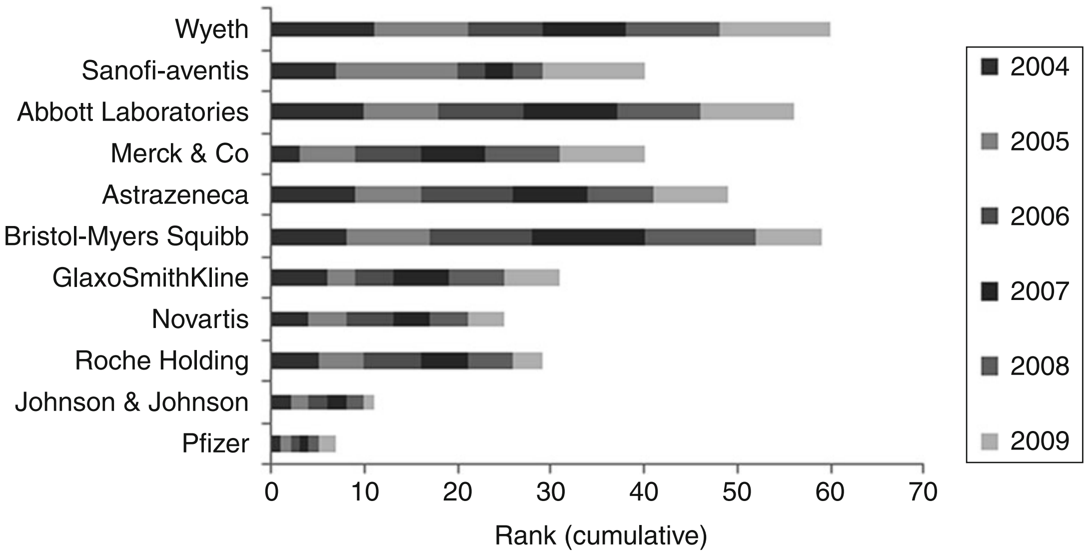
The *k*-core structures of maximum order obtained at industry and sector level are compared, and differences in these structures are discussed. As described below, the *k*-core analysis provides an interesting characterization of these differences and of temporal variations in network structures at each level.

Fingerprints of the structural changes at industry level between one snapshot (first period, 2000–2001) and the other (last period, 2006–2007) are provided in Fig. 3.

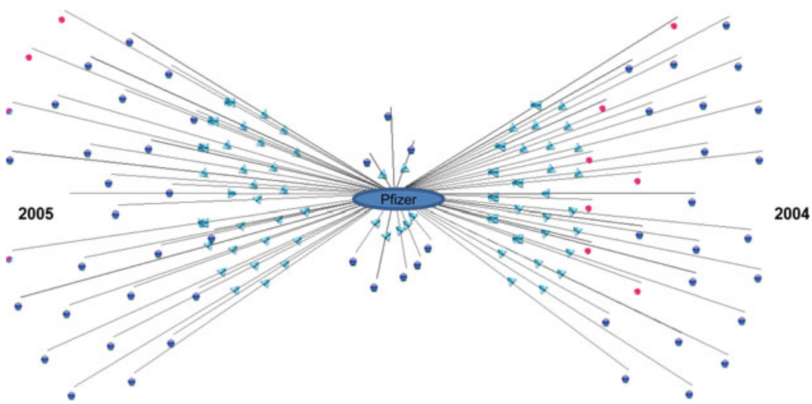
Figures 3 and 4 show the clear and constant domination of major pharmaceutical companies at industry level, in line with their performance. Interestingly, the *k*-core of maximum order is the highest in 2000–2001 (*k*-core max = 7) and contains a mix of pharmaceutical and biotech players. This high cohesiveness decreases afterward until 2006–2007, where the *k*-core structure becomes essentially driven by big pharmaceutical players (Fig. 3).

As the industry seems to be repeatedly dominated by pharmaceutical hubs, looking at their alliance portfolios is essential. As shown in Fig. 5, the turnover of the transactions is extremely high at all times. Pharma hubs make many new alliances each year and mostly with new partners. Stability at node level is therefore offset by instability at link level.

Figure 5 also illustrates that major companies are mostly making in-licensing agreements, thus capturing continuously innovation in terms of technologies and products (information summarized from the data base of transactions). The database highlights that 70% to as much as 90% of the transactions of the 7 first pharmaceutical hubs were in-licensing agreements between 2004 and 2007.



Networking Entrepreneurship, Fig. 4 Top performers in the pharmaceutical industry, period 2004–2009. The ranking is based on a mix of four metrics: sales, profit, assets, and market value (Source: Adapted from Forbes 2000, data available starting in 2004)



Networking Entrepreneurship, Fig. 5 Pfizer (*center*) high turnover of alliances from 2004 (*right*) to 2005 (*left*). Repeat partners are placed by VisuGraph in the center close to Pfizer. Links are directed inward for out-licensing agreements and outward otherwise. Blue dots represent licensors, pink ones licensees (Sources: Proprietary database of alliances for the pharmaceutical industry. VisuGraph software is used for network visualization)

Figure 6 illustrates the dramatic change in network topology the biotech sector undergoes from 2000–2001 to 2006–2007. At sector level, the *k*-core of maximum order is quite low in 2000–2001 (*k*-core = 2 against *k*-core = 7 at industry level for the same period). Three small biotechs (Medarex, Abgenix, Cambridge Antibody Technology) having proprietary key technologies that introduced radical change in the antibody sector then dominate the network. The database reveals that these new biotech entrants become hubs essentially by granting access to their technologies or providing products derived from it. In 2006–2007, however, two of these hubs have been bought by incumbents, and many more actors with different strategies (buying, selling, or both) operate within the then much larger and cohesive network (k-core of maximum order = 6) (Fig. 6).

Alliance dynamics differ from one network layer to another. While pharma hubs such as Pfizer made over 30 deals on a yearly basis at industry level, biotech hubs made yearly 5–50 transactions at sector level, but maximum degree, or number of alliances, occurred early in the life cycle of the sector and then diminished constantly while the number of new entrants increased. Few biotech firms stayed hubs during the whole period studied, and the biotech network was infiltrated increasingly by large pharmaceutical incumbents as it evolved. Additionally, 57% of the biotech firms involved in 2006–2007 had been created recently, between 2000 and 2007, while 43% had been created between 1992 and 1999. More generally, 75% of new entrants did not maintain themselves in the network from 1 year to another. The system is thus completely unstable at sector level in the sense that it is defined by a high turnover of links but also by persistent entry and exit of firms, including hubs.

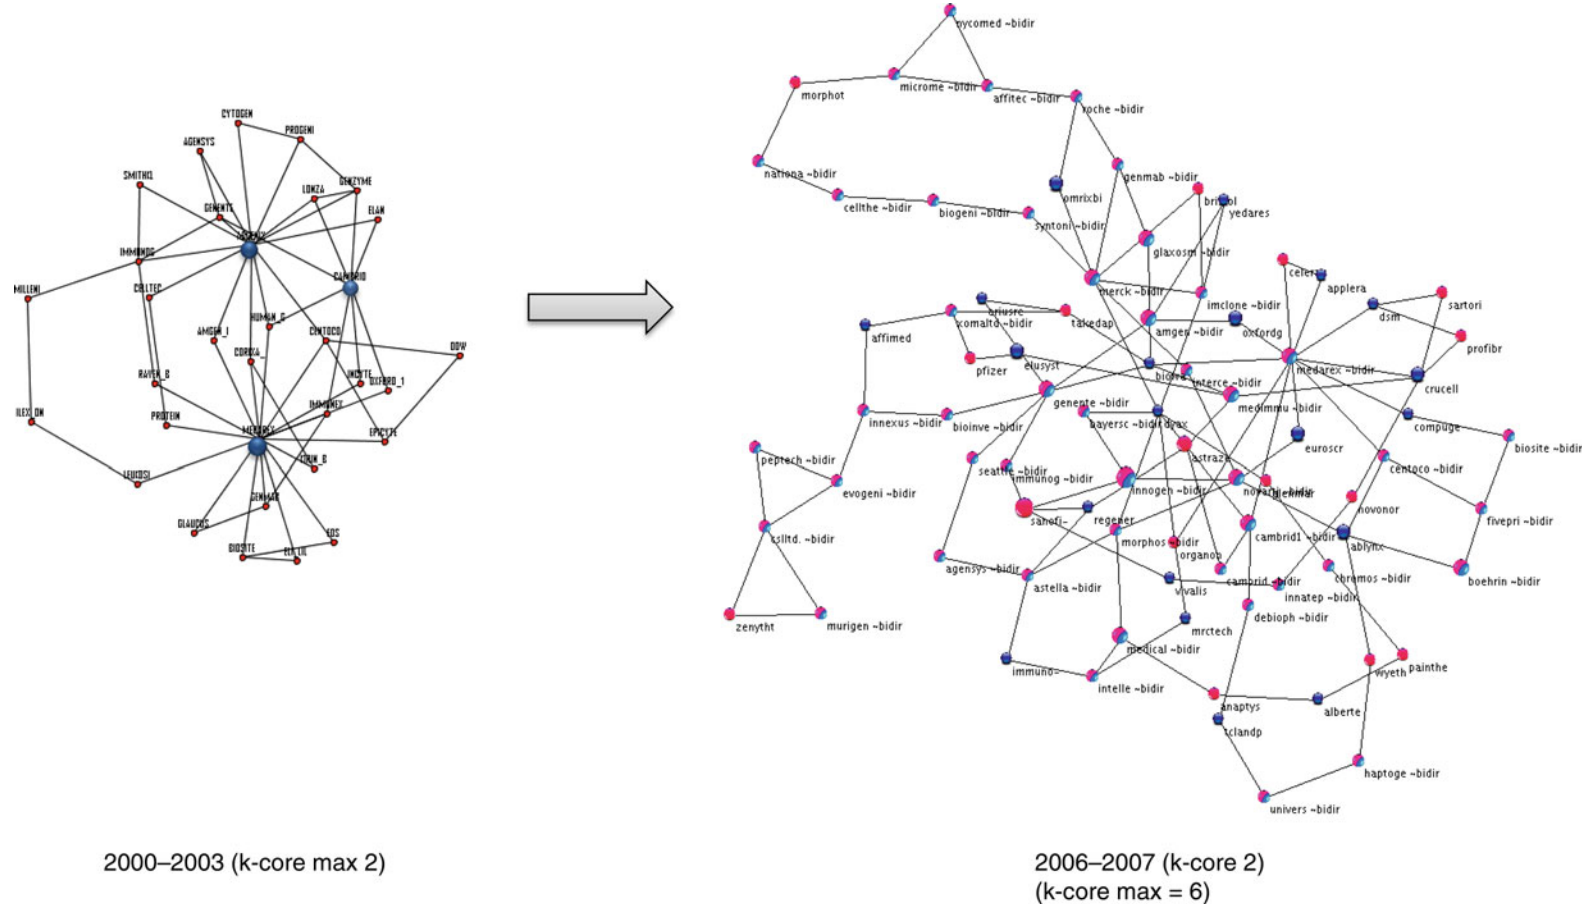
Looking at multilevel networks thus presents interesting results. At sector level, the system is unstable (high turnover of nodes and links) until it finally rests on more actors and more incumbent firms and acquires stability. At industry level, the system is stable for large incumbent firms as they are the main performers at all time (whether measured by alliance numbers or sales, profit, assets, and market value). These “money” hubs can stay high performers owing to the high turnover of alliances they use to divest some assets while constantly acquiring others (Fig. 7).

The Sheer Advantage of Size

A major drawback of research on complex networks is that it is static and, with a few exceptions (e.g., Lazega et al. 2008; Gay 2008, 2011), does not address the complementary nature of individual and organizational resources and the interdependencies of multilevel networks. Research on social capital has first emphasized position in social structure. Position was found to affect the actions and opportunities of the social actor (Burt 1992; Uzzi 1996, 1997) as well as innovation and financial performance (Powell 1998). High centrality is typically taken as a measure of the prestige or prominence of an actor in a network (Wasserman and Faust 1994). Centrality is correlated with firm success in strategic alliance research, and hence centrality has often been used as the dependent variable to determine firm performance (Ahuja 2000; Walker et al. 1997). However, the literature, using resource and social embeddedness theories, offers more a descriptive account of which ties are formed as networks evolve rather than how they are formed by firms (Gulati 1998; Gulati and Gargiulo 1999). Powell et al. (2005) in a study of the biotechnology industry interpret central firms as a form of accumulative advantage obeying a rich get richer process (Barabási and Albert 1999). Multiconnectivity (multiple forms of cooperation such as R&D, finance, marketing, or manufacturing) expands as a group of actors increases. Multiconnectivity logic dominates biotech over money or market power. Correspondingly, Gulati (1999), working on network structure, has proposed a model whereby strategic behavior is influenced by network embeddedness that gives access to informational resources accumulated through time. The social structural context within which a firm is positioned influences its strategic action.

For Bae and Gargiulo (2003), however, new ties are seen as building blocks of emerging network structures. Network structure is built dynamically and therefore destabilized constantly by the permanent formation of new links, affecting firm performance and preventing its ability to completely position itself autonomously in the overall network through alliance portfolios. New entrants entering multiple ties grow faster though increased embeddedness (cohesive structure in their network neighborhood) has a negative influence on network growth. Additionally, Kogut (2000) considers that a strong intellectual property, control of bottleneck resources, as well as rules for cooperation will lead to central players in an industry.

Therefore, opposite theories compete, offering either a deterministic account of network



Networking Entrepreneurship, Fig. 6 *k*-core analysis of the antibody sector from 2000–2001 to 2006–2007. The network hierarchical structure and firms' transactional activities are very different in the two periods. In 2000–2001, three highly innovative biotech hubs, Medarex, Abgenix, and Cambridge Antibody Technology (*blue dots*) are essentially selling their technologies or products derived from these technologies to other firms (*pink dots*). Different types of firms of all sizes are present in 2006–2007. These firms either sell (*blue dots*), buy (*pink dots*), or both buy and sell (*blue-pink dots*) assets (Sources: Proprietary database of alliances for the pharmaceutical industry. VisuGraph software is used for network visualization)

Networking Entrepreneurship, Fig. 7 Network instability at different levels, summary results

Industry level	Sector level
Hubs = « Rich » firms	**Hubs = « Innovative » firms**
Stability of hubs	Instability of hubs (fast change in hubs opportunity structure)
Instability of links	Instability of links
Link asymmetry **(in-licensing)**	Link asymmetry **(out-licensing)**
Relative stability of network structure (hubs; *k*-core)	Complete renewal of network structure (*k*-core)

evolution or that of an unstable construction, and raise three questions: that of the degree to which network structure constrains strategic action, that of how novel innovative entrants can become central players compared to socially embedded incumbents, and that of systems stability. These questions are difficult to address without longitudinal data on the different categories of actors and network levels that characterize industries. This chapter thus investigates a rather new trend in network research, that of multilevel network analysis and dynamics, and the role different categories of central players, entrepreneurial or incumbent firms, may play in shaping and connecting entwined layers.

The analysis of interfirm alliances and networks at industry or market levels demonstrates that, due to intense competition, global systems can be very unstable, the level of instability differing at different levels.

Moreover, different network levels are basically led by only one of two categories of hubs, young highly innovative firms when breakthrough innovations are needed or large incumbents. Incumbents or rich firms operate in the industry quasi-passively in the sense that they rely essentially on a high turnover of links to capture others' innovation, while innovative firms leverage essentially on idiosyncratic value mostly applicable to unique market segments; link asymmetry defines clearly the different roles: giving away or receiving assets. The position and thus survival of innovative organizations is constantly challenged by innovation dynamics within the biotech sector. A high instability at market level (high turnover of firms and alliances) is therefore witnessed as innovation cycles follow one another until increased structural cohesion is observed epitomizing a stable, mature, sector. At industry level, major firms first share the industry with major biotechs in 2000 with the rapid emergence of the biopharmaceutical industry. They then increase their control of the whole industry. In 2006–2007, the inner core of the industry presents a much simpler structure held essentially by big pharmaceutical incumbents.

Taken together, these results support extant research and notably an extreme archetype of industrial evolution that some researchers have called "Schumpeter Mark 1" regime (Dosi et al. 1995; Malerba and Orsenigo 1995) as well as a model of industrial dynamics that builds on this archetype (Winter et al. 2000) whereby only entrants have a positive probability of advancing the current state of technological knowledge, while incumbent knowledge is highly inertial.

At industry level, large incumbent firms are central, and long-term dynamics seem to favor them. Conversely, in the biotech sector or industry subnetwork, centrality for biotech firms is linked to a strong intellectual property, the value of which decreases rapidly due to a highly competitive environment. The sector is built by a dynamic flow of entrants that are carriers of innovation, shifting centrality metrics indicating successive technological phases (Gay and Dousset 2005). System growth depends on technical progress (and on demand since value must be perceived by the market), and the process of competition and collective growth is fed by an unending process of entry and exit.

Conclusion and Future Directions

A network perspective on alliances at firm and market or industry level can be a valuable asset for theories of strategic management and organizational theory, the more so in unstable environments. It can also be used by managers of biotech firms to continuously assess their position in the market segment in which they operate as well as that of their partners and competitors. It can also be used by managers of major pharmaceutical companies to address the complexity of managing in complex, fast-paced, environments by looking globally and separately at the many high-tech segments into which they must invest constantly today. With a few exceptions, researchers have treated network metrics regarding alliances as static. This study adds emphasis on the different layers or levels that make up an industry and their constant restructuring. Distinct categories of central players operate at different levels though durably or temporarily and use fundamentally opposite, asymmetrical, strategies to do so. The *k*-core analysis demonstrates the certain advantage of sheer size in hierarchical systems.

These results on the instability of systems are exploratory and should be replicated in other industries and economies. Further research in this area is needed as systemic instability has high consequences for entrepreneurial firms.

Introduction

The analysis of social networks in scientific innovation has seen a remarkable boom since the late 1990s: research on networks has developed into an interdisciplinary field comprising numerous mathematicians, physicists, and computer specialists, and no longer solely anthropologists, psychologists, and sociologists. A major reason for this boom is the availability of larger data sets and greater computer capacities for analyzing these data. Today, analyses quite commonly focus on co-publications with tens of thousands of researchers, co-citations between several million papers, or patent applications over periods of several decades. These data sets have improved the possibilities of investigating the mechanisms of network evolution and their role in scientific innovation (Chen and Redner 2010; Jones et al. 2008; Fleming et al. 2007; Wuchty et al. 2007; Newman et al. 2006; Powell et al. 2005).

This entry discusses key questions to approach selected findings from recent literature; a summary follows them: (1) What are networks in science and how are they defined? (2) What structures and characteristics do such networks have? (3) How do such networks arise and develop? (4) What is their role in scientific innovation?

What are Networks in Science?

In the terminology of mathematical graph theory, graphs consist of a finite number of nodes, connected by vertices. If all the vertices point in one direction, one speaks of a directed graph, otherwise, of an undirected graph. The number of vertices ending in a node is called the node degree; with directed networks, an indegree is distinguished from an outdegree. In the terminology of social network analysis, graphs are called networks, nodes are called actors, and vertices are called relationships.

When speaking of networks in science, one refers to collaboration among scientists, for example, in the framework of experiments, projects, or publications. Such cooperative relationships have the production and distribution of new knowledge or new technologies in the foreground. Here, the term *social networks* suggests itself. An indicator for social networks often used in the literature is joint authorship in the form of *co-publications* (*copub*). These are especially visible relationships that usually emerge from diverse formal and informal kinds of collaboration. Copub networks always consist of undirected relationships.

Networks in science also include intellectual connections among scientists arising through reference to the work results of colleagues. In the foreground of such reference relationships is usually the embedding of new arguments and findings within existing knowledge, where this is not based on collaborations. Here, the term *cognitive networks* suggests itself. An indicator for cognitive networks often used in the literature is *citation* (*cit*) *or co-citation* (*cocit*). Here, too, one deals with especially noted relationships to already published knowledge, which are far from being able to comprise all the real intellectual relations of a publication. Cit networks (A cites B, B cites C, etc.) always consist of directed relationships, while cocit networks are composed of undirected relationships (A and B cite C, B and C cite D, etc.).

Social and cognitive relationships can be analyzed not only on the microlevel of scientists. Empirical studies also investigate such relationships on higher levels of aggregation. These include research organizations, disciplinary communities, national research systems, and the global science system. The selection of the level of aggregation is generally determined by the knowledge the respective study is interested in. But analyses on a higher aggregation level also have the advantage of using temporal and disciplinary limitation to counter the long-familiar methodological problem of network analysis, namely, that there are no clearly derivable rules defining where a network begins and where it should end. With the *temporal limitation* to specific years or decades and the *factual limitation* to specific disciplinary communities (Chen and Redner 2010), research organizations (Jones et al. 2008; Heinze and Kuhlmann 2008), or – as in the case of the global science system – to selected databanks (Milojevic 2010; Jones et al. 2008), the boundaries of the networks to be investigated are defined pragmatically.

Structures and Characteristics of Networks in Science

Once the data basis is defined, the first important step of network analysis consists in investigating the fundamental structures and characteristics of the relationships. These include, in particular, the distribution of node degrees, the network's degree of differentiation, and its cohesion.

Distribution of Node Degree. For some years now, there has been intensive discussion about how the distribution of node degrees follows from copub and cit networks (Newman et al. 2006: 335ff). In many networks, the node degrees are not normally distributed around the mean, as they would be with the bell curve. Rather, there are many extreme values, so-called hubs, that is, actors who collaborate extremely often or articles that are extremely frequently cited. Networks with such hubs can be better described with the power law distribution (PLD), the distribution that is also valid for the productivity of scientists (Lotka's Law). But the PLD typically registers only observed values within a certain range of values that does not cover the entire distribution. In the case of a copub network in nanotechnology investigated by Milojevic (2010), for example, this value range lies between 20 and 200 coauthors. Below the threshold of 20 coauthors, there is a lognormal distribution.

The distribution of the node degrees is of great theoretical importance, because it is tied to the question of the mechanisms responsible for the rise and reproduction of network ties. There is a general consensus in the literature that the PLD results from the mechanism of *cumulative advantage* (CA), which was already described by Merton (1973). The hypothesis here is that scientists with higher node degrees are more likely to have new collaboration partners than are scientists with lower node degrees. Small initial differences grow over time into greater inequality. CA thus leads to a higher concentration of relationships in a few nodes. The close connection between PLD and CA means that whenever other distributions can be shown in addition to PLD, as in the case of Milojevic (2010), mechanisms other than CA are obviously at work in the genesis of the network. What mechanisms these are will be discussed below (cf. section "Mechanisms of Network Formation and Network Evolution").

Degree of Differentiation. There is also an intensive discussion about the effective identification of sub-communities and thematic fields within disciplines. In addition to the traditional procedures of social network analysis, for example, the analysis of cliques, clusters, or block models, in recent years a promising algorithm has been developed that identifies densely connected segments of the network without requiring knowledge of the content of the field covered by the network (Newman et al. 2006). Within a value area that is simple to interpret ($0 < Q < 1$), this *modularity* algorithm measures a network's degree of differentiation. For example, for the cit network of the journal family Physical Review, Chen and Redner (2010) calculate $Q = 0.543$, corresponding to 274 delimitable thematic areas. These thematic areas are in turn differentiated to different degrees. While high-temperature superconductivity ($Q = 0{,}198$) and Bose-Einstein condensation ($Q = 0.217$) have only a few subfields, metals/alloys ($Q = 0.481$) and quantum mechanics ($Q = 0.447$) are each markedly more differentiated.

Cohesion is another important concept for characterizing social and cognitive networks.

N

It is measured, on the one hand, by the average number of nodes lying between two randomly chosen nodes. As Newman (2001) is able to show for copub networks in various disciplines, the average distance is about six nodes and thus an order of magnitude comparable to that of other social, biological, and technological networks. In the global science system, a researcher thus needs only six intermediate steps to reach another, randomly selected researcher.

Another indicator for cohesion is the *cluster coefficient*, which measures the relative frequency of transitive triads (A publishes with B, B with D, and A with D). For the aforementioned copub networks (excepting in biology), Newman (2001) calculates probabilities between 30% and 70% that relationships A-B and B-D will result in a relationship A-D. These results are very similar to the idea of Granovetter (1973) that whenever strong relationships exist between A-B and B-D, there is social pressure on A-D to enter into a similarly directed relationship and thereby to bring about a *transitive triad* (also: closed triad). In the case that the relationship A-D does not come about, the social cohesion between A, B, and D is endangered. Granovetter (1973) coined the triple constellation that lacks the A-D relationship a *forbidden triad* (also: open triad) and points out that transitive triads arise only where relationships are strong. Where relationships between A-B and B-D are weak, A-D typically do not enter into a relationship; here, B remains a broker who mediates between A and D. Newman's results thereby indicate that, in the copub networks he investigated, between 30% and 70% of the relationships are strong. At the same time, Newman's findings indicate that here there is another mechanism leading to the rise of social relationships that effects the *formation of transitive triads* (FT). The extremely low probability of transitive triads in biology (7%) is an indication that in this discipline the majority of relationships are weak and biologists therefore do not customarily recruit new collaboration partners from the group of their own collaboration partners. Powell et al. (2005) confirm this finding (cf. section "Mechanisms of Network Formation and Network Evolution").

Mechanisms of Network Formation and Network Evolution

In the booming interdisciplinary context of network research on scientific innovation, an intensive discussion is being conducted on what mechanisms are crucial for the formation and evolution of networks. On this, the following discusses randomness, cumulative advantage, homophily, trend-following, and multiple connections.

Random Attachment. In many studies, randomly generated connections between actors play an important role. This is because mathematically oriented network analysis has always studied randomly generated graphs (model networks) and uses the characteristics it finds in them for comparisons with real networks (Newman et al. 2006: 229ff). But by far, not all the characteristics of randomly generated networks can be found in real networks of relationships. One especially striking deviation was found for the aforementioned cluster coefficients, where real networks often display a large multiple of what is measured in randomly generated networks. The reason for this deviation is the aforementioned FT mechanism, which ensures that real networks consist of many small clusters (cf. section "Structures and Characteristics of Networks in Science"). It is interesting that the high degree of cluster formation in real networks leads one to expect a relatively long average path length. This would mean that contacts spanning more than one cluster would be rare and that the actors would need long routes to reach an actor in another cluster. But as Watts (2003: 69ff) shows, the path lengths in real networks are typically quite short and differ only slightly from those in randomly generated networks. Many real networks, and especially copub networks, display high local densities and at the same time good global accessibility (Newman 2001). In the literature, networks with these two opposing characteristics are called "small worlds" (Newman et al. 2006: 9ff, 286ff).

How can relatively short path lengths arise despite the FT mechanism? Watts (2003: 83ff) argues that the short average path lengths could be produced by reconnecting existing relationships randomly. The underlying idea is simple: in networks with high local density, the probability that a random reconnection will produce a very distant relationship is quite high. This means that each reconnection very probably results in a connection with a previously unconnected cluster, which in turn reduces the average path length. The crux of the matter in this consideration is that randomness not only serves as heuristics for modeling the rise of real networks. Watts (2003) explicitly points out that forces of disorder and unforeseeability affect every real network, so that relationships among actors arise partially randomly. Taking this argument seriously, then, in the example of path length, randomness appears as a corrective to the FT mechanism. Thus, in the genesis of relationships between actors and in the dynamic of networks, random connections play a substantial role.

Cumulative Advantage. As already noted, the CA mechanism has the effect that already reputed and networked scientists can win new collaboration partners more frequently than less well-known or peripheral colleagues can. The logic of CA is thereby that small initial differences among researchers can grow over time to become a distribution in which a few researchers have a great many collaborative relationships and many colleagues have only a few (PLD). In the analysis of CA, progress has been made by carrying out a longitudinal study of extensive copub networks. For example, Barabási et al. (2002) analyze mathematics and the neurosciences on the global level in the years 1991–1998. New actors and relationships are added to the network each year, so Barabási et al. (2002) examine two sub-mechanisms. CA-1 means that young scientists co-publish with established researchers. Each increase of new researchers should thus lead to an increase in the average node degree. CA-2 means that the probability of a first-time collaboration between two established researchers within the network increases linearly with the frequency of their prior collaborations. CA-1 and CA-2 are both empirically confirmed.

Trend-Following and Homophily. In the literature, it is non-controversial that CA is an important element in the explanation of network emergence. However, in their study of the dynamics and evolution of inter-organizational networks between biotech companies in the period 1988–1999, Powell et al. (2005) identify additional social mechanisms. Trend-following (TF) means that one chooses the partner whom one's own circle perceives as attractive. Homophily (HP) means that partner selection is shaped by the principle that "birds of a feather flock together." Each of these mechanisms, however, has been only partially empirically confirmed. This means that, when choosing new partners, the biotech companies initially take their orientation from the conventions of their circles. Those partners are selected whom the circle perceives as attractive. But TF is not valid for repeated contacts; here, the biotech companies manage to emancipate themselves from the trend. A similar pattern emerges for HP. New contacts are extremely frequently begun with spatially close partners, but spatial closeness plays no role for repeated contacts.

Multiple Connections. Whether a biotech company repeats its collaboration with a partner depends, rather, on whether the partner brings diversity into the relationship and whether the partnership holds promise of long-term gains. Multiple connections thus mean, first, a preference for heterogeneity in choice of partners (MC-1) and, second, a preference for deepening existing partnerships (MC-2). As Powell et al. (2005) show, in biotechnology or the life sciences, there is a marked preference for competences and contact structures that one does not possess oneself. Collaboration partners with a diverse contact portfolio are thus especially attractive, because they open up access to new knowledge and new technologies. The great preference for heterogeneous knowledge and know-how is reflected in the fact that young beginners are especially coveted, in contrast to established biotech companies (MC-1). However, Powell et al. (2005) also show that, once a high level of diversity is achieved, the search for new partners slackens. In this case, the biotech company deepens its relationships to its partners and bonds them to it for the long term (MC-2). As a social mechanism that steers the formation and continuation of relationships in networks, multiple connections thus entail a tension between the search for new knowledge and know-how, on the one hand, and the search for a stable and fruitful partnership, on the other. Overall, the results of Powell et al. (2005) indicate that MC-1 and MC-2, rather than CA, are the dominant social mechanisms that explain the rise and evolution of inter-organizational partnerships in the biotech sector. The authors thereby confirm Newman's (2001) finding that, in biology and the life sciences, it is less customary than in other disciplines to make contacts within the circle of one's own collaboration partners (cf. section "Structures and Characteristics of Networks in Science").

Networks and Scientific Innovation

Networks are not only important in the biotech sector but also in other scientific fields and disciplines. For example, Fleming et al. (2007) examine the collaborative networks of inventors in the United States, based on 2.8 million patent specifications from the years 1975 to 2002. The starting point for this study is the question whether brokered structures with open triads or cohesive structures with closed triads increase the productive capacity of networks (cf. section "Structures and Characteristics of Networks in Science"). The authors show that collaborative networks with brokers often lead to technical innovations. At the same time, however, technical innovations from brokered networks are less frequently used again than are those from cohesive networks. These results indicate that new knowledge spreads better in socially integrated contexts, while brokered contexts create hurdles for the spread of new ideas. Fleming et al. (2007) point out that there is a paradox here, namely, that the network structures suitable for developing technical innovations are not suitable for their diffusion, while vice versa those network structures that are unsuitable for bringing about technical innovations are especially suitable for spreading them. Fleming et al. (2007) sketch a possible escape from this paradox: recruiting actors in cohesive networks who have a broad spectrum of knowledge, have gathered experience in various organizations, and also initiate contacts outside their own work contexts. In this way, the structural disadvantages of cohesive networks in giving rise to new ideas can be at least partially compensated.

Networks also influence scientific productivity capacity and rankings in research. Jones et al. (2008) show in their analysis of the 662 largest universities in the United States that, based on the Web of Science, in the period 1975–2005 interuniversity copub relationships more than doubled, both among the natural and engineering sciences and among the social sciences. Today, about a third of all papers are published by interuniversity teams. This growth derives essentially from decades of the generally increasing proportion of co-publications in the global science system. Also based on the Web of Science, Wuchty et al. (2007) calculate that, in the period 1955–2000, the number of co-publications in the social sciences rose from 18% to 52% and in the natural and engineering sciences from 50% to 83%. At the same time, the average number of coauthors in the social sciences increased from 1.3 to 2.3 and in the natural and engineering sciences from 1.9 to 3.5.

As Jones et al. (2008) further show, interuniversity publications are cited substantially more often than are publications by authors who all belong to a single university. The greater visibility of interuniversity publications is unequally distributed: the greater the number of citations from a site, the more it profits from interuniversity collaborations. This means that the effect of interuniversity publications on visibility and thus also on scientific prestige is concentrated on elite organizations. Here, the gap in visibility and prestige between elite and periphery increased markedly in the period 1975–2005. The increasing density of interuniversity copub networks thus amplifies the already marked institutional stratification of the university system in the United States. Finally, Jones et al. (2008) show that collaborations between different sites of the university elite (and incidentally also, separately, between peripheral sites) are more frequent than mixed relationships. This indicates that the aforementioned HP mechanism decisively shapes the genesis of interuniversity relationships (cf. section "Mechanisms of Network Formation and Network Evolution").

Conclusion and Future Directions

In sum, it can be noted that many interesting things about network formation, network evolution, network structures, and their influence on innovative science are known. The availability of large longitudinal data sets makes it possible to conceptualize and empirically examine the connection between the statistical distribution of cognitive and social relationships, the mechanisms of their emergence and reproduction, and their role in fostering research productivity and scientific innovation. The wide spectrum of investigated networks has also resulted in a better understanding of the cultural differences between various disciplines and fields of research. Good examples of this are the life sciences, whose networks markedly differ from other disciplines, in particular from physics (Powell et al. 2005; Newman 2001).

With regard to the aggregation levels mentioned at the beginning of this entry, recent research on networks has produced some studies of the global science system (Wuchty et al. 2007; Newman 2001), but the majority of the analyses still focus on disciplines and fields of research (Chen and Redner 2010; Milojevic 2010). In this regard, recent interdisciplinary research on networks follows an established path to the disadvantage of research organizations. There are only a few studies that address the theme of universities or non-university institutes, including industry research, as nodes of social or cognitive networks and their role in scientific innovation (Jones et al. 2008; Powell et al. 2005). There is a clear need to pay more attention to the organizational level with regard to networks and scientific innovation in the future.

Business creation; Start-ups in services

Introduction

The question of entrepreneurship and its links with services is not a new one since most new businesses operate within the tertiary sector. Few studies, on the other hand, have addressed the link between entrepreneurship and innovation in services (Gallouj and Djellal 2010). The leading theoretical reference in the field of entrepreneurship and innovation is undoubtedly Schumpeter, who has developed two well-known models of innovation. His first model (Schumpeter Mark 1) describes the characteristics of an entrepreneur: (1) his capacity to detect, from among a stock of accumulated knowledge, an invention suitable for socialization, that is, transformation into an innovation, and (2) his capacity to mobilize an interessement ("know-who") network to bring about this socialization. In the second model (Schumpeter Mark 2), knowledge is more explicit, to the extent that the Schumpeterian spirit of enterprise is endogenized in corporate departments specializing in knowledge creation. Expanding on Schumpeter's theory, we have hypothesized the existence of a Schumpeter Mark 3 model (Gallouj 2002a), based on interaction with knowledge-intensive service firms (engineering and consulting). The Schumpeter Mark 2 model appears to be incompatible with the characteristics of the service economy. In fact, R&D departments (in the traditional sense) are extremely rare in the service sector, and the endogenization of the entrepreneurial function takes the form of multifaceted and transitional project groups, in which customers are also included. To a certain extent, this reduces the risk of the "bureaucratization" and the stifling of the enterprise spirit evoked by Schumpeter.

There are no studies, to our knowledge, devoted specifically to the Schumpeterian entrepreneur in services (i.e., to the "Schumpeter Mark 1 model," the model of the entrepreneur who creates a business in relation to a "new combination"). As regards services, the subordination approach to innovation or to spatial location and regional economic dynamics, regularly highlighted and criticized in the literature, can be applied very naturally to the field of entrepreneurship. While the service sector would appear to be the principal host of "routine entrepreneurship" (the creation of traditional businesses), "innovation entrepreneurship" seems to be based elsewhere. If we underestimate innovation in services, we logically underestimate its stakeholders. However, the service-specific literature appears to imply the existence of four new entrepreneurial figures which are outlined below and merit a more in-depth theoretical, empirical, qualitative, and quantitative analysis: the "cognitive" entrepreneur, the "social" entrepreneur, the "ecological" entrepreneur, and what we have called the "entrepreneurial" entrepreneur (see Table 1).

The "Cognitive" Entrepreneur

The "cognitive" entrepreneurs are experts who root the creation of their business in new

New Forms of Entrepreneurship in a Sustainable Knowledge-Based Service Economy, Table 1 New figures in service entrepreneurship

Types of entrepreneurship	Possible examples or subcategories (non-exhaustive list)
Cognitive entrepreneur	Consultant entrepreneur, doctor entrepreneur (researcher), e-entrepreneur
Social entrepreneur	Gray market entrepreneur, toddler entrepreneur, emergency outreach entrepreneur
Ecological entrepreneur	Ecotourism entrepreneur, "green technologies" entrepreneur
"Entrepreneurial" entrepreneurs	Nurseries, hives, incubators

knowledge (new fields of knowledge) that they have either helped develop or benefited from without contributing to it. This new knowledge may or may not be incorporated into technical systems. It can belong to the natural sciences and engineering or to the human and social sciences.

"Cognitive" entrepreneurship is a heterogeneous category. It is probably possible to distinguish between several types of entrepreneurs within "cognitive" entrepreneurship itself, depending on the main field of knowledge addressed and their contribution to knowledge in this field.

The first interesting example of cognitive entrepreneur is the setting up of a consulting firm based on a new field of knowledge or expertise. The *consultant entrepreneur* is closely related to what we term "new expertise-field" innovation (Gadrey and Gallouj 1998; Gallouj 2002b) to describe the detection of an emerging field of knowledge and the provision of consulting services in this area. This type of cognitive entrepreneur does not create the field of expertise: they detect it, appropriate it, and construct it socially. They can be said to create it in the same sense that it is sometimes said that insurance "creates" risk. The "objective" origin of these fields of expertise is the dynamic of institutional, technological, economic, and other types of change. Although they do not create these fields of knowledge objectively, the consultant entrepreneurs can contribute knowledge, methods, etc., to them. Examples of expertise-field innovation include the entry of lawyers into new legal fields (such as space law, computer law), the expertise in civil partnership contracts, the enlargement of the EU, and the environmental and sustainable development issues Many different fields of knowledge are therefore involved and cover the complete spectrum of business functions (technological, legal, social, etc.).

The second type of cognitive entrepreneur is the *researcher entrepreneur* (or *doctor entrepreneur*). This type of entrepreneurship refers to the creation of businesses by university researchers (young doctors making use of their thesis results and senior researchers drawing on their research). Unlike a consultant entrepreneur, the researcher entrepreneur plays a decisive role in the production of the exploited knowledge. They actually create this knowledge and not just socially. Business creation is based both on expertise in the hard sciences and in the social and human sciences. Social and human sciences play a significant role (which should not be neglected) in defining R&D in services. In other words, social and human sciences, like natural sciences, can provide the foundation for cognitive entrepreneurship. They should not be underestimated. When knowledge is not incorporated into technologies or tangible entities, the line between consultant entrepreneurs and researcher entrepreneurs can be very tenuous. The "researcher entrepreneur" category raises an interesting theoretical issue in that it challenges the validity of the notion of the Schumpeterian entrepreneur, to the extent that, in Schumpeter's theory, invention and innovation are defined as two fundamentally different phenomena, just like their corresponding stakeholders – researchers and entrepreneurs.

The doctor entrepreneur is the subject of a quite numerous literature (Murray 2004). The sector-specific variable (i.e., taking into consideration, if appropriate, the specific nature of the services) is never factored into these studies, which are primarily focused on the link between human capital (the researcher's expertise) and social capital (the capacity of the researchers to mobilize a network and incorporate themselves into it).

The third expression of cognitive entrepreneurship is what we might call *e-entrepreneurship* or *cyber-entrepreneurship*, which includes service entrepreneurship linked to new information and telecommunication technologies (incorporated or otherwise and produced by the entrepreneurs themselves or adopted). e-Entrepreneurship could be a specific example of the two previous definitions of cognitive entrepreneurship (such as an IT researcher who creates a business to apply his or her results or who sets up a consulting firm). However, since this form of entrepreneurship (closely linked to the dominant information paradigm) is so important, we have treated it separately here and consider it as an independent category. Cognitive entrepreneurship's field of intervention is broader still. It covers all service activities developed to take advantage of NICTs (examples include people who set up websites and web designers) along with, if we adopt an even broader understanding of this form of entrepreneurship, all business activities designed to promote and sell goods and services via ICT networks: e-commerce (Internet sales) and e-business (all types of business transactions performed on the Internet).

The "Social" Entrepreneur

The field of action of social entrepreneurs is the social and solidarity economy. Social entrepreneurship consists of creating new organizations to manage, in an original (i.e., innovative) manner, certain disadvantaged or vulnerable sections of the community, such as young children, the elderly, or people with disabilities of all kinds – socioeconomic, physical, and psychological. In other words, the aim of social entrepreneurship is to resolve social problems. The form that concerns us here provides an innovative solution to these problems. Social entrepreneurship, like any form of entrepreneurship, can be performed at a local, national, or international level.

It is not necessarily a nonprofit entity (a nonprofit organization entrepreneur). It can also be a public organization or a private company and increasingly a hybrid form of commercial and noncommercial activities. It is therefore, as with the previous form of entrepreneurship, a heterogeneous category (both on an institutional and a functional level). We have, however, been able to identify three major groups. They are not independent nor do they constitute an exhaustive typology.

The first group includes organizations (firms, public organizations, nonprofit organizations, etc.) created to meet, in an innovative way (in terms of services provided or service provision methods), the needs of the elderly (all types of care services). Taking into account demographic developments, the "gray market" or the "seniors market" (although the entry threshold for this category is not always clearly defined) has a major development potential. *"Gray market" entrepreneurs* may operate in the commercial field or the noncommercial field.

The target of the second group is services for young children. This "toddler" market is at the origin of what we might term *"toddler" entrepreneurship*, which is the mirror image of *gray market entrepreneurship* and which can also operate in both the commercial and noncommercial fields.

The third group consists of what we have termed *"emergency outreach" entrepreneurship*. This refers to the creation of organizations that offer innovative, supportive solutions in the fight against all forms of insecurity and social exclusion at a local, national, and international level. One of the most widely publicized examples of this type of entrepreneurship is the free distribution of food to the homeless by the French organization "Les Restos du Cœur." However, there are many other examples, including microfinance schemes, that is, the granting of microloans, savings or insurance schemes for poor people excluded from the traditional banking system, and inclusive schemes for people in difficult circumstances. Unlike the two previous forms of social entrepreneurship, this particular form exists exclusively in the noncommercial field.

Although a fairly large number of studies have been devoted to the social and solidarity economy and the major role played by local services in this field, very little attention has been paid in economic theory to the entrepreneurial dimension of this economy and even less so from the point of view of services. The same cannot be said for the management sciences, which, for a number of years, have held an obvious interest for the notion of social entrepreneurship and more generally the social dimension of all forms of entrepreneurship (This interest is not only reflected in the large number of studies on this issue. It is also institutionalized within university courses.) (Leadbeater 1997). In any event, the theory – economic, sociological, and management – in this field lags behind social practices. The current debate on the social utility of organizations in this field and, more generally, on new wealth indicators could, we believe, help provide a better understanding, in socioeconomic terms, of the nature and role of social entrepreneurship (associated with innovation in services).

The "Ecological" Entrepreneur

The field of action of *"ecological" entrepreneurs or "ecopreneurs"* is environmental prevention and the quest for sustainable development. Once again, the few studies to have addressed this subject (Issak 1998) lag behind social practices. This form of entrepreneurship is often considered as a specific expression of the former if the social dimension is widened to include the sustainable inclusion of man in his environment among the social problems addressed.

The ecological entrepreneur is also a heterogeneous category. Once again, we are not concerned, at this stage, with providing a typology for it; instead, we will simply identify interesting groups by way of example.

The first interesting group of ecological entrepreneurs is developing its activities in the traditional service sectors to take advantage of ecological and environmental opportunities and the drive toward sustainable development. The tourism sector and the various components of this composite service (hotels, restaurants, leisure, etc.) include numerous examples of this type of entrepreneur who invests in opportunities and niches, particularly by supplying new tourism opportunities related to the local social fabric or new discovery activities, including agricultural tourism, industrial tourism, and cycle tourism. With this type of entrepreneurship, the service derives its innovative status from its ecological characteristics.

Another group has developed around the use of what are sometimes called green technologies – in other words, technologies that protect the environment. This could include technologies in both the tangible and intangible sense of the term, that is, technical systems, methods, or protocols. This group can overlap the cognitive entrepreneurship group when, for example, a researcher develops a "green technology" that he or she exploits by creating a business. Although there are studies devoted to ecological entrepreneurs who develop their activities around "green technologies," they mainly focus on agricultural or industrial entrepreneurship (Andersen 1998). The service eco-entrepreneur is rarely taken into consideration in these studies. One example we could give is "car sharing," which consists of institutionalizing informal car sharing practices and which falls somewhere between private car ownership and car rental, particularly when used as a means of reducing pollution and urban congestion. Unlike the social entrepreneur (in the strict sense), the ecological entrepreneur appears to work, in the main, in a commercial environment (Hockerts 2003).

The "Entrepreneurial" Entrepreneur

The "entrepreneurial" entrepreneur refers to a set of service mechanisms targeted at producing entrepreneurs and which are generally called business incubators. Incubators are mechanisms designed to encourage and support, in different ways, the gestation, birth, and first steps of a company and thereby increase its viability. We use the term incubator in the generic sense to refer to this particular group of (still semantically variable) mechanisms that include nurseries, hives, and incubators. This category involves a different analytical approach to the previous categories since incubators are defined as *"entrepreneurial entrepreneurs."*

The incubator is an organization providing complex services that aims to create entrepreneurs (who may belong to the different categories mentioned previously). In some ways it is a "laboratory of entrepreneurs." In the case of innovative entrepreneurship (which is what interests us here), the innovation incubator is a new form of the endogenization of the entrepreneurial function, which complements the two Schumpeterian models and the model that we have, for our purposes, called Schumpeter 3 or the interactional innovation model. The incubator builds on the Schumpeterian analysis in an interesting way, in that it unexpectedly combines the Schumpeter 1 model and the Schumpeter 2 model. In fact, the incubator can be considered as a machine or a laboratory to "produce" entrepreneurship rather than innovation.

Conclusions

Defining and qualifying the notion of service entrepreneur offers a potentially interesting line of research. If we understand the notion of entrepreneur in its Schumpeterian sense (i.e., closely related to the issue of innovation), it would involve verifying if, like the activities in which they operate, the service entrepreneur is specific in nature.

The categories of entrepreneurs working in services (in sales, retail, etc.) are not all taken into consideration in the four types of entrepreneurs mentioned above. They are, rather, relatively new and particularly dynamic forms of innovation entrepreneurship.

These four forms of entrepreneurship in services are not separate wholes. Entrepreneurship can obviously develop simultaneously in different fields – cognitive, social, and ecological. In fact, an innovation based on scientific research (PhD thesis) can, for example, be applied to environmental protection (e.g., the decontamination of polluted sites and "green" technologies) or the protection of disadvantaged people ("senior technologies"). A new consulting activity in the field of organic farming emerging, for example, from the enactment of new EU regulations, falls into both the cognitive and ecological fields of entrepreneurship. A business devoted to social inclusion through economic activities that specialize in an original form of waste recovery and treatment service relates to both ecological and social entrepreneurship. An open source software developer can be both a social entrepreneur and a cognitive entrepreneur. Lastly, business incubators themselves can specialize in one of the previous forms of entrepreneurship. In the United States, for example, there are incubators that specialize in women's entrepreneurship, ethnic minorities, nonprofit organizations, etc.

Introduction

This entry will start, first, with a very short discussion of a set of linear models of innovations which are usually characterized by two important features. On the one hand, these models are specified in sequential stages and linearity, thus, refers to a set of different innovation stages which have to be passed in time consecutively. On the other hand, linearity can be linked to the types of

Nonlinear Innovations, Fig. 1 A research-based linear innovation model (Source: Michael Eigner [WISDOM])

Nonlinear Innovations, Fig. 2 An invention-based linear innovation model (Source: Michael Eigner [WISDOM])

relations between these different stages which can be assumed as linear as well.

As a next step, these linear models will be transformed into nonlinear configurations. Here, the focus shifts to nonlinear aspects of innovation processes as well as to the still predominant Schumpeterian framework for the cyclical diffusion of innovations.

The third part of this entry will advance a general nonlinear innovation framework which is largely based on complex, nonlinear network theory. This general nonlinear framework for innovations can be characterized by a considerable amount of comparative advantages, especially in comparison to the traditional innovation perspective in the Schumpeter tradition.

Linear Innovation Models

Usually, linear models of innovation assume at least three different stages where the third stage comprises either technological innovations or their diffusion processes. Figures 1 and 2 show two different linear innovation models where the first one has its focus on scientific research and the second one on technological inventions. Figure 1 assumes a three-stage sequence in which basic research provides the potential for technological applications which, finally, can be implemented as economic innovations. Figure 2 focuses on the invention process, the transformation of an invention into an economic innovation and its subsequent diffusion. In both cases, time and information flow from the left side to the right side and provide a strict temporal as well as informational order.

The general scheme for linear innovation models may comprise longer innovation chains of more than three stages. Again, the information flows as well as the arrow of time move from one stage to the next in a strict sequential manner.

Additionally, linear innovation models usually operate with linear relations, adhering to the rules of additivity and homogeneity. The additivity rule requires a decomposition of a function $f(x + y) = f(x) + f(y)$, and the homogeneity rule can be specified as $f(\alpha x) = \alpha f(x)$ for all α. In sum, the relations between the different stages exhibit a linear pattern as well where, for example, a higher input into basic science leads to a proportionate increase in basic science outputs and a proportionate advancement for the applied sciences as well as for innovations.

These linear models turn out to be highly problematic because they do not allow for feedback loops within an innovation chain, and they assume that all these different stages have to be passed in a strictly sequential mode with linear effects only. In sum, the sequential and linear nature of relations renders linear innovation models as highly artificial and not very fruitful for the analysis of innovation processes.

Nonlinear Models of Innovations

Linear models can be transformed into nonlinear variants either by abandoning the temporal and

Nonlinear Innovations, Fig. 3 A research-based nonlinear innovation model (Source: Michael Eigner [WISDOM])

informational order of a set of stages or by assuming nonlinearity in the diffusion process of innovations and by allowing for nonlinear features like path dependencies, lock-ins, or sensitivities to initial conditions.

Thus, the first transition from linear to nonlinear forms of innovations is accomplished by admitting feedback loops across the different stages of the innovation processes. These feedback loops imply that information can flow freely between various stages and that innovations and their diffusion processes can take a variety of different trajectories, starting, for example, in the field of applied science, moving to the basic science area, and proceeding from there directly to the innovation stage. Figure 3 presents a nonlinear counterpart to the linear science-based model.

Turning to nonlinear innovation relations, the dominant framework here has been provided by Joseph A. Schumpeter with an elaborated theory of long, medium, and short innovation waves which was published in 1939 in his English version of *Business Cycles*. Here, the central focus of the explanation lies in the capitalist innovation dynamics and in the leading role of entrepreneurs.

It is important to note, first, that Schumpeter saw innovations as a very broad phenomenon which moves well beyond the realm of technologies or technological change. Aside from technological changes in the production of commodities already in use, innovations in the Schumpeterian sense comprise also the opening up of new markets or of new sources of supply, Taylorization of work organization, improved handling of material, and the setting up of new business organizations such as department stores – in short, any "doing things differently" in the realm of economic life. Formally, Schumpeter defines innovations as any change which does not alter the quantities of production factors of a production function but which leads to a variation in the production function itself.

Schumpeter explains this cyclical clustering of large-scale innovations on the basis of a diffusion- and imitation-oriented theory of learning. Imitation is facilitated in successful large-scale innovations by a continuous removal of obstacles and thresholds. The steadily decreasing demands for implementing innovation can be met by an increasing number of entrepreneurs whose propensity for innovations can be assumed to be unequally distributed.

Over the last decades, the theoretical and empirical contributions on nonlinear innovations have been undertaken mostly from the position and perspectives of the giant shoulders of Joseph A. Schumpeter. Five of the more original contributions to the existing analyses are worth mentioning.

In the late 1970s, Gerhard Mensch published "Stalemate in Technology," in which the long cycle of innovation is substantiated with data taken from the history of inventions. Inventions, too, tend to cluster in the downward phases of long waves, creating the conditions for a new upswing.

Furthermore, the S-shaped logistic curve has become the standard nonlinear model for the diffusion of innovations (Everett 2003 or Fagerberg et al. 2007), and long waves have been formalized in the modeling framework of so-called Schumpeter clocks (Weidlich and Haag 1983; Weidlich 2000). Moreover, innovations and their diffusion have been formulated within an evolutionary framework (Nelson and Winter 1982 or Müller 1999) and are being studied in institutional settings of national innovation systems (Lundval 1992; Nelson 1993, 2005 or Leydesdorff 2006).

Thirdly, Christopher Freeman, Luc Soete, and others have provided a large number of summaries and surveys which provide historical, statistical, and theoretical support for the propagation of long waves (Freeman 1983, 1987, Freeman and Soete 1982 or Freeman and Soete 1994, 1997). In a recent anthology that offers a *summa* of contemporary contributions and insights on the subject of long innovation waves, most of the authors are affirmative regarding the more than 200-year reproduction of cycles as a result of surges in technological development or basic product innovations (Devezas 2006).

Fourth, nonlinear innovation models have been advanced further by stressing additional important characteristics. For example, W. Brian Arthur (1994, 2009) has placed special emphasis on increasing returns to scale especially during the take-off phase of long innovation waves. James M. Utterback (1996) and others have stressed the role of path dependencies, lock-ins, the sensitivity to initial conditions, and the divergent technology trajectories despite similar initial levels.

Finally, nonlinear innovations as a cyclical pattern have been used in the structuration of technological-organizational regimes as exemplified by French regulation theory (Boyer and Saillard 2002). Additionally, long waves helped to define long-term societal and even world systems phases of development, namely, for the ups and downs of hegemonic phases in the evolution of a capitalist world system (Friedman 1982; Fröbel et al. 1981 or Hopkins and Wallerstein 1980).

However, a Schumpeterian framework for nonlinear innovations, both as an empirical phenomenon and as an explanatory strategy, exhibits serious deficits, inconsistencies, and interpretation problems.

A particularly strong counterargument to a pattern of long innovation waves is based on the very limited range of these basic industrial revolutions, like the construction of the railroad systems, which only rarely superseded 10% of the annual net investments. Conversely, apparently 90% or more of the annual net investments take place outside of the long wave segment (Hoffmann 1965 or Spree 1977).

Another argument against long innovation waves lies in their periodicity, which can hardly be maintained in a clockwise fashion. These difficulties with respect to the time periods of long waves have led to serious variations in the time scales and in the duration of cyclical ups and downs (Ayres 2006). Strong empirical doubts have again and again been raised regarding the statistical significance of long waves, and only insignificant differences have been noted for the individual periods of upswings and downswings. Interestingly enough, authors in Devezas (2006) who worked with statistical and time-series methods were mainly critical about long waves and classified them largely as artifacts.

A third, notorious problem lies in the relationships between long, medium, and short cycles, leading to the following dilemma. On the one hand, these relations can be specified additively – each long wave consists of a fixed number of medium-term cycles, which in turn consist of a fixed number of even shorter cycles. Along this path, one is confronted with the insurmountable problem of analyzing economic ensembles as majestic or trivial clockworks and not as evolving and complex configurations. On the other hand, one could define these periodicities in a nonadditive way which, however, leads to multiple problems of overlap. Moreover, there is the problem of consistency in explaining long, medium, or short cycles, since the explanatory variables for long waves cannot simultaneously account for upswings and downswings of medium and short duration.

Toward a General Framework for Nonlinear Innovation Models

The third part of this entry will undertake a profound change in the conventional view of innovations, nonlinear or otherwise. In particular, this new framework has its focus on:

- Innovation networks of various types as primary units of analysis
- Power-law distributions as the characteristic nonlinear configuration for small-, medium-, and large-scale innovations
- Preferential attachments as primary generative mechanism for self-generative nonlinear innovation processes

Starting with innovation networks (Hage and Hollingsworth 2000 or Mote et al. 2008) as units of analysis, an expanded typology for innovations in general will be introduced. If one differentiates between innovations according to their output in product and process innovations, as well as between a low, medium, and high diffusion potential of innovations, then one reaches a configuration with a total of six different innovation types, of which only a single group at the interface of product innovation/high diffusion potential corresponds to the long Schumpeter waves. Within the new framework, the other five types play a significant role and are viewed as necessary for the emergence of product innovations with a high diffusion potential.

It would be tempting to introduce Schumpeterian entrepreneurs or enterprises as the basic agents of innovation networks, but such a restriction would prove to be too limited since not just entrepreneurs and their enterprises but also the state sector, the civil realm, as well as the private sphere – households – appear as parts of innovation networks. The fourth industrial revolution with automobiles and road networks does not just require the participation of households as consumers of automobiles. The individualization of mobility also brings about a reversal in the modal split (Gershuny 1983) and a radical change in lifestyles. On an abstract level, thus, network actors can be of various types – entrepreneurs, inventors, companies, households, public organizations, NGOs, etc. (Müller 1999).

Moreover, the network linkages, like the network actors themselves, can also be of different types. Such linkages range from physical connections – lines, cables, pipes, high-frequency signals, etc. – and from the attributes of network actors such as personal acquaintances, trust, or social capital to activities of network actors like the migration of employees between enterprises, the movement of customers between products or product groups, and much more.

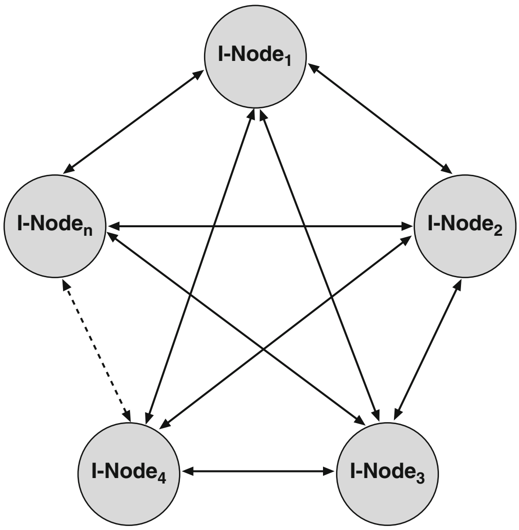
- Flow networks have, as their *differentia specifica*, physical connections between their network nodes and manifest themselves, *inter alia*, as railroad networks, power grids, water networks, road networks, the Internet, high-frequency networks for mobile telephony, etc.
- Relational networks comprise attributes or operations of network actors and do not involve physical connection lines. Relational networks can be based on kinship, on friendship, on acquaintance, on cooperation, etc.

A third network typology must be introduced with respect to the operational domains of networks where a separation is suggested into infrastructural, economic, and societal networks.

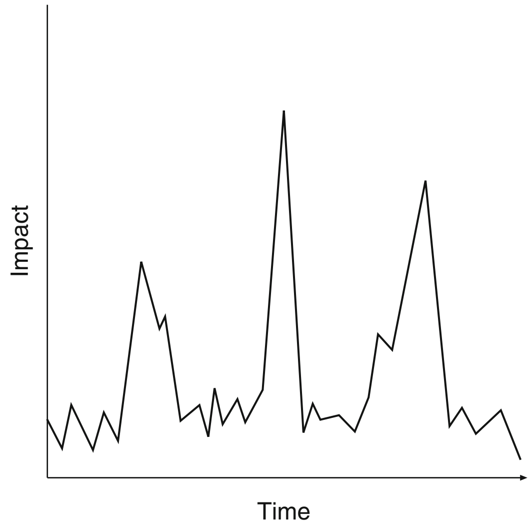
- Infrastructural networks are focused on the domains of energy, information, and transport and are organized as flow networks. They lie at the core of the evolution of long waves because all industrial revolutions so far were concentrated on energy (steam engine, electricity), transport (railroads and automobiles), or information (the current wave of information and communication technologies). Due to their overriding importance for societal evolution, economic innovation networks have been singled out as a special domain.
- All other innovation networks fall under the heading of societal networks and are situated in domains as different as politics, science, culture, households, and the like. These network domains can be combined as well to infrastructural-economic networks or to infrastructural, economic, and societal networks.

Figure 4 offers a general depiction for all three different types of innovation networks, which can be composed of a small, medium, or large number of network actors with flow or relational links, which can be situated in a variety of societal domains and which are focused either on product or on process innovations of marginal, medium, or basic novelty.

As for the network topologies (Barabási 2002, 2010; Buchanan 2002; Hollingsworth and Müller 2008; Newman 2005; Newman et al. 2006; Sornette 2003, 2006; Watts 1999, 2003, 2004), innovation networks of various types can be differentiated into two different architectures or



Nonlinear Innovations, Fig. 4 Nonlinear innovation networks as the reference configuration (Source: Michael Eigner [WISDOM])



Nonlinear Innovations, Fig. 5 Long waves at first sight (Source: Michael Eigner [WISDOM])

forms, namely, into so-called random or egalitarian networks and into complex networks, scale-free or aristocratic networks.

- Random networks evolve in a configuration in which the emergence of new nodes or links is not dependent on the prehistory of the overall topology. A typical random network, like the street connections of a region, links all relevant nodes.
- Scale-free networks emerge where the creation of new connections does not take place randomly. Global air traffic – but also the Internet – exhibits such a complex architecture in which new connections tend to orient themselves to the most connected nodes.

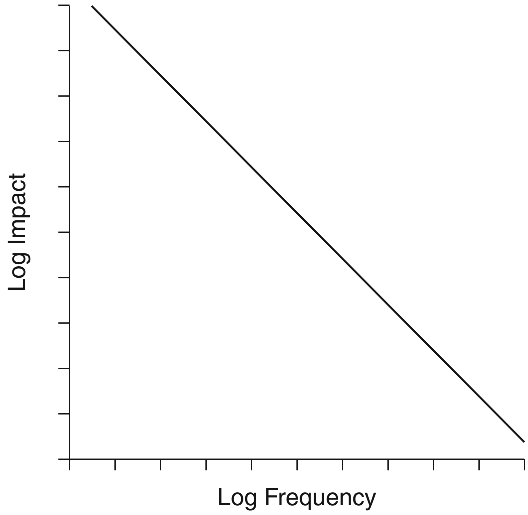
The second element in the new innovation framework, aside from different types of innovation networks, shifts the focus to the overall distribution of innovations. Here, innovations are not primarily arranged as long waves, reserved for a very few infrastructural revolutions, but in a power-law distribution, composed of a very large number of marginal or incremental innovations, of a limited number of medium-sized innovations, and of a very small number of innovations with a very high level of diffusion.

Figure 5 reproduces fluctuations in a typical sequence of small, medium-sized, and large innovations, which, at first glance, appear as three large innovation waves. Figure 6, by contrast, shows that there is a highly structured power distribution behind or underlying the three cycles from 5. Power-law distributions, as shown in Fig. 6, can be either very steep or rather flat, depending on the exponential coefficient in (1). For instance, for $\gamma = 1$, the slope consists of a 45° gradient.

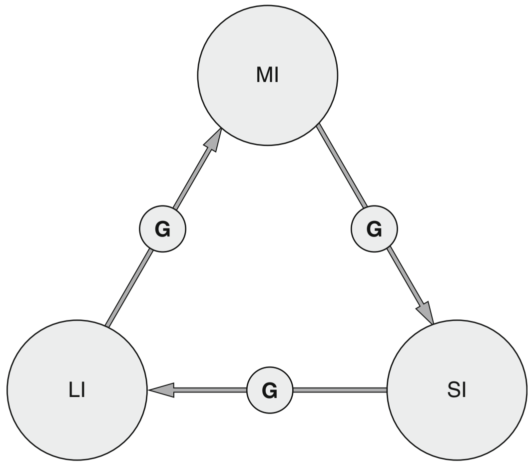
$$P(k) \sim k^{-\gamma} \tag{1}$$

In the context of Fig. 6, seemingly cyclical patterns of big surges in large-scale innovations are transformed into a highly structured configuration with a very small number of innovations with very large-scale effects – the classical long waves – and a very large number of small changes with marginal or small effects.

As a third element for the new nonlinear framework, one needs a general generative mechanism that activates the microdynamics of network actors and keeps them drifting to such a power-law configuration. These innovations of different types and sizes turn out to be generative



Nonlinear Innovations, Fig. 6 A power-law distribution of innovations at second glance (Source: Michael Eigner [WISDOM])



Nonlinear Innovations, Fig. 7 The generative relation between small-, medium-sized, and large-scale innovations across domains. *LI* large innovations, *MI* medium-sized innovations, *SI* small innovations (Source: Michael Eigner [WISDOM])

where two forms of dynamics can be distinguished.

- Pull dynamics: The first dynamic type refers to the diffusion process of innovations and to the emergence of new linkages which are due to the imitation of already available innovations.
- Push dynamics: The second type of network dynamics is focused on the creation of innovations and of the potential new linkages which are opened up by such a new innovation.

The important point here is that these push and pull dynamics generate each other. Many small-scale innovations in economic or societal domains usually lead to bottlenecks and shortages mainly in the infrastructural networks which increase the propensity for a new large-scale innovation in one of the three infrastructural networks. Likewise, a very large-scale product innovation in one of the three infrastructural networks enables a number of medium-sized as well as smaller innovations across other economic or societal domains. Additionally, small- and medium-sized innovations in emerging peripheral fields add to potential shortages in the infrastructural innovation networks. Figure 7 illustrates this generative and productive pattern between the many small, the less frequent medium-sized, and the rare large-scale innovations.

As for the generative mechanisms for the push and pull dynamics, probably the most interesting models come from complex networks (Dorogovtsev 2010; Easley and Kleiberg 2010; Jackson 2008 or Newman 2010). Here, two conditions must be met simultaneously, namely, a growth process which leads to a production of new components or nodes as well as nonrandom linkage formations which have been classified as preferential attachments.

Preferential attachments work in the case of push and pull dynamics in a trivial way (Bak 1996; Barenblatt 2003; Jensen 1996; Laughlin 2005; McComb 2004; Ong and Bhatt 2001 or Sornette 2003, 2006). Modern societies are characterized by a permanent production of new nodes, that is, new enterprises, households, and nonprofit organizations either in already existing segments or in newly emerging domains. These formations do not evolve randomly but exhibit complex systemic components. New companies are established preferably in new and hot technology fields with high profit expectations and expansion opportunities; new civil society formations or public organizations operate in new societal problem areas.

In terms of pull dynamics, network actors establish new links to already available innovations. Large-scale infrastructural innovations for railroads, for electricity, for automobiles, or for information and communication technologies (ICT), due to their comparative advantages, become attractive for a very large segment of economic or societal network actors, including especially the financial markets, as well as for the two other infrastructural networks. Moreover, in the typology of scale-free networks, the velocity of these new network formations is comparatively high.

With respect to the push dynamics, new innovation networks emerge constantly either in new peripheral areas like biotechnology, in already established innovation networks especially in the form of process innovations, or in the three infrastructural innovation networks of energy, transport, and information. These innovations provide either new solutions for bottlenecks or open new frontiers for the expansion of the overall landscape of innovation networks.

Conclusion and Future Directions: Comparative Advantages of the New Nonlinear Framework for Innovation Research

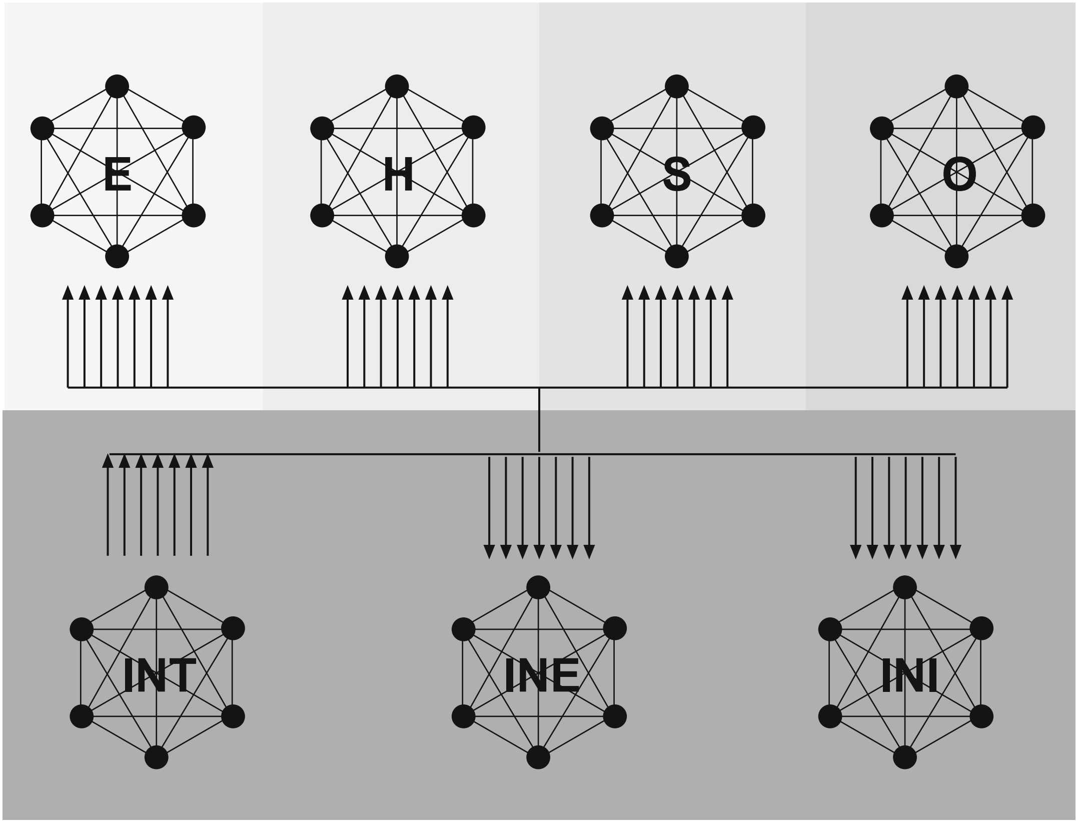
Toward the end of this entry, some of the comparative advantages of this new nonlinear innovation framework can be summarized.

Probably, one of the greatest assets of the new approach is the new distribution of generative functions between small, medium-sized, and large innovations of various types. Within the Schumpeterian paradigm, a manifold of small or medium-sized innovations only offered background noise, which was to distort or disrupt the basic crescendo (Joseph A. Schumpeter) of the long wave symphony. From the new network perspective, small, medium, and large innovation networks both reproduce and recreate each other. As a precondition of the unfolding of a large-scale infrastructural innovation, an endless number of small or marginal innovations become necessary which create the conditions for the new and large-scale innovation within the infrastructural networks in order to remove emerging bottlenecks in the societal capacities in energy, information, or material transport.

Moreover, through the new framework, it becomes clear why the industrial revolutions so far are concentrated in the three infrastructural networks of energy, transport, and information. These infrastructural domains can be described as configurations with a maximum diffusion potential, as shown in Fig. 8 (Müller 2010b). Here, IN_i ($i = T, N, I$) stands for infrastructural networks, EN for the network of economic networks, and SN for societal networks outside the economic sphere. A large-scale infrastructural innovation either in energy, information, or transport is capable of revolutionizing its own domain, other infrastructural ensembles, and the economic or societal networks. Economic or societal innovations, however, leave the available capacities in energy, information, and transport mostly unchanged and cannot, therefore, reach a maximum diffusion level.

The new perspective also exhibits a special sensitivity for processes of creative destruction and of lock-ins, for the disappearance of potentially viable alternatives, as well as for the inevitability of a crowding out of these alternatives once a new infrastructural regime has effectively started to move along its diffusion trajectory. Here, fascinating issues can be raised which, to date, have not been properly analyzed, even on a superficial level.

Another important point lies in the inhomogeneous coevolution of the three infrastructural networks of energy, information, and transport and in the role of a large innovation wave in a single infrastructural network for the development of the two other infrastructure networks. Normally, a large-scale infrastructural innovation leads to shortages and typical bottlenecks in the other two infrastructural networks, thereby creating the conditions for a new large-scale innovation in another infrastructural network with critical shortages. Historically, it becomes highly relevant that one can observe a shift from energy (steam engine) to transportation (railroads) to energy (electricity) to transportation (automobiles) and, finally, to information. Relations (2) and (3) show that a large-scale innovation wave



Nonlinear Innovations, Fig. 8 The maximum diffusion potential of an infrastructural revolution for modern societies (Source: Michael Eigner [WISDOM])

LI in a specific infrastructural network IN_i at time t lowers the probability P for another large-scale innovation in the same domain at t' (t' > t). Rather, a large-scale innovation in one infrastructural network at t increases the probability P for a new and large-scale innovation wave in another infrastructural ensemble $(IN_{j,\,t'})(i \neq j)$ at t'.

$$LI(IN_{i,t}) :< P(IN_{i,t'}) \quad (2)$$

$$LI(IN_{j,t}) :> P(IN_{j,t'}) \quad (3)$$

With respect to a large-scale innovation, it becomes one of the challenging tasks in economic history to reconstruct and recreate the diversity of alternatives and also their viability in the early phase of an infrastructural revolution. One could refer, for example, to the classical study by Robert W. Fogel (1964), who envisioned for the USA a network of channels as a possible alternative to the railroad system in the transport sector and also, albeit to a limited extent, as a viable one. Thus, the infrastructural revolution in transport was contingent and dependent on the relative strengths of the emerging networks of railroads and tracks versus steamships and canals.

Furthermore, one can point out to the centrality of the peripheries in the overall landscape of innovation networks, since the central network actors of a new infrastructural revolution are not present – or if at all, only marginally – at the beginning of the preceding revolution. Most entrepreneurs for the electrification of the world were not born nor were the technological components for the subsequent revolution available when railroads were capturing the imagination of wider circles of economy and society in the 1840s. Thus, a new infrastructural revolution operates, at first, within an empty infrastructural niche in the overall innovation space.

A further interesting point has to do with network architectures and their risk potentials. In light of the new perspective, the emergence over the past 50 years of mostly complex networks – international air traffic or the Internet – becomes a relevant topic for inquiry. Additionally, the new perspective offers a different assessment of risk potentials for historical as well as present-day societies. For example, complex networks are characterized by a higher degree of robustness with respect to the failure of randomly selected nodes. By contrast, in complex networks, the elimination of few central nodes can result in the breakdown of the entire network (Müller 2010a).

In sum, these comparative advantages of the new framework for nonlinear innovations should give rise to a stream of self-similar innovation research across different levels, ranging from the microlevels of single researchers or small innovation networks to the medium or mesolevels of organizations to the macrolevels of national, supranational, or global innovation networks (Hollingsworth and Hollingswort 2011 or Müller 1999, 2011). A general long-term perspective in innovation and technology research should no longer focus on cyclical patterns and on the recurrence of long waves. Instead, it should orient itself toward infrastructural random or complex networks, their fluctuations and accumulations, as well as the generative mechanisms, which produce and perpetuate a few large-scale innovations in the infrastructural domains of energy, information, and transport along with a larger number of medium-sized and a practically endless number of small or marginal innovations; *round and round, round and round* – endlessly and seamlessly.

Novology

Andrei G. Aleinikov
International Academy of Genius, Monterey, CA, USA

Definition

Novology is the science of newness.

Introduction

The number of research works on creativity and innovation has been growing exponentially. G. Wallace (Wallas 1926) is credited with the first research on creativity and J. Schumpeter, with offering the term "innovation" (Schumpeter 1942, see the Russian article Инноватика in Wikipedia). Researchers, studying creativity (see, e.g., the history of creativity research in Albert and Runco 1999) and innovation, often operate in the realm of intuition because the sciences of creativity and innovation are still in the process of development (See ► Science of Creativity). This statement directly applies to the concept of newness, the meaning of which (*new, novel, innovative*, etc.) is widely used for both creativity and innovation definitions, but has never been categorized. It has become clear that efforts to build sound theories on creativity and innovation may be wasted without understanding the concept of newness as a founding phenomenon. On the other hand, if the founding concept of newness is formalized, this may give a boost to both creativity and innovation research.

Since newness is ontologically present everywhere in nature, it lends itself to research. The challenge for the researcher is to develop concepts and laws that will apply universally. The goals are to discover the general mechanism of newness existence, to formulate the laws of newness production/consumption, to find ways to accelerate the process, and to predict the future directions of research. That is what novology, the science of newness, does. Novology gives one general explanation for various phenomena, thus making the domain of newness easier to comprehend.

History

Novology, the science of newness, was first introduced in 1991 in Russian, then briefly described in English (Aleinikov 1999a, 2001), and finally detailed in a separate article in 2002 in a monograph by presenters for the Dr. E. Paul Torrance Annual Lecture Series 2000, Athens, Georgia, where the author was a keynote speaker (Aleinikov 2002a).

New Science

Traditionally, every new science begins from gathering empirical data. This initial stage of gathering information is not yet a science, but the first step to it. Only after the accumulation of some data, the first patterns are recognized and the first experiments are carried out. When these patterns and experiments are explained, a theory evolves, then another one. When theories are combined and united into one logically acceptable system, when data is measured and calculated, science emerges. This science usually explains numerous features or regularities by one or several laws and makes reality image compacted and, therefore, comprehensible, teachable, and reproducible. That is the economy of force principle acting everywhere, including science. The final step for a science to be proven a science is to have specific results (broadening the vision of the world for humanity) and to foresee the future since a science should save humankind from troubles, problems, and challenges by explaining the past, better organizing the present, and predicting the future.

Novology: The Science of Newness

Creativity has many definitions, and hundreds of them are collected and published (Aleinikov et al. 2000, Treffinger 1995; See ► Creativity Definitions, Approaches). Most of them state that creativity is the generation of novel and useful ideas. The main concept in the traditional vision of creativity is the notion of "new" (*novel, innovative*). Creativity, as it was and is understood by the majority of people, is about generating *new* ideas, producing *new* concepts, inventing *new* objects and processes, etc. Note that the words, which are most frequently used in the definitions of creativity, are used in other fields of research. For example, the words "generation" and "ideas" belong to the field (and the science) of psychology. The words "useful" and "usefulness" belong to the field (and the science) of pragmatics. However, the words "new" and "newness" in the definition of creativity do not have a science to relate to. Accidentally or not, these words are also widely used in another field – the innovation field (see some classics like Rogers 1962; von Hippel 1988; as well as the creativity and innovation bibliography at the International Center for Studies in Creativity, Buffalo State College, the cradle of creative education in the USA). Except for some fragmentary analysis at the dictionary and etymology level, there is no explanation to the concept of new. It means that the words "new" and "newness" have never been categorized, that is, scientifically shaped to be terms. They are still used on the intuitive or prescientific level.

The Encyclopedia of Creativity, an outstanding collection of research (Runco and Pritzker 1999), does not offer any article on newness. On the other hand, every business emphasizes innovation. Books on innovation are in the hundreds and articles in the thousands. Empirical research that employs the concept of newness (see, e.g., "'*Newness*' and the risk of occupational injury" or "Small social groupings and the emergence of *newness*") clearly demonstrates that practical cases require theoretical reflection, thus corroborating the general statement "practice requires a theory (a science)." The Internet and non-Internet organizations promoting innovation and researching innovation are becoming increasingly popular. In the last decades, the topics of creativity and innovation have become so common for business, education, and social life that it is becoming obvious – there is a need for a science. Moreover, the International Creativity Day is now celebrated, and this century is sometimes called "the Century of Creativity and Innovation." It is time to provide a scientific explanation for all of the above-mentioned phenomena.

As all other well-established sciences, a new science includes the following elements:

- Name
- Objective
- Specific subject of study
- Classification
- Units of measurement
- Specific methods and results
- Laws
- Predictions

For novology, these elements have been defined as following:

Name

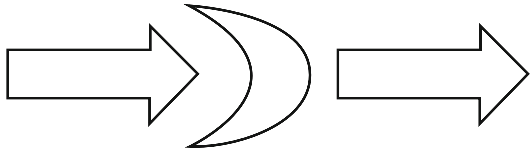
The term "novology" was selected from a list of candidates. The root *nov* comes from Latin *novus* which means *new*. The second part -*logy* comes from Greek *logos – word, study of*. The term novology was selected because it is short (which is important for any scientific name, especially the name of a science) and it follows the model of other, well-established sciences like geology, biology, psychology, mythology, graphology, and morphology.

Objective of Novology

The objective of novology is to make newness (novelty) described, understood, classified, calculated, and consequently increased. For example, chemistry increased the speed of production processes because it helped to describe, understand, and calculate the regularities of combining atoms of certain substances into molecules of other (new) substances. The same happens with all other sciences.

Newness as Subject of Study

Newness is a quantitative or qualitative difference caused by change and causing change. The essence of newness is reflected by the model in Fig. 1.



Novology, Fig. 1 Newness as a result of change and cause of change

If change is depicted as an arrow on Fig. 1, then every instance of newness exists between the change that caused newness (left arrow) and the change this newness causes (right arrow).

However, to make the process more complete, it has to show the previous and the next stages of change, as in Fig. 2:

Newness illustrated on Fig. 2 is the difference between State 2 and State 1, as well as between State 3 and State 2 separated by the arrows of change. Mathematically (quantitatively), newness (N) is the difference (delta) between the states $N_1 = \Delta\ S_2 - S_1$. Also, $N_2 = \Delta\ S_3 - S_2$.

Figure 2 shows the quantitative change: from 1 object to 2 objects and then to 3 objects. Newness could also be a qualitative change like the change of color in Fig. 3:

Figure 3 illustrates the color change of the object from white (left) to gray (middle) and black (right). Arrows illustrate the change.

The change may also be a form change, while the number and the color remain the same as in Fig. 4.

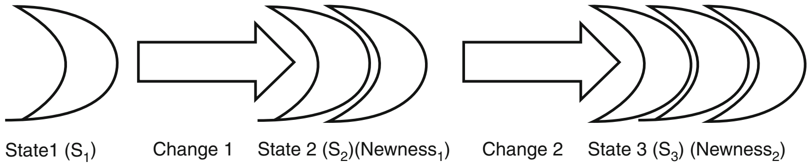
The shape (object shown on the left) on Fig. 4. undergoes change (arrow) and becomes bigger (middle), then it undergoes another change (arrow) and becomes bigger again (right).

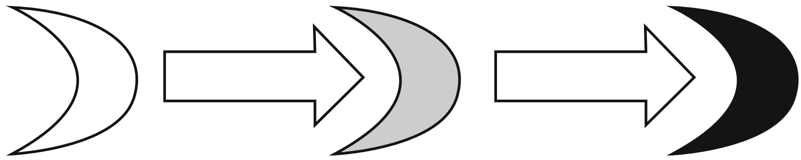
In addition to number, color, and shape, there may be a change in position, as it is shown in Fig. 5.

The same shape (object on the left) under the influence of change (arrow) depicted on Fig. 5 makes a clockwise rotation resulting in a position switch (middle), and then after the second change (arrow) makes another clockwise position switch (right).

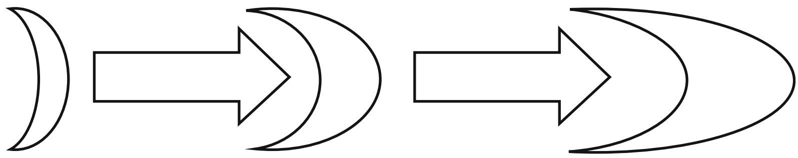
These are the examples of only basic types of newness intuitively known since childhood, but

Novology, Fig. 2 Stages of newness

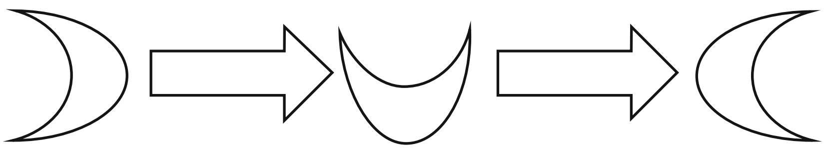




Novology, Fig. 3 Change in color



Novology, Fig. 4 Change in form



Novology, Fig. 5 Change in position

the amount of calculated newness will be different when only one change is applied or 2, or 3, or 4, or 5 at once. Calculations should show the difference in newness of the object depending on the amount of change.

Newness as a concept is based on the word "new." The form of the word "new" goes back to Greek *neos*, that appeared in English as *new* but also exists in the altered forms like *nei* – for example, in *misoneism* meaning "hatred to the new" (from Greek *misein* hatred + *nei* coming from *neos*). The word "novel" goes back to Latin *novus* "new." The derivatives from both the Greek and Latin language stems are numerous: neology, neologism, neocortex, neophil, neologize, neophyte, Neolithic, nova, supernova, novel, novate, innovate, innovation, novelize, renovate, etc. On the other hand, the sema (minimum unit of meaning) of "new" exists in hundreds of other words which seemingly in their form have nothing to do with the above-mentioned Greek and Latin roots. This sema *new* certainly exists in the following words: fresh, unused, inexperienced, original, additional, recent, modern, further, extra, other, raw, immature, untried, untouched, unfamiliar, changed, altered, mutated, different, converted, unskilled, unconventional, etc. All these words describe or denote some kind of newness, or some essence of newness appearing in numerous phenomena. This essence may be explicit (in the root) or implicit (hidden).

Newness as a phenomenon exists everywhere: new photon, new collision of elementary particles, new star, new baby elephant (or any baby), new generation of butterflies, etc. Particles change trajectories and collide. Atoms lose and acquire electrons, get into combinations, and form molecules. Molecules grow and change. Organisms reproduce and mutate. Nature is a huge pool of interacting objects and forces. Nature experiments in its natural labs using natural resources. Successful (productive) newness spreads within the physical, chemical, biological, and social domains. Those new processes, new objects, and new features which are more able (faster, stronger, better camouflaged, or accommodated, more flexible, etc.) survive and disseminate; the others perish.

In the human activity domain, newness may be both suppressed and cultivated, but the production of the new accelerates immensely. It begins to acquire a faster and sometimes even planned character. Language and instruments become the powerful force of change. Individuals, as social beings, come to an understanding that it is newness that allows them to survive. A wheel, a spear, a bow, a fishing rod, a plow, a machine – all these and millions of others are the steps in this survival. Original decisions at work or in the battle, new tools or new weapons, new strategies or new tactics, new technical decisions and new production lines, new educational equipment, new methods, and new policies – all serve for the benefit and survival of certain societies or social groups. Truly, creativity is the process of accelerated generation of newness (on the psychological level), and innovation is the process of consumption of the generated newness (on the social level). The more open the society is for accepting the new, the faster it will grow and develop.

In general, everything in this world is, was, or will be new. Everything, never mind what people are talking or thinking about,

- Comes into existence (appears *anew*)
- Grows (shows *new* features, sizes, colors, etc.)
- Matures (climbs to *new* peaks of development)
- Ages (acquires *new* features, or loses *new* features)
- Disappears or dies (turns into a *new* state).

The Big Bang theory states this universe started one moment some thirteen–fifteen billion years ago as a huge explosion. The religious point of view and creationism state God created the world. The creation myths in different ethnic origins describe the world birth. What remains invariable in all approaches, however, is that this world somehow came into existence – it was born, it started *anew*, it was *new*, and it is *new*.

The *new* as a subject to study was in this world from the beginning. It is interesting that nobody noticed such an obvious subject to study.

Classification of Newness

Classification is conventionally the first step to transforming the gathered data and descriptions into collections, studies, and theories. Sciences generalize the data about reality and divide this data into classes, subclasses, types, subtypes, etc.

Classes: Material or Ideal

The most general category for classification is material versus ideal newness. Any newness occurring in the objective world, environmental change, growth of trees, grass, animals, buildings, and so on – every tangible change – constitutes material newness. Any newness occurring in the subjective world, ideas, images, concepts, etc. – every intangible change – constitutes ideal newness. These classes contain some subclasses and sub-subclasses, but this is beyond the scope of this entry.

Types: Natural or Artificial

Another major differentiation of newness is types of newness. The two basic types are natural newness (produced in nature and naturally) and artificial newness (produced by human beings or human society).

Levels: Function, Substance, and Structure

The next division of newness on the way down from philosophical heights (abstracts) to the ground-level practicality (concreteness) is the so-called general systems theory (L. von Bertalanffy and others after 1930s). This approach has discovered that all objects, processes, and organisms are systems having structures, elements (substance), and functions. Therefore, from the systems point of view, novology must differentiate functional newness, substance newness, and structural newness. Illustrations are numerous. For example, the same object can be used for various functions (functional newness). Also, the same structure can be manifested in various substances, like wood, brick, and metal (substance newness). Finally, changing the structure itself (relations between elements) constitutes structural newness. These differentiation levels may have sublevels within.

Stages of Newness

One more important parameter of classification is the aspect of time. Changes in general include certain stages: appearing, growing, culminating, decreasing, and disappearing – all within a certain time range. Consequently, newness may be of different stages and substages within these stages.

Forms of Newness

According to the way newness is manifested, novology distinguishes forms of newness: latent (hidden) versus open, and within open, it may be emphasized versus non-emphasized. So forms and subforms of newness may be analyzed.

Layers of Newness

Depending on the step in the movement from objective (material) to subjective (ideal), there may be different layers of newness. The layers of reflection that exist in any reflecting system, including the human mind, may be used as an example. These layers can be identified and even divided further into sublayers. The language activity, consisting of multiple layers of understanding and analysis (reflection), is a good example. Newness certainly can exist in any of these layers.

Patterns in Varieties

As a result of classification effort, people must deal with classes and subclasses, types and subtypes, levels and sublevels, layers and sublayers, forms and subforms, and stages and substages of newness. It must be already a six-dimensional matrix to embrace the varieties of newness. What is more important, this is not the final list: it is rather open than not. Therefore, multidimensional matrices are used for newness classification.

Units and Measurements

The fields of research become sciences when they acquire calculations. Calculations make the research results testable (measurable) and repeatable.

Linguistics, a very well-structured field of research, illustrates how it can be done, and novology follows the modus operandi. Just as phoneme (Greek *phone*- "sound" + *eme* "unit") is the basic unit of phonology, morpheme (Greek *morphe*- "form") is the basic unit of morphology, lexeme (Greek *lexis*- "word") is the basic unit of lexicology, and sememe (or seme, Greek *sema*- "sign") is the basic unit of semantics, novology creates its own basic unit called *noveme*.

As phonemes in phonology are divided into vowels and consonants, novemes are divided into:

- Qualitative units (qualitemes)
- Quantitative, or measurement units (quantemes)

  Quantemes are divided into:
- Obnov (*ob*jective *nov*elty) for measuring the quantity of objective newness
- Subnov (*sub*jective *nov*elty) for measuring the quantity of subjective newness

  The qualitative units (qualitemes) include:
- Shifteme (newness within the paradigm)
- Transeme (newness of paradigm switch)
- Leapeme (jump over paradigms)
- Revolueme (revolutionary switch from one set of paradigms to another set of paradigms)

Special Instruments: Methods and Techniques

The history of humanity shows that the most impressive results are often achieved not by pure force, pure power, or harder training, but by genuine bright idea and by new method or technique. For instance, never mind how sharp a human eye sight is and how strong one's desire for star counting is, a telescope invented by Galileo leaves all unarmed eye observations in dust.

So what are these special instruments offered by novology?

- The quantitative and qualitative analysis of newness introduced above is an instrument.
- The new definitions of creativity and innovation (Aleinikov 2000) are tools for new research.
- The new models (like a four-side universal model of sign, language consciousness, speech act, and heuristic act) are instruments (Aleinikov 1994).
- The regularities and laws of newness existence (Aleinikov 2002a) are instruments of understanding and accelerating newness production.

With the help of these scientific instruments (just like with the help of telescopes and microscopes), humankind is now able to disassemble and assemble reality, to manipulate the elements of this reality to make it work faster and thus achieve better results in a shorter period of time. Creativity is ectropy accelerator (see ► Creativity). Moreover, creativity in the field of science, like this particular case of creating a new science for improving the study of creativity and innovation, is a meta-accelerator.

Laws of Novology

Novology offers five laws for the science of newness:

- The 1st law: Newness exists as an objective phenomenon – it exists as the changing nature's aspect.
- The 2nd law: Newness is the result of change and the cause of change; it never appears from nowhere or nothing, and it never disappears without a trace.
- The 3rd law: Newness is instrumental: the faster the production of newness, the higher the probability of surviving and succeeding.
- The 4th law: Newness is functionally oriented: the higher the system in the hierarchy of nature development, the higher the necessity to produce newness.
- The 5th law: The inter-function of newness production is organization: the higher the speed of producing newness, the larger its influence on world organization.

Examples of these laws working in nature are numerous, but the volume of this entry sets restrictions.

Specific Results and Predictions

Novology describes theoretical and practical results achieved due to the introduction of a scientific category of newness. One of them is the development of the creative output measurement (new unit) and, as a consequence, the development of the most powerful methodologies in creative output – BAMMA (Brainstorming Advanced by Morphological Matrix Analysis), allowing a leap to MegaCreativity (Aleinikov 2002b). Another significant result is the design of most accelerated methodologies of changing human behavior in education – Genius Education Methodology (Aleinikov 2002b). Novology also forms a number of predictions. It foresees the formulation of a new vision (worldview), formation of new languages and sublanguages for its description, new methods of reality changing, new types of education, and even new objections to novology as a science. But more importantly, novology paves the way to the creation of the science of creativity, whether it is called sozidonics (Aleinikov 1994) or creatology (Magyari-Beck 1999), as well as innovatics (Rus. инноватика) and/or any other science studying innovation.

Conclusion and Future Directions

Novology, the science of newness, is a further step in understanding creativity and innovation (see ► Creativity and Innovation: What Is the Difference?), united by the underlying category of newness. When newness becomes measurable, both creativity and innovation acquire the fundamentals necessary for being understood deeper, described more precisely, and reflected scientifically. Newness, as a vast subject of study, receives a system of terms and laws to reflect it. Novology, on the other hand – as a system of study that has its specific name, objective, subject of study, instruments of research (methodologies, methods, and techniques), its own classification and units of measurements, specific results (never achieved by other sciences), and its own predictions of the future – has the full right to be called a science.

The new science of novology, in addition to the new vision of newness and new definitions of creativity and innovation, creates the gnosiological foundation necessary to move further in understanding complex psychological and social phenomena. It opens new horizons for future investigators and researchers in science, technology, business, and education, political, economical, and social life. It will be applied to the evaluation of most advanced scientific discoveries and technological inventions (see ▶ Invention Versus Discovery) for committees like Nobel Prize or McArthur Foundation with its "genius" fellowship. Novology must develop tools for selecting the technological trends because a single mistake can be costly not only for the company but also for the country. One of the most important directions is also education where novology has to apply its tools to determining the amount of newness needed for various groups for them to reach the level of genius (see ▶ Genius), to become ideal learners (see ▶ Creative Pedagogy), or to stay at least successful students on all levels of education. This alone can solve numerous educational problems because when some students are ready to move forward, the others cannot still digest the amount of newness in the given material, so they protest, they revolt, they quit, etc. Novology is a must for future evaluations in advertising (now done on the intuitive level) where millions of dollars can be saved or earned by calculating the precise amount of newness needed to influence the viewer/listener most effectively (see ▶ Business Creativity). Finally, novology has a huge potential for political campaigns to determine the newness of the given platform and to help politicians shape a better program to lead to the future with most innovative ideas (see ▶ Creative Leadership).

N-Tuple of Helices

Loet Leydesdorff
Amsterdam School of Communication Research (ASCoR), University of Amsterdam, Amsterdam, The Netherlands

Synonyms

Complex dynamics

Definition

As a generalization of a biological double helix and an institutional triple helix, the *n*-tuple of helices is based on Luhmann's distinction of symbolically generalized media and codes of communication that can be functionally differentiated as the economy, polity, science, etc.

In response to Carayannis and Campbell's (2009) introduction of a Quadruple Helix and the further extension to a Quintuple Helix by Carayannis and Campbell (2010), Leydesdorff (2012) argued that an *N*-tuple of helices can be expected in a pluriform and differentiated society. The metaphor of a Triple Helix (TH) of university-industry-government relations (Etzkowitz and Leydesdorff 2000) more or less invites proposals to extend the model to more than three helices.

In a discussion which focused on bringing "society" or "the public" back into the model as a fourth helix, Leydesdorff and Etzkowitz (2003) argued that the helices represent specialization and codification in function systems which evolve from and within civil society. A pluriform "society" is no longer coordinated by a central instance, but functions in terms of interactions among variously coded communications. Money, for example, can be considered as a prime example of a symbolically generalized medium of communication (Parsons 1968): It enables us to pay without having to negotiate the price of a commodity. Power, truth, trust, and affection are other "performative" media (Luhmann 1975, 1995).

Following Merton (1957), Luhmann (1995) historicized the possible functionalities in social communication in terms of "performative" media. For example, one can raise the question of whether a new code has emerged at the interface between the sciences and the economy since patents became increasingly organized at the interfaces as a vehicle for the protection of intellectual property rights (Leydesdorff 2008). Simon (1962, p. 478) conjectured that any complex system operates with an alphabet. Thus, there may be 20+ symbolically generalizable media of communication available in interhuman interactions. While this plurality of codes can be expected to resound latently in interhuman interactions, some of the codes of communication can be specifically deselected in institutional settings. A discourse in court, for example, is structured differently from a scholarly discourse.

The differences in meaning provided in the various communications can be translated by reflexive (human or institutional) agency. From this systems perspective, communicative competencies thus are developed in the plural (cf. Habermas 1981; Leydesdorff 2010). University-industry-government relations, for example, can be expected to flourish when all partners in the arrangement are provided with feedback from the interactions meaningfully to their own further development.

In a knowledge-based economy, in other words, one should not only optimize the retention of "wealth from knowledge," but also nourish the generation of further research questions from social and economic demand. Variety is required in the different dimensions of a triple or *n*-tuple helix so that differently coded discourses can select upon each other and interact (Ashby 1958).

One may wish to move beyond the Triple Helix model with three relevant selection environments, but every further dimension requires substantive specification, operationalization in terms of potentially relevant data, and sometimes the further development of relevant indicators (Leydesdorff and Sun 2009).

Global Interorganizational Networks and the Embeddedness of Open Business Models

Entrepreneurs have to keep up today with an ever more complex, global, and dynamic environment. The term "global innovation arms race" was used to highlight the competitive pressure that forces firms to accelerate their rates of innovation in products, services, and business models to keep up with others. The sale, licensing, and trading of technology has hence become a

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,

large-scale activity. Recent data demonstrate that the number of alliances per firm has indeed gone up significantly, and it is common for large firms to manage over 500 alliances simultaneously (Hagedoorn et al. 2005). Firms have also to face the increased pressure for short-term yields coming from private equity funds backed by investment banks, asset management firms, and hedge funds.

Networks are ubiquitous in the real as well as in the financial economy. Entrepreneurs and their firms are therefore tied through legal binding agreements to complex and ever-varying networks of agents, as they operate within interrelated spheres, the real economy and financial capitalism, and therefore between innovation and finance (Gay 2011).

By opening its business model through economic transactions, a company can be more effective in creating as well as capturing value. Firms thus leverage other companies' assets but also let other organizations leverage their assets. They are hence constrained by the continual moves of others, the different networks they are embedded in playing an important role in influencing their performance as shown in a number of studies. A common proposition is also that firms' differential positioning within a network structure has an important impact on resource flows and hence on their performance.

Moreover, there is but one type of firm populating our modern-day changing environment spurred by intense and global competition. Companies are in reality predominantly quite small and short-lived, coming and going on a much smaller time scale than large firms. Interestingly, small firms are much more innovative than their larger counterparts (U.S. Small Business Administration 2006). When firms operate within global enmeshed networks, the question arises as who actually benefits from innovation. Who harvests the value highly innovative firms led by risk-taking entrepreneurs create?

Though the importance of networks and of central positioning for firm performance is generally acknowledged, small companies, and particularly start-ups, depend heavily on deal flows and contracts with dominant market players for performance as well as on venture capital strategic financing.

Consequently, entrepreneurs can only infer the outcomes of their small innovative firms if they understand the different global networks within which they operate as well as the open business models their dominant partners use to capture value/innovation as they interact with, or invest in, smaller entrepreneurial firms. A small set of examples borrowed from the pharmaceutical industry are used in this chapter to represent the dynamics of the open business models of large venture capital firms and major pharmaceutical companies as they maneuver in this industry. Even though the strategies used by venture capital firms and large pharmaceutical companies are quite different, both categories of players use networks of alliances as a "wheel" to rapidly grab value in the form of open innovation as it is produced by smaller firms. Small biotech companies are little more than commodities for both major venture capital firms and dominant pharmaceutical companies. Pharmaceutical, biotech companies, and life science venture capital are intertwined in networks, but their fate is not. Open innovation seems to benefit essentially larger players whether they belong to the financial or to the real sphere.

The Business Logic of Open Innovation: Interdependency and the "Buy Side"

The business model is an important construct in entrepreneurship research. Various perspectives exist regarding the definition, nature, structure, and evolution of business models (see Morris et al. 2005, for a unified viewpoint). This work focuses on the open business perspective epitomized by Chesbrough (2003, 2007) which starts with the statement that open systems are today more successful than closed systems.

The first function of a business model, creating value, as summarized by Chesbrough (2007), requires the definition of a series of activities or value chain (from raw materials through to the final customer) that will lead to a new product or service; value being added as each step of the value chain is processed. The second function which is to capture a portion of that value requires that the firm has one or more unique assets within the value chain allowing the firm to enjoy a competitive advantage (Chesbrough 2007).

A business model is thus in essence a "system that is made up of components, linkages between the components, and dynamics" (Afuah and Tucci 2000). Zott and Amit (2009) conceptualized a firm's business model as a system of interdependent activities that transcends the focal firm and spans its boundaries. Value creation arises from multiple sources and relates to strategic network theory (Jarillo 1995) and cooperative strategies (Dyer and Singh 1998). An open perspective on the business model therefore also implies a system perspective. The further firms open their boundaries, the further they become at the same time interdependent and embedded within complex networks of interactions.

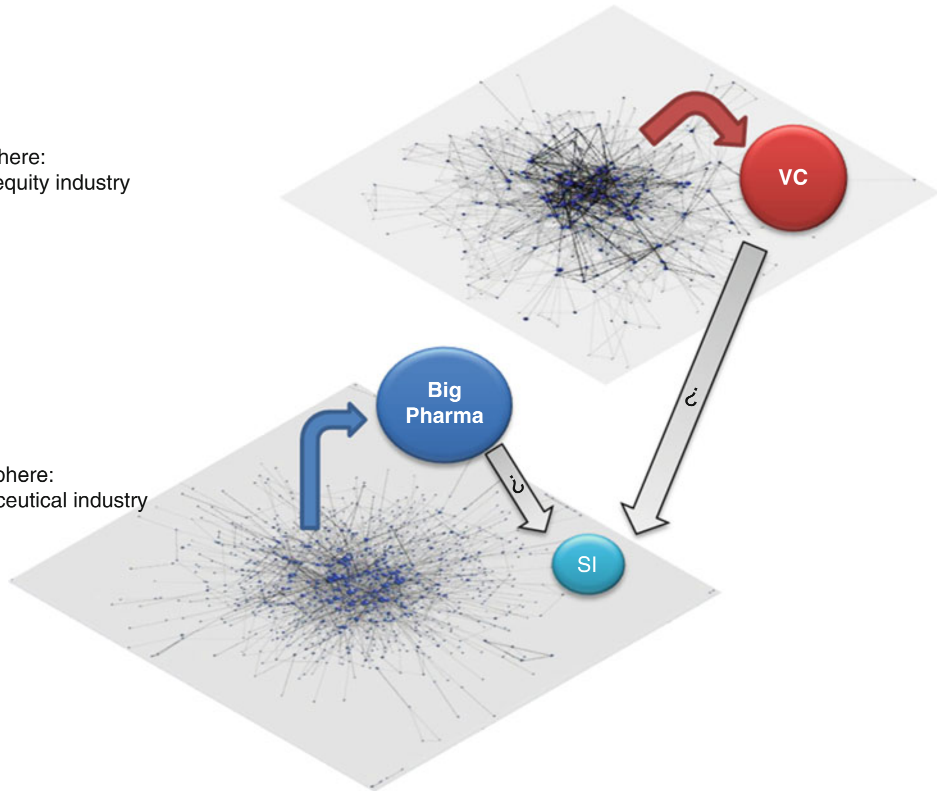
Moreover, as clearly stated by Chesbrough (2003), open business models are in fact about dividing the work of innovation. Business success depends on capturing external resources or creating value that can be used internally and/or placed into other firms' business models. The premise is that powerful advantages will be conferred to any firms willing to open their business models. This is however especially evident for firms profiting from other firms' innovation. Open business models indeed attack the cost side (rising development costs) by leveraging external R&D resources and the revenue side by licensing external technologies or products worldwide. These models are also more efficient to show shareholders a return on R&D investments. Therefore open business models that leverage external research and development resources work best. Indeed, when briefly summarizing the open innovation principles or "new rules of the new realities," as elaborated by Chesbrough (2003), the core of the model resides in that firms should leverage innovation outside ("not all the smart people work for us . . . External R&D can create significant value . . .. We don't have to originate the research to profit from it . . . Building a better a better business model is better than getting to market first . . ."). Openness is then mostly a strategy that allows rapid access to valued innovation worldwide while reducing operating costs and removing supply chain dependencies. The benefits of open systems cannot possibly accrue equally to the other side, that is, that of the sellers or young companies that can base openness only on their new, often unproven, technology. Moreover the business models of their partners affect necessarily young innovative companies.

The Strategy of Open Innovation: How Big Players Operate Within and In-Between Networks

Open business models are not made in isolation. As firms interact with one another, they weave an ever-changing network of interactions into which they embed themselves and which may constitute an asset or a liability. For any company, the interdependency of the many "open" business models at play needs to be understood. A firm immerged in connected worlds can master its own business model only if it realizes that the business models of its partners can have a significant impact on its own performance and survival.

The biopharmaceutical industry is a clear example of an industry where the open innovation paradigm is in place (Chiaroni et al. 2009). However, very few biotech companies have demonstrated the ability to sustain profits in this very difficult industry (Pisano 2006). It is important to understand if the open innovation philosophy per se benefits firms or if indeed only one side of innovation, value capture, outperforms the other side, value creation.

Partnering money is highly important for innovative biotech companies as it constitutes a large percentage of biotech funding, increasing from 42 % in 2007 to 59 % in 2008 (Huggett et al. 2009). Top deals in particular are made with



Open Innovation and Entrepreneurship, Fig. 1 Relations between small innovative companies (SI) and their partners, in particular large players in the industry and in the financial sphere (VC firms and big pharmas in the chosen example) (Sources: Proprietary database of alliances for the pharmaceutical industry, VentureXpert Database for the venture capital industry. Visugraph Software (Gay and Loubier 2009) is used for network visualization. Nodes in the networks represent firms and links represent legal binding agreements between firms)

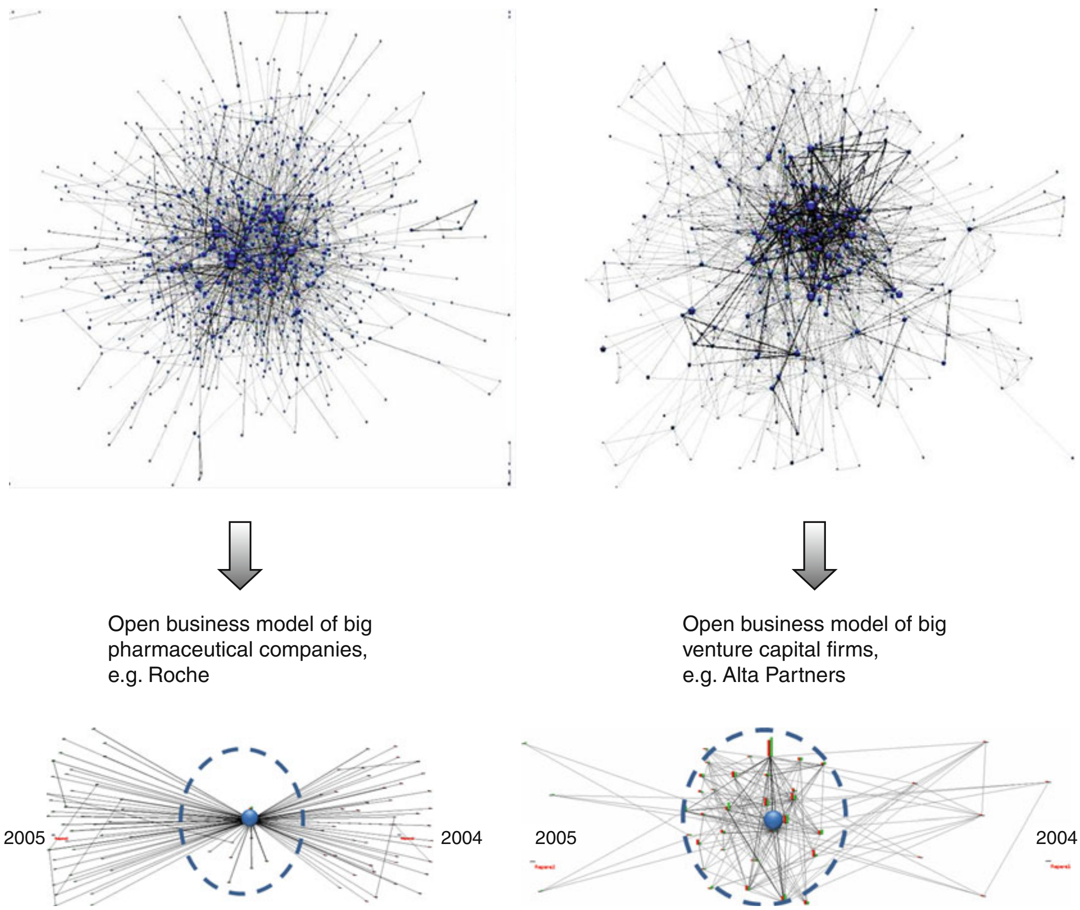
large incumbent companies. For example, Sanofi-Aventis entered in 2010 into a global strategic alliance with Regulus Therapeutics to discover, develop, and commercialize microRNA therapeutics. The alliance is the largest microRNA partnership to date, worth potentially $750 million to Regulus Therapeutics.

Venture capital (VC) is another major source of investment provided by VC firms to high-technology firms to finance their growth and product development. VCs are financial go-betweens between the financial and economic spheres. They first raise funds from institutional investors and then make equity investments in companies.

Understanding the critical link between high-growth, high-technology firms and their main capital providers, large players in the pharmaceutical and in the VC industries require that analysts know how these two categories of actors operate in their respective spheres, economic and financial, and how they explicitly deal with entrepreneurial firms (Fig. 1).

Figure 2 depicts the unique and complex connected environments into which the different agents operate: the network of interfirm transactions in the pharmaceutical industry and the network of syndicated deals VC firms make in order to invest into innovative biotech companies. A syndicate is formed when two or more VC firms take an equity stake in an investment for a joint payoff (Brander et al. 2002; Manigart et al. 2006).

Both big pharmaceutical companies and large VC players are the most active firms in their

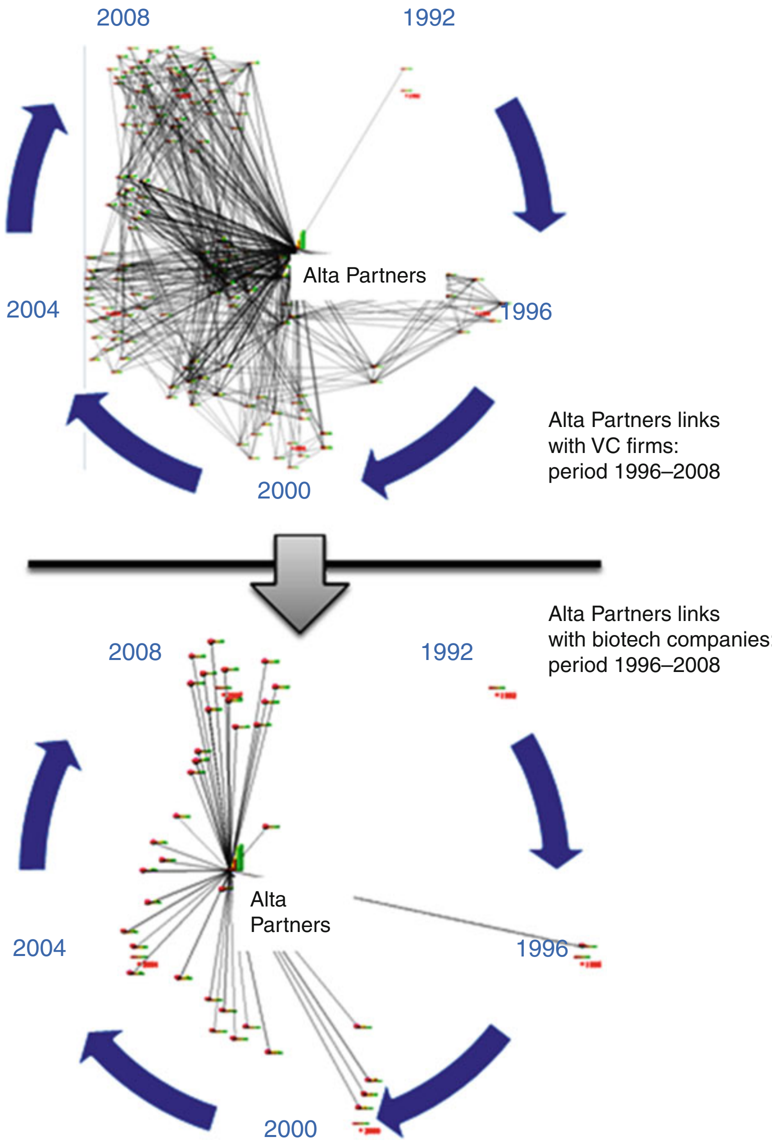


Open Innovation and Entrepreneurship, Fig. 2 Networked industry landscapes and open business models (*Top*) Open business landscapes, here the pharmaceutical and the private equity industries between 2004 and 2005 are in fact meshes of entwined firms. Node size in all maps is scaled to standardized network degree, or number of deals per firm, in the total network. Larger nodes, or firms with the highest transactional activity, are major players in each industry (e.g., Roche in the pharmaceutical industry and Alta Partners in the equity industry). The *lines in bold* between any two institutions indicate the presence of repeated ties between the same firms. The two landscapes have very different structures, the VC network being much more cohesive and its central players interacting repeatedly among themselves, contrarily to the pharmaceutical industry network. (*Bottom*) The open business models of the major players in each business landscape are very different (period 2004–2005). Roche for example (*left graph*; *blue dot* at the center of the graph), one of the world's leading healthcare companies, makes each year many new, dyadic transactions with many different partners. Links represent mainly in-licensing activities. The stable partners with which Roche interacts are few (*inner circle*). Conversely, Alta Partners (*right graph*; *blue dot* at the center of the graph), a leading venture capital firm in life sciences, interacts repeatedly with its partners (*inner circle*). Novel partners are few each year and Alta Partners links them to partners with which it has recurring partnerships (Sources: Proprietary database of alliances, VentureXpert Database. Visugraph Software is used for network visualization)

respective industries. However, their respective strategies are very different (Fig. 2).

Big pharmaceutical companies essentially interact with many new and smaller partners on a yearly basis (Fig. 2). They mostly leverage external assets. Conversely, biotech companies are in effect on the sell side of the open business model. (See other contributions in this book and Gay et Dousset 2005).

Contrarily to big pharmaceutical companies, when they syndicate with other VCs, large VCs interact repeatedly with previous relations as well

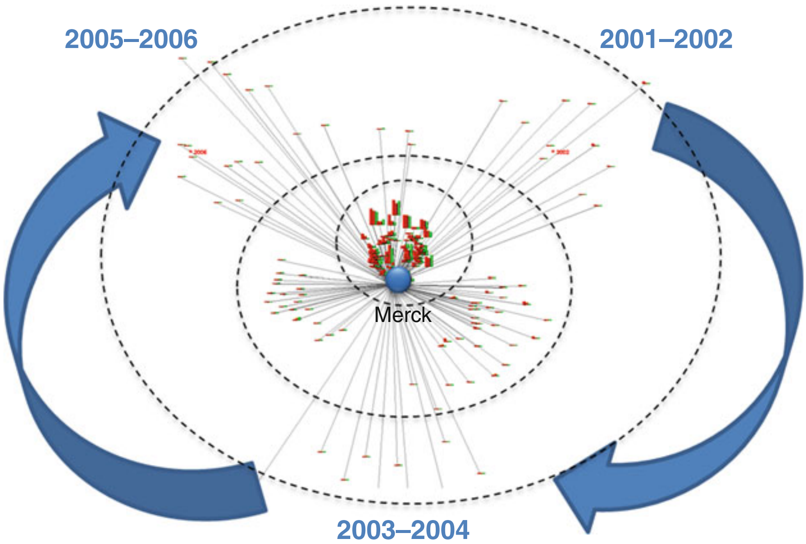


Open Innovation and Entrepreneurship, Fig. 3 Alta Partners' business model, the two levels (*Top*) Alta Partners interactions with other VC firms from 1996 to 2008. VisuGraph software allows seeing the firm's interactions as they happen in a clockwise manner. Interactions are extremely cohesive. Alta Partners, funding over 145 companies in the industry since 1996, increases its interactions with other VCs suddenly after 2000, with the rapid takeoff of the biotech industry following the sequencing of the human genome. (*Bottom*) The many cohesive links Alta Partners has with other VC partners (in particular after 2000 as seen in the *top figure*) allows it to invest in many biotech companies (*pink dots*; *bottom figure*) on a timely basis. Alta Partners is thus able to rapidly expand its portfolio of biotech companies after 2000 (Sources: Proprietary database of alliances, VentureXpert Database. Visugraph Software is used for network visualization)

as conjointly develop new partnerships with other VCs (Fig. 2). However, akin to big pharmaceutical companies, this open business model allows them to also invest rapidly in many biotech companies when deals are considered attractive (see Fig. 3 as an example).

A consequence of the constant search of new partners by dominant pharmaceutical companies is, as illustrated in Fig. 4 (See other contributions in this book), that it becomes extremely difficult for small companies to maintain themselves for an extended time in an industrial network.

Thus, on the "buyers" side, be it equities or assets, business models function as wheels that move forward extremely fast as needed. Open "wheel" practices on the "buyer" side constitute a challenge for small innovative biotechs as they are basically made into commodities that any firm with capital can rapidly trade in the market place.



Open Innovation and Entrepreneurship, Fig. 4 Open business model of Merck (*blue dot* at center of the graph) Merck, a global healthcare leader, makes some alliances with large incumbent players (large histograms) with high transacting activity (*inner circle*) from 2001 to 2006. It interacts otherwise essentially with many companies that are not able to maintain themselves in the pharmaceutical industry more than 4 (*intermediary circle*) or 2 (*outer circle*) out of the 6 years and have low transacting activity (very small histograms) (Sources: Proprietary database of alliances, VentureXpert Database. Visugraph Software is used for network visualization)

Conclusion and Future Directions: The Entrepreneurial Firm Dilemma

A main contribution of the chapter is to outline the interdependency of open business models and, in particular, how business models on the "buy" side affect business models on the "sell" side. In highly competitive markets, open "wheel" practices on the "buy" side allow big players to rapidly invest into innovative companies. Big pharmaceutical companies use in-licensing as a main contractual form. Linkages therefore constitute quasi-market mechanisms that give these large players the opportunity to continually grab valuable resources ceaselessly produced by a plethora of small firms, competition among innovative firms being foremost. Repeat interactions are few and small biotech firms are mainly used as commodities, their value equating that of their technologies or products. Another interesting finding is that open business models can be structured very differently. Unlike that of big pharmaceutical companies, the business model of VC firms is based on repeat, cohesive interactions with many partners. The endpoint is however the same, it allows rapid investment into many biotech companies for maximum profit.

Network analysis software has been used here to highlight that openness in fact leads to (inter)dependencies which need to be investigated. Emphasis has also been brought on the fact that open business models are not static; wheels are turning very fast, and partners come and go. Further research in this area is needed, in particular regarding the different possible structures of open business models and the linkages between firms' distinct assets and possible models and outputs. Researchers need also to solve the entrepreneurial firm dilemma, that of its survival when assets are exchanged very fast and their value limited by both competition, fast obsolescence, and the business models of large partners.

Introduction: Which Factors Influence Innovation

Innovation as a dependent variable has a rich tradition in empirical research (Damanpour 1991). And certainly, organizational slack is neither the only nor the most researched determinant of innovation. Alternative concepts investigate the impact on innovation on different levels of analysis. Accordingly, innovation has been researched at the individual level by examining a range of different characteristics such as personality, motivation, cognitive ability, job characteristics, or mood states. On a group level, team structures, team climate, team member characteristics, processes, and leadership styles have been researched. Finally, on the organizational level, structure, strategy, size, (slack) resources, and culture have been looked at (Anderson et al. 2004). Somewhat as a revival, the entrepreneurship literature has been gaining momentum recently especially in the fields of social entrepreneurship. Finally, organization external factors such as organizational environment are analyzed in the field of innovation research (Meyer and Rowan 1977; DiMaggio and Powell 1983; Zucker 1987; March and Olsen 1989; Powell and DiMaggio 1991; Scott 2003, 2001; Fernandez and Wise 2010).

Since organizational factors have not been researched as prominently as individual factors recently, a focus on organizational slack helps to shed light on this blind spot. Additionally, at the organizational level of analysis, theoretical as well as empirical literature has brought forward promising results concerning the relation between organizational slack and innovation.

Organizational Slack

Since its introduction to organizational literature by Cyert and March (1963), the concept of organizational slack has widely been recited, altered, advanced, and specified. These processes took place in two main areas, with the first concerning definitions and the second concerning measurement. The slack construct was established under the framework of the organizational behavior theory. More concisely, slack was conceptualized as the difference between the total amount of resources and the necessary payments to the members of an organization to protect the coalition from dissolving (Cyert and March 1963: 42).

A broader definition by Bourgeois (1981: 30) refers to organizational slack as "*that cushion of actual or potential resources which allows the organization to adapt successfully to internal pressures for adjustment or to external pressures for change in policy, as well as to initiate changes in strategy with respect to the external environment.*" As opposed to Cyert and March (1963), who focus their definition on payments, Bourgeois (1981) in his frequently cited article "On the Measurement of Organizational Slack" refers to an unspecified set of resources that could contain financial, factual, or human resources.

By summarizing the state of slack research in the beginning 1980s, three roles are attributed to slack in organizations, which are represented in the definition provided above. Firstly, slack functions as a cushion that guarantees an organization the flexibility to quickly adapt to rising demands, i.e., slack as an insurance against an unforeseeable future. Secondly, slack is a tool applied by top management to enable strategic changes where slack provides the extra resources necessary to carry through these change processes to adjust to new environmental demands. Thirdly, organizational slack takes on the role as a means for permitting innovation processes, either product innovations or process innovations. Finally, another important conceptual contribution of Bourgeois is the idea of slack and its association with organizations' success. The argument is that either zero slack or too much slack is connected with considerable disadvantages for the organization because zero slack leaves the organization too inflexible, while too much slack results in inefficiencies accelerating the organizations' termination. Consequently, the proposed relationship between success and slack is inversely U shaped, an idea which has been widely acknowledged in slack research subsequently (cf. Geiger and Cashen 2002; Geiger and Makri 2006; Herold et al. 2006; Kim et al. 2008; Love and Nohria 2005; Nohria and Gulati 1996, 1997; Tan 2003; Tan and Peng 2003).

Out of an almost infinite pool of definitions for organization slack, a more recent concept from Geiger and Cashen (2002: 69) seems to be very suitable and perfectly applicable to understand the concept: "The resources in or available to an organization that are in excess of the minimum necessary to produce a given level of organizational output." This definition is viable as it incorporates different dimensions of slack that are distinguished in the relevant literature (Bourgeois and Singh 1983; Bowman et al. 2005; Geiger and Cashen 2002; Herold et al. 2006; Lant 1985; Love and Nohria 2005; Sharfman et al. 1988; Singh 1986). The idea to frame organizational slack as a multidimensional concept was originally developed by Bourgeois and Singh (1983) in their study "Organizational Slack and Political Behavior among Top Management Teams," where they identified the need to develop a more sophisticated and differentiated concept of slack. Advancing the findings from Bourgeois' 1981 paper, where he developed a measurement tool based on financial indicators, it is now observed that these financial indicators are not homogeneous concerning their availability and transformability from one resource into another. Imagine, for instance, excess liquidity, which is easily accessible and can rather quickly be transformed from monetary into any other form which might be needed in the organization, e.g., computer equipment or a new ambulance car. If the slack resource does not exist in the form of excess liquidity but overhead cost, then both the access and the transfer of slack are not as easily possible any more since reducing overheads often requires restructuring or streamlining processes first. Consequently, before overheads can be transformed into another resource, it has to be made available, turned into liquid funds, and redeployed. This example already clarifies that organizational slack can emerge in very different forms with substantially different effects in organizations.

A more elaborated slack model was constructed that takes into account the different degrees of ease-of-recovery, i.e., their degree of incorporation in the organization's structures, processes, and routines. These three slack dimensions comprise (1) available slack, being the resources that have not yet been absorbed by the organization, e.g., excess liquidity or retained earnings, (2) recoverable slack, being the resources that have already been assimilated into the organization's structures, processes, or routines, typically as excess overhead costs, and finally (3) potential slack, as the organization's capacity to generate additional resources from outside, e.g., debts, loans, and equity capital (Bourgeois and Singh 1983: 43).

Another concept pointing in the same direction is that of absorbed and unabsorbed slack resources (Singh 1986). Similar to available slack, unabsorbed slack denotes resources that are in excess and liquid resources that are not committed to any organizational task or activity. Absorbed slack would therefore equal recoverable slack that signifies some excess costs in an organization, i.e., absorbed slack indicates waste since it does nothing else but increase the cost of production in the respective organization (Singh 1986: 567).

Yet another way to distinguish between the different dimensions of slack is to concentrate on the degree of discretion resources allow. Clearly, uncommitted resources can more flexibly be shifted – thus leaving managers with greater possibilities for following their aims – which can but do not have to align with the organization's goals. In their research on the antecedents of organizational slack, Sharfman et al. (1988) follow the argument of a multidimensional slack concept but add a different perspective by focusing on the degree of managerial discretion that is determined differently by each slack dimension. Accordingly, Sharfman et al. (1988: 602) distinguish between high-discretion slack, which would basically equal available slack, and low-discretion slack, which equals the recoverable slack dimension.

Organizational Slack and Innovation

Following the conceptual and theoretical considerations about organizational slack and innovation as formulated in behavioral theory (Cyert et al. 1959, 1963), which assume that organizational slack might provide the necessary cushion for experimentation, hence innovation, first empirical insights were still pending at that time.

Among the first to test the slack-innovation-proposition empirically were Aiken and Hage (1971) in their study on organizational design and innovation. Slack was measured by (1) the percent increase in the organization's budget and (2) whether or not the resource base changed during a 3-year period and correlated with the rate of innovation during the same period. The findings supported the assumption that innovation requires increased financial resources since the data showed that the innovative organizations had increased resources available (Aiken and Hage 1971: 78). A major shortcoming of this study is that only a correlation analysis was conducted which cannot answer the question of causality.

The positive influence of organizational slack on innovation was also shown by Miller and Friesen (1982), who found in their study of 52 business firms from the Montreal region that resource availability and innovation were positively correlated in the case of conservative firms (Miller and Friesen 1982: 13). Further quantitative studies that confirmed the supposed linear positive association between organizational slack and innovation were conducted by Nystrom et al. (2002); Greve (2003); Barrett and Sexton (2006); Geiger and Makri (2006); Ruiz-Moreno et al. (2008); Franquesa and Brandyberry (2009); Pohl and Elmquist (2010). Finally, the meta-analysis by Damanpour (1991) is outstanding within the research on slack and innovation as it reviews 23 empirical studies. Statistically significant associations are found for slack resources, specializations, functional differentiation, professionalism, centralization, managerial attitude toward change, technical knowledge resources, administrative intensity, as well as internal and external communication.

However, although there seems to be thorough empirical evidence for a positive relationship between slack and innovation, there are also studies that came to contrary conclusions. Not so much building on the organizational behavior theory (Cyert and March 1963) but adhering to propositions from economic approaches and agency theory (Fama 1980; Leibenstein 1966) and conceptual papers reasoning a negative relationship (cf. Child 1972; Jensen 1993), this research found negative associations between organizational slack and innovation.

Katila and Shane (2005), for instance, revealed in their quantitative study among a large sample of 964 US firms' innovation attempts that new firms were more innovative when suffering from a lack of resources (Katila and Shane 2005: 826). Similarly, Zajac et al. (1991) found in their qualitative and quantitative investigation among hospitals that slack exerted a negative influence on innovation. But the results for the slack variables were not significant, which was partly explained by sample characteristics (Zajac et al. 1991: 181). Yet another study by Manns and March (1978), which was rather in the tradition of behavioral theory, unveiled that university departments enjoying high reputation and a convenient resource outfit were less prone to innovate (in terms of introducing new curricula) compared with their less-equipped counterparts. Bolton (1993) also confirmed in his study the negative impact of slack resources on innovation and found that instead substandard performance seemed to stimulate organizational innovation.

Echoing the ambiguous incidences on the relation between slack and innovation ranging from positive to negative, with each of them featuring strong theoretical and empirical evidence for their findings, Herold et al. (2006: 372) still ask the question: "What is the relationship between organizational slack and innovation?"

Most obvious, there is no simple linear relation. One of the most prominent empirical studies investigates the association with a sample of multinational business firms and asks the question "What is the optimum amount of organizational Slack?" (Nohria and Gulati 1997). The authors show empirically that the relationship between slack and innovation is neither purely linearly positive nor entirely linearly negative. Rather, it seems as if the relationship can best be described as inverse U shaped, meaning that up to a certain level of organizational slack in the organization, the impact of slack resources on the innovative behavior is positive, but when this point is exceeded, then additional slack resources imply adverse effects on innovation.

Two major variables are identified that shape the association between slack and innovation. On the one hand, there is the propensity to experiment. Since innovations are always subject to risk and uncertain outcome, a resource cushion can facilitate to master the ups and downs along an innovation project. Additionally, managerial attention is increasingly focused on long-term projects in the presence of slack resources, as compared to low-slack situations, when managerial attention is tight and emphasizes short-term projects (Cyert and March 1963). Consequently, when slack resources rise, also the number of innovation projects can be expected to increase but only to a certain level because then the opportunities for innovations decrease and suggest diminishing returns from experimentation. However, the second variable, which is discipline, influences innovation propensity in a different direction. The presence of slack resources also relaxes control mechanisms exerted by management and leads to a situation where the degree of discipline in selecting, pursuing, and terminating innovation projects shows adverse outcomes (Leibenstein 1969). Nohria and Gulati (1997: 605) name two errors that might occur. The type I error describes situations when innovation projects get funded but should not be funded due to negative net values, and type II errors are decisions that stop projects that should be continued. However, not only can too lax discipline diminish innovation, this is also the case with too stringent discipline. Low levels of slack result in tight controls and therefore impede innovation projects. These findings, particularly the aspect of an inverse U-shaped relation between slack, have been reconfirmed by a number of follow-up studies (cf. Geiger and Cashen 2002; Herold et al. 2006; Kim et al. 2008; Mishina et al. 2004; Nohria and Gulati 1996).

While the two investigations by Nohria and Gulati (1996, 1997) do not distinguish among different forms of organizational slack as proposed by Bourgeois and Singh (1983), the study by Geiger and Cashen (2002) includes available, recoverable, and potential slack measures. Recognizing suggestions that different slack dimensions exert a different impact on the innovation, three different hypotheses were established, with each of them relating to one of the three slack dimensions. Consequently, it was argued that available slack was related inversely U shaped with innovation, recoverable slack was supposed to behave similarly, and potential slack was predicted to be related in a linearly positive way with innovation.

The study was based on a random 250 firm sample over a 10-year period drawn from the Fortune 500 database. Innovation was operationalized as the R&D intensity of the firm, available slack was measured by the quick ratio, recoverable slack was measured by sales expenditure, general and admin expenditure through sales, and potential slack was captured by the debt to equity ratio. Risk, firm size, product diversification, time, and administrative structure were included as control variables. The subsequent linear regression models illustrated that all hypotheses were confirmed. Thus, available and recoverable slack show the inverse U-shaped association with innovation, and potential slack seemed to have the positive linear relationship.

In contrast, Herold et al. (2006) argue that only unabsorbed slack measures are suitable to investigate the influence of slack on innovation. This is because all other slack resources are already incorporated into the organization, the recovery of which might be a difficult and lengthy process probably not supporting the role slack is supposed to play for innovation (Herold et al. 2006: 374). Unabsorbed slack was predicted to have an inverse U-shaped relation with innovation. Therefore, the quick ratio was the independent variable representing available slack, and the dependent variable innovation was operationalized by taking a look at the impact of a firm's innovation based on the number of citations referring to a specific company's patent. The statistical analysis supported the inverse U-shaped theory for available slack. Also, Kim et al. (2008) focused on only a single dimension of slack, which was financial slack as measured by the ratio of quick assets to liabilities. Innovation was captured as R&D investments with the statistical analyses of 253 Korean manufacturing firms resulting in an inverse U-shaped relationship between financial slack and innovation.

After all these empirical endeavors, is there any conclusion about the relationship between organizational slack and innovation? Empirical evidence supports three different assumptions. The first assumption holds a linearly positive relationship between organizational slack and innovation (cf. Aiken and Hage 1971; Barrett and Sexton 2006; Damanpour 1991; Franquesa and Brandyberry 2009; Geiger and Makri 2006; Greve 2003; Miller and Friesen 1982; Nystrom et al. 2002; Pohl and Elmquist 2010; Ruiz-Moreno et al. 2008). These results, however, are doubted by a number of other researchers, who found thorough evidence for their assumption, which supposes a linearly negative relationship between organizational slack and innovation (cf. Bolton 1993; Katila and Shane 2005; Manns and March 1978; Zajac et al. 1991). Thirdly, more recently researchers have commenced to combine both assumptions in a new model which proposes an inverse U-shaped relationship between organizational slack and innovation. The synthesis (inverse U-shaped relation) of the thesis (positive relation) and its antithesis (negative relation) found empirical support repeatedly (Fernandez and Wise 2010; Geiger and Cashen 2002; Herold et al. 2006; Kim et al. 2008; Nohria and Gulati 1996, 1997).

Conclusion and Future Directions

The analysis of organizational slack and its impact on innovation focuses on the organizational level. Therefore, factors situated at the individual level, e.g., the personal characteristics of innovators, their motivation, and cognitive abilities, but also characteristics of specific jobs are neglected. Slack is not even the most important organizational factor, as research has identified a number of further influencing variables such as structure, strategy, size, or culture. Assuming that one single variable explains how innovation emerges would be far too simplistic and myopic. On the other hand, innovation research has not yet come up with a comprehensive model considering all different levels of analysis and variables simultaneously (Damanpour 1991), and organizational slack shows at least some strong relationship with innovation in organizations. What can be learned from these results is that organizations need to be well equipped with resources to stay competitive through being innovative.

This basic interpretation of the literature is consistent with empirical findings according to which organizational slack enables innovation (cf. Fernandez and Wise 2010; Franquesa and Brandyberry 2009; Geiger and Makri 2006; Greve 2003; Herold et al. 2006; Kim et al. 2008; Nohria and Gulati 1997; Pohl and Elmquist 2010;

Ruiz-Moreno et al. 2008). However, discipline seems to be an important variable in funneling slack resources into innovation. With reference to theoretical considerations and empirical results yielded by Nohria and Gulati (1996, 1997), arguing for the considerable effect discipline exerts on the relation between slack and innovation, the disciplining external influence seems to stem from competition.

In view of the empirical results, there is still the question which mechanisms are at work to make slack impact on innovation. Recalling Nohria and Gulati (1997: 609), they suggest the following: “We propose two underlying mechanisms to explain the relationship: (1) the effect of slack on the process of experimentation, and (2) the effect of slack on the discipline exercised over experiments.” They argue that on the one hand, organizational slack enables creativity and experimentation, the probability of which to result in innovation is higher when simultaneously disciplinary forces are present as well. Otherwise, so the suggestion, slack resources would indeed increasingly be used for unproductive behavior. This interplay between slack resources on the one hand and a certain degree of discipline on the other hand is also reflected in the stage-gate model which proposes a sequence of stages enabling creativity and experimentation and gates, where thorough discipline is intended to streamline the innovation process (Cooper 2008: 214 p). A whole bulk of literature advocates distinguishing between available, recoverable, and potential slack. Even empirically, it has been shown that these different slack dimensions impact differently on innovation. Despite the convincing arguments, there is still room to doubt the relevance of this distinction.

The point here is that recoverable slack is a highly underspecified category since it might include financial slack, slack of human resources, slack of tangible assets, etc. Thus, when a lot of relevant variables are per se in the recoverable slack pool, as is the case with all HR-related slack variables, the difference has vanished and has moved to another level. A potential explanation is that the skills and motivation which are brought into the organization by its employees are key resources for organizations. Likewise, Pohl and Elmquist (2010, p. 380) argue that HR slack is responsible for the radical innovation process at VOLVO Cars even in the absence of financial slack. Therefore, employees equipped with both high motivation and a superior qualification and education background may contribute not only to routinized operations but to innovation as well.

To sum up, an in-depth analysis within the category of recoverable slack is essential to identify where differences emerge between the various slack measures and their impact on innovation. Prior research suggests that it is mainly slack in human resources, namely, motivation, skills, and competencies of employees, which foster innovation.

Nevertheless, even after 50 years of slack research, the question of causality between innovation and organizational slack has not been answered definitely. Theoretical slack models provide clear arguments for proposing that organizational slack fosters innovation. However, empirical results cannot doubtlessly confirm these theories. One major problem in empirical research is to solve the hen and egg problem, i.e., to concisely separate whether organizational slack is the consequence of successful innovations or vice versa.

Hospice and Palliative Care: Reactions in Modern Society

Until a few decades ago, people in Europe knew how to deal with the fateful destiny of death. Dying, death, and grief were all incorporated within the cycle of familial life. The social place for the beginning and the end of life was, in the broadest sense, the home (from the Greek *oikos*), the economy of the house, and the life – relationships within families and neighborhoods. Dealing with these crises of life was facilitated through natural, social, and traditional rituals and customs. People lived in a closely woven network of normative and ritualized customs and certainties. The menacing threats unleashed throughout life needed fencing in, taming, and domesticating: For centuries the ancestors had prayed, "From hunger, disease and war, plague, keep us, O Lord." As it was a relatively enclosed living environment, this construction of social reality was socially reinforced and confirmed. The religious concept of *heaven* (Gronemeyer 2012), arching almost self-evidently over individual and collective life, gave meaning and hope, as well as guidance in both good times and in bad, while the European Christian tradition provided the assurance that life does not end with the end of earthly existence. On the contrary, death and dying could be put in perspective with a glance at the sky – a view into the afterlife. Death, the care for the dead, and the survival of the mourners were in certain ways socially and ritually manageable.

Nowadays in Europe, this horizon of heavenly confidence is only observable in a religious minority. These religious certainties have lost much of their plausibility. Life has been radically secularized. How then should the modern, secular man handle his final frontier, and deal with his individual death? Should he just resign himself to fate? Or fight – planning and controlling his life, and taking his death in his own hands?

Today, the differentiation of society has given people radical freedom, releasing them from

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*, DOI 10.1007/978-1-4614-3858-8, © Springer Science+Business Media LLC 2013

socialties, and designing their own paths for life and death. Within society's market of opportunities, in the juggle between powers and ideologies, people will be forced to choose how to lead their own individual lives. It only stands to reason that you will have to tailor the last coat (*pallium*) for yourself. Modern society has developed a new branch of care which offers possible options for "end of life" as part of its healthcare management. With advance directives by the patient, an individual picture will be built around one's death, along the question of what is desirable (or undesirable) for them at the end of life. A growing network of professionalized and highly specialized hospice and palliative care staff ensures that the end of life will correspond to that picture. What people do not want is to be alienated, lonely, in pain, suffering needlessly, attached to machines and deprived of freedom – just a part of a large, anonymous medical system. An individual death, which is peaceful, gentle, with a suitable preparedness "to go," has emerged as the normative leading model. This is a question of "leading a good death" – something that does not seem possible without outside assistance. It is about quality of life in death, which can apparently only be delivered by professionals. The idea is to have a choice between euthanasia, and hospice and palliative care, a reality already possible in some European countries (Netherlands, Belgium, Luxembourg, and partially in Switzerland).

Palliative Care is at the Root of the Hospice Movement

Palliative care originates from the International Hospice Movement, whose implementation in German-speaking countries began with a slight delay – arriving behind their English and American counterparts in the 1980s. Within the framework of international euthanasia societies (right-to-die-movement, DGHS = German Society for Humane Death) calling for dignified death, for the purposes of criminal law and legalizing active euthanasia, and in the rapid development of highly specialized and technology-dominated medicine, it seemed impossible to have a dignified death in a hospital: The image of a "cold lonely death in a broom closet" was overwhelming. This compelled a focus for the hospice movement, with the objective of being able to die in dignity and character by the people concerned.

The thanatology research, substantiated by the Swiss physician Elizabeth Kuebler-Ross living in America, has made it clear: Even patients who have exhausted all therapeutic options have needs for contact and relationships, want to be respected and not abased, and will experience different dimensions of affective-cognitive altercation to their impending death. They will require empathic communication and extensive attention as a basic human right. This ground-breaking work has spread throughout the world, though it had long been misunderstood in the sense of a linear step system.

The British doctor, carer, and social worker Cicely Saunders, who saw herself as a committed Christian, is regarded as a pioneer of modern hospice work and Palliative Care. She helped open St. Christopher's Hospice in London in 1967 – after a 20-year "pregnancy" with this idea of establishing a home for the dying. The terms *hospice (work)* and *palliative care* were always used interchangeably in their mother country of England.

The hospice concept continues to live on under the idea of European and ancient oriental hospitality. Human life, conceived as a pilgrimage, is reliant on hospitality to find its path and the destination. Hospices offer hospitality without ulterior motive – they provide unconditional interest in others and for the sake of others in their own right. These hospices are not just buildings, but rather they represent an approach and attitude to people and culture in society. In times of increasing commercialization and managerialism of health care (*It counts only if you can count it!*), the hospice currently provides a critically different option in offering care and attention to people in need via assistance and support for end-of-life requirements. First and foremost, the hospice movement is simply a citizens' movement, supported by volunteers – dedicated people committed to the right and the opportunity for a good, dignified, and individualized death at the end of life, regardless of religion, race, gender, and financial status. In the German-speaking countries, palliative care (in Germany translated as *palliative medicine*) had eventually become marked by a profound process of professionalization, dominated by medicalization and institutionalization, and is still so influential today.

The term "palliative" is derived from the Latin *pallium* – meaning *coat*, and for a German-speaker, this would be described firstly as *enveloping*, or *wrapping*, in the sense of "caring protection." Etymologically, this Latin has roots in Indo-European: "Palliative" originates from "*pel*," meaning something akin to "fur" or "animal skin," and thus creating the meaning of "*pelte*," that is, defensive shield weapons for military use (cf. Morris 1997, cited by Clark and Seymour 1999). This dual aspect of "palliative" provides the affected persons to consider a more active role, and also highlights a "radical orientation for the affected persons" (Heller and Knipping 2007) by this approach in the modern health care system. The situation is always about an appropriate balance between too much and too little (invasive and therapeutic measures); it is about balancing the deceleration and acceleration of death, as described by the accepted WHO definition.

Conceptual Perspectives of Palliative Care

According to the globally accepted definition of the World Health Organization (WHO), palliative care is "*. . . an approach by which the quality of life of patients and their families will be improved if they are faced with a life-threatening illness and its associated problems. This shall be achieved through the prevention and relief of suffering by means of early identification, faultless assessment and treatment of pain and other physical, psychosocial and spiritual problems.*" (*WHO* 2002).

This definition includes the focused involvement of relatives and carers – that is, of persons affected by the suffering and of those connected to them – and of sharing in their concerns and care. Particular attention is given to the grief which sets in not only after death, but often also over the lengthy period of the diagnosis of a chronic disease, the multiple treatments until the death, and beyond. Although discussions concerning active euthanasia are currently in constant debate in many countries, the WHO definition is clearly limited in scope (Steffen-Bürgi 2007), though it is in the meanwhile seen as a normative guideline in the palliative care community.

In the revised version of the original definition dating back to 1990, there is a clear emphasis that the palliative care approach should come in very early on within the disease process – indeed, in parallel with other curative measures (WHO 2002). It remains open as to how these conceptual building blocks are to be implemented within different healthcare systems: thus, a variety of structures and forms have developed in Germany, Austria, and Switzerland over the past 20 years.

Specialist proposals resulted in an idea implemented through the development of primary care, and were mainly carried out by differentiated educational training and further education – from introductory training of volunteers to Master's courses in palliative care. (The first German-language training programs in palliative care were and are being offered by the IFF Faculty since 1999 as an interdisciplinary study in Vienna; other universities and colleges have followed suit according to this model, for example, Dresden, Freiburg, Salzburg, and St. Gallen). Another starting point is to look at the teething and interweaving of the development of individuals with the development of organizations; this is based on the view that a culture respecting death is always an *organizational* culture respecting death (Heller 2000a). Hospice work and palliative care are viewed as healthcare concepts focused on different emphases, especially in German-speaking countries.

Based on this understanding, palliative care will often be translated as "*Palliativversorgung*" in German, literally meaning *palliative provision or supply*. This simple translation does not imply the rich diversity of the English term *care*. The term *care* is not without problems, since it insinuates a division of labor in which it treats one party as the subject of care and the other as an object of care. Therefore, it seems appropriate linguistically to use the Scandinavian-origin concept of *Umsorge*, literally meaning *nurture* or *care*, when speaking of hospice and palliative care-culture.

Palliative Care – A Matter of Age?

In the development of the hospice concept, the applicability of these conceptual elements for the chronically ill and elderly was never strictly excluded – indeed they were even decidedly highlighted by Cicely Saunders: *Terminal care should not be a facet of oncology, but of geriatric medicine, neurology, general practice and throughout medicine* (Saunders and Baines 1983: 2).

Nevertheless, the concept was based on and developed for terminally ill individuals with cancer. Academic palliative medicine has been largely rooted within the context of university-oncology. There are, however, many other groups of affected persons (only about 25 % of people in Central Europe die from a tumor-based disease – 75 % die from something else altogether). The focus of attention in the last few years has been, in particular, on the deaths of older men and women. There have been pilot projects trying to establish a hospice and palliative culture in nursing homes (Heller and Kittelberger 2010).

For several years now, there has been a systematic dedication in palliative care discourse at the international level, focusing on other target groups, including older persons.

Creating a close link between Gerontology and Palliative Care, Seymour and Hanson (2001: 102) write, *"Both attend to the pursuit of symptom control, while advising the judicious use of investigations and rejecting highly invasive and aggressive treatment modalities; both make the person and their family the unit of care, and have led the way in developing multidisciplinary and community-based models of care. In so doing they have developed parallel discourses of 'patient-centered' care, 'quality of life,' 'dignity,' and 'autonomy.' Further, both disciplines focus on areas – aging and cancer – that tend to provoke strong, even 'phobic' reactions from the public at large."*

Showing the way is a WHO publication entitled "Better Palliative Care for Older People" (Davies and Higginson 2004). It calls for public health strategies at the national level, with the objective of improving palliative care for older people. The term *palliative geriatrics* has been experimented with in German-speaking countries, and it certainly insinuates a "medicalizing tendency" (Clark 2002). It does not accommodate appropriately for either the practice or the daily lives of the elderly, or the interdisciplinary theoretical reflection of the concerns and care of the elderly.

The revolutionary notion in this approach of a new care-culture at the end of life views the individual person, as a woman, man, child, or adolescent within the context of their life-relationships. The "care unit" is, therefore, the social system, not just the individual.

According to the concepts and "discovery" of Cicely Saunders, people suffer *comprehensively* (her concept of "total pain") – that is, biopsychosocially and spiritually. This multidimensionality in the anthropology of "Caring" is indeed a revolution which is not only represented by conventional medicine. It makes interdisciplinary theory and practice essential – a logical consequence designed to complement interprofessionalism, especially for the so-called voluntary workers, the citizens (in a civic concept of civil society) who maintain the continuity of care.

The WHO definition of palliative care also stresses the spiritual needs of dying people. In recent years, this information has raised the awareness with regard to other non-medical dimensions of end-of-life care: Different approaches were discussed either via an interreligious approach (Heller 2000b), or based on the reinterpretation of the role of pastoral care and medicine. Similarly, the area of gender-sensitive hospice and palliative culture is becoming increasingly important (Reitinger and Sigrid 2010), as is the realization that gender is also a significant dimension in the experience of suffering and pain (Lehner 2010).

Conclusion and Future Directions

Palliative care can be understood as an innovation within the healthcare system, both as an organizational and social innovation: interdisciplinary theory and practice are essential in the palliative care concept, while the "unit of care" is not just the individual, but the whole social system. The multidimensionality in the anthropology of "Caring" (on biopsychosocial and spiritual levels) can be seen as a revolutionary notion in this new care-culture, where the so-called voluntary workers and the "civil society" maintain the continuity of care.

Insofar the palliative care concept is also relevant for the knowledge society, because knowledge is not derived by the experts or professionals, but by the laymen. It is an anti-elitist approach, in which professionals act as supporters and facilitators, focusing on the needs of the persons concerned.

It must be noted that palliative care, within this multidimensional concept, has proven resistant to any form of machine-like image of man; it respects and recognizes people as subjects of their own lives, and strives for the required balance of autonomy and care needs in order to assist their social caregivers. It makes it necessary to reflect on the comprehensive work of the entire team, in both the outpatient and inpatient sectors, as well as being a part of a comprehensive care-culture within society.

Insofar that hospice work and palliative care have been forming a profound innovation within the healthcare system – and because this gap has been discovered and revealed as the "place for action" – the movement, as such, is guided by interdisciplinary, inter-professional, inter-organizational, interreligious, and intercultural principles.

Interestingly, hospice work is also an area where a new image of a "healthy death" (Wenzel 2012) can be created. Death is understood and attended to not as a result of disease or organ failure, but as part of a (spiritual) developmental process of a person, wherein pain may also be considered as an approach to a central dimension of life. "Healing" may then be possible, even if "curing" no longer is (Rakel and Weil 2003).

In this sense, hospice work and palliative care serve as a thorn within the medically and curatively oriented healthcare system, demanding a challenging discussion about death despite all the achievements of modern medicine not only for the dying individual, but equally for the relatives, carers, and professionals. Hospice work and palliative care do not only remind but also allow to trace (a society) back to the power of civil society, who is concerned to form and participate in new "cultures of care."

Introduction

Scholars have considered entrepreneurship only as a creation by an independent entrepreneur for a long time. However public policies reconsidered this view in the 1980s and encouraged the development of two new kinds of entrepreneurships: first, academic entrepreneurship during the 1990s, and second, corporate entrepreneurship (CE) in the following decade (Phan et al. 2009). At the end of the 1990s, public policies tried to improve the system of innovation and to speed up the conversion of fundamental research into commercial innovation. So, it encouraged the development of academic entrepreneurship (Nicolaou and Birley 2003). Academic entrepreneurship is a real breakdown with the traditional culture of university that focuses on the production of knowledge, and not on commercial purposes. Corporate entrepreneurship includes various kinds of organizational practices that allow the firm to develop new innovations in internal such as in external ways (Narayanan et al. 2009). Internally, the parent company creates a structure that remains linked to her by property rights. Scholars call such situation as a "quasi-firm." Externally, the means that are used to develop CE are more varied. The parent firm can purchase license, buy other firms, create joint venture, or use any kind of strategic alliances between organizations.

Scholars have discussed for a long time about the definition of partnership. Partnership can take two main definitions. In the first and larger definition, partnership can be assimilated to interfirms cooperation. Economists use more the term of cooperation whereas managers use the notion of strategic alliance, but the meaning is quite similar. Interfirms cooperation is defined by the fact that two or more organizations, that remain legally independent, will coordinate their objectives and can share various means of production (human, financial know-how, etc.) to attain a common goal. But the organizations are still competitors in the end-product market (Imai and Itami 1984). Such situation is often qualified as "co-opetition" because firms use both competition and cooperation. Interfirms cooperation can take various concrete forms: subcontracting is the more frequent form, R&D contracts, agreement of joint R&D, joint venture, etc.

In the narrower second sense, partnership is defined only as the evolution in the interfirms relationships from subcontracting to more equal relationships. In fact, subcontracting is in general linked with unequal relationships between firms. With this evolution to more equality the subcontractor becomes co-owner of the product and it is encouraged to innovate to regularly improve the product. The narrower definition is less used because it is too restrictive. Afterward we will use the first definition.

These two definitions appeared following the rapid increase of partnerships in the 1980s, especially between competitors. This point challenged scholars about this kind of organization of interfirms relationships. Scholars developed two main theoretical approaches to explain this growth of partnerships. The two approaches are the neo-institutional economics (Williamson 1975, 1985) and the resource-based theory of the firm and the evolutionist approach (Wenerfelt 1984; Teece and Winter 1990).

The emergence of partnerships will be different in the three kinds of entrepreneurships. Entrepreneurs in start-ups can mobilize partnerships to develop their firm only when it has been created (after the registration of the status). Before the setup of the firm, we will qualify the interaction with other organization as a social network. But before this moment the firm cannot use an interorganizational link by definition.

CE is not systematically linked with partnerships. In the case of internal creation, in most of the cases, the parent company grants self-determination to the spin-out to allow it to explore any risky innovation projects, reducing the financial risk for the rest of the organization. The parent company keeps stakes in the capital of the spin-out but it can sell them if the project fails. The amount of the stakes will determine the degree of autonomy of the spin-out and its ability to conclude partnerships by itself. We can talk of partnerships only when they are concluded with another organization than the parent company. As far as external means are concerned, purchasing license and buying another firm are generally not considered as partnerships, however joint venture and strategic alliance can be qualified of partnerships.

Academic entrepreneurship is characterized by its origin. Academic entrepreneurs come from the research sector and they keep their relationships with their former colleague. So, the entrepreneur uses former networks that come from links into the academic world to be informed about new opportunities and to set up a new organization.

What are the relationships between partnerships and entrepreneurship? First, we will begin by the influence of partnership on the development of entrepreneurship, and in the second part, we will treat the opposite relationship.

The Influence of Partnership on Entrepreneurship

Setup of a new organization needs different stages: detection of opportunities, pre-setup, setup, and then very often a reorientation of the project to assure the sustainability of the project development. In fact, the difficulty for setup is to pass from one stage to another. The new firm manages to pass the different stages by recombining resources networks and partnerships or by creating new resources. Doing so, the firm recombines and makes evolves it links with other organizations. The entrepreneur mobilizes first its social network before building a professional inter-organizational network. So, time is important to understand the relationships between entrepreneurship and partnership.

Evolution of the Nature of the Links Between Organization and Its Environment

A new entrepreneur, in order to set up his firm has to mobilize a network that must be more dense and must include as many diversified resources as possible to favor the setup of the firm.

The pre-setup stage is associated with social network (including family members, friends, and neighborhood) (Schutjens and Stam 2003). Such network cannot be defined as partnership because partnership is only an inter-organizational linkage. And at the stage of pre-setup, the organization does not exist. But when the start-up is set up on the market it begins to establish such inter-organizational links. Then, the social network of the entrepreneur evolves toward partnership. New entrepreneurs can mobilize partnerships with customers and suppliers of the firm where they were employed before the setup of their own firm, or they can create totally new partnerships with new actors.

Public Policy Toward Start-Up: The Rise of Public-Private Partnerships (PPP) and Their Influence on Entrepreneurship

States used PPP since the nineteenth century to provide collective services when the budget necessary to fund them was too important for the state's budget. They were used especially to build large infrastructures or collective equipment (as hospital or schools). But PPP were used extensively only in the 1980s because public debts became too important in most of the European countries. PPP in the field of innovation obey the same logic as the one described above. For the traditional economic theory of innovation, knowledge produced during innovation activities is a public good characterized by non-rivality and non-excludability. These characteristics justify public intervention. So states must fund public research to sustain innovative activity (Arrow 1962). PPP includes devices to encourage entrepreneurship but they are not really efficient.

During the 1980s, countries that have used the model of furniture of knowledge by the state, via public organism of research, encountered many technological failures. In France, for example, the "plan calcul" failed. So the European Union, especially France, tried to correct their innovation policies. France had to face the lack of private R&D funded by firms. So, it tried to increase the investment in fundamental research, and PPP device was a means to increase private spending. France impulsed this device quite recently, during the 2000s. Many kinds of PPP relative to innovation are used such as RRIT, CNRT, CRITT or devices for human resources such as ERT, CIFRE, and corthechs. More recently, the device of pole of competitivité and the increase of the part played by the organism in charge of the transfer of technology was encouraged. PPP should also increase entrepreneurship especially the academic one. RRIT gathers all the actors of a technological field: public organism of research, firms, universities, school of engineers, professional organization of a field, and club of entrepreneurs. But in practice, in France, very few PPP include entrepreneurs. The evaluation of RRIT demonstrated that it was incumbent firms that have proposed projects of innovation and not start-up. But in fact, if PPP are not an efficient device to promote entrepreneurship it is because public policy dissociates innovative projects in partnerships and measure to sustain entrepreneurship (MESR 2009). And the point is validated even if the definition of the device of PPP allows gathering all the actors in the field, including the entrepreneurs. The experience of other European countries gives the same mitigated result. For example, in Portugal, on 100 PPP studied, if almost all of them included associations of entrepreneurs of national regional or sectoral level, only eight PPP traduced on the development of innovative projects new entrepreneurs.

Influence of Entrepreneurship on the Kind of Partnerships Established

Difficulties for Start-up to Establish New Relationships

To introduce the point, we can remember that almost new entrepreneurs have a lot of difficulties to establish relationships with external organization and to create partnerships. Only 30% of new firms have two partnership relationships at the end of their first year of existence in addition to their standard relationships with suppliers and customers (Schutjens and Stam 2003). Besides, firms have many difficulties to stabilize these relationships during their first 3 years of ongoing business. Firms modify their networks during these years, diminishing their number to focus on the most important.

New technology based firms (NTBF) do not face such difficulties to establish new partnerships (Colombo et al. 2006). Seventy percent of the NTBF have at least one relationship during the first years. However the authors underline one difficulty; it seems that these firms face threshold effects, because of their lack of credibility in the marketplace. These firms are created around the innovative project and the competence relative to R&D and sometimes around the competence of development of products. They develop the competences of commercialization later. Throughout the first stage of development, they are too small to develop internally functions of commercialization and marketing. So they use partnerships with incumbent firms to access these competencies and the networks of distribution. NTBF are skilled in R&D and do not search in priority technological partnerships, but they can use partnerships in technology as complementary activities. For example, they can work as subcontractor on R&D contracts. In many cases, NTBF remain specialized on subcontracting of R&D and never develop capacities of production (Perez and Martinez Sanchez 2003). So commercial partnerships are dominant and represent 70% of the total of partnerships for NTBF versus 30% for technical partnerships. This kind of partnership remains important during the first 5 years of the firms and then they decline.

New firms have to establish partnerships, but in practice, many of them are reluctant to do so because they understand very well that such behavior is risky. NTBF that are highly skilled in scientific research are especially conscious of the risk to be expropriated from their knowledge by large incumbent firms. And their knowledge is a strategic asset for this kind of firm (Colombo et al. 2006). So, this behavior of large firm slows down the formation of NTBF's new partnerships till firms are able to protect their know-how, by patenting for example.

So, the most important difficulty for new firms will be to pass from the social to the professional network and to do so being able to protect their strategic asset.

Influence of the Entrepreneurs' Characteristics on the Kind of Partnerships: Difficulties to Diversify the Partnerships

Partnerships of New Independent Firms

Networks of new entrepreneurs evolve, after the start-up creation, from a social to a professional network (Schutjens and Stam 2003). The traits of the entrepreneurs influence the characteristics of partnerships they create. The question of the existence of a difference in the network of male and female entrepreneurs is still debated. Schutjens and Stam (2003) do not confirm the hypothesis, but Hoang and Antoncic (2003) found no difference between the two kinds of networks. Besides, characteristics of the firms influence its ability to establish partnerships. The intensity of R&D has an influence on partnerships. Firms that spend more in R&D establish more relationships than others. This relationship was regularly validated by econometrical studies since the 1980s. To own patents is a factor that influences positively the probability to establish relationships. Patents act as a signal of technological ability and help firms to create credibility to attract partners.

Small firms create fewer partnerships than bigger firms (Schutjens and Stam 2003). Firms in industry would create more partnerships than in services. But this result is validated only for technical partnerships (Colombo et al. 2006). Firms in service sector develop more commercial partnerships. At last, urban firms would have more partnerships than rural firms (Schutjens and Stam 2003).

Specificities of CE on the Kind of Partnerships Established

When a parent firm creates a spin-out, in fact the parent will serve as incubator for the spin-out. In function of the degree of autonomy that the parent let to the spin-out, the spin-out will have different possibilities to create partnerships (Parkhangras and Arenius 2003). These authors analyzed the creation of spin-out and identified three types of new firms. In the first group, the parent dissociates a subset of the company to explore risky technological project. It provides resources, such as financial or human or equipment, and then it only takes some stakes in the capital of the start-up. During all the exploration stages of the project, there are very few relationships between the parent company and the spin-out. This kind of spin-out never becomes an independent firm because if the project succeeds, the parent company buys all the stakes of the start-up and re integer it into the parent company. In this group, the spin-out has never enough time to establish partnerships with external organization.

In the second group, the parent company and the spin-out have the same technical basis. In most cases, the parent created the spin-out to provide it some special component that was difficult to purchase in the marketplace. R&D cooperation is strong in this group but with the parent company. As the time goes by, the marketplace can provide the components and purchasing on the market becomes less difficult. The parent firm can give autonomy to the spin-out and let him develop by himself. But then, the spin-out has to survive in the marketplace. As it is now an independent firm it can create the same partnerships as the one described in the first point. Spin-out of the third group is old and dissociated from the parent a long time ago. It is the case in more traditional sector, for example. At the beginning, the parent company plays the same part of incubator as described before; it shares resources with all the spin-outs. Then, the parent company generally refocuses on its core activity that is in most cases different from the core activity of the spin-outs. And at last, the spin-out becomes more and more a process developer. Links with the parent company loosen. Then the situation becomes the same as that described just before.

Academic Entrepreneurship and Partnership

Public policy tried to encourage academic entrepreneurship since the 1980s. Public policy maker's goal was to speed up the conversion of technological opportunities into commercial innovation. Literature on academic entrepreneurship takes up the literature about entrepreneurship and then brings to the fore the specificities of academic entrepreneurship. The literature underlines above all the lack of entrepreneurial culture in universities (Nicolaou and Birley 2003). Public policy tried to sustain the creation of start-up by academics, but in France, academic entrepreneurships are in fact in three fourth of cases scientific advisors in firms (MESR 2009). So scientific researchers do not often create their own start-up but let another person do it in most cases, such as an entrepreneur or an experienced manager.

Academic entrepreneurship can be associated to various degrees of implication of the scientific in the new firm. Scientific that give up their academic position are more implicated in the new firm and generally, this kind of firm grows faster. But, the academic diminishes his links with his prior university and at the same time takes the risk to slow down the speed of innovation in his start-up. Academic start-up generally maintains dense links with research and the scientific field. These traits are specific to the academic entrepreneurship, but contrary to more commercial start-up, academic entrepreneurs have often many difficulties to create market links with customers and suppliers (Perez and Martinez Sanchez 2003). But factors that slow down the establishment of networks can be the problem of trust in relationships with large incumbent firms (Colombo et al. 2006). In fact, many academic start-ups, at the end of any years of ongoing business, do not still commercialize any products at all, but remain specialized as subcontractor of R&D contracts. That choice of specialization reduces their need to establish partnerships.

Besides, these firms have difficulties to diversify their partners. Spin-outs located in scientific parks, for example, have relationships with the university of the academic but not very dense and very few relationships with other external partners.

Conclusion and Future Directions

Partnerships have grown very quickly since the 1980s. But theoretical approach of partnerships is not still taking into account all the implications of that growth, as Chesbrough (2003) indicates with the debate around the model of open innovation. Scholars have conceptualized innovation activity as an internal activity of the firm for a long time. All the innovative activities from research to development of the products should be developed internally. From Chesbrough's point of view, this model is coherent when scholars think innovative knowledge as a strategic asset of the firm. The main drawback of this way of thinking is the risk of the "Not invented here" syndrome for the firm. In fact, many large firms do not detect very profitable innovative project because they lose their perception of the competitors' projects and the evolution of clients' needs, thinking all their projects internally. The model of open innovation is a way of thinking project development by screening all the competitors' projects and clients' need and by using all the external sources possible to innovate. It implies that if a firm cannot develop a part of a project internally it can buy the technology developed outside or establish partnerships to develop it. This model encourages firms to create a dense set of partnerships for each firm. But on the other hand, the model does not question the risk of partnerships especially for small SMEs. Open innovation could have a positive impact on the corporate entrepreneurship, because this model encourages firms to stay innovative by screening their environment to pick up future profitable projects. The best way to achieve this goal is to be able to create spin-out regularly.

As far as public policy is concerned, various points are at stake, which are as follows.

Firstly, public policy has difficulties to sustain entrepreneurship in efficient ways. This point was underlined analyzing the PPP's device, where entrepreneurship was dissociated from innovative projects. More generally, in France, public policy about entrepreneurship follows two main goals: on the one hand, to encourage the creation of start-up, especially in the more high-tech sector of the economy, but on the other hand, to encourage the creation of their own job by the entrepreneurs during the time of economic crisis. This second way often leads to the creation of small firms in the service sector that are less innovative than the first kind of firms. Public policy puts in place various devices for each kind of new firms, but these devices are often not linked to each other that increase the difficulty for new entrepreneurs to identify the measure.

Secondly, as far as academic entrepreneurship is concerned, the main problem is the link of the new firm to the marketplace. This kind of new firm is well connected to the scientific research but often lacks the production and commercial skills needed to allow the growth of the start-up. It can also be the case when these academic entrepreneurs try to sell their knowledge. One of the possible measures of public policy should be to incite more systematically the academic entrepreneur to create their firm with another entrepreneur specialized in management or commercialization.

At last, public policy often underestimates the risks associated with partnerships especially for SMEs; besides, for these kinds of firms, knowledge constitutes very often their unique strategic asset (Colombo et al. 2006). The problem is the protection of intellectual property for small firms and for start-ups that are generally small. In general, SMEs do not perceive the importance of the protection of their intellectual assets and actual means of protection that fit for the large firms but not for SMEs. It is are case for patents, for example. Besides, European public policy develops at this time a pro-patent trend and does not create specific tools designed for SMEs.

Patent System

Eskil Ullberg
Interdisciplinary Center for Experimental Science, George Mason University, Fairfax County, VA, USA

Synonyms

Intellectual property rights; IP system; Patent

Definition

The patent system grants and enforces temporal exclusive, transferrable, and licensable private rights on inventions – that provide solutions to (mostly) technical problems in the area of products and processes – in exchange for disclosure of the invention to the public at a level that can be understood by a person skilled in the art.

In order for an inventor to receive such a right, the invention typically has to meet three criteria: (1) The invention has to be new, i.e., after search there is no prior art found, (2) There is an inventive step or non-obviousness to the idea, i.e., new prior art is created that required a flash of genius or long toil thus advancing technical knowledge that others can build on (not so simple anyone could discover it), and (3) The idea has to be industrially applicable or useful – which excludes schemas as natural laws, mathematical formulas, and some military strategic inventions – i.e., has a focus on industrial (economic) productivity. The ideas have to be technical in nature, except in the USA where nontechnical ideas also can be granted patents since the 1990s.

The patent system can be seen as operating under the principle of exchange between the inventor (or firm, university, research institution) and the state: An exclusive and tradable right is given for a limited time in exchange for disclosing to the public – teaching the world – about the invention, opening up for everyone to build on this previously private knowledge and invent further, thus creating *competition* in technical inventions. The system also establishes private and *tradable* property rights on new technology, creating the fundaments for a market in technical ideas. Such markets aught to allow, like all competitive markets, for specialization and specialization for increased productivity, wealth creation, and economic growth.

From an institutional perspective, the patent system is divided into two parts: the *patent office* and *patent enforcement* which sometimes is organized in specialized courts or specialized appeals courts. When granted, the patent is *presumed* valid and when enforced can be declared valid or be annulled. If patents are infringed by a third party, injunctions and stiff penalties can be deemed to the infringer based on the loss for the patent holder. However, an estimated 95 % of court cases are dropped prior to enforcement, resulting in a licensing agreement instead. The mechanism thus serves to give incentives for negotiation. It is important, for the well functioning of the patent systems, that procedures do give this incentive and not to rent seeking behavior.

The patent system was first established in Venice in 1474 and then spread via the Italian city states to first most European countries and in the nineteenth and twentieth centuries the industrialized countries of the world. Today, many emerging market countries are developing patent systems. See WTO/TRIPS agreement. The patent systems are national systems since about 150 years but remain essentially the same as the first system when it comes to the private, transferrable, and licensable right in exchange for disclosure.

A patent gives to its owner an exclusive right on a product or process which is new, inventive, and has an industrial application (in the USA, this third criterion is broader in the sense that the invention needs not to have an industrial application but must merely be useful). From a legal point of view, a patent is a negative right. It gives the right to exclude but not necessarily to use an invention, if this use leads to infringe a right held by someone else. The maximum duration of the patent protection is 20 years after the first application (but a majority of patents does not last this long). Also, in most countries, patent applicants must provide a description of their invention which, 18 months after the first application, is made public (made available to everybody). The description must be sufficiently clear and exhaustive in order to allow a person knowing the state of the art to reproduce the invention simply by reading the patent.

Originally, the patent system has been designed to provide entrepreneurs with incentives to invest in research and development (R&D) while, in the same time, ensuring a minimal level of knowledge diffusion (they are intended to solve the Arrow dilemma also called the incentives-diffusion dilemma, Arrow 1962). On the one hand, patents improve the level of appropriability over inventions (since they enable inventors to exclude imitators), which should increase incentives to invest in inventive activity. On the other hand, they participate to disseminate new knowledge since they are published. With respect to this double mission (provide entrepreneurs with incentives to both invent and disclose their invention), standard economic studies have thus been able to analyze the optimal length, width, and depth of the patent system (Scotchmer 2004).

Yet, in the last three decades, most economic studies (both theoretical and empirical) have questioned this traditional and simplistic view of the patent system (Levin et al. 1987; Mazzoleni and Nelson 1998; Jaffe 2000; Cohen et al. 2000). First, they show that patents are often not an efficient tool to prevent imitation because they are easily turned around and because they are often difficult to enforce in court (judicial trials are uncertain, long, and costly). Second, those studies also show that, for entrepreneurs, appropriation failure is usually not as important as considered by the classical view. Often, entrepreneurs can easily appropriate the value of their inventions without relying on patents (because, for instance, secrecy can be preserved, or the knowledge base is tacit, or technology is complex, i.e., not easy to reproduce). Third, recent economic studies stress that the production of innovation also faces a strong *coordination failure* and not only an *appropriation failure*. Innovation being a collective and interactive process, actors involved in this process need to interact, to collaborate, and to exchange knowledge. Yet, this collective process of knowledge production is often impeded by information imperfection and by the tacit dimension of the knowledge base. In sum, in a knowledge-based economy, the economic role of the patent system is likely to be more complex than what is presented by the traditional view (which considers only the role of patent as an instrument to exclude).

The following of this entry is divided in two parts. First, it describes the role of the patent system for entrepreneurs in a knowledge-based economy. In particular, it stresses that there is not one single role but a multiplicity of uses, according to the context. Second, it introduces the costs of patents for entrepreneurial activities and shows how patents may sometimes impede innovation.

The primary role of the patent system is not merely to restore appropriation but also to ensure the coordination of the innovation process. Patents are, in a sense, structuring elements of open innovation (Chesbrough 2003), because they cumulate two important properties: They both secure and disclose new knowledge. Those two properties imply that patents can improve both market and nonmarket coordination of the innovation process:

– *Market coordination*. Patents sustain the raise of markets for technology (Arora et al. 2001). Thanks to the patent system, innovative firms can directly specialize in knowledge production and sell their technologies to manufacturing firms via licensing agreements. They can also cross-license their patents, as it is typically observed in industries with complex technologies (in this second case, they barter their patents on markets for technologies) (Grindley and Teece 1997).
– *Nonmarket coordination*. Patents can also promote directly collaboration and knowledge exchange. First, because they signal relevant knowledge, which makes it easier for firms to find partners and to coordinate around a focal point, and second because, by securing technologies, they facilitate interfirm agreements. At the extreme, patents can also promote open-source type of knowledge production by preserving the openness of the knowledge base (Pénin and Wack 2008).

The role of the patent system for entrepreneurs is therefore very different from the image found in most economic textbooks. In a sense, patents may enable entrepreneurs to “include” other actors in the innovation process more than they “exclude.” This is all the more relevant that the invention is emerging, i.e., knowledge is tacit, and opportunities (market and technological) are uncertain. In those emerging situations, it is indeed likely that needs of coordination overcome needs of exclusion, which may induce entrepreneurs to use the patent system essentially in order to smooth coordination problems and to foster open innovation.

This evolution of the utilization of the patent system also leads to rethink the rationales to patent for entrepreneurs. In most cases, firms apply for a patent not in order to effectively prevent imitation and to exclude competitors but, more subtly, in order to obtain access to technologies held by rival, to signal competencies, to trade technologies on a market, to prevent other firms to patent, etc. Entrepreneurs must therefore acknowledge and exploit this multiple and strategic role of the patent system.

In particular, patents play a critical role to sustain the emergence of entrepreneurial firms (start-up, spin-offs, etc.) (Arora and Merges 2004). Those “fabless” firms (they do not have tangible fabrication) produce only knowledge, which is intangible and, in the absence of patents, can be appropriated only to a limited extent. Hence, it is straightforward to understand why patents are often critical to the survival of these firms: They contribute to solve the Arrow paradox (1962). Without patents it is likely that they would find it difficult to make money out of their knowledge and hence could hardly raise venture capital funds. In sum, patents may sustain the emergence of a new industrial organization, with a vertical division of labor between fabless firms, which produce knowledge upstream, and then sell their technologies to manufacturing firms located downstream on the value chain. The cases of the pharmaceutical and of the electronic sectors are two famous examples of such a new industrial organization, which sees the emergence of fabless, entrepreneurial firms.

However, the role of the patent system is not homogeneous across sectors. It depends critically upon the characteristics of the firm and of the industry it belongs to, in particular the competitive intensity and the technological regime. The technological regime of a sector defines all the features of the basic technology which underlies a given industrial production and which affects the strategy of the actors. Its main dimensions are the degree of appropriability of the technology, its more or less modular nature, its degree of complexity, the existence of network effects, etc. Different technological regimes lead to largely different patenting strategies, and this explains the major differences observed in the use of patents in sectors such as pharmaceuticals, electronics, software, chemistry, etc. Due to heterogeneous technological regimes, actors of the innovation process in those sectors must rely on different patenting strategies.

For instance, the simple nature of the technology in pharmaceuticals, coupled with the specificity of the regime of appropriation in this sector (natural appropriation is weak but legal appropriation via patent is strong), explains why, in line with the traditional view of the patent system, pharmaceutical firms use patents primarily to exclude. Conversely, the complex, multicomponent nature of the technology in electronics explain why in this sector patents are used primarily in a defensive way, i.e., not to exclude imitators but to prevent being excluded, hence preserving firms’ freedom to operate (Kingston 2001).

To sum up, in many industries patents are critical strategic instruments for entrepreneurs, which explain the burst of patent applications in fields such as life sciences and information technologies. Furthermore, the use of patents by entrepreneurs is not uniform and is not based solely on strategies of exclusion. It varies according to the context. The second part of this note aims now at exploring the problems that this new role of patents may raise.

Indeed, if the evolution in the utilization of the patent system can hardly be denied, a strategic use of patents can also entail serious costs and largely contribute to harm entrepreneurial activities. Standard economic theory mostly stresses the monopoly deadweight loss generated by the patent system. Since patents give monopoly power to their owner, during their period of validity they inevitably contribute to raise prices above marginal cost, which generates a loss of surplus for society. This static loss is believed to be the price to pay in order to foster dynamic efficiency (to increase entrepreneurs' incentives to innovate). Within this view, patents have only positive effects in the long run. They can never damage the innovation process and undermine the dynamic evolution of the system.

Yet, when patents are used strategically, costs that stem from the patent system may be very different and, above all, may affect the innovation dynamics, i.e., may have negative consequences on the long run. First, patents can impede the dynamics of innovation by preventing entrepreneurs from accessing existing knowledge. Innovation proceeds indeed cumulatively, and today's inventions feed tomorrow's inventions (knowledge is both an input and an output of the innovation process). It is hence primarily important for entrepreneurs to have access to existing knowledge. Yet, patents give an element of control on this knowledge, thus potentially raising the cost to access it. In other words, the exclusive right conferred to inventors must not be too strong in order to preserve incentives to develop future innovations. This is all the more the case with respect to sequential innovations, in which a delicate balance must be found in order to preserve incentives to invest both in first- and second-generation innovations (Scotchmer 2004; Pénin and Wack 2008).

Second, the multiplication of overlapping patents in some sectors (this is especially true in sectors such as electronics where the technology is complex) may generate what authors have referred to as a "tragedy and the anticommons" (Heller and Eisenberg 1998) or a "patent thicket" (Shapiro 2000). The idea is that the proliferation of fragmented patents on a given technology makes it prohibitively costly for entrepreneurs to develop this technology (it is the well-known problem of multiple marginalization). Each patent owner having a right of veto over the overall technology, potential developers must bargain with all the stakeholders, which, at the end, may undermine the development of this technology. Patent thickets may hence deeply influence the choice of research programs and affect technology trajectories. They may lead to closing some technological fields which, from a pure research point of view, would be worthwhile pursuing, thus generating huge dynamic inefficiencies.

Third, the development and institutionalization of the patent system may give birth to perverse behaviors which, in the long run, could harm innovation (Jaffe and Lerner 2004). For instance, opportunistic strategies of "patent trolls" or "patent sharks" on markets for technology may radically decrease incentives of entrepreneurs and manufacturing companies to invest in R&D. Trolls indeed use the patent system for the sole purpose of litigation, without any intention to use the technology protected by the patent. The business model of those firms is therefore literally to be infringed (in order to earn money via litigation fees), thus hijacking radically the primarily role of the patent system (to prevent infringement). While perfectly legal, this strategic use of the patent system is likely to harm innovative activities by decreasing the incentives of genuine entrepreneurs to invest those activities.

Conclusion and Future Directions

In the knowledge-based economy, patents are important strategic tools for entrepreneurs who, in many innovative sectors, could hardly develop their activity without them. But in the same time, patents are also susceptible to seriously damage the pace of innovation, mainly by increasing the cost of accessing existing knowledge and technologies, which entrepreneurs need in order to develop tomorrow's technologies. The net benefit of the patent system for society is the outcome of those two counterbalancing forces.

This discussion on the role of the patent system is essential because it contributes to introducing new dimensions to comprehend the present debate on intellectual protection.

Yet, future research will have to complete it at least with respect to three issues:

First of all, future research will have to develop a framework to understand the determinants of firms' optimal patenting strategies. This note has suggested that the technological regime may be a central determinant of firms' choices. Yet, future work will have to go further and build a theoretical framework which, ideally, should be detailed and precise enough so that it can help with decision making for practitioners and policy makers.

A second important research track deals with the normative implications of the strategic use of patents. As soon as patents are also considered as tools of coordination or even of collaboration in a framework of open innovation, conducting a welfare analysis becomes very difficult. New threats may appear in the long run (anticommons, patent thickets), but also new benefits (markets for technology, open innovation). Hence, improving the normative understanding of patents is essential since proper public decisions can only be taken provided that we understand the likely consequences of each possible change.

A third "hot spot" with respect to the strategic use of patents deals with their financial value. In a knowledge-based economy, in which firms' main assets are their knowledge and technologies, it is highly important to be able to properly evaluate the financial potential of those technologies. Putting a value on a technology (patented or not) is critical, just to give a few examples, any time firms are trading technologies on a market (licensing in and out), are looking for capital, are buying other firms, are funding a joint venture, etc. It might therefore become primarily important to develop financial tools in order to assess the value of technologies and of patents.

Again, if, as assumed by the traditional framework, the role of a patent is just to secure a monopoly position, it is feasible (but not easy) to evaluate its financial value. Methods exist in order to forecast the size of the market and to compute the current value of future expected profits with more or less precision. But those methods neglect completely the strategic dimension of patents. And with respect to this issue, very little is known. For instance, how to evaluate with accuracy the financial value of a signal? A collaboration? Freedom to operate? Precise results and methods are still lacking.

Patterns of Technological Evolution

Boris Zlotin and Alla Zusman
Ideation International Inc., Farmington Hills, MI, USA

Synonyms

Engineering (engineered) systems; Laws; Tendencies; Trends

Introduction

One of the most valuable outcomes of G. Altshuller' s endeavor with the *Theory of Inventive Problem Solving* (TRIZ) was the discovery that technological systems evolved not randomly but rather following objective *Patterns of Technological Evolution*. These patterns could be identified based on the analysis of historical development of various technological systems; once having been documented, they could be purposefully used for further system development of systems avoiding numerous blind trials. Eventually, patterns of technological evolution provided a means for *TRIZ Forecasting* and *Directed Evolution*® (registered Trademark of Ideation International Inc.) – controlling the evolution of technological systems rather than merely solving ongoing problems.

The relatively wide practical application of the first *TRIZ knowledge base tool – 40 Inventive Principles* during the 1970s revealed the dramatic range of efficacy of the principles: while certain principles prompted fairly conventional solutions (such as principle 3, *local quality*), others yielded strong solutions with narrow application (32, *changing the color*) and some offered robust and widely applicable solutions that could be further refined and strengthened. In time it became clear that the most powerful Inventive Principles represented strong, recurrent Patterns of Technological Evolution (such as 15, *dynamicity*) or supported them (25, *self-service* as a way to increase *the ideality of a system*).

The first set of Patterns of Technological Evolution was distributed by Altshuller among TRIZ schools in the spring of 1975. This seven-page manuscript became the most valuable component of TRIZ and established the foundation for TRIZ as a science (Altshuller 1984).

The set of patterns included three groups named after the laws of theoretical mechanics as follows:

Group 1 – Statics – determines the beginning of a system's life cycle, including:

1. Completeness of an engineered system
2. Energy flow in an engineered system
3. Harmonization of the synchronization rhythms or parts in an engineered system

Group 2 – Kinematics – determines the general evolution of a system, including:

4. Increasing ideality of an engineered system
5. Nonuniform evolution of subsystems comprising an engineered system
6. Transition to the overall system

Group 3 – Dynamics – reflects evolution in contemporary conditions involving certain physical and technical factors, including:

7. Transition from macro- to micro-level in an engineered system
8. Increasing substance-field involvement

While continuing his work on the Patterns, Altshuller established several critical requirements a pattern of evolution should comply with: be ***informative*** (describing how systems evolve), ***prognostic***, making it possible to predict the directions in which a given system would evolve; and ***instrumental***, helping to realize these directions and ultimately control the system's evolution.

In the fall of 1975, Boris Zlotin began teaching the first course on the Patterns of Technological Evolution to second-year students at the St. Petersburg People's University for Technical Innovation (SPUTI). During this and subsequent courses, Altshuller's patterns were presented in detail and illustrated with many examples, including military weaponry and even tactics and strategy. The active participation of many of the students (among whom were a number of talented engineers) prompted new ideas on the subject, encouraging attempts to further develop structure of the patterns via introducing *subpatterns* that were later called *Lines of Evolution* (sequences of actual steps within a particular Pattern). Although this structure was later criticized for its redundant complexity, the most important output of this attempt was the recognition that much room existed for enhancing and further developing the Patterns. Research efforts of various TRIZ theoreticians included studies in biological evolution (Vladimir Petrov and Boris Zlotin) as well as the evolution of science, art, language, social systems, etc.

In 1982, at the TRIZ conference in Petrozavodsk, Russia, Vladimir Petrov presented the forecasting of the evolution of electrical welding equipment (the first large-scale forecasting based on the Patterns of Technological Evolution). The second full-scale TRIZ forecasting was conducted by Boris Zlotin and Svetlana Visnepolschi for water pumps. The project also included a comparison of traditional forecasting and TRIZ forecasting methods.

Until 1985, the majority of studies on the Patterns were in technology, although examples of nontechnical applications were known and utilized in educational courses. Later, TRIZ forecasting projects included banks, mercantile and stock exchanges, educational systems, certain social systems, etc.

At the TRIZ conference in Novosibirsk, Russia, in 1984, several interesting works on the Patterns of Technological Evolution were presented, including:

- The "pulsing" model of evolution, by Yury Salamatov and Igor Kondrakov
- The increasing complexity and simplification of technological systems in the process of evolution, by Igor Vertkin
- Evolutionary patterns of methods and devices for curing broken extremities, by Nikolai Predein
- Two ways of increasing ideality of technological systems, by Boris Zlotin and Alla Zusman

By 1985, further development of the patterns of evolution became the primary focus of the Kishinev TRIZ School. The founders of this school changed the approach from working primarily with the patent library to studying the history of technology. The first results were published the same year (Altshuller et al. 1985), including:

- Upgrading the pattern of *coordination of rhythms* to *matching-mismatching of all technological system parameters*
- Introducing two new patterns: *reduction in human involvement* and *increasing dynamism and controllability*
- A new structure for the patterns, including multiple Lines of Evolution

In addition, several of Altshuller's patterns were omitted from the new system, in particular:

- Two patterns from the group Statics (*completeness* and *energy flow* in technological systems), as they represented the conditions for a system's emergence rather than its evolution. Moreover, certain cases were found that contradicted these patterns.
- The pattern *increasing substance-field involvement* related more to system models than to the evolution of real technological systems. However, the essence of the pattern related to the actual utilized field evolution, which was included as a line of evolution within the pattern *transition to the micro-level*.

Eventually, the following system of patterns was suggested (Zlotin and Zusman 1989):

- Stages of evolution (infancy, growth, maturity, and decline)
- Evolution toward increased ideality

- Nonuniform development of system elements
- Evolution toward increased dynamism and controllability
- Evolution toward increased complexity followed by simplification
- Evolution with matching and mismatching elements
- Evolution toward micro/multi-levels and the increased use of fields
- Evolution toward decreased human involvement
- TRIZ and elements of creative education

Given the above, it can be said that over the last 65 years TRIZ has grown from a problem-solving methodology to a ***science of technological evolution***, with the Patterns of Evolution at its core. At the same time, all known patterns are empirical in nature and therefore can describe the main direction ("what") of a system and its actual evolution ("how") but lack the "why" – that is, an explanation of the origin and driving forces of technological evolution. Obviously, finding answers to these questions is critical for revealing and structuring the patterns and for TRIZ becoming widely recognized as a science.

Another important aspect of converting knowledge about evolutionary patterns into a real science is consensus with regard to the main definitions and assumptions. To date, TRIZ literature refers to laws of evolution, patterns of evolution, trends of evolution, and lines of evolution. Different translations from Russian into English and other languages also contribute to the confusion.

Definitions and Assumptions

Definitions

The first attempt to clarify definitions for English terms for the main TRIZ elements related to technological evolution was made as follows (TRIZ in Progress 1999):

An *evolutionary trend* is a sequence of events directly and/or indirectly connected through cause-effect relationships. Each event in the chain (alone or together with the others) leads to the next one and thus increases the probability of its emergence. A trend may represent a limited (specific) model of an evolutionary process that describes its specific feature(s). Examples of trends in social life, technology, science, fashion, art, etc. are well known.

Examples.
- *Growth of "high-tech" technologies*
- *Increasing attention to the environment*
- *Increasing utilization of synthetic materials*

A *Pattern of Evolution* represents a strong, historically recurring tendency in the development of technological systems.

Examples.
- *Evolution toward decreased human involvement*
- *Evolution toward increased dynamism and controllability*
- *Evolution toward micro-levels and the increased use of fields*

A *Line of Evolution* reflects the historical sequence of changes that a technological system undergoes during its evolution.

Example. *A multistep transition that includes the following steps:*
1. *Use of a permanent field*
2. *Transition to a pulsed field*
3. *Utilizing a pulsed field with matched frequency*

While a trend might be a short-lived event (e.g., certain styles in consumer products) patterns and lines represent the strongest long-term (often permanent) trends. In other words, a pattern of evolution addresses *what* exactly will happen as a result of evolution (e.g., increasing dynamism); a line of evolution shows *how* this goal will be accomplished (step-by-step).

Selected Assumptions

Evolution at the Expense of Resources

A system's evolution proceeds via the consumption of various *resources* existing in the system itself, its neighboring systems, and/or the system environment. Each evolutionary step generates new resources that can be used to further develop the given system as well as other systems. However, negative resources that can cause undesirable effects might also result from the evolutionary process (Zlotin and Zusman 2001).

Short-Versus Long-Term Forecasting

A system's short-term evolution (improvement) depends primarily on the resources inherent in the system. Long-term development, including next-generation systems, breakthroughs, etc., depends on the evolution of the overall technology and/or market rather than on the particulars and resources of the given system.

Limited Number of Ways to Perform a Function

A function can be realized in a limited number of distinguishable ways based on the utilization of available resources. New types of resources might arrive as a result of a discovery.

Formation of Specialized Lines of Evolution

For a specific system or for systems of a certain type (e.g., measurement and control systems, milling systems, software, etc.) a set of specialized lines of evolution can be developed that will reflect and take into consideration the main particulars of that system or system type.

Driving Forces of Technological Evolution

Any TRIZ specialist practicing TRIZ forecasting or Directed Evolution for products and/or technologies would eventually realize that to make a reliable forecast for a particular subsystem (such as a car door or cleaning products) one must first understand where the higher-level system is headed (the automobile for the car door, the home for the cleaning products). Furthermore, the design of the car or home might be governed by certain environmental and/or social regulations. At the same time, requirements imposed by a higher-level system are always dominant and "force" the subordinate system (or subsystem) to evolve accordingly (with the "permission" from technology, of course). Indeed, technological evolution is not an isolated process but rather is an aspect of the more general evolution of society; moreover, the evolving world resembles a Russian nested doll (*matreshka*) with multiple evolution processes of different scale taking place both independently and interdependently.

Given the above, it can be suggested that the evolutionary trends/patterns of the higher level serve as evolutionary driving forces of the lower levels. This suggestion can explain why the Patterns of Technological Evolution are so strong and reliable. For example, the pattern *increasing dynamism* is strong because increased dynamism means more flexibility – an important performance feature that in turn provides more convenience for the user. This pattern also could be considered long-term (or even permanent or "eternal") because convenience is an "eternal" user's benefit.

Orientation according to the main user benefits can help create a certain structure for evolutionary patterns. These main user benefits could be listed as follows (in no particular order):

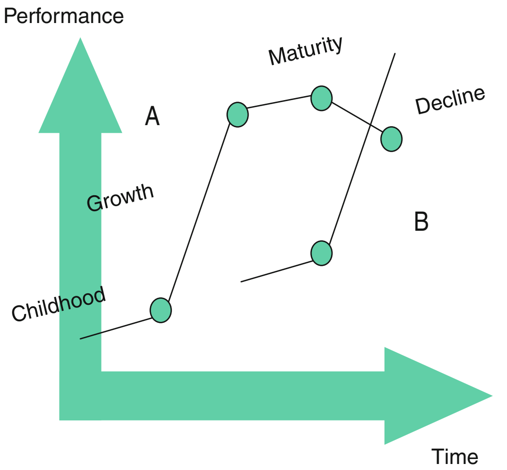
- System performance (i.e., providing a certain positive function)
- Cost
- Quality (reliability, absence or limited number of drawbacks and side effects)
- Safety/security
- Fun associated with the owning and/or utilization of the given system

It seems reasonable to suggest that these main requirements serve as a natural selection mechanism for all man-made systems.

General Patterns of Technological Evolution

Stages of Evolution

In the process of evolution, technological systems evolve along S-curve with specific definite stages as shown below (Fig. 1).



Patterns of Technological Evolution, Fig. 1 Stages of evolution (Altshuller 1984)

Stage 1 (Childhood) – A new system A appears due to a high-level invention and begins slow development.
Stage 2 (Growth) – Begins when society recognizes the value of the new system.
Stage 3 (Maturity) – Begins when the resources of the system's original concept is mostly exhausted.
Stage 4 (Decline) – Begins when a new system B or next system generation emerges to replace the existing one.

Depending on the stage, different recommendations on further development of the given system are recommended (Altshuller 1984, Zlotin and Zusman 2001).

Later, an extended and more detail S-curve was introduced (Fig. 2):

Under this approach, two additional stages have been indicated:
Stage 0 – A system does not yet exists but important conditions for its emergence are developing.
Stage 5 – Begins if the new system does not completely replace the existing system, which still has limited application.

In addition, stages 1–4 have been divided into three substages (beginning, middle, and end) as the system behavior could be very different during different parts of a stage.

Selected lines for this pattern include for each stage:
- Typical objectives
- Typical mistakes
- Typical features

Evolution Toward Increased Ideality

Technological systems evolve in the direction of increasing *ideality*. Ideality for a given system can be defined as the ratio of the sum of its useful features (benefits) to the sum of harmful (or undesired) factors. Therefore, system's ideality can be increased by increasing its useful features, reducing the harmful ones, or both.

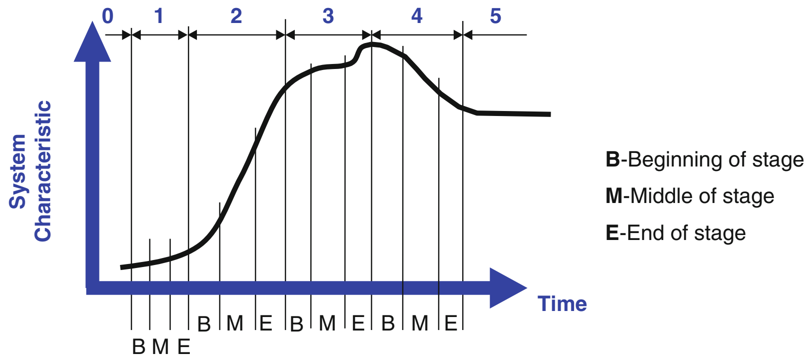
Typical lines for this pattern include:
- Increasing system benefits
- Reducing harmful factors
- Increased involvement of *resources*

Given the above, there are several possible general ways to gradually increase Ideality:
1. Increase the number of useful functions/features, including:
   - Absorbing the useful functions of other systems nearby the given system, or of the environment
   - Inventing new useful functions
2. Improve the quality (and other parameters) of the useful functions
3. Reduce the number of harmful factors, including:
   - Eliminating/preventing harmful factors
   - Diverting harmful factors to other systems or parts where the harmful influence is less critical
   - Finding useful applications for harmful factors
4. Reduce the magnitude of harmful parameters
5. Combine the above actions to ensure a higher ratio

Non-uniform Development of System Elements

In the process of evolution, different components of a technological system usually evolve according to their own schedule. As a result, they might reach their inherent limits at different times, causing *contradictions* preventing further evolution of the given direction.

Patterns of Technological Evolution, Fig. 2 Extended S-curve (Zlotin and Zusman 2001)



A component that reaches its limit first is usually "holding back" the overall system development. To ensure further system development, the component(s) holding the system back have to be identified and contradictions limiting further evolution have to be removed (resolved).

Evolution Toward Increased Dynamism and Controllability

In the process of evolution, technological systems become more dynamic and allow better handling (higher controllability), that is, become more adaptive to contradictory requirements and to the environment.

Increased dynamism and controllability allows the system to conserve high ideality in changing conditions. An airplane wing, a car seat, a bed, and many other things became changeable, flexible, and thus much more comfortable.

Typical lines for this pattern include:

- Transition to multifunctional performance
- Increasing degree of freedom

System's dynamism could be increased via:

- Decreasing the degree of stability
- Transition from a stationary to a mobile condition
- Dividing into mobile parts
- Introducing a mobile object
- Applying different physical and chemical effects

System's controllability could be increased via introducing:

- Control field
- Controllable additive
- Controllable antiprocess
- Self-control of the system
- Negative or positive feedback

Evolution Toward Increased Complexity Followed by Simplification (Reduction)

In the process of evolution, technological systems tend to develop first toward increased quantity and quality of system functions (function deployment) resulting in increased system complexity. After improved functionality is achieved, the system developers try to simplify the system (reduction) maintaining the achieved functionality.

In a particular system evolution, the stages of deployment and simplification take place in turn forming cycles (each cycle includes one deployment and one simplification). They also can partially overlap. For example, while the overall system is in the simplification process, its subsystems can still be in deployment, and vice versa.

Typical lines for these patterns include:

- Transition to mono-bi-poly-system
- Idealization

There are several scenarios for system deployment:

- Introducing new subsystems extending functional capabilities
- Segmentation (dividing the system into parts with different functions assigned)
- Integration, including duplication, multiplication, or Integration "up" (the given system is included into a higher-level system as a part together with some others)

- Hybridization (combining systems with similar functions implementing different principle of operation)

For simplification step, one can use the following selected recommendations (other techniques known as *trimming* and *idealization* could be also utilized):

- Excluding duplicate elements
- Using more highly integrated subsystems
- Excluding auxiliary functions
- Introducing self-service
- Simplification through total replacement (changing principle of operation of subsystems)

Evolution with Matching and Mismatching Elements

In the process of evolution, systems' elements and parameters are undergoing a number of steps involving matching and/or mismatching to improve performance or to compensate for undesired effects.

The process of matching starts from the beginning of the system's existence when necessary system elements are selected and combined in one system. Besides providing minimal performance, these elements have to be compatible. Compatibility is very important for the overall performance; that is why sometimes the elements with the best individual performance might not be the best from the overall system performance point of view.

Matching/mismatching could be applied to the following elements:

- System structure
- Materials
- Functioning
- Parameters

One of the typical lines for this pattern is shown below. These steps constitute a cycle that can be repeated as the system evolves.

Step 1: From unmatched elements to matched ones

In the beginning of a system evolution, the system could be assembled from subsystems and parts that are available and have never worked together before. Next, various adjustments are made to improve their compatibility.

Example. *The first automobile was assembled from a horse carriage, an engine, and other elements. Later, these elements were modified to work in a new environment.*

Step 2: Intentionally mismatched systems

In many situations, the system elements can be intentionally mismatched to obtain new useful features or avoid negative effects.

Example. *Automobile front wheels are made slightly nonparallel to ensure that after making a turn a steering wheel automatically returns to the straight position.*

Step 3: Dynamic matching-mismatching

Often a system should work in changing (dynamic) conditions. In this case, the system would alternate its state to match those conditions.

Example. *An airplane wings change its shape to match higher speed and goes back when the speed drops.*

Evolution Toward Micro/Multi-levels and Increased Use of Fields

In the process of evolution, systems tend to utilize multiple systemic (structural) levels available in the given system, capitalize on their properties and increase use of *fields* and various physical states.

Typical lines for this pattern are shown below:

1. Utilization of deeper structural levels or combinations of these levels, using:
   - System made of elements with specific shapes
   - Poly-system made of elements with simple shapes
   - Poly-system of small elements (powder, microspheres, granules, drops, etc.)
   - Effects associated with substance structure (super-molecular or crystal level)
   - Molecular phenomena
   - Atomic phenomena
   - Field actions instead of substances

Patterns of Technological Evolution, Table 1 Utilization of fields and/or combinations of fields (Table 1, Zlotin 2001)

Basic field	Specific fields	Special corresponding substance(s)
Mechanical	Gravity	
	Pressure	
	Shocks, vibration	
	Explosion	Explosives
	Acoustic waves	
Thermal	Heating/cooling Aggregate state transformation	Water-ice-vapor
		Bimetals
		Shape-memory effect materials
Chemical		Catalysts, inhibitors
Electrical	Electrical charges	Dielectric materials
	Electrical current	Conductive materials
Magnetic	Electrical current	Conductive materials
	Permanent magnetic field	Magnetic materials, magnets, ferromagnetic particles

2. Utilization of the following fields and/or combinations of fields (Table 1, Zlotin 2001):

Evolution Toward Decreased Human Involvement

In the process of evolution of various systems, gradual reduction of human involvement has been taking place, increasing the level of systems automation until the system becomes completely manless.

Typical lines for this pattern include reducing human involvement in:

1. Operation (execution), using:
   - Simple mechanical tools instead of hands, teeth, etc.
   - Mechanical energy transformers and accumulators for human power, such as levers, gears, jacks, bow, springs, sling, etc.
   - Nonhuman energy sources (animals, wind, water, steam, chemical power, electrical power, nuclear power, etc.)
2. Process control (management), using:
   - Tools to control system functioning, such as rudders, steering wheels, airfoils, guides, etc.
   - Special devices to transform control commands, such as amplifiers, reducers, filters, rectifiers, stabilizers, modulators/demodulators, etc.
   - Devices to produce control commands, such as cams, gyroscopes, punched cards, etc.
3. Decision making, using:
   - Various sensors (mechanical, thermal, chemical, electrical, magnet, etc.) instead of human senses as information tools
   - Devices for processing information – that is, analyzing, summarizing, measuring, verifying, etc.
   - Devices to make decisions based on information analysis

Conclusion and Further Directions

1. Over the last 65 years, TRIZ has grown from a problem-solving methodology into the ***science of technological evolution***, with the Patterns of Evolution as its core. At the same time, we know that all known Patterns are empirical in nature and therefore can describe the main direction ("what") of a system and its actual evolution ("how") but lack the "why" – that is, an explanation of the origin and driving forces of technological evolution.
2. Technological evolution is not an isolated process but rather is an aspect of the more general evolution of society; higher-level evolutionary trends/patterns serve as the driving force for evolution at the lower level. Because higher-level super-systems include human needs and social requirements, Patterns of Technological Evolution are enforced by the general demand and expectation of customers.
3. Using knowledge of the Patterns of Technological Evolution in conjunction with analytical methods and other instruments provides the following benefits:
   - Ensuring a substantial advantage over competition

- Avoiding costly and often irreparable strategic mistakes in product development and marketing.

4. In spite of over 30 years of history, Patterns of Technological Evolution is a rather new area of research. Further directions could be:
   - Finding an optimal structure of exiting patterns
   - Development of additional lines of evolution, including specialized lines
   - Obtaining actual statistical data on known patterns of evolution
   - Extending the concept of patterns of evolution into other areas, including nontechnical areas, like evolution of arts, social evolution, etc.

Planned Economy and Entrepreneurial Function

Jesus Huerta de Soto
Catedrático de Economía Política, Universidad Rey Juan Carlos, Madrid, Spain

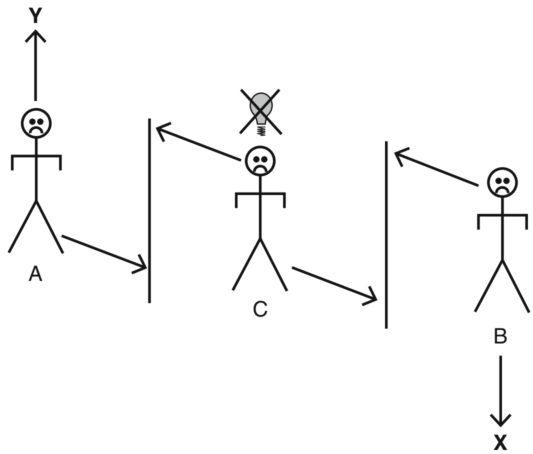
Synonyms

Entrepreneurial creativity; Entrepreneurial knowledge; Government commands; Institutional coercion

Entrepreneurship is a key concept for any definition of the planned economy. In fact, the planned economy or "socialism" could be defined as any *system of institutionalized aggression against the free practice of entrepreneurship* (Huerta de Soto 2010, p. 49). *Aggression* or *coercion* must be understood to mean any physical violence or threat of physical violence which is originated toward and performed on an individual by another human being or group of human beings. As a consequence of this coercion, the individual, who would have otherwise freely carried out his or her entrepreneurship, is, in order to avoid a greater evil, forced to act differently to the way he/she would have acted under other circumstances, thus modifying his or her behavior and adapting it to meet the ends of the person or persons who are coercing him or her. Aggression, thus defined, is considered to be the antihuman action par excellence. This is so because coercion prevents a person from freely carrying out his or her entrepreneurship, that is, from seeking the objectives he/she has set using the means which, according to his or her information and to the best of his or her knowledge, he/she believes or considers to be accessible to him or her for reaching these objectives. Aggression is, therefore, an evil because it prevents the human being from carrying out the activity which is most characteristic of him or her and which essentially and most intimately corresponds to him or her (Hayek 1959, pp. 20–21; Rothbard 1970, pp. 9–10).

There are two types of aggression: systematic or institutionalized and nonsystematic or noninstitutionalized. The latter type of coercion, which is, by nature, dispersed, arbitrary, and more unpredictable, affects the execution of entrepreneurship to the extent that the individual considers there to be a greater or lesser probability that, in the context of a specific action, force will be used upon him or her by a third party, who may even appropriate the results of his or her entrepreneurial creativity. Although nonsystematic outbreaks of aggression are more or less serious, depending on the circumstances, institutionalized or systematic aggression is far more serious as regards coordinated human interaction. This type of aggression constitutes the essence of the given definition of socialism (Hoppe 1989, p. 2). In fact, institutionalized coercion is characterized by being highly predictable, repetitive, methodical, and organized. The main consequence of this systematic aggression against entrepreneurship is to make largely impossible and perversely divert the execution of entrepreneurship in all the areas of society where the said aggression is effective. Figure 1 presents the typical situation resulting from the systematic practice of coercion.

In Fig. 1, it may be assumed that, in an organized and systematic way, the free human action of C in relation to A and B in a specific area of life in society is prevented by coercion. This is represented by the lines which separate C from A and B. As a consequence, it is not possible, as systematic coercion prevents it by the threat of serious evils, for C to discover and take advantage of the profit opportunity which he would have if he could interact freely with B and



Planned Economy and Entrepreneurial Function, Fig. 1 Human action and coercion (Source: Author)

with A. It is very important to clearly understand that the aggression does not only prevent him from taking advantage of the profit opportunity, but also prevents the discovery of this opportunity. The possibility of obtaining gains or profits acts as an incentive to the discovery of these opportunities. Therefore, if a determined area of life in society is restricted by systematic coercion, the actors tend to adapt to the said situation, they take it for granted, and therefore, do not even create, discover, or become aware of the opportunities which are latent. This situation is presented in the figure by crossing out the light bulb which indicates the creative act of pure entrepreneurial discovery.

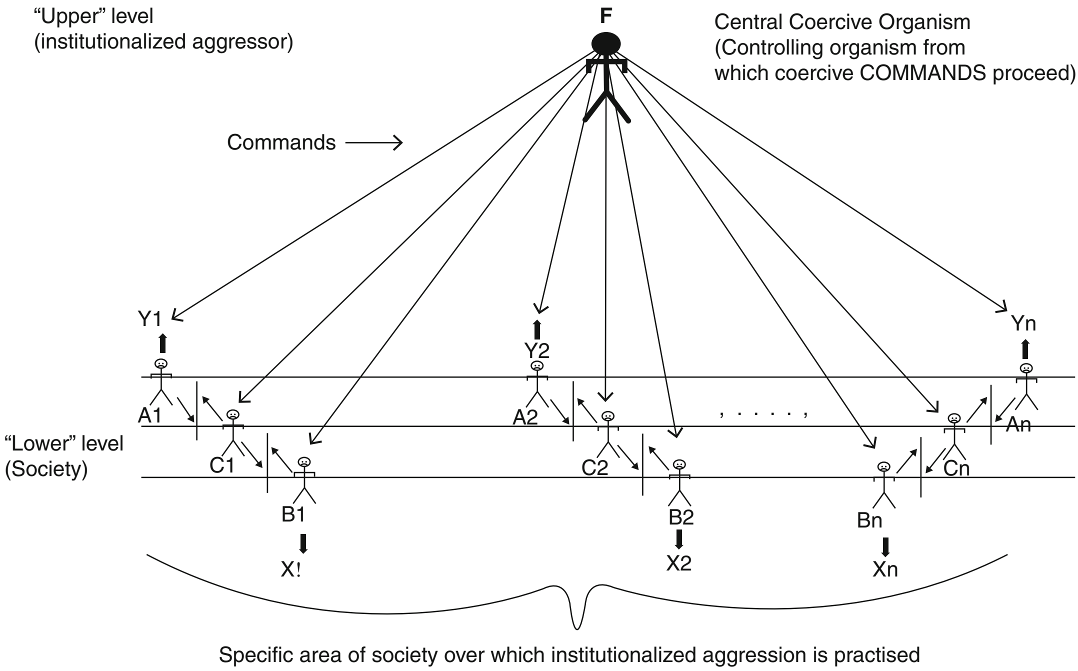
If the aggression falls systematically upon one social area and, as a consequence, entrepreneurship cannot be carried out in that area, none of the other typical effects of the pure entrepreneurial act will take place. In fact, in the first place, new information will not be created, nor will it be transmitted from actor to actor. Second, which is a cause for even more concern, the adjustment necessary in cases of a lack of social coordination will not occur. As the discovery of opportunities for profit is not permitted, there will be no incentive for the actors to become aware of situations of lack of adjustment or coordination which arise. In short, information will not be created, it will not be transmitted from one agent to another, and the different human beings will not learn to discipline their behavior in accordance with that of their peers.

Thus, as C cannot carry out entrepreneurship, the system is maintained continuously uncoordinated (Fig. 1): A cannot pursue end Y due to lack of a resource which B has in abundance and does not know what to do with. He, therefore, squanders and misuses it, unaware that A exists and needs it urgently. As a conclusion, the main effect of the planned economy, as it is defined in this text, is to prevent the action of the coordinating forces which make life in society possible. Does this mean that the proposers of the planned economy are advocating a chaotic or uncoordinated society? On the contrary, apart from a few exceptions, the proposers of the socialist ideal defend it because, tacitly or explicitly, they believe or suppose that the system of social coordination not only will be undisturbed by the existence of the institutionalized and systematic violence which they favor, but will be made much more effective by the fact that the systematic coercion is performed by a controlling organism which is supposed to possess knowledge (regarding both the ends and the means) and valuations which are better, both quantitatively and qualitatively, than those which the coerced actors may possess at a lower level. From this perspective, the definition of the planned economy given at the beginning of this section is now completed, stating that *it is all systematic and institutionalized aggression which restricts the free performance of entrepreneurship in a determined social area and which is carried out by a controlling organism which is in charge of the tasks of social coordination necessary in the said area*. Under the following heading, the analysis will discuss the point to which socialism, as defined above, is or is not an intellectual error.

Socialism as an Intellectual Error

Life in society is possible thanks to the fact that individuals, spontaneously and without realizing it, learn to modify their behavior, adapting it to the needs of other people. This unconscious learning process is the natural result of the practice of entrepreneurship by human beings (Kirzner 1973, 1979, 1985, 1989). This means that, upon interaction with his peers, each person spontaneously initiates a process of adjustment or coordination in which new information – tacit, practical, and dispersed – is continually being created, discovered, and transmitted from one mind to others. The problem posed by the planned economy is whether it is possible, by the coercive mechanism, to verify the processes of adjustment and coordination of the conduct of different human beings, which depend upon each other and which are indispensable if life in society is to function – all the foregoing taking place within a framework of constant discovery and new creation of practical information which makes it possible for civilization to advance and develop. The ideal put forward by socialism is, therefore, highly daring and ambitious (Mises 1981, p. 40) as it implies the belief that not only may the mechanism of coordination and social adjustment be made effective by the controlling organism which performs the institutionalized coercion in the social area in question but that, in addition, this adjustment may even be improved by the coercive procedure.

Figure 2 is a schematic representation of the planned economy as it is defined in this text. On the "lower level" are human beings, endowed with knowledge or practical information, who, for this reason, try to interact freely among themselves, although such interaction is not possible in some areas due to institutionalized coercion. This coercion is represented by the vertical lines which separate the figures forming each group. On the "upper level," there is the controlling organism which, as an institution, practices coercion in determined areas of life in society. The vertical arrows in opposite directions, which come from the figures on the left and right of each group, represent the existence of unadjusted personal plans which are typical of a situation where there is a lack of social coordination. Cases of lack of coordination cannot be discovered and eliminated by entrepreneurship because of the barriers imposed by the effect of institutionalized coercion



Planned Economy and Entrepreneurial Function, Fig. 2 Schematic representation of the planned economy (Source: Author)

on entrepreneurship. The arrows which go from the head of the controlling figure toward each human being on the lower level represent the coercive commands which comprise the aggression typical of the planned economy, aimed at compelling the citizens to act in a coordinated way and to pursue end F which is considered "right" by the controlling organism.

The command may be defined as any specific instruction or stipulation, the contents of which are clearly defined, which, regardless of the legal form it takes, prohibits, or compels determined actions to be taken under specific circumstances. The command is characterized by the fact that it does not allow the human being to freely carry out his or her entrepreneurship in the social area it refers to.

Commands are, moreover, deliberate decisions of the controlling organism practicing institutionalized aggression and are aimed to force all the actors to fulfill or pursue, not their personal ends, but the ends of those who govern or control.

In view of the foregoing, planned practices or "socialism" is an intellectual error because it is not theoretically possible that the organism in charge of practicing institutionalized aggression possesses sufficient information to endow its commands with the contents of a coordinating nature. The next section will examine this simple argument with more detail from the overall perspective of the human beings who constitute society and who are coerced.

The Impossibility of Socialism from the Perspective of Society

The Static Argument

First, from the point of view of human beings who interact among themselves and constitute society (the so-called lower level as in Fig. 2), it must be remembered that each of them possesses exclusive practical and dispersed information, the majority of which is tacit and, therefore, cannot be articulated. This means that it is logically impossible to conceive of its possible transmission to the controlling organism (the so-called upper level in Fig. 2). In fact, it is not only that the total volume of practical information sensed and handled by all human beings at an individual level is so enormous that its conscious acquisition by the controlling organism is inconceivable, but, above all, that this volume of information is disseminated among the minds of all men in the form of tacit information which cannot be articulated and, therefore, cannot be formally expressed or explicitly transmitted to any controlling center.

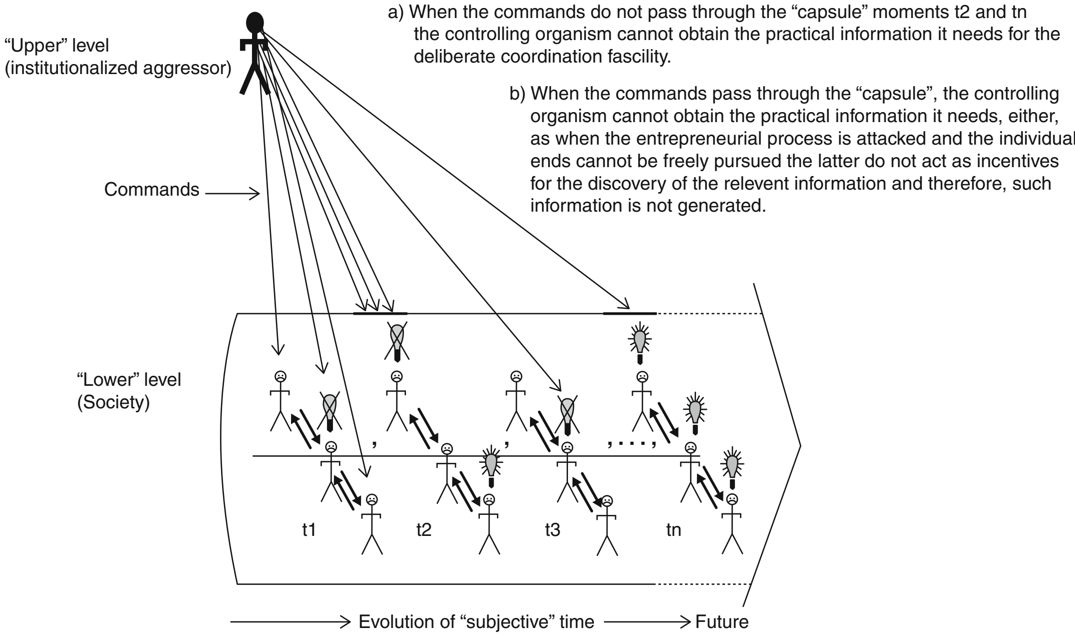
Information relevant to life in society is created and transmitted implicitly in a disseminated way, that is, neither consciously nor deliberately. In this way, the different social agents learn to discipline their behavior in relation to that of other people but are not aware that they are the protagonists of this learning process or that, therefore, they are adapting their behavior to that of other human beings: they are simply conscious that they are acting, that is, trying to obtain their personal ends using the means they believe to be within their reach. Therefore, the knowledge discussed here is a knowledge which is only possessed by human beings acting in a society which, in view of its intrinsic nature, cannot be explicitly transmitted to any central controlling organism. As this knowledge is indispensable if different individual behaviors are to be coordinated socially, thus making society possible, and cannot be transmitted to the controlling organism given the fact that it cannot be articulated, it is logically absurd to think that a planned economic system can work.

The Dynamic Argument

Socialism is impossible not only because the information possessed by the actors is intrinsically unable to be transmitted explicitly, but because, moreover, from a dynamic point of view, human beings, on carrying out entrepreneurship, that is, on acting, constantly create and discover new information. It would be very difficult to transmit to the controlling organism information or knowledge which has not yet been created, but which is continually arising as a result of the social process itself to the extent that the latter is not attacked.

Figure 3 represents the actors who are continually creating and discovering new information throughout the social process. As time, in its subjective sense, elapses, those who perform their entrepreneurship in interaction with their peers are constantly becoming aware of new profit opportunities, of which they try to take advantage. Consequently, the information possessed by each of them is constantly undergoing modification. This is represented in the figure by the different bulbs which light up as time passes. It is clear not only that it will be impossible for the controlling organism to have all the information necessary to coordinate society by commands at its disposal, given that this information is dispersed, exclusive, and impossible to articulate, but also that, moreover, this information will be continually modified and will arise ex nihilo as time passes. It is highly unlikely that it is possible to transmit to the controlling organism information which is at each moment indispensable for the coordination of society but which has not yet even been created by the entrepreneurial process itself.

Thus, for example, when it looks rainy at dawn or there is any other series of meteorological circumstances, the farmer realizes that, as a result of the change in the situation, he/she will have to modify his or her decision on the different tasks that should be done on the farm on that day, without being able to articulate formally the reasons why he/she is taking such a decision. It is not possible, therefore, to transfer this information, which is the result of many years of experience and work on the farm, to a hypothetical controlling organism (e.g., a Ministry of Agriculture in the capital) and await instructions. The same may be said of any other person who carries out his or her entrepreneurship in a determined environment, be it a decision as to whether he/she should invest or otherwise in a certain company or sector, or whether he/she should buy or sell certain stocks or shares, or contract certain persons to collaborate in his or her work, etc. One may, therefore, consider that the practical information not only is, as it were, in a capsule, in the sense that it is not accessible to the controlling organism which practices institutionalized aggression, but, in addition to being in a capsule, is continually



Planned Economy and Entrepreneurial Function, Fig. 3 Dynamic argument against socialism (source: Author)

being modified and regenerated in a new form, as the future is created and made step-by-step by the actors-entrepreneurs.

Lastly, to the same extent as the state coercion is practiced on a more continual and effective basis, the free pursuit of individual ends will be made increasingly impossible and, therefore, the latter will not act as an incentive and it will not be possible to discover or generate the practical information necessary to coordinate society through entrepreneurship. The controlling organism is, therefore, faced with a dilemma impossible to eradicate, as it has an absolute need of the information generated in the social process, which it cannot obtain under any circumstance, because if it intervenes coercively in such process it will destroy the capacity to create information and if it does not intervene, it will not obtain the information either.

As a conclusion, from the perspective of the social process, socialism may be considered as an intellectual error, as, for the following reasons, it is not possible to conceive that the controlling organism in charge of intervening with commands can obtain the information necessary to coordinate society: first, because of the volume (it is impossible for the intervening organism to consciously assimilate the enormous volume of practical information which is spread over the minds of human beings); second, given the fact that the necessary information is essentially impossible to transfer to the central organism (as it is tacit and impossible to articulate); third, because, in addition, it is not possible to transfer information which has not yet been discovered or created by the actors and which only arises as a result of the free process of the practice of entrepreneurship; and fourth, because the practice of coercion prevents the entrepreneurial process from discovering and creating the information necessary to coordinate society.

The Impossibility of Socialism from the Perspective of the Controlling Organism

Second, now from the perspective of what has been called the "upper" level in the figures, that is, from the standpoint of the person or group of persons, organized to a greater or lesser extent, who, systematically and institutionally, carry out aggression against the free practice of entrepreneurship, a series of considerations can be made which confirm, even more, if that is possible, the conclusion that socialism is simply an intellectual error.

For dialectic purposes, one may accept, as did Mises, that the controlling organism (regardless of whether it is a dictator or leader, an elite, a group of scientists or intellectuals, a ministerial department, a group of representatives elected democratically by "the people" or, in short, any combination, of a greater or lesser complexity, of all or some of these elements) is endowed with the maximum technical and intellectual capacity, experience and wisdom, together with the best intentions, which is humanly conceivable (These hypotheses are not true in reality for the reasons presented below). However, what cannot be accepted is that the controlling organism is endowed with superhuman capacities or, specifically, that it has the gift of omniscience (Mises 1996, p. 92), that is, that it is capable of assimilating, knowing, and interpreting simultaneously all the scattered and exclusive information which is dispersed over the minds of all the beings who act in society and which is continually being generated and created ex novo by these beings. The reality is that the greater part of the controlling organism, sometimes also called the planning organism or organism of central or partial intervention, does not know or only has a very vague idea as to the knowledge which is available dispersed among the minds of all the actors who may be submitted to its orders. There is, therefore, a small or nonexistent possibility that the planner may come to know, or discover where to look for and find, the elements of dispersed information which are being generated in the social process and of which it has such a great need in order to control and coordinate such process.

Moreover, the controlling organism will unavoidably have to be composed of human beings, with all their virtues and defects, who, like any other actor, will have their own personal ends which will act as incentives and lead them to discover the information relevant to their personal interests. Most probably, therefore, the men who constitute the controlling organism, if they use their entrepreneurial intuition correctly from the point of view of their own ends or interests, will generate the information and experience necessary to keep themselves in power indefinitely and justify and rationalize their acts to themselves and to third parties, practice coercion in an increasingly sophisticated and effective way, present their aggression to the citizens as something inevitable and attractive, etc. Contradicting the "well-intentioned" hypothesis set out at the beginning of the preceding paragraph, these will generally be the most common incentives and will prevail over others, particularly over interest in discovering the practical, specific, and relevant information which exists at each moment dispersed over society and which is necessary to make the coordinated functioning of the latter possible through commands. This lack of motivation will determine, moreover, that the controlling organism does not even realize, that is, become conscious, of the degree of its own ineradicable ignorance, sinking into a process which distances it more and more from the social realities which it is trying to control.

In addition, the controlling organism will become incapable of making any kind of economic calculation, inasmuch as, regardless of its ends (and one may again imagine that they are the most "humane" and "morally elevated" ones), it cannot know whether the costs incurred in pursuing such ends have, for itself, a value even greater than the value which it attributes subjectively to the ends pursued. The cost is merely the subjective value which the actor attributes to what he/she must renounce in pursuit of a determined end. It is obvious that the controlling organism cannot obtain the knowledge or information necessary to become aware of the true cost incurred in accordance with its own scale of values, as the information necessary to estimate costs is spread over the minds of all the human beings or actors who make up the social process and who are coerced by the controlling organism (democratically elected or otherwise) in charge of systematically practicing aggression against the body of society.

Conclusion and Future Directions

If the concept of responsibility is defined as the quality of the action which is executed once the actor has come to know the cost thereof and takes such cost into account by the corresponding estimated economic calculation, it may be concluded that the controlling organism, regardless of its composition, system of choice, and value judgments, as it is unable to see and appreciate the costs incurred, will always tend to act irresponsibly. There exists, therefore, the unresolvable paradox that the more the controlling organism tries to plan or control a determined area of life in society, the fewer possibilities it will have of reaching its objectives, as it cannot obtain the information necessary to organize society, creating, moreover, new, serious imbalances and distortions to the precise degree that its coercion is carried out more effectively and limits the entrepreneurship of human beings. One must, therefore, draw the conclusion that it is a serious error to think that the controlling organism can make economic calculations in the same way as the individual entrepreneur. On the contrary, the more developed the planned organization, the more practical first-hand information which is indispensable for economic calculation will be lost, making economic calculation completely impossible to the precise degree to which obstacles to free human action are placed by the organism practicing institutionalized coercion.

Human inequality; Political creativity; Political entrepreneurship

Political leadership, in a parsimonious definition, refers to the impact on decision-making and political outcomes that results from action by the holder of political office. Thus, it is connected with leadership style and may be rooted in certain character traits of the leader's personality.

As such, however, it is at odds with core principles of democracy, most evidently equality coupled with the doctrine of popular sovereignty and guarded by the constitutional division of powers. Democracy ultimately rests on the premise of the rule of many embedded in rule of law. Hence, in terms of liberal and democratic theory, political leadership and democracy are contradictory.

Speaking empirically, the relationship between the two is slightly more ambiguous. The practice of liberal democracy is based on – the ensurance and endurance of – representatives' accountability and responsivity. Voters are principals, who direct as their agents politicians. Consequently, the relationship between innovation and political leadership is asymmetric, predominantly established by innovations *in* economy, society, and media and their effect *on* political leadership.

The Modus Operandi of Political Leadership and Democracy

Where to Find Potential Leaders: Bringing States Back In

Although liberal democracies by definition and in practice seek to level out hierarchies and disperse power, political leadership in the world of democratic politics is not entirely absent. After all, change describes the essential trigger of leadership. For the sake of simplicity, this entry will not differentiate (a) between various decision-making arenas and (b) over the course of decision preparation, decision-making, and policy implementation/supervision.

In the reality of political change taking place in liberal democracies, the term innovation denotes medium-scale impact. It hereby markedly differs from the large-scale leadership possible under dictatorship on one hand, and the mere office holding typical for some democracies characterized by extensive power sharing on the other hand. Blondel, in his two-dimensional typology of potential leadership impact (Blondel 1987: 97), defines "innovators" as those bringing about large change limited by specialized scope (thereby exceeding the routinized maintenance-oriented role of the managerial type). At this scope, typically policy areas are addressed and "innovators" as implementers of new policies get identified, e.g., land reform.

However, it is difficult to find clear examples of political leaders in democracy fulfilling these criteria. Adaptive reaction and response to changes and challenges characterize the relationship between change and political leadership, whereas leaders rarely implement large-scale changes, alter procedural rules of the game, or redirect public response in problem-solving tasks. An entrepreneurial style initiative of politicians culminates mostly in adaptive response, and even pioneering leadership seldom unfolds any revolutionary appeal.

Having said this, macro-level political and economic developments in the course of the twentieth century raised doubts as to whether politics does matter at all. Globalization hand-in-hand with the emergence of civil society has imposed challenges to prerogatives of national politics to govern authoritatively and effectively. Nation states and hence national governments have witnessed considerable pressures from:

– Outside (economic globalization and transnational companies)
– Above (supranational political and economic bodies)
– Below (NGO's, public dissatisfaction with representatives/parties)

This has lead to "hollowing out" in the sense of reduced steering capacity. Against this background, critics have described conventional political competition as virtual and political decision as either overthrown or dominated by (organized) business interests (coined "post democracy"). Why then not focus on political leaders in civil society? In the end, negotiations of state actors and policy networks (the paradigm of governance) still take place in the shadow of hierarchy. In turn, if individual politicians matter at all, leadership potential would be obviously limited to those few ranked on the top. The "empty box" character of executive politics, however, has put severe limitations on attempts to probe into empirics of executive leadership. Tellingly, social scientific study of leadership in its beginnings was characterized by the absence of state-centeredness but instead was preoccupied with the wealth of phenomena related to leadership in "voluntary organizations," most notably churches and trade unions.

Somewhat seconding and affirming this notion, cross-country analysis shows substantial variation in the formal powers of presidents and prime ministers. The (d)evolution of powers offers much insight: when chief executives indeed played a key role in institutional redesign, it had almost never been an attempt to expand their power base. Quite the opposite, it mostly had the intended effect of shifting power away, as was the case with devolution under Tony Blair in Great Britain and reforms in a number of semi-presidential countries.

The Interplay of Office, Personality, Leadership Style, and the Role of Creativity

Constitutional democracy consists, among others, of rule of law and has established separation of powers. Beyond that, however, it stipulates the approximation of popular will by government realized through fair and, in this sense, competitive elections (resulting in many countries in "responsible party government"). The notions of moral hazard and rent-seeking, figuring prominently in applications of rational choice theory, signal the threat of undermining responsivity and accountability in principal agent relations. Inevitably, therefore, neither a certain formal position nor character trait, or leadership style on its own, guarantees political leadership, whether pioneering, innovative, or merely adaptive in nature. This holds true even for the combination of great political powers in the hands of a charismatic holder of office. Looking at "idolized heroes" (e.g., John F. Kennedy), Burns denied they could act as transformative leaders because "no true relationships exists between them and the spectators – no relationship characterized by deeply held motives, shared goals, rational conflict, and lasting influence in the form of change" (Burns 1978: 248).

To provide an interim summary, political leadership in democracy is highly contingent and requires a careful analysis of institutional and cultural parameters as well as situational factors. For instance, in some countries, institutional pluralism has led to the notion of "semi-sovereignty," most notably Germany, where effective leadership rather depends on means of coordination than authoritative decision-making. In many countries, extraordinary leaders (often those privileged as first holders of the office following its creation and those acting in times of crisis) established themselves as widely accepted role models (Washington, FDR, Germany's Adenauer). In the USA, ambiguities of the constitution allowed single presidents in the early age of the presidency acting as innovators. Typically, across Western democracies, innovative leaders would be succeeded by inheritors, and strong leaders would be followed by mediocre ones.

Focusing on leaders' personality, even if top-level politicians were willing to take on entrepreneurial routes of leadership, basically risk taking and initiative, they usually lack the creativity required to make a difference. Here one deals with collective inability stemming from politics as career (resembling "politics of survival"), in contrast to politics as vocation. In addition, political leaders today lack the time to familiarize with political theory and develop original political thoughts. Eventually, this appears also to be a product of biographical standardization that inspired observers to conceptualize politicians (elected and/or appointed) as members of a political class, constituted by similar social and educational background as well as shared political interest. As Tucker writes on political creativity, "[A]t bottom it is a gift bestowed on some individuals by nature and life circumstances in combination" (Tucker 1977: 386).

This image of political class provides stark contrast to the agency of political competition in democracy for allowing innovation in the spheres of science, business, and media. As Carayannis and Campbell emphasize for the genuine feature of political competition in democracy, "Political pluralism in democracy cross-refers to creativity-encouraging heterogeneity and diversity of different forms, modes and paradigms of knowledge and innovation" (Carayannis and Campbell 2011: 342).

One step further, in distinguishing seven different forms of bad leadership, Kellerman links lack of creativity with innovative malfunctioning: "Although they may be competent, they are unable or unwilling to adapt to new ideas, new information, or changing times" (Kellerman 2004: 419). The alternative selection modus based on policy expertise (mostly occupational, often managerial, sometimes genuinely scientific) has not proved to overcome such shortcoming. Experts given political mandates plausibly scored even lower compared to professional politicians in terms of political creativity. Similarly, policy expertise and involvement of leaders as professional politicians "may make powerful prime ministers in parliamentary democracies but at the same time it stands out as a central feature of some only moderately successful US presidents" (Helms 2012).

Overall, boundaries between leader and follower roles have been blurred in Western democratic societies. Especially for a public that is both more politically involved and dissatisfied, authoritative top-down decision-making has become costly for its exponents. There is some evidence that effective leaders in current democratic societies act as agents of followers and that performance of allegiance roles to publics lies at the heart of executive leadership. To some observers, leaders are not only bound to popular will but as leaders they appear to be "created by the led" (Kellerman 2004). Consequently, in this perspective, follower action in many instances determines the success and failure of leaders. At the very bottom of the relationship between leaders and followers, as in foreign politics, one of the prime leadership tasks is to generate "soft power" and to combine its means creatively with "hard power."

Political Competition and Innovative Forms of Leadership

Schumpeter's Entrepreneurial Style Leaders

Various theorists of democracy have employed market metaphors in describing the logic of the political process. Among them, Joseph A. Schumpeter stands out for assuming an imperfect market in politics (Schumpeter 1950). Already in his theory of development he had firmly emphasized the incompatibility of perfect competition and economic progress. According to him, "Practically every innovation (. . .) at first creates that kind of situation which is designated by the term Monopolistic Competition" (Schumpeter 1989: 167). The political process in representative democracy exhibits oligopolistic as well as monopolistic features because it is geared toward majority building and interest aggregation, which is ultimately required to secure governability. Furthermore, as elections take place rather infrequently in a world of information (dis-) advantage and passive roles of some constituents, this results in rather low competence levels compared to the sphere of economics.

The Schumpeterian assumption of imperfect markets contrasts, e.g., the economic theory of democracy elaborated by Anthony Downs, which rests on the neoclassical equilibrium model of economy. It is exactly this difference that allows for leadership to be regarded as a potential driver of the political process and the sole originator of endogenous qualitative change. Equating the influence of entrepreneurship in business, leadership in politics in Schumpeter's view has the effect of creating new demand on the side of customers, who are of course the voters in the political realm. Unlike in the equilibrium model of Downs, leaders are not forced to perpetually trail behind shifting voter preferences but quite the contrary are able to shape those. For Schumpeter, again in contrast to Downs, the political process is multidimensional and voters' preferences are multi-peaked, producing cyclical majorities.

Thus, innovative entrepreneurial style leadership for Schumpeter displays a permanent association to politics and can be exercised by leaders as political entrepreneurs again and again. But what can be understood as "political innovation" in the Schumpeterian sense? In any case, innovation is the crucial element in creating qualitative change, consisting of something untried and irreversible, and perhaps even difficult to be repeated, at least by mere imitation. Though Körösényi lists a number of ways to affect public policy, he ultimately regards all of them as being rooted in the ability to "overcome resistance" (2011: 10). Similarly, as noted above, the overall character of political competition is oligopolistic because of the need to create political majorities.

Riker's Heresthetics

Schumpeterian accounts of entrepreneurial leadership share a commonality in their rootedness in political competition. If political leaders are perceived as innovators themselves, they would act as agents of ideas and policies with the ultimate goal to create political majorities at different levels and places in the political process (e.g., the public, in cabinet, in nonmajoritarian institutions, at the decision-making stage, in the phase of implementation, throughout a process of supervision and reevaluation). Following Schumpeter, William H. Riker has shown in his seminal work on *heresthetics* how political actors motivated to win politically may successfully combine agenda setting abilities with rhetorical skills and manipulation of issue dimensions to create new majority coalitions (Riker 1986).

Innovative leadership for Riker means manipulation in order to win. Based on positive political theory, he identified three crucial ways that may make a politician succeed, in addition to the evergreen influence of rhetorics in persuading others. The heresthetic leader skillfully employs three categories or strategies: agenda control, strategic voting, and manipulation of dimensions. As social choice theory has emphasized, voting outcomes are closely related to voting procedures (e.g., Condorcet paradoxon: A wins over B, B wins over C, C wins over A). Moreover, those called upon to vote show a plurality of preferences characterized by different salience and distance to ideal points. From this perception, it follows that redefinition of the situation and/or moderate strategic shifts of the political measures envisaged create plenty of opportunity to rally alternative, stronger coalitions of support.

According to Riker and empirical investigations of a number of scholars, political change as an outcome of *heresthetics* is a rare event when looking at really important issues (motions). The leadership-based "invention of a new viewpoint" alone, not to speak of environmental resistance and the (counter-)strategic moves of many other actors involved, requires literally "artistic creativity" as Riker resumed himself (Riker 1986: 1, 34).

The Impact of Knowledge Revolution on Political Leadership

Knowledge Society and Programmatic Competition

The concept of "knowledge society" was developed at the eve of postindustrial society. Knowledge society, embedded in welfare states of varying size, has led to massive job creation in the educational and health sector. This development has facilitated the emergence of two-dimensional political space. Parties and candidates, once solely competing in the redistributive left–right dimension, now also are judged on sociopolitical and sociocultural grounds. The opening-up of political space limits the ability of both parties and leaders to rally heterogeneous voting coalitions behind them (Kitschelt and Rehm 2011); this, in the sphere of party choice, goes at the expense primarily of centrist catch all parties, while it opens up leverage for entrepreneurial style populist leaders that combine charisma with broking skills (to overcome programmatic inconsistency) as long as they do not enter government, e.g., Bossi in Italy, Haider in Austria, and Wilders in the Netherlands. Often, innovation in political leadership in this respect takes the form of reshaping and redrawing group boundaries. The above-mentioned prime exponents of entrepreneurial style leaders in politics profit from the rise of cultural and identity politics relative to redistributive politics, a process resulting in political realignment of the working class.

Knowledge Democracy and Entrepreneurial Leadership

At times political leaders become subject to innovation attached to central goals of the political process. This is most prominently the case for the trend of personalization transmitted by the multimedia age. The innovation of candidate debates on screen revealed substantially different performances across countries and in some cases probably decided the race for office, e.g., in the 1960 campaign for American presidency.

Technical innovation has affected governing in the media age quite profoundly. Yet, it has not made political leadership more likely, far-reaching, rooted in personality, or innovative. Leaders have increasingly become the center of public attention, and electoral campaigns (making them more vulnerable to public failures and dependent on high approval rates) are "sold" as brands and often engage in unmediated communication with public (the hypothesis of presidentialization of prime ministers).

The emerging concept of knowledge democracy by definition assumes from the presence of network society and media politics great demand for a new mode of governance as legitimacy of traditional representative democracy unpreventably vanishes. It therefore puts a premium on institutional and functional reform. Consequently, advocates of the concept of knowledge democracy have largely bypassed aspects of leadership by individuals (e.g., In 't Veld 2010). Governance appears to be a substitute for government. It should be noted, however, that at a closer look governance and government do not constitute polar extremes but are able to coexist and supplement each other (Helms 2012). While proponents knowledge democracy tend to largely ignore the intact linkages between citizens and parties/politicians (and the above mentioned realignment in favor of populist radical right parties), it also has identified a connectedness of media revolution and populist leadership. More specifically, this kind of leadership proved successful when exerted by political entrepreneurs.

Linkages between political entrepreneurship and leadership might be created in two ways. First, business leaders may enter (sub-)national politics; second, politicians may exercise leadership tasks by conscious or unconscious orientation toward entrepreneurial activities. Most importantly, and by far most prominently, political leaders as entrepreneurs "sell" themselves (*branding*). In some notorious cases, they do so supported by the mass media that they themselves own. In Italy, media tsar Berlusconi aspired a formal leadership position and was elected prime minister a number of times. His success rested on widespread distance to more conventional political parties in many Western democracies and his image as self-made billionaire.

Again, the case of Berlusconi demonstrates the contextuality and crisis boundness of political leadership – Berlusconi initially profited from the breakdown of the established party system in Italy in the early 1990s. The kind of innovation that emanated from his entrepreneurial style leadership, however, hardly could be described as generating a surplus to quality of democracy (equating Schumpeter's "creative destruction"). New public demand was created due to appeals of politainment, met by the prime minister in the guise of anti-politics. In other words, he was offering a combination of somewhat effective leadership and bad governance. Accordingly, the founded political vehicles, avoiding traditional party image, are presented in the fashion of political movements. Whether this self-description accurately depicts the actual operative mode is much debated in current comparative party political research.

Conclusion and Future Directions

Constitutional democracy in interaction with knowledge society leaves virtually no ground for old style political leadership. This applies, for instance, to leadership as a reflection of a politician's personality and forms of top-down individual leadership. When political leadership is tangible, structural features and contextual factors clearly outnumber effects of personality and leadership style.

While innovative political leadership in general is hard to be established, entrepreneurial style leadership in politics has flourished as a consequence of transformation and innovation in

– Economy (e.g., postindustrial job creation)
– Society (e.g., individualism, pluralization of lifestyles, political aspiration of NGOs)
– Media (e.g., Internet access, televized candidate debates)

This populist entrepreneurial version of political leadership, at best, possesses a mixed record in terms of quality of democracy. At the same time, societal demand for innovative leadership prevails and should be accommodated. Political leadership has to be rescued as an effective mode of governance through conceptual and practical innovation. Most importantly, potentially effective leaders would have to accept the logic of network society and dispersed democratic leadership. Furthermore, they have to gain awareness that reshaping of group identity as this is one vital and perhaps dominating cleavage in the future, and they are needed to develop an inclusionary vision of, e.g., citizenship.

It seems justified to discover to lie at the heart of both innovative political leadership and innovation *in* political leadership securing trust in politicians. For that purpose, leaders (a) collectively are demanded to pursue institutional reform of the selection process of politicians at all levels, envisaging greater biographical variation (the import of self-made billionaires, economic entrepreneurs, and policy experts does not sufficiently compensate for that). (b) With reference to political communication, the collective of leaders is required to practice a mix of blame avoidance, credit claiming and technocratic policies both in order to foster political legitimacy, realize good governance conduct, and satisfy output criteria. Likewise, looking upward, it makes rescaling of people's expectations in political leaders necessary.

These are prerequisites in search for acceptance of a mixture of representative and direct democracy in a shrinking world of "hollowing out" of core executive politics. Still in the future, political leaders will play a pivotal role in finding balance of, in the words of Abraham Lincoln, government of, for, and by the people – a matter far too big to be dealt with by political leaders as individuals.

Introduction to Polynomiography and Its Applications

Throughout the history of science, reaching back to the Sumerians in the third millennium B.C., the task of finding the *zeros* of *pol*ynomials has been one of the most influential in the development of mathematics. The problem has been studied by the most famous of mathematicians and even today, it remains to be a useful problem in every branch of math and science.

Finding a zero of a polynomial is solving for the unknown. Solving for the unknown is a necessity in life and human survival. The task has played a significant role in the development of human intellect, leading to advancements in math, science, and art. A layman may need to figure out what is 17 % of 85. This amounts to solving a linear equation. A carpenter may need to estimate the length of the diagonal of a square having sides of a particular size. This is already the beginning of something deep: computing square-roots, a very special case of solving a quadratic equation taught in middle and high schools across the entire world. These are examples of polynomial equations.

Even though a very small percentage of the world population may actually know the quadratic formula, solving a quadratic equation is a need in everyday life. Of those who know the quadratic formula, an even a lesser percentage knows how to estimate a mundane number such as the square-root of two. They would need the use of a calculator. How does a calculator compute the approximation of the square-root of a number? How can the twentieth or even one-millionth digit in the decimal expansion of the square-root of two be computed?

The famous American artist Jasper John has an axiom describing how one may create art: "Take an object. Do something to it. Do something else to it." What he is perhaps suggesting is *iteration*. Before him, Isaac Newton suggested a method for finding the square-root of two, or the square-root of any other number: Take an initial guess. Then iterate by a certain recipe that would become known as *Newton's method* to get a new estimate that would hopefully come closer to the actual value of the square-root, i.e., having more accuracy. Then iterate again with the new estimate and repeat this process.

Formally, a polynomial, written as *p(x)*, is defined as a linear combination of integral powers of a variable, say x. Thus, a polynomial is sum of terms such as 16, $7x$, $-24x{\bullet}x$, 5 $x{\bullet}x{\bullet}x$, etc. Here "•" *means multiply*. When x is multiplied by itself so many times, it is convenient to write this with an exponent having integral powers. Thus, the integral powers in the examples are 0, 1, 2, and 3. The highest integral exponent of x is called the *degree* of the polynomial and the constant multipliers are called *coefficients*. The degree of a linear equation is one and that of a quadratic is two, and so on. A *zero* or a *solution* to a polynomial equation is a value such that when substituted for x and simplified, the equation yields a value of zero. To formally compute 17 % of 85 is equivalent to solving the linear equation, $17\,x-85 = 0$. To find the square-root of two is equivalent to solving the quadratic equation $x{\bullet}x - 2 = 0$.

A celebrated theorem about polynomials is the *Fundamental Theorem of Algebra (FTA)*, first proved by one of the greatest mathematicians of all times, Carl Friedrich Gauss. The theorem guarantees that a polynomial has as many zeros as its degree. The solution to a polynomial equation is not always a real number, but the FTA guarantees that a *complex number* will always exist as a zero of the polynomial. A complex number is an object of the form a + **i**b where a and b are ordinary numbers corresponding to *real* and *imaginary* parts, respectively, but **i** is a symbol that obeys the rule, **i**•**i** $= -1$. With this convention, the point in the Euclidean plane having coordinate (a, b) becomes a number, a complex number. Then, like the ordinary numbers, two complex numbers can be added, subtracted, multiplied, and divided by each other. This turns the points in the plane into objects that can be algebraically manipulated. Two teenagers can play a game with locations: One could tell the other to meet him at a location x such that when multiplied by the location of the cafe A becomes the location of the theater B. In summary, the roots of a polynomial equation are or correspond to locations in the Euclidean plane.

It is not always possible to find the exact value of zeros of a polynomial. The square-root of two is an example. The exact value of zeros of a quadratic polynomial cannot always be computed, even though an exact formula is available, namely, the high school quadratic formula. Even worse, a deep but negative result about polynomials asserts that for polynomials of degree five or higher, there is no general formula for their zeros. Thus, at best, the roots of a general polynomial can only be approximated. However, this can algorithmically be achieved to any desirable accuracy. Given a polynomial *p(x)*, Newton's method can be viewed as an iterative process that takes a point in the plane and moves it somewhere else, then somewhere else, repeating the process in the hope of getting closer and closer to a root.

Polynomiography can be considered as a visualization of the root-finding process, driven by the FTA. However, the goal of Polynomiography is not the mere approximation of the location of the roots of a polynomial equation, but the entire process of finding the roots and the way this process influences all other points within a particular rectangular region that may or may not include any of the roots. This results in capturing 2D images called the *Polynomiograph*. The process of root-finding is not limited to the use of Newton's method. Polynomiography software offers much more. Like a camera that offers many lenses, settings, and parameters to capture photographs of a single object, Polynomiography software offers many processes (*iteration function*) that are encoded as algorithms for solving polynomial equations, as well as many coloring schemes. These essentially make it possible to capture an infinite number of Polynomiographs from a single equation.

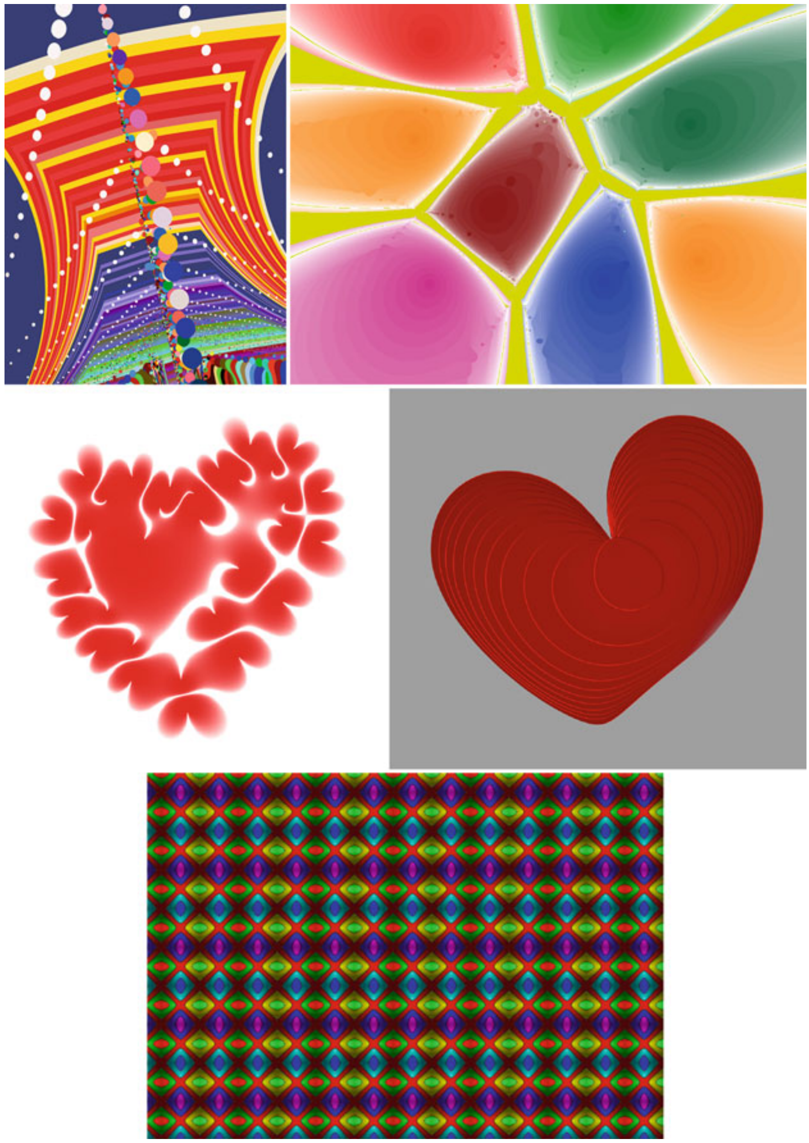
Polynomiography software makes use of the many encoded processes to create artwork. In particular, in the context of visualization and art, one can reverse the role of the ancient root-finding problem and select the location of roots so as to create desirable designs or effects.

Polynomiography and Innovation, Fig. 1 Example Polynomiographs from single polynomials (Bahman Kalantari)

Polynomiography thus turns the root-finding problem upside down and into a visualization tool of art and design, and a serious medium for creating artwork of great variety and diversity through a combination of human creativity and computer power. The following metaphoric description is from the book (Kalantari 2008):

> Solving a polynomial equation could be considered as a game of hide-and-seek with a bunch of tiny dots on a painting canvas. We hide the dots behind a polynomial equation, we then seek them using a formula or an algorithm. Polynomiography is the algorithmic visualization of the process of searching for the dots, and painting the canvas along the way.

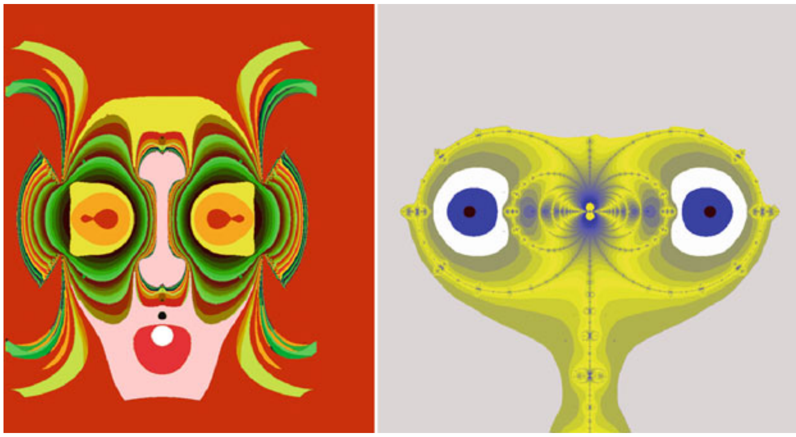
On the one hand, Polynomiography can be considered a digital form of painting, using only a finite set of points, the roots of a polynomial as the generating set. As such it is an art form capable of creating a vast variety of images by manipulating this finite set of points, whether given implicitly through the coefficients of a polynomial equation, or selected explicitly as the roots by the clicks of a mouse. In a sense, Polynomiography is a minimalist and abstract art form, albeit one of enormous power and diversity. What is magical in Polynomiography is that this finite set of points, when combined with one or many iteration functions that are made transparent to the Polynomiography software user, results in a coloring scheme, giving a 2D Polynomiograph. Thus, the initial set of points offer much more than the shape it defines. The input set is very small while the output set is a full 2D image. The Polynomiographer's personal creativity and choice, and the great variety of methods to view a polynomial equation amount to a powerful tool for artistic creation. Even with polynomials of small degree, artists, teachers, or students can learn to produce interesting images on a laptop computer in a reasonable amount of time. Some examples are given in Figs. 1–3, using Polynomiography software.



Polynomiography and Innovation, Fig. 2 Sample artwork, the *bottom* image is from tiling of a single Polynomiograph (Bahman Kalantari)

Innovative Possibilities of Polynomiography in Education

Polynomiography is based on sophisticated algorithmic visualization in solving polynomial equations. Using inventive programming, it creates a medium where an individual, independent of his/her mathematical background, age, and artistic background, is rewarded with satisfying images, while being playful, experimental, artistic, expressive, or scientifically curious. Very significantly in the cases of younger individuals, Polynomiography helps them learn about concepts in mathematics that they would otherwise be much less motivated to study or would find too dry. Polynomiography can be used as the basis of a technology that would lend itself to the encouragement of creativity and innovation in multidisciplinary teaching and learning experiences. It can lead to development of curricula for a wide range of educational courses in K-12 and higher education.



Polynomiography and Innovation, Fig. 3 Polynomiography could even result in characters, artistic (*left*) and cartoon-like (*right*) (Bahman Kalantari)

Prototype Polynomiography software in several settings has already been tested, and proven to be an enthusiastically popular medium for students in middle and high schools, and teachers who are interested in introducing it in their curricula. Survey of students (some as young as 11–13) who have been introduced to Polynomiography shows that these students have become, as a result, interested in learning about polynomials which are central to mathematics and science. Thus, young students get closer early on to these critical building blocks of sciences and mathematics and related complex notions that are otherwise too distant to them.

On the one hand, polynomials are one of the most important building blocks of mathematics, science, and engineering, having numerous applications. Polynomials help approximate functions which in turn approximate science and modeling. In education, polynomials are indispensable abstract objects as well. Through them, students are introduced to more general functions, graphs, equation-solving, calculus, and much more. On the other hand, mathematics education needs to popularize the subject because mathematics is often considered to be dry and not visual enough. Polynomiography can help young students who are always in the need for visual stimulation to connect to mathematics through playful learning and creativity. This in turn will help them learn complex math. Polynomiography is a medium that helps students play, express themselves, enjoy themselves, while picking up easy mathematics, medium mathematics, and even sophisticated mathematics to reach new frontiers in math and science. This in turn has profound consequence in science and culture.

Polynomiography is a by-product of the author's theoretical research into the ancient but historically significant problem of solving polynomial equations. It has received enthusiastic support from artists, engineers, mathematicians, scientists, and the general public, many of whom await a more robust and complete version of the software. This interest stems from the fact that they all foresee new applications to their particular fields. Polynomiography is also related to *fractals* through the process of iteration and as a result, some of its images are in fact fractal, more precisely, *fractal Polynomiographs*. However, it is not a subset of fractals. The word *fractal*, invented by Mandelbrot, see (Mandelbrot 1983) and (Mandelbrot 1993) is associated with many processes resulting in self-similarity. In addition to fractal Polynomiographs, Polynomiography also result in images that are not fractal in any sense. It is a much more focused subject than fractals based on general iterations. This feature of Polynomiography together with the fact that it has a well-defined foundation, namely, root-finding, makes it a more easily appreciated subject than general fractals. It is this basic foundation and the fact that polynomials are so widely present in science and math that turns Polynomiography software into a meaningful tool. This can be contrasted with playing with any software that merely renders images based on an iteration which may not enjoy any meaning, or not be designed to do a particular task. Indeed Polynomiography can be used to teach about fractals and turn the concept into a more tangible subject. In the context of fractals, Polynomiography allows *control* and this feature is very significant. In terms of imagery, Polynomiography also enhances and strengthens fractals because it makes use of more sophisticated iterative methods. Aside from the fractal images in Polynomiography, some of its techniques give rise to very rich class of non-fractal images. This can be seen in some examples images given in the Figs. 1–3. For more details on Polynomiography and its foundation, see (Kalantari 2004a, b, 2005, 2008) and the other references.

Innovative Possibilities of Polynomiography in Art

Artistically speaking, Polynomiography can be described as a minimalistic art form capable of creating interesting variety of artwork. The collective shape of the points, their relative gravity with respect to each other, as dictated by the iteration functions which are analogous to the lenses of a camera, and the window through which a polynomial is viewed, together with the Polynomiographer's personal creativity and choice of coloring could all result in a tool of infinite artistic capabilities. Not only can Polynomiography bring art and design into mathematics' and sciences' curricula and education, it can bring mathematics and computer technology to artists who may normally not use mathematics. An artist can learn techniques without the need to have learned the underlying math or algorithms. Thus, Polynomiography offers new creative and innovative possibilities for artists. Polynomials, these fundamental objects of sciences and math, will suddenly find wider and deeper appreciation by the population at large. Just as a camera could help turn a photographer into an artist, Polynomiography software can turn a person not considered an artist to think differently of art and conceive of possibilities that would not have been imagined otherwise. Like photography and painting, many techniques can be developed in Polynomiography and Polynomiographers can discover new techniques of their own, possibly even combining two or more different artforms. Some examples of such work are given in Figs. 5–9. These are produced by the author's students or collaborators.

The author has developed and taught different courses on Polynomiography at Rutgers University to undergraduate students and to high school students at summer, see (Fig. 4) programs. In an interdisciplinary course taken by students from different majors, students must complete a project based on their interest area while using Polynomiography software. The student projects have ranged from such diverse applications of Polynomiography as: art, dance, linguistics, psychology, math, education, computer graphics, computer science, symbology, music, architecture, ecology, neuroscience, special education, chemistry, and religion.

Entrepreneurial and Commercial Possibilities of Polynomiography

Polynomiography is a US patented technology that can lead to a variety of commercial products such as software and other induced products. As a software tool in K-12 education, it has tremendous potentials as evidenced by teachers and students themselves, ranging from 6th to 8th graders to high school students and higher education. It has the potential to be introduced to K-12 education not only in the USA but other countries. In fact, some high school students in USA, Austria, Japan, and South Korea have already gained favorable experiences with the software. This by itself is a promising area of entrepreneurship and could lead to an industry

on educational material that could be built around the software technology. Not only could such software be used in several different math classes in K-16 education but in science and art classes as well.

Aside from the above-mentioned educational applications which have actually been studied by a group of MBA student at Rutgers university with profitable forecasts, Polynomiography can be integrated into social media and Smartphone technology for variety of applications. Polynomiography is a true fusion of math and art, which through its software renders artistic visuals made from polynomials, and words or numbers turned into polynomials. As an entrant into the applications industry, it can be of interest to users on social networking websites such as facebook, as well as users of Smartphones such as the iPhone or other popular technologies. The word "Applications" has been a buzzword in the consumer economy for the last few years. Whether it is the growing population of facebook or the growth in Smartphone users, applications are becoming more and more popular among consumers today. Polynomiography as an application aspires to spread virally on facebook through the youth who have a high need for affiliation and self-expression as well as an interest in new and unique applications. Allowing users to express themselves and their identity in a unique manner, Polynomiography can change any word, message, name, etc., into art that will appear on an individual's profile and be commented upon by all their friends on facebook. This could actually have an appeal across all age groups as it allows the user to quickly generate a unique image that can be shared with their friends. This appeals to the user in that it allows them to convert words and sentences into unique images. Viral buzz also tends to be strong among the young population as those between the 13 and 17 year age group as they are more likely to copy their friends' actions as a "trend" and thus spread an application version of Polynomiography.

The Need for Funding and Support

In order to develop Polynomiography as a successful commercial technology, there is the inevitable need to receive seed funding as well as gaining opportunities that would help develop it and to move forward. Two distinct types of support are necessary: (1) financial support, and (2) developmental support to help bring it to a deserving level of appreciation and utilization in education, art, and more. These include funding to help bring in the needed expertise to develop and maintain a successful software, and to help develop its business aspect. The second level of support includes opportunities to carry out interdisciplinary activities, such as designing lesson plans for teachers, holding training teacher and student workshops, holding exhibitions that would help bring Polynomiography to a wide range of audiences, including children, youth, and the general public.

Fortunately, based on much evidence, including business studies by MBA students in more than one study, Polynomiography can succeed without the need for a large amount of investment. However, the seed money needs to be brought in through national or private agencies. Also, through national science and educational agencies, there is a need to gain grant funding that would allow working with experts to develop interdisciplinary curricula for art, math, and science courses, to hold teacher/student workshops, and to design of new creative educational activities.

Conclusions and Future Directions

There is an inevitable need for a wider appreciation of science and math in the USA. In order to make this happen, there is a need to promote creativity and innovation. This entry has introduced a technology that has the potential to turn polynomials into a very popular, if not a household, word. The technology, called Polynomiography, can lead to new forms of art, and advancements in science, math, and education, and help introduce the public to the deep and ancient subject, rooted in the most significant drive in mankind: solving for the unknown.

With the increasing role of visual tools and technologies, through computer-generated algorithmic visualizations, Polynomiography leverages information technology for the teaching, learning, and promoting of mathematics as a means for inducing striking appreciation of the connections between creativity in art and the intrinsic beauty of mathematics. Polynomiography has the potential to become a powerful medium for extending the capability of human creative thinking. This capacity needs to be examined in the context of funded pilot projects to lay groundwork for future development and highly collaborative, interdisciplinary research.

The inspirational power of Polynomiography is multifaceted and extends to many domains, including mathematics, the sciences, education, fine arts, and performance arts. Already there are seeds for cultivating interdisciplinary collaborations of different kinds, and the impact of such pilot projects will be to fuel further developments that stimulate creativity and innovative approaches to education that reward creative thinking and problem solving.

However, in order for such a technology to grow as an educational medium, an artistic tool, or a commercial product, there needs to be support of various kinds. These include institutional support, and seed funding to expand its software, to design interdisciplinary activities, to organize exhibitions and workshops in order to bring it to a wide range of audiences, including children, youth, and the general public. These would help bring about a wider appreciation of science and math and inspire new activities.

National government or private agencies that fund science or art projects need to pay more attention to the growth of science and math through interdisciplinary innovations that help combine art, science, and math. In doing so, these agencies need to think outside of the box and to support new and nontraditional avenues of creativity and innovation. At present, these foundations are not spending sufficient funding to promote creative thinking. The USA has one of the strongest programs in higher education in the world, attracting international students from the best universities in numerous countries. However, its expenditure in K-12 education falls short of many countries. This needs to change since according to studies, K-12 students generally do not score as high in science and mathematics as their international counterparts. Risks must be taken and new topics and inventions must make their way into classrooms.

Likewise, institutions such as universities themselves need to promote and support interdisciplinary research that combines art, science, and math and help these subjects grow. It is often believed that there is not enough time to introduce new curricula into old courses, as if curricula are to permanently remain unchanged. There are many reasons to believe that Polynomiography has the potential to enter math, science, and art curricula at many levels, from elementary school classes, all the way up to college level courses.

Preparing a "Creative Revolution" – Arts and Universities of the Arts in the Creative Knowledge Economy

Gerald Bast
University of Applied Arts Vienna,
Vienna, Austria

Synonyms

Aesthetic innovation; Aesthetic research; Re-culturalization of societies; Social design; Societal transformation

Creative Industries or Creative Societies

While in the 1930s, Theodor W. Adorno still was able to say "art is magic – relieved from the lie to be truth," works of the arts more and more are transformed to mere objects of trade. But is not this politically and historically only consistent in an economy-driven society when pieces of art rather have the status of shares at some kind of stock market than artistic statements. Is it really surprising that art dealers change to brokers and art collectors to speculators?

It would be wrong to claim that art would uncouple itself from the social and political relevance. It is rather the *society*, which virtually strategically is going to be depoliticized by increasingly dominant economic structures. Apparently unbiased economic mechanisms take the place of political, cultural, and educational impact parameters in our societies. And this development has not passed by art. How should it? This paradoxically is exactly the evidence of the convexity still existing between art and society. In times when the social and political systems of values are replaced by the shareholder value, when educational contents get degenerated to statistically quantifiable measurements and educational institutions to knowledge-providing factories for the purpose of producing employability to increase economic growth – in such times it would be more than surprising, if this tendency toward the economization of our society would stop in front of the arts?

Since the late 1980s of the twentieth century, the "invisible hand" of the market increasingly has taken over the steering wheel in the stormy system of the arts and the artists are the rowers – although autonomous rowers. The artists, once depending on religious or secular rulers, became producers for the Creative Industry: galleries, fashion and music labels, training companies, theaters or publishing houses, etc. The artists transform to suppliers for the Creative Industries – and only a few of them succeed in actively influencing the market system by taking over the roles of art producer and bidder at art auctions at the same time – like Damian Hirst did.

Promoting the term "Creative Industries" as a political trademark is a real masterpiece of political strategy, initiated by the Blair government in the UK and then perfectly continued by the institutions of the European Union. In 1997, the UK Creative Industries Task Force was established by the Blair administration.

In 1998, the UK Department for Culture, Media and Sport defined the creative industries as "those industries, that have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual property." (Creative Industries Mapping Document 1998).

In the same year, the UK Department for Trade and Industries continued in a White Paper: "In the increasingly global economy of today, we cannot compete in the old way. Capital is mobile, technology can migrate quickly and goods can be made in low cost countries and shipped to developed markets. British business must compete by exploiting capabilities, which its competitors cannot easily match or imitate. These distinctive capabilities are not raw materials, land or access to cheap labor. They must be knowledge, skills and creativity, which help create high productivity business processes and high value goods and services. That is why we will only compete successfully in future if we create an economy that is genuinely knowledge driven" (White Paper 1998, http://webarchive.nationalarchives.gov.uk/20000517080533/http://www.dti.gov.uk/comp/competitive/wh_int1.htm). In 2000, the European Council adopted the so-called Lisbon Strategy. Its aim was to make the EU "the most dynamic and competitive knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion, and respect for the environment by 2010." In 2003, the European Commission demanded: "Europe needs excellence in its universities, to optimize the processes which underpin the knowledge-society and meet the target, set out by the European Council in Lisbon, of becoming *the most competitive and dynamic knowledge-based economy in the world*." (Communication from the Commission – The role of the universities in the Europe of knowledge/* COM/2003/0058final)(http://eurlex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:52003DC0058:EN:HTML).

In 2005, the European Cultural Foundation declared the Creative Sector as an "Engine for Diversity, Growth and Jobs in Europe. The important role of the arts and heritage for the economic development of cities and regions, based on direct and indirect revenues and their employment effects, is of particular importance for regions suffering industrial decline in a post-Fordist age." (The Creative Sector 2005).

And the 2010 document about the EU-flagship Initiative Innovation Union points out clearly again: "Businesses should also be more involved in curricula development and doctoral training so that skills better match industry needs building for instance on the University Business Forum. There are good examples of inter-disciplinary approaches in universities bringing together skills ranging from research to financial and business skills and from creativity and design to intercultural skills. Design is of particular importance and is recognised as a key discipline and activity to bring ideas to the market, transforming them into user-friendly and appealing products." (Brussels 2010).

The strategy was quite sophisticated and multilayered:

1. Tell the cultural sector that it is necessary to stress its effects on economic growth and jobs

to gain a better position in the political decision-making processes.
2. Transform the semantics from Cultural Sector to Creative Industries – thus indicating, that culture now is a part of the industrial sector.
3. Make the members of the former Cultural Sector proud and give them a new feeling of social importance by telling them they would be the new heroes of the society by replacing the weakening old economy.
4. Transform the leading management guidelines of the former cultural sector toward the rationalities of entrepreneurial business administration by implementing a system of mainly quantitative performance indicators for measuring success or failure and for indicating the direction of future development.
5. Express that the mission of the whole Creative Industries Sector is to strengthen the economy and the labor market by providing creativity for innovation.
6. Deplore that cultural activities, which do not have enough short-term quantitative measurable economic effects, cannot have political priority in these hard times.
7. And then declare that Creative Industries is about to become the leading term in cultural policies.

Yes. Cultural industries *are* on the way to become the most important economic sector – especially in urban areas and especially when the leading economic sectors are in trouble. The creative industry does not give a complete image of the system of the arts, not even of the cultural sector, but signs and symbols in communication are important factors – structures and semantics effect habits and minds. So: What does it mean for a musician, a video artist, a poet, and an actor, if he or she is told to be part of the creative industries, because he or she is generating or exploiting intellectual property to earn revenues?

What does it mean for orchestras, dance companies, theaters, art galleries, design-studios, and architects to tell them that their activities are socially justified primarily because they contribute to economic growth and to the stability of the labor market.

What does it mean to art schools if they are told that their existence is socially and economically justified because they contribute to the aim of making Europe the most competitive and dynamic knowledge-based economy in the world?

The mission of art schools is not just to produce human resources for the creative industries, but there would be no art schools if there were no possibilities for graduates to earn money with their artistic skills within the cultural sector. Architects do not plan buildings because they want to support the construction industry – but finally they want to physically realize their plans. Painters do not create their works because they want to increase the economic impact of galleries and museums – but what would happen to all the painters, if there were no galleries, museums, and art fairs? Poets do not write books, because they want to strengthen the printing industry – but what would happen to poets if there were no editors, no printing industry, no theaters, and no broadcasting industry? What would happen to the graphic designers if there was no advertising market? What would happen to the filmmakers if there were no film-industry, no producers, no distributors, and no cinemas?

Creative Industries are not a threat for the arts but the advancement of this term semantically represents the recent social and political developments toward a commercialization of the society quite clearly. The subsectors which are summarized under the term "Creative Industries" of course are important elements of any society. The problem is the hierarchy. Universities are not important, if and because they improve the economy. Culture is not "the heart of knowledge based economy," as the European Cultural Parliament stated (ECP, Lisbon Agenda Research Group 2006). Culture, art, and even science should not primarily be seen as the engine for the vehicle called *economy*, which is moving the society. No, *culture* has to be recognized as the vehicle, which moves the society. And in fact, it *is* like that. To paraphrase Bill Clinton: It is the *culture* stupid! At least in the long run, it is the broad range of culture that matters and that remains in history. Just look at cultural history: Music, theater, literature, architecture, visual arts, visual communication; changing techniques, and changing media from stone carving to digital media, from affecting human thinking and behavior to recently even manipulating genetic and microbiological material – for centuries, these were and still are some of the most significant factors of human development. Factors caused and influenced by the arts.

The main directions of action, interaction, and mutual influence between societal subsystems in general and between the sociopolitical paradigms of economy and culture are of crucial meaning for the direction of societal development.

Two centuries after the Industrial Revolution and in the middle of the Information Revolution, again standing on societal and economic crossroads, the crucial question now is: Is it possible to make the development as well as the realization of creative ideas and visions the very trademark of our societies? If ever human societies can succeed in turning themselves into creative innovation societies – and for the sake of the future generations, this option undoubtedly must be undertaken! –the next societal and economic revolution will have to be a "creative revolution." Thus, the valences of societal paradigms must be shifted – from a mere commercialization toward a re-culturalization of the society – which in particular demands consequences for the educational and economic systems. Instead of the fabrication of products, the creation of new ideas will have to be the focus point for the shape of educational and economic systems. Therefore, providing creativity will have to be the leading mission of educational systems and creativity must not be a separate sector of the economy (creative industries vs. noncreative industries). Following these principles, the arts in general and art education in particular need to be integrated parts of education and economy as the economy will have to become a creative economy in *total*. Of course, this is a revolution indeed and naturally, the usual arguments can be heard: Regarding the recent nature of industrial companies, the employment structures, and the needs of our population, it is not possible to change the types of the existing economic structures! But similar concerns were raised on the threshold of the beginning industrial age when most of the population was working in and living from agricultural production.

The education system in so-called western societies is still characterized by the spirit of the industrial revolution, whose engines were fragmentation, specialization, and rationalization. Art education and art schools have to be counter-models to this development. Not isolated specialized knowledge is the basis for later success, but creativity, flexibility, the ability to think and act in interdisciplinary and intercultural contexts, questioning existing intellectual as well as behavioral habits arriving at with new scenarios and producing amazement with its own work. Thus, the arts and art schools are indispensable elements of societal infrastructure – at least as important for the development of societies as streets and financial services. The political positioning of the arts and art schools has to be changed from a servant of economic growth toward a leading factor of societal progress, at least in a role of an equal partner to the economy in steering the society!

With industrial-production increasingly moving away from the developed world, creative education will be one major stronghold on the way to securing the economic as well as intellectual and social future. Transformations of the workplace as well as throughout our societies require art-institutes to rethink their societal role and emancipate themselves as crucial players on the way to a creativity-based and innovation-driven future society. On the way toward the highest and competitive aims, not only the so-called western societies will be moving away from industrial, agriculture, and service-based economic structures and increasingly focus on the development of an economy coined by visions, ideas, and a permanent drive for innovation. This new creativity-driven economic model must help to erase the economic structures in place since the Industrial Revolution. Creativity, intellectual flexibility, and innovation must become the very basis of all economic efforts. To meet this aim, significant changes in the educational and economic systems as well as in the interrelations between education and economy are to be implemented: Creativity and creative skills will have to penetrate the education sector as well as the economic sector in general.

It was at the end of the twentieth century when politics exclaimed the end of utopias. Economic and political pragmatism should dominate and secure the future; feasibility and quantifiability increasingly became the rulers in education and science. Was it really by chance that a few years after proclaiming the end of utopias, after having stopped searching for totally new ideas and paradigms for the future of our social and economic systems, the waves of economic crisis overwhelmed most societies in rapid sequence. With the crisis of the existing market-oriented economic and social system "the chance may arise for a repositioning of the arts as well as art schools within society – not in terms of a re-politicization of art according to historical examples, but rather in the sense of a 're-socialization' of the arts focussing communication and identification." (Bast 2010) Maybe this could be the first step towards a creative revolution.

Of course, it is correct to say that the arts have become massive economic factors and that art education at the universities must refer to practicality and requires contacts, projects, and cooperation with the economic sector – namely the creative economy sector as well. But, at the same time, practicality is not the primary task of universities. Undoubtedly, it seems that the universities and the people connected to them are steadily submitting to economic pragmatism, when in fact, they should be generating the courage to experiment with regard to thought, design, and action: A courage, which – paradox enough – in the final analysis, is also in the interests of economic prosperity. Art schools must be associated more than ever with the development of the arts and the emergence of new artistic approaches, and not be perceived only as places where artistic traditions are passed on, or where students merely prepare for other places outside the art schools where artistic innovation actually happens. In the twenty-first century, the potential for the renewal of art and art education lies in the synergistic coupling and integration of artistic research and art production, aesthetic innovation, and scientific research, preparing artists for the traditional art market as well as for the various means of societal communication.

Conclusion and Future Directions

Art universities and academies will have to decide quickly whether they will continue in the future to be merely a supplier of human capital for the art, architecture, design, music, and theater market, or if they themselves want to claim the organizational rights to the art system and attain effective power: power in terms of fostering, creating and – yes – even defining aesthetic innovation. Of course, such a goal will require not only a change of consciousness, but also a change of contents and structures.

If art universities, in their function as aesthetic research laboratories, are to develop into an effective force beyond the university walls with an impact on the system of arts and on society, if they are to have even more of a social presence when it comes to contemporary art, architecture, and design as well as music, dance, and theater, then the existing institutions must be prepared to expand their traditional roles and spheres of activity. The universities of the arts must seek closer ties with museums and exhibition houses, with activities in the field of urban and social innovation, with theaters and the music industry, as well as connections to current forms and platforms of alternative and popular culture. And art universities must focus on artistic research – much more than they have done so far.

In current social perception, which is colored by the media and politicians, the term "innovation" is more than ever associated with technological and economic progress.

Therefore, the universities of the arts must take care that they do not stumble into an identity trap. The *Zeitgeist*, which dictates that universities – like factories – must also be as efficient and practically oriented as possible, is placing increasing pressure.

Cheaper and quicker output, necessity, need, and economic utility are the dominating arguments in discussions about universities and art universities in particular. The principal ideas of what is university seem to get paler and paler in present times. Universities do not produce products; they had and still have to generate ideas, attitudes, and perspectives in the hearts and in the brains of people who are enthusiastic enough to meet the challenge of leaving the trodden paths of thinking and acting.

In other words: The output of universities in general and especially of universities of the arts is shaping the future. Therefore, universities of the arts should adopt an offensive and self-confident attitude in the societal competition relating to the definition of progress and, thus, generate courage.

Preparing Students for Learning Through Invention Activities

James Day
Department of Physics and Astronomy, University of British Columbia, Vancouver, Canada

Introduction

Different forms of instruction are better suited to different learning outcomes. For example, repetition is commonly used for developing motor skills and reinforcement is commonly used for fostering desired attitudes or behaviors. Regardless of the specific pedagogy used, humans generate knowledge and meaning from an interaction between their experiences and their ideas. Many educational settings make it difficult for students to make this connection. For example, some disciplines focus mostly on problem-solving routines, but instruction in problem-solving routines is unlikely to prepare students for many other situations they are likely to encounter. Instead of focusing exclusively on problem-solving techniques, instruction should also focus on students' abilities to learn from new situations and resources. Preparing students for future learning, arguably the greatest educational outcome an instructor could hope to achieve, requires the development of new instructional methods as well as the development of assessments that can reliably evaluate whether or not students have been prepared to learn. One such recent and evolving instructional method is the use of so-called invention activities in the classroom. To quantify the effectiveness of such techniques and subsequently optimize them, an increased emphasis must be placed on the development of assessments that can reliably measure this very preparedness of a student to learn.

Key Concepts and Definition of Terms

Key Concepts

1. Experts and novices differ in meaningful ways. The study of these differences has revealed important distinctions in how experts learn new ideas and how they organize and apply their existing knowledge. This is important because it provides insight into the nature of thinking and problem solving – specifically, it provides insight into the nature of learning.
2. The transfer of knowledge is a highly desirable and worthy educational outcome. This is an outcome distinct from simply learning new ideas or from applying existing knowledge to the context in which it was taught.
3. Simply providing students with the expert knowledge – whether it be facts, formulas, or other – can be an efficient method of teaching. Often, this efficiency is a shortcut to some final piece of information, the price of which is that students do not develop integrated knowledge structures. It has been demonstrated (Schwartz and Martin 2004) that telling students the expert knowledge is much more effective after the students have investigated the structure of the phenomenon or idea.

Definitions

Expert: Someone with comprehensive knowledge and/or substantial ability in a specific, well-distinguished domain. Being an expert usually translates to being widely recognized as a reliable, authoritative, and credible source of information, technique, or skill.

Transfer: The application by an individual of the skills, abilities, or knowledge acquired in one setting to a second, unfamiliar setting. Neither a clear nor objective demarcation exists between near and far transfer, but attempts have been made to outline a spectrum along which transfer tasks may be placed (Barnett and Ceci 2002).

Invention Activity: An exercise in which students receive a set of carefully selected cases and their task is to invent a compact description of the data that generalizes across the cases. Students do not need to discover the correct answer. Instead, the invention activity helps students to notice important structure in the cases and to form an organizational framework that prepares them to understand conventional descriptions. After the invention activity, students are ready to be told the expert knowledge.

Metacognitive Scaffolding: The provision of support (e.g., in the form of templates, guides, or reflective questions) to promote awareness of learning when concepts and skills are first introduced to students. Such supports can be gradually removed as the student develops autonomous learning strategies.

Theoretical Background and Open-Ended Issue

The study of differences between experts and novices has revealed important distinctions in how they organize and apply their existing knowledge and how they learn new ideas (Ericsson 2006).

People who have developed expertise in particular areas are, by definition, able to think about problems or perform in situations with efficacy in those areas. It is not simply general abilities (such as memory or intelligence, strength or dexterity) that differentiate the expert from the novice nor is it just the application of general strategies. Rather, experts have acquired vast knowledge and experience that affects not only what they notice in their environments but also how they in turn coordinate, constitute, and construe that information. These are the processes that, consequently, affect abilities to recall, reason, and resolve problems or perform tasks. Understanding expertise is important: not because we want to develop our students into experts of any particular discipline, but rather because it provides meaningful insight into the nature of thinking and problem solving.

Numerous examples of how experts differ from novices are outlined in the second chapter of Ref. (Bransford 2000) and include: that experts have well-developed abilities to notice relevant features, structure, or patterns of information in evidence or situations; that experts possess a mental framework for organizing their knowledge that novices lack; that experts' knowledge cannot be reduced to sets of isolated facts or propositions but instead reflects context of applicability; that experts are able to flexibly retrieve important aspects of their knowledge with little attentional effort; and that experts have varying levels of flexibility in their approach to new situations.

The primary goal for educators should be to equip their students with the skills and attitudes that will be of value to them no matter what may be their later path in life. All the same, it is only natural for an instructor to teach under the assumption that their students will continue studying the current discipline being taught (e.g., a physics teacher assumes they are teaching future physicists). So, how does one position novices onto a path to expertise? Verbally communicating the expert knowledge to the students gives the impression of being an efficient way to teach, but it seems so because it is a shortcut. The cost of this shortcut is that students do not develop integrated knowledge structures. This does nothing to progress students towards the expert characteristics listed above. However, the act of telling becomes much more effective if the students have already engaged in investigating the structure of a phenomenon or idea. Instructors must remember that what is an obvious structure for them may not exist for the student. Students will need to investigate this structure on their own. Investigating the structure does not mean solving a series of discrete or step-by-step problems, because students are likely to treat each step as a separate exercise. Instead, instructors can use invention activities as a proven way to get students to explore structure: students receive a set of carefully selected cases, and their task is to invent a compact description that generalizes across the cases. Students do not need to discover the correct answer. Rather, the invention activity helps students notice important structure in the cases and to form an organizational framework that prepares them to understand conventional descriptions. After this invention activity, students can be told the expert knowledge which they will experience as an elegant solution to an authentic problem.

While this approach may help students to learn content, it does not necessarily guarantee that they become more expert-like in their behaviors. A particular question in this regard is: How do we teach better for transfer? The notion of transfer is at the root of our educational system. Teachers want more from learning activities than simply being successful with the lesson at hand, confined geographically and temporally to their classroom. Educators want learning activities that transcend their classroom and benefit their students in the real world. They are hopeful that students will show evidence of transfer in a variety of situations: from one problem to another within a course; from one course to another within the school year; from one school year to the next; and from problems encountered in school to problems encountered in the real world. Even when certain expertise is present, it does not follow that the transfer of particular skills to new situations (termed "adaptive expertise") will result (Bransford 2000). The question of teaching better for transfer remains mostly unanswered. This is in large part because, after decades of intense research activity on the topic of transfer, scholars remain as divided on the issue as they were at its inception. There are some who claim that transfer is exceptionally rare, there are some who state that transfer is increasingly prevalent, and there are some who opine that the situation is plainly unresolvable and that consensus might never be reached. The corpus of scientific knowledge reasonably makes the case that transfer is indeed a salvageable concept (Barnett and Ceci 2002), and some recent evidence suggests that one of the more promising avenues for the improved teaching of transfer is the proper use of invention activities.

Rather than stumbling through the dark in search of other pedagogical techniques for the teaching of transfer, it is worthwhile to focus our attention to methods that we have already identified as fruitful. In looking under the light, researchers and educators have considered how invention activities could be better delivered. There is good evidence to suggest that transfer is greatly aided by invention (Schwartz and Martin 2004). There also exists evidence that demonstrates how scaffolding these discovery learning activities can boost learning outcomes. Activity scaffolding can occur in a variety of different ways (Lajoie 2005). As some of the loftiest learning goals for introductory university courses involve some form of metacognition (e.g., to have students learn to become better learners), it seems reasonable to complement invention activities with metacognitive scaffolding. Such metacognitive scaffolding might include reflective questioning (does your quantitative final answer run counter to your gut feeling?), structuring the order of operations in a problem (before constructing your analytic solution, first list the properties it should possess), and peer evaluation (have another student critique your solution). Beyond seeming reasonable, this complement of techniques has the benefit of being testable. Researchers can actually measure whether or not students learn content or concepts better and, in principle, whether or not students transfer better when metacognitive scaffolding is built into an invention activity.

The difference between what is possible in principle versus in practice is paramount. How do we measure whether students have improved their transfer skills from invention activities? This question is likely to remain a difficult one for researchers and educators alike. What is needed is that reliable and valid methods of assessment are created to properly measure a students' ability to transfer.

Implications for Theory, Policy, and Practice

The delivery of a learning activity is at least as important as the learning activity itself. Invention activities are no magic bullet and specific care must be taken to ensure that the invention activity is properly delivered. Without proper execution of the activity, students can become frustrated with the activity and both their motivation and their willingness to learn will decrease. In principle, a good invention activity has some rather specific characteristics.

First and foremost, a good invention activity should present a clear and challenging goal to the student – an authentic problem. The goal is often to develop a compact and consistent description or representation of the important features across the given cases. Typically, the description entails integrating multiple features into a single representation, such as a ratio in the simplest case. Examples of these goals could be to find an index for pieces of wood that will allow one to predict whether they will float or sink, or to create a graphical representation that displays the important patterns of an experiment, or to design a cell membrane that allows certain substances to pass through but not others. An appropriate goal is consistent with what an expert does when trying to describe or present novel findings.

The use of contrasting cases in an invention activity is also exceptionally important. Contrasting cases can help novices to notice the distinctive features of each case which they might not otherwise notice (like glasses of wine tasted side by side). An invention activity should comprise multiple cases concurrently, so that students notice both the structure itself and the structural variations across cases that transcend their superficial differences. Ideally, these contrasting cases are made to vary systematically on key parameters, so that students can see how the variations relate at a deeper, structural level. When variables are presented in a confounded way, the contributions of their effects to the parameter under study become significantly more difficult to extract (imagine determining the quality of two wines made from different grapes, served at different temperatures, and paired with different meals). Two to four contrasting cases will provide a reasonable level of difficulty, but a single case can be made to work as well, provided that students will spontaneously generate contrasting cases. If the contrasting cases are structured so that a reasonable but wrong description can be created by the students (e.g., based on just one or two of the given cases and failing to work for the others), then assurance can be taken in having selected suitable cases.

It is also necessary to be mindful of the context and wording of the invention activity, as well as its level of difficulty. The invention activity should involve material that is relatively familiar and meaningful to the students. When such context is lacking, students might not be able to recognize when a description or representation fails for a given case. (Specific demographics have been observed to stall in the earliest stages of certain activities because of an unfamiliarity with things like pitching machines or pumpkin pies.) The task and cases must make sense to the students. Beyond context but still related to making sense, the invention activity should be worded in a manner which avoids jargon. Use of specialized language can trigger the very common student response of equation-hunting ("What was that formula we learned?"), rather than the desired preparing-to-learn response ("This is a new task!"). For instance, in the example above with the pieces of wood sinking or floating, one should avoid the term density. If students attempt to force some previously learned process or concept upon the task or, worse, if they immediately try to look up the solution, then it should be taken as an indication that language has short-circuited and sabotaged their thinking. That is not to say that recalling familiar concepts should be discouraged, only that the blind use of tangentially related concepts is undesirable. Ironically, this camouflaging of the concept in an authentic problem seeks to prevent (initial) transfer of such tangential concepts and allows students to observe the underlying deep structures. Concerning level of difficulty, students should have partial success and not be expected to come up with the solution that covers all cases and took experts centuries to discover. If one is interested in teaching complex ideas, multiple activities should be used that are each limited in scope. To this end, each activity should be used to introduce one or two new structural parameters. If the students are able to get started but seldom find the perfect/complete answer, then the invention activity probably has an appropriate level of difficulty.

Invention activities work best when attempted by pairs (or small groups) of students and so should be completed collaboratively. By explaining to their partners how they have reached a conclusion requires of the student an analysis of their own thought processes; conveying these ideas to others helps deepen their understanding because the student has to explain it in a manner that their peers can also understand. In this way, small group work fosters deep learning. Furthermore, establishing meaning and understanding through presentation to others aids in memory encoding, storage retention, and retrieval.

The structure of the invention activity should not allow for students to be able to divide up the task and work independently; rather, the classroom should be filled with exchanges similar to "But would that method work for this case?" or "Does this solution make qualitative sense?"

Finally, authors of invention activities should anticipate a design cycle. Ideally, one should field-test the activity with a few representative students first and modify as needed before using it with a class. Realistically, modifications are typically made to the following year's class based on what was learned in the previous year. If, when completing the invention activity, students slowly begin to notice and try to represent the key structures that an expert can see easily in the cases, then the invention activity is probably in suitably functional form.

An example of a simple invention activity is shown in Fig. 1. The premise of this invention activity is that students will be better prepared to understand the formula for standard deviation when first afforded an opportunity to differentiate the elements of variability for which the formula must account. Working in small groups, the students try to generate a formula that accounts for all the given quantitative properties (e.g., dispersion or sample size). At the end of the exercises, students should be shown the variability formula used by experts. Other explicit examples of effective invention activities which precede direct

Preparing Students for Learning Through Invention Activities, Fig. 1 A sample invention activity, in the domain of statistics (Modified from data published in Bransford and Schwartz (1999))

Pat, Alex, Chris, and Lee are all members of the Little City Basketball Team. After five games of the regular season, the four begin contemplating their offensive contributions to the team.The table below shows how many points have been scored by each player per game.

Player	Game 1	Game 2	Game 3	Game 4	Game 5
Pat	6	4	8	10	2
Alex	6	5	7	8	4
Chris	10	2	10	10	2
Lee	14	-	8	12	-

Goal: Create one or more mathematical formulas that summarize how each player tends to score in a game.

instruction can be found, for example, for the case of teaching variability in data and the difference between accuracy and precision (Schwartz and Martin 2004) and for the case of creating histograms and calculating standard deviation (Day et al. 2010).

The main purpose of an invention activity is to prime students for learning; therefore, direct instruction must follow the invention activity. Upon detecting the important structure in the cases, students are better able to build an organizational framework that prepares them to understand the conventional description then presented by the instructor – the "elegant solution" to an authentic problem.

The potential benefits of an invention activity are nearly completely lost if this final step is not taken. Conversely, great outcomes can result from proper execution. For example, in a sequence of design experiments on the teaching of descriptive statistics, Schwartz and Martin (2004) demonstrated the effectiveness of invention activities when they preceded direct instruction, even though these students failed to produce canonical conceptions and solutions during the invention phase. In this study, it was observed that invention activities, when coupled with subsequent learning resources like lectures, led to strong gains in procedural skills, insight into formulas, and abilities to evaluate data from an argument. Most importantly, invention activities were found to significantly boost students' future learning, when compared against direct instruction (simple "tell-and-practice") alone.

Conclusion and Future Directions

There is a growing body of literature demonstrating the existence of benefits derived from invention activities on present and future learning. An apparent relationship between failure and mental frameworks forms a common thread through many of the diverse research programs investigating how students learn. The central findings of these research programs can collectively be interpreted as an argument for the delay of structure in learning and problem-solving situations, be it in the form of feedback and explanations, coherence in texts, or direct instruction. The convergence of evidence is pointing to the efficacy of learner-generated processing, conceptions, and understandings, even though such conceptions and understandings may, in the shorter term, not be correct and the process of arriving at them not as expeditious.

One future direction is to deliver these activities with computer-based intelligent tutoring systems. These are used to coach students while they are problem-solving. While intelligent tutoring systems offer sufficient support with proven learning gains, the tasks they facilitate (e.g., basic descriptive statistics or simple graphical representations) are relatively constrained and do not require students to practice their inquiry and scientific reasoning and learning skills. One recent step in this direction has been termed the Invention Lab (Roll et al. 2010), which is an environment that complements the benefits of constructivist tasks (e.g., quantifying the spread of data about the mean of its set) with adaptive support (e.g., an algorithm that generates contrasting cases on the fly). The Invention Lab facilitates invention activities that are structured, more or less, as outlined above by an ex tempore analysis of students' inventions and subsequent creation of new problems to match the perceived gaps in their understanding. In so doing, the Invention Lab offers support without reducing critical elements of the constructivist activity. More recently, these ideas have been extended even further. There exists a computer-based interactive learning environment, called the Invention Support Environment (Holmes 2011), that was built to both improve the in-class use of invention activities and act as a research tool for studying the effects of these activities (for the case of scaffolding relatively complex learning (Reiser 2004), what role does domain-general scaffolding of invention activities play in supporting the acquisition of domain knowledge and of scientific reasoning skills?). The system was designed to support various levels of domain-general scaffolding, as well as invention and reasoning skills. The system also features a platform for which new invention activities may be created and requires minimal programming experience (if any).

A salient characteristic of many research studies usually involves the use of a final transfer task in a "sequestered problem-solving" (SPS) way. In other words, the subjects are isolated while working on the transfer task so that they do not have opportunities to invoke support from other resources (e.g., texts or peers) nor may attempt various solutions, receive feedback, or revise their work. Along with the SPS paradigm is the conception that effectively defines transfer as the ability to directly apply (DA) one's previous learning to a new setting or problem. Of course, there exist alternatives to the union of SPS methodology and DA theory. One such alternative is the approach that appreciates the validity of the SPS/DA position but also extends the concept of transfer by introducing an emphasis on the student's "preparation for future learning" (PFL). In the PFL model, the focus shifts from sequestered tasks to assessments of the student's abilities to learn in knowledge-rich environments and from single-shot task performance to extended learning. The better prepared a student is for future learning, the greater will be the transfer (in terms of speed and/or quality of new learning). So, what does this mean for how research on transfer might look in the future? From the PFL perspective (Bransford and Schwartz 1999), it means that assessments of people's abilities can be improved by moving from static (single-shot, summative testing) to dynamic assessments (environments that provide opportunities for new learning). What one currently knows is clearly important for future learning – this new perspective further proposes the hypothesis that a dynamic assessment of a student's ability to learn over an extended period might better predict that student's success "in the end" than a single-shot SPS test at the beginning. This is a major challenge for future research.

Principal–Agent Model in Universities, Problems and Solutions

Andreas Panagopoulos
University of Crete, Rethymnon, Greece

Synonyms

Agency dilemma; Lack of disclosure

Introduction

The modern day university acts as a powerhouse of indirect economic activity that stems from the scientific discoveries, inventions, and innovations that university scientists develop. Bearing in mind that it is hard to assess the potential of novel discoveries, the university is facing the so-called principal–agent problem in the way it incentivizes the research of faculty members.

Definition of the Principal–Agent Problem

The principal–agent problem (henceforth PA problem), which is also known as the agency dilemma, concerns the difficulties in motivating one party (the agent), to act on behalf of another (the principal). In universities, the PA problem is manifested in (1) the way the university motivates faculty research and (2) in the way the university motivates disclosure of faculty inventions to the university Technology Transfer Office (TTO), which is also known as Technology Licensing Office (TLO). The role of the TTO is to act as a technology-transferring mechanism that allows the university to profit by assigning the rights of faculty-made scientific discoveries to a third party.

The Principal–Agent Problem in Motivating Faculty Research

In terms of motivating faculty research, universities rely on the so-called peer-review system, where peer review is a process of evaluation involving qualified individuals within the relevant field. Accordingly, faculty members are rewarded (in terms of tenure or promotion) depending on how many journal publications they amass in journals that follow the peer-review system. Furthermore, reward depends on the quality of the peer-reviewed journal per se, as well as on how many citations such publications stockpile. In effect, the university outsources the solution of its PA problem to independent scientific journals. Thus, it is up to these journals (which usually lack formal ties with the university) to determine what is published and where, and it is up to the readers of such journals to cite the published work or not.

Consequently, with little effort, the university has at hand a cardinal measure of faculty quality on which to base its decisions.

The Principal–Agent Problem in Motivating Disclosure of Faculty Inventions

The facts of university technology transfer are, in theory, surprisingly simple. Upon invention the faculty scientist is obliged to disclose her invention to the TTO, and the TTO must then try to assign the rights of the said inventions to a third party. In this manner the university can derive pecuniary benefits that are then shared with the faculty scientist. Unfortunately, in practice, university technology transfer is not as simple, and only a subset of all faculty inventions are disclosed to the TTO. In fact, as Markman et al. (2007) show, high-valued inventions are never disclosed, leading to a considerable loss of profits for the university. This is not surprising as the benefits accruing to faculty scientists upon disclosure are commonly in the range of 30 % of licensing proceeds, with the university keeping the rest.

It has been argued that the solution to such unwillingness to disclose is a simple reallocation of proceeds. As Thursby and Thursby (2004) note, disclosure is linked to the pecuniary rewards that faculty attains from licensing. Therefore, as suggested by Lach and Schankerman (2004), disclosure can be achieved by shifting the distribution of licensing proceeds in favor of faculty members. This seems easier said than done. In fact, as Markman et al. (2012) display, high-valued inventions will only be disclosed to the TTO if the scientists effectively free-ride, attaining 100 % of the licensing proceeds, in which case the university is left with naught.

Notwithstanding the above, as TTOs have been accused of failing to attract quality licensees (further worsening the lack of disclosure), the distribution of proceeds is but one of the problems plaguing faculty disclosure. In illustrating this point, Markman et al. (2005a) find that TTOs are extremely risk-averse and follow suboptimal licensing strategies focusing on short-term cash maximization. Along these lines, Siegel et al. (2004) present evidence indicating that TTOs appear to do a better job in serving the needs of large established firms, instead of small entrepreneurial firms; even though it is the latter who usually have a greater capacity for adding value to the invention.

In addition, Siegel et al. (2003a) find that informational/cultural barriers exist between TTOs and small firms. This argument is in line with Markman et al. (2005b) who focus on the bureaucratic nature of TTOs. As they argue the bureaucratic nature of TTOs creates barriers for disclosure. This observation is in agreement with Siegel et al. (2003a), and Siegel et al. (2003, 2004) who suggest that the key obstacles to effective university technology transfer seem organizational in nature. As they note, university technology transfer is obstructed by differences in organizational cultures between universities and firms (especially smaller firms), incentive structures, and staffing/compensation practices followed by TTOs.

Solving Principal–Agent Problem in Motivating Disclosure of Faculty Inventions

The main solution used so far is monitoring, which as Markman et al. (2012) display has thus far provided limited results because it is difficult to prosecute academic personnel failing to abide with the TTO's objectives. It stands to reason that the optimal solution to the PA problem would be one that allows faculty scientists a free hand in dealing with their inventions, while fully informing the TTO of their actions, allowing the university to appropriate part of the proceeds. Panagopoulos and Carayannis (forthcoming) formulate such a solution.

As Panagopoulos and Carayannis (forthcoming) display, by altering the TTO's role, from a monitoring office that licenses/transfers university technology to an office that offers faculty scientists some form of "insurance" that guarantees them a positive return if/when they have failed to license their technology (on their own), full disclosure can be achieved. Furthermore, this "insurance" does not have to be pecuniary. In fact, it can take the form of extra brownie points (or any other form of social currency) in appreciation for the faculty scientist's (important yet unlicensed) research. Such a focus on nonpecuniary incentives is in line with Hayter (2011) who suggests that faculty scientists do not solemnly define success in terms of monetary gains and can be also motivated by peer recognition or the choice of public service.

The rationale behind this proposal rests on the following principle. Consider an agent who is bargaining with another party on how to split some value. If this agent is left destitute upon failing to negotiate an agreement, she is obliged to bargain with her back against the wall, accepting even suboptimal arrangements. By contrast, the same agent should expect a better bargaining outcome when she bargains having something to rely on (i.e., a positive outside option) just in case bargaining fails.

The above example suggests that in licensing negotiations by pumping up an agent's outside option, she can expect a better bargaining outcome. The implication of this reasoning is that a faculty scientist (who aims to negotiate her own licensing deal with a perspective licensee) should be willing to disclose her invention to the TTO in order to be granted the aforementioned outside option. All that is needed for achieving disclosure is for the TTO to charge a price (i.e., the licensing proceeds that the university keeps) that does not exceed the additional benefits accruing to the scientist because of this outside option.

Taking a Closer Look at This Policy

Following Binmore (1992, pp. 189–191), cooperative game theory suggests that bargaining can be modeled, via a technique known as Nash bargaining, by using the so-called Nash product. This product accounts for how two parties split up a certain value they are bargaining on depending (1) on how much each party gets if bargaining is fruitful and (2) on one's outside option if bargaining fails. In terms of point (2), maximizing the Nash product (in order to find the optimal bargaining share of each party) immediately lays the argument bare.

Specifically, the bargaining share that accrues to the faculty scientist must always be a positive function of her outside option. In brief, by increasing this outside option the faculty scientist stands to gain a greater share from splitting the value of the technology she is trying to license. The intuition behind this point is almost elementary as it suggests that agents who do not have much to lose can barter a better deal compared to agents who face a negative outcome upon failure and are thus inclined to accept even suboptimal bargaining shares.

As a result, since her share of the licensing fees increases, the faculty scientist should be willing to pay for such an outside option (the abovementioned "insurance") by disclosing her technology to the TTO, allowing the TTO to charge a fee for its services. Consequently, all that is needed to achieve full disclosure is for the TTO to offer some "insurance" that does not exceed the pecuniary benefits accruing to the faculty scientist because of this additional outside option that she enjoys. In determining the value of this "insurance," as well as the TTO's share of the proceeds, one must compare the faculty scientist's payoff from licensing in the absence of such a scheme with the payoff she derives by disclosing her technology to the TTO in exchange for the said "insurance."

For this scheme to work, two are the important parameters that if calibrated correctly can lead to full disclosure for all types of inventions, (1) the value of the "insurance" and (2) the share of licensing fees that accrue to the TTO upon disclosure. Nevertheless, a few interesting points can be immediately differed from the above discussion. Specifically, as Panagopoulos and Carayannis (forthcoming) note, since an increase in the university's "insurance" policy increases the bargaining share of the faculty scientist, in principle the university could charge a greater fee for such a service by appropriating a greater share of the scientist's licensing fees.

In a nutshell, the TTOs share of the proceeds must be positively related to this "insurance."

Conclusion and Future Directions

This policy is effectively a forward looking policy that aims to solve the problem before it emerges. Furthermore, by solving the problem of disclosure this policy further promotes technology transfer, speeding up the innovation process. In this respect, this method adds to a well-established arsenal of incentives that promote innovation, an arsenal that includes patents and prizes as incentive mechanisms. However, prizes and patents do not address the PA problem. In this fashion, the incentive mechanism described here shares some common aspects with the Phoenix Awards, pioneered by the Economic Development Board (EDB) of Singapore. Specifically, since 2000 the Phoenix Award "*seeks to acknowledge technology-related entrepreneurs who have weathered the storm prior to success*." For this award, which seems to be largely dormant at the moment, nominees are evaluated on the way they managed to overcome past business failures prior to finding success using technology. Since the Phoenix Award is backward looking, taking place after the inventor has failed to implement her technology, it is not directly comparable to the "insurance" described here. Nevertheless, the way the award has been structured (and the process used in deciding who gets the award) could offer some important insights on how to accurately come to a decision on the magnitude of the "insurance" that each individual faculty member may require.

Nowadays, fierce competition and industry relocation toward developing countries, entrepreneurship, and innovation are widely recognized as key factors in competitiveness. The shortening of the product life cycle (products and services), the need to differentiate from competitors and reduce manufacturing costs, and effective logistics and marketing are all reasons to create and develop innovations to meet these challenges. For many countries, the private sector and entrepreneurship have been a powerful engine of economic growth and wealth creation. The formation of new businesses leads to job creation and has a multiplying effect on the economy. Socially, entrepreneurship empowers citizens, generates innovation, and changes mindsets. To that effect, studying the processes that lead an entrepreneur to look for new business concepts and then new product development processes is central to the innovation dynamics.

Entrepreneur Abilities

The most well-known definition of an *entrepreneur* is that of Schumpeter (1934). Indeed, since the 1930s, he has argued that the role of the entrepreneur is essential for economic dynamics and that the individual entrepreneur is the real source of innovation. He said that an entrepreneur is not considered as an inventor, but seems to have a particular momentum, a sense of authority and challenge enabling him to achieve a *new combination* of factors. However, it should be noted that the concept of producing a *new combination* has been somewhat questioned by Perroux (1951) who emphasizes the vagueness of the role of the entrepreneur in the Schumpeterian definition. "A comprehensive analysis of this concept leads ineluctably to the recognition that it denotes a series of separate operations. To achieve the full meaning of the term *new combination*, it must incorporate not only the principle design, assess its implementation plan, decide on the execution, overcome resistance, or raise capital and skills but also agree to take on the production risks permanently. The latter agreement, the latter act, is decisive. Until it is done, all the others remain futile." In other words, the entrepreneur's role is to transform the idea into reality, allowing us to consider innovation as "creativity in action" or the opening up of new areas of design. Indeed, innovation allows the exploration of new areas of knowledge, unsuspected at first, which results in opening up realms of possibilities and the introduction of a high degree of variability into the innovation process (Smith 1996).

The result is, in fact, a higher level of risk to be managed by taking into account a global, systemic approach incorporating information from the environment that has an impact on the process of creating a new business.

Consequently, new methods and skills are needed to enable entrepreneurs to identify opportunities at any time, leading to the integration of a "constructivist" process of thinking (Smith 1996).

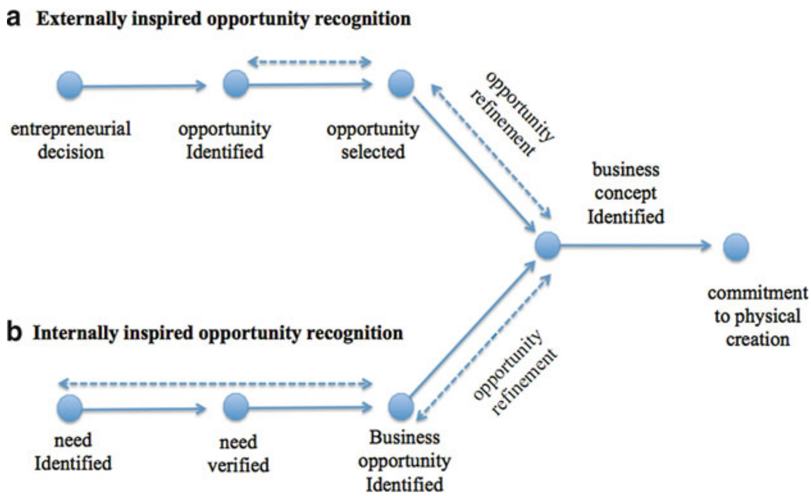
Business Concept and Entrepreneurship

Based on the fact that every business concept has its origin in the ability of the entrepreneur to generate an idea, Bhave (1994) has formalized the existence of opposition in the mind of the entrepreneur at the time of the creative spark, recalling the well-known paradox of the chicken and the egg. Is it the idea or the desire to create a new business which comes first? The author demonstrates that if entrepreneurial desire precedes the identification of an idea, the business process is generated by identifying, selecting, and adjusting an opportunity that becomes a business concept (A). A second case occurs when the creative spark is the identification of a particular need. In this case, the need has to be verified before the business opportunity is identified (B). In both cases, adjustments to the opportunity are formalized in a business concept.

So, the creation of a new business with development potential must satisfy a specific need to claim to become a success. The business concept includes the clear identification and formalization of the unsatisfied need that the new product will provide. For example, how this "product" is new or better than existing ones or what is the unserved market to which it will respond. For Minniti and Bygrave (2001), an entrepreneur's decisions are the result of two types of knowledge: the first from information about market conditions, business opportunities, technologies, or new ideas and the second related to his/her personal experiences, capabilities, and skills as entrepreneur.

The origin of the information used to make decisions is twofold: the entrepreneur's previous experience and beliefs and new information resulting from the formalization phase of the project. The research study by Parker (2006) has shown that on average, these individuals adjust their expectations of unobserved productivity in the light of new information by only 16%. This suggests that while entrepreneurs do exploit new information, they give much greater weight to their prior beliefs when forming their expectations. So the "business concept" appears to be largely predetermined. He also found that, among other things, the age of the entrepreneur and cultural factors significantly alter the influence new information has on decisions (the young entrepreneur seems more receptive to external information because of his reduced feedback or expertise).

Furthermore, it appears that the process of ideation is the result of exchange and confrontation between two spaces of exploration and exploitation. While the first is based on the



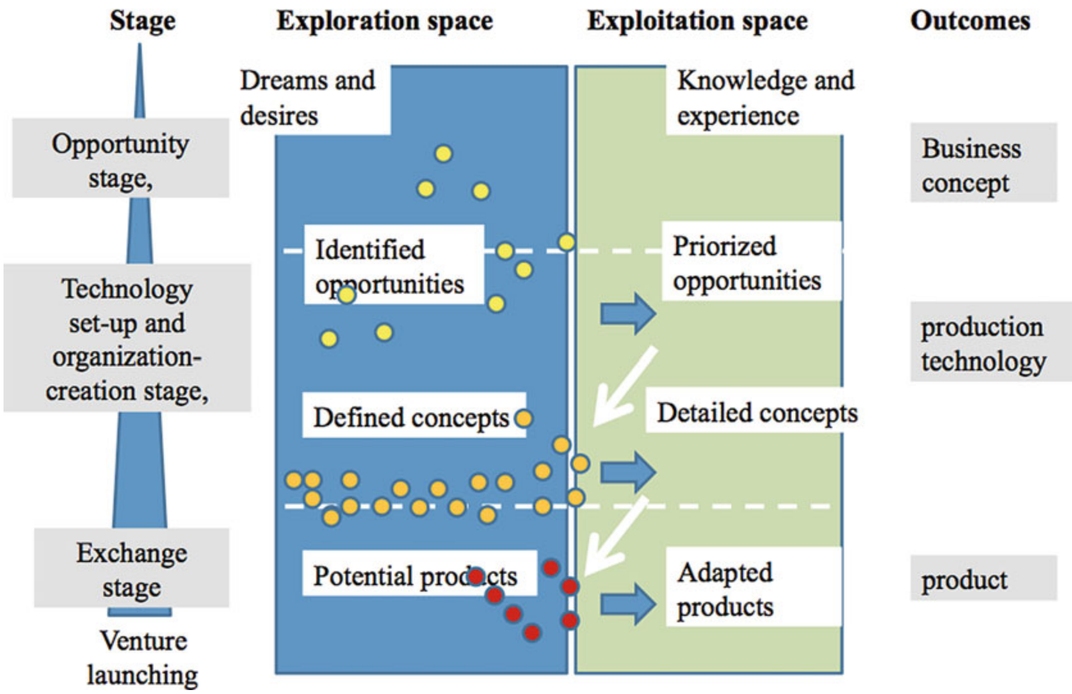
Product Development, Business Concept, and Entrepreneurship, Fig. 1 Opportunity recognition stage in the venture creation process (Source: Adapted from Bhave 1994)

entrepreneur's ability to dream and move forward from his current knowledge and skills leading to innovation, the second reflects a desire to work more in his comfort zone that is based primarily on concepts and processes which are well known and mastered.

Figure 2 shows an overview of the exchange process between the two areas described above. Originally, the model included seven stages (internally and externally stimulated opportunity recognition, commitment to physical creation, production technology setup, organization creation, product creation, connecting to markets, and customer feedback), but for analytical convenience, the author divided the process into three stages: the opportunity stage, the technology setup and organization creation stage, and the exchange stage. Note that the business concept, production technology, and product are the core variables representing the three stages respectively:

– *Opportunity recognition*: This stage includes the process described in Fig. 1, starting from the preparation (internally or externally inspired opportunity recognition) and incubation of the idea through an intuitive non-intentional thinking process allowing the consideration of possibilities or options to solve a problem. This stage ends with the insight (eureka, aha!) and occurs when the entrepreneur consciously realizes that the idea may represent an entrepreneurial opportunity and how it could create value. The main outcome of this stage is the business concept.
– *Technology setup and organization creation*: This involves the tangible actions needed to create an organization, a production technology, a product or service, as well as the first customer contacts. Also, the original idea is further refined toward a more detailed business concept, a practical commitment to actually realizing the idea, and implementing this realization. At the end of this stage, the organization and production technologies are not only defined but the emerging product concept is also evaluated with other people in the entrepreneur's networks.
– *Exchange*: This involves connecting to markets and customer feedback. At this stage, even if the venture has been launched, the product concept and the organization structure must be continually evaluated and adapted from customer feedback until final product definition. There is a growing trend of incorporating latent customer needs as soon as possible in order to reduce the risks inherent to introducing innovation onto the market. A comprehensive analysis of these approaches is made in Ben Rejeb et al. (2011).

In summary, the process of venture creation is a recursive process. Indeed, as pointed out by



Product Development, Business Concept, and Entrepreneurship, Fig. 2 Dynamics of the entrepreneurship process (Source: Our research)

Lumpkin et al. (2004), although the components of the process have been called "stages" here, it is important to note that they are not necessarily linear and may not follow any predetermined sequence.

Business Model and Entrepreneurship

Two schools of thought coexist in entrepreneurship: researchers who argue that a systematic plan and clear business model need to be produced upstream, leading to better performance of the future business, and others who advocate that the entrepreneur's learning ability, flexibility, and strategic management resources are the factors most critical to success, especially in uncertain environments. Furthermore, in a comprehensive literature study using meta-analysis, Brinckmann et al. (2010) reviewed 50 studies in order to explore the effects of a priori planning of the business model on the performance of small businesses already created and entrepreneurial projects. There were two major conclusions:

– First, the positive impact of a priori planning is greater among businesses already established, thanks to their prior knowledge of the industrial sector and information collected about the innovation project to be launched.
– Then, in the case of an entrepreneurial project, basic non-exhaustive planning is enough to start the project. Success will be conditioned by the reliability, quality, and quantity of information gathered and by events requiring the entrepreneur's learning ability and flexibility.

Based on the observation of many several innovation and entrepreneurship projects, a conclusion could be certainly made: the earliest materialization of the idea in product development and the iterative nature of its fine-tuning have a decisive role in defining the business concept to be validated. As previously mentioned, the business concept will be translated paying particular attention to customer definition, the value proposition and compelling story, the product/service proposal, and the identification of the distribution and commercialization process resulting in the development of the most suitable business model. Nevertheless, the choice of business to be undertaken remains complicated. Indeed, the entrepreneur will change back and forth along a path of possibilities from the development of an activity by incremental innovation, which is thus less risky, or focusing his choice on disruptive innovation that, even while it may have more associated risk, can bring the greatest benefits. But this is part of that could be called the "entrepreneur dilemma."

Conclusions and Future Directions

The increasing need to minimize risk and validate the relevance of a concept has led the research into new ways to integrate the customer into the development process as early as possible in order to reduce the uncertainty of the business model definition. In recent years, emerging approaches have appeared based on the open-innovation paradigm, for example, the living labs.

Living labs are innovation environments where stakeholders form a partnership of entrepreneurs, users, public agencies, and research organizations. Cooperation is established for creating, prototyping, and using new products and services in real-life environments. Users are not seen as subjects for innovation and customers, but as early stage contributors and innovators (Følstad 2008). The living labs can therefore be seen as user-driven open-innovation environments with the following features:

Users' integration: In a LL approach, users are considered as cocreators and not simply as observed subjects. In practice, the goal is to increase the degree of user involvement during the product development process. The difficult aspect in this approach is to make users express their preferences consciously.

Interdisciplinary (between partners and users): According to the open-innovation principle, the interdisciplinary approach helps to increase creativity. The interdisciplinary approach allows specifications to be formulated so as to create and develop a product better suited to users' needs.

Experimentation in a real-life context: Taking into account the context for use can have a significant influence on the product's use. The experimentation step is essential for evaluating the potential acceptance/adoption of the product (good, service, application, etc.).

Almirall et al. (2009) defined the implications of involving users as codevelopers under the living lab model for entrepreneurship and more precisely for business concept definition as:

- A reduction in personal entrepreneurial risk
- Support for entrepreneurship through selecting, coordinating, and funding assistance for the innovation network
- The creation of an innovation arena where experimentation can take place
- Fostering an initial demand allowing further development

Indeed, innovation is gradually being perceived, from a systemic viewpoint, as the result of increasingly large groups that were represented first as teams and, later, as networks and communities, leading to an understanding of innovation as an emerging open process based on collaboration and discussion.

Definition

General innovation – It is a process that takes an idea or invention and converts it into a product or service that the general public purchase or possess. Innovation(s) are replicable, have economic costs, and satisfy a need. As related to business, innovation is the application of an idea, which reduces the gap between needs of customer and the performance of the company.

(Source: Business dictionary.com http://www.businessdictionary.com/definition/innovation.html).

Specific Definition of Innovative Organization – It relates to new approaches to work and how work is organized, how workflows operate to enhance customers and employee performance, employee retention, and increase in employee knowledge (Kustoff 2008). Organizational innovation requires a culture that supports new ideas, processes, and new ways of doing business. Organizational innovation values knowledge acquisition and learning. As such, continuous learning is necessary for organizational innovation to succeed. Organizational knowledge should focus on change, better processes, better business outcomes, higher customer satisfaction, and increased sales revenue (Kustoff 2008).

Organizational Innovation

As goes innovation so goes a company's competitiveness, sustainability, and a society's economic growth. Growth and sustainability are dependent on continuous innovation. Change and globalization have forced companies to innovate, change, or go out of business. While some believe this state of affairs is disastrous for a company, for people, and for the survival of society as a whole, it is also thought that this process of change and innovation catalyzed by globalization is crucial to our long-term wellbeing and sustainability. As difficult economic times continue to challenge every manager in every part of the world, innovation becomes the one element of hope for the future sustainability of economic development. Unfortunately, many executives indicate that they have not had the extra cash to invest in business innovation and development. Additionally, the pace of change and globalization has been so fast and intense that executives have not had time to really think through how innovation would allow them to compete more efficiently and effectively. So businesses are in a squeeze. They must innovate, but it is necessary to have the correct financial situation and competitive situation to innovate properly. So what direction do companies pursue? Well, Joseph Schumpeter would tell them to continue thinking, continue to find ways to innovate because in the long run, the concept of "creative destruction" will eventually take care of their business and their competitiveness. Everything will change and new products and processes will emerge whether one company likes it or not. Creative destruction is the driving force for innovation and it is and will continue to affect all people and all organizations whether they like it or not (Reisman 2004; Diamond 2007; Beaugrand 2004).

Industry context, strategy preferences, and technological capacities many times determine the innovative direction of an organization. In some cases, organizational structures can hinder the innovative process by relying on history, strategy, and operational design (Bishop, 2008). Since it is almost impossible to achieve any level of innovation without the proper organization, it is imperative that managers find ways of constructing organizational structures that bypass these obstacles in order to promote innovation of products and processes. Using innovative resources to produce these products and services is absolutely essential (Lam 2004). This means that to achieve organizational innovation among employees and structures, it is essential that there be a culture that promotes learning and knowledge creation (Singh 2011).

So, for organizations to remain competitive, they must think about organizational innovation. This means that organizations need to consider not just innovating new products and services but also about organizational innovation. Organizational innovation refers to creating business models, management techniques, strategies, and organizational structures that will form the foundation for meeting these competitive challenges of the time. Without organizational innovation, as stated in the above definition, product and service innovation cannot evolve or take place. At the core of business innovation are three organizational constructs:

First, *business model innovation* – this is required in order to focus on different markets for selling goods and services. It may move from a low cost producing company to a value-added company. Thus, it will change the dynamics of the production supply chain and sales management (American Management Association 2006).

Second, *business structure innovation* – to meet strategic goal(s) or focus on new innovations, companies need to change structure(s) to meet these needs. Such innovation can be achieved through merger, acquisition, reorganization, or developing different structures that did not exist in the past (American Management Association 2006). This is an innovative approach where entrepreneurs thrive by exploiting new opportunities.

Finally, *business process innovation* – this is a very popular and common practice among business entities. As new demands occur, new ways of developing and producing products can and do emerge. It focuses on how to produce the product and service versus what is produced or delivered in services. Many times the company can increase productivity and quality through business process innovation (American Management Association 2006).

With this in mind, organizational innovation is a concept that managers and executives have to deal with every day in order to meet the global business competitive demands. So, all organizations, to be successful, must learn how to be a versatile, innovative company that is able to sustain its competitiveness. By developing new processes, creating an innovative culture, and recognizing and rewarding employees who are innovative, managers can achieve a constant and continuous creative system that removes many of the obstacles inhibiting innovation (Singh 2011). As David Neeleman, founder and CEO of Jet Blue, has stated: "Innovation is trying to figure out a way to do something better than its ever been done before" (Singh 2011, p.714).

A central tenet of organizational innovation rests upon the notion of organizational learning. That is the belief that no organization can achieve any innovation of any form unless it promotes organizational learning among its employees. The learning that occurs in the organization offers new knowledge that can be used to develop new business models, new organizational processes, and new business structures. The knowledge sharing provides the key to creating and catalyzing the development of new ideas that lead to different types of innovation (Singh 2011). As the interface of the organizational structure, organizational culture, and organizational learning take place, it can be seen that the development of more elaborate organizational innovation leads to more competitive products and services offered to the global markets (Singh 2011).

Within the context of all innovation, four approaches exist that catalyze any thinking and acting managers or scientists have about moving forward in this area. Innovators must decide whether they will be involved with radical or incremental innovation and whether they will approach the innovative process from a linear or a nonlinear perspective. The two most popular types of innovation can be described as follows:

(a) Radical product, service, or process innovation consists of extraordinary breakthroughs that produce a new or fundamentally altered product, process, or service. Organizations or businesses that achieve success with radical innovation can increase their profits, their prestige, and growth of their organization(s). Specific examples include online shopping, iPad, and cell phones.
(b) Contrarily, incremental innovation improves the existing products, service, or process in such a way that the value of the product, service, or process is significantly enhanced for a period of time. Examples of this include quality management or TQM activities, Six Sigma (Center for Business Innovation 2012).

From another perspective, there are two ways to proceed in initiating and pursuing innovative activity. One way is the traditional linear method of innovation. According to this method, innovation begins with basic research that continues on by adding applied research and development to the results of the first step and then concludes with production and diffusion of the innovative outcomes (Godin 2005). The other way is the nonlinear approach, which means that innovators can take different paths in the innovative process. Generally, this method deviates from the lock-step linear approach. The innovators can pursue different iterations, testing, observations, discovery, and retest. Serendipity is a common element of this approach with a moment of eureka being fantastic for the innovator. The nonlinear path does not require a lock-step method to reach the ultimate conclusion of the process (Creativityland 2011).

The approach taken in the innovative process depends on the philosophy or orientation of the people involved. Moreover, the organization sponsoring the innovation may dictate which method should be used. Either way, the final goal is to produce a better product, a better service, or a better process.

In the final analysis, to innovate is a critical business decision. A company's innovation potential resides in the human resources (talent) it recruits, the organizational culture it creates, and the desire to remain competitive. As such, organizations need to have a clear understanding of what their innovative ambitions really are and what innovation goals they want to accomplish. They also need the funding to pursue its ambitions and a pipeline management approach where not only products are services continuously thought about but acted upon (Nagji and Tuff 2012). Some companies will fail, some will succeed but not having a belief in a desire for or an organizational structure to accommodate innovation will be problematic to any organization, which desires future sustainability. Joseph Schumpeter's "creative destruction" concept is like time and tide; it will wait for no one. Either a company innovates or its existence is in jeopardy and their future will not exist.

Implementation

Thinking about innovation is a relatively simple activity when compared to the execution of the decisions to make innovation happen. The hard work relates to implementing the organizational mechanisms both structurally and culturally that will get results. To effectively employ the innovation process or any innovation project, managers must focus on several important elements:

(a) *Attention to policies and practices* that exist or need to exist companywide to insure that proper training transpires, technology is available, and mechanisms are in place for professionals and staff to access the necessary resources to achieve the innovation goals. If there are too many obstacles in terms of rules and procedures, innovation will be difficult to achieve.

(b) *Attention to the importance* of the innovation and its implementation. If there is an attitude that it is just another ole project with limited importance, then proper implementation will be stifled.

(c) *Participation by managers* – in the implementation process is critical. For managers to stand back and just watch the process will not be appropriate or effective. Managers must take an active role in the innovation process and work associated with implementation of innovation.

(d) *Attention to the financial resources*. Without proper allocation of resources, nothing can be completed and no innovation can really take place. The correct amount of financial resources is also an important consideration in this process.

(e) *Having an organization that is oriented to learning* is absolutely critical. Employees who are enthusiastic about the innovation project and excited about learning will go a long way in helping the implementation process.

(f) *Finally, having patience* – this is one element that seems to be fleeting in many organization's projects. Good things take time to emerge and develop. While time is always of the essence in the innovation business, patience is a critical factor in making sure the innovation project is implemented efficiently and effectively (Klein and Knight 2005).

Conclusions and Future Direction

The way an organization innovates depends on how it is structured. Some are formed to accept incremental change while others are structured to move forward with disruptive change. Being flexible and dynamic in its approaches to innovation is the hallmark of a successful organization. Innovative organizations have to have flexible workflows, adaptable administration, and a dynamic culture. The organization needs to develop different approaches to meet the needs of the context within which it operates (Junarsin 2009). All managers in the contemporary business environment must understand that the pathway to organizational growth and development resides in being innovative. Learning how to manage innovation is critical to a company's success in just about any environment. Mastering this task will pay big dividends in both returns on investment and future competiveness of the organization (Nagji and Tuff 2012). The critical focus of managers should be on making sure that time is spent on efficiently and effectively developing the organization's internal environment and innovative capacities of the entire firm. This investment has large return on investment (ROI) in the future. Being innovative is a growing imperative so now, not tomorrow, is the time for action focused making sure the organization is innovative.

What does the future hold regarding innovation and organizations? Understanding and the preconditions for any innovation to take place is an organization that accepts it as an imperative activity and designs the structure that allows innovation to happen. The following outlines areas of management that will have to be considered for organizational innovation to occur:

(a) New business models that create and capture value within the value chain.

(b) Inexpensive innovation needs to occur where managers have to look for venues for developing innovation in low-income markets that can be transferred to more developed markets (Eagar et al. 2011).
(c) Increasing the speed of innovation in order to reduce the time to market phenomena (Eagar et al. 2011).
(d) Developing appropriate leadership styles that recognize and provide the capabilities to move innovative resources to the right pathways in order to meet complex global market demands.
(e) Development of interorganizational relationships that will create networks for joint ventures that focus on innovative product and service development (Annual Review of Sociology 1999).

Innovation is a timeless exercise, but without it, all organizations lose. There is no time better than the present to begin developing resources and management infrastructures designed to create organizations that are capable of promoting continuous and sustainable innovation(s).

Promoting Student Creativity and Inventiveness in Science and Engineering

Introduction

In his 2011 State of the Union Address, President Obama captured the essence of recent national blue ribbon panels and the conclusions of many economists: "We need to out-innovate, out-educate, and out-build the rest of the world" he said. But to create a workforce with enhanced critical and creative thinking skills, we need to train experts in science and engineering who can find innovative solutions to problems. Scientists and engineers in the laboratory or field frequently encounter ill-structured problems that can have many solutions and multiple solution paths. To approach such problems, "higher order" mental operations are crucial. These include analysis, synthesis, and abstraction but in addition, creative thinking, which according to Bloom's taxonomy of learning skills is the most complex and abstract of the higher order cognitive skills (Krathwohl 2002). It is creative thinking that allows restructuring of problem parameters and often produces solutions through unexpected insights (DeHaan 2009, 2011).

It is unfortunate that, in the science or engineering classroom, we often teach as if creativity is not important and as if our fields deal only with well-structured problems with known answers and a single way to find the "correct" solution. Not only is no attention paid to creativity, but – with some exceptions such as Eric Mazur's "Peer Instruction," Jo Handelsman's "Scientific Teaching," or Wendy Newstetter's "Problem-driven Learning Labs" – there is little teaching of any of the higher order cognitive skills in most classrooms. For example, Diane Ebert-May and her colleagues found in a national sample of 77 life science courses taught by 50 different instructors that fewer than 1 % of the items on tests and quizzes were judged to require students to use any of these higher level skills. Could this be one reason that Mark Cracolice at University of Montana and his colleagues report that only about one fourth of US college students have the reasoning skills necessary to solve conceptual problems?

The primary question to be addressed here is how undergraduate students can be taught to enhance their higher order thinking skills and especially how to improve the most abstract and complex of these, that is, to think more creatively. There exists an extensive literature promoting instructional strategies to help students be more creative (For reference citations see DeHaan (2009, 2011). But creativity is a complex construct with many components and therefore not easy to define or assess, especially in the context of science. Nonetheless, evidence reviewed by Michael Mumford and colleagues (Scott et al. 2004) demonstrates that the mental operations required for creativity can be taught and that the instructional strategies that work best are relatively simple modifications of those most effective for teaching abstraction and problem solving.

What Is Creativity?

Theoretical Frameworks that Underlie Creativity

Inventiveness or creativity is often seen as a special talent associated with a Mozart, Michelangelo, or Einstein. This is what Kaufman and Beghetto (2008) call big-C creativity, the ability of individuals to generate new ideas that alter an entire intellectual domain. Howard Gardner defined such a creative person as one who "regularly solves problems, fashions products, or defines new questions in a domain in a way that is initially considered novel but that ultimately comes to be accepted in a particular cultural setting" (Gardner 1993, p. 35). Creativity has been defined within two different theoretical frameworks. In one, a novel idea or solution to a problem occurs in the mind of a single individual as a sudden, seemingly unanticipated creative insight or an "aha" experience. In the other, creativity is a social phenomenon that occurs during interactions among knowledgeable individuals. Kevin Dunbar at McGill University has performed ethnographic analysis of interactions of exceptionally productive scientists during their weekly laboratory meetings. These studies reveal that new hypotheses or models are most often generated through discussions among knowledgeable peers. Dunbar reports that when faced with a series of unexpected results, scientists suggest alternative hypotheses or models to test during their lab discussions through "distributed reasoning." This is most effective when the lab group has scientists from diverse backgrounds that have worked with different organisms and a range of different techniques.

But there is another kind of creativity termed mini-C creativity. Mini-C creativity is widespread among all populations and is represented by the "aha" moment when a student first sees two previously disparate concepts or facts in a new relationship, or a worker suddenly has the insight to visualize a new, improved way to accomplish a task. These are both examples of a kind of creative insight; what Arthur Koestler, in the mid-1960s, identified as *bisociation*, "perceiving a situation or event in two habitually incompatible associative contexts." A classic example in science, among numerous personal accounts, is that of Francois Jacob, co-discoverer of the operon. In a recent essay in *Science*, Jacob describes a creative insight that led to the discovery. Referring to the laboratory of Jacob and Monod at one end of a hall in the Institute Pasteur and that of Boris Ephrussi's group at the other, Jacob says: "Much later came a day in 1958 when, my mind wandering on a lazy July evening, I sensed in a flash that there were important analogies between the systems studied at the two ends of our corridor."

More is known about the mental operations required to produce a creative insight or "aha" experience in an individual mind than the distributed reasoning mechanisms that underlie social creativity. Mark Runco reviewed the evidence in 2004 that two kinds of thinking are required to produce an aha experience in an individual: associative (divergent) thinking, in which thoughts are defocused, intuitive, and receptive to a broad range of associations to a given stimulus, and analytical (convergent) thinking, which provides the capacity to analyze, synthesize, and focus. Efforts to systematically define divergent thinking, which was initially thought to be the main creative element, go back to the 1950s when J. P. Guilford and E. P. Torrance recognized that underlying the construct of creativity were other cognitive variables. According to these pioneers of the field, component mental constructs included ideational fluency (i.e., number of ideas); novelty or originality of ideas; flexibility of thinking (or the ability to produce different types of ideas), as well as sensitivity to problems or missing elements in a situation; and knowing how to search for multiple solutions by making guesses or establishing hypotheses.

Paul Thagard and T. C. Stewart of the University of Waterloo recently introduced the idea of "neural convolution" as a mechanism for integrating disparate concepts or facts in a new relationship in an associative insight. They note that such creative insights often follow conceptual reorganization or a new, nonobvious restructuring of a problem situation. Neuroscience experiments employing magnetic resonance imaging show that different regions of the brain are activated during associative thinking than during analytical problem solving. This is shown when subjects are given remote association problems to solve by associative thinking while lying in a functional magnetic resonance imaging scanner (e.g., find a word that forms a compound word or phrase with each of the following three words: sauce, crab, pine; solution: apple). In this circumstance, brain regions such as the right superior temporal gyrus are more strongly activated than in similar subjects who are given problems to solve by analytical reasoning (Subramaniam et al. 2009). According to Pamela Ansburg and Katherine Hill of Metropolitan State College in Denver, Colorado, associative thinking increases the probability of accessing ideas that are weakly associated with a stimulus, whereas analytical thinking increases the probability that only strongly associated ideas will be accessed from memory.

M. H. Kim and colleagues at Sungkyunkwan University in Korea published a 2007 review of cognitive studies of architects and industrial designers. Their study summarizes the evidence that experts in these fields use strategies for prolonging associative thinking as a means to increase the creativity of design solutions. When design experts encounter an ill-structured problem, they decompose and rearrange components in different contexts, striving to increase the range of associations they apply. Associative thinking is seen as an essential component of creative insight, underlying the argument that science and engineering students, no less than design students, need assistance in enhancing and prolonging associative thinking when dealing with ill-structured scientific problems.

There are numerous strategies meant to achieve this goal. One might be a modification of brainstorming, a technique invented by the advertising executive Alex F. Osborn, that has been shown in modified form to be hugely successful in stimulating inventiveness. In a convincing 2008 *New Yorker* essay, Malcolm Gladwell describes such work by Nathan Myhrvold, the creator of Microsoft's Research Division. Myhrvold has routinely gathered groups of engineers and scientists around a table for daylong sessions to brainstorm about a prearranged topic, say self-assembly or medical imaging. In the previous weeks, participants will have reviewed the relevant scientific literature and recent patent filings in order to be abreast of the latest information on the topic in their area of expertise. The meetings begin as simple conversations, with few ground rules, but at the end, the group will have produced many patentable ideas. Does the method work? Since it was founded in 2000, Myrhvold's firm, Intellectual Ventures, has filed hundreds of patent applications in more than 30 technology areas, applying the "invention session" strategy. Currently, the company ranks among the top 50 worldwide in number of patent applications filed annually.

The main point from all of these works is that creativity is not a mysterious hard-to-measure property or act. While the relationship between creativity in social groups and individuals remains to be explicated, there is ample evidence that a creative insight requires both divergent and convergent thinking and that it can be explained by reference to other well-understood mental skills such as pattern recognition, model building, ideational fluency, analogical thinking, and exploration and testing of alternatives.

Relationship Between Creativity and Expertise

Creative abilities increase in children up to the age of about 8 years and then steadily decrease with further schooling. Most youngsters become increasingly sensitive to the opinions of their peers and adults after age eight, care more about "fitting in," and become conscious of using objects for their intended use rather than for more whimsical purposes. The result is a decline of creativity that usually continues through college. This situation raises a number of interesting questions:

- Are expertise and creativity mutually exclusive?
- Does the very education that gives a prospective scientist or engineer the expertise required to solve difficult problems decrease the likelihood that he or she will be able to invent creative solutions to those problems?
- Are there instructional strategies for teaching complex, content-laden subjects such as science and mathematics that can enhance inventiveness and creativity instead of dampening these abilities?

An extensive literature suggests answers to those questions. It is clear that experts can be creative. Although traditional teaching methods that rely heavily on lectures and rote memorization may dampen creativity, instructional methods that enhance inventive problem solving have been tested successfully. Teaching students to be innovative demands instruction that promotes creativity but does more than that. A large body of research on the differences between novice and expert cognition indicates that creative thinking arises from a certain level of expertise and fluency within a knowledge domain. Ill-structured problems that arise in the real world can be solved best by individuals who know enough about a field to grasp meaningful patterns of information, who can readily retrieve relevant knowledge from memory, and who can apply such knowledge effectively to novel problems. These individuals exhibit what is referred to as *adaptive expertise*. Adaptive experts are able to learn through problem solving as opposed to simply applying knowledge and familiar heuristics to problems. Instead of applying already mastered procedures, adaptive experts are able to draw on their knowledge to build new models and invent new strategies for solving unique or novel problems within a knowledge domain (Nersessian 2010). They are also able, ideally, to transfer conceptual frameworks and schemata from one domain to another. Such flexible, innovative application of knowledge is what results in inventive or creative solutions.

What Is Known About How to Teach Creativity

Promoting Creativity in the Science and Engineering Classroom

Following the Myrhvold model, imagine a classroom in which the instructor takes the role of facilitator in a monthly "invention session."

For this meeting, the topic might be biofuels from algae or nanoparticles as semiconductors. Members of each team of four to five students will have primed themselves on the topic by reading selected articles from accessible sources such as *Science*, *Nature*, and *Scientific American* and searching the worldwide web, triangulating for up-to-date, accurate background information. Each team knows that their first goal is to define a set of problems or limitations to overcome within the topic and to begin to think of possible solutions. The instructor might spark the discussion by asking one of the teams to describe a problem within this topic in need of solution. Although a classroom invention session may seem fanciful as a means of teaching students to think about science as something other than a body of facts and terms to memorize, engaging learners in the excitement of problem solving, helping them discover the value of evidence-based reasoning and critical thinking skills, and teaching them to become innovative as problem solvers have long been the goals of science and engineering education reformers (Handelsman et al. 2007; Felder and Brent 2009). But the means to achieve these goals, especially methods to promote creative thinking or scientific problem solving, have not become widely known or used.

An important part of solving the problem of how to teach creativity is devising conditions to foster such a mental state. On the website of the Center for Development and Learning, Robert Sternberg and Wendy M. Williams offer 24 "tips" for teachers wishing to promote creativity in their students (www.cdl.org/resource-library/articles/teaching_creativity.php). Among them are the following admonitions:

- Model creativity – students develop creativity when teachers model creative thinking and inventiveness.
- Build self-efficacy – all students have the capacity to create and to experience the joy of having new ideas, but they must be helped to believe in their own capacity to be creative.
- Sprinkle question throughout every lecture – make questioning a part of the daily classroom exchange. It is more important for students to learn what questions to ask and how to ask them than to learn the answers.
- Encourage idea generation – students need to generate their own ideas and solutions in an environment free of criticism.
- Cross-fertilize ideas – avoid teaching in subject-area boxes, a math box, a science box, etc.; students' creative ideas and insights often result from learning to integrate material across subject areas.
- Imagine other viewpoints – students broaden their perspectives by learning to reflect upon ideas and concepts from different points of view.

Strategies like these have been grouped under the term "scientific teaching," a highly successful pedagogical approach designed to reduce rote memorization and to promote active learning on the part of the student (Handelsman et al. 2007; Ruiz-Primo et al. 2011). But even in those courses where active learning instruction has been employed, the emphasis has generally been limited to analysis, synthesis, and critical reasoning, the higher order cognitive skills that are less abstract than creative thinking on Bloom's scale (Krathwohl 2002). We expect science and engineering students to solve problems, but we rarely ask them to search for novel problem solutions through the extended exercise of associative thought. Students need to be reminded that there may be other ways to view a problem than the way it is presented; to list the problem features and then try to rearrange or restructure them, or look at them from different angles; and to generate many ideas about possible solutions before beginning to evaluate which of them may be best.

Do these strategies work to enhance creative thinking? A meta-analysis of 70 creativity training studies revealed that the number and diversity of associations could be increased by teaching students techniques to increase associative thinking (Scott et al. 2004). Below are some specific strategies from a prior publication (DeHaan 2011) that are thought to increase students' access to creative insights. With practice, each strategy should take no more than 4 min when inserted into a standard 50-min lecture.

- *Think-Pair-Share-Create*: This variation of the classic think-pair-share strategy is especially useful for fostering associative thinking in ill-structured problem solving. Part way into a lecture, the instructor poses an open-ended question or problem, gives students 1 min to think individually about an answer, asks them to pair up with a neighbor to briefly discuss and reconcile their responses, and finally, reminds students to list the features of the problem, try to restructure or reframe their ideas, and to think of as many solutions as they can. The instructor then calls on several individuals or pairs (not volunteers) to share their responses. This exercise can also serve as preparation for a design-based project to be carried out later in a laboratory setting.

- *Peer Instruction*: As modified from the work of Eric Mazur, the instructor poses a question and asks students first to find as many answers as possible on their own, again by feature listing and reframing. They then attempt to justify their best answer to one or more of their peers, and finally they record a consensus response.
- *Think-Aloud-Pair-Problem Solving*: Retrieving information from memory (self-testing) is known to be a better learning strategy for students than restudying the same information. In this maneuver, modified to promote associative thinking, the instructor poses a problem from previous readings for the class and has the students form pairs with one member serving as the *explainer* and the other as the *questioner*. The explainers are given 2 min to recombine from memory components of the original problem into a new configuration with a different solution, while the questioner asks for clarifications or gives hints when necessary. The instructor repeats this with a different problem at another point in the lecture with the students in reversed roles. The process is stopped after the allotted time, and several explainers are asked to report their new solutions.

Conclusion and Future Directions

If this entry achieves its goal, it will stimulate new research on both the role associative thinking plays in science and engineering, as well as in creativity in these fields. Studies are needed especially to test the hypothesis that teaching students to increase their associative thinking will increase the originality and novelty of the solutions they pose to ill-structured problems. A small but growing number of science and engineering instructors are already engaged in active learning pedagogies aimed at improving students' scientific concept formation (Nersessian 2010) and reasoning skills (Felder and Brent 2009; Ruiz-Primo et al. 2011). They and their more reluctant colleagues deserve encouragement to try some of the strategies described above. If the result is that more of our students learn to think like creative scientists and engineers, it will be well worth the effort.

Proximity Relationships and Entrepreneurship

André Torre
AgroParistech, UMR SAD-APT, Paris, France

Introduction

Proximity Relations at the Heart of Firms' Strategies

In the present days of clusters, localized production systems, districts, or technopoles, it is not surprising that the question of proximities is raised with force in the analysis of firms' strategies and the relations they form with their partners, competitors, and more generally with the economic and social environments in which they conduct their everyday activities. Moreover, this aspect has not escaped the makers of economic, industrial, or innovation policies, who unceasingly plead in favor of structures in which economic activities are concentrated, whether they be competitive clusters in France, industrial districts in Italy, technopoles and science parks in Britain and Japan, or the different types of clusters that exist all over the world (OECD 2001).

The studies devoted to the analysis of proximity relations are based on research situated at the

André Torre is research director at INRA (National Institute of Agronomical Researches) and AgroParisTech in Paris. He is past President of the French-speaking section of ERSA, director of the PSDR (For and About Regional development) research programs, and head of the "Proximity team" in Paris. André Torre has published more than 100 articles and 11 books, mostly on issues related to space and coordination between people or groups of people, on the topics of proximity, innovation, and regional development. Its research was for a long time at the crossroads of spatial and industrial economics; it has in recent years become more multidisciplinary and focused increasingly on questions related to land use planning and sustainable development processes. It currently focuses on the analysis of proximity relations and on their importance in processes of coordination between people, and centers on two main areas: local interactions between innovative firms and, more particularly, the role played by geographical proximity in the transfer of knowledge, land use, and neighborhood conflicts.

intersection of industrial and spatial economics (Torre and Gilly 1999), which found, in the 1990s, that one could not study enterprises and their strategies without taking into account the spatial and geographic dimensions of their activities (see entry "▶ Territory and Entrepreneurship"). This has resulted in a large number of studies – some of which are presented below – all of which refuse to dissociate the economic from the geographical aspects and all of which take into account various dimensions of proximity relations. The relational or organizational dimension is combined to the spatial dimension of proximity – which is the most obvious. One may feel close to people located great distances away, and this is true of work and personal relations.

The analysis of proximity relations has subsequently been extended to many other fields, such as that of environmental questions and of urban or transport policies, for example. But the industrial and productive dominance has remained strong, and there has been a marked interest in issues related to innovation and knowledge-based economy. Thus, a large part of the research on the different types of proximity is devoted to two topics related, primarily, to questions of entrepreneurship (see entry "▶ Entrepreneur"), with the idea that a firm must take into account, in its strategies, the two categories of proximity relations. Thus, some studies focus on analyzing interfirm relationships, approached from the perspective of local or long-distance collaboration and of firms' ties with their local environment. Many other research studies have examined innovation questions related to innovative firms and their productive and scientific environments or to firms that wish to acquire or transfer technologies or knowledge (see entry "▶ Innovation and Entrepreneurship").

Definitions

The following definitions of the proximity-based approach are based on a division according to two main dimensions – spatial and nonspatial – which include more refined and detailed categories (Torre and Rallet 2005).

Geographical Proximity

Geographical proximity is above all about distance. In its simplest definition, it is the number of meters or kilometers that separates two entities. But it is also relative in terms of the morphological characteristics of the spaces in which activities take place, of the availability of transport infrastructure, and of the financial resources of the individuals who use these transport infrastructures.

Geographical proximity is neutral in essence, but it can be activated or mobilized by the actions of economic and social actors, in our case, firms, labs, or institutions. Depending on their strategies or strategic choices or according to their perceptions of their environment, the behaviors and attitudes of these actors vary, and they mobilize geographical proximity differently. More precisely, actors might seek to get closer to or further away from certain people or places, or they might feel satisfied or dissatisfied with the geographical proximity of certain people, places, or technical objects. Geographical proximity can be enhanced in the context of an urban area by the creation of localized innovation clusters (see entry "▶ Clusters"), for example, or by the development of local networks of producers, exchanging knowledge and information through face-to-face contacts.

Organized Proximity

Organized proximity too is a potential that can be activated or mobilized. It refers to the different ways of being close to other actors, regardless of the degree of geographical proximity between individuals, the qualifier "organized" referring to the arranged nature of human activities (and not to the fact that one may belong to any organization in particular). Organized proximity rests on two main logics, which do not necessarily contradict each other and which are called the "*logic of belonging*" and the *"logic of similarity."*

The logic of belonging refers to the fact that two or several actors belong to the same relationship graph or even to the same social network whether their relation is direct or intermediated. It can depend on the sector they are operating on; in this case, they share common creative or innovation capital. It can be measured in terms of degrees of connectivity, reflecting more or less high degrees of organized proximity and therefore a more or less great potential of interaction or common action. Cooperation will, a priori, develop more easily between researchers and engineers who belong to the same firm, the same technological consortium, or innovation network (see entry "► Network and Entrepreneurship").

The logic of similarity corresponds to a mental adherence to common categories; it manifests itself in small cognitive distances between some individuals. They can be people who are connected to one another through common projects, or share the same cultural, religious (etc.) values or symbols. Social norms and common languages partake of this organized proximity. It can also, however, correspond to a bond that sometimes emerges between individuals without them having had to talk in order to get to know one another. It facilitates the interactions between people who did not know one another before but share similar references. Engineers who belong to the same scientific community will easily cooperate because they share, not only the same language, but also the same system of interpretation of texts, results.

Temporary Geographical Proximity

Temporary geographical proximity (TGP) constitutes one form of geographical proximity that enables actors to temporarily interact face-to-face with one another, whether these actors are individuals or organizations such as firms or laboratories, for example. It corresponds to the possibility of satisfying needs for face-to-face contact between actors by traveling to different locations. This traveling generates opportunities for moments of geographical proximity, which vary in duration, but which are always limited in time. TGP is limited to certain times; this form of geographical proximity should not be mistaken for a permanent co-location of firms or laboratories.

The development of communication technologies and ICT nowadays facilitates long-distance exchange. A large part of the information and knowledge that are necessary for production or innovation activities can be transferred from a distance, through telephone or Internet-mediated exchanges, for example. Consequently, co-location no longer constitutes an absolute necessity. However, times of face-to-face interaction are necessary and beneficial in this context. Face-to-face interaction cannot altogether be eliminated, including in the case of communities of practice, for example (see Torre 2008). As a consequence, ICT cannot be considered as substitutes for face-to-face relations: Both are useful tools to support or enhance the interaction between two or several individuals. Space matters but in a new way: one that consists of temporary face-to-face contact between two or several individuals.

Theoretical Origins and Debates Regarding the Concept

The first research studies on proximity were conducted in the early 1990s and led to the creation of the so-called Proximity Dynamics group in 1991 and later to the publication in 1993 of a special issue of the *Revue d'Economie Régionale et Urbaine*, entitled "Economies of Proximity" (Bellet et al. 1993). In that special issue, which was written entirely by researchers of this movement and which subsequently resulted in the creation of what is now commonly called the "French School of Proximity," were published various articles, all of which presented the concept and approached in different ways questions pertaining to production and innovation processes. All the articles are devoted to production-related questions and place emphasis on the geographical component of these relations. This journal's special issue advocates the integration of the spatial dimension in the analysis of industrial relations and provides a first interpretation of proximity relations. It introduces two types of proximity, called "geographical proximity" and "organizational proximity," respectively; at the intersection of both categories, one finds the so-called territorial proximity: a notion which deals with the complex interplay between productive relations and spatial relations and their being inextricably linked.

The following publication by the group of a multiauthored book (Rallet and Torre 1995) shows that the authors, most of whom are either industrial economists interested in spatial questions or spatial economists interested in industrial issues, all prove to be passionate about the topic of productive relations, and their development at the level of territories, and have a particular interest in approaches to innovation. Their analysis did not develop out of nothing, nor without any theoretical bases. These authors inherited analyses carried out from a territorial perspective, on questions pertaining to localized production systems, and more particularly of industrial districts and innovative milieus (see entry "▶ Innovative Milieux and Entrepreneurship (Volume Entrepreneurship)"). They are the followers of a relatively heterodox tradition and reject both the idea that the economy is only dependent on commercial relations and that of a separation of the productive dimensions – mostly studied by economists – from the more spatial dimensions, which are generally examined by geographers. Thus, the approach is meant to be multidisciplinary, even though it emerged from economic analyses.

Standard economics has not paid much attention to the questions of proximity and has seldom used the term. Indeed, it generally prefers approaches in terms of distance or location: Space is, at best, treated as data, the effects of which on economic activities and therefore firms must be taken into account. The models are characterized by a tension between interfirm competition – which forces them to go further away in order to obtain selling space for their products – and their search for advantages drawn from location close to clients or to competitors. The benefits of proximity, much praised, are seldom explained and are to a large extent mistaken for the very process of spatial agglomeration, to which proximity can contribute without necessarily being associated to it. Even the New Economic Geography, which is a relatively recent movement, has not shown any interest in the question.

But other studies have attempted to open the "black box" of proximity relations. Whereas the standard approaches consider proximity relations as causative variables, without their content being ever considered, other works have tried to understand proximity relations by attempting to highlight their significance as well as their different contents. This movement has been largely inspired by the highly influential district, milieu, and SPL approaches, which have opened the way to un-self-conscious research on "the local." The authors in this research movement have placed emphasis on the relations between firms and on the networks that develop, mostly at local level. They have highlighted the systematic nature and the importance of these systems' structures and modes of organization. They also showed that industrial districts are not the result of a concentration of firms initially attracted by favorable factors, such as primary resources for instance. Rather, they are built upon an organizational settlement in the territory which makes the "disengagement" from relations to an area or a local system difficult for producers, given the presence of local skills and trained workers.

A second track of research into the origins of the externalities of proximity resides in the approaches that emphasize the horizontal links within localized production areas. The traditional analysis of external economies is challenged here because the frontier of the firm fades in favor of the organization into networks, like that found in the emblematic case of the Silicon Valley (Saxenian 1994). Beyond the characteristics purely linked to the specificity of the technologies in question, three main dimensions are at the origin of the competitiveness of these industrial systems: (a) the existence of local institutions guaranteeing the circulation of a local culture, (b) the specificity of the firm's internal organization, and (c) the presence of a particular industrial structure based on the existence of recurrent contacts between local actors.

The third track of analysis is found in the so-called geography of innovation (Feldman 1994) which emphasizes the process of spatial concentration of innovative activities, be there within regions or smaller geographical areas, and directly introduces the notion of proximity into the analysis. Innovation is concentrated essentially in a few zones in which one can find not only units of production but also public research laboratories or universities (see entries "▶ Invention and innovation as creative problem-solving activities" and "▶ University Research and Innovation"). This empirical evidence reintroduces the idea of the importance of the relations of proximity in the generation of the new technologies. Moreover, the link between this movement and that of the spatial concentration of industrial activities is made: Firms' choice of location can be explained by their need to develop relationships not only with other firms (interfirm relations) but also with science (science-industry relations).

The group has also inherited a great deal from the research conducted on industrial economics, on value chains and industrial groups, or on the microeconomics of imperfect competition and firms' strategies. But it is also largely indebted to evolutionist and institutionalist approaches. The role of institutions is always emphasized, and industrial relations are presented as forces driving the processes of change and of transformation of economies, which mostly rest on innovations and technological changes. Similarly, the research on proximity moves, from the start, beyond methodological individualism by repositioning the individual or the firm within a network of social or economic relations. The firm is never considered as an isolated entity, but it is always regarded as being part of groups of actions, local systems, or long-distance networks.

Applied Studies and Theoretical Advances

On the basis of these principles, a large series of applied studies were conducted, focusing primarily on industrial firms and their relations or on technological interactions, and these applied studies have rested on a proximity-based approach. They have mostly examined the case of France and have focused essentially on productive systems such as the Toulouse, Grenoble, or Marseilles "technopoles" or on organizational structures such as innovation networks or cooperatives for instance. They reveal that the formation of relations between firms located in the same areas is not exclusively related to their geographical proximity. Social ties, interfirm relations, trust, networks of actors, friendships, and successful collaborations all contribute to forming a web locally: a web which matters at least as much as co-location. In light of this network, one clearly understands the factors of what can be called the firms' "ties to their territory." Each tie is fragile and must be nurtured and stands as a veritable resource for firms, which hesitate all the more to move to different locations as the web they have woven with other local actors is strong.

Nevertheless, the development of the research on proximity, which continues to give rise to collective publications that provide provisional assessments of the analysis and of its progress (see, e.g., Torre and Gilly 1999, or Pecqueur and Zimmerman 2004), has quickly led to an in-depth debate on the different forms of proximity. Besides the authors who argue that there are two main types of proximity, called geographical and organized (or organizational) proximity, respectively – as seen above – there is a variant school of thought that considers that the political and institutional dimensions play such a central part that it is necessary to posit the existence of a third category: institutional proximity. The latter is defined as the actors' adherence to a space that is defined by common rules of action, representations, and thought patterns (Kirat and Lung 1999). The authors of this school reckon that the political dimension, the importance of the legal component, of the rules that govern the social and economic relations justify the creation of this category, all the more so as organized proximity is thought to be essentially cognitive in nature. As for the defenders of the first approach, they consider that these dimensions are encapsulated within the logic of similarity.

With the rising popularity of the research on proximity, new, non-French-speaking researchers have, since the 2000s, joined the debate and have contributed new directions and taken into account new concerns. One of the most remarkable contributions has resulted in an increase in the number of proximity categories, which the founding fathers had preferred to limit for the sake of analytical coherence, but which has exploded in order to take into account the different facets of proximity and reveal their extraordinary malleability as tools of reflection. Five types of proximity are nowadays often described: They are called cognitive proximity (common knowledge bases and competences), organizational proximity (the extent to which relations are shared in an organizational arrangement), social proximity (the embeddedness of the trust relations based on friendship, family ties, and experience), institutional proximity (adherence of the economic actors to common rules, such as structures, laws, political rules, and common values), and geographical proximity (Boschma 2005).

Simultaneously, as a result of the emergence of new societal concerns and of the arrival in the group of sociologists, geographers, and land planning experts, there has been an extension of the topics and themes addressed. This extension has taken several directions consisting, for example, in taking into account issues related to the environment, land planning, transport, urban or rural planning, or of a question of particular interest to us: the importance of new information and communication technologies in the relations between firms located in proximity to or far from one another. It has also sounded the knell of the eulogistic way of looking at proximity. The negative dimensions of the various types of proximity are now highlighted, particularly those of geographical proximity, which appears not only to generate land use conflicts in situations where space is scarce but also to be conducive to problems in terms of relations between innovative firms, for example: Indeed, a classic finding is that geographical proximity facilitates industrial espionage and therefore the unwanted appropriation of knowledge by firms' rivals, and also that production systems that give priority to internal relations at the expense of external relationships may find themselves in negative development trajectories.

Many research studies have been conducted, particularly in European countries, on the basis of the proximity-based approaches, and often by using field data and the econometric tools. They often begin with the analysis of one particular sector – software or aeronautics, for example – with a marked interest in knowledge-intensive industries or technological innovation sectors. They seek to test the importance of the different types of proximity in firms' performance and often confirm that geographical proximity cannot alone ensure high performance, nor does it in itself facilitate the exchange or interactive creation of knowledge. Thus, it is the nonspatial dimensions of proximity that now have the place of honor, and more particularly their role in the creation of networks of economic actors, located either in proximity to or far from one another: Indeed, these networks rest mostly on different dimensions – social, relational, cognitive, etc. – which do, indeed, correspond to the components of the different types of proximity (Boschma and Frenken 2010).

Conclusion and Future Directions

The most recent development of the analysis of proximity relations, dating from the second half of the 2000s (Torre 2008), has been the publication of research studies on the temporary dimensions of proximity and particularly of geographical proximity. They have been based on three findings. The first has to do with the increasing number of fairs, trade shows, and conventions, which bring together, in given places and for very short periods of time, people located varying distances away from one another but who nevertheless are able to communicate through ICT. The second finding is related to the increasing mobility of individuals, mobility which concerns private persons but also engineers or business owners or managers. The third and last finding is linked to the analysis of the relations developed by firms that form clusters in specific fields such as that of biotechnologies, for example: Though they reap financial and real estate-related advantages from being located in the same areas as other firms that belong to the same sectors of activity, they often prefer to form relationships with outside firms so as to prevent problems related to the leaking or loss of intellectual property between themselves and rival companies.

This has led some researchers to examine the way in which firms located distances away from one another communicate. One knows that they mostly do so through ICT but also through the inevitable implementation of geographic interfaces: Different cases of communication are examined: long-distance communication, fairs, and conferences, as well as temporary "platforms" of project teams, implemented by large manufacturing groups such as EADS or Renault in order to enable the participants of a project to work together in the same place for short periods of time, participants who will subsequently go back "home" and work together from a distance. As has always been shown since the first research studies on proximity were performed, space and geography do matter, but researchers have moved far beyond the exclusive analysis of clusterized firms, even though these new considerations have considerably enriched it.

Psychological Aspects of Entrepreneurial Dynamics

Entrepreneurial behavior; Entrepreneurial development; Entrepreneurial personality

Introduction: Basic Concepts and Variables

Both terms "entrepreneurial" and "dynamics" address a non-static perspective, emphasizing the ongoing processes and the driving aggregate forces associated with entrepreneurship. The intervening psychological variables concern the human actors involved in these processes.

On the micro- and intermediate levels, the mentioned concepts refer to entrepreneurs and entrepreneurial interactions, that is, their capacity to act as a motor of move (implying undertaking spirit, initiative, capability of recognizing opportunities, creative imagination, ability of transforming emerging ideas into concrete-projects, etc.). Entrepreneurial actors are often starting up and conducting one or several challenging projects and the related tasks.

On the community and organizational levels, the concepts refer to the enterprise as the formal frame, as well as to the community of the companies contributing together to the collective movement of change. The emergent collective forces generated are the result of the actions of individual entrepreneurs and their companies, which in return influence the entrepreneurial behavior and orientation of individuals and firms.

Entrepreneurial action and the dynamics resulting from it comprise an important psychological component. Its relevance results from the fact that entrepreneurial action is based on interactive activities and that human actors, especially entrepreneurs, cannot be reduced to cold, passionless, emotionless, and rationally calculating actors. On the contrary, it is typical for them to associate their behavior with passions, feelings, emotions, and individual and collective thinking. Human action, in general, and that of entrepreneurs, in particular, is charged with emotions, subjective goals and perceptions. It can be supposed that mental processes, feelings, perceptions, ideas, and ways of thinking and behaving must represent an important aspect of entrepreneurial dynamics.

Psychological variables have a varying influence on entrepreneurship. Many scholars have particularly been interested in the role played by psychology in the early phases of nascent entrepreneurship, where uncertainty is high and the individual entrepreneur is highly involved (eventually assisted by one or more other entrepreneurial persons). Aldrich (1999), in an evolutionary perspective, distinguishes the phases of "conception," "gestation" (nascent entrepreneurs), "infancy" (new firms), and "adolescence" (establishment of the founded firms).

Theoretical Origins and Debates: The Relationship Between Economics and Psychology and its Assimilation by Entrepreneurship Research

The psychology of economic behavior has interested numerous scholars since a long time. An example is the pioneering contribution of Gabriel Tarde in nineteenth-century France who has studied the phenomenon from the point of view of the philosophy of difference (Lazzarato 2002). For Tarde, the concepts of imitation and invention are central which are directly linked to psychological variables (belief and desire). Later on, other famous scholars of the twentieth century known for linking economics and psychology are, for example, James G. March or Herbert Simon. Both were particularly interested in the role that cognitive and psychological variables may play in decision making – an activity which is recognized as central for entrepreneurship.

In the field of entrepreneurship research, there has then emerged a more or less clear and fundamental opposition between two types of schools, which for a long time should mark the development of psychological approaches to entrepreneurship: on the one hand, those who focused on the psychological characteristics of the individual entrepreneur (trait approach), linking entrepreneurship directly to the psychological profile of the entrepreneur, and, on the other, those refuting such an approach, claiming that the entrepreneurial interactive process is central for analysis, independently of any individual characteristics of the entrepreneur.

However, more recently, attempts were made to overcome this opposition and to develop more appropriate and more complex psychology-based explanations by combining the different perspectives. In the following sections, firstly the traditional trait approach perspective will be presented, secondly its critique, and thirdly some of the attempts made to develop more sophisticated and more complex explanation models.

The Trait Approach

The trait approach represents a major psychological perspective applied to entrepreneurship. It has been particularly influent in the 1980s and stimulated a lot of research work during this decade. The starting point is the idea that personal characteristics or "traits" of the people running firms matter and indeed are seen as determinant for the development of these latter. This applies as well as to incumbent as to new firms, but the approach has been used especially for new firms and founders. In this case, in general, attempts were made to explain the success or failure of a start-up company by the psychological profile of its founder(s).

This perspective has important theoretical implications. It includes a rather strange paradox: Whereas the entrepreneur normally is supposed to be a *dynamic* actor, oriented toward innovation and change (economic, technological, institutional, etc.) – which itself logically would require a dynamic theoretical perspective – the conceptualization of this actor in the trait approach in contrast reflects a rather *static* thinking. According to this view, the entrepreneur is supposed to have a fairly stable personality profile, which is innate: either one is an entrepreneur or not. This is seen as a question of psychological character and personality. The basic idea is that an entrepreneur has certain internal characteristics and dispositions which influence or determine his entrepreneurial behavior.

However, it remains an open empirical question if these personality factors are generally dominant, how they interact with situation and context, and what influence these latter have. In addition, the postulate of the relative stability of traits may be questioned: Can traits evolve and change over time? Are they inborn or acquired through socialization and learning? Does "learning by doing" play a role in the domain of entrepreneurship? Do people develop certain entrepreneurial traits thanks to the experience of founding and running a business?

A lot of research has been done in order to identify "who is an entrepreneur" (Gartner 1988) and to study what distinguishes him from non-entrepreneurs. Among the mostly studied attributes figure "need for achievement," "locus of control," or "risk taking," but this short list is not exhaustive; others and less mentioned are, for example, "values" or "age" (Gartner 1988: 11–12). People with high levels of need for achievement are those privileging challenging, but achievable tasks; people with an internal locus of control are those who think being able to determine their destiny themselves (in opposite to people with an external locus of control who feel to be constrained by their external environment); finally, risk taking is generally seen as a typical attribute, but it is also recognized that entrepreneurs are not foolish; their risk taking is rational and calculated. More examples are included in the table presented by Gartner in his article, among which figure "self-discipline and perseverance," "action orientation," "goal orientation," "autonomy," "aggression," "innovative tendencies," "creativity," "desire for money," "tolerance of uncertainty," "tolerance of ambiguity," and so on, quoting only some of the numerous characteristics attributed to the entrepreneur in the literature (Gartner 1988: 16).

The different traits (separately or in combination) were not only used by scholars to differentiate entrepreneurs from non-entrepreneurs, or from managers, but also to compare different types of entrepreneurs, such as "nascent entrepreneurs," "novice entrepreneurs," "habitual entrepreneurs," "serial entrepreneurs," or "portfolio entrepreneurs" (Chell 2008: 9). Different trait approaches can be distinguished. For example, Chell (2008: 84) presents a typology of no less than seven different ways of using trait theories: (1) single trait approach, focusing on one particular trait which is studied; (2) multiple trait approach, studying a combination of traits; (3) personality structure, identifying a coherent system of traits; (4) cognitive traits, focusing on the cognitive dimension of personal characteristics (beliefs, perceptions, cognitive styles); (5) biologically based traits, linking traits to biological differences between people; (6) abnormal traits (e.g., depression, psychopathy, hypochondria, etc.); and (7) psychodynamic theories, insisting on the importance of childhood experiences and the resulting subconscious, firmly implanted, compulsions and anxieties.

Trait theory finally has evolved further, and an emergent consensus is developing around scholars about the necessity to develop more complex models, among others, by recognizing the interrelationship between trait characteristics and situational or more general environmental conditions. In addition, modern trait research is increasingly concerned by a search of and the research on new traits (Chell 2008: 247), alternatively to the dominant classical ones mentioned above (which were need for achievement, internal vs. external locus of control, and risk taking). In her book on the entrepreneurial personality, Elisabeth Chell enumerates several newly emerging traits, among others, for example, “opportunity recognition,” “proactive personality,” “self-efficacy,” “social competence,” and “intuition” (Chell 2008: 247). The emergence of these new traits in the theoretical debate emphasizes not at least the growing importance given to a cognitive view of entrepreneurial action. Studying entrepreneurial cognition may be seen in this context as a promising research strategy that might allow “to bring the entrepreneur back into entrepreneurship” (Krueger 2003: 105) by suggesting that the cognitive infrastructure of entrepreneurs (the way how entrepreneurs think, memorize, and learn to perceive opportunities) differentiates them from other people.

Major Criticism Addressed Toward Trait Research

Trait research developed particularly well since the late 1970s and became rather popular among scholars especially during the 1980s. However, it never formed a very homogenous theoretical school. The field of entrepreneurial trait research was rather heterogenous and dispersed and, in addition, provoked a very critical and conflictual debate among scholars in the second half of the 1980s. The critique of Gartner (1988, 1989) at the end of the 1980s is very instructive in this regard and summarizes the main critiques of that time. One of the arguments presented concerned the difficulty to define the entrepreneur and to identify clearly the traits that would differentiate him from non-entrepreneurs. While Gartner insisted on the impossibility to develop a generic definition, he criticized trait scholars for defying the doubts and attempting to distinguish entrepreneurs from other people by their personality characteristics. Gartner criticized that many different, and often vague, definitions of the entrepreneur were used, many researchers even not taking the effort at all to define the entrepreneur, and that the heterogeneity of the research samples finished by making it completely impossible to distinguish clearly between entrepreneurs and the rest of the population, or between successful and unsuccessful entrepreneurs. A “psychological profile” of the entrepreneur assembled from the different studies, according to Gartner, “would portray someone larger than life, full of contradictions, and, conversely, someone so full of traits that (s)he would have to be a sort of generic ‘Everyman’” (Gartner 1988: 21).

Gartner’s final conclusion was quite radical: He stated that the trait view is inadequate for understanding the entrepreneurial phenomenon. Instead of focusing on the personal and psychological characteristics of the entrepreneur, research should better concentrate on the study of the concrete behavior and activities of entrepreneurs, that is, adopt a process-oriented view (behavioral approach). Gartner illustrated his argument by a comparison with sports. For example, in the case of baseball, “a baseball player is not something one is, it is something one does” (Gartner 1988: 22). What would be important is the baseball *game* and **not** the *player*. In sum, entrepreneurship research should focus on what may be seen as central, which according to Gartner’s interpretation is synonymous with the start-up process, the efforts made by individuals to create organizations, and their outcomes (Gartner et al. 2004).

The general orientation of such criticism at a first glance could appear as a turnabout in the theoretical debate at that time. However, like the classical trait approach, it was based in reality on an artificial isolation of one particular element of entrepreneurship, impeding a full understanding of the phenomenon. In the end, it led to a rather unfruitful opposition between two contrasting perspectives: a trait perspective on the one hand which was strongly criticized and an exclusively behavioral (or process) perspective on the other. While the former put the entrepreneur in the center of its model, the latter, on the contrary, had as a consequence to fade out his potential role in the theory.

Further Developments

In their reaction to Gartner (1988), Carland et al. (1988) argued that it is inappropriate to separate the process of business creation from the characteristics of the founders and entrepreneurs because both aspects are inseparably tied. In a more recent article, Carland and Carland (2000) further criticized the tendency of contemporary economics to favor statistical reasoning and mathematical models, instead of exploratory study, which as a consequence tends to neglect the individual level of entrepreneurship, pushing the entrepreneur out of the explanation model. They suggest on the contrary to pay more attention to the entrepreneur's characteristics and reasoning and to the cognitive process leading to venture creation. This would mean to take into account the individual "entrepreneurial psyche" which may be conceived "as a gestalt of multiple personality factors" (traits, cognitive styles, entrepreneurial drives). Such an argumentation finally may also offer a solution to the problem of differentiating the entrepreneur from non-entrepreneurs, since it does not necessarily imply a dichotomous vision (entrepreneur vs. non-entrepreneur) but allows to interpret the phenomenon as a relative one, which means that it would be compatible with the observation that entrepreneurship can manifest itself in quite heterogenous forms.

While the scientific debate in the 1980 produced an important movement for questioning the common psychological approach of the entrepreneurial personality used at that time, that is, the widespread focus on the psychological traits of the entrepreneur, later research was characterized by attempts to reequilibrate the psychological traits and behavioral perspectives. This meant to bring back the entrepreneur into the theoretical explanations and to develop more complex models which would take into account as well the role of personality as the contextual factors affecting entrepreneurship.

The new trends in research on the psychological aspects of entrepreneurship, after the conflictual debate of the 1980s, went toward the development of more interactionist and cognitive approaches (Chell 2008: 142 ff.). Regarding the different topics studied, Chell (2008: 171) mentions, among others, the cognitive research on heuristics or shortcuts, cognitive scripts, cognitive biases (e.g., illusion of control), overconfidence, errors in decision making, self-efficacy (feeling/perception of personal efficacy), regretful thinking and feelings of disappointment, opportunity recognition and evaluation, and social and cognitive aspects of creativity.

The knowledge developed through this research suggests that if the entrepreneur's psychological dispositions may have some roots in innate traits, the interaction with others, as well as cognitive and social learning processes, plays a decisive role with regard to the construction of the entrepreneurial personality. The scientific field here is rather differentiated, different theoretical schools contributing to the ongoing scientific debate. According to Chell (2008: 204), four major categories of theories can be distinguished: trait theory, social constructionism, social cognitive theory, and social psychological theories.

While trait theory supposes the existence of some, in the middle term, relative stable, behavioral patterns – independently from the question if these are inborn and/or developed throughout primary and secondary socialization (especially during the process of entrepreneurial experience) and more or less independent from situational influences – the other approaches relativize the role attributed to individual, in comparison to contextual and process factors, by linking, in different ways, both dimensions.

The social constructionist approach, for example, is based on the idea that entrepreneurs are not socially isolated individuals. On the contrary, it postulates that the entrepreneurial personality is much a social construction which is permanently created and recreated through social interaction and interpersonal discourse.

Social cognitivist approaches, in comparison, focus especially on the cognitive dimension of entrepreneurial behavior. The consistency of this latter is interpreted as an effect of the cognitive structures in long-term memory (context-specific social knowledge, beliefs, motivations, socially learned behavior, procedural skills, etc.). Again, this perspective tends somewhat to stress the static elements of entrepreneurial behavior and to attribute less attention to its dynamic aspects.

Finally, the fourth category of approaches enumerated by Chell (2008: 204), the social psychological perspective, is different in this respect: Under this theoretical angle, the dynamics resulting from the interaction with the social and institutional environments are conceived as being relatively more important and even central. In this approach, environmental influences are seen to be decisive, especially for the self-development of the entrepreneur.

Recent and current research continues to be interested in the link between personality and entrepreneurship, representing a particular research strategy to approach the psychological aspects of entrepreneurial dynamics. A recent example is the *Journal of Economic Psychology* and its decision to edit a special issue on "Personality and Entrepreneurship" (Journal of Economic Psychology, Vol.33, issue 2, April 2012).

Besides that, the cognitive dimension is still studied by numerous scholars, a rather dynamic research field comprising (and being open to) many different topics (e.g., entrepreneurial cognition, cognitive adaptability, entrepreneurial opportunity recognition and evaluation, entrepreneurial decision making, entrepreneurial intentions, and cognitive motivations).

Finally, another type of research work not mentioned yet, but of certain interest for the topic developed here, concerns the organizational level of entrepreneurship as the aggregate level of individual entrepreneurial behavior. An important indicator for the development of this type of work is the increasing number of research realized during the last years on "entrepreneurial orientation" (firms with entrepreneurial orientation are seen to be characterized by proactiveness, autonomy, innovation, risk taking). While the focus is on organizational issues and firm-level entrepreneurial behavior, it can be easily imagined that the organizational level, being the social arena for human action, is indirectly influenced by the psychological processes initiated on the micro- and intermediate levels of entrepreneurs and entrepreneurial groups.

Conclusion and Future Directions

Psychology plays an important role in entrepreneurial processes, since their basis are *human interactions*. However, it proved to be a challenging task in the past to develop theoretical models allowing to seize appropriately the psychological aspects of entrepreneurship. Important advances in academic knowledge have been realized during the past decades, with different theoretical focus. A very general trend in research seems to be the evolution away from the classical trait models of the 1980s toward more interactionist and/or cognitive approaches. An important point is that this does not necessarily imply questioning the potential role played by personal characteristics of the entrepreneur. On the contrary, current research again is considering the integration of these aspects into the theoretical models.

Key Concepts and Definition of Terms

Defining Creativity

Creativity is arguably our most uniquely human trait. It enables us to escape the present, reconstruct the past, and fantasize about the future, to envision something that does not exist and change the world with it. The elusiveness of the construct of creativity makes it that much more important to obtain a satisfactory definition of it. Defining creativity presents difficulties; for example, not all creative works are useful, and not all are aesthetically pleasing, though both usefulness and aesthetic value capture, in some sense, what creativity is about. Nevertheless, psychologists have almost universally converged on the definition originally proposed by Guilford over 60 years ago. Guilford (1950) defined creativity in terms of two criteria: *originality* or novelty, and *appropriateness* or adaptiveness, i.e., relevance to the task at hand. *Surprise* is sometimes added as a third criterion (Boden 1990). Some add *quality* as a separate criterion (Kaufman and Sternberg 2007), while others use the term appropriateness in a way that encompasses quality. Creativity has also been defined as a complex or syndrome, and some would insist that any definition of creativity include such cognitive and personality characteristics as problem sensitivity, flexibility, and the ability to analyze, synthesize, evaluate, and reorganize information, engage in divergent thinking, or deal with complexity. However, it is the "originality and appropriateness" definition that is encountered most often and that appears to have become standard (e.g., Amabile 1996; Feldman et al. 1994; Runco 2004; Sternberg 1988). While this definition provides a much-needed departure point for discussion about and measurement of creativity, there is probably no one-size-fits-all definition of creativity. For scientific or technological enterprises, appropriateness might be more important, whereas in the arts, originality might be weighted more heavily. Thus, creativity must be assessed relative to the constraints and affordances of the task.

The Four P's of Creativity

It is often said that creativity involves four P's: person, process, product, and place. The creative *person* tends to exhibit certain personality traits. Creativity is correlated with independence of judgment, self-confidence, attraction to complexity, aesthetic orientation, risk taking, openness to experience, tolerance of ambiguity, impulsivity, lack of conscientiousness, and high energy. There is some evidence that creative individuals are more prone to anxiety and affective disorders. Creative individuals differ with respect to whether they are internally versus externally oriented, person-oriented or task-oriented, and explorers (who tend to come up with ideas) or developers (who excel at turning vague or incomplete ideas into finished products).

A pioneering effort toward demystifying the creative *process* was Wallas' (1926) classification of the creative process into a series of stages. The first of Wallas' stages is *preparation,* which involves obtaining the background knowledge relevant to the problem, its history (if known), and any instructions or past attempts or preconceptions regarding how to solve it. It also involves conscious, focused work on the problem. The second stage is *incubation* – unconscious processing of the problem that continues while one is engaged in other tasks. The preparation and incubation stages may be interleaved, or incubation may be omitted entirely. Wallas proposed that after sufficient preparation and incubation, the creative process is often marked by a sudden moment of *illumination*, or insight, during which the creator glimpses a solution to the problem, which may have to be worked and reworked in order to make sense. The idea at this point may be ill defined, "half baked," or in a state of *potentiality*; the ability to work with an idea in this state is related to the personality trait of tolerance of ambiguity. Wallas' final phase is referred to as *verification*. This involves not just fine-tuning the work and making certain that it is correct, as the word implies, but putting it in a form that can be understood and appreciated by others.

The creative *product* can take the form of a physical object (e.g., a painting), or behavioral act (e.g., a dance), or an idea, theory, or plan of action.

The last of the four P's of creativity, *place*, concerns the environmental conditions conducive to creativity. Certain individual situations, such as education and training, role models and mentors, and perhaps surprisingly, childhood trauma, are correlated with historical creativity. Economic growth appears to have a stimulating effect on creativity, whereas war appears to have a depressing effect.

Historical Versus Personal Creativity

Although the term "creative" is often reserved for those who are known for their creative output, some make the case that daily life involves thinking things and doing things that, at least in some small way, have never been thought or done before and, thus, that *everyone* is somewhat creative (Beghetto and Kaufman 2007; Runco 2004). Psychologists now distinguish between different kinds and degrees of creativity, such as between historical and personal creativity (Boden 1990). When the creative process results in a product that is new to all of humanity and makes an impact on the course of civilization, it is referred to as *historical creativity* (H-Creativity). Historical creativity is also sometimes referred to as *eminent creativity* because the creator tends to become famous. When the creative process results in a product that is new to the creator, but someone else has come up with it before, or it is not creative enough to exert an impact on human civilization, it is referred to as *personal creativity* (P-Creativity). Although personal creativity does not change the world, it can be a source of pleasure and amusement. Clearly there are shades of gray between these extremes.

A concept that is closely related to personal creativity is *everyday creativity*. Everyday creativity manifests in everyday life; it comes through in how one prepares a meal, decorates a room, or interprets and shares experiences. Everyday creativity generally begins with an innovative, often unconventional approach to life that involves capitalizing on hidden opportunities, undertaking common tasks in uncommon ways, and finding unique solutions to challenges as they arise.

Historical and personal creativity are also sometimes referred to as *Big C creativity* and *Little C creativity*, respectively. Some additionally make the case for *Mini*

C creativity, which involves making novel and personally meaningful interpretations of objects and events, and which can form the basis for more substantial creative acts (Beghetto and Kaufman 2007).

Creativity Versus Discovery and Invention

Creativity is sometimes distinguished from two related concepts, discovery and invention. *Discovery* involves finding something *already present* and sharing it, e.g., Columbus' discovery of America. It is relatively impersonal in the sense that if one person had not discovered it, someone else would have. *Invention* entails unearthing something that was *not present before,* e.g., Alexander Bell's invention of the telephone. Like discover, it is relatively impersonal. Creativity also involves unearthing and sharing something that was not present before. Some psychologists additionally require that for something to qualify as creative, it must be profoundly personal in the sense that one feels the presence of a unique individual in the work, e.g., Leonardo da Vinci's art.

Theoretical Background and Open-Ended Issues

Early Conceptions

In early times the creative individual was viewed as an empty vessel that was filled with inspiration by a divine being. Psychologists initially paid little attention to creativity because it was thought to be too complex and frivolous for scientific investigation. Freud believed that creativity results from the tension between reality and unconscious wishes for power, sex, love, and so forth. While this view is not as prominent now as it was in his time, his notion of the *preconscious* – a state between conscious and unconscious reality where thoughts are loose and vague but interpretable – is still viewed by many as the source of creativity. The year 1950 marks a turning point for psychological interest in creativity, when it was the subject of Guilford's address to the American Psychological Association.

Current Psychological Approaches to Creativity

Creativity is now of interest to many disciplines and approached from many directions. Even within the discipline of psychology, it is addressed in a variety of ways. Cognitive psychologists study cognitive processes considered to be creative, such as analogy, concept combination, and problem solving, and they write computer programs that simulate these processes (e.g., Finke et al. 1992). Those who take a psychometric approach develop tests of creativity, the most widely known being the Torrance Test of Creative Thinking (Torrance 1974). Examples of such tests are the *Unusual Uses Test* in which participants are asked to think of as many uses for a common object (e.g., a brick) as possible, or the Product Improvement Test, in which participants are asked to list as many ways as they can to change a product to make it more useful or desirable (e.g., to change a toy monkey so children will have more fun playing with it). Developmental psychologists study creativity in children and throughout the lifespan. Social psychologists examine how family dynamics, group dynamics, and cultural influences affect creativity. Clinical psychologists look at how art therapy, music therapy, and dance therapy can help patients open up and express themselves in ways that verbal communication may not. Neuroscientists investigate the biological basis of creativity. Organizational psychologists study creativity as it pertains to entrepreneurship and successful business strategies. Finally, comparative, evolutionary, and cultural psychologists address the question of how humans came to possess their superlative creative abilities, how these abilities compare with those of other species, how creativity compares across different cultures, and in what sense creative ideas can be said to evolve over time.

The Relative Contributions of Expertise, Chance, and Intuition

While most psychologists believe that creativity involves a combination of expertise, chance, and intuition, they differ with respect to the degree of emphasis they place on these factors.

Expertise theorists point to evidence that it takes approximately a decade to master a creative domain (Hayes 1989). Experts are better than beginners at detecting and remembering domain-relevant patterns and are more adept at generating effective problem representations and, when necessary, revising initial hypotheses. Expertise theorists posit that creativity involves everyday thought processes such as remembering, planning, reasoning, and restructuring. They claim that no special or unconscious thought processes are required for creativity, just familiarity with and skill in a particular domain (Weisberg 2006).

Critics of this view note that entrenchment in established perspectives and approaches may make experts more prone than beginners to set functional fixedness and confirmation bias. Those who emphasize the role of *chance* include advocates of the Darwinian theory of creativity, according to which the creative process, like natural selection, entails blind generation of possibilities followed by selective retention of the most promising of them (Simonton 1999).

Other psychologists view creativity as not so much a matter of generating and selecting among predefined alternatives but of intuiting an idea and then, by considering the idea from different perspectives or trying it out different ways, taking it from an ill-defined state of potentiality to a well-defined state of actualization (Gabora 2010). Those who emphasize the actualization of potentiality and the role of *intuition* emphasize the association-based structure of memory and note that creative individuals tend to have *flat associative hierarchies,* meaning they have better access to *remote associates*, items that are related to the subject of interest in indirect or unusual ways.

The Relative Importance of Process Versus Product

To many it seems natural to value the creative process for the products it gives rise to; indeed creative products have significantly transformed this planet. Others view the creative process itself as more important than the product. They stress the *therapeutic value of creativity*. In this view the primary value of the creative process is that it enables the creator to express, transform, solidify, or unify the creator's understanding of and/or relationship to the world, while the external product provides a means of tracking or monitoring this internal transformation. This view is more prominent in Eastern than Western cultures. It also figures prominently in creative therapies such as art therapy, music therapy, and drama therapy.

Is Creativity Domain Specific or Domain General?

Psychologists who emphasize the role of expertise tend to view creativity as highly *domain specific;* expertise in one domain is not expected to enhance creativity in another domain. They note that expertise or eminence with respect to one creative endeavor to be only rarely associated with expertise or eminence with respect to another creative endeavor (Baer 2010). For example, creative scientists rarely become famous artists or dancers.

Psychologists who emphasize intuition and associative processes, on the other hand, tend to view creativity as somewhat *domain general* because associative thinking can result in metaphors that connect different domains. Studies involving self-report scales, creativity checklists, and other sorts of psychometric or personality data tend to support the view that creativity is domain general (Plucker 1998). The relevance of these studies to the general versus specific debate has been questioned because they do not actually measure creative outputs but rather traits associated with the generation of creative output. However, those who stress process over product claim that these data tell us about the internal, less visible, but equally important counterpart to the *external* manifestations of the creative process. An emphasis on product rather than process may have resulted in exaggeration of the extent to which creativity is domain specific. That is, if one asks not, "are individuals talented in multiple creative domains?" but, "can individuals use multiple creative domains to meaningfully develop, explore, and express themselves?" the answer is more likely to be affirmative. Most psychologists believe that the truth lies somewhere between the extremes. That is, creativity in one domain may help but not guarantee creativity in another; it is neither strongly domain specific nor domain general.

Is There a Dark Side to Creativity?

Although creativity is clearly stimulating and indispensable to cultural and technological advancement, many believe it has a dark side (Cropley et al. 2010). There is considerable evidence that eminent creativity is correlated with proneness to affective disorders, suicide, and substance abuse. Moreover, it is not necessary for everyone to be creative. We can all benefit from the creativity of a few by imitating, admiring, or making use of their creative outputs. Excessive creativity may result in reinventing the wheel, and absorption in ones' own creative ideas may interfere with assimilation or diffusion of proven effective ideas. Computer modeling suggests that society self-organizes to achieve a balance between relatively creative and uncreative individuals (Leijnen and Gabora 2009). The social discrimination that creative individuals often endure until they have proven themselves may aid in achieving this equilibrium.

Implications for Theory, Policy, and Practice

The psychology of creativity has implications for theory, policy, and practice in a number of arenas. A first area of application is clinical. Creative activities such as art making, music making, dance, and drama are increasingly seen to have therapeutic effects that can be effective in both clinical and nonclinical settings. The transformation that occurs on canvas or on the written page is thought to be mirrored by a potentially therapeutic sense of personal transformation and self-discovery that occurs within. Immersion in the creative task has been referred to as a state of *flow* that may share characteristics with deeply spiritual or religious experiences.

A second, related area of application is child rearing and education. For example, creative play in childhood facilitates access to affect-laden (emotional) thoughts, which may enhance cognitive flexibility and divergent thinking abilities. Amabile's (1996) work on *intrinsic motivation* showed that rewards for creative work may actually inhibit creativity because focusing on an external reward leads people to neglect the internally rewarding nature of creative acts.

A third area of application is in business settings. For example, psychological work on *brainstorming sessions*, in which people get together as a group and put forward ideas in an open and accepting environment, has shown that it may be more effective when group work is followed immediately by individual work or when individuals communicate by writing so as to avoid the problem of everyone talking at once.

Conclusion and Future Directions

It is our creativity that perhaps most distinguishes humans from other species and that has completely transformed the planet we live on. The psychological study of creativity is an exciting area that brings together many different branches of psychology: cognitive, developmental, organizational, social, personality, clinical, neuroscience, and even computational and mathematical models. Past and current areas of controversy concern the relative contributions of expertise, chance, and intuition, whether the emphasis should be on process versus product, whether creativity is domain specific versus domain general, and the extent to which there is a dark side to creativity. Promising areas for further psychological study of creativity include computational modeling and work on the neurobiological basis of creativity as well as environmental influences on creativity.

Difficulties in Defining "Quality" Within Higher Education

This entry gives an overview of the intersection of quality assurance/quality enhancement within the

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,

sector of higher education and innovation. When focusing their function of creating knowledge, the institutions of higher education themselves can be taken as examples for organizations oriented toward innovation. Furthermore, measures of quality assurance and/or quality enhancement are – or at least should be – devised in a way that they foster continuous innovation of the organizations (by means of learning and improvement). This can be seen as a process of change management within institutions often appearing strongly stratified and where the complex interaction of external (e.g., stately) regulations and powerful internal resistance (e.g., of traditional academic demeanor) must be taken into account.

The distinction of "quality assurance" and "quality enhancement" was introduced to point to different aspects of procedures used during the evaluation of the quality of higher education (for the following definitions, cf. Harvey 2004–2012). Thus, quality assurance is supposed to concentrate on regulatory processes when reviewing quality so that external accountability of the institution is ascertained and that stakeholder confidence in the services provided is established. Quality enhancement (or, perhaps stated even more clearly: quality improvement) is meant to emphasize the formative function of such procedures and therefore includes feedback processes with the purpose of changing the practices reviewed to the better.

One of the major difficulties met when dealing with the assurance or enhancement of the quality of higher education is the definition of the quality in question: The kind of quality looked for may differ from the point of view of the different stakeholders (society, state, students, teachers, university management); the good or service delivered is of manifold nature (instruction for a job within professional life or science, creation of new knowledge, formation of reflected personalities and citizens that can make a valuable contribution to society, etc.); the use and value of the education for the ones experiencing it can only be assessed properly when using it; and the organizations supplying the education are complex and have different institutional setups according to their historical and political contexts. So it has become topical within the literature of this subject to comment on that problem of definition, which does not hinder some fundamental understanding of the underlying notion of quality. In a seminal article, Harvey and Green (1993) highlighted the role of stakeholders in higher education (Harvey and Green 1993: 11) and came up with five possible definitions of quality in higher education, describing it as exceptional/excellence, as perfection, as fitness for purpose (one might add: and fitness of the purpose pursued), as value for money, and as transformation. Especially the last dimension of quality – that it had to embrace the potential of the services provided by an institution to change and to improve – became influential for the resulting discussion as Harvey and Knight (1996) made explicit. Furthermore, the three dimensions of quality as described by Donabedian (1980) – originally developed for the system of health care – were largely adopted: When talking about quality in higher education, it has been regarded as a valuable instrument for an analytical approach to differentiate between the quality of the structure (e.g., the institution and its facilities or staff), of the processes (e.g., of teaching or administrating), and of the outcomes (e.g., of numbers of graduates vs. dropouts, of exam results, of rates of employment of alumni within relevant professional fields, etc.). Due to this wide range of applicability of the term "quality" within higher education, some authors thought it more consequent and suitable to speak of different "qualities" rather than one single one.

Quality Assurance Within Higher Education: Path Dependency and Political Factors

In order to understand how the discussion of quality assurance and/or quality enhancement was introduced into higher education and how it was (and still is) led in different countries, one has to consider historical, regional, and political factors: The institutional status and the decisive contexts of the university sector will vary according to the evolution of tertiary education in the countries concerned – relatively young university landscapes in countries still developing face different problems than well-established institutions in OECD countries; a university sector largely based on private institutions, like in the USA, has some characteristics different to a largely state-run system like in Continental Europe, and so on. For the following findings on the rise of the procedure of quality evaluation in higher education, one has to bear in mind the path dependency that policies are submitted to – in surroundings different to the ones outlined here, different discussions and results will be likely to be considered.

The rise of the quality regime within the sector of tertiary education is often associated with a lack of trust of the public (the state) regarding the educational standards held at a number of institutions. This can be read as a result of the massification of higher education when universities no longer host a small elite of their age cohort, but are frequented by large numbers of students, thereby generating a great number of study programs and/or new institutions that do not share the confidence traditionally attributed by the public to universities and their supply of education. Thus, the need for checking standards is incited by a factor that came about from the educational system as a consequence of a historical development of society (the emerging "knowledge-based society"). It is stimulated further by questions concerning the effective use of financial resources spent by the universities (do they offer adequate value for money?) and their capacity to adapt to the new challenges of an altered environment (are they able to innovate and fulfill the new tasks required of them in terms of content as well as organization?).

According to Jeliazkova and Westerheijden (2002), different phases can be discerned in quality assurance systems, which correspond to different measures taken to ensure the desired quality: After a first phase of doubts about educational standards gleaned from descriptive records or performance indicators and resulting in governmental accreditations or reports, there was arguably another phase of doubts regarding the efficiency of the educational system. The issue of public accountability is raised here; by identifying good practices and/or rankings of institutions, the universities seek to make their point as being responsible and quality-oriented institutions. A third phase is identified when doubts about the capacity for innovation and the ability for securing quality have risen. This is another facet of public accountability and often encountered with governmental audit reports or within the institution. When the need to establish a sustainable quality culture is eventually perceived, the focus is widened from mere fulfillment of public demands of accountability (often felt as external to traditional academic tasks by many of the institutional actors) to an improvement-oriented approach that enhances self-regulation of the institution as a means of its active (and autonomous) shaping. As outlined by Vroejenstijn (1995), this relation of accountability and improvement is regarded as being strained by many of the protagonists involved, which is also expressed in the proposition of different concepts of quality assurance and quality enhancement: They seem to be "navigating between Scylla and Charybdis," as the title of Vroejenstijn's (1995) influential handbook suggests. It remains to be seen whether this widely perceived tension between improvement and accountability will be unveiled as an illusionary one, as argued by Harvey and Newton (2007).

Nonetheless, one has to admit that the issue of quality was introduced in the sector of higher education from the outside, due to a lack of trust that should be reestablished by quality assurance and/or quality enhancement systems that on the one hand secure the basic requirements of institutions and their study programs and on the other hand play an active role for their improvement and innovation. It is important to note that the actual establishment of these systems can be interpreted in a quite divergent way within different political contexts: They may be seen as a means of the state ruling the institutions when looking at educational systems with traditional high autonomy of the universities (as in the UK or the USA), thereby diminishing this autonomy. For educational systems that traditionally relied on state guidance of universities (like in many countries of Continental Europe), the opposite can be true: By defining ex-post-standards of tertiary education instead of the former ex-ante-criteria of ministerial rule, the state would hand over greater autonomy to the single institution.

The Impact of Managerialism on Higher Education

Independent of the actual situation of a country's higher education system regarding the aforesaid aspect of institutional autonomy, there is another overlying trend to be observed when it comes to the explanation of the growing spread of the quality agenda within universities: An increasing weight of managerial governance in the running of universities (replacing the former power of the professorial estate) went along with the intrusion of managerial thinking. Thus, the quality discourse reached its peak with the adaptation of ideas of the so-called new public management. This did not only affect organizational structures or employment relations but also the methods thought to be adequate to form and improve universities. Then concepts of quality and quality assurance or quality enhancement became – as Stensaker (2007) put it – a "fashion" for the governance of universities. Management principles originally developed for enterprises, and profit organizations were taken over and/or accommodated in order to fit academic contexts. This could take the form of mere policy copying (like giving monetary incentives to professionals for special efforts, say in the field of research or – less frequent – teaching) or the form of translation (thereby paying more attention to the peculiarities of the academic organization). One might say that the older paradigm of effectiveness of organizations was superseded by that of quality at a certain point of time when the quality discourse leaned strongly toward management literature. Also it seemed to suit the purpose of academic organizations better than merely looking for efficiency, for example, in producing large numbers of graduates without investigating the nature of their acquired qualifications. It is the adaptability to academic contexts that explains to a large extent why certain management ideologies were embraced more eagerly than others. So, for example, a concept like Total Quality Management (TQM) with its "quality chain" – considering aspects like a customer-driven definition of quality ("customer" here often being translated into "student"), cultural change, or organizational structure with the end of constant improvement – was often esteemed as one applicable to academia, albeit even here, the differences between an originally business-oriented thinking and the academic world are obvious. To name but an example given by Harvey and Green (1993): The measurement of results within TQM largely relies on quantitative performance measures – a restriction to such performance indicators (like financial resources or the ratios of students to teachers) is in danger of overlooking the qualitative performance aspects that make a noteworthy share when it comes to approaching "academic quality." Nonetheless, Management principles with a focus on quality – next to TQM, one might think of the model of the European Foundation for Quality Management (EFQM) – had and have a great impact on the governance of higher education institutions.

As not uncommon for management principles – or, in broader terms, for policies in general – changes of approach and methods of quality assurance/quality enhancement may be observed every now and again. Taking the example of the US higher education system, Ewell (2007) identified certain historical phases of what he calls the "quality game." After an era of "Pre-Quality" characterized by a high level of trust in higher education institutions by public officials, a first period of quality assessment took place during the 1980s when universities faced the first calls for accountability from politics, often answering it – still in a rather friendly public atmosphere – with assessment operations at institution level. In the 1990s, this was superseded by a notion of "value for money" in terms of public utility and the feeling of state authorities that they should engage themselves in actively steering higher education so that it served public purposes. The method of choice frequently used during this period was the application of performance measures (a row of examples will follow below) and attaching money to the fulfillment of these indicators. After 2000, a second period of quality orientation took a somewhat different approach in emphasizing issues of institutional improvement and adopting more and new methods of quality review (like academic audits), especially with the participation of third party reviewers. From then on, the process of teaching and learning was the main focus when inquiring about the outcomes of that central activity of universities.

It is important to notice that these changes in policies and methods were mostly stimulated by external events of national or international politics (and/or economy). Also it should be pointed out that the increased burden for the institutions – the rising costs of maintaining and developing sophisticated systems of quality assurance and quality enhancement – may lead to evasive reactions on behalf of the institutions. Especially smaller universities without the necessary financial resources, but also institutions where the leaders are not convinced of the eventual beneficial effects of quality enhancement, the temptation may be great to signal only compliance to external-driven quality evaluation while letting the core functions of academic life remain as protected and unaltered as possible. It is evident that quality assurance merely practiced as a kind of ritual – as enforced by some state authority – has little or no impact on the innovation of institutions.

Conclusion and Future Directions

Although it has been found that the concept of "quality" in higher education in many respects still remains vague to some extent, this has not impeded its career as a paradigm notion for shaping and innovating higher education institutions. As a general observation, it can be stated that measures and programs of quality assurance and quality enhancement have diversified and grown in importance as a consequence of shifts in educational politics (especially the often-quoted "lack of trust") and the intrusion of management principles into academia. The following list – not claiming to be comprehensive – is meant to give an overview on the array of approaches used by giving examples for some of the most popular tendencies:

(a) Accountability and performance indicator reports focus on a variety of factors like: factors of input (e.g., staff-student ratios, staff qualifications, student selectivity, funding, facilities, curriculum plans), process factors (e.g., student and alumni feedback on courses and study programs respectively, hours per course unit, etc.), factors of throughput (intermediate results of exams, resits, grade point averages), and output factors (final results of graduation rates vs. dropouts, the time needed to reach the degree, employment rates).
(b) A movement of assessment-and-outcomes tries to develop performance measures by calling attention to questions of value and learning outcomes.
(c) Total Quality Management focuses on continuous improvement and customer satisfaction.
(d) External Quality Monitoring delegates accountability to third parties (also including measurements of assessment-and-outcomes).

Quality assurance in general uses measures like (all following citations taken from Harvey 2004–2012): accreditation ("establishment of the status, legitimacy or appropriateness of an institution, program or module of study"), audit ("process for checking that procedures are in place to assure quality, integrity, or standards of provision and outcomes"), assessment ("all methods used to judge the performance of an individual, group, or organization"), and external examination ("uses people external to the program or institution to evaluate quality or standards," which can also include techniques of benchmarking, ranking, or report cards). Due to the variety of procedures, the term quality "monitoring" sometimes takes the place of "assurance." A regulatory component is felt within the use of this concept which is not present in the term quality enhancement (described as a "process of augmentation and improvement") that stresses the formative component. Among the teaching and learning activities often encompassed by quality enhancement, there are also qualitative elements like curriculum development to communities of practice.

As can be seen from this short listing of methods, indicators, and procedures, the fields of quality assurance and quality enhancement yield a wide spectrum of activities and practices with sometimes divergent theoretical backgrounds. What seems one of the consequences of the increasingly refined applications of quality-oriented procedures within higher education and the yet ongoing movement toward an improvement-driven concept of quality enhancement is the growing understanding for the necessity of an outcome-based education. That postulated "shift from teaching to learning" will operate by means of an expressed learning intent; it is supposed to result in a process that enables the intended learning to be achieved, and it has to lead to the formulation of criteria for assessing learning.

It is clear that such ambitious goals implying a serious change of academic teaching and learning activities not only rely on the active support of the institutional leaders (which is true for any action of management change) but have to be based on a well-defined analytical framework of the policies of quality assurance chosen. Perellon (2007: 161) suggests five dimensions concerning the choices to be made within quality assurance in higher education:

- *Objectives*: What should be the aims and objectives of quality assurance policy?
- *Control*: Who should control the process of quality assurance?
- *Areas*: What are the domains covered by quality assurance procedures setup?
- *Procedures*: How are the quality assurance procedures set up?
- *Use*: How is the information collected used?

Quality assurance and quality enhancement within higher education claiming to be more than the mere fulfillment of ritualism or tokenism driven by external pressure of public accountability will have to show accountability itself by reflecting on the methods and the outcomes of their activities and procedures. Accordingly, the argument of Harvey and Newton (2007: 235) on behalf of a "research-informed, improvement-led approach to quality evaluation" should be considered if quality assurance and quality enhancement are to make a contribution toward the innovation of the higher education sector. The advantages of this concept seem obvious: A research-informed approach will choose and improve procedures in terms of better efficacy of quality assurance; also it can hope for increased acceptance from academics as it reflects on its methodology in a scientifically valid way; finally, it is appropriate for self-regulating institutions as it largely relies on internal processes and internal motivators (which should motivate the institutional actors, allowing for greater autonomy). However, due to the contingencies of political and economic contexts, it remains an unanswered question if and to what extent such a transformation of quality evaluation procedures toward an improvement-led, self-regulating system within higher education institutions is to be realized in different countries during the coming years.

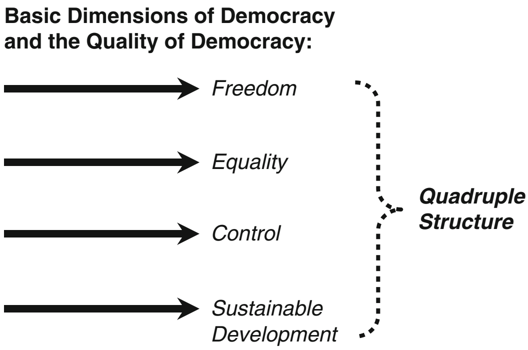
The Conceptual Definition of Democracy and of the Quality of Democracy

How can democracy and the quality of democracy be conceptualized? Such a (theoretically justified) conceptualization is necessary in order



Quality of Democracy and Innovation, Fig. 1 The basic quardruple-dimension structure of democracy and the quality of democracy (Source: Author's own concoptualization and visualization, based on Campbell (2008, p. 32) and for the dimension of "control" on Lauth (2004, pp. 32–101))

for democracy and the quality of democracy to be subjected to a democracy measurement, *whereby democracy measurement, in this case, can be examined along the lines of conceptually defining democracy (thus democracy measurement is also to be utilized to improve the theory of democracy)* (see Campbell 2012). Hans-Joachim Lauth (2004, pp. 32–101) suggests in this context a "three-dimensional concept of democracy," which is composed of the following (conceptual) dimensions: *equality, freedom, and control* (see Fig. 1). These dimensions can be interpreted as "basic dimensions" of democracy and of the quality of democracy. Lauth (2004, p. 96) underlines that these dimensions are "sufficient" to obtain a definition of democracy. The term "dimension" offers a conceptual elegance that can be applied "trans-theoretically," meaning that different theories of democracy may be put in relation and may be mapped comparatively in reference to those dimensions. Metaphorically formulated, dimensions behave like "building blocks" for theories and theory development. With regard to democracy and the quality of democracy, every interest in analysis and assessment is confronted with the following point-of-departure question and challenge: whether (1) democracy exclusively refers or should refer to the political system (political dimension) or whether (2) democracy should also include social (societal), economic, and ecological contexts (nonpolitical dimensions) of the political system. This produces implications on the selection of indicators to be used for democracy measurement. How "limited" or "broadly" focused should be the definition of democracy? This is also reflected in the *minimalistic (minimalist)* versus *maximalistic (maximalist)* democracy theory debate (see Sodaro 2004, pp. 168, 180, and 182). In this regard, various theoretical positions elaborate on this concept. Perhaps, it is (was) from an orthodox point of view of theory to limit democracy to the political system (Munck 2009, pp. 126–127). More recent approaches are more sensitive for the contexts of the political system, however, still must establish themselves in the political mainstream debates (see, e.g., Stoiber 2011). Nevertheless, explicit theoretical examples are emerging for the purpose of incorporation into the democracy models the social (societal), economic, and ecological contexts. The theoretical model of the "democracy ranking" is an initiative that represents such an explicit example (Campbell 2008).

Over time, democracy theories are becoming more complex and demanding in nature, regardless, whether the understanding of democracy refers only to the political system or includes also the contexts of the political system. This also reflects on the establishment of democracy models. The most simple democracy model is that of the "electoral democracy" (Helms 2007, p. 19), also known as "voting democracy" ("*Wahldemokratie*," Campbell and Barth 2009, p. 212). An electoral democracy focuses on the process of elections, highlights the political rights, and refers to providing minimum standards and rights, however, enough to be classified as a democracy. Freedom House (2011a) defines electoral democracy by using the following criteria: "a competitive, multiparty political system"; "universal adult suffrage for all citizens"; "regularly contested elections"; and "significant public access of major political parties to the electorate through the media and through generally open political campaigning." The next, qualitatively better level of democracy is the so-called liberal democracy. A liberal democracy is characterized by political rights and more importantly also by civil liberties as well as complex and sophisticated forms of institutionalization. The liberal democracy does not only want to fulfill minimum standards (thresholds) but aims on ascending to the quality and standards of a developed, hence, an advanced democracy. Every liberal democracy is also an electoral democracy, but not every electoral democracy is automatically a liberal democracy. In this regard, Freedom House (2011a) states: "Freedom House's term 'electoral democracy' differs from 'liberal democracy' in that the latter also implies the presence of a substantial array of civil liberties. In the survey, all the 'Free' countries qualify as both electoral and liberal democracies. By contrast, some 'Partly Free' countries qualify as electoral, but not liberal, democracies." Asserting different (perhaps ideal-typical) conceptual stages of development for a further quality increasing and progressing of democracy, the following stages may be put up for discussion: *electoral democracy*, *liberal democracy*, and *advanced (liberal) democracy* with a *high quality of democracy*.

In *Polyarchy*, Robert A. Dahl (1971, pp. 2–9) comes to the conclusion that mostly two dimensions suffice in order to be able to describe the functions of democratic regimes: (1) *contestation* ("public contestation," "political competition") and (2) *participation* ("participation," "inclusiveness," "right to participate in elections and office"). Also relevant are Anthony Downs' (1957, pp. 23–24) eight criteria in *An Economic Theory of Democracy*, defining a "democratic government," but it could be argued that those are affiliated closer with an electoral democracy. In the beginning of the twenty-first century is the conceptual understanding of democracy and the quality of democracy already more differentiated, it can be said that crucial conceptual further developments are in progress. Larry Diamond and Leonardo Morlino (2004, pp. 22–28) have come up with an "eight dimensions of democratic quality" proposal. These include (1) *rule of law*, (2) *participation*, (3) *competition*, (4) *vertical accountability*, (5) *horizontal accountability*, (6) *freedom*, (7) *equality*, and (8) *responsiveness*. Diamond and Morlino (2004, p. 22) further state: "The multidimensional nature of our framework, and of the growing number of democracy assessments that are being conducted, implies a pluralist notion of democratic quality." These eight dimensions distinguish themselves conceptually with regard to procedure, content, and results as the basis (conceptual quality basis) to be used in differentiating the quality of democracy (see Diamond and Morlino 2004, pp. 21–22; 2005; see also Campbell and Barth 2009, pp. 212–213). The "eight dimensions" of Diamond and Morlino may be interpreted as "secondary dimensions" of democracy and the quality of democracy for the purpose of democracy measurement.

"Earlier debates were strongly influenced by a dichotomous understanding that democracies stood in contrast to non-democracies" (Campbell and Barth 2009, p. 210). However, with the quantitative expansion and spreading of democratic regimes, it is more important to differentiate between the qualities of different democracies. According to Freedom House (2011b), in the year 1980 no less than 42.5 % of the world population lived in "not free" political contexts; by 2010, this share dropped to 35.4 %. Democracies themselves are subject to further development, which is a continuous process and does not finish upon the establishment of a democracy. Democracies have to find answers and solutions to new challenges and possible problems. Democracy is in a constant need to find and reinvent itself. Observed over time, different scenarios could take place and could keep a democracy quality going on constantly; however, democracy quality could erode, but also improve. *A betterment of the quality of democracy should be the ultimate aim of a democracy. Earlier ideas about an electoral democracy are becoming outdated and will not suffice in today's era.*

Gillermo O'Donnell (2004a) developed a broad theoretical understanding of democracy and the quality of democracy. In his theoretical approach, quality of democracy develops itself further through an interaction between human development and human rights: "True, in its origin the concept of human development focused mostly on the social and economic context, while the concept of human rights focused mostly on the legal system and on the prevention and redress of state violence" (O'Donnell 2004a, p. 12). The human rights differentiate themselves in civil rights, political rights, and social rights, in which O'Donnell (2004a, p. 47) assumes and adopts the classification of T. H. Marshall (1964). Human development prompts "...what may be, at least, a minimum set of conditions, or capabilities, that enable human beings to function in ways appropriate to their condition as such beings" (O'Donnell 2004a, p. 12), therefore in accordance with human dignity and, moreover, the possibility of participating realistically in political processes within a democracy. O'Donnell also refers directly to the *Human Development Reports* with the *Human Development Index (HDI)* that are being released and published annually by the United Nations Development Program (UNDP) (for a comprehensive website address for all *Human Development Reports* that is publicly accessible for free downloads, see: http://hdr.undp.org/en/reports/global/hdr2011/). Explicitly, Gillermo O'Donnell (2004a, pp. 11–12) points out: "The concept of human development that has been proposed and widely diffused by UNDP's *Reports* and the work of Amartya Sen was a reversal of prevailing views about development. . . . The concept asks how every individual is doing in relation to the achievement of 'the most elementary capabilities, such as living a long and healthy life, being knowledgeable, and enjoying a decent standard of living'" (O'Donnell 2004a, pp. 11–12; UNDP 2000, p. 20). *If the implementation of O'Donnell is reflected upon the initial questions asked in this contribution for the conceptualization of democracy and the quality of democracy, it can be interpreted but also convincingly argued that "sustainable development" can be suggested as an additional dimension ("basic dimension") for democracy, which would be important for the quality of democracy in a global perspective* (for a systematic attempt of empirical assessment on possible linkages between democracy and development, see Przeworski et al. 2003). As a result of the distinction between dimensions (basic dimensions) for democracy and the quality of democracy, the following proposition is put up for debate: in addition to the dimensions of *freedom, equality, and control* as being suggested by Lauth (2004, pp. 32–101), *the dimension of sustainable development should be introduced as a fourth dimension* (see again Fig. 1). Regarding suggestions for defining sustainable development, Verena Winiwarter and Martin Knoll (2007, pp. 306–307) commented: "In the meantime, as described, multiple definitions for sustainability exist. A fundamental distinction within the definition lies in the question whether only the relation of society with nature or if additionally social and economic factors should be considered."

In political context and in political competition, equality often is associated closer with left-wing political positions and freedom with right-wing (conservative) positions (e.g., see Harding et al. 1986, p. 87). *A measure of performance of political and nonpolitical dimensions in relation to sustainable development has the advantage (especially in the case where sustainable development is understood comprehensively) that this procedure is mostly (often) left–right neutral. Such a measure of performance as a basis of the assessment of democracy and quality of democracy offers an additional reference point ("meta-reference point") outside of usual ideologically based conflict positions* (Campbell 2008, pp. 30–32). It can be argued in a similar manner that the dimension of control mentioned by Lauth (2004, pp. 77–96) positions itself as left–right neutral as well. The definition developed by the "democracy ranking" for the quality of democracy is "Quality of Democracy = (freedom & other characteristics of the political system) & (performance of the nonpolitical dimensions)" (Campbell 2008). *This definition is interpreted as a further empirical operationalization step and as a practical application for the measurement of democracy and the quality of democracy, respectively, which is based on the theory about the quality of democracy by Guillermo O'Donnell* (see also O'Donnell 2004b). However, the conceptual democracy formula of the "democracy ranking" has been developed independently (Campbell and Sükösd 2002).

Conclusion and Future Directions

There are different theories, conceptual approaches, and models for knowledge production and innovation systems. In the Triple Helix model of innovation, Etzkowitz and Leydesdorff (2000, p. 112) developed a conceptual architecture for innovation, where they tie together the three helices of academia (higher education), industry (business), and state (government). This conceptual approach was extended by Carayannis and Campbell (2009; 2012, p. 14) in the so-called Quadruple Helix model of innovation systems by adding as a fourth helix the "media-based and culture-based public" as well as "civil society." *The Quadruple Helix, therefore, is broader than the Triple Helix and contextualizes the Triple Helix*, by interpreting Triple Helix as a core model that is being embedded in and by the more comprehensive Quadruple Helix. *Furthermore, the next-stage model of the Quintuple Helix model of innovation contextualizes the Quadruple Helix, by bringing in a further new perspective by adding the "natural environment" (natural environments) of society*. The Quintuple Helix represents a "five-helix model," "where the environment or the natural environments represent the fifth helix" (Carayannis and Campbell 2010, p. 61). In trying to emphasize, compare, and contrast the focuses of those different Helix innovation models, it can be asserted that the Triple Helix concentrates on the knowledge economy, the Quadruple Helix on knowledge society and knowledge democracy, while the Quintuple Helix refers to socio-ecological transitions and the natural environments (Carayannis et al. 2012, p. 4; see also Carayannis and Campbell 2011; European Commission 2009; Fischer-Kowalski and Haberl 2007). *For explaining and comparing democracy and the quality of democracy, a "quadruple-dimensional structure" has been proposed here that refers to four different "basic dimensions" of democracy that are being called freedom, equality, control, and sustainable development* (Fig. 1 offers a visualization on these). Here, actually a line of comparison may be drawn between concepts and models in the theorizing on democracy and democracy quality and the theorizing on knowledge production and innovation systems. This opens up a window of opportunity for an interdisciplinary and transdisciplinary approaching of democracy as well as of knowledge production and innovation, also of "democratic innovation" (Saward 2000) and "democratizing innovation" (Von Hippel 2005). *In conceptual terms, the quadruple-dimensional structure of democracy could also be rearranged (re-architectured) in reference to helices, by this creating a "model of Quadruple Helix structures" for democracy and the quality of democracy*. The metaphor and visualization in reference to terms of *helices* emphasizes the fluid and dynamic interaction, overlap, and coevolution of the individual dimensions of democracy. As basic dimensions for democracy were proposed to identify freedom, equality, control, and sustainable development. Figure 2 introduces a possible visualization from a helix perspective for a theoretical framing of democracy.

Specific challenges for future research but also for future reform and development are as follows:

1. Is there an unfolding relationship, perhaps also coevolution, between democracy, knowledge democracy, and the quality of democracy?
2. Do innovations in and of democracy produce and create an innovative democracy?
3. Does innovative democracy support knowledge production and knowledge application (innovation) in the knowledge society and knowledge economy?
4. Is sustainable development, in the long run, only possible, when democracy, innovation, and entrepreneurship find together by forming in balance a complex and sensitive interaction and coevolution?

Quality of Democracy and Innovation, Fig. 2 The quadruple helix structure of the basic dimension of democracy and the quality of democracy (Source: Author's own conceptualization based on Etzkowitz and Leydesdorff (2000, p. 112), Carayannis and Campbell (2012, p. 14), Danilda et al. (2009), Campbell (2008, p.32) and for the dimension of "control" on Lauth (2004, pp. 32–101))

Introduction

Due to the escalation of "global warming," it is time for humanity to think and act responsibly and determine sustainable solutions. Global warming, in addition to climate change, has caused the world to undertake new responsibilities (see IPCC 2007a), which not only include further climate change but in the long term also hold humanity accountable in the prevention of new political and/or social conflicts, war on resources, new environmental catastrophes, as well as serious crises in the market economies (see UNDP 2007; UNEP 2008). The special challenge of global warming can be tackled by "sustainable development." The definition of the Brundtland Commission states that sustainable development "meets the needs of the present without compromising the ability of future generations to meet their own needs" (United Nations 1987a, b). Sustainable development concerns us all and takes place on the local as well as global level. Hence, sustainable development has to be understood in the context of "gloCal knowledge economy and society" (see Carayannis and Campbell 2011; Carayannis and von Zedwitz 2005; Carayannis and Alexander 2006). Therefore, we must perceive global warming not as a challenge, but rather as an opportunity to live innovatively and effectively in union with nature for a better tomorrow.

To a large extent, humanity itself has caused the climate change; therefore, something must be done (see IPCC 2007b; Le Monde diplomatique 2009, pp. 72–73; Friedman 2008). However, there are hardly any comprehensive models or concepts to answer the "WHY" that truly show "HOW" we can act and learn accordingly, or provide any demonstrative methods, suggestions, and examples "HOW" we can improve our actions in the present. Our analysis presented here suggests understanding the "WHY" and consequently offers a "model of innovation," which demonstrates a feasible, step-by-step method to tackle the "HOW."

In the current academic debate, it is undisputed that a solution or a suitable answer regarding the challenge of global warming can only be found through utilizing the asset of human knowledge (see Carayannis and Campbell 2010, p. 42; Bhaskar 2010, p. 1). The key to success, as is being determined by our propositions, lies in using the available and newly created "knowledge" in correspondence with the *Quintuple Helix Model* (Carayannis and Campbell 2010, p. 62). The *Quintuple Helix* is a model of innovation that can tackle existing challenges of global warming through the application of knowledge and know-how as it focuses on the social (societal) exchange and transfer of knowledge inside subsystems of a specific state, nation-state (see Barth 2011a, pp. 5–7). The "nonlinear" innovation model of the *Quintuple Helix*, which combines knowledge, know-how, and the natural-environment system together into one "interdisciplinary" and "transdisciplinary" framework, can provide a step-by-step model to comprehend the quality-based management of effective development, to recover a balance with nature, and to allow future generations a life of plurality and diversity on earth (see Carayannis and Campbell 2010, p. 42; Barth 2011a, p. 2). To sum up, our thesis is as follows: The *Quintuple Helix* represents a suitable model in theory and practice offered to society, to understand the link between knowledge and innovation, in order to promote lasting development. This contribution, under the aspect of global warming, focuses on the potential of a nation-state in the twenty-first century and on the following pivotal question: *How can sustainable development, with regard to global warming, be practiced step by step with and within a quintuple helix model?*

The structure of our analysis is as follows. Section "The Challenge of Global Warming and the Resource of Knowledge" is a short delineation about challenges of global warming and the organization of the resource of knowledge. In Sect. "What is a Quintuple Helix Innovation Model?", the *Quintuple Helix* Model is defined. Next comes Sect. "The Challenge of Global Warming in a Quintuple Helix Innovation Model" that visualizes the *Quintuple Helix Model* as a "nonlinear" model of innovation in correspondence with social (societal) subsystems and along with a descriptive step-by-step example of how the challenge of sustainable development (under the aspect of global warming) may be adopted. Section "Conclusion and Future Directions" offers a conclusion in reference to the *Quintuple Helix Innovation Model*.

The Challenge of Global Warming and the Resource of Knowledge

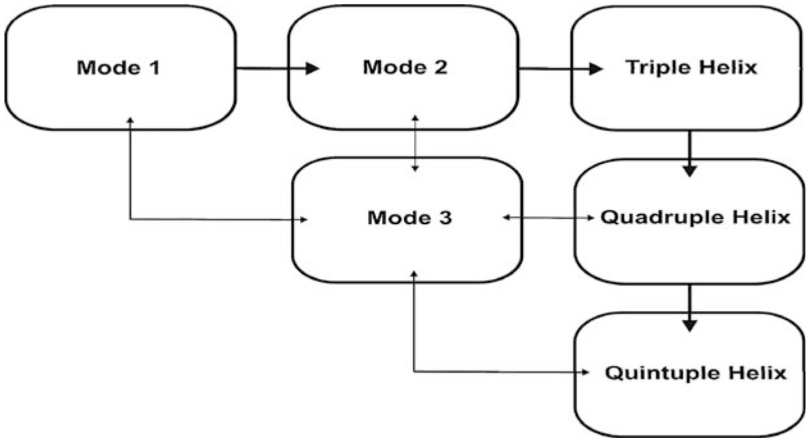
The challenge of sustainable development (under the aspect of global warming) proves that there are currently several crucial questions that need to be answered (see Carayannis 2011): So new political goals must be formulated, in reference with CO_2 emission limits, in the quest for a long-term sustainability. Furthermore, there is rising demand for "new green" knowledge solutions and know-how in order to utilize resources innovatively for society and the economy in an environmentally conscious manner. Moreover, our present way of life and lifestyle must be scrutinized under a sustainable impact assessment. Apart from environmental protection, it also demands the protection of biodiversity (see Barth 2011a; Bhaskar 2010; Le Monde diplomatique 2009, pp. 22–23, 72–73, 92–93; UNDP 2007). Global warming concerns us all as it takes place on a "local" as well as "global" level and implies ramifications for the "gloCal knowledge economy and society" (see Carayannis and Campbell 2011; Carayannis and von Zedwitz 2005; Carayannis and Alexander 2006). It is clear that the challenge of global warming is accompanied with the challenge of sustainability (for the world) in the twenty-first century (see Carayannis 2011). Therefore, there are nine areas, of which Carayannis and Kaloudis write about, that require "sustained action," political and economical "leadership" or "empowerment," and "intelligent use of technology" (Carayannis and Kaloudis 2010, p. 2):

1. "Financial/economic system": The area of "financial and economic system" refers to financial and economic aspects of the effects of climate change. The following question arises (among other things): How should the two systems effectively change or adapt with each other in order to reduce or exclude crises in consequence of climate change (see, e.g., Barbier 2009; Barth 2011a; Green New Deal Group 2008; Hufbauer et al. 2009; Meyer 2008; OECD 2010; Sen 2007)?

2. "Environmental challenges": The area of "environmental challenges" has to do with causes and effects of climate change and which political and social measures should be taken to increase environmental conservation and sustainability (see, e.g., IPCC 2007a, b; Giddens 2009; Høyer 2010a; Müller and Niebert 2009; Stern 2009).
3. "Feed and heal the world challenges": The area "feed and heal the world challenges" emphasizes new and solution-oriented approaches under the aspect of knowledge and care in the course of climate change (see Parker 2010; Höll et al. 2006).
4. "Energy challenges": The area of "energy challenges" highlights new green technologies and renewable energy, which lead to sustainable development (see also Barbier 2009; Green New Deal Group 2008; Høyer 2010b; UNEP 2008).
5. "Educational challenges": The area "educational challenges" is based on a better education as a key for empowerment, equality of chances, and new knowledge for sustainability and development (see, e.g., OECD 2009; O'Donnell 2004; Sen 2007; UNDP 2010).
6. "Political democratic reform across the world": The area "political democratic reform across the world" promotes democracy as being a local and global key for sustainable development. Here, also the themes of democratization, freedom, equality, policy making, gender, and political culture are relevant (see, furthermore, Barth 2011b; Biegelbauer 2007b; Campbell 2007; Campbell and Schaller 2002; Kreisky and Löffler 2010; Otzelberger 2011; Ulram 2006).
7. "Transformative government across the world": The area "transformative government across the world" has to do with the political standing or rating of a nation-state. Examples here are the search for democracy, quality of democracy, types of political systems, etc. (see also Barth 2010, 2011a, b, c; Campbell 2008; Campbell and Barth 2009; Campbell et al. 2010; Diamond and Morlino 2005; O'Donnell 2004; Rommetveit et al. 2010; Schumpeter 1976; Tilly 2007).
8. "Equity and security across the world": The area "equity and security across the world" refers to equity and security as being basic prerequisites to foster and support sustainable development (see, e.g., UNDP 2011; Barth 2011a).
9. "Technology, innovation, and entrepreneurship as drivers of knowledge societies": The area of "technology, innovation, and entrepreneurship as drivers of knowledge societies" emphasizes the fact that a sustainable development in knowledge societies can only be achieved when new knowledge is promoted and produced and when innovations (with a new entrepreneurship) are developed further (see here the idea and concept of the "Academic Firm," Campbell and Güttel 2005; see also and furthermore Bhaskar 2010; Biegelbauer 2007a; Campbell 2006; Carayannis and Campbell 2006, 2009, 2010, 2011; Dubina 2009; Dubina et al. 2012; Kuhlmann 2001; Lundvall 1992; Nowotny et al. 2003).

Let us consider now in greater detail the production of the resource of knowledge. Knowledge (e.g., the advancement of green technology) can act as key to success for sustainable development. Essentially, it should be understood today that nation-states that concentrate on progress of society, a higher competitiveness of their economies or a better and sustainable quality of life, have to apply the resource of knowledge. In the transformation to a knowledge-based society, knowledge-based economy, or knowledge-based democracy (see Carayannis and Campbell 2009, p. 224), also under the aspect of climate change, it is possible to generate new and usable knowledge in conjunction with sustainable development. The resource of knowledge, therefore, turns into the "most fundamental resource" (Lundvall 1992, p. 1), with qualities of a "knowledge nugget" (Carayannis and Formica 2006, p. 152). Knowledge, as a resource, is created through creative processes, combinations, and productions in so-called Knowledge Models or Innovation Models and thus becomes available for society: "We can also call this the creativity of knowledge creation" (Carayannis and Campbell 2010, p. 48). We want to refer here specifically to six currently existing

Quintuple Innovation Helix and Global Warming: Challenges and Opportunities for Policy and Practice, Fig. 1 The evolution of the models of knowledge creation (Source: Authors' own conceptualization)



models of knowledge creation and innovation creativity (see also Fig. 1, below):

"**Mode 1**" (see Gibbons et al. 1994): Mode 1 "focuses on the traditional role of university research in an elderly 'linear model of innovation' understanding," and success in mode 1 "is defined as a quality or excellence that is approved by hierarchically established peers" (Carayannis and Campbell 2010, p. 48).

"**Mode 2**" (see Gibbons et al. 1994): Mode 2 can be characterized by the following five principles: (1) "knowledge produced in the context of application," (2) "transdisciplinarity," (3) "heterogeneity and organizational diversity," (4) "social accountability and reflexivity," (5) and "quality control" (Gibbons et al. 1994, pp. 3–4).

"**Triple Helix**" (see Etzkowitz and Leydesdorff 2000): The "Triple Helix overlay provides a model at the level of social structure for the explanation of Mode 2 as a historically emerging structure for the production of scientific knowledge and its relation to Mode 1," and it is a "model of 'tri-lateral networks and hybrid organizations' of 'university-industry-government relations'" (Etzkowitz and Leydesdorff 2000, pp. 118, 111–112).

"**Mode 3**" (see Carayannis and Campbell 2006): "The concept of Mode 3 is more inclined to emphasize the co-existence and co-evolution of different knowledge and innovation modes. Mode 3 even accentuates such a pluralism and diversity of knowledge and innovation modes as being necessary for advancing societies and economies. This pluralism supports processes of a mutual cross-learning from the different knowledge modes. Between Mode 1 and Mode 2 manifold creative arrangements and configurations are possible, linking together basic research and problem-solving" (Carayannis and Campbell 2010, p. 57). Mode 3 "encourages interdisciplinary thinking and transdisciplinary application of interdisciplinary knowledge" as well as "allows and emphasizes the co-existence and co-evolution of different knowledge and innovation paradigms" (see Carayannis and Campbell 2010, pp. 51–52).

"**Quadruple Helix**" (see Carayannis and Campbell 2009): The *Quadruple Helix Model* is based on the *Triple Helix Model* and adds as fourth helix the "public," more specifically being defined as the "media-based and culture-based public" and civil society. This "fourth helix associates with 'media,' 'creative industries,' 'culture,' 'values,' 'life styles,' 'art,' and perhaps also the notion of the 'creative class'" (Carayannis and Campbell 2009, pp. 218, 206).

"**Quintuple Helix**" (see Carayannis and Campbell 2010): The *Quintuple Helix Innovation Model* is based on the *Triple Helix Model and Quadruple Helix Model* and adds as fifth helix the "natural environment." "The Quintuple Helix can be proposed as a framework for transdisciplinary (and interdisciplinary) analysis of sustainable development and social ecology" (Carayannis and Campbell 2010, pp. 51 and 62) (see also later our analysis in Sect. "What is a Quintuple Helix Innovation Model?").

About these six briefly described models can be concluded that in a *knowledge society*, at the national level, a network-style linkage of knowledge is being processed, and each model fulfills a specific contribution for the "creation, diffusion and use of knowledge" (see Carayannis and Campbell 2006 and 2010). In reference to sustainable development, under the aspect of global warming, we should add whether in future a state (nation-state) leading in world politics as well as in the world economy is also being determined by its social (societal) potential to balance new knowledge, know-how, and innovation with nature. Hence, for more detail, we look in the following Sect. "What is a Quintuple Helix Innovation Model?" at the *Quintuple Helix Model*.

What Is a *Quintuple Helix Innovation Model*?

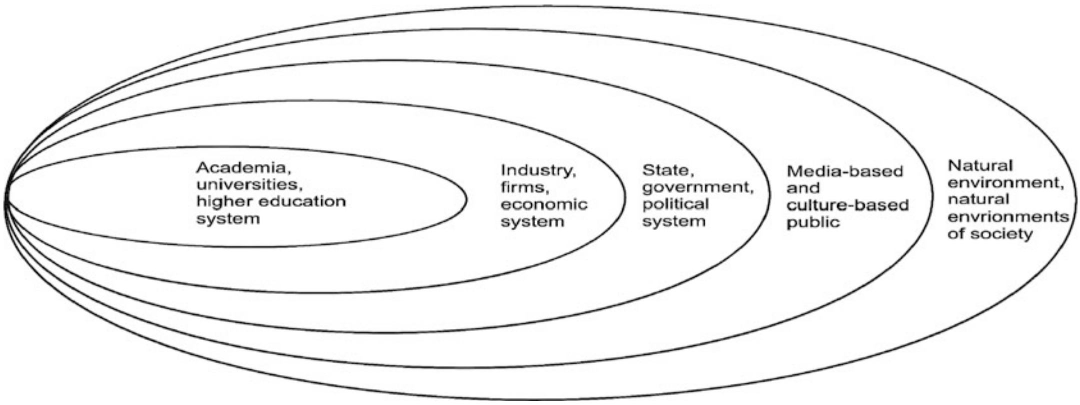
Knowledge in a *Quintuple Helix Model* is the pivotal force and driver for progress. The *Quintuple Helix* is a model, which grasps and specializes on the sum of the social (societal) interactions and the academic exchanges in a state (nation-state) in order to promote and visualize a *"cooperation system"* of knowledge, know-how, and innovation for more sustainable development (see Carayannis and Campbell 2010, p. 62). The specialty of the *Quintuple Helix Model* can thus be described in the following way:

> The Quintuple Helix Model is interdisciplinary and transdisciplinary at the same time: the complexity of the five-helix structure implies that a full analytical understanding of all helices requires the continuous involvement of the whole disciplinary spectrum, ranging from the natural sciences (because of the natural environment) to the social sciences and humanities (because of society, democracy and the economy). (Carayannis and Campbell 2010, p. 62)

Thus, the goal of the *helix conception* is accomplished through the resource of knowledge, which produces additional value for society in order to lead in the field of sustainable development. The pivotal question of the *Quintuple Helix* defines itself in the following way:

> How do knowledge, innovation and the environment (natural environment) relate to each other? (Carayannis and Campbell 2010, p. 42)

The analytical point of origin of the *Quintuple Helix*, as described in Sect. The Challenge of Global Warming and the Resource of Knowledge, is the "*Triple Helix Model*" of Etzkowitz and Leydesdorff (2000) and is the "*Quadruple Helix Model*" of Carayannis and Campbell (2010). The social (societal) cooperation system defines itself based on the model of a *Triple Helix*, which consists of a combination of university (= *education system*), industry (= *economic system*), and government (= *political system*) (see Etzkowitz and Leydesdorff 2000, pp. 111–112). To this combination, the authors (Etzkowitz and Leydesdorff) refer to as "university-industry-government relations," linking together the creation and exchange of knowledge between these three subsystems. Carayannis and Campbell acknowledged the "nonlinear" dynamics within *Triple Helix* and extended this to the "*Quadruple Helix*" (see Carayannis and Campbell 2009, p. 218): The *Triple Helix* is broadened within the *Quadruple Helix* through a "*media-based and culture-based public*" subsystem. The purpose of this extension is to include the public as well as civil society as a fourth subsystem. The *media-based public* supports the diffusion of knowledge in a state (nation-state), but also the *culture-based public* with its values, experience, traditions, and visions promotes knowledge for the knowledge society (Carayannis and Campbell 2009, pp. 217–227). Let us now have a closer look at the *Quintuple Helix Model*. In the year 2010, the authors Carayannis and Campbell developed the "*Quadruple Helix*" further by adding a fifth helix to the modeling of knowledge and innovation, being the *natural environment*. The "*Quadruple Helix*" developed into the "*Quintuple Helix*" (see Fig. 2) (Carayannis and Campbell 2010, p. 62).



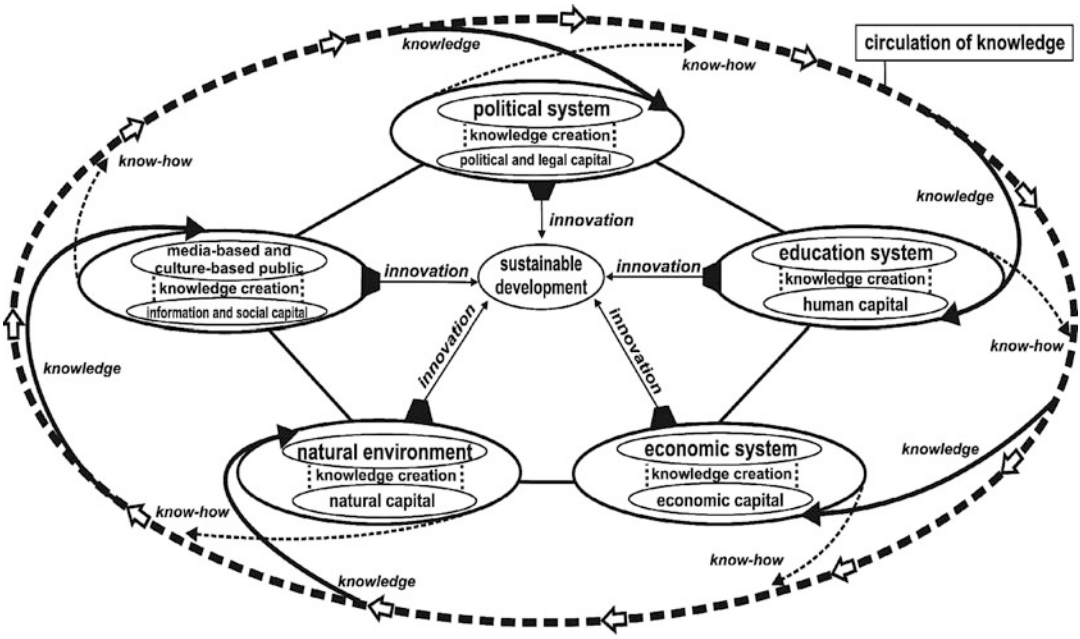
Quintuple Innovation Helix and Global Warming: Challenges and Opportunities for Policy and Practice, Fig. 2 The subsystems of the Quintuple Helix Model (Source: Authors' own conceptualization based on Etzkowitz and Leydesdorff (2000, p. 111) and on Carayannis and Campbell (2009, p. 207, 2010, p. 62))

The goal and interest of the *Quintuple Helix* are to include "*natural environment*" as a new subsystem for knowledge and innovation models, so that "nature" becomes established as a central and equivalent component of and for knowledge production and innovation. The *natural environment* is for the process of knowledge production and the creation of new innovation particularly important because it serves for the preservation, survival, and vitalization of humanity, the making-possible of new green technologies, and humankind, after all, should learn more from nature (especially in times of climate change). With the *helix of natural environment*, "sustainable development" and "social ecology" become constituent for social (societal) innovation and knowledge production (Carayannis and Campbell 2010, pp. 58–62):

> The Quintuple Helix furthermore outlines what sustainable development might mean and imply for 'eco-innovation' and 'eco-entrepreneurship' in the current situation and for our future. (Carayannis and Campbell 2010, pp. 62–63)

The most important constituent element of the *Quintuple Helix* – apart from the active "human agents" – is the resource of "knowledge," which, through a circulation (= *circulation of knowledge)* between social (societal) subsystems, changes to innovation and know-how in a society and for the economy (see Barth 2011a, p. 6). The *Quintuple Helix*, thereby, visualizes the collective interaction and exchange of "knowledge" in a state (nation-state) by means of the following five subsystems (= *Helices*): (1) *education system*, (2) *economic system*, (3) *natural environment*, (4) *media-based and culture-based public (also civil society)*, (5) and the *political system* (see Carayannis and Campbell 2010, pp. 46–48, 62). To analyze sustainability in a *Quintuple Helix* and to make sustainable development determining for progress therefore means that each of the five described subsystems (*Helices*) has a special and necessary asset at its disposal, with a social (societal) and academic (scientific) relevance for use (see Fig. 3, below; see also Barth 2011a, p. 6 and 2011b, pp. 30–31; Meyer 2008, pp. 89–95; Carayannis 2004, pp. 49–50):

1. The *education system*: The *education system*, as the first subsystem, defines itself in reference to "academia," "universities," "higher education systems," and schools. In this helix, the necessary "human capital" (e.g., students, teachers, scientists/researchers, academic entrepreneurs, etc.) of a state (nation-state) is being formed by diffusion and research of knowledge.
2. The *economic system*: The *economic system*, as the second subsystem, consists of "industry/industries," "firms," services, and banks. This helix concentrates and focuses the "economic capital" (e.g., entrepreneurship, machines,

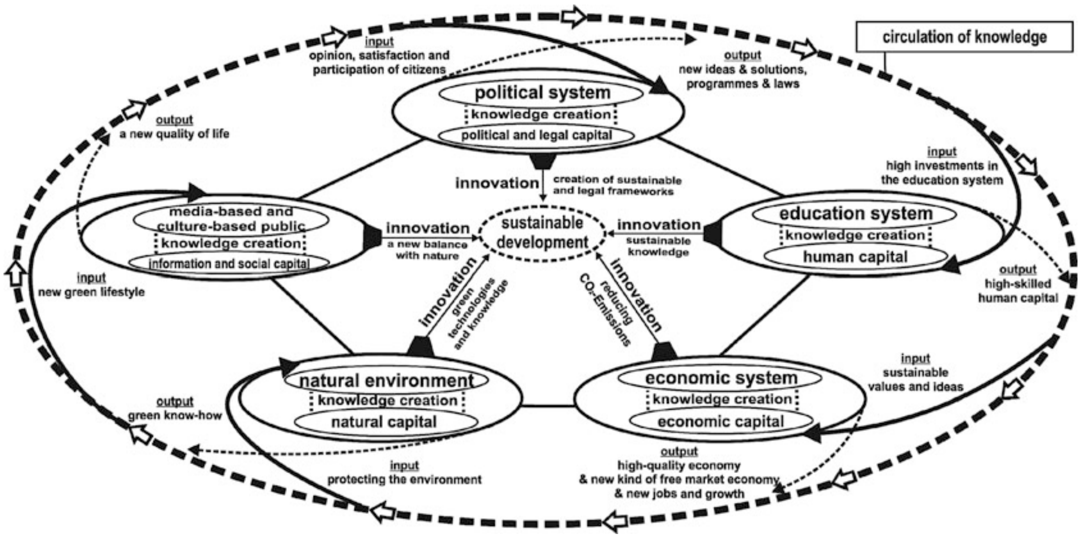


Quintuple Innovation Helix and Global Warming: Challenges and Opportunities for Policy and Practice, Fig. 3 The Quintuple Helix Model and its function (functions) (Source: Authors' own conceptualization based on Etzkowitz and Leydesdorff (2000), on Carayannis and Campbell (2006, 2009, 2010), and on Barth (2011a))

products, technology, money, etc.) of a state (nation-state).

3. The *natural environment*: The *natural environment* as third subsystem is decisive for a sustainable development and provides people with a "natural capital" (e.g., resources, plants, variety of animals, etc.).
4. The *media-based and culture-based public*: The fourth subsystem, *media-based and culture-based public*, integrates and combines two forms of "capital." On the one hand, this helix has, through the *culture-based public* (e.g., tradition, values, etc.), "social capital." On the other hand, the helix of *media-based public* (e.g., television, Internet, newspapers, etc.) contains also "capital of information" (e.g., news, communication, social networks).
5. The *political system*: The *political system*, as a fifth subsystem, is also of crucial importance because it formulates the "will," where to the state (nation-state) is heading toward in the present and future, thereby also defining, organizing, as well as administering the general conditions of the state (nation-state). Therefore, this helix has a "political and legal capital" (e.g., ideas, laws, plans, politicians, etc.).

In summary, the *Quintuple Helix Model* can be described in the following way (see Figs. 2 and 3, above): It is a theoretical and practical model for the exchange of the resource of "knowledge," based on "five" social (societal) subsystems with "capital" at its disposal, in order to generate and promote a sustainable development of society (Carayannis and Campbell 2010, pp. 60–62). In this *Cumulative Model of Quintuple Helix*, the resource of "knowledge" moves through a "*circulation of knowledge*" from *subsystem to subsystem* (see Barth 2011a, p. 6). This *circulation of knowledge* from subsystem to subsystem implies that knowledge has qualities of an *input* and *output* of and for subsystems within a state (nation-state) or also between states. If an *input* of knowledge is contributed into one of the five subsystems, then a *knowledge creation* takes place.



Quintuple Innovation Helix and Global Warming: Challenges and Opportunities for Policy and Practice, Fig. 4 Effects of investments in education for sustainability (Source: Authors' own conceptualization)

This *knowledge creation* aligns with an exchange of basic knowledge and produces new inventions or knowledge as *output*. The *output* of *knowledge creation* of a subsystem has therefore two routes (ways): (1) The first route leads to an *output* for the production of innovations for more sustainability in a state (nation-state); (2) the second route leads to an *output* on new know-how back into the *circulation of knowledge*. Through the *circulation of knowledge*, the new *output* of newly created know-how of a subsystem changes into *input* of knowledge for a different subsystem of the *Quintuple Helix* (see Carayannis and Campbell 2010; Barth 2011a). About the *input* and *output* of knowledge, it can be said consequently:

> On the one hand, knowledge serves as an input or resource for advanced societies and economies, which increasingly depend on knowledge. On the other hand, knowledge production (knowledge creation) also generates knowledge as an output, which then is being fed back (recycled) as a knowledge input. (Carayannis and Campbell 2006, p. 4)

Therefore, in a *Quintuple Helix* by and with the means of five *helices*, the exchange of knowledge in a state (nation-state) is being dealt with all its conjunctions, in order to promote knowledge-production-based sustainable development.

The Challenge of Global Warming in a *Quintuple Helix Innovation Model*

This brings us to the main question of our analysis: *How can sustainable development, with regard to "Global Warming," be practiced step-by-step within a Quintuple Helix Model?* As we have seen, the resource of knowledge is the most important "commodity" in a *Quintuple Helix*. The *circulation of* knowledge continually stimulates new knowledge. As a result, all systems in a *Quintuple Helix* influence each other with knowledge, in order to promote sustainability through new, advanced, and pioneering innovations. With the example of a targeted investment into the *education system* of the *Quintuple Helix Model*, we will describe "how" more sustainable development can be considered feasible, in reference to "global warming," for the national level and for positive effects that may arise for society (see Fig. 4, below):

Step 1: When more investments flow into the *helix* of the education system to promote sustainable development under the aspect of global warming, the *Quintuple Helix Model* shows and demonstrates that, as an *input*, investments create new impulses and suggestions for *knowledge creation* in the *education system*.

For example, targeted investments produce new equipment, new places for scientists and teachers, and a higher research opportunity. Therefore, a larger *output* of innovations from science and research can be obtained. At the same time, teaching and training can improve their effectiveness. Particularly, the investment in education should have a positive impact on "human capital" as a manifestation of *output* of the *education system:* because of more resources, teaching and training should be more effective, allowing "human capital" to realize chances and to target uses more directly. The *output* that arises from "human capital" for a greener development or sustainable development is in turn also an *input* in the *helix* of the *economic system.*

Step 2: By means of *input* of new knowledge through "human capital" in the *helix* of the *economic system*, the "value" (*values*) of the *knowledge economy* or of an *advanced knowledge economy* consequently increases. Through the enhancement of knowledge, important further production facilities and development opportunities for a sustainable, future-oriented (future-sensitive) green economy, based on *knowledge creation*, can be stimulated and achieved. Not only that such a *knowledge creation* realizes in the *economic system* new types of jobs, new green products, and new green services, also new and decisive impulses for *"green and greener economic growth"* are possible. In this subsystem, new values (like *corporate social responsibility*) are being demanded, enabling and supporting a new *output* of know-how and innovations by the *economic system*. Thus, in addition, Barth writes:

> The economic capital of know-how is in this context sustainability. Here, the output of economic know-how will be a high-quality and sustainable economy, but in fact, the special know-how which the economic system implies now, is probably a new harmony of human beings with nature. (Barth 2011a, p. 8)

Step 3: This new sustainability as an *output* of the *economic system* will be a new input of knowledge in the *helix* of *natural environment*. This new knowledge "communicates" to nature that it will be increasingly protected, as lesser exploitation, destruction, contamination, and wastefulness (extravagance) is taking place. The *natural environment* can, thus, regenerate itself and strengthen its "natural capital," and humanity can also learn again and further more from nature (= *knowledge creation)*. The goal of this *helix* should be to live in balance with nature, to develop regenerative technologies, and to use the available, finite resources sustainably and in a sensitive approach. Here, particularly natural science disciplines come into play to form new green know-how for humans. This know-how as *output* of the subsystem of the *natural environment* can provide more environmental protection and a superior quality of life to people. Moreover, the development of new environmentally friendly technologies can reduce the CO_2 emissions more effectively and can aid in diminishing climate change. In summary, the following can be explained in context with Barth about the *helix* of *natural environment*: "The output of the natural environment hence is a green know-how" (Barth 2011a, p. 9).

Step 4: The *output* of the *natural environment* is followed by an *input* of new knowledge about nature and a green (greener) lifestyle for the subsystem of *media-based and culture-based public*. In this *helix*, it is of crucial importance to communicate and to live a green lifestyle. Here, the *media-based public* receives a new and crucial function (= *"information capital"*), which is spreading through the media the information about a new green consciousness and the new human lifestyle. This capital should provide incentives, how a green lifestyle can be implemented in a simple, affordable, and conscious way (= *knowledge creation*). This *knowledge creation* promotes the necessary "social capital" of the *culture-based public*, on which a society depends for sustainable development. This "social capital," therefore, must pass on information about wishes, needs, problems, or satisfaction of citizens as *output* into politics or the *political system*. The know-how *output* of the *media-based and culture-based public* serves thereby as new *input* for the *helix* of the *political system*.

Step 5: The *input* of knowledge into the *political system* is the know-how from the *media-based and culture-based public* and represents also the collective knowledge from the three other subsystems of society. The important discussions on this new knowledge in the political systems are necessary impulses for *knowledge creation*. The goal of this *knowledge creation* is a "political and legal capital," which makes the *Quintuple Helix* more effective, more high quality, and more sustainable. Consequently, the newly obtained know-how is an *output* of suggestions, sustainable investments and objectives. The new *output* of knowledge and know-how of the *political system* leads across the *circulation of knowledge* back again into the *education system, economic system, natural environment*, and *media-based and culture-based public*.

Conclusion and Future Directions

In summary, as we illustrated by the example of the discussion in Sect. "The Challenge of Global Warming in a Quintuple Helix Innovation Model" ("five-step flow analysis"), it should be clear that all systems in a *Quintuple Helix* perform a pivotal function, influencing each other. If more sustainable development is being considered (and demanded) on a national level, as a result of "global warming," and if, for instance, more targeted investments in a specific *Helix* of the *Quintuple Helix* start flowing, then there will be a positive impact on all other subsystems and on the society as a whole. The *Quintuple Helix Innovation Model* demonstrates that an investment in knowledge and a promotion of knowledge production brings into play new and crucial impulses for innovation, know-how, and the advancement of society. By initiating small steps toward sustainability, *long-term and leading knowledge societies* can emerge, which will live in balance with nature and ultimately, perhaps, lead to a *"green economic wonder."*

To conclude, the *Quintuple Helix Innovation Model* makes it clear that the implementation of thought and action in sustainability will have a positive impact on society as a whole. The new quality management for more sustainability lies therefore in the creation of new knowledge, know-how, and innovation in balance with nature (see Carayannis and Campbell 2010, pp. 58–62). One chief objective of the *Quintuple Helix* is to enhance *"value in society"* through the resource of knowledge. The discussion about the *Quintuple Helix Model* indicates that striving for the promotion of knowledge as a "knowledge nugget" should be regarded as being essential (see Carayannis and Formica 2006, p. 152): This means that knowledge is the key to and for more sustainability and to a new quality of life. Today, knowledge is the "most fundamental resource" (Lundvall 1992, p. 1). Nevertheless, whether a state (nation-state, beyond nation-state) is leading in different fields in the future will be primarily, if not even solely, be decided by its potential to develop new knowledge, know-how, and innovation in balance with nature. However, the improved exchange of knowledge and the striving for knowledge, new know-how, and innovations through the *Quintuple Helix Model* can be or at least offer a solution for the challenges of sustainable development under the aspect of "global warming" in the twenty-first century.

Key Concepts and Definition of Terms

Defining Research

Research can be defined as an objective, systematic investigation for the purpose of testing theories, establishing facts, and advancing knowledge. Psychology is often subdivided into experimental psychology, which is research oriented, and clinical psychology, which is practice oriented. Thus, psychological research on creativity is primarily, though not entirely, the domain of experimental psychology. Educators, business people, people in the entertainment industry, and others also study creativity.

Defining Creativity

Creativity is arguably our most uniquely human trait. It enables us to escape the present, reconstruct the past, and fantasize about the future to visualize something that does not exist and change the world with it. Defining creativity presents difficulties. For example, not all creative works are useful, and not all are aesthetically pleasing, but both usefulness and aesthetic value capture, in some sense, what creativity is about. Nevertheless, psychologists have almost universally converged on the definition originally proposed by Guilford over 60 years ago. Guilford (1950) defined creativity in terms of two criteria: *originality* or novelty and *appropriateness* or adaptiveness, that is, relevance to the task at hand. *Surprise* is sometimes added as a third criterion (Boden 2004). Some add *quality* as a separate criterion, while others use the term appropriateness in a way that encompasses quality. Creativity has also been defined as a complex or syndrome, and some define it so broadly as to include novelty-generating processes in the biological world or the universe at large. However, it is the "originality and appropriateness" definition that is encountered most often and that has become standard (Sternberg 1988; Feldman et al. 1994; Amabile 1996; Runco 2004). While this definition provides a much-needed departure point for discussion about and measurement of creativity, there is likely no one-size-fits-all definition of creativity. For scientific or technological endeavors, appropriateness might be more important, whereas in the arts, originality might be weighted more heavily. Thus, creativity must be assessed relative to the constraints and affordances of the task.

The Four P's of Creativity

It is often said that creativity involves four P's: person, process, product, and place (Rhodes 1961).

Research focused on the creative *person* can take the form of studies that investigate what personality traits are correlated with high creativity, or case studies of particular creative individuals. It can also include *historiometric methods*, which involve obtaining qualitative data on eminent creators (i.e., number of paintings produced throughout their career), transforming it into quantitative data, and performing statistical analyses, with the aim of finding general laws or statistical relationships that transcend particulars of person, time, or place.

The second P of creativity concerns the *process* by which ideas come about. Process-oriented research can involve testing descriptive models of the stages of the creative process, investigations into what kind of thought processes are contributing to the creative ideation in these different stages, or studies of creative individuals at work. These studies may be observational, involve questionnaires, or neuroscientific methods such as functional magnetic resonance imaging (fMRI).

The third P of creativity, the *product*, can take the form of a physical object (e.g., a painting) or behavioral act (e.g., a dance) or an idea, theory, or plan of action. Western approaches to creativity have tended to focus more on the product than Eastern approaches.

The last of the four P's of creativity, *place*, concerns the environmental conditions conducive to creativity. Certain individual situations, such as education and training, role models and mentors, and perhaps surprisingly, childhood trauma, are correlated to historical creativity. Economic growth appears to have a stimulating effect on creativity, whereas war has an inhibitory effect.

Historical Versus Personal Creativity

Psychologists distinguish between different kinds and degrees of creativity, such as between historical and personal creativity (Boden 2004). When the creative process results in a product that is new to all of humanity and makes an impact on the course of civilization, it is referred to as *historical creativity* (H-creativity).

Historical creativity is also sometimes referred to as *eminent creativity* because the creator tends to become famous. When the creative process results in a product that is new to the creator, but someone else has come up with it before, or it is not creative enough to impact human civilization, it is referred to as *personal creativity* (P-creativity). Although personal creativity does not change the world, it can be a source of pleasure and amusement. Clearly there are shades of gray between these extremes.

A concept that is closely related to personal creativity is *everyday creativity*. Everyday creativity manifests in daily life; it comes through in how one prepares a meal, decorates a room, or interprets and shares experiences. Everyday creativity generally begins with an innovative, often unconventional approach to life that involves capitalizing on hidden opportunities, undertaking common tasks in uncommon ways, and finding solutions to challenges as they arise.

Historical and personal creativity are also sometimes referred to as *big-C* and *little-C creativity*, respectively. Some additionally make the case for *mini-C creativity*, which involves making personally meaningful interpretations of objects and events and which can form the basis for more substantial creative acts (Beghetto and Kaufman 2007). Daily life involves thinking things and doing things that, at least in some small way, have never been thought or done before and thus that *everyone* is somewhat creative (Runco 2004).

Creativity Versus Discovery and Invention

Creativity is sometimes distinguished from two related concepts: discovery and invention. *Discovery* involves finding something *already present* and sharing it, for example, Columbus' discovery of America. It is relatively impersonal because if one person had not discovered it, someone else would have. *Invention* entails unearthing something that was *not present before*, for example, Alexander Bell's invention of the telephone. Like discovery, it is relatively impersonal. Creativity also involves sharing something that was not present before. Some psychologists additionally require that for something to qualify as creative, it must be profoundly personal in the sense that one feels the presence of a unique individual in the work, for example, Leonardo Da Vinci's art.

Theoretical Background

Early Conceptions

In early times, the creative individual was viewed as an "empty vessel" that was filled with inspiration by a divine being. In the first half of the twentieth century, there was little research on creativity because it was thought to be too complex and frivolous for scientific investigation. A pioneering exception to this was Wallas' (1926) classification of the creative process into a series of stages. The first of Wallas' stages is *preparation*, which involves obtaining the background knowledge relevant to the problem, its history (if known), and any instructions or past attempts or preconceptions regarding how to solve it. It also involves conscious, focused work on the problem. The second stage is *incubation* – unconscious processing of the problem that continues while one is engaged in other tasks. The preparation and incubation stages may be interleaved, or incubation may be omitted entirely. Wallas proposed that after sufficient preparation and incubation, the creative process is often marked by a sudden moment of *illumination*, or insight, during which the creator glimpses a solution to the problem, which may have had to be worked and reworked to make sense of it. Wallas' final phase is referred to as *verification*. This involves not just fine-tuning the work and making certain that it is correct, as the word implies, but putting it in a form that can be understood and appreciated by others. Empirical investigation of Wallas' theory yielded mixed results. Another shortcoming is that it is merely descriptive; it does not explain how or why the stages occur.

The year 1950 marks a turning point for research in creativity when it was the subject of Guilford's address to the American Psychological Association. Creativity came to be a subject of interest to many disciplines and to be approached from many directions.

Cognitive Approaches

Cognitive approaches to creativity focus on the mental processes by which creative outputs are generated. These processes include concept combination, expansion of concepts, imagery, metaphor, and divergent thinking. *Divergent thinking* is often assumed to involve the generation of multiple, often unconventional, possibilities (Guilford 1968; for a review, see Runco et al. 2010). Another view is that creative thinking is divergent not in the sense that it generates multiple possibilities, but in the sense that it produces a raw idea that is vague or unfocused and requires processing to become viable (Gabora and Saab 2011).

Some who take a cognitive approach viewed the mind, metaphorically, as a computer (or computer program). They proposed that creativity involves a *heuristic search*, in which rules of thumb guide the inspection of different states within a particular state space (a set of possible solutions) until a satisfactory solution is found (Newell et al. 1957). In heuristic search, the relevant variables of the problem or situation are defined up front; thus, the state space is generally fixed. Examples of heuristics include breaking the problem into subproblems, and working backward from the goal state to the initial state. It has since been proposed that creativity involves heuristics that guide the search for a new state space itself, rather than just a new possibility within a given state space (Boden 1990a; Kaplan and Simon 1990). This involves switching from one representation of the problem to another, sometimes referred to as *restructuring* (Weisberg 1995).

Modifications to Wallas' classic four-stage model of creativity (discussed above) have been proposed. Some incorporate a phase that involves *problem finding* (noticing that something is amiss), problem posing (expressing the problem), problem construction (developing a detailed representation of the problem), or problem definition and redefinition (Amabile 1996; Guilford 1950). Problem finding may involve sensing gaps or disturbing missing elements (Torrance 1963). It may take the form of identification of a "seed incident" around which the creative project takes shape. Another modification of the four-stage model is the addition of a frustration phase prior to incubation, in which straightforward attempts to solve the problem prove unfruitful. Not all modifications *add* to the four stages; for example, Geneplore is a two-stage model involving *generation* of crudely formed ideas referred to as pre-inventive structures followed by *exploration* of them through elaboration and testing (Finke et al. 1992). Defocused attention, by diffusely activating a broad region of memory such that everything seems to be related in some way to everything else, may be conducive to the divergent thought that characterizes idea generation. Focused attention, by activating a narrow region of memory and treating items in memory as distinct chunks that can be readily operated on, may be conducive to the convergent thought that characterizes elaboration (Gabora 2010).

Psychometric Approaches

Those who take a psychometric approach develop tests of creativity as well as methods for improving creativity.

The most widely known creativity test is the Torrance Test of Creative Thinking (Torrance 1974). It consists of multiple components or subtests. Examples include the *unusual uses test*, in which participants are asked to think of as many uses for a common object (e.g., a brick) as possible, or the product improvement test, in which participants are asked to list as many ways as they can to change a product to make it more useful or desirable (e.g., to change a toy monkey so children will have more fun playing with it). Since then, other tests of creativity have been proposed. Perhaps the most successful of these is Amabile's (1996) consensual assessment technique, in which a panel of expert judges is asked to rate the creativity of products in their area of expertise, for example, story writing, poetry, or collage making.

The most well-known technique for improving creativity is *brainstorming*, which takes place in groups and involves encouraging them to suggest all the ideas they can, no matter how seemingly "crazy," and discouraging criticism of ideas. Such techniques are used by businesses and organizations to develop successful business strategies and in business schools to foster entrepreneurship.

Developmental and Personality Approaches

Developmental research focuses on creativity in children and throughout the lifespan. One interesting set of findings to come from this research concerns the relationship between emotions and creative play during childhood. The extent to which children access affect-laden (emotional) thought is correlated with ratings of associative thinking, cognitive flexibility, and creativity, and the extent to which children engage in fantasy and play (Russ 1993). Moreover, the degree of fantasy and imagination at ages six to seven was shown to be related to the divergent thinking ability in high school.

Personality approaches to creativity focus on the personality traits associated with creativity (Feist 1998). Creativity is correlated with independence of judgment, self-confidence, aesthetic orientation, risk-taking, openness to experience, tolerance of ambiguity, impulsivity, lack of conscientiousness, high energy, attraction to (and ability to handle) complexity, problem sensitivity, flexibility, the ability to analyze, synthesize, evaluate, and reorganize information, and the ability to engage in divergent thinking. There is also evidence that creative individuals are more prone to anxiety and emotional (affective) disorders. Creative individuals differ from one another with respect to whether they are internally versus externally oriented, person-oriented or task-oriented, and explorers (who tend to come up with ideas) or developers (who excel at turning vague or incomplete ideas into finished products).

Social and Cultural Approaches

Social and cultural approaches examine how family dynamics, group dynamics, and cultural influences affect creativity, and how creativity compares across different cultures.

Maslow believed that creativity is fostered by environments that are supportive and free of evaluation, which he claimed are conducive to self-actualization. However, it is not the case that positive social environments necessarily lead to creativity. For example, highly creative people tend to experience a lack of parental warmth and are more likely to have experienced the death of a parent at an early age, and raise fewer children, than average.

According to the *systems approach*, creativity occurs through an interaction between (1) the *individual*, that is, the creator, (2) a *field* which is a set of relevant individuals in society, that is, the people involved in same creative endeavor as the individual, and (3) the *domain*, that is, a set of relevant ideas in the culture (Csikszentmihalyi 1997; Sawyer 2006). The creative process is thus viewed as highly entwined with the process of persuasion.

Case Studies

In the early days of scientific psychology, experiments in strictly controlled laboratory conditions were encouraged; case studies of individuals, and particularly introspective accounts, were not taken seriously. Recently, researchers have acknowledged the artificiality of many laboratory studies, and here is stronger appreciation for taking an *ecological* approach. This involves studying people in their everyday environments engaged in everyday tasks and treating individual differences not just noise, but as interesting in their own right. Individual differences are particularly important in the study of creativity. Thus, although case studies and introspective accounts are notoriously flawed and will never take the place of more controlled approaches, they have a place in the scholarly effort to achieve a nuanced and multifaceted understanding of the creative process.

Case studies of scientists have led to enhanced appreciation of the importance of problem finding. Einstein, for example, famously claimed that real advance in science is marked by regarding an old problem from a new angle and the formulation of a problem is often more challenging than its solution. Real-time studies of individual artists and designers have also yielded interesting insights. For example, they have shown that creative ideation involves elaborating on a “kernel idea,” which takes shape through ongoing interaction between artist and artwork (Feinstein 2006; Locher 2010).

Clinical Approaches

As mentioned previously, there is evidence that creative individuals are more emotionally unstable and prone to affective disorders such as depression and bipolar disorder and have a higher incidence of schizophrenic tendencies than other segments of the population (Andreason 1987; Flaherty 2005; Jamieson 1993). There is also evidence that they are more prone to suicide (Goodwin and Jamison 1990) and to abuse drugs and alcohol (Ludwig 1995).

Clinical approaches to creativity are not focused exclusively on the negative. Freud's notion of the *preconscious* – a state between conscious and unconscious reality where thoughts are loose and vague but interpretable – is still viewed by many as the source of creativity. Clinical approaches to creativity also investigate how art therapy, music therapy, and dance therapy can help patients open up and express themselves in ways that verbal communication may not. Ironically, the notion of verification, as it has traditionally been construed since it was first proposed by Wallas as the final stage of the creative process, involves making the idea appealing to others takes into account the minds of those who will be exposed to the creative work, while not taking into account the effect of the idea on the mind of the one who creates it. Researchers are now beginning to take this into account.

Biological Approaches

Biological approaches investigate the extent to which there is a genetic basis to creativity as well as the underlying neural and physiological mechanisms underlying creativity. Twin studies and other sorts of evidence suggest creative abilities are, at least to some extent, genetically inherited (Eysenck 1995). One way to go about investigating the brain mechanisms underlying creativity involves dissecting the brains of people who were particularly creative during their lifetimes. It has been shown that Einstein's brain had (1) a partially absent Sylvian fissure, which may have facilitated communication between different parts of the brain, and (2) a high ratio of glial cells to neurons in both area 9 of prefrontal cortex, which is associated with planning, attention, and memory, and area 39 of the left inferior parietal cortex, which is associated with synthesizing information from other brain regions.

A less dramatic but more common way to investigate the brain mechanisms underlying creativity involves examining brain activity when people engage in creative activities using *electroencephalography* (EEG) or *functional magnetic resonance imaging* (fMRI). Though application of such methods is stymied by the fact that many brain areas are active during creative thought, some interesting findings are emerging (Bristol et al. 2012). There is evidence that different kinds of creativity (deliberate vs spontaneous and emotional vs cognitive) involve different neural circuits (Dietrich 2004). Creative thought appears to be facilitated by lower levels of noradrenaline and dopamine – catecholamines directly linked to cognitive control, prefrontal functioning, and cortical arousal. EEG experiments show that divergent thinking tasks produce decreased beta range synchrony and increased alpha range synchrony over the frontal cortex, providing further evidence for a loosened cognitive control and lower prefrontal cortical arousal during creative thought. There is also indirect neuroscientific support for the contextual focus hypothesis, that is, the notion that creativity involves the ability to match where one's mode of thought lies on the spectrum from associative to analytic. Prior to finding the solution to an insight problem, there is neural recruitment of the prefrontal and executive memory networks as well as the so-called default network associated with spontaneous mind wandering. This suggests that mind wandering has a utilitarian function and provides neurological support for the notion of expanded receptivity through neural recruitment during divergent thought.

This is further supported by physiological research into creativity, which has revealed evidence of an association between creativity and high *variability* in physiological measures of arousal such as heart rate, spontaneous galvanic skin response, cortical activity, and EEG alpha amplitude (Jausovec and Bakracevic 1995). For example, although creative people tend to have higher *resting* arousal levels, when engaged in creative problem solving, they tend to have lower than average arousal levels. These findings in conjunction with the cognitive findings discussed previously suggest that during creative activities, creative individuals are particularly prone to enter a state that is quite different from their normal resting state, a state that has both a physiological aspect (low arousal level) and a cognitive aspect (associative mode of thought).

Biological approaches to creativity also address what is going on at the level of neurons. The vagueness of a "half-baked" idea, the sense that it holds potential, as well as its capacity to actualize in different ways depending on how one thinks it through may be the side effects of interference. *Interference* refers to the situation wherein a recent memory interferes with the capacity to recall an older memory because they are encoded in overlapping distributions of neurons in the brain. It is generally thought of as detrimental, but it may be a side-effect of a phenomenon that is on the whole beneficial with respect to creativity. When two or more items are encoded in overlapping distributions of neural cell assemblies they may get evoked simultaneously, a new idea may be the result. This phenomenon has been referred to as *creative interference*. The vagueness of the new idea may reflect that it is uncertain how, in the context of each other, the interfering components come together as a realizable whole. The ability to work with an idea in this state is related to the personality trait of tolerance of ambiguity.

Evolutionary Approaches

Comparative and evolutionary approaches address the question of how humans evolved their superlative creative abilities, how these abilities compare with those of other species, and in what sense ideas can be said to evolve.

The earliest preserved signs of human creativity include primitive stone tools approximately 2 million years ago (Mithen 1998). Since this corresponds with an increase in brain size, it has been suggested that this enabled memories to be encoded in more detail, such that there were more ways in which one experience could evoke a reminding of another. This provided more ways of chaining thoughts and experiences into an integrated understanding of the world, which both enabled and constrained the generation of creative ideas. Computational modeling has provided support for this hypothesis (Gabora and Saberi 2011).

The Middle/Upper Paleolithic marks the beginnings of art, science, and religion and has been referred to as the "big bang of creativity" (Mithen 1998). It has been suggested that this is due to onset of the previously-mentioned capacity to spontaneously shift between divergent and convergent modes of thought. Once it was possible to shrink or expand the field of attention and thereby tailor one's mode of thought to the demands of the current situation, the fruits of one mode of thought could be used as ingredients for the other, resulting in a richer understanding of the world and enhanced potential to creatively change it. Tasks requiring either mode of thought or both at different stages of the creative process could be carried out more effectively.

Another evolutionary approach uses societies of artificial agents that invent ideas and imitate neighbors' ideas to understand how ideas evolve over time. This approach has provided evidence that the evolution of ideas gives rise to many of the phenomena observed in biological evolution, such as (1) an increase in complexity and fitness (usefulness) over time and (2) an initial increase in diversity as the space of possibilities is explored followed by a decrease associated with convergence on the fittest possibilities. If even a small fraction of agents are creative, new ideas spread by imitation in waves throughout the society, reaching other creators who put another spin on them, and over time they evolve. The more creative the agents are, the fewer of them there must be in order to maximize the evolution of fitter ideas, suggesting that more creativity is not always better. In collaboration with archaeologists, creativity researchers also trace the process by which one creative idea or technological invention paved the way for another (Dasguptas 1996). They are using evolutionary theories and computational models to aid the process of organizing human-created artifacts into cultural lineages.

Computational Approaches

We saw that computational modeling is particularly useful to those who investigate hypotheses concerning the mechanisms by which humans became creative. Because the onset of such mechanisms left no detectable trace, one begins by establishing which hypotheses are at least computationally feasible. However, researchers studying the evolution of creativity are not the only ones to take a computational approach; indeed, efforts to develop computational models of creativity date back to the 1950s and 1960s. Herbert Simon developed a computer program called BACON that came up with scientific laws. The 1990s and early 2000s witnessed a plethora of computer programs that generate music, art, stories, screensavers, and so forth. Computational models have been used to model incubation and insight (Helie and Sun 2010), concept combination (Thagard and Stewart 2011), and the shifting between two distinct modes of thought in the creative process (Martindale 1995).

Open-Ended Issues

The Relative Contributions of Expertise, Chance, and Intuition

While most psychologists believe that creativity involves a combination of expertise, chance, and intuition, they differ with respect to the degree of emphasis they place on these factors.

Expertise theorists point to evidence that it takes approximately a decade to master a creative domain. Experts are better than beginners at detecting and remembering domain-relevant patterns and are more adept at generating effective problem representations and, when necessary, revising initial hypotheses. Expertise theorists hypothesize that creativity involves everyday thought processes such as remembering, planning, reasoning, and restructuring. They claim that no special or unconscious thought processes are required for creativity, just familiarity with and skill in a particular domain (Weisberg 2006).

Critics of this view note that entrenchment in established perspectives and approaches may make experts more prone than beginners to psychological phenomena that reinforce familiar perspectives and approaches such as set, functional fixedness, and confirmation bias. Those who emphasize the role of *chance* include advocates of the Darwinian theory of creativity, according to which the creative process, like natural selection, entails blind generation of possibilities followed by selective retention of the most promising of them (Simonton 1999).

Some view creativity as not so much a matter of generating and selecting among predefined alternatives but of intuiting an idea and then, by considering the idea from different perspectives or trying it out different ways, taking it from an ill-defined state of potentiality to a well-defined state of actualization (Gabora 2010). Those who study the role of *intuition* and the actualization of potentiality emphasize the association-based structure of memory and note that creative individuals tend to have *flat associative hierarchies*, meaning they have better access to *remote associates*, items that are related to the subject of interest in indirect or unusual ways (Mednick 1962).

The Relative Importance of Process Versus Product

While the tradition in the West is to focus almost exclusively on creativity as the process by which a new and useful or entertaining product is generated, Eastern conceptions focus more on creativity as a process that can bring about therapeutic change, that is, that expresses, transforms, solidifies, or unifies the creator's understanding of and/or relationship to the world. In the extreme, the external creative work can be viewed as a mere by-product of the internal transformation brought about through engagement in a creative task. In this view, the primary value of the creative process is that it enables the creator to express, transform, solidify, or unify the creator's understanding of and/or relationship to the world, while the external product provides a means of tracking or monitoring this internal transformation. This view figures prominently in creative therapies such as art therapy, music therapy, and drama therapy.

Is Creativity Domain Specific or Domain General?

Psychologists who emphasize the role of expertise tend to view creativity as highly *domain* *specific;* expertise in one domain is not expected to enhance creativity in another domain. Support for domain specificity comes from findings that expertise or eminence with respect to one creative endeavor is only rarely associated with expertise or eminence with respect to another (Baer 2010). For example, creative scientists rarely become famous artists or dancers.

Psychologists who emphasize intuition and associative processes tend to view creativity as more *domain general* because associative thinking can produce metaphors that connect different domains, and we gain understanding and control over experiences by translating and reexpressing them through the constraints of different domains. This view is supported by studies involving self-report scales, creativity checklists, and other sorts of psychometric or personality data that tend to support the view that creativity is domain general (Plucker 1998). It is also supported by experiments showing that if you recognize someone's creative style in one domain, for example, creative writing, there is an above-chance probability of recognizing works by that individual in another domain, for example, art (Gabora et al. in press).

Most researchers probably believe that the truth lies somewhere between the extremes. A focus on product as opposed to process, and on *talent*, which is treated as one-dimensional, as opposed to *style*, which is multidimensional, may have resulted in exaggeration of the extent to which creativity is domain specific. Creativity in one domain may help but not guarantee creativity in another; it is neither strongly domain specific nor domain general. Although social recognition of achievement in multiple domains may be rare, individuals use multiple creative domains to meaningfully develop, explore, express, and understand themselves and their world. Characteristic stylistic elements of these explorations may be transported from one domain to another since all of an individual's creative outputs are expressions of an individual's particular uniquely structured internal model of the world.

Is There a Dark Side to Creativity?

Although creativity is clearly stimulating and indispensable to cultural and technological advancement, many believe it has a dark side (Cropley et al. 2010). In addition to the evidence that eminent creativity is correlated with proneness to affective disorders, suicide, and substance abuse, discussed above, excessive creativity may result in reinventing the wheel, and absorption in ones' own creative ideas may interfere with assimilation or diffusion of proven effective ideas. Moreover, it is not necessary for everyone to be creative. We can all benefit from the creativity of a few by imitating, admiring, or making use of their creative outputs. Computer modeling suggests that society self-organizes to achieve a balance between relatively creative and uncreative individuals (Leijnen and Gabora 2009). The social discrimination that creative individuals often endure until they have proven themselves may aid in achieving this equilibrium.

The Relationship Between Creativity and Intelligence

Early research suggested that creativity and intelligence are correlated up until an IQ of approximately 140, after which point they diverge; thus, an individual can be very smart but not terribly creative, or highly creative but not terribly smart. Recent research suggests that the relationship between the two is more complex. Clearly it depends on how the constructs of creativity and intelligence are being measured.

Implications for Theory, Policy, and Practice

Research in creativity has implications for theory, policy, and practice in a number of arenas. A first area of application is clinical. Creative activities such as art making, music making, dance, and drama are increasingly seen to have therapeutic effects that can be effective in both clinical and nonclinical settings. The transformation that occurs on canvas or on the written page is thought to be mirrored by a potentially therapeutic sense of personal transformation and self-discovery that occurs within. Immersion in the creative task has been referred to as a state of *flow* that may share characteristics with deeply spiritual or religious experiences (Csikszentmihalyi 1997).

A second, related area of application is childrearing and education. For example, creative play in childhood facilitates access to affect-laden (emotional) thoughts, which may enhance cognitive flexibility and divergent thinking abilities. Amabile's (1996) work on *intrinsic motivation* showed that rewards for creative work may actually inhibit creativity because focusing on an external reward leads people to neglect the intrinsic rewarding nature of creative acts.

A third area of application is in business settings. For example, psychological work on *brainstorming sessions*, in which people get together as a group and put forward ideas in an open and accepting environment, has shown that it may be more effective when group work is followed immediately by individual work or when individuals communicate by writing so as to avoid the problem of everyone talking at once.

Conclusion and Future Directions

It is our creativity that perhaps most distinguishes humans from other species and that has completely transformed the planet we live on. Research in creativity is an exciting area that brings together many different fields: neuroscience, education, and business, as well as computational and mathematical modeling. Past and current areas of controversy concern the relative contributions of expertise, chance, and intuition, whether the emphasis should be on process versus product, whether creativity is domain specific versus domain general, and the extent to which there is a dark side to creativity. Promising areas for further research in creativity include computational modeling, and work on the neurobiological basis of creativity, as well as environmental influences on creativity.

Definitions

Entrepreneurship

Entrepreneurship is an activity involving the discovery, evaluation, and exploitation of business opportunities in order to introduce new goods and services, new organizational structures, markets, processes, and materials using resources that may not have existed before.

Uncertainty

Uncertainty pertains to not knowing future events.

Business Opportunity

Business opportunities stem from social norms, which shape individuals' behavior and make them predictable and reliable by building an economic environment favorable to the transgression of those norms.

Risk

Risk is an advantage or disadvantage to which an individual is exposed. It occurs when the fallouts

Yvon Pesqueux is a professor at CNAM (Conservatoire National des Arts et Métiers) and head of the Chair "Développement des Systèmes d'Organisation". He earned his Ph.D. in Economics from the University of Paris 1 Panthéon-Sorbonne (1975); his special interests are management, philosophy and ethics, business and society, and corporate social responsibility. He has published several scientific articles and books. He is also an editor of Society and Business Review (Emerald Publishing – www.emeraldinsight.com/sbr.htm).

of a taken decision or undertaken action are *more or less likely*.

Theoretical Background and Discussion

Today, uncertainty is portrayed as the lie of the land of a changing and unstable world where the rhetoric of adaptation and anticipation stands as a bulwark against unexpectedness, which generates business opportunities. Adaptation and anticipation are elevated to useful modes of action and reduce uncertainty to a discursive object that actually aims to legitimate them. The project laid out in this way is coupled with a substitution process, that is, if not conceptual at least language based: uncertainty fades away to risk. This discursive development can be viewed as resulting from the substitution of one concept for the other. It may also reveal a shift from a general and, say, economic conception to commerce-oriented thinking. The latter assumption implies that the two notions are distinct in substance. Are uncertainty and risk only related notions or are they clearly distinct from one another, as common sense seems to suggest? While the first one has a largely negative connotation today, the second one has been mythologized in ways that blur the original sense ascribed to it in management or political sciences (Méric et al. 1999).

Where is the dividing line between uncertainty and risk? Language, dictionaries, and their usage suggest that uncertainty is about not knowing future events and risk the direct result of this ignorance, which occurs when the outcomes of a taken decision or undertaken action are unknown. In the business field, F. Knight (1921) makes a clear distinction between uncertainty and risk. According to Knight, an uncertain situation refers to the impossibility to form a distribution of the different possible outcomes, for two types of reasons: the ignorance of the future course of events and the lack of relevant probability models. An event is described as uncertain when one does not know for certain if it will happen, regardless of its probability. Accordingly, risk occurs in uncertain situations where uncertainty has been reduced through the use of information and the implementation of probability measurement tools. Thus, the distinction between uncertainty and risk hinges upon the degree of accuracy of the knowledge.

> To preserve the distinction (. . .) between the measurable uncertainty and an unmeasurable one we may use the term "risk" to designate the former and the term "uncertainty" for the latter (. . .) If our reasoning so far is at all correct, there is a fatal ambiguity in these terms, which must be gotten rid of, and the use of the term "risk" in connection with the measurable uncertainties or probabilities of insurance gives some justification for specializing the terms as just indicated. (Knight 1921, Part III, Chapter IV, p. 1)

The French word "risque" may trace back to the sixteenth century, and its etymology may be related to maritime business activity (the risk born by goods traveling by sea), which expresses the danger related to an enterprise and, in its military version, the soldier's luck or misfortune. As B. Laperche (2003) observes, there is a clear connection between "risk, an expression of danger, and the necessity to reward or reduce it." Drawing upon scholastic exegesis (twelfth to thirteenth centuries), F. Braudel (1997) bridges "risk" with "capital" to account for interest, due to the risk taken by the loaner, at a time when insurance activity was expanding.

To risk is synonymous with to attempt, to undertake, which underpins the distinction throughout the development of capitalism between the risk to undertake (profit) and the risk of financing (interest). These two risks are complemented by the risks on human capital in the sense that today's firms are large-sized organizations viewed as risky collectives. This kind of risk focuses specifically on the manager's talent and their willingness to take risks given that the resulting profit is a major aspect at stake. Besides, technical risk is also viewed as related to business opportunity.

The two theorists of the "entrepreneur – opportunities" link are J. A. Schumpeter (1990) and I. M. Kirzner (1975). The former argues that the existence of new information is critical to understanding new opportunities and working out the appropriate response, whereas the latter holds that the incompleteness of knowledge on resources is what creates gains and shortages of those resources and generates opportunities.

He introduces notions such as process (entrepreneurial), learning (and its corollary, learning time), and knowledge (due to entrepreneurial alertness). J. A. Schumpeter conceived of the entrepreneur as a disruptive force contrasting with I. M. Kirzner's equilibrium-based conception: "entrepreneurship and competition are two sides of the same coin." Entrepreneurial spirit is not only worthwhile in the long run ("new ideas," "departures") but also in the short term, as price-based competition is viewed as equally entrepreneurial. Thus, I. M. Kirzner incorporates advertising and information (given or requested) in the entrepreneurial process.

J. B. Say is credited with having promoted the figure of the entrepreneur in economic life. The following quotes taken from *Catéchisme d'économie politique* illuminate this statement: "*Whom do you give the name of industrious*? The name industrious or industrial is given to men who draw their main income from their industrial skills; still, they can also be capitalists, if they earn an income from any capital, and landowners, if they earn an income from a property. *What do you first observe about the incomes of industry entrepreneurs?* They are variable and uncertain because they depend on the value of products, and the needs of men and the price of products aimed for them cannot be predicted beforehand. *What do you further observe*? That of all industrious men, industry entrepreneurs are those who can lay claim to the highest profits. If several of them go bankrupt, the greatest riches also lie with them. *How do you account for this effect when it does not result from an unexpected circumstance?* Because the kind of service that entrepreneurs provide to production is scarcer than the kind of service of other industrious men. *Why is it scarcer?* First, because one cannot form a business without owning, or at least without being equipped to borrow the necessary capital, which rules out many competitors. Second, because this advantage must be paired with qualities that are not common to all, such as judgment, activity, consistency, and some knowledge of men and things. Those who do not have all these prerequisites are not competitors, or at least they are short-lived competitors as their enterprises cannot sustain themselves. What are the most profitable enterprises? Those whose products are the most consistently and unfailingly in demand, and therefore those that contribute to the making of food products and the most necessary objects."

On Risk

The economic sense of risk is probably one that has led to the most important developments. This holds for the categories related to incentive contracts, which are justified by the expected potential benefits with a view to balancing risks and incentives in relation to business opportunities. As P. A. Samuelson (1973) points out, "A person is risk-averse when the pain from losing a given amount of income is greater in magnitude than the pleasure from gaining the same amount of income (...) People are generally risk-averse, preferring a sure thing to uncertain levels of consumption: people prefer outcomes with less uncertainty and the same average values." In this definition, risk stands as a counterforce to the legitimacy given to an essentially entrepreneurial society. It is about actively addressing potential perils ahead.

Risk can be "objective" – resulting from a noninterpretive rational approach to risk – or "perceived" depending on the agent's position in their exposure to risk and/or their psychology (Goddard et al. 2003). In this respect, it is worth mentioning the importance of cognitive biases and the weight of representations, and distinguishing between "riskophiles" and "riskophobes" as risk is ultimately undefined by and of itself. As vehicles of representation, the media play a major role in this duality as they reinforce the weight of perception over a rational approach. N. Luhman (1993) distinguishes between the "risky object" (for our purposes, the risk of business opportunities) and "risk perpetrators" (here, the entrepreneur who takes them) and points out that risk springs from a linkage between the two. This approach is based on an individualistic and behaviorist conception of social issues. In fact, this compensation-based perspective implies that anything (including life) has a price that dooms the average "risk-averse" individual to consolation. Two anthropologies of risks are here stated, one is economic and the other is moral and negative.

Arguably, risk emerges as a major theme in contrast to the overestimation of individual interest in the late twentieth century. Thus, our societies have attributed a normative value to risk (see Beck 2001). Interest, of individualistic nature, may contrast with risk, of generalist nature, from a cognitive and emotional standpoint. Risk can only be "reflected upon" from an individualistic perspective as it occurs at the same time as the Other. In other words, the absence of the Other is risk-free. An individualistic philosophical anthropology based on interest contrasts with a general anthropology and a heroization of the risk-taker in what could be called risk aesthetics, adding to its ethics. Risk, thus, emerges as one of the current eschatologies, yet one that culminates into business opportunities. Risks and their embracing seem to be all beneficial: they open up prospects of returns resulting from activity creation by bringing to the fore a proactive dimension. Thus, risk is a sort of phylogenetic factor as business opportunities are viewed as unplanned experiences leading to "happy outcomes."

Business Opportunities and Entrepreneurship

In this area, one should first mention the importance of institutionalized clichés such as "the entrepreneur is the person who seizes opportunities" as well as the frequent and indeterminate shifts between "leader" and "entrepreneur," on one hand, and "leadership" and "entrepreneurship" (a process-based occurrence), on the other. This also applies to the "entrepreneurship – innovation" overlap.

When it comes to entrepreneurs, innovators, or leaders, there are three approaches to consider:

– A theory of facts that represents the entrepreneur, innovator, or leader based on three personality traits. The pursuit of these traits supposedly helps single out an entrepreneur and/or innovator or leader. The two generic traits emphasized are focus (on a project, therefore a projective focus) and passion, which are then viewed as constituents of their identity. However, it is important to stress the limiting obscurity of this essentialist perspective.
– A situationist perspective which premises that an individual becomes an entrepreneur and/or innovator or leader through situations. The limitation of this consequentialist perspective is its relativism.
– An interactionist perspective grounded on the interweaving of personal dimensions and situations. The limitation is its indeterminacy. However, it is relevant insofar as it consolidates previous positions by addressing contextual elements, either personal (relatives, family background), biographical (encounters, events), or environment-derived (cultural background, responsiveness of society, education system, level of development – businesses created in developing countries differ from those of developed countries).

Empirically, entrepreneurship pertains to the creation of new businesses and self-employment. Organizing is the process that leads the entrepreneur to create or alter an organization based on market and context rationales that he/she will use to exploit a business opportunity. Organizing is an uncertain process because it is implemented before any feedback on the validity of the opportunity is available, with many questions still unanswered. It is implemented based on the entrepreneur's knowledge with regard to their education, past experiences, etc. But even if entrepreneurs draw upon existing aspects (they imitate what other companies do), the organizing process implemented is driven by creativity. In order to leverage an opportunity, the entrepreneur chooses a mode of exploitation that shapes the scope of the new organization.

It is based on the following premises: the existence of business opportunities and differences between individuals (and the entrepreneur is a risk taker). Thus, it is a process that interweaves innovation and organizational activities.

The term "entrepreneur" is also bound up with the very popular notion of "stakeholder," which justifies the management-centered conception prevalent in "stakeholder theory" (Freeman 1984). The theory emphasizes the growing instability of identifying and classifying stakeholders as one edges away from the core of the firm. This classification of "entrepreneurship" may then result in substituting an event-based description of the firm for a political description in which the firm's action is to seize business opportunities. In this respect, stakeholders are "firm-based" (they are its substance somehow). They point to a self-produced image of the firm catered toward citizens for the agonist purposes of virtuous interaction, excluding the resort to an outside third party, mostly the State.

The relationships between the entrepreneur and entrepreneurship are routinely examined in management sciences as they highlight the logic that underpins the shift from the figure to actual action. To refer to entrepreneurship rather than the entrepreneur is to assert the institutionalization of business opportunity. The person is the reference, whereas the notion is institutionalized action and the possibility of extensiveness. This also applies to "intrapreneurship," which operates in and around the corporation (spin-off/out is also the term in usage). It is about recapturing the drive of the entrepreneur by building the conditions for seizing business opportunities. More trivially, it is also a mode of reclassification for laid-off employees. One could also add the notion of "exoentrepreneurship," which characterizes the creation and development of a business in a given country from the assets and/or skills of an expatriate.

Conclusion and Future Directions

Finally, one should note the emphasis on the foundational character of the entrepreneur figure, an emphasis that intertwines "mission" and "vision" within the notion of "business opportunity." The notion of mission should be understood in its religious sense (the notion of belief is here emphasized; a missionary is someone who believes in their mission) as well as its sense of priority (a mission builds a contingency, a heteronomy that outweighs the subject's autonomy). The forms of engagement related to the mission range from activism to consistency. But there cannot be a mission without a vision. In the sense discussed here (note that vision is also related to eyesight), vision can be viewed as a resilient guide since vision changes in response to significant changes (supposedly, at least). This makes it opportunistic. The term vision derives from "to see/visualize," but it is anchored in time. To have a vision is to see into the future. Coupled with rationalist logic, the vision is both the representation of a desirable future and a possible future, in other words a somewhat "acceptable prediction" that can ground a commitment. In that way, "vision" is close to "representation" as it indicates individual energy focused toward the formalization and fulfillment of the vision. This is why vision leads to mission. The vision of a business opportunity is somewhat of a performative image spawned by a form of inspiration based on beliefs and values, something intangible made tangible and therefore possible. This is at the core of the phrase "strategic vision of the entrepreneur." From a political point of view, vision is both inclusive and engaging. This definition is supposedly a characteristic of the entrepreneur, innovator, and leader alike. Vision is a direction (from the instigator to the outside). This is why mission and vision are connected to the figure of the entrepreneur.

What Is Intuition?

Definitions and Perspectives

Intuition has been described as a natural, but complex, process that occurs at an unconscious level. The process provides new information, usually about a topic of importance, through a range of "unusual" mechanisms. These include sudden "aha's," internal dialogues regarding what is right or wrong about a situation, and unexplained feelings – either physiological or emotional. From the recipient's perspective, the actual process is opaque. There is no obvious means by which one could explain, or justify, the conclusion; it is almost as if the information is created out of thin air.

Even though the intuitive process is shrouded in mystery, several schools of thought have emerged, each with their own explanation of how intuition works and what is required for its development. The differences between the schools are largely explained by their stances on where the underlying information originates. Broadly speaking, scientific researchers regard intuition as the product of subconscious processing: tacit sensory perception, domain expertise, and past experiences. Adherents to more spiritual paths explain intuition by reference to hidden knowledge, and divine communication.

Irrespective of the actual explanation, intuition could therefore be seen as a process through which people unconsciously make meaning from internal sources of information and integrate it into their conscious thinking.

Words commonly associated with intuition are hunch/gut feeling, tacit knowledge, unconscious, sensing patterns, knowing without knowing why, insight, and visionary.

Logic Versus Intuition

Logic can be defined as reasoning conducted, or assessed, based on recognized principles of validity that rely on concrete evidence, proof, or inference on the same. When logic is employed in a creative process, it is typically experienced as external to the individual and used as a means to gather information, understand the situation at hand, and explore and weigh options. Logical thinking provides people with the capacity to link decisions and actions to specific knowledge, evidence, or proof and create a chain of justification that can be externally validated. In this way, a person's thinking processes become evident and communicable.

Intuition, by its nature, operates in a very different manner. It acts as a data source and a conduit to the internal world of the individual, offering information and synthesizing emotion without conscious evidence of how it came to be. Intuition functions on trust and uses a touchstone of validity which is simply an individual's experience or "feeling" that it is right, or not right, to take a specific action.

Intuitive and Cognitive Insight

The terms "intuition" and "insight" are often used interchangeably. While it is true that insights are often produced via intuition, it is important to recognize that it is possible to gain deep understanding through purely cognitive mechanisms. The key distinction between these two forms is that in the case of a cognitively derived insight, the individual could explain the development of their understanding, whereas, with an intuitively derived insight, the mechanics of its apprehension are hidden within the process.

Myths of Intuition

Intuition, like creativity, is a much debated and often misunderstood phenomenon. When this is coupled with the arcane nature of the intuitive process, it is not surprising that the topic has acquired a number of myths. Some of the more common myths include the following: intuition does not exist; that it exists and is reserved for only a chosen few; that it is the domain of the supernatural; and that using intuition as the basis for decision making is ungrounded and foolhardy.

The truth about intuition is that it is innate to all humans and available to everyone. However, just as with creativity, the intuitive capability of any one individual is largely a function of their commitment to its development. Developing one's intuition is therefore a personal choice that demands expertise of self which is described as a composite of self-awareness, self-esteem, self-acceptance, and the capacity to trust one's self. Those who value intuition as a source of information tend to have developed their respect by paying attention to their intuitive insights and gradually gaining comfort in using them as a guide post for sensemaking and decision making.

The myth that making decisions based on intuition is ungrounded or foolhardy is derived from cultural preference toward logical and rational thought. Clearly, the careful application of logic is a hugely powerful tool that allows people to evaluate decisions, before leaping into action. Externalized, rational decision-making has played a major role in the development of humanity. Many of the luminaries who have been responsible for these advances, however, have also credited their intuition in the development of their ideas. It is therefore important to note that just because intuition is not deeply understood does not mean that its "products" are wrong, or any less valid than those produced through a more transparent, logical process. In fact, recent developments in the fields of neurology, and behavioral science, lend validity to the complex set of circumstances that produce intuitive "hits."

Several neurological studies have uncovered physiological evidence of intuition as a literal "gut feeling." These sensations result from a chain of biological and neurological events, triggered by heuristics, which are derived from experience and strengthened through feedback loops. The loops are created through the application of the heuristics and their subsequent unconscious evaluation. It appears to be the case that as one means of preparing oneself to deal with future uncertainties, heuristics are stored in the brain centers associated with emotions, feelings, and memories (the basal ganglia and the amygdala parts of the brain known as the emotional or limbic brain). When encountering a new and ill-defined situation, one's brain draws upon these decision rules and synthesizes cumulated learnings to make a decision. These parts of the emotional brain therefore provide a source of wise conclusions and communicate primarily through activating the circuitry extending into the gastrointestinal tract, hence, the "gut feeling."

Other research into decision making has uncovered new information that shows that decisions are made across a spectrum of logic and intuition and whether a decision proves to be good or foolhardy is not so much about whether the decision was made based on intuition or logic but rather the process by which the decision was made, and the level of awareness and trust the decision maker has in the sources drawn upon to make the decision. Many executives and highly trained professionals admit to a decision-making protocol that relies on their intuition as the first or final steps, regardless of the logic or rational evidence that supports doing so. In reality, the validity of a decision, whether intuitively or logically made, is not always immediately evident. Details about the adequacy, appropriateness, efficiency, and effectiveness of a decision unfold over time. In the past, mankind rationalized the world was flat, the earth the center of the universe, and that time was an absolute phenomenon. Through the intuitive insights of creative individuals and the willingness to hold that there may be another possibility, it is now recognized that the world is round, the sun the center of our universe, and that time is relative.

The Role of Intuition in Creativity and Innovation

Locating Intuition Within Deliberate Creative Processes

Is intuition an element within a creative process or is the creative process an intuitive activity, which has had logical elements added to it?

Discussion in the creativity literature regarding the role of intuition in creativity falls all over the map. Some researchers position intuition within the incubation phase of the creative process. Others describe the whole creative process as intuitive. The truth may be found as a blend of these perspectives; exactly how the blend is calculated depends upon one's understanding of both intuition and creativity and how one views the interaction of person with process.

Certainly from the perspective of creative problem solving, a significant proportion of the work designed to support deliberate creativity has approached the topic from a logical, cognitive, and semantic perspective. For adherents of this school, creativity is a process that can be both understood and amplified through the application of the right tools and techniques. It is also true that this view has been ascendant within the business and scientific spheres.

However, creativity researchers also recognize that the emphasis on logical, rational process and tools does not accord with the reported experience of highly creative people. Both Steve Jobs and Albert Einstein are frequently held up as examples of eminent creators who relied heavily upon their intuition. And there is little doubt that they demonstrated the significance of harnessing this important way of knowing. But, perhaps more interestingly, Tim Cook (the new CEO of Apple) also cites the role of intuition in his professional life, suggesting that Apple itself might have an organizational predilection toward intuition: "Engineers are taught to make a decision analytically but there are times when relying on gut or intuition is most indispensable." As a result of recognizing this mismatch between theory and practice, a number of researchers have called for the deliberate development of intuition in order to create a more holistic creative problem solving process.

Regardless of where researchers land in their recognition of the role of logic versus intuition in creativity, it is clear that intuition is intrinsically aligned with the core creative process. Creativity, by its very nature, requires that we take a leap of faith, keep open to possibility, and trust in our intention to create something new, particularly when the reasons and means for doing so are not known, ambiguous, and yet to be discovered.

Intuition as Data

Intuition, by its very nature, emerges through an opaque process. In the field of creativity, this raises the question of how one might assess the validity of data gained in this manner. There are two schools of thought on this topic. One group of researchers holds that intuition is an inherently unreliable process and that the insights will be distorted through emotional and experiential biases. The other group argues that intuition offers a route to "deep" knowledge by allowing people to access their tacit knowledge and associated heuristics.

In the end, there is no clear answer to the question, "is intuitive data valid"? Each situation must be judged on its own merits. However, what is clear is that intuition does offer an additional, and potentially important, source of data. Granted, the data could be distorted based on how the receiver interprets the information or chooses to use it and the same could hold true for logical data.

The key point is that there is value in spending time reflecting upon one's data sources, whether intuitively or logically derived, and working to understand their potential significance. Deliberate creative processes benefit from a diverse set of data. Enhanced understanding – through any mechanism – is likely to strengthen the quality of the resulting decision. For this reason, involving intuition in the creative process offers important benefits.

Strategies for Leveraging Intuition in Creative Problem Solving

Creativity research suggests intuition is favored when faced with working in ambiguous, poorly structured, and uncertain contexts. Creative Problem Solving (CPS), the most widely used and researched model for creative problem solving in the world, is particularly suited to organize thinking and support the discovery and resolution of open-ended, ambiguous, challenging, and multifaceted predicaments or opportunities.

Despite its suitability to ambiguous situations, CPS as a model for creative problem solving is observed as being rationally, cognitively, and semantically oriented. This presents a bit of a conundrum and certainly highlights the necessity for having strategies for the deliberate use of intuition in CPS. Originally introduced by Osborn (1953), it elevates a strictly intuitive process to being highly explicit, offering a means to flexibly employ distinct process steps based on the task at hand. Additionally, it integrates underlying principles of creative thinking (divergence followed by convergence) and establishes challenge questions as an organizing principle (how to, how might, in what ways might, and what might be all the ways) to its use.

When learning about Creative Problem Solving (CPS), students are often reminded to "trust the process." If one were to focus on strategies for leveraging intuition in creative problem solving, the same sage advice would apply – trust intuition as a process for providing information and learn how to use it. As indicated in the discussion on myths about intuition and creativity, one's capacity to leverage intuition in CPS is related to one's self-awareness and how one values and understands intuition as a data source.

Assuming one has made the commitment to develop and use intuition, there are specific strategies that can be employed to leverage intuition in CPS and return it to a more explicit, rather than inferred existence. These strategies include allowing time for incubation, encouraging participants to consciously engage their intuitive capabilities, and using intuitive skills to function more effectively across the entire model.

Allowing for Incubation

Reviews of the history of inventions and major innovations as well as creativity research studies have repeatedly demonstrated the connection between incubation and the production of intuitive insights. Researchers do not agree on an explanation for this connection. Some think that incubation allows the mind to recuperate, while others suggest that it provides an opportunity to forget incorrect solutions or to make new connections with outside stimuli.

Irrespective of the explanation, creating the opportunity for incubation is an important step toward fostering intuitive insights. There are many ways to promote incubation, and some of the more commonly cited methods include taking breaks, going on excursions, engaging in a completely different activity such as cooking, painting, or even, most notably in the literature, by going to sleep.

While incubation provides clear benefits, it is not without its detractors. Building time for incubation is often viewed as inaction or "wasting time," particularly in very action-oriented cultures. These views can discourage people from engaging in incubation and ultimately may damage their thinking process. If there is insufficient time to incubate, there is the chance that intuitive insights will not be reached, and some of the most effective and useful ideas missed.

A group, or individual, may not be allowing themselves sufficient time for incubation if they are not producing the desired results from a CPS workshop; if the group is not naturally taking advantage of incubation opportunities within a process; if, at the end of the session, the group feels that there is unexplored territory but is unable to define it rationally; or if the group is "stuck" and unable to determine why. In any of these situations, making a conscious effort to create greater opportunities for incubation might provide a significant shift in thinking.

Directly Soliciting Input from Users' Intuitive Capabilities

The more deliberate use of intuition in CPS involves directly soliciting input from participants' intuitive capabilities. This, obviously, requires specific tools and techniques that allow people to call upon their intuition.

Some researchers suggest that the existing CPS tool set – given its orientation to rational, cognitive, and semantic-based approaches – lacks the tools to encourage intuition. Others have observed that a tools-based focus misses the opportunity to more actively engage intuition by evolving the entire process. An evolved CPS process would actively encourage affective skills, as well as work to establish a creative climate that normalizes and honors gut feeling insights.

Within the context of the current CPS process, a facilitator might directly solicit input from participant's intuitive capabilities by employing one of the following techniques: encouraging participants to share gut reactions throughout the process, conducting an unstructured dialogue by asking participants to free-flow their ideas, using metaphors and analogies, employing tools in the traditional CPS tool set indicating that logical and intuitive data sources are welcome, and improvising tools and techniques from other domains that are more holistic in nature or that rely predominantly on right-brain thinking strategies. In the case of individual users of CPS, the same approaches could apply.

Using Intuitive Skills

The most recent evolution of CPS, the Creative Problem Solving Thinking Skills Model (CPSTSM) developed by Puccio, Mance, and Murdock (2010), introduces enhancements to creative thinking guidelines and comprises three broad stages – clarification, transformation, and implementation. Related to these broad stages are six cognitive and one meta-cognitive process steps, each with a primary and nonexclusive thinking skill, each of which in turn is correlated to a primary and nonexclusive affective skill. As a process map with thinking tools, CPSTSM, like its predecessors, is particularly suited for use in complex, ambiguous, and multifaceted situations.

The affective skills introduced through the CPSTSM refer to the ways in which one deals with the attitudinal and emotional aspects of learning, recognized as including feelings, appreciation, enthusiasm, motivations, attitudes, and values. While their research linked specific affective skills (mindfulness and sensing gaps), and the requirement to stay focused while converging, to intuition, further research conducted by Burnett (2010) identified certain affective skills in the CPSTSM model as intuitive skills, either because of their reliance on intuition as a data source or because they specifically enable intuitive insights to emerge.

These intuitive skills include tolerance for ambiguity, mindfulness, sensing gaps, and sensitivity to environment. They fall within the domain of expertise, are developed through deliberate practice, and are a by-product of metacognition, time, and experience in the self-aware.

Tolerance for ambiguity in CPSTSM is what allows one to deal with uncertainty and to avoid leaping to conclusions (Puccio et al. 2010). When viewed through the lens of intuition and creativity, it seems as though there are two separate, and related, aspects to this skill – one affective and the other intuitive. The affective aspect relates to the ability to manage one's emotions in such a way as to tolerate the ambiguity. The intuitive aspect gives one the ability and tools to navigate the ambiguity. Without affective capacity, a person might find ambiguous situations too stressful to allow them to engage in an intuitive exploration. Likewise, without intuitive capacity, ambiguous situations may persist beyond anyone's tolerance. These two aspects therefore reinforce and support one another.

Mindfulness is the conduit for intuitive insights on progress, next steps, and actions. When using CPS, one must navigate the spectrum of process, content, context, and self. Mindfulness is what allows us to regulate our focus of attention across this spectrum with curiosity, openness, and acceptance by attending to thoughts, feelings, and sensations relative to the present situation (Bishop et al. 2004). Its underlying principle is metacognition which draws upon reflective thinking as a means to allow us to think about our thinking and awareness as a means to direct cognitive process.

Without regulation of one's attention, it would be difficult to hear the "quiet voices" of intuition and bring them into awareness. Without curiosity, openness, and acceptance, it would be difficult to avoid the trap of logic acting as the tacit censor of one's intuitive thoughts. Ultimately, without mindfulness, it would be difficult to recognize where we are across the spectrum of process, content, context, and self in achieving an outcome and to engage intuition in service of creating that outcome.

Sensing gaps is what allows one to become "consciously aware of discrepancies between what currently exists and what is desired or required" (Puccio et al. 2010) and relates to the innate ability to recognize that something "is not working" or "not adding up." Sensing gaps as an intuitive skill is developed over time, reinforced by experience, i.e., experts are more able to perform this function, and relative to one's capacity for mindfulness and sensitivity to environment. This gives greater weight to the idea that intuitive skills can be developed, irrespective of whether that development is deliberate or simply a side effect of time and experience.

Sensitivity to environment is a gauge to quantify the degree to which we are aware of our physical and psychological environment and our capacity to understand "the interrelated conditions and circumstances that will support or hinder success" (Puccio et al. 2010). The context, or environment, within which we work, provides a frame of reference for status quo, the rules, values, beliefs, and other boundaries within which we must perform. The greater our understanding of the environment within which we operate, the greater our potential for recognizing opportunity and navigating our way through the subtle nuances of our creative challenges. By being sensitive to the environment, we learn to become aware of "decision rules" and develop expertise on what is acceptable and unacceptable within a culture. By taking the time to understand the nature of the box within which we are operating and its underlying assumptions, we increase our capacity for finding entry points to new realities. As Louis Pasteur so astutely observed, "chance favors only the prepared mind."

Conclusions and Future Directions

Intuition is a fundamental part of human thinking. It provides a mechanism by which our subconscious mind can communicate perspectives and insights to our conscious mind. Intuition, however, is a quiet process. It speaks through a range of channels and can only be perceived if one pays attention. Unfortunately, because we lack a thorough understanding of the intuitive process, the products of our subconscious mind tend to be given less credence than those of its louder, cognitive counterpart. This means that in an age in which creativity is seen as increasingly important, there is an even greater need to encourage the development of intuitive skills.

In the future, there is an opportunity to restore a balance between the logical and intuitive aspects of human creativity and to normalize the use of intuitive data in creative process. What if, instead of continuing the debate that places logic and intuition as polar opposites, we recognized that it is possible that they could be equally important data sources, each possessing a synthesis of learned knowledge and both subject to evaluation in service of creative outcomes? What if all data sources, like ideas, were welcome in your next creative problem solving session?

As creativity professionals and researchers, we can make a commitment to develop our intuitive skills and help others to do the same. Through encouragement and literature support, we can leverage more than 60 years of research into the development and application of the CPS process by complementing rational, cognitive, and semantic-based approaches with an expanded, more intuitive tool set and by improvising holistic applications of tools in the existing tool set. By being deliberate in our efforts to nurture and employ intuition, its value to creative process becomes explicit, its voice heard, and our capacity to be creative all the more.

Schumpeterian Entrepreneur

Francis Munier
BETA, Université de Strasbourg,
Strasbourg, France

The Portrait of the Entrepreneur

The author, J.A. Schumpeter (1934), presents a portrait of this very particular economic agent as follows. Being an entrepreneur is not a profession at all, and certainly not a conventional rule, or even a comfortable state. Very briefly, a person is an entrepreneur if he performs new combinations, even if he is not the creator of the materials of the new combinations (in fact, this is not the most important for the author). J.A Schumpeter uses also the metaphor of a closed circuit in order to explain that when the entrepreneur loses this specific character, he continues to operate, but only within a circuit created by the company. The entrepreneur could be either a founder or an employee. But the image of a "captain of industry" or a creator seems to be a more consistent concept according to the Schumpeterian entrepreneur.

J.A. Schumpeter (1934) insists on the very specific character of the entrepreneur. He compares the entrepreneur to people who belong to a particular species. The implementation of new combinations is a picky function, a kind of privilege for only a few people who are able to recognize the opportunities of new combinations and to implement them. This agent has rare qualities such as intelligence, intuition, ability of vision, etc.

J.A. Schumpeter considers that the entrepreneur belongs to the quarter highest group (top 25% group) of the population, and forms a type that characterizes the extent of these outstanding qualities in the sphere of the intellect and the will. The motives of the Schumpeterian entrepreneur are three. He wants first to make his dream come true and he has the will to found a private kingdom. The will of the conqueror is essential. The joy of finally creating a new economic form is a third group of motivation. The entrepreneur should therefore be able to demonstrate a willingness in order to impose the novelty, to "break" the routine. This implies that he is also able to act as a real leader.

What the Schumpeterian Entrepreneur Is Not

J.A. Schumpeter notes that during the nineteenth century, the entrepreneur is defined within the generic term of "management" which means control, hierarchy, or discipline. This observation does not agree with the idea that this management work is too much administrative, or bureaucratic. It means that the entrepreneur is not a kind of intermediary, in the process of economic cycles, between the one who holds the resources and the final consumer. Hence J.A. Schumpeter (1939, 1951) comes to the

E.G. Carayannis (ed.), *Encyclopedia of Creativity, Invention, Innovation, and Entrepreneurship*,
DOI 10.1007/978-1-4614-3858-8,

conclusion that the source of evolution lies in the supply. In the end, the needs of consumers do not impose their will upon the unit of production. The author considers rather that the producers guide the consumers" needs. But what it is important is the focus on the assertion that not just any producer is able to guide the need of consumers, but only a handful of them, namely, the entrepreneurs.

At this stage, it is also important to distinguish between the inventor and the entrepreneur. Generally, the functions of the inventor or the engineer and, that of the entrepreneur do not coincide.

Moreover, the entrepreneur is also distinguished from the capitalist. This distinction allows the author to highlight the importance of credit, and the process of the creation of money in economic development. To summarize, the implementation of new combinations requires the input of resources provided by the banker, the capitalist. Thus the "*bourgeoisie*" plays a crucial role in society in the sense that it offers a kind of shelter for people who want to innovate.

This difference between these roles as economic agents allows then J.A. Schumpeter to go further away from the notion of *knightian* risk (F. Knight 1921) who considers the entrepreneur as a risk taker. In the Schumpeterian vision, it is only the capitalist who bears the risk of novelty.

Entrepreneur, Innovation, and Creative Destruction

The Schumpeterian entrepreneur is also considered as the real cornerstone of capitalism. Within the capitalism system, the development of the economy is considered as a dynamic process. It is important to insist on the fact that this idea of dynamics is quite different according to the mainstream concept of equilibrium. The entrepreneur needs always evolution and of course, it is not possible to consider that his dynamics could be ending because of an ultimate equilibrium point. In other words, the evolution does not cease in order to avoid a regime without innovation.

This dynamics provides a sense of the figure of entrepreneur.

As Schumpeter points out, innovation is the main source of economic development, but the entrepreneur is the real fundamental catalyst of the innovation process. As we have already specified, his function is to perform new combinations. These could be the following possibilities listed by J.A. Schumpeter:

- Manufacture of a new good
- Introduction of a new method of production
- Opening a new market
- Conquest of a new source of raw material
- Creation of a new organization

For J.A. Schumpeter, the essence of the entrepreneur is then the ability to break away from routine, to destroy existing structures, to move the system away from equilibrium. It means that the most important element is not a quantitative evolution of variables but rather a kind of qualitative evolution or mutations which express the dynamics of the process of innovation. The author uses the metaphor of blood inside the body in order to explain the notion of flow within a closed circular.

The entrepreneur is the disruptive force that dislodges the market from the somnolence of equilibrium.

The primary consequence of the Schumpeterian entrepreneur is the importance allocated to the long-run economic development of the capitalist system. This so-called creative destruction is the process of industrial mutation that continuously revolutionizes the economic structure from within, incessantly destroying the old one, continually creating a new one. This process is the essential feature of capitalism and the focal point of the Schumpeterian entrepreneur.

Entrepreneur and Monopoly

This basic principle of creative destruction, which is deduced from the primacy of the entrepreneur in the implementation of innovation, allows the author to explain the nature of profit. Since only the entrepreneur is able to create a profit from the output of the innovation, it is different in particular from rent, wages, or the normal return on capital.

This distinction is decisive to qualify the link between profit and monopoly. When new products appear for the first time in the market, the entrepreneur has no competitors; their prices are formed, wholly or within certain limits, according to the principles of monopoly prices. Thus, besides the fact that some basic conditions are observed, the entrepreneur grants himself an advantage because he creates a monopoly.

However, this monopoly, and the resulting benefits are not sustainable and lead to a difference between the concept of profit and the gain from a monopoly. This dichotomy between the benefit of the entrepreneur and the return linked to the monopoly analysis prefigures J.A. Schumpeter' vision concerning the disappearance of capitalism due, in reality, to the appearance of sclerotic corporate monopoly because of the lack of entrepreneurial initiatives.

The Obsolescence of the Schumpeterian Entrepreneur

The collapse of capitalism is explained by its own logic (J.A. Schumpeter 1942). In addition to the disappearance of opportunities of investment, which leads also to the disappearance of the shelter of the "bourgeoisie," it is primarily the decline of the function of the entrepreneur which is the cause of the transformation of capitalism into socialism. The only solution for society to survive is to evolve toward a socialist system because of the destruction of the support for the entrepreneur which provides him with the capability to be and to do.

Considering a situation of satiation, the author considers that capitalism, which is essentially an evolutionary process, will be in a situation of atrophy. The entrepreneur would be deprived of any field of activity. The profits and, simultaneously, interest rates will converge toward zero. The layers of bourgeoisies, who live in profits and interest, would tend to disappear. Companies would all lead to bureaucracy. These ideas summarize the causes and the consequences of the disappearance of capitalism according to the obsolescence of the Schumpeterian entrepreneur.

This destruction of the institutional framework of the capitalist society is accompanied by a destruction of the protective *shelter* provided by the "bourgeoisie." The decay of this class illustrates precisely the breakdown of the defenses of capitalism, including the fact that the "bourgeoisie" is detached from its own values. In this regard, the author considers that faced with the hostility growing around them and then the consequences, in terms of practice legislative, administrative, and judicial, generated by this hostility, entrepreneurs and capitalists – in fact all the social strata who accept the program of bourgeois existence – will eventually stop performing their duties. The growing hostility experienced by capitalism in this respect is the final factor in the process of disappearance.

Size of the Firm and the Schumpeterian Entrepreneur

Two visions of the relationship between the size of the firm and innovation are attributed to Schumpeter. The first, called "Schumpeter Mark I," is developed in *The Theory of Economic Development*. Small firms play a major role in the process of innovation. Entrepreneurs perform new combinations, create new firms. In this approach, only the small business is the vector of technical progress. The second vision, "Schumpeter Mark II," is developed in *Capitalism, Socialism, and Democracy*. Innovation is initiated by large companies with a research laboratory and only the large companies innovate.

Innovation is the engine of economic development, notably for the capitalism. The factor of innovation is the entrepreneur. In this – theoretical – context, since the entrepreneur is no longer the reference, capitalism is led to decline. The main reason for the disappearance of the function of entrepreneur is based on the appearance and development of R&D departments in large firms, a source of bureaucratic and "routinized" technological progress. The big companies are responsible for the disappearance of the entrepreneurial function and of the capitalism. The emergence of large structures destroys the institutional framework based on small businesses: the process inevitably destroys the economic foundations on which small business enterprises are built.

Conclusion and Future Directions: The Concept of the Manager-Entrepreneur

Since the work of F. Munier (1999a, b), one future direction has been to highlight the concept of manager-entrepreneur.

F. Munier defines a kind of hybrid agent called the "manager/entrepreneur." The dichotomy of the behavior of manager/entrepreneur is as follows: on the one hand, he takes care of ongoing activities that are more short term, the pursuit of profit and reduction of transaction costs; on the other hand, he tries to mobilize knowledge, to find and develop sources of learning, manage and develop individual and collective skills. This involves a tradeoff between the forms of centralization and decentralization needed to encourage the creation of knowledge while providing a pipeline for new useful knowledge.

The manager/entrepreneur is faced with several dilemmas to simultaneously maintain authority, stimulate creativity, and motivation of individuals. The manager/entrepreneur must solve the tensions between centralization and decentralization, between control and commitment, between change and stability, between order and disorder in the firm.

Centralization is a source of coherence, but also a source of inertia if it seems too heavy. However, decentralization is about creativity, but an extreme situation can cause the disappearance of the organizational structure, thus wiping out all references and codes. To allow the creation of skills in the firm, the manager/entrepreneur must consider both the advantages and disadvantages of each mode of governance.

The concept of manager/entrepreneur leads to the concept of duality of the firm (Munier 1999b) which provides meaning to the Schumpeterian entrepreneur as the cornerstone of creativity within the firm.

Science of Creativity

Andrei G. Aleinikov
International Academy of Genius, Monterey, CA, USA

Synonyms

Creatology; Sozidonics

Definition

The science of creativity is the study of the complex phenomenon of creativity.

Introduction

As with any new field of research, the creativity research at a certain moment of time develops into a science. Creating (structuring, designing) a new science is an act of creativity. If scientists create new methods of research, new models, new hypotheses, new theories, new devices, new experiments, and these are all creative acts, then the creation of a science can be considered one of the largest creative acts in the field of science. In the history of science, the founders of new sciences are often referred to as "fathers," such as Gregor Mendel, the father of genetics, or Norbert Wiener, the father of cybernetics.

On the ontological level, the humanity as a whole exists, works, and creates newness of all kinds without thinking about creativity. Then there appears a group of thinkers (philosophers, scientists) who detect some patterns in the acts of creation and begin to observe this process and reflect its regularities. This reflection constitutes the gnoseological level – the level of knowledge. After gathering lots of data and creating a few theories, there appears a need to create a science of creativity for the world of creation to become reflected scientifically. The data on creativity gathered by the efforts of hundreds of scientists around the globe becomes the pool for shaping the science of creativity. This is how creativity in science shapes the science of creativity.

From a Field of Research to a Science: Sozidonics or Creatology

Millenniums of technological inventions, poetic and artistic explorations that resulted in cultural masterpieces, scientific discoveries, and theoretical breakthroughs had to be scientifically explained. Creativity, the most human of all human abilities, called for explanation. During the last century, scholars researched:

- Relationship between creativity and intelligence
- Neurological processes associated with creative activity
- Creative abilities
- Genetic factors versus training in creativity
- Correlation between creativity and personality types
- Relationship between creativity and mental health
- Educational methodologies and human potential for fostering creativity
- Educational applications for improving the efficiency of learning
- Technological augmentations of creative abilities
- Creativity boosters and creativity squelchers
- Effect of chemical substances on creativity
- Relationship between teaching creativity and recidivism reduction
- Top creative achievers (genius), etc.

The list of scholars who contributed to the development of science of creativity is so long that it goes well beyond the references pattern of this encyclopedia. Nevertheless, at least mentioning the names of the most prolific ones is a must to give them credit for their dedication and enormous work. Often their scientific work is "irretrievably interwoven," as Sidney G. Roth (1963) says, with education and training, but they still find time to do their research. Here are the names of these heroes of science whose creativity in science builds the science of creativity (in alphabetic order): T. M. Amabile (Componential Model of Creativity, Consensual Assessment), G.S. Altshuller (TRIZ), J. Arnold (Useful Creative Techniques), M.S. Basadur (Creative Problem Solving in Business, Simplex), B. Bleedorn (Education Track for Creativity), T. Buzan (Mind mapping, Everyday Genius), B. Crammond (Creativity in the Future), M. Csikszentmihalyi (Creativity: Flow), G. Davis (Creativity is Forever), E. De Bono (Serious Creativity), I. Dubina (Creativity as a Phenomenon of Social Communications), G. Ekvall (Creative Climate), R. Epstein (Behavioral Approaches to Creativity, Generativity Theory), F. Eysenk

(Genius: The Natural History of Creativity), R. Firestien (Leading on the Creative Edge), M. Fisher (The IdeaFisher), R. Florida (The Rise of the Creative Class), S. Freud (Creativity and the Unconscious), H. Gardner (Creating Minds), M. Gelb (How to Think Like Leonardo da Vinci), W. Gordon (Synectics), K. Goff (Everyday Creativity: an Easy-to-Read Guide), J.K. Gowan (Right Hemisphere Imagery), H.E. Gruber (Systems Approach to Creative Work, Creativity and Human Survival), S. Gryskievicz (Positive Turbulence), J. Guilford (Intellect Model), N. Hermann (The Creative Brain, HBDI), D. Horth (Creative Competencies for Contemporary Leadership), S.G. Isaksen (Creativity Model, CPS, Frontiers of Creativity Research), M. Kirton (Styles in Creativity and Problem Solving, KAI), P. Kline (The Everyday Genius), A. Koestler (The Act of Creation), L. Kubie (Neurotic Distortion of the Creative Process), I. Magyari-Beck (Creatology), A.H. Maslow (Towards a Psychology of Being), J.H. McPherson (Creative Problem Solving Methods), M. Michalko (Cracking Creativity, Thinkertoys), M. Murdock (Nurturing and Developing Creativity), K. Neethling (Whole-Brain Sexuality, South African Creativity Foundation), R. Noller (Creativity Formula), V.M. Odrin (Morphological Synthesis), A. Osborn (Creative Problem Solving, Brainstorming, Creative Education Foundation), S.J. Parnes (Creative Problem Solving, Creative Education Foundation, Magic of the Mind), K.H. Pribram (Brain and the Creativity Act, Languages of the Brain), G. Prince (The Practice of Creativity), S. R. Pritzker (Encyclopedia of Creativity), G.J. Puccio, (Buffalo Creative Process Inventory, etc.), M. Runco (Theories of Creativity, Encyclopedia of Creativity), D.K. Simonton (Creativity, Eminence, Genius, Darwinian Approach, Historiometry), M. Stein (Stimulating Creativity, Creativity and Culture), R.J. Sternberg (The Nature of Creativity), E. P. Torrance (Torrance Test of Creative Thinking, Torrance Kids), D. Treffinger (Creativity Definitions, Creative Thinking), A. Van Gundy (Idea Power, Organizational Creativity and Innovation), R. von Oech (Creative Think), G. Wallas (The Art of Thought), W. Wenger and S. Wenger (Project Renaissance), M. Wertheimer (Productive Thinking), F. Zwicky (Morphological Analysis), and many others (see ► Research on Creativity).

Their research and publications show that the advent of the science of creativity was actually predetermined. The only variables were when, where, and by whom?

Origin and History of Research

It is generally accepted that research on creativity started with G. Wallas' work in which he dissected the act of creativity into four stages: preparation, incubation, illumination, and verification (Wallas 1926). Prior to this publication, creative people were referred to as "marked by God"; no explanation was given either by these people or by researchers on how creativity appears, how it develops, how it works, etc. Some brilliant insights on the issue were scattered and were so insignificant that they can be considered only some kind of pre-research.

The next major advance in igniting interest to topic happened thanks to J.P. Guilford's famous speech for the American Psychological Association in 1950, in which he called for action on the sorely neglected area of creativity research (Guilford 1992).

Dr. Sidney Parnes, one of the co-founders (with Alex Osborn) of Creative Problem Solving (CPS) (see ► Creative Problem Solving) and Creative Education Foundation (CEF), Buffalo, NY, sketched the following periods in the development of creativity research domain:

- 1940s – cry in the dark
- 1950s – the hope and hunch stage
- 1960s – the research, replication, and report stage
- 1970s – the widespread application stage
- 1980s – the mainstream application stage (Parnes 1992)

This sequence of stages vividly shows the formation of applied science, i.e., research going together with practice and returning to practice immediately. These first steps provide the foundation for building a science.

Trends and Approaches

The history of science in general demonstrates three major approaches in creating sciences:

- Bottom-up
- Top-down
- Cross-section

The bottom-up approach happens when a researcher discovers something so unusual and important that it later leads to unveiling a new field of research built on this discovery. Typical examples are Gregor Mendel who discovered and described similarities in bean coloring generation after generation (later he was considered the “father of genetics”) and Wilhelm Conrad Röntgen who discovered x-rays in 1895 and thus “fathered” the field of radiology.

The second type, the top-down approach, occurs when somebody generalizes the huge amount of data under one concept. Good examples are the general systems theory by Ludwig von Bertalanffy (1968) and cybernetics by Norbert Wiener (1948).

The third type, the cross-section approach, happens when a scientist works at the borderline of two sciences and proves that there is a field of research between the two. A bright example is Hermann von Helmholtz who mastered two disciplines (medicine and physics) and with his synthesizing approach to science is now considered to be the “father of biophysics” (the cross-section between biology and physics).

In the field of creativity, there is no groundbreaking discovery of one fact, but there is a huge amount of data to generalize. Therefore, it is obvious that the science of creativity is being developed by the top-down approach. However, since it deals with other sciences and is derived from the other fields of research, the process has the features of the cross-section (interdisciplinary) approach.

In addition to the approaches mentioned above, there are trends in development of the concept. The major trends in the development of the creativity concept are:

- From exclusive to inclusive
- From nonscientific (popular) to scientific

The trend from exclusive to inclusive means that the ability to create was first ascribed only to God and the true creation was only from nothing to something (exclusive). Later in history, the ability to create was ascribed to poets, then to artists, then to actors, and so on and so forth to include actually everybody (inclusive).

The second trend means that researchers move from explaining creativity to the public in popular terms (just for the public to know what it is to apply it to business, education, etc.) to scientific reflection that may be less popular or less understood but more adequate and more precise in nature.

Trends and approaches explaining creativity are best seen in the search of proper definitions (see ► Creativity Definitions, Approaches) and theoretical models of creativity.

Conceptual and Graphic Models

After Wallas, mentioned above, there appeared many other models. In 1968, McPherson conducted a comparative analysis of 18 models and presented them in one table. These models included two to eight stages (McPherson 1968).

The first models were simplistic and gave little in defining the operational steps. As a response to the practical needs, there appeared operational models. One of the most famous operational models belonged to Alex Osborn and later was improved by Sid Parnes and is now known as Osborn-Parnes model.

Quite popular are graphic models:

- The 4 Ps model picturing creativity as intersection of *P*eople, *P*rocess, *P*roduct, and *P*ress (Isaksen 1987)
- The Torrance’s model showing creative behavior as a mix of abilities, motivation, and skills (see ► Creative Behavior)
- The Amabile’s componential model depicting creativity as an intersection of expertise, creativity skills, and task motivation (Amabile 1997)
- The divergent/convergent thinking model consisting of splitting and then converging arrows (see ► Convergent Versus Divergent Thinking)

- The two-stage "great idea" dynamic model that showed diverging from the beaten path to a great idea and then applying this idea (Davis 1981)
- The five-stage dynamic creative act model that depicted a new result as well (Aleinikov 1989) that paved the way to Creative Pedagogy (see Aleinikov 1990a, 1991, ▶ Creative Pedagogy)
- And many others (see ▶ Multiple Models of Creativity)

An original approach was offered by G.P. Guilford whose graphic model of intellect (box) included divergent/convergent thinking (Guilford 1968).

The development of conceptual and graphic models for creativity, creative acts, and creative problem solving is going on and contributes to the new science of creativity. However, a major theoretical breakthrough was needed to create the science itself.

The New Science's Place in the Classification of Sciences

The new science of creativity has to belong to the field of social sciences that study human behavior and societies, as opposed to natural sciences, like physics and chemistry, and formal sciences, like mathematics and logic.

Within the social sciences, the science of creativity is grounded in psychology, most closely related to education (see ▶ Creative Pedagogy), linguistics (see ▶ Creative Linguistics), and certainly related to anthropology, archaeology, history, sociology, and other sciences.

Historically, the science of creativity, like all other sciences, started as empirical research (that continues all the time), got through the stages of experimental research and separate theories (see ▶ Creativity, Experiential Theories), and now is in its theoretical design stage that crowns the formation of the science.

During this formation, one has to remember that social sciences are much younger than natural and formal sciences that were established centuries ago. That is why in the process of creating a new science, the well-established sciences can be viewed as examples to follow or sources for borrowing the concepts and methods of research.

The Science of Creativity

As all well-established sciences, the science of creativity has to have the following elements:

- Name
- Objective
- Subject of study
- (New) vision of the subject (definition)
- Classification
- Model of the subject
- Special methods of research
- Units and measurements
- Results (some practical applications that illustrate the power of the theory)
- Predictions

So the task is either to find them or formulate them.

Name for the New Science

There are two candidates for the name of the science of creativity: creatology (Aboganda and Cortez 1972, Magyari-Beck, 1977–2008) and sozidonics (Aleinikov 1994).

Creatology

The term creatology consists of two roots derived from Latin *creō, creatus*, the past participle of *creare*, meaning *to make, bring forth, produce, beget* plus *logy* coming from *logos* meaning *word, the study of.*

The Psychology Wiki site states, the term Creatology, as a new science of creativity, was first used by Rafael Nelson M. Aboganda and Ricardo S. Cortez in a paper entitled "Towards a Positive Understanding of Creativity – Creatology: The Science of Creativity" published in October 1972 by the Philippine Inventors Commission (PIC), now Technology Application and Promotion Institute (TAPI) an agency of the Department of Science and Technology (DOST), in the Philippines.

Creatology was later introduced and proposed by a Hungarian scholar Dr. Istvan Magyari-Beck in his presentation "About the Necessity of Complex Creatology" made on the International Sociology of Science Conference in Budapest, in 1977. In 1979, this paper was published in the book *Sociology of Science and Research*, edited by János Farkas, Akadémiai Kiadó, Budapest, pp. 175–182.

Dr. Sayed Mahdi Golestan Hashemi (Founder and Head of Iran Research Center for Creatology and International Center for Science of Creatology) is developer of Creatology as an interdisciplinary (GTC): Creatology is Scientific Study of various aspects of Creativity, Invention and Innovation by different approaches. Creatology has many sub-disciplines such as:

- Analytical Creatology
- Psychological Creatology
- TRIZ-based (TRIZical) Creatology
- Inventology
- Bionical Creatology"

Retrieved from http//: psychology.wikiw.com/wiki/Creatology psychology.wikia.com/on February 4, 2012.

It was Dr. Magyari-Beck's article titled "Creatology" in the *Encyclopedia of Creativity* that made the term popular (Magyari-Beck 1999). In 2008, Dr. Magyari-Beck also published an article titled "Creatology from 1977 to 2007" in the *Society and Economy* journal that summarized 30 years of concept development.

Sozidonics

The term sozidonics was published first in English in 1994 (Aleinikov 1994).

It is related to a Russian word созидание/*sozidanie* that has only one meaning "*creation of positive things*" – a very rare case in the language because usually words have several meanings. This word has a neutral variant создание/*sozdanie* with the meaning *creation* that can be used for both positive and negative things. The prefix со-/*so-* means *together*, like *co-* in English. The root of the word -зида-*(*-зда-*)*/-зьдъ/-*zida (zda)-* is a Proto-Slavic root "*zida*" *clay* (not used separately anymore), but seen in Russian words здание/*zdanie* (*building*), зодчий/*zodchiy (architect)*, Bulgarian *zid*, Serbo-Croatian **zidъ/-zid*, and Romanian *zid* in the meaning *wall*. The final part of the term sozido*nics* is usual for sciences and may be seen in mathem*atics*, cyberne*tics*, bio*nics*, gene*tics*, etc.

The etymological connection here is obvious: *so-zid* means building together, like in creativity, something is created for the benefit of others. Clay as the building material was certainly used for house walls, church walls, and town walls. Going back into history, clay hypothetically might be the first material that could provoke a primitive human mind for a creative act. Clay's plasticity when wet and ability to harden when dried might have sparked an ancient human to create some objects or even first sculptures out of it. Ceramics started from clay pieces dropped in fire. As opposed to clay sculptures, wood carving and stone sculptures would have required much more elaborate tools and techniques, which place them much later in the history of arts and crafts (Aleinikov 1994).

Comparison

The term creatology is more traditional. It is coined from the well-known Latin roots and easily understood. This advantage, however, can turn into disadvantage: it makes it prone to parallel usage in technology and marketing which overshadows the scientific meaning and usage. For example, the Google search on "creatology" delivers hundreds of items *not* related to the science of creativity, like Creatology™ coloring poster, Creatology™ 3D Kits, Creatology Wooden Puzzle, photo of Creatology®, Creatology Doll Furniture, Creatology Wooden Temple of Heaven review, Creatology: an experimental blog coupling creativity and science...

Obviously, this word, registered and trademarked, is widely used for technologically based toys as well as for experimenting. As a result, after some time, it may look like creatology as a science of technological advances of the company called creatology. Also, most importantly, what was supposed to be a term (a word with one meaning) has become a usual word with numerous meanings and, therefore, has stopped being a term.

Finally, according to the founders, the word creatology is used for the science of creativity, invention, and innovation. So it is *not* the term specifically for the science of creativity.

The term sozidonics, on the contrary, is nontraditional. It has the following advantages: First of all, it is a term, not a usual word: it has one sound (or graphic) form related to one meaning. Second, etymologically, it relates to the first creative acts in the past. Third, it refers to positive and only positive creativity (as it should be in the ideal!). Fourth, it sounds original (not boring, not traditional) as the term for the science of creativity implying *originality* should be. Finally, what is most important, it precisely names the science of creativity, *not* the science of creativity, invention, and innovation.

The issue may be resolved after analyzing the subjects of study covered by creatology and sozidonics (see below). History will make the final selection.

Objective of the Science of Creativity

Since science (from Latin *scientia*, "knowledge") in general is the activity of building and organizing "knowledge in the form of testable explanations and predictions about the universe," the objective of the science of creativity is to build and organize knowledge about creativity.

Creativity as a Subject of Study

The main task for the researchers shaping the science of creativity is to define the volume of the concept, i.e., to place it where it belongs. A theorist of science has to determine the most probable place between the two extremes: maxi-creationism (longing for eternity) and mini-creationism (longing for zero).

The first one states that creativity is everything and everywhere. God (nature) created universe, so God (nature) is creative. Atoms create molecules, molecules create organisms, organisms create psyche and societies, psyche creates reflection and reflections of reflections (knowledge), etc. So God (nature) is creating and recreating the universe and its own reflection; the science of creativity, therefore, has to study everything (∞).

The opposite approach states that creativity is a very specific (extremely short, like a flash) moment that happens in the mind of an individual (or God). So, actually, there is nothing (0, zero) or a close-to-nothing moment to study.

Science of Creativity, Table 1 Creatology and its subscience domains

Science name	Creatology = the science of		
Subject studied	creativity,	invention, &	innovation
Subscience name	?	Inventology	?
Sub-subject studied	Creativity	Invention	Innovation

The majority of scientists are somewhere in between, but here begins the heated discussion on where creativity belongs and how it is separated from all the other concepts like imagination, innovation, invention, etc. (see ▶ Nature of Creativity).

The analysis of creatology concept makes it a good example. As it is seen from the blog text cited above, creatology claims to study various aspects of creativity, invention, and innovation. Thus, the subject of creatology is not only creativity but also invention and innovation. Since creatology founders also offer a separate science for studying inventions, the structure of the subject and sub-subjects claimed to be covered by creatology (as mentioned above) looks like Table 1.

If the name inventology is offered for the study of inventions (one of three subsciences), then the question marks in the Table 1 indicate the absence of specific names for the science of creativity as well as for the science of innovation.

Research shows that Russian scientists introduced the science of innovation, called Инноватика/*Innovatica* (or better *innovatics*) in 1980–1990s. There are departments of innovatics at some universities. Books on innovatics are published (Poskryakov 1988). Obviously this term and this science fit the structure of domains depicted in Table 1 and fill the empty cell on the right.

With the innovation domain covered by innovatics, the only subdomain left uncovered is that of creativity. Sozidonics, described above as the science of creativity specifically dedicated to this (and only this) subject, meets the need and can be placed in the left empty cell.

Science of Creativity, Table 2 Creatology, sozidonics, inventology, and innovatics

Science name	Creatology = the science of		
Subject studied	creativity,	invention, &	innovation
Subscience name	**Sozidonics**	Inventology	**Innovatics**
Sub-subject studied	Creativity	Invention	Innovation

The terms added to Table 2 are in bold

In this case, the structure of sciences covered by creatology could look like that in Table 2.

New Vision of Creativity

Dr. Magyari-Beck in his article "Creatology" states that "the word creativity has already lost its previous, merely linguistic meaning and has gradually acquired a position of a new scientific term which should be defined in a new and much larger way within its own frame of reference" (Magyari-Beck 1999). Then there follows the reference to the article *Definitions of Creativity*, which offers *no* definitions of creativity at all.

The article on creatology does not offer any new vision (new definition) of creativity either.

Sozidonics has to fill the gap.

To help people visualize the place of creativity as a phenomenon and the new vision of creativity, here is the explanation and the logic behind it.

Big Picture

The new vision, or a new approach to creativity, is a top-down approach, i.e., a theoretical approach rather than empirical one built from bottom-up. It starts from the vision of nature as a whole.

Nature, whether it is the creation of God or a self-developing entity, is an everlasting process of newness production. Humans are both the largest producers and the largest consumers of newness: new products, new events, new presidents, new movie stars, new tragedies and comedies, new discoveries and mistakes, new. . .new. . .new....

Since newness is everywhere in nature, it makes for a huge object of study, and the task of a researcher is to discover the general mechanism of newness production, to classify this newness, to find the laws of newness production, and to find the ways of predicting the future development. Novology (see ► Novology), the science of newness, does this (Aleinikov 2002b).

There are five main, easily identifiable levels of organization in nature and, therefore, five levels of newness: physical (particles, rays, atoms), chemical (molecules), biological (cells and organisms), psychological (self-reflecting, or psyched organisms, called individuals), and social (societies). Numerous sublevels are available within every level, but this is beyond the scope of this article. These levels are interconnected and interdependent. When placed in the hierarchical order, they look better like this:

5. Social (societies)
4. Psychological (organisms with psyche, individuals)
3. Biological (cells, organisms)
2. Chemical (molecules)
1. Physical (particles, atoms)

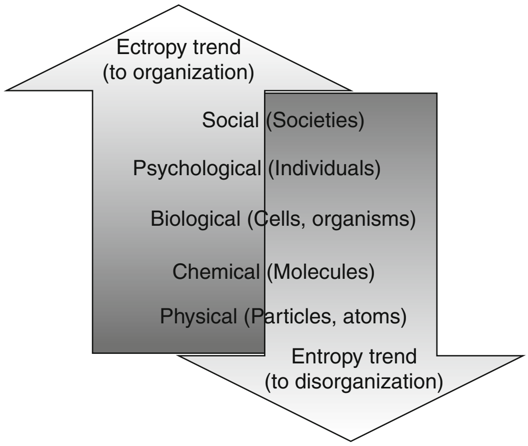
One essence unites all these levels. This is order or organization as a state. Obviously, the higher the level, the more organized it is (because it incorporates the organization of the previous level and adds its own organization) and vice versa: the lower the level, the less organized it is. The movement from the lower level to the higher level is called ectropy (the trend to higher order, the process of organization), while the movement to the lower level is called entropy (the trend to lower order, the process of disorganization).

The trends, levels, and elements of nature development are shown on Fig. 1.

Creativity definitely belongs to the ectropy trend on the psychological level (level 4, Fig. 1), while innovation belongs to the social level (level 5, Fig. 1). **Creativity is the production of newness (new order of things and processes, new organization), while innovation is the consumption of this newness by the society**.

However, creativity is not just production of newness but the process of accelerated newness production. The point is that new images, new emotions, new thoughts, new associations, etc., exist in the everyday life of every individual. This is *not yet* creativity. This is the natural speed

Nature Trends and Levels (Elements)



Science of Creativity, Fig. 1 Trends, levels, and elements of nature development

psychological life. Only when this natural process gets accelerated, and as a result, new ideas, new thoughts, new products are produced faster than is considered natural, then people call the person doing it "creative."

Therefore, the scientific definition of creativity is the following: **creativity is a human activity of accelerating the natural process of organization and/or decelerating the natural process of disorganization**, or even shorter: **creativity is a human activity of accelerating organization and/or decelerating disorganization** (see ► Creativity Definitions, Approaches).

In everyday life, the organization processes are called birth, growth, development, etc., while the disorganization processes are called decline, decrease, withering, death, disintegration. Any entity in the universe, including universe itself, has its birth, development, peak of development, and then decline and death.

The following figure illustrates the essence of creativity.

Notice how Fig. 2 shows that at a certain moment of time (T_1 or T_2), the organization level O_1 (accelerated development) of any entity is higher than O_2 (natural speed development), and the organization level of O_3 (restoration, repairing to decelerate the decline) is higher than O_4 (natural speed decline).

Business people, trainers, consultants, and engineers favor this scientific explanation of creativity because now they request funds for *better organization*, for *faster processes*, and for *accelerated production* (not just for creativity training that looks "fluffy" to some managers and corporate leaders).

On a bigger scale, society needs individual creativity for *better organization* of the society. Moreover, the society (country, state, city, business, educational institution, etc.) that encourages creativity and provides training in creativity increases the creative output of its members and thus is developing (to better organization) in an *accelerated manner*, i.e., faster.

Examples are convincing:

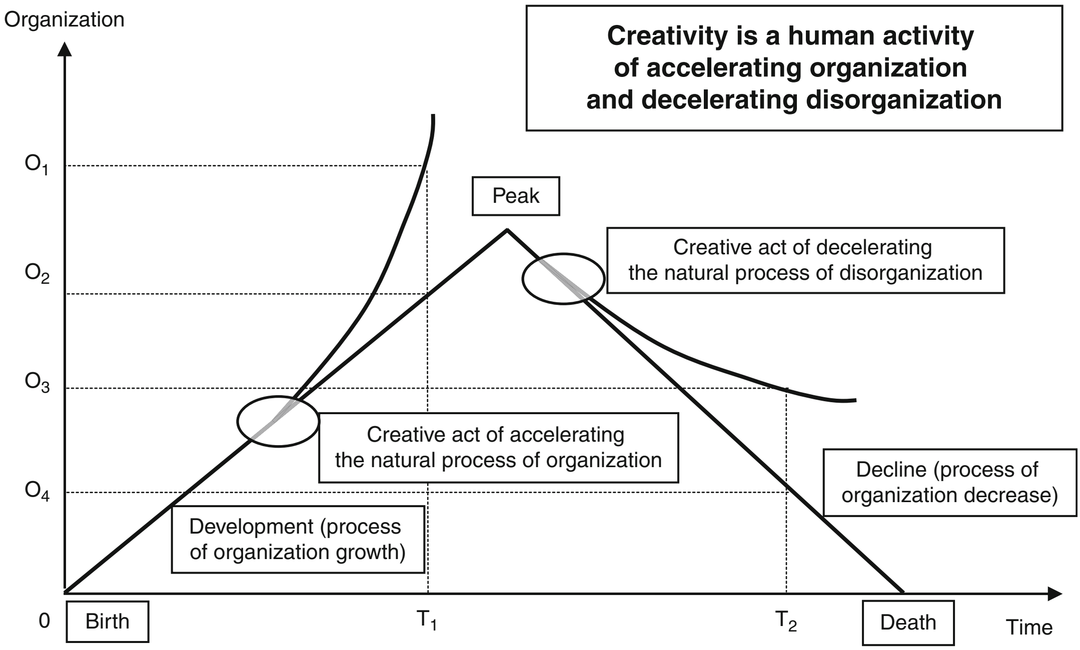
- The Soviet Union (and socialist bloc) was *not* allowing the flow of information, restricted freedom of speech, excluded the free market business relationship, expanded bureaucratic control, eliminated patenting (technological creativity), minimized royalty for creative output in arts, and thus slowed down the society development, began to fall apart, and finally disintegrated (to lower organization).
- Democratic societies, on the contrary, allow more creativity in all spheres of life thus encouraging creative output from individuals, and therefore, these societies gain better technology, better results in sports, medicine, and social activities, and finally climb to *better organization*.

This explains why and how democracy wins over all other political systems and certainly over dictatorships. Creativity – the accelerator to better organization – is the key to faster development!

Sozidonics, the science of creativity, explains not only what creativity is but also how it influences the accelerated development of the society.

New Models of Creativity: Strive for Universality

The new science of creativity needs a model of creativity that is applicable to all domains, all levels, styles, types, and kinds of creativity. It has to reflect the smallest creative act (like a speech act) and the largest creative act,



Science of Creativity, Fig. 2 The essence of creativity

like a discovery. Even God's act of creation (not to mention all the other human acts) should be reflected by the model. Universality is the #1 requirement for science. Repeatability and testability are #2 and #3, respectively.

Analysis of available creativity models demonstrates that they miss one greatly important aspect: all ideas/solutions/decisions have to be expressed, i.e., pronounced, written, performed, sculptured, painted, etc. The system of expression has to be in the model. It may be a language system or any other system of signs, but it has to be material to represent the ideal idea/solution/decision. Otherwise, neither the simplest idea nor the most complex solution can be transferred to others or, in the final run, even detected.

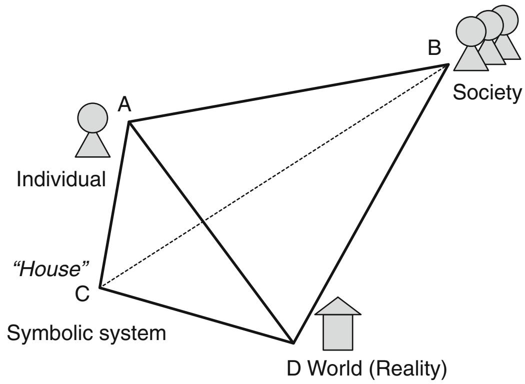
In everyday life, an idea should be worded, voiced, articulated, written, jotted down, and scribbled. In case of the top-level creative achievement, the genius idea should be expressed in some semiotic system, the system of symbols, and then published, exhibited, and publicized. Whether it is a formula, a theory, a discovery, a melody, a painting, a sculpture, or a pedagogical approach, it must be expressed in a system of signs (see ▶ Genius).

With this element added, the creative act situation becomes a particular case in the universal state of order reflected by the universal model of sign, language, language awareness, speech and heuristic acts, first developed in 1977 and then adapted for creative linguistics (see ▶ Creative Linguistics and Aleinikov 1988a). This is a four-sided model in 3D (Aleinikov 1985; 1988b).

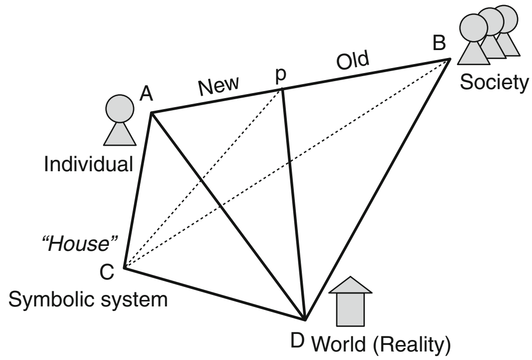
The universal model of sign, language, speech act, and heuristic act looks like Fig. 3.

In general, as Fig. 3 shows, an individual (A) is the person who creates a vision of the world (D), expresses it in symbols of the system (C), and sends it to the society (B). Society is understood as any person, or persons, speaking the same language or using the same semiotic system. The message (AB) is received by the society (B), evaluated, and appreciated or not appreciated.

The real human mind in the process of thinking/creating may run over this model in different directions: from A to B, from A to D, from A to C, from C to D, from D to B, from C to B, and in all



Science of Creativity, Fig. 3 Universal model of sign, language, language awareness, speech and heuristic acts



Science of Creativity, Fig. 4 The new/old plane in the model

directions back. The human mind may do it several times, loop after loop, before delivering the message (AB), but invariably in any speech and creative act, there will be the reflection of all four absolutely necessary (universal) elements:

- Who (A, individual, sender, creator)
- To whom (B, society, receiver, evaluator)
- What (D, world, vision of the world)
- Expressed by what (C, symbolic system)

  Here is the test:

- A fine artist or a sculptor (A) expresses his unique vision of the world (D) in his/her personal manner (C) and shows it to public (B) that evaluates it.
- A scientist (A) finds a new fact, process, regularity of one's field (D), writes an article in scientific terms (C), and sends it to the publisher (B) for publication.
- A teacher (A) creates a new method of teaching in education domain (D) and makes a report (C) for her colleagues (B).
- An actor (A) in his/her specific manner (C) performs a role in a play about the world of love (D) on stage for spectators (B).

In the particular case of a genius (top creativity level), the message (AB) is so uniquely expressed in a symbolic system (C) and reflects such a highly innovative vision of the world (D) that it is top-valued by the society (B). That is why this individual (A) is named a genius (see ▶ Genius).

Notice how the pattern repeats itself in the explanations above. It is exactly what science is: it provides testable and repeatable knowledge.

The next issue to address here is how much newness is expressed by the individual (A) for the expression (AB) to be evaluated by the society (B) as low creative, quite creative, or highly creative.

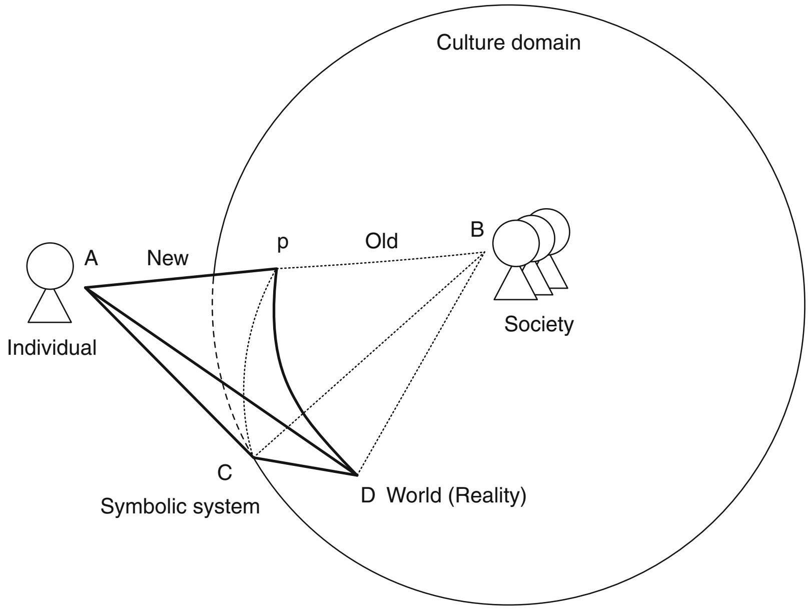
For this purpose, the model contains a special plane that cuts the old and the new in the message. The cutting plane (CDp) looks in general like Fig. 4.

As is illustrated by Fig. 4, any creative act (statement, report, article, book, research, painting, show music, theatrical performance, etc.) consists of the old (BCDp) and the new (ACDp) parts. In the case of everyday creativity, this newness part is smaller. In the case of theater performance, conference presentation, or gallery show, this newness part should be bigger. In the case of genius, this "new" part (what genius has discovered and now communicates to the society) is much larger than the "old" part (what society already knows).

The model of interaction between the individual creator and the society with its culture in general looks like Fig. 5.

As Fig. 5 demonstrates, an individual (A), who discovered, found, invented, thought up, learned something new, or in other words created a new vision of the world (D), has to pack this new vision into an acceptable code (language)

Science of Creativity, Fig. 5 Model of creative act expanding culture



or express it in some symbolic system (C) also known to the society (B) and then sends a message (AB) consisting of known volume (pBCD) and also new volume (pACD) that is expanding the volume of culture (knowledge, experience, customs, beliefs, etc.). This is the modification of the figure published first in the article titled "Humane Creativity" (Aleinikov 1999a).

This model of creative act is universal, repeatable, and testable. It works for any creative act (including God's creation), and it also promotes deeper analysis of the creativity act, such as systems' organization levels (function, substance, structure), coding planes, and so on when needed (see ▶ Creative Linguistics). It permits profiling newness (see ▶ Novology) and picturing genius results (see ▶ Genius).

Classification of Creativity

In addition to traditional classification of creativity as artistic creativity, technological creativity, scientific creativity, etc., which follows the domain of human activities, sozidonics offers a new classification that is based on the described above five levels of nature organization.

Sozidonics differentiates the following types of creativity:

- Existential (how to exist physically, how to survive)
- Communicational (how to relate, to communicate, to interact)
- Instrumental (how to develop tools, new organization)
- Orientational (how to select the social goals and objectives, where to use the tools)
- Innovational (how to implement the found newness)

This new classification allows sozidonics and geniusology that stemmed from it to detect new types of geniuses, or in new science terms, "the most powerful accelerators to better organization" (see ▶ Genius).

Units and Measurements for Measuring Creativity

Measuring human mental characteristics in general is quite popular. Some websites list about 4,000 commercially available tests. Measuring creativity is a significant part of it (see ▶ Measurement of Creativity). As Gerard Puccio, the Head of the International Center for Creativity

Studies, Buffalo, NY, states, "since 1950 researchers have developed an array of formal methods for measuring creativity" (retrieved from http://www.acsu.buffalo.edu/~stferry/ March 6, 2012). It can be measured by self-assessment, aptitude, and ability tests; by interviews and observations; by rating scales in peer, parent, and teacher rating/nomination; by products created; by awards (recognition), etc.

According to the above-mentioned Isaksen's model of creativity, there are 4 P's that can be measured: person, process, product, and press (environment pressure).

- Just to mention a few that assess the *person*: Creativity Attitude Survey, Creativity Tests for Children, Creative Behavior Inventory, Khatena-Torrance Creative Perception Inventory, Myers-Briggs Type Indicator, Hermann Brain Dominance Instrument (HBDI) by Ned Hermann, Neethling Brain Instrument by Kobus Neethling, etc.
- The most well known among measurements that address the *process* are Buffalo Creative Process Inventory (by G. Puccio) and Kirton Adaptation-Innovation Inventory (KAI).
- The instruments that assess characteristics of creative *products* include Consensual Assessment Technique and Creative Product Semantic Scale.
- One tool that assesses the *press* or the climate for creativity and innovation is KEYS (originally called Work Environment Survey) developed by the Center for Creative Leadership.

According to the Creatology Matrix, introduced by Magyari-Beck, it is the abilities, process, and product of the person, group, organization, and culture that need to be measured. In 1990, A. Aleinikov designed the ALEANDR creativity test battery that measured individual and group creativity at the same time (Aleinikov 1990).

The most well-known system of evaluating creativity as **ability** is the Torrance Creative Thinking Test (Torrance 1986). This test presents some tasks to people and then rates their abilities. Longitudinal research is possible with such an approach, and Dr. Torrance made a colossal effort to follow up his "Torrance kids" for 50 years (see ▶ Creativity Tests).

Another well-known system of evaluating creativity that measures the **style** of creativity (not **level of abilities**) and differentiates "innovators" (tending to change the system) and "adaptors" (tending to preserve and improve the system) with "bridgers" in between is called the Kirton Adaptation-Innovations Inventory, KAI (Kirton 1994) (see ▶ Adaptive Creativity and Innovative Creativity).

Despite numerous attempts to measure various aspects of creativity, there is still no such a thing in creativity research as unit of measurement, like meter, second, gram, Ohm, Hertz, or Volt in physics, like parsec in cosmology and byte in cybernetics.

The presence of units in this or that field of research to some extent shows whether it is a science or not. Qualitative units and quantitative units of measurement are a must. Measurements are the foundation of any science.

Therefore, in general, when transforming the creativity research field into the science of creativity, one has to move from general measurements to specific measurements and from empirical measurements (often commercial use oriented, used for testing and training purposes) to theoretically based measurements.

With the development of the new vision of creativity and new definition of creativity that emphasize the acceleration to higher organization (discussed above), sozidonics developed a new measurement system and a new unit that measures the efficiency of creative output, i.e., the number of ideas per second. The new unit of measurement established as 1 idea per second is called Alein just as in physics, 1 cycle per second is called Hertz.

This measurement allows researchers not only to evaluate individual performance but also objectively to evaluate the creative power of methods that boost creativity.

Illustration

Case A. Alex Osborn mentioned that brainstorming allowed people to generate 90 ideas in one and a half hours (Osborn 1953). Truly, brainstorming is the most famous technique in the creativity enhancement market; it made history!

Case B. Max Fisher many years later offers a new "revolutionary" (as he claims) method "IdeaFisher" in the book with the same title *IdeaFisher*. This is how it is described, "Those without the list (of words) only worked an average of 55 min, when they "ran out of ideas." Those with the list worked an average of 78 min – a 42% increase. There was also a statistical difference in the number of ideas. Those without the list produced an average of 55 ideas. Those with the list produced an average of 86 ideas – an increase of 56%" (Fisher 1996).

Comparison

Calculation shows that the efficiency of creative output in the brainstorming session in *Case A* equals 1 idea/min (90 ideas/90 min).

The efficiency of creative output in *Case B* (without lists) is exactly the same as in brainstorming (*Case A*): 1 idea/min (55 ideas/55 min). The efficiency of creative output in the session with the lists is 86 ideas divided by 78 min = 1.1 ideas/min.

So when the author states a 42% increase in time of work and 56% increase in idea output, these are calculations in absolute numbers. The result looks good and may sound "revolutionary." However, in objective calculation (new measurement), using the concept "specific creativity," the increase in creative output efficiency is only 10%, (1.1 vs. 1). This result is quite far from "revolutionary" – not 10 times (1,000%) or 100 times (10,000%) increase.

If calculated in new units, the creative output efficiency of brainstorming is 1 idea/1 min = 1 idea/60 s = 0.017 Alein, and the creative output efficiency of IdeaFisher is 1.1 ideas/60 s = 0.018 Alein. The word "revolutionary" is certainly out of context here.

The introduction of the new type of measurement made it possible to compare the generative power of techniques, methods, and methodologies for boosting creativity and finally led to the development of methods delivering 1,000 ideas/min (kilocreativity), 1,000,000 ideas/min (megacreativity), and more (Aleinikov 1999b, 2002a). Teaching these methods allows human beings (whether children or adults) to overcome the generative power of natural genius (about 100 ideas/min = 1.8 Alein) 10 times and even 10,000 times.

This is how the new scientific approach expanded the natural human creativity power.

Practical Applications of the Science of Creativity: Improving and Accelerating the Existing Results

The formation of the new science of creativity is worth doing only if it leads to outstanding results, only if it shows a leap to unusual achievements (like genetics led to genetic engineering, cybernetics led to the computer age, etc.), thus demonstrating that the new science is much more powerful than the prescientific approaches or the situation without established science.

The first applications of the new science showed significant achievements in the four main areas: science and arts, business and education, as well as some other areas.

- **When applied to the field of science**, the new scientific understanding of creativity led to the *accelerated creation* of 7 new sciences and 3 new fields of research, as well as the *accelerated discovery* of 11 new laws of conservation and 12 new measurement units, not to mention new models, new theories, new concepts, etc.
- **When applied to the field of education**, the new science led to the *most accelerated methodologies* of human mind reorientation from passive, disinterested, negative, lazy, and having low goals into active, interested, positive, ready to work hard, and having high goals.
- **When applied to the field of business** (in this particular case, the business of publishing), the new science led to the Guinness World Record results, i.e., *most accelerated* – (certified) top world accelerated speeds in publishing.
- **When applied to the field of arts**, the new science allowed a group of students in

Psychology of Creativity class to create a new style of arts. So what usually needs 50–100 years *was accelerated* to 10 h of classes.

- **When applied to the field of creativity** itself, the new science led to the design of the *most accelerated methods* of boosting creativity to the megacreativity level and above.

Some details are as follows:

Result #1. The new scientific definition of creativity (see ▶ Creativity, definition entry, and ▶ Creativity Definitions, Approaches) leads to establishing the science of creativity (sozidonics). Thus, what was called the "emerging discipline" or "the field of research" is *accelerated to a higher organization* – transformed into a well-organized science.

Result #2. The research and the experience of structuring the new science of creativity led to general understanding on structuring new sciences. As a result, new sciences, such as agogics (see ▶ Creative Leadership), geniusology (see ▶ Genius), novology (see ▶ Novology), organizology, and intensiology (Aleinikov and Gera 2006), as well as new fields of research, such as creative linguistics (see ▶ Creative Linguistics) and creative pedagogy (see ▶ Creative Pedagogy), have been designed and introduced for scientific research. This is expanding the modern science horizons. The discovery of these new sciences and research domains not only corroborates the process of *acceleration* in science development (seven new sciences and three new fields of research) but also clearly illustrates a direct giveback from the new science of creativity to the creativity of science.

Result #3. The research of new discovery methodologies, in particular Robert Oros di Bartini's achievements, led to the discovery of a new law of conservation (Aleinikov 2007a) and then 10 more new laws of conservation by a California-based group of researchers (Aleinikov and Smarsh 2010). For comparison, the previous (natural) development of physical science showed the tempo of one conservation law per 50–100 years. Now, the new understanding of creativity and research of genius methods of thinking from this new point of view allowed researchers to *accelerate the physical science organization* to two new laws per year, i.e., about 200 times acceleration.

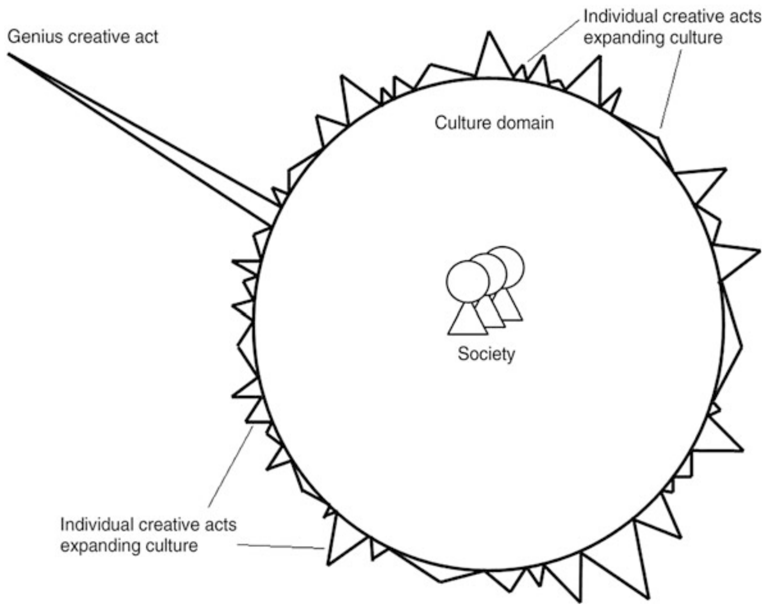
Result #4. Search for new creativity-enhancing methods and techniques led to introduction of simple techniques like 4Delays4GeniusWays and semiotic modeling (Aleinikov 2002a) but also to the introduction of methods that *accelerated* creative output many times to achieve kilocreativity (1,000 ideas/min), megacreativity (1,000,000 ideas/min), and more (Aleinikov 1999b, 2002a). See comparison of brainstorming and IdeaFisher above. For more techniques, see ▶ Creativity Techniques.

Result #5. New measurement units for measuring objective and subjective newness, quantitative and qualitative newness, as well as the efficiency of creative output have been developed to *accelerate* the application of mathematical means to creativity research (see ▶ Novology and, for comparison, and ▶ Measurement of Creativity).

Result #6. New tools of research, such as a universal model of creative act, which generalizes and explains everything from a speech act to a heuristic act (see ▶ Genius as well as *Models of Creativity*), have been introduced. Since it is a graphic model (in terms of graph theory), it allows researchers to visualize creative activities (one picture is worth a thousand words), thus *accelerating* the comprehension of complex concepts and processes. Moreover, having one model for many phenomena follows the principle of economy of force in education, thus *accelerating* the learning process.

Result #7. New definitions (new understandings) led to the development of new educational methodologies and new pedagogy aiming at creation of ideal learner, active, interested, enthusiastic, and ready to work hard, which *accelerates* the study of *any* material, whether it is languages, natural or social sciences (see ▶ Creative Pedagogy). Some of these new

Science of Creativity, Fig. 6 Genius creative act expanding culture



methods like *M*ethod of *A*pplied *N*onverbal *Do*minance (MANDo) and genius expectations, genius achievements (GEGA) have been published and republished as "Classic" by the *Teaching for Success* online magazine (Aleinikov 2007b, 2009). The new approach to education has been published as an editorial by the *International Journal of Innovative Higher Education* (Aleinikov 1995). These methodologies change children and adults, teachers and professors, schools and colleges. Students and teachers who learn to apply these new methodologies receive their educational institutions' and even countries' top awards. Some description of the educational results may be found in Aleinikov (1996) and Aleinikov (1990b) (see ▶ Creative Pedagogy and ▶ Genius).

Result #8. New educational methodologies, based on the new definitions, turned out to be so effective that they allowed educators to raise the plank from traditional education goals (learning some material and testing well) to nontraditional goals, like changing the mind set and aiming at the highest levels of self-improvement – the top creativity level – genius. Genius Education Methodology (GEM) has proven to be saving geniuses and revealing hidden genius in the children – even those seemingly lost by traditional education (see ▶ Genius and ▶ Creative Pedagogy). This *accelerates* the natural process of genius growth. Also, in the future, these "geniuses" will *accelerate* the development of the countries that initiated the process (see Fig. 6). As Fig. 6 demonstrates, the Genius creative act is much more powerful and much more advancing the society than usual individual creative acts. That's why geniuses cause much more accelerated society development, or, in new term, accelerated expanding of culture domain.

Result #9. New university-level subjects have been introduced to the higher education field: Creative Linguistics (ENG2210), Psychology of Creativity (PSY3390), and Foundations of Creative Pedagogy (EDU6625). This introduction *accelerated* the exposure of adult students to creative learning while learning languages, psychology, and education.

Result #10. The new definition of creativity as accelerating organization led to such outstanding business applications as the Guinness World Record in publishing for the fastest written, printed, and published book titled "Making the Impossible Possible" (15 h and 46 min "from scratch to publication") in 2001 in South Africa. It has proven that such a tedious task as book writing (traditionally from a year to 25 years) and book publishing (from 6 months to a year) can be reorganized in such a manner that the process is *accelerated* over 300,000 times.

From the list above, it becomes obvious that the correctly defined **scientific essence** of the phenomenon of creativity, as it usually happens with any science, can make correct predictions, boost practical results, and lead to accelerated development in any field.

Conclusion and Future Directions

Since in the history of humanity creativity was used for solving problems in practically all fields, it varied greatly in its outlook, and that is why it was often not even seen as creativity. After a century of thorough studying, when the creativity phenomenon had been investigated by numerous sciences, the convergent stage of collecting and rethinking the data has been mainly completed. The processes of generalization, restructuring, and designing of the new understanding led to a logical conclusion – the science of creativity.

As a new science, the science of creativity has a new name – sozidonics. It formulates its objectives and the subject of study. It offers a new vision of creativity (new definition), new model of creativity, new classification of creativity, new units and measurements for measuring creativity, thus fulfilling the main criteria for becoming a science.

The new scientific concepts, models, and theories have been tested in the domains other than creativity: in science and arts, business and education where they helped achieve high level results. With the theoretical and practical results so advanced and the proof of success so obvious, sozidonics has proven its right to be considered a science and is now ready for its next divergent move.

First of all, the pattern of creating new sciences (like sozidonics, novology, and geniusology) would be applied for the development and description of already announced new sciences. Organizology and intensiology are waiting for their turn.

Second, at present, in addition to already developed directions, sozidonics is spreading to such diverse areas as:

- New ways of resources conservation
- New ways of treatment in medicine
- New methods of training in sports
- New methods of education in early childhood
- New engines and tools in the financial arena
- New methods of gang fighting and crime prevention

Thus, the new science of creativity in the terms of Sid Parnes, the "father of creative problem solving," opens "for new challenges." The prediction is that with most accelerated methodologies, it will achieve outstanding results in these areas too.

Third, and final, sozidonics, as with any science, is never completed. It should and it will continue to develop itself: the horizons and the opportunities are unlimited.

Scientific Creativity as Combinatorial Process

Dean Keith Simonton
Department of Psychology, University of California, Davis, CA, USA

Synonyms

Blind-variation and selective-retention theories of scientific discovery

Introduction

The progress of science depends on creative ideas. An idea is creative if it is novel, useful, and surprising. A novel idea has never appeared before; a useful idea entails a theory, technique, or empirical result that advances a particular scientific discipline; and a surprising idea is one that is not an obvious derivation from an already existing idea. These three criteria closely parallel those that the US Patent Office uses in evaluating whether inventions warrant patent protection. Given these definitions, the fundamental question then becomes: Where do scientists get their creative ideas? One answer is to make appeals to "strokes of genius," "flashes or insight," "brilliant intuitions," or some other romanticized concept. Such responses do not provide a scientific basis for understanding creativity in the sciences. They seem to suggest that creative ideas can emerge de novo. Yet for science to constitute a cumulative enterprise, even the most creative scientists must build upon the theories, techniques, and results of their predecessors. Even Isaac Newton admitted that he stood on the "shoulders of giants."

The mathematician Henri Poincaré (1921) provided a superior answer: Creativity is combinatorial. Old ideas are recombined to generate new ideas. He even suggested that this combinatorial procedure is effectively random. Nonetheless, it is not necessary that the combinations be random so long as they are blind, that is, the ideas are generated without knowing in advance, which combinations will prove fruitful and which will fail. This latter provision is assumed in blind-variation and selective-retention theories of scientific discovery (Campbell 1960). Although all random combinations are blind, not all combinations are random. To illustrate, a systematic search is blind without being random.

Combinatorial models have made important contributions to comprehending scientific creativity (e.g., Fowler 1987; Thagard 2012). To provide an overview, the three systems involved in creativity are defined first. Then implications are drawn for each of the systems.

Three Systems

Scientific creativity requires the interaction of three systems: the domain, the field, and the individual (Simonton 2010). The domain and the field together constitute a scientific discipline. The domain consists of a set of ideas that define a particular discipline. The field consists of the fellow scientists who are actively contributing to that domain. These colleagues are ultimately responsible for deciding whether any scientist has contributed to the discipline. This decision is made in peer review and citation practices. Fields can also vary in size: New fields tend to be small, old fields large. Finally, the individual is one of the members of the field. In most combinatorial models, he or she is the actual locus of creativity (e.g., Simonton 1988; Thagard and Stewart 2011; but see Fowler 1987).

Combinatorial creativity cannot begin until each individual scientist first obtains a sample of ideas from the domain. Presumably, these ideational samples are acquired during education and training, albeit a significant portion can be acquired through independent reading and study. Furthermore, the samples are not identical for each scientist, even for scientists active in the same field. For one thing, scientists can vary in the sheer size of their ideational samples. Whereas some scientists may be extremely focused on a very narrow specialty area, other scientists will exhibit much broader interests that encompass most or all of the ideas representing a given domain. Another important difference is whether the samples of ideas are confined to a particular domain or instead cut across two or more domains. An instance of the latter is the scientist who changes fields, bringing the knowledge of one domain to bear on the new knowledge acquired in another domain. A final contrast is related to the previous two: to what extent the scientist's sample of ideas overlaps the samples of other scientists working in the same domain.

Each individual's ideational sample is then subjected to combinatorial procedures. These procedures may be either implicit (intuitive and haphazard) or explicit (conscious and systematic). Of all the combinations generated, only a small number will prove sufficiently creative. These ideas will then undergo development and elaboration into a completed paper that can be submitted for publication. If the paper passes peer review, its creative ideas become part of the domain and thus can enter the ideational samples of other scientists. The upshot is a cyclical process that allows for the accumulation of knowledge.

Individual System

Combinatorial models at the individual level attempt to describe the key features of scientific productivity (Simonton 1988). One of these features is how scientists vary in total lifetime output. This variation is characterized by an extremely skewed distribution with a long upper tail. As a result, a smaller percentage of the scientists in any field account for a disproportionate amount of the creative products. Specifically, the top 10 % may account for as much as half of all output. This skewed distribution is surprising insofar as most individual-difference variables underlying creativity – such as intelligence, openness to experience, and divergent thinking – would be expected to be normally distributed. Nevertheless, if it is supposed that the domain samples of each type of scientist are of unequal size, and if it is assumed that the size of these samples is normally distributed across members of the field, then it follows that the total number of ideational combinations that can be generated must be described by a highly skewed lognormal distribution. That results because the number of combinations increases exponentially with the number of ideas being combined.

More complex are the combinatorial models that attempt to try to explain how total output is distributed across the course of a scientist's career (Simonton 2004). The simplest models predict that creative ideas will be randomly distributed across the career. That prediction arises under the assumption that the combinatorial process operates according to BVSR, that is, blind variation and selective retention. That is, because the scientist cannot anticipate the novelty and utility of a combination until after it is generated and tested, creative combinations will come and go throughout the career. In contrast, if the combinatorial process were highly sighted, then the best ideas would be produced first, and the less creative ideas would appear later in the career. In short, in the absence of BVSR, scientists should show a progressive decline in creativity with age.

The previous model is highly simplified. It just assumes that scientists are merely pulling balls randomly out of an urn and then saving the combinations that satisfy some criterion. For example, the balls might be marked with integers, and the individual must identify those combinations that represent prime numbers (as in the sieve of Eratosthenes). More sophisticated models allow for the fact that the creative process is more complex than that (Simonton 2010). For instance, one model posits that creativity consists of the two-step process of ideation and elaboration. Combinations of ideas are generated in the ideation stage, but these combinations must then be elaborated into final creative products. Because of the temporal delay imposed on the combinatorial procedure, creative ideas will be distributed unevenly over the course of the career. In particular, annual output will rise rapidly to a peak productive age after which a gradual decline sets in, approaching a zero productivity rate asymptotically. With the addition of further complications, such models can account for the finer features of output. For instance, if the ideation and elaboration rates are allowed to vary across domains (to reflect the nature of the ideas in those domains), then different output trajectories will be predicted for various domains. Thus, because the ideation and elaboration rates are much faster in mathematics than in the earth sciences, mathematicians will have earlier career peaks than holds for earth scientists.

These and other predictions have been successfully tested against empirical data, lending support to the conjecture that individual creativity depends on combinatorial procedures (Simonton 2004). Moreover, computer simulations have provided insights into how the combinatorial process might operate (Thagard and Stewart 2011). Lastly, it should be noted that the hypothesized combinatorial process is compatible with those psychological theories of the creative process that assume the involvement of remote association, divergent thinking, and defocused attention (Simonton 2010). These provide the means for freely linking the ideas making up a scientist's domain sample.

Domain System

It was said that the three-system cycle permits the accumulation of scientific knowledge. This growth raises the issue of how fast that knowledge accumulates. As a first approximation, because the total number of scientists has been increasing exponentially, one might suppose that scientific knowledge has also been increasing exponentially. Yet this inference neglects the repercussions of having the domain size increase as well. If the addition of new ideas is a joint function of field size and domain size, then the growth will be accelerated even more (Fowler 1987), providing the basis for the "information explosion." One consequence of this explosion is that disciplines will much more quickly fragment into largely independent subdisciplines. The domains and fields become too vast to continue as coherent endeavors. Of course, this accelerated trend also puts more pressure on scientists to become much more specialized, reducing the prospects for grand integrative theories.

Field System
