Foreword

From a practitioner's point of view, this encyclopedia offers a wealth of academic rigor in regard to the use of information technology in both clinical and health care administrative settings. Many people working in the field find they encounter challenges when using technology with the goal to improve patient outcomes. One key challenge is finding ways to financially support research, develop, implement, and sustain new health care delivery processes. There has been some success achieved in small local settings and in countries where there is an inherent culture for collaboration. But it seems that large macro national and international achievements are still very allusive. Unlike any other market sector, health care is one of the most universal. This is evident with its demanding and globally accepted academic standards. This leads one to believe that health care is a perfect candidate to continuously deliver world wide successes. So why is it such a challenge to realize large-scale improvements in health care using technology?

When trying to implement new health care technology initiatives, the financial challenge may be a symptom of a much deeper problem. Upon further analysis, one possibility is there is a gap between practitioners and researchers. Both these players have a vital role in transitioning an idea to realization in the use of technology in health care. A researcher provides the academic rigor and peer review to achieve consensus, whereas a practitioner uses experience to implement these ideas in the field and supply quality data to support enhanced patient outcomes. Through their joint efforts, a unique core competency can be formalized and designed for the ever growing knowledge-based economy, with the hope that these endeavors will produce effective and efficient enhancements in the health system; a system that supports physicians, nurses, and other health care givers in patient care without access or cost barriers. Removing any gaps between research and its practice may be the catalyst necessary to produce results that achieve international acceptance and justify funding for worldwide execution.

Building new partnerships between researchers and practitioners may be the beginning of a new era in applying technology in health care. New linkages can be formed where both groups are working together on the same project. The researcher views it as a data collection project to support their studies and the practitioner views the project to support their technology implementations. Success is measured on how quickly the partnership can achieve a positive and global impact in health care.

In addition to offering a wealth of knowledge on health care information systems for researchers to share ideas, this encyclopedia is an excellent resource for practitioners potentially seeking new partnerships. Using this publication, practitioners have a wonderful opportunity to read, discover, and contact researchers that can help accelerate global achievements in applying health care information systems.

In summary, the encyclopedia can be viewed as a starting point to help form new information technology partnerships that support the growth of the knowledge economy, remove barriers from care giving, and enhance health care delivery for the most important person: the patient.

Preface

Health care is an important industry that touches most, if not all of us at some time in our lives. Health care is noted for using leading edge technologies and embracing new scientific discoveries to enable better cures for diseases and better means to enable early detection of most life threatening diseases. However, the health care industry globally, and in the U.S. specifically, has been extremely slow to adopt technologies that focus on better practice management and administrative needs. Presently, health care is grappling with many challenges both nationally and globally, including escalating costs, a move to a preventative care environment, and a technology savvy patient with high expectations. The underlying goal for health care is to provide cost effective quality treatment, that is, realize its value proposition in this challenging environment. In order to do this, health care needs to maximize its information management and utilize information communication technologies (ICTs) prudently as has been noted by leaders of U.S. and the EU as well as leading bodies that focus on global health care issues and policy. During his State of the Union Address in January 2004, President George Bush affirmed the intention of the government to emphasize the role of technology in administration and delivery of health care in the United States (Bush, 2004) and allocated over $200 million for research and development of information technologies in health care. Similar sentiments have been voiced by the European leaders (Global Medical Forum Foundation, 2005; The Oslo Declaration on Health, Dignity and Human Rights, 2003) and the World Health Organization (E-Health in the Eastern Mediterranean, 1997; World Health Organization, 1998). Both European and U.S. authorities define their initiatives primarily in terms of medical information technology centering on computerized patient record (CPR) or, in more acceptable parlance, the HER electronic health record (Brailer & Terasawa, 2003). WHO's platform statement (World Health Organization, 1998) speaks of "health telematics policy," an all inclusive term that incorporates not only HER but essentially all health care services provided at a distance and based on the use of information communications technologies (ICT).

It is useful to think of the major challenges facing today's health care organizations in terms of the categories of demographics, technology, and finance. Demographic challenges are reflected by longer life expectancy and an aging population; technology challenges include incorporating advances that keep people younger and healthier; and finance challenges are exacerbated by the escalating costs of treating everyone with the latest technologies. Health care organizations can respond to these challenges by focusing on three key solution strategies; namely (1) access—caring for anyone, anytime, anywhere; (2) quality—offering world class care and establishing integrated information repositories; and (3) value—providing effective and efficient health care delivery. These three components are interconnected such that they continually impact on the other and all are necessary to meet the key challenges facing health care organizations today. Moreover, it is at the confluence of these key solution strategies that the role of ICTs in health care becomes of particular significance.

Access to health care for anyone, anywhere, and at any time is a goal that is very far from being achieved. ICT has a crucial role to play in improving access to health care. Although ICT cannot by itself perform such actions as diagnosing a medical condition, it can provide low-cost communication between physician and patient that makes a diagnosis possible and innovations could dramatically improve the effectiveness of such remote access as well as address minimal invasive surgery. Other aspects of access are less obvious, but are critical to controlling quality and costs of health care. These include timely access to medical records and universal accessibility to data among disparate information systems and medical devices (AHRQ, 2003; PITAC, 2001). In each case, improvements in ICT design and standards can dramatically increase access.

Quality in health care has six key goals (Wickramasinghe, Schaffer, & Geisler, in press):

1. **Safety:** Avoiding injuries to patients from the care that is intended to help them
2. **Effectiveness:** Providing services based on scientific knowledge to all who could benefit and refraining from providing services to those who will not benefit(i.e., avoiding under-use and overuse)

3. **Patient-centered:** Providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patient values guide all clinical decisions
4. **Timeliness:** Reducing waiting and sometimes harmful delays for both those who receive care and those who give care
5. **Efficiency:** Avoiding waste
6. **Equitability:** Providing care that does not vary in quality based on personal characteristics.

These quality aims will be negatively impacted by poor information quality, flow, and integrity. Conversely, higher quality, flow, and integrity of information can help to reduce the large number of medical errors that currently permeate the health care system (Geisler, Lewis, Nayar, & Prabhaker, 2003; Moore & Wesson, 2002).

Value of health care incorporates the overarching goal of increased productivity, but this goal has distinct aspects depending upon one's perspective, and only some of these aspects are primarily monetary. To patients, the value proposition may be enhanced by reducing time spent in obtaining health care, lowering stress and worry, and increasing satisfaction with the experience. To physicians and clinical support personnel, value may be enhanced by the ability to remotely access medical records and monitor prescribed regimens and patient symptoms. To managers and investors, value may be enhanced by lowering costs of delivering health care in ways that do not compromise access or quality.

Because of the rapidly-decreasing cost structure of hardware, IT is now able to provide many functions that were not previously available, such as connectivity through mobile devices. Thus, IT innovations hold great potential for enhancing the value of health care to patients and stakeholders. Yet, it is not simply the introduction of IT per se that provides a good solution, but often it is necessary to combine IT with new management techniques such as total quality, knowledge management, and business process redesign to achieve success (Sharma, Wickramasinghe, & Gupta, 2004). When we look at health care, we can see that in order to enhance value, we must not simply focus on clinical care but also be cognizant of education, research, and administrative needs of this industry.

This encyclopedia provides an extensive and rich compilation of various ICT initiatives and the role that ICT plays and will play in the future of health care delivery be it in terms of enhancing clinical delivery or enabling administrative activities. International experts address one or more of the areas of access quality and value and thereby represent ways in which health care delivery can be made superior and the health care industry can begin to address it's the major challenges it faces in the 21st Century so that ultimately the most important person in the web of health care players, the patient, can be confident of receiving high quality cost effective health care anytime anywhere.

Presently, to the best of our knowledge, no such comprehensive encyclopedia exists that focuses on ICTs in health care. Hence, this encyclopedia is truly unique and serves to fill an important void in the existing literature. Moreover, given the sentiments of both EU and U.S. leadership regarding investing in ICTs to support superior health care delivery, the timing of this encyclopedia is most opportune.

The purpose of our encyclopedia is to bring together articles by international experts pertaining to critical concepts about the use, adoption, design, and diffusion of ICTs in health care. Ultimately the role of ICTs in health care must address the challenges faced by today's health care environment. We have identified that any truly beneficial solution must focus on access, quality, and value, and thus the management of medical technologies must relate to addressing and facilitating one or more of these solution strategies. We believe that in order to do this in a meaningful and systematic fashion it is essential to focus on five important themes, namely:

a. Generation, adoption, and utilization of medical technologies. This thrust includes research on the organization, financial and managerial aspects of the process of need identification for medical technologies by health care organizations, and the acquisition, diffusion, utilization, updating, replacement, and resources allocation for such technologies.
b. The nature of medical technologies and innovation and the role it plays in health care delivery. This thrust focuses on studies of the generation of medical technologies in industry, universities and the government sectors, and the processes by which such technologies are marketed to the health care delivery sector and their consequent impact on resolving the challenges faced by health care globally.
c. Evaluation of medical technologies. Included in this thrust are evaluation, assessment, monitoring, and auditing of costs and benefits from medical technologies, in health care delivery organizations, and in the supporting industries, such as insurance, regulatory agencies, manufacturing of medical technology, and pharmaceuticals.
d. Ethics, social implications, and patient value. This thrust focuses on ethical considerations and the role of patients in the health delivery sector. The center conducts research on accessibility, availability, and value derived from health care delivery, and the role that medical technologies play in this regard for patients in general, the underserved and uninsured, and the emerging empowerment of patients.

e. Management of medical information and emerging technologies. This thrust focuses on studies of emerging technologies such as telemedicine, telehealth, computerized medical records, e-health, knowledge and knowledge management, knowledge in health care, and the future of medical informatics. Topics include diffusion, evaluation, economics, and applications of these technologies to the health care sector.

These themes also form the thrust for our own on going research endeavours at IIT's Centre for the Management of Medical Technology (CMMT; http://www.stuart.iit.edu/cmmt/). Contributing authors have focused their article(s) on one or more of the above five general themes or thrusts which taken together are naturally not exhaustive but do serve to underscore the key areas within health care delivery.

The significance of ICTs in health care cannot be understated. A recent survey by the Cleveland Clinic noted that health care is the number one or two key issue for U.S. citizens, ahead of employment, war, and the economy. Health care is also the number two topic searched by users of the Internet worldwide and there are over 100,000 commercial Web sites dedicated solely to health care. In both the U.S. and globally, health care cannot survive without the application and adoption of a whole spectrum of technologies and since health care impacts all of us, it becomes a priority to all readers, both health care professionals and general citizens, to develop an understanding and appreciation of the various possibilities for ICT use within the health care domain. We are confident that this encyclopedia will be used by all leading health care organizations throughout the U.S. and globally as well as be a vital part of any universities reference collection in the area of ICT use in health care. We encourage all individuals wanting to understand the role of technology in health care delivery and more especially the nuances pertaining to the management of medical technology to also use this as a useful reference. We trust that all readers will enjoy this compilation and become more enlightened on the subject.

Acknowledgment

It is not possible to successfully complete a project of this magnitude without the cooperation and contributions of many people. We are most grateful for all the efforts, input and support given to us by the contributors, reviewers, our advisory board and the staff at IGI Global. We would especially like to thank Mehdi Khosrow-Pour for inviting us to produce this magnum opus, Jan Travers for managing this project, and Kristin Roth for sustaining us through the process and keeping us to schedule. We also acknowledge Stuart School of Business, Illinois Institute of Technology for affording us the time to work on this project and are indebted to our colleagues and students for many stimulating discussions and assistance throughout the process. Finally, a special thanks to our families.

Nilmini Wickramasinghe and Elie Geisler

About the Editors

Nilmini Wickramasinghe (PhD; MBA; GradDipMgtSt; BSc Amus., piano; Amus. A, violin) researches and teaches in several areas within information systems, including knowledge management, e-commerce and m-commerce, and organizational impacts of technology with particular focus on the applications of these areas to health care and thereby effecting superior health care delivery. She is well published in all these areas with more than 60 referred scholarly articles and several books. In addition, she regularly presents her work throughout North America, as well as in Europe and Australasia. Dr. Wickramasinghe is the U.S. representative of the Health Care Technology Management Association (HCTM), an international network of scholars that focuses on critical health care issues and the role of technology within the domain of health care. She is the associate director of the Center for the Management of Medical Technologies (CMMT) and holds an associate professor position at the Stuart School of Business, Illinois Institute of Technology. In addition, Dr. Wickramasinghe is the editor-in-chief of two scholarly journals: *International Journal of Networking and Virtual Organisations* (IJNVO – www.inderscience.com/ijnvo) and *International Journal of Biomedical Engineering and Technology* (IJBET- www.inderscience.com/ijbet), where she was also the journal's founder. Both journals are published by InderScience.

Elie Geisler is a distinguished professor at the Stuart School of Business, Illinois Institute of Technology and director of the IIT Center for the Management of Medical Technology. He holds a doctorate from the Kellogg School at Northwestern University. Dr. Geisler is the author of nearly 100 papers in the areas of technology and innovation management, the evaluation of R&D, science and technology, and the management of health care and medical technology. He is the author of several books, including: *Managing the Aftermath of Radical Corporate Change* (1997), *The Metrics of Science and Technology* (2000), also translated into Chinese, *Creating Value with Science and Technology* (2001) and *Installing and Managing Workable Knowledge Management Systems* (with Rubenstein, 2003). His forthcoming books are: *Knowledge and Knowledge Systems: Learning from the Wonders of the Mind*, and a textbook: *Knowledge Management Systems: Theory and Cases* (with Wickramasinghe). He consulted for major corporations and for many U.S. federal departments, such as Defense, Agriculture, Commerce, EPA, Energy, and NASA. Dr. Geisler is the cofounder of the annual conferences on the Hospital of the Future, and the Health Care Technology and Management Association, a joint venture of several universities in 10 countries. He serves on various editorial boards of major journals. His current research interests include the nature of knowledge management in general and in complex systems, such as health care organizations.

3D and 4D Medical Image Registration Combined with Image Segmentation and Visualization

INTRODUCTION

Image registration, segmentation, and visualization are three major components of medical image processing. Three-dimensional (3D) digital medical images are three dimensionally reconstructed, often with minor artifacts, and with limited spatial resolution and gray scale, unlike common digital pictures. Because of these limitations, image filtering is often performed before the images are viewed and further processed (Behrenbruch, Petroudi, Bond, et al., 2004). Different 3D imaging modalities usually provide complementary medical information about patient anatomy or physiology. Four-dimensional (4D) medical imaging is an emerging technology that aims to represent patient motions over time. Image registration has become increasingly important in combining these 3D/4D images and providing comprehensive patient information for radiological diagnosis and treatment.

3D images have been utilized clinically since computed tomography (CT) was invented (Hounsfield, 1973). Later on, magnetic resonance imaging (MRI), positron emission tomography (PET), and single photon emission computed tomography (SPECT) have been developed, providing 3D imaging modalities that complement CT. Among the most recent advances in clinical imaging, helical multislice CT provides improved image resolution and capacity of 4D imaging (Pan, Lee, Rietzel, & Chen, 2004; Ueda, Mori, Minami et al., 2006). Other advances include mega-voltage CT (MVCT), cone-beam CT (CBCT), functional MRI, open field MRI, time-of-flight PET, motion-corrected PET, various angiography, and combined modality imaging, such as PET/CT (Beyer, Townsend, Brun et al., 2000), and SPECT/CT (O'Connor & Kemp, 2006). Some preclinical imaging techniques have also been developed, including parallel multichannel MRI (Bohurka, 2004), Overhauser enhanced MRI (Krishna, English, Yamada et al., 2002), and electron paramagnetic resonance imaging (EPRI) (Matsunoto, Subramanian, Devasahayam et al., 2006).

Postimaging analysis (image processing) is required in many clinical applications. Image processing includes image filtering, segmentation, registration, and visualization, which play a crucial role in medical diagnosis/treatment, especially in the presence of patient motion and/or physical changes. In this article, we will provide a state-of-the-art review on 3D/4D image registration, combined with image segmentation and visualization, and its role in image-guided radiotherapy (Xing, Thorndyke, Schreibmann et al., 2006).

BACKGROUND

3D/4D Medical Imaging

A 3D medical image contains a sequence of parallel two-dimensional (2D) images representing anatomic or physiologic information in 3D space. The smallest element of a 3D image is a cubic volume called voxel. A 4D medical image contains a temporal series of 3D images. With a subsecond time resolution, it can be used for monitoring respiratory/cardiac motion (Keall, Mageras, Malter et al., 2006).

Patient motion is always expected: faster motion relative to imaging speed causes a blurring artifact; whereas slower motion may not affect image quality. A multislice CT scanner provides improved spatial and temporal resolution (Ueda et al., 2006), which can be employed for 4D imaging (Pan et al., 2004). Progresses in MRI imaging have also been reported, including parallel multichannel MRI (Bodurka, Ledden, van Gelderen et al., 2004).

Because PET resolution and speed are limited by the physics and biology behind the imaging technique, some motion suppression techniques have been developed clinically, including patient immobilization (Beyer, Tellmann, Nickel, & Pietrzyk, 2005), respiratory gating (Hehmeh, Erdi, Pan et al., 2004), and motion tracking (Montgomery, Thielemans, Mehta et al., 2006). Motion tracking data can be used to filter the imaging signals prior to PET image reconstruction for reliable motion correction. Motion blurring, if uncorrected, can reduce registration accuracy. Visual-based volumetric registration technique provides blurring correction (filtering) before registration, by defining the PET volume with reference to the CT volume, causing blurred PET surface voxels to be rendered invisible (Li, Xie, Ning et al., 2007).

Image Segmentation and Visualization

Medical image segmentation defines regions of interest used to adapt image changes, study image deformation, and assist image registration. Many methods for segmentation have been developed including thresholding, region growing, clustering, as well as atlas-guided and level sets (Pham, Xu, & Prince, 2000; Suri, Liu, & Singh et al., 2002). Atlas-guided methods are based on a standard anatomical atlas, which serves as an initial point for adapting to any specific image. Level sets, also called active contours, are geometrically deformable models, used for fast shape recovery. Atlas-based level sets have been applied clinically for treatment planning (Lu, Olivera, Chen et al., 2006a; Ragan, Starkschall, McNutt et al., 2005;) and are closely related to image registration (Vemuri, Ye, & Chen, et al., 2003). Figure 1 shows automatic contours. Depending on how the 3D image is segmented, it can be either 2D-based or 3D-based (Suri, Liu, Reden, & Laxminarayan, 2002).

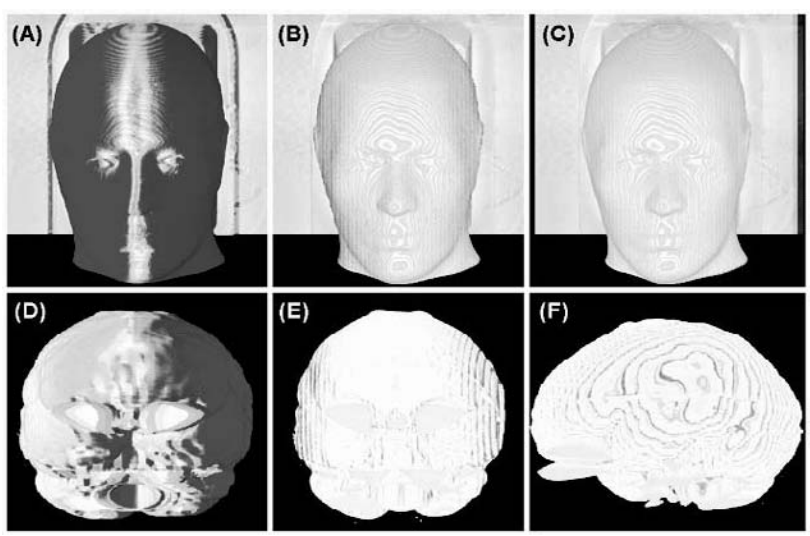
3D medical image visualization has been increasingly applied in diagnosis and treatment (Salgado, Mulkens, Bellinck, & Termote, 2003), whereas 2D-based visualization is predominantly applied clinically. Because of the demand on computing power, real-time 3D image visualization is supported by specialized graphics hardware (Terarecon, Inc.) (Xie, Li, Ning et al., 2004) or high-end consumer graphics processors (Levin, Aladl, Germanos, & Slomak, 2005). 3D image visualization has been applied to registration of four imaging modalities with improved spatial accuracy (Li, Xie, Ning et al., 2005; Li et al., 2007). Figure 2 shows 3D volumetric image registration using external and internal anatomical landmarks.

Rigid Image Registration

Rigid image registration assumes a motionless patient such that the underlying anatomy is identical in different imaging modalities for alignment. Three approaches to rigid registration are: coordinate-based, extrinsic-based, and intrinsic-based (Maintz & Viergever, 1998). Coordinate-based registration is performed by calibrating the coordinate system to produce “co-registered” images. Multimodality scanners, such as PET/CT and SPECT/CT, are typical examples.

Figure 1. Orthogonal 2D-views of CT images and comparison of automatic recontours (solid-lines) and manual contours (dash-lines) in different phases (A&B) of a radiotherapeutic treatment (courtesy of Dr. Weiguo Lu)

Figure 2. 3D-views of CT (A, B, and C: head) and MR (D, E, and F: segmented brain) phantom images. The homogeneity of color distributed on an anatomic landmark is used as the registration criterion. From (A) to (C), three images (red, green, and blue) are approaching registration with shifts from 5.0mm to 0.5mm and 0.0mm, respectively. From (D) to (E and F), four images (grey, blue, green, and red) are 5.0mm apart from each other (D) and registered in front (E) and side (F) views.



Extrinsic-based image registration relies on the alignment of extrinsic objects placed in/on a patient invasively/noninvasively. Such objects can be fiducials or frames that are visible in all imaging modalities and serve as local coordinate markers (sets of points) for rigid registration. Examples are gold seeds for prostate localization in radiotherapy and head frame for stereotactic radiosurgery.

Intrinsic-based image registration uses a patient's anatomy (anatomic landmarks, segmented geometries, or intact voxels) as the registration reference. Alignment of visual landmarks or segmented geometries requires user interaction, so the registration is manual or semi-automatic. The statistical similarity of the intact voxels (grayscale) of two images, such as mutual information (Viola & Wells, 1995), has been widely used for fully automated registration (Pluim, Maintz, & Viergever, 2003).

Automatic image registration requires three key elements: a metric function, a transformation, and an optimization process. One common voxel-based image registration uses mutual information as the metric, a rigid or nonrigid transformation and a maximization algorithm. Recently, the homogeneity of color distributed on a volumetric landmark has been used as quantitative metric, assisted by the ray-casting algorithm in 3D visualization (Li et al., 2007). Figures 3 and 4 show clinical examples using the 3D visualization-based registration technique.

Deformable Image Registration

Deformable image registration contains a nonrigid transformation model that specifies the way to deform one image to match another. A rigid image registration is almost always performed to determine an initial position using rigid transformation with six variables (3 translations and 3 rotations). For nonrigid transformation, the number of variables will increase dramatically, up to three times the number of voxels. Common deformable transformations are spline-based with control points, the elastic model driven by image similarity, the viscous fluid model with region growth, the finite element model using rigidity classification, the optical flow with motion estimation, and free-form deformation (Chi, Liang, & Yan, 2006; Crum, Hartkens, & Hill, 2004; Lu, Olivera, Chen et al., 2006b).

The image similarity measures are ultimately the most important criteria for determining the quality of registration. They can be feature-based and voxel-based (Maintz & Viergever, 1998). The former is usually segmentation/classification based, adapting changes in shape of anatomical landmarks, while the latter is based on statistical criteria for intensity pattern match-

Figure 3. 3D-views of before (A, B, and C) and after (D, E, and F) 3D volumetric image registration, using homogeneity color distribution as registration criterion. Voluntary patient head movement is corrected in three MR images, T1 (green), FLAIR (red), and T2 (blue), which are acquired in the same scanner with time interval of 3 and 20 minutes.

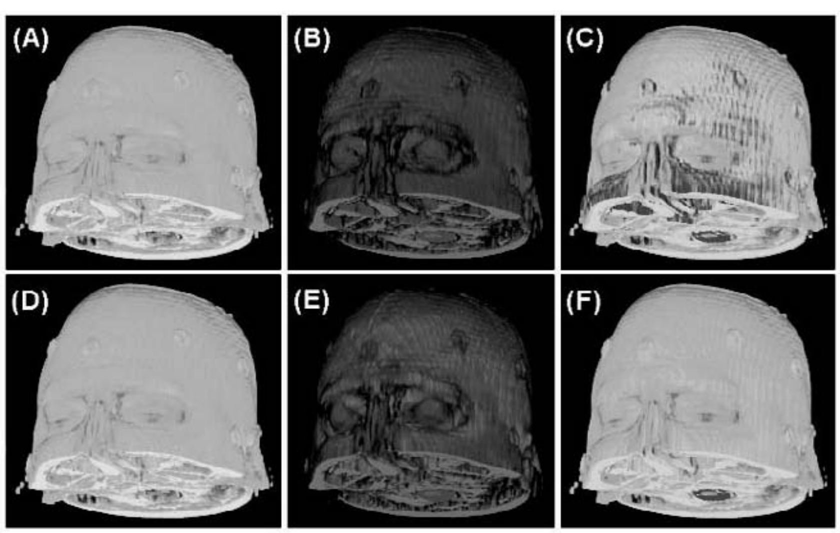


Figure 4. 3D-views of before (A, B, and C) and after (D, E, and F) rigid volumetric image registration of PET/CT images, correcting patient movement.

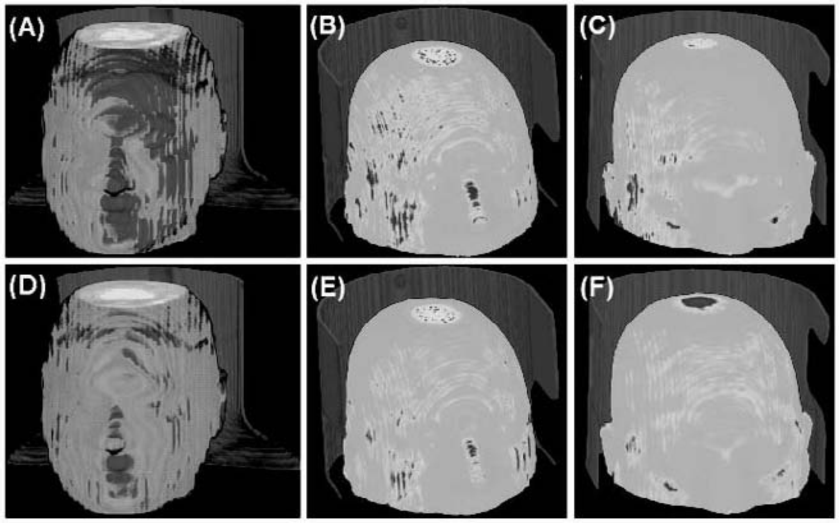

Figure 5. Orthogonal 2D-views of before (A) and after (B) deformable image registration of two 3D images (red and green) in a 4D CT image (courtesy of Dr. Weiguo Lu)

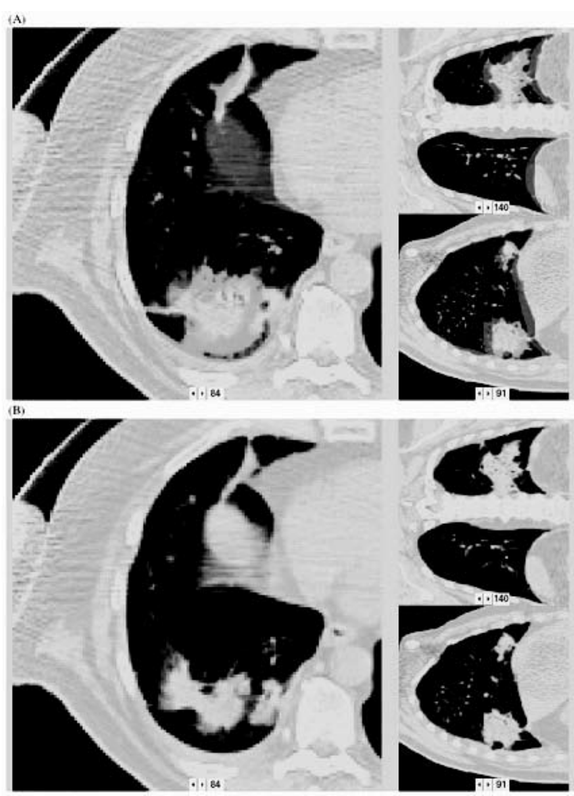

ing, including mutual information. Most deformable registrations are automated. Combining the two methods can improve registration accuracy, reliability, and/or performance (Hellier & Barillot, 2003; Liu, Shen, & Davatizikos, 2004; Wyatt & Noble, 2003). Figure 5 shows one example of deformable registration.

A Challenge from 3D/4D Conformal Radiotherapy: Deformable Image Registration

Broadened Concept of 4D Medical Imaging

The 4D imaging concept has been broadened to cover various time resolutions. The common 4D image has subsecond temporal resolution (Pan et al., 2004), while a series of 3D images, reflecting patient changes over a longer time span, should be also qualified as a 4D image with sufficient resolution to assess slower changes, including tumor growth/shrinkage and weight gain/loss during a course of treatment.

Registration of a 3D image to a 4D image involves a series of deformable registration. Because patient motion/change is inevitable, deformable image registration is the key to combining these images for clinical use. Clinically, MVCT images can be acquired daily and used for patient daily setup via rigid registration to the reference planning image, assuming minimal patient changes. Within a treatment, 4D CT imaging has shown dramatic anatomical changes during respiration (Keall et al., 2006). Image-guided frameless cranial and extra-cranial stereotactic radiosurgery has been performed clinically (Gibbs, 2006). Rigid image registration provides the best current solution to these clinical applications. Ultimately, deformable image registration will improve the registration accuracy substantially (Lu et al., 2006b), permitting highly conformal 3D/4D radiotherapy (Barbiere, Hanley, Song et al., 2007; Mackie, Kapatoes, Ruchala et al., 2003).

Challenges in Deformable Image Registration

For deformable image registration, the underlying anatomy changes, therefore voxel mapping among images is a challenge. First, the deformable transformation handles a large number of positioning variables that must be determined for every voxels within the anatomy. This can be abstracted as a multiple variable optimization problem in mathematics, limiting the performance of deformable image registration for many years (Crum, 2004). Second, the deformable registration is extremely difficult to be validated as there is lack of absolutes with respect to the location of corresponding voxels. Therefore, the accuracy and reliability of deformable registration should be evaluated on a case specific basis (Sanchez Castro, Pollo, Meuli et al., 2006; Wang, Dong, O'Daniel et al., 2005).

Regardless the limitations above, progress has been made by combining image registration and segmentation/classification to provide intrinsic simplification and cross verification. It remains a challenge, however, to develop a fully automated deformable registration algorithm because image segmentation often requires human interaction.

Deformable image registration is generally a "passive" mapping process. It does not anticipate how patient anatomy might deform. An example is whether superficial 3D contour information detected by a real-time infrared camera can be used to predict the motion of internal organs (Rietzel, Rosenthal, Gierga et al., 2004). Anatomically, the correlation between superficial and internal organ motion should exist, although as a complex relationship. Therefore, an anatomic model based image registration with motion estimation can provide an "active" mapping process, but is beyond the current scope of deformable image registration.

Gaps between Frontier Research and Clinical Practice

Despite of the advances in 3D and 4D imaging and image registration, 2D-based rigid registration techniques are predominantly used in the clinic; although automatic rigid registration methods exist in most commercial treatment planning software. Two reasons are primarily responsible for this disconnect: First, the user must visually verify the final registration using the 2D-based visualization tools available for image fusion in most commercial software. Second, most clinical images have some degree of pre-existing deformation so that automatic rigid registration can prove unreliable but manual methods allow the user to perform local organ registration. Some recent commercial software has recognized this problem and provides the option of selecting the region-of-interest to ease the deformation problem. This method, however, is only a partial solution to cope with image changes.

The gap between the clinical research and routine practice can be reduced by translational research and development. Recently, open-source medical image processing and visualization tool kits have become available for public use. Many recently published algorithms in medical image processing are implemented in a generic, object-oriented programming style, which permits reusability of such toolkits.

FUTURE TRENDS

3D rigid image registration will dominate clinical practice and will remain essential as more specialized complementary 3D imaging modalities become clinically relevant. Although the simplicity of automatic image registration is more attractive, manual image registration with 2D/3D visualization is irreplaceable because it permits incorporation of medical knowledge for verification and adjustment of the automatic registration results.

As awareness of the problems of the patient motion and anatomic changes increases, further research on 4D imaging and deformable registration will be stimulated to meet the clinical demands. Motion correction in the PET/CT and SPECT/CT will continue to improve the “coregistration” of these images. Interdisciplinary approaches are expected to offer further improvements for the difficult registration problem. With advances in hybrid registration algorithms and parallel computing, more progresses are expected, resulting in improved accuracy and performance.

CONCLUSION

Higher dimensional deformable image registration has become a focus of clinical research. The accuracy, reliability, and performance of 3D/4D image registration have been improved with assistance of image segmentation and visualization.

KEY TERMS

3D Medical Imaging: A process of obtaining a 3D volumetric image composed of multiple 2D images, which are computer reconstructed using a mathematical "back-projection" operation to retrieve pixel data from projected image signals through a patient, detected via multichannel detector arrays around the patient.

4D Medical Imaging: A process of acquiring multiple 3D images over time prospectively or retrospectively, so that patient motions and changes can be monitored and studied.

Imaging Modality: A type of medical imaging technique that utilizes a certain physical mechanism to detect patient internal signals that reflect either anatomical structures or physiological events.

Image Processing: A computing technique in which various mathematical operations are applied to images for image enhancement, recognition, or interpretation, facilitating human efforts.

Image Registration: A process of transforming a set of patient images acquired at different times and/or with different modality into the same coordinate system, mapping corresponding voxels of these images in 3D space, based on the underlying anatomy or fiducial markers.

Image Segmentation: A process in which an image is partitioned into multiple regions (sets of pixels/voxels in 2D/3D) based on a given criterion. These regions are nonoverlapping, homogeneous with respect to some characteristics such as intensity or texture. If the boundary constraint of the region is removed, the process is defined as classification.

Image Visualization: A process of converting (rendering) image pixel/voxel into 2D/3D graphical representation. Most computers support 8-bit (256) grayscale display, sufficient to human vision that can only resolve 32-64 grayscale. A common 12/16-bit (4096/65536 grayscales) medical image can be selectively displayed based on grayscale classification. Window width (display range in grayscale) and linear level function (center of the window width) are frequently used in adjusting display content.

The ABC Approach and the Feminization of HIV/AIDS in the Sub-Saharan Africa

Lynette Kvasny

Jing Chong
The Pennsylvania State University, USA

INTRODUCTION

The growing prevalence of HIV/AIDS infections among women in African nations south of the Sahara is a complex and pressing public health concern. In this article, we examine how HIV/AIDS prevention campaigns construct women as the new face of HIV/AIDS in Sub-Saharan Africa. We do so by providing a feminist analysis of the US Government's Abstain, Be faithful, and correct and consistent use of condoms (ABC) health campaign. President Bush's Emergency Plan for AIDS Relief is the largest commitment ever made by a single nation towards an international health initiative—a five-year, $15 billion approach to combating HIV/AIDS. The centerpiece of the prevention component of this plan is the ABC approach (Office of the United States Global AIDS Coordinator, 2005). Abstinence, according to this theory, should take precedence for people who are not in a relationship. Those who are in a relationship should remain faithful to their partners. And if the first two strategies fail for any reason, condoms should be used to prevent the transmission of HIV. Global AIDS Coordinator Randall Tobias endorsed a provision in U.S. law requiring that at least one-third of all U.S. assistance to prevent HIV/AIDS globally be reserved for "abstinence-until-marriage" programs. In effect, this makes "abstinence-until-marriage" advocacy the single most important HIV/AIDS prevention intervention of the U.S. government.

In our feminist analysis, we view this HIV/AIDS prevention campaign from a cultural perspective (Cheng, 2005; Sontag, 1990; Treichler, 1999; Waldby, 1996), rather than structural determinants of risk such as public policy, globalization, industrialization, and the economy**.** For us, the feminization of this disease operates as an epidemic of signification, which takes the gendered, raced, and sexualized body of women as its subject. Far from the "gay white men's disease" of the 1980s, HIV/AIDS is infecting and affecting women more than ever before. As the epidemic enters its third decade, women now account for half of the 42 million people living worldwide with HIV/AIDS. Of the 3.1 million people who died of AIDS in 2002, 1.2 million were women. In Sub-Saharan Africa, the transmission rate for women has surpassed that of men with six HIV-positive women for every five HIV-positive men (UNAIDS/WHO, 2004).

Women, the dominant subjects of AIDS discourses, are placed at risk by common systems of oppression such as gender, race, class, and social and spatial location. Through the health campaigns which are disseminated and reproduced through television, radio, newspapers, and more recently the internet, women are uniquely constructed by privileged "experts" from the West as consumable subjects. In the case of women in Sub-Sahara Africa, we found that health campaigns which feminize AIDS are rooted in largely hegemonic cultural images which portray women as vulnerable subjects under siege. Through our analysis, we problematize the ABC health campaign and its appropriateness for women in Sub-Saharan Africa.

BACKGROUND

Women in Sub-Saharan Africa have become the new face of HIV/AIDS . While calling attention to women may help to end their silent suffering, if not done sensitively, it may unwittingly reproduce a discourse that depicts Africa in largely pessimistic terms. Media images of Black children with emaciated bodies, impoverished communities facing environmental and epidemic catastrophes, and bare-breasted women standing besides grass huts are imprinted on the collective consciousness of citizens in the West. The internet provides a global forum for disseminating "afropessimism" through a broad range of communication channels, including televised and printed media reports, news outlets, medical journals, Web sites, press releases, and policy documents, among others.

Through these pessimistic portrayals, African women have come to serve as a convenient trope for signifying the worst of the global HIV/AIDS pandemic, a fate to be both feared and avoided by other nations. The human suffering resulting from HIV/AIDS in Sub-Saharan Africa has become entrenched in the psyche of the general U.S. population. For instance, the Kaiser Family Foundation's *2004 Survey of Americans on HIV/AIDS* found that more than eight in 10 (83%) correctly acknowledged Africa as the part of the world that has been hardest hit with HIV/AIDS. However, only four in ten (39%) knew that about half of all new HIV infections in the U.S. occur among African Americans, and a similar share (40%) knew that half of all new infections in the U.S. occur among people under age 25. Thus, it appears that Americans know more about the HIV/AIDS situation in Africa than they do about their own country.

The American publics' understanding of the AIDS pandemic in Sub-Saharan Africa is dominated by media outlets which, unfortunately, often portray negative imagery and misguided generalizations. For instance, in this same Kaiser Family Foundation survey, when Americans were asked where they get information about HIV/AIDS, a large majority (71%) say that most of the information comes from the media. About half (51%) report they have seen a lot about the problem of AIDS in Africa in the last year, while less state they have seen a lot about the problem of AIDS in the U.S. (34%), Asia (11%), Latin America (7%), and Eastern Europe (5%). And while most Americans are aware of the problem of AIDS in Africa, it is difficult to contextualize this information, because Africa is often depicted in monolithic terms, even though it is a continent of 11.5 million square miles and 53 culturally, linguistically, and religiously diverse nations (Geshekter, 1995).

Distorted media accounts and a general lack of rounded understanding of African nations and culture conspire to maintain the historical, economic and psychological relationship between "us and them" (Clark, 2004; Mayhew, 2002). One such relationship, the association between AIDS and Africa, has become almost reflexive (Geshekter, 1995) with nearly every report beginning with the recitation of the HIV/AIDS statistics for women—Women comprise about half of all people living with HIV worldwide. In Sub-Saharan Africa, women make up 57% of people living with HIV, and three quarters of young people infected on the continent are young women aged 15-24 (UNAIDS/WHO, 2004).

Within this milieu, the ABC approach has been adopted as a public health campaign to combat HIV/AIDS in Africa. However, the ABC health campaign may be unrealistic for many African women and men. In what follows, we provide a feminist reading of the ABC approach, identifying why this health campaign may be problematic. We organize our analysis around each component—abstinence, be faithful, and condom use.

Abstinence

The feminization of AIDS focuses efforts on protecting "vulnerable" women and their children. Female sexuality is constructed around purity, selfrestraint, and the denial of sexual pleasure, with chastity and morality as the underlying logics (Cheng, 2005). Thus, the health message for women is to abstain from premarital and extramarital sex—"Abstinence is the only sure way to prevent sexual transmission of AIDS and other sexually transmitted diseases."

While the health message is clinically accurate, we find moral judgments about self control and sexuality embedded in the call for abstinence. Personal choice over when and how to engage in safer sexual activities is less prominent. And while moral assumptions may not reflect the cultural practices and beliefs of many African women and men, all HIV/AIDS prevention programs funded by the U.S. federal government are required to promote abstinence. Moreover, in the 2004 State of the Union Address, President Bush called for a new emphasis on abstinence-only education, and doubling the funding for abstinence-only programs (Office of National AIDS Policy, 2005). Thus, the U.S. government is not a neutral, philanthropic provider of aid**.** Rather, donations are subject to U.S. political interests that influence policy decisions to support programs and services, which may in fact be incompatible with local needs.

It is not just the content of the abstinence health message, but who has the power to determine the content of the health messages. "ABC has become little more than an excuse and justification to promote their

[U.S. government's] long-standing agenda regarding people's sexual behavior and the kind of sex education they should receive - A for unmarried people, bolstered by advocacy of B, but for most people, anything but C" (Cohen, 2003).

However, abstinence is difficult in practice. Virgins are prized by older men attempting to avoid contacting HIV infections (Gupta, 2000). This places young girls at risk for becoming infected by men who may already be HIV positive. Women also suffer from forced sex. The forces may be physical such as in rape, but women may also be forced into sex purely for survival. In areas which have been badly hurt by economic recession, many women and girls find economic refuge in "sexual networking," or exchanging sexual favors for money, gifts, and protection.

Be Faithful

The "be faithful" message privileges mutually faithful monogamous relationships in the context of marriage as the expected standard of human sexual activity (Collins, Alagiri, & Summers, 2002). However, mounting evidence suggests that married monogamous women are among the groups at greatest risk of infection. For instance, in Kenya and Zambia, data reveal higher rates of infection among young married women (age 15 to 19) than among their sexually active, unmarried (female) peers. These studies found that the rate of HIV infections in husbands was higher than in the boyfriends of sexually active single teenage women. Women in marital relationships were also more frequently exposed to unprotected sex (UNAIDS/WHO, 2004). Women with no economic independence feel constrained to adopt whatever behavior is necessary to protect their marital status, including overlooking their partner's infidelities (Gupta, 2000).

Patriarchal Power is one factor which helps to explain elevated risks for monogamous, married women. Patriarchal Power is often expressed and reproduced through societal norms regarding female sexuality (not abstain from premarital and extramarital sex), and expectations about if and when women are to be married. Patriarchal Power inscribed in the law requires that married women give up their name, property, and personhood. Patriarchal Power is sometimes used to construct the argument that African men are largely unfaithful to their significant others, unwilling to curb their sexual drive, and averse to condom use (Roberts, 2003). Wives are expected to be sexually passive, while husbands are expected to actively pursue sex. Women cannot turn down sex from their husband, and they cannot fully enjoy sex. Thus, wives are dissuaded from participating fully and actively in sex. This may promote the spread of the virus, because some men suggest that their wives "just lie there," and use this as a rationale for soliciting prostitutes (Schoofs, 1999).

Hence, husbands are seen as promiscuous and less deserving of sympathy, while wives are seen as vulnerable and sexually compliant. Sexual compliance is part of the social role and expectations for married women, and is just one example of the way in which Patriarchal Power is intimately intertwined with social justice and HIV prevention. A faithful woman will find it difficult to reduce her risk of contracting HIV/AIDS in an otherwise misogynist material context (Gavey, 1992).

HIV testing is integral to the "be faithful" message, because it lets both partners know their status. However, introducing voluntary testing and counseling would not be easy, as there was a still a lot of fear and stigma surrounding the disease. "Somebody just can't go for testing because it means one thing: you are going find out whether you are going to die or not," (UN Office for the Coordination of Humanitarian Affairs, 2005). There are few positive messages about living with HIV. Therefore, this is still seen as a disease that kills, which makes it extremely difficult to encourage people to be open about their HIV status.

Condoms

Consistent and correct use of condoms is the third component of the ABC health campaign. This message is generally targeted at heterosexual women, and suggests that women should act assertively to control the course of their sexual encounters to ensure that the male partner uses a condom (Gavey, McPhillips, & Doherty, 2001). This message may, however, be problematic for several reasons. First, the discourse of condom use is couched in Western notions of individualism and personal responsibility. This creates contradictions in gender roles and personal identity as a women's desire to be a faithful and committed partner. It also contradicts the cultural significations of sexual intercourse as an expression of monogamy, commitment, love, and trust. This demand for condom use also calls for women to enact assertive sexual behaviors that may go against their feminine identity to acquiesce irrespective of her desire not to have unprotected sex. Some women think of sex as something that happens to them, rather than something they choose. Thus, if a woman's desire to acquiesce overrides her desire to be assertive, then condoms provide little support. For instance, a study in Zambia found that fewer than 25% of the women interviewed believed that a married woman could refuse to have sex with her husband, even if he had been demonstrably unfaithful and was infected. Only 11% thought that a woman could ask her husband to use a condom in these circumstances (UNIFEM, 2001).

Second, this message places women in the position of negotiating with her partner, and suggests the possibility of an individual, rational solution in a relation dominated by the male (Giffin, 1998). At the same time, it ignores the constraints on women's ability to control condom use. Women throughout the world have relatively less control over their sexuality or over their partners' sex behavior (Gupta, 2000). In parts of Sub-Saharan Africa, for instance, poverty and lack of alternatives sometime lead adolescent girls to exchange sex for food, school fees, money, and other commodities, often with men who are much older. Her male partner may force her to engage in unprotected sex, which exposes her to the danger of physical force from their male partner. In this way, health campaigns that promote condom use for women reinforce heterosexuality and the dominance of the male sex drive (Gavey et al., 2001). However, a male partner may also refuse to have sex, which would interfere with a women's sexual pleasure, and jeopardize her chances of continuing a consensual sexual encounter.

Third, condoms carry a stigma. Studies on every continent demonstrate that both men and women perceive condoms for use when having sex with "others," not stable partners. Condoms are for "women of the street, not the home." Even sex workers who are scrupulous about using condoms with clients tend to avoid them with boyfriends and husbands. All too often, condom use has become a sign for the level of trust in a relationship, rather than simply a sensible means of protection (Gavey et al., 2001).

DISCUSSION

While the discourse surrounding the ABC approach appropriates a feminist tone in its concern for women, it is in some ways limited in its promotion of legitimate debate on gender relations. According to Kofi Annan, former UN Secretary General, the ABC approach requests individual change without enacting the societal change that would facilitate women's agency. The driving forces for HIV transmission in southern Africa are linked to structural inequities such as poverty, the economic and social dependence of women on men, and a fear of discrimination that prevents people from openly discussing their status. Women are not able to disclose to their partners that they may have been exposed to HIV in case they are vilified, deserted, and left destitute. Society's inequalities also put them at risk through the lack of access to AIDS treatment, coercion by older men, and men having several partners (UN Office for the Coordination of Humanitarian, 2004). This broader sociopolitical context contributes to the AIDS crisis in Africa. Ecological degradation, migratory labor systems, rural poverty, and civil wars are the primary threats to African lives (Geshekter, 1995).

This, however, does not discount the moral imperative for providing reliable information about HIV/AIDS prevention, and equitable access to condoms and life sustaining medications. In targeting different prevention messages to different groups of people (married women remain faithful, unmarried women abstain, and sexually active women outside of marriage should condomize), the ABC approach fails to consider that a woman may need different messages at different stages of life. For example, a young woman who abstains until marriage is likely to want and need condoms in order to be able to plan childbearing and protect herself from HIV. After a few years of marriage, this same woman may want to become pregnant. However, until non-spermicidal microbicides are developed, this woman has no method for safely becoming pregnant while protecting herself from the risk of HIV/AIDS from a husband who may have other sexual partners (Cohen, 2003). Reproductive health is clearly not distinct from HIV/AIDS prevention, because women often are trying to prevent both HIV/AIDS and unplanned pregnancies simultaneously. The lack of reproductive technologies available to women who are trying to conceive may place them at increased risk.

Massive condom distribution and access to antiretroviral drugs are necessary for preventing both unplanned pregnancies and HIV infection. However, the need simply exceeds the resources of many of the world's poorest nations.

"Abstinence cannot happen in an illiterate community where people have sex early. 'Be faithful' is not going to happen, and 'condomise' - we are ready to use them, but we have no access to money. Condoms are not freely available, and at the price of 500 Ugandan shillings (25 cents) for a packet of three, are luxuries many cannot afford ... people can spend that money on condoms or food ... they are not going to spend their food money on a piece of rubber" (UN Office for the Coordination of Humanitarian Affairs, 2005).

Given these challenges, it seems arrogant and ineffective to impose a Western health campaign without careful adaptation to the various economic, social, and cultural forces that exist in the nations of Africa.

KEY TERMS

ABC Health Campaign: The centerpiece of the prevention component of President Bush's Emergency Plan for AIDS Relief. Abstinence should take precedence for people who are not in a relationship. Those who are in a relationship should remain faithful to their partners. And if the first two strategies fail for any reason, condoms should be used to prevent the transmission of HIV.

Acquired Immune Deficiency Syndrome (AIDS): AIDS is a human disease characterized by progressive destruction of the body's immune system. It is widely accepted that AIDS results from infection with HIV. Although treatments for both AIDS and HIV exist, there is no known cure.

Afropessimism: An unremittingly bleak view of Africa. The persistence of the menacing image of Africa in the West is highlighted at the present time by the AIDS pandemic.

Human Immunodeficiency Virus (HIV): Immunodeficiency means having a faulty immune system so that a person can become very ill or die from a disease that others can fight off. Acquired means that HIV is passed from person to person through blood or other bodily fluids, through a transfusion of infected blood, to a baby from its mother, through use of contaminated hypodermic needles, or through sexual contact with a person who has the disease.

Sub-Saharan Africa: The region of Africa south of the Sahara desert. Sub-Saharan Africa, one of the poorest regions in the world, still suffering from the legacies of colonial conquest and occupation, neocolonialism, and internal conflict. The region is comprised of 48 nations, many of which are among the least developed countries in the world

Acoustic Feature Analysis for Hypernasality Detection in Children

INTRODUCTION

In the treatment of children with fixed Cleft Lip and Palate (CLP), problems such as hipponasality and hypernasality, which are related to vocal emission and resonance, might appear. Nevertheless, according to the report presented in Castellanos et al. (2006), hypernasality is more frequently found than hipponasality (90% vs. 10%). The interest shown in hypernasality detection is that its occurrence points out problems of anatomical and neurological sort that are also related to the peripheral nervous system (Cairns, Hansen, & Riski, 1996). The presence of hypernasality, understood as the leak of nasal air and compensatory articulations, leads to low intelligibility of speech. This declining of the subject's communication capabilities may end up in behavioral and social changes.

In velopharyngeal learning, the distortion of the acoustic production leads up to nasalized voice. Moreover, since air loss or nasal leak is massive, articulator mechanisms are compromised. The patient can not speak clearly and intelligibly, and thence they replace their velum palatine sphincter by glottal articulation that allows for clearer speech: /p/, /t/, /k/, /b/, /d/, /g/ come from glottal stops, while sounds like /ch/, /s/, /t/, /j / are accompanied by hoarseness (Habbaby, 2002). Although hard palate has been repaired surgically, it might not provide velopharyngeal competence necessary for a normal speech production. Even if the palate is potentially capable after surgery, previous speech habits might have developed compensatory articulations or physiologic compensations that aimed to approx to intelligibility that enhance the number of pathological patterns in speech. As a result, compensatory articulations persist generally, even after undergoing post technical or post surgical manipulation that had forecasted a plenty shutting. Thus, they have to be fixed before increasing the performance of the velopharyngeal sphincter throughout language therapy.

In the last years, there has been a growing interest for acoustic speech analysis (ASA) as an alternative method for diagnosis and treatment in identifying functional disorders in children's voices (González, Cervera, & Miralles, 2002; Niedzielska, 2000; Niedzielska, Glijer, & Niedzielski, 2001). This type of analysis exposes great advantages over traditional methods due to its noninvasive nature and potential to obtain a quantitative measure on the clinic state of the larynx and vocal tract.

Acoustic features or objective parameters are frequently used to represent the pathologic voice on held vowels (Hadjitodorov & P.Mitev, 2002; Kent, Vorperian, & Kent, 200; Yu, Ouaknine, Revis, & Giovanni, 2001). However, such vectors are limited in their robustness because of their estimation complexity in real conditions with perturbations of nonstationary structure (Gupta & Gilbert, 2001). Although several analysis of effectiveness have been made around the different kinds of proposed features for objective evaluation of speech disorders (Frohlich & Michaelis, 2000; Yu et al., 2001), they can not be taken as a standard set of parameters for hypernasality identification because each disorder affects differently diverse aspects of speech emission.

The present work analyzes the statistical effectiveness of different acoustic features in the automatic identification of hypernasality. Acoustic features reflect part of information contained in perceptual analysis; in part, due to their estimation is derived directly or indirectly from the vocal cords behavior. Consequently, it is convenient to apply multivariate analysis techniques in determining the effectiveness of voice features. The effectiveness is studied by using multivariate analysis techniques that are meant for feature extraction and feature selection, as well (latent variable models, heuristic search algorithms).

BACKGROUND

Nasalization and Nasal Emission

Nasalization is defined as the link between nasal cavity and the rest of the vocal tract; while nasal emission refers to abnormal air loss through nasal route. This abnormal leakage reduces intra-oral pressure causing distortion in consonants. When air loss turns into an audible reblowing, the nasal emission is more obstructive and speech is seriously affected. Nasality commonly named hypernasality refers to low speech quality, which results from inappropriate adding of the resonance system to vocal tract. Conversely to nasal emission, nasality does not involve large flows of nasal air, so that there is no significant change in intra-oral air pressure. For this pathology, identification studies based on signal modeling (specialized diagnosis) can be related to acoustic features by using pattern recognition techniques.

Nasalization Model

Considering that normal voice is made of resonances at different frequency formants F_k, the following acoustic model (Cairns et al., 1996) is proposed:

$$S_n(\omega) = \sum_{k=1}^{K} F_k(\omega)$$

In contrast to normal voice, nasalized voice is the appearance of the antiformants $\widehat{F}'$ and nasal formants $\widehat{F}$:

$$S_h(\omega) = \sum_{k=1}^{K} F_k(\omega) - \sum_{l=1}^{L} \widehat{F}'_k(\omega) + \sum_{m=1}^{M} \widehat{F}_m(\omega)$$

It has been suggested that the intensity in the reduction of the first formant is a primary indicator of nasality. In Cairns et al. (1996), the superior formants are filtered in such a way that filtered normal voices will have one component, while nasalized voices will correspond to a signal with several components, which can be estimated using Teager's instant power operator.

In a general way, patients with CLP manifest nasality with a deficiency of the velopharyngeal port, coupling their nasal cavity to vocalic sounds that gives place to appearance of an additional resonance in the amplitude-frequency feature of the vocal tract, and so a noticeable decrease in the formants F1 and F2 (Baken, 1996) as shown in sections (a) and (b) of Figure 1.

ACOUSTIC FEATURES AND MULTIVARIATE ANALYSIS

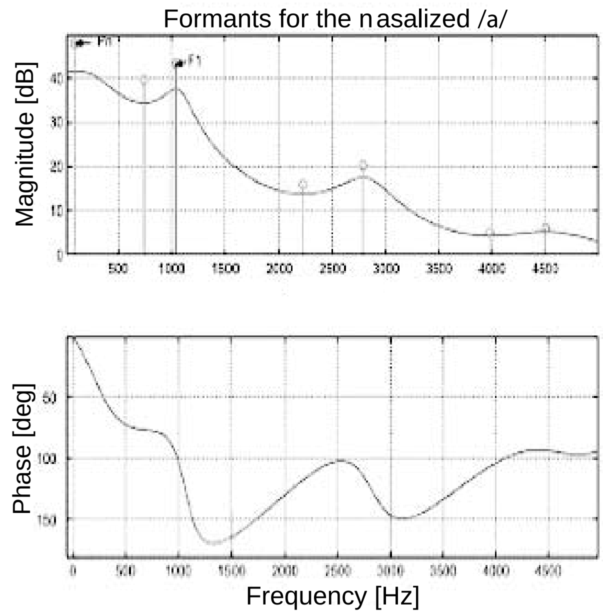
Acoustic features can be split into two categories according to the acoustic properties to be measured. Based in additive noise, among them: Harmonic to Noise Ratio (HNR), Normalized Noise Energy (NNE), Glottal Noise Excitation (GNE), defined as the noise estimation and it is based in the assumption that resulting glottal pulses from collisions of vocal folds head to a synchronous excitation of the different band frequencies, Normalized Error prediction (NEP) that can be expressed as the relationship between geometric and arithmetic means of spectral model, and Turbulence Noise Index (TNI).

Other acoustic features are associated to frequency modulation noise, among them pitch or fundamental period of the signal and jitter, which is defined as the average variation percentage between two consecutive values of pitch. In addition, there are considered features associated to parametric models of speech generation. Among them: cepstral coefficients derived from linear prediction analysis (LPC Linear Prediction Coefficients), cepstral coefficients over pounded frequencies scale (MFCC Mel-Frequency Cepstrum Coefficients), and RASTA coefficients (Relative Spectral Transform) (Castellanos, Castrillón, & Guijarro, 2004).

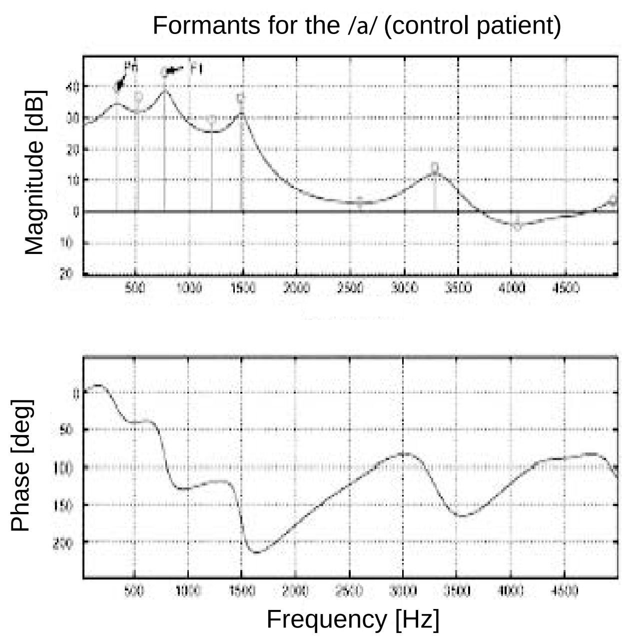
Multivariate Analysis

Latent Variable Models. The set X of measured variables can be seen as the linear combination of generative factors Z and perturbations ε over the measurement process.

Figure 1. Pitch energy for distinguishing glottal stop



(a) Pitch Energy (Pathological case)



(b) Pitch Energy (Normal case)

$$X = WZ + \varepsilon$$

Where W is the weight matrix that assigns the influence of each factor on each observed variable.

Different assumptions about how this factors and perturbations distribute derive in the well known feature extraction techniques. In particular, we consider Principal Component Analysis (PCA), Factor Analysis (FA), and Independent Component Analysis (ICA), for our experiments. A detailed description of these topics can be found in Hyvärinen, Karhunen, and Oja (2001), Jolliffe (2002), and Rencher (2002).

Feature Selection. The proposed methodology for reducing the initial spaces is based on strong relevance analysis, which studies the correlation among features. Reduction methodology considers combining heuristic techniques such as Sequential Forward Search (SFS) (Webb, 2002) with multivariate analysis for further evaluation of feature subsets. Particularly, multivariate analysis of variance (MANOVA) is used as the intrinsic cost function to assess the discriminative power of a given set (Rencher, 2002).

EXPERIMENTAL BACKGROUND

Database

The sample is constituted by 68 children. Classes are balanced (34 patients with normal voice and 34 with hypernasality) and evaluated by specialists. Each recording is conformed by five words of Spanish language: /coco/, /gato/, /jugo/, /mano/, and /papá/. Signals are acquired under low noise conditions using a dynamic, unidirectional microphone (cardioide). Signal range is between (−1, 1).

Table 1. Variable elimination by preprocessing

Word of Analysis	Reduced Space Dimensionality (Reduced/Original)
/coco/	31/40
/gato/	29/40
/jugo/	12/40
/mano/	16/20
/papá/	28/40

INITIAL FEATURE SPACE

A complete set of considered features are: Pitch (F0) (mean value and standard deviation) (Manfredi, D'Aniello, Bruscaglioni, & Ismaelli, 2000; Sepúlveda, Castellanos, & Quintero, 2004), Jitter, Shimmer (Childers, 2000), TNI (Hadjitodorov & P.Mitev, 2002), HNR (Yumoto & Gould, 1982), NNE (Kasuya, Ogawa, Mashima, & Ebihara, 1988), and Mel Frequency Cepstrum Coefficients (MFCC) (13 coefficients) (Huang, Acero, & Hon, 2001). Depending on the analysis word, the aforementioned features can be extracted for one or two voiced segments, which imply that 20 or 40 features represent each register.

Data Preprocessing

The main target of data processing is to reduce or even eliminate the influence of measurement errors. Among them: systematic errors during acquisition, occasional failures in the measurement instruments, and so on. It is also used for controlling the homogeneity principle of the different statistical properties of phenomena in analysis. Data preprocessing consists of analyzing odd logs for each feature and assessing their normality (Peña, 2002).

Classification

The employed classifier is Bayesian. Five classifiers of this kind are used; each of them for analyzing the error between classes (hyper-nasal and normal or control) for each one of the words previously mentioned. Besides, a leave one out cross-validation was conducted to observe the variation in the classifier's parameters and its generalization capability (Webb, 2002).

RESULTS

Acoustic feature effectiveness can be measured according to classification performance. Next, the results are displayed for each one of the stages. The abnormal value detection is conducted for each feature. It allows making clear the quality of the measurements. Those features with 10% or more outliers in either population samples are discarded. Acoustic features results are shown on Table 1. Average reduction for word-set is between 30% to 35%.

/coco/	12	0,7059	18	0,6912	10	0,6176	11	0,8382
/gato/	10	0,9557	5	0,9265	10	0,9559	3	0,9559
/jugo/	5	0,9853	5	0,9412	5	0,9853	1	0,8824
/mano/	4	0,5441	10	0,75	4	0,5441	4	0,8235
/papá/	9	0,7206	17	0,7206	9	0,7206	7	0,8088

Table 3. Classification accuracy of preprocessed data

	Methods							
	PCA		FA		ICA		MANOVA	
Word	**N.L.V.**	**C.A.**	**N.L.V.**	**C.A.**	**N.L.V.**	**C.A.**	**N.L.V.**	**C.A.**
/coco/	7	0,5882	15	0,7353	3	0,6324	7	0,8088
/gato/	9	0,9706	6	0,9853	7	0,7353	3	0,9265
/jugo/	3	0,9412	6	0,9559	3	0,9412	1	0,8824
/mano/	4	0,5882	8	0,7206	4	0,5882	4	0,7647
/papá/	8	0,7059	13	0,75	5	0,6324	6	0,8088

In what concerns normality verification, Gaussian structure of data can be achieved by using a hypothesis test; in this case, a kurtosis test.

The paramount purpose of effective variable selection and feature extraction is to find a reduced representation set that allows for better discrimination among classes. As previously mentioned, feature extraction is carried out by using linear models of latent variables and feature selection is accomplished by using a heuristic technique for growing a subset called "filter." MANOVA becomes then the cost function. The effective feature selection is applied twice: (a) without data preprocessing (Table 2), and (b) after data preprocessing (Table 3). Although, classification accuracy decreases after preprocessing, this is due to size of samples that are small to provide better estimates. Overall results displayed in Table 4 show the MFCCs as good descriptors for detecting hypernasality (N.L.V. stands for number of latent variables or selected features and C.A. for classification accuracy).

FUTURE TRENDS

In the case of hypernasality detection, it would better to design specialized diagnostic features that reflect the nature of the irregularities in the functional state of speech. Such features might offer similar detection levels compared to acoustic features, nonetheless being less computationally complex. Moreover, training a classifier would not be necessary; the compromise degrees of resonance in the pathology could be estimated directly from the estimated features.

Detecting the hypernasality degrees is important because in diagnosis as well as in treatment and surgery, the specialists need to have available a taxonomic reference system that can be useful for relating the different compromise degrees of resonance to velopharyngeal patterns, generating, then, different alternatives for treatment while excluding others.

A

/coco/	TNI, HNR and MFCCs.
/gato/	MFCCs.
/jugo/	MFCCs.
/mano/	MFCCs.
/papá/	MFCCs.

CONCLUSION

Acoustic features can be applied to discriminate pathological from normal speech with fair accuracy. One of the main problems for clustering voice features in hypernasality analysis is their sensibility to acoustic properties. This mutual dependency might be one of the reasons for their contradictory interpretation along literature. Consequently, phonemes of velar articulation patterns with enough discriminating power ought to be identified (lip posture detection) and vocal emission (acoustic analysis). Previous e-tudies have suggested the use of MFCCs in pathological voice detection (Godino-Llorente, Gómez-Vilda, & Blanco-Velasco, 2006). This situation has been corroborated here, since MFCCs were the resulting feature after applying variable selection algorithms.

KEY TERMS

Acoustic Features: Physical characteristics of speech sounds such as color, loudness, amplitude, frequency and so forth.

Bayesian Classifier: A simple probabilistic classifier based on applying Bayes' theorem with strong (naive) independence assumptions.

Heuristic Search: Any search strategy which makes use of heuristics to suggest the best nodes to consider at each stage of the search.

Hypernasality: A quality of voice in which the emission of air through the nose is excessive due to velopharyngeal insufficiency; it causes deterioration of intelligibility of speech.

Latent Variable: A variable in the model that is not measured.

Multivariate Analysis: An analysis of the relationships between more than two variables.

Nasalize: To make nasal or produce nasal sounds.

Adoption of ICT in an Australian Rural Division of General Practice

Patricia Deering
Victoria University, Australia

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

Many information technology (IT) products have been developed to support medical general practitioners (GPs) in all aspects of their work (GPSRG, 1998), and much research and development in this area has already been done. It is apparent, however, that GPs are not making as much use of these systems as they could. Our research showed that there is still reluctance, in particular from many rural general practitioners to fully implement information and communication technologies (ICT) in primary health care in rural Australia (Everitt & Tatnall, 2003). While a simple analysis of the statistics of the numbers of computers in medical practice shows that there are computers in most general practices, it is not so clear how, or even whether, they are being used. Rural GPs, however, operate very much in the mode of small business (Burgess & Trethowan, 2002). Some national research shows that GPs use ICT mainly for administrative and some clinical functions, but that much less use is made of online functions (NHIMAC, 1999; GPCG, 2001). This is even more pronounced for rural GPs.

It is clear that the introduction of the Practice Incentives Program by the Australian Government in 1998 dramatically accelerated the adoption of computer technologies (Tatnall, Everitt, Wenn, Burgess, Sellitto, & Darbyshire, 2004); however, the question still remains—do the GPs use the computers they have acquired, and if so, for what? If they do use computers, then why do some GPs use them more extensively than others? The answers to these questions are not simple and do not appear to be related to the age of the GPs. The aim of the research project described in this chapter was to explain in detail the reasons for adoption or nonadoption of ICT in these medical practices and to develop a model that illustrates the process of decision-making in relation to ICT innovations.

The view that research such as this needs to be grounded in the real world of health practice is supported by continuing increases in health costs and complexity of health delivery. The amount of medical information available to medical practitioners has increased the need to find better ways to manage medical practice, and although hospitals are also experiencing these problems, it is on general practitioners that much of the information management burden falls. Many GPs are examining ways that information can be better managed, and various types of information management systems are becoming an important focus of their work.

USE OF ICT BY MEDICAL GENERAL PRACTITIONERS

While one might expect that highly educated professionals such as most GPs would be at the forefront of the information management revolution; however, our research has shown that this is not entirely the case (Everitt & Tatnall, 2003).

It appears that the slow uptake has continued to some degree in all areas of medical general practice, despite continued support and promotion of computer use (Tatnall et al., 2004). The Commonwealth Department of Health and Aged Care, along with the General Practice Computing Group, also report that general practitioners in Australia are still being encouraged via their Divisions of General Practice to adopt electronic information systems to enhance clinical and practice management. However, Richards (1999) notes, "The adoption of computers by Australian general practitioners has been slow in comparison with other English speaking countries." It is clear that over a long period of time, much research and development have been done on the use of medical ICT, and many products

Table 1. General practice computer use (GPSRG, 1998)

Use of Computers	Level of Usage (%)
Administrative functions	85
Clinical functions	76
Script writing	60
Generating referral letters	57
Receiving results electronically and running recall systems	57

have been developed for GPs. Despite this, however, reluctance on behalf of GPs to use ICT continues and appears to be a fact of life for many of the rural members of the profession.

Table 1 represents the main uses for computers that were identified by a 2001 General Practice Computing Group (GPCG) study of 1,202 GPs.

METHODOLOGICAL FRAMEWORK FOR THE RESEARCH

Many factors and entities are involved in determining how GPs adopt and use ICT, and any approach that ignores the inherent complexity of this sociotechnical situation is unlikely to produce useful answers. This chapter will argue that a qualitative approach using the Actor-Network Theory (ANT) allows for the views of all subjects to be fully documented and explained. This approach was necessary because the complexity of health delivery in Australia has increased the need to manage information in medical practices, leading to a multistakeholder environment involving human and nonhuman entities. Our research aimed to explain the patterns of computer use by rural GPs in an Australian Division of General Practice, and to draw out the factors that contribute to patterns of computer use. In undertaking this research, we compared two theoretical approaches that seek to explain the adoption and use of computers by GPs: Innovation Translation (from the Actor-Network Theory) and the better-known theory of Innovation Diffusion.

In regard to the theoretical approach being taken, there has been a search for a seamless design approach to research in ICT for several decades, but often the methodology for ICT research has been transferred from science. This has not always been successful, as these approaches imply that the scientific method produces reliable knowledge because consistency, dependability, and regularity are the benchmarks for science. However, according to Latour (1987b), despite the fact the scientists aim to subscribe to morally and technically efficient methods that are impersonal and objective with results that are open to everyone, research seldom happens in this manner because science reacts to social pressures just like any other ordinary and mundane system of action.

In his discussion of the Innovation Diffusion model, Rogers (1995) asserts that an individual's decision to adopt an innovation is not an instantaneous act, but rather a process that occurs over time, consisting of a series of actions and decisions. Anything new causes uncertainty, and so there is a lack of predicability and people will seek information to change that situation. In this model, diffusion could be considered a process of information exchange aimed at reducing uncertainty. "The new ideas upon which an innovation is based are communicated over time, through various types of communication channels, among members of a social system through which the innovation diffuses" (Rogers, 1995). There are thus four main elements of any theory of innovation diffusion: characteristic of the innovation itself; the nature of the communication channels; the passage of time; and the social system. Diffusion is considered to be an information exchange process among members of a communicating social network particularly concerned with the characteristics of the innovation. A simplistic view of this project might be that the GPs will make their adoption decisions primarily because of the characteristics of ICT, and would miss other influences due to interbusiness interactions and the backgrounds of the people involved.

While diffusion models (Rogers, 1995) of innovation have had considerable success in explaining the movement (diffusion) of technology in the large scale, they have had much less success in explaining *individual* cases of technology adoption or nonadoption (Latour, 1986; Tatnall & Gilding, 1999). Although Rogers' (1995) approach has increasingly moved toward the inclusion of social factors to explain the diffusion and adoption of technology, we argue that it has not gone far enough. In the field of technology studies, there is an increasing body of work that suggests that there are many complex social factors involved in the interaction of society and technology (Good 1990; Latour, 1987a, 1988; Mol & Law, 1994) and that any process of technology adoption in such an environment must inevitably involve a set of complex negotiations among all those involved. Furthermore, the final outcome typically will involve any devised product being *translated* (Law, 1992) from the form initially proposed to a form suitable for actual use. Most GPs operate in a small business environment, and research has suggested (Tatnall, 2002; Tatnall & Lepa, 2003) that adoption of technology in small business and by special groups can be better explained using an approach such as *innovation translation* (Callon, 1986a; Latour 1986, 1996), for which Latour (1992) claims several advantages: respect to the actors and their individual differences; allows for all entities; pays respect to the outcomes; failures have the same explanations as successes so no hierarchy of dominance is produced; all links in the network are accounted for; and when information is translated from one form to another, it can still be credited to its origins.

The translation model (Latour, 1996) posits the continuous *transformation* of an innovation into new forms by all those who touch it. The essentialist tenets of innovation diffusion—that there is some property in the innovation, the society, or the potential adopter that facilitates diffusion—differ radically from the translation view in which it is the potential adopters who hold the key in their actions. There are occasions when diffusion does not occur despite the excellence of the idea or the technical quality of the innovation, and the diffusion model finds these difficult to explain. Innovation translation concentrates on issues of network formation and investigates the human and nonhuman alliances and networks built up by the various actors involved. It concentrates on the negotiations that allow the network to be configured by the enrolment of both human and nonhuman allies, and considers the

Table 2. Innovation diffusion and innovation translation (McMaster, Vidgen, & Wastell, 1997)

	Innovation Diffusion	**Innovation Translation**
Discipline of origin	Social science and communication theory	Semiotics, sociology of scientific knowledge
Definition of innovation	A technology perceived to be new by a potential adopter	A technology that has yet to be black-boxed
Shaping of innovation	Generally decided at design stage	Shaped by the network of actors
Communication	Communication channels categorized as cosmopolite vs. localite, mass media vs. interpersonal	Translations are made by actors in enrolling the innovation
Time	Speed of decision to innovate, rate of adoption is important	Network dynamics in enrollment, control and dissemination are what matter
The social system	Sharing of interests of human actors	Interessement among actors (human and nonhuman) and goals
Spread of ideas	Diffusion from a single source	Occurs through social/network interactions
Origin of power	Usually vested in a single powerful entity or change agent	The result of interactions among entities in the network
Motivating force	Early adopters provide the example for others to follow	Resides in the network of actors—habits, routines, and institutional behaviors inhibit movement
The technology	Changes made to form and content of the technology as a result of experience during implementation (re-invention)	Technology is translated through being enrolled, regardless of whether its form or content is modified
Socio-technical stance	Social system and technology are separate, diffusion is the adoption of technology by a social system	The social system and the technology are inseparable

IT system's characteristics only as network effects resulting from association (Wenn, Tatnall, Sellitto, Darbyshire, & Burgess, 2002). Innovation translation theory suggests that it is not any *innate properties* of these systems that are important, but rather *network associations* (Callon, 1986b; Bijker, Hughes, & Pinch, 1987), such as the extent to which the medical practice has been enrolled in the advantages of the new system. It looks at the process of redefinition in which the medical practice tries to seek compromises from the IT system and how the system imposes definitions of how the technology should be used; how it "interested" the medical practice and then got them to follow its interests, so becoming indispensable to them. What is finally adopted for this task is not the IT system originally examined as such, but rather a translation of this in which it becomes a tool for their particular medical practice use. Innovation translation is thus more attuned to the human and political issues involved in organizational decision-making, and so offers a useful approach to modeling innovation in small business (Tatnall, 2002).

Innovation diffusion and innovation translation are based on very different philosophies. Table 2 illustrates some of the main differences between these two innovation models.

RESULTS AND CASE STUDY

A significant difficulty experienced in collecting data for this project related to making contact and establishing working relationships with individual GPs, who typically must be accessed via their practice manager. As GPs have such a busy schedule, making time to take part in a research project can be a big time sacrifice and, as they are aware of this, the practice managers are often reluctant to facilitate access. We have learned to regard the practice managers as some of the key contacts in the research project, and as important people who were not at first acknowledged as being important to the study. They act as gatekeepers of the information, so to speak, and are important contacts in reviewing how IT works in medical practices. Another issue arose around doing qualitative research in an industry that is only just coming to grips with research of this type and the processes involved. Continually having to justify the premise for qualitative research certainly keeps the researcher on his or her toes and ensures that the source of funding is given credit. The study also provided a chance to sell qualitative practice in the health sector and contribute in a very positive manner to the development of research methodology in this sector.

The following data relate to a rural Division of General Practice not far from Melbourne, Australia, where this study was conducted. The data come from 98 participating GPs (approximately two-thirds of those currently practicing in this division), of whom 89 were male and nine were female. Of these GPs, 42 practiced full-time and 56 part-time. The most common practice size comprised four GPs (there were 10 of these practices) followed by four larger practices (with more than four GPs) and two solo medical practices. There were 55 GPs in the age range 25 to 35, 27 from 36 to 45, and 16 older than 45. Each practice made some use of computers, and all had been doing so for at least 12 months, with about 60% using them for both clinical and administrative purposes and the remainder using them only for practice administration.

In addition to this quantitative data, the following brief case study provides a snapshot of one medical practice of several GPs located in a small country town. The Practice Principle was the sole decision maker and is very active in promoting adoption of ICT and Information Management. This practice reports wide use of computers for generating prescriptions, investigation request slips, current medication lists, and referral purposes, as well as for the usual administrative needs. The principle of this practice discussed the following concerns:

- Changing the way the doctors work
- The high cost of changing and updating computer technologies
- Doctors learning to type
- Losing patients who do not like the GP/patient/computer interface
- Losing information by accident (erasing information)
- Confidentiality
- Losing valued staff as change to computerization take place
- Money loss as productivity is reduced while learning new technologies
- Security of electric power supply in the country

The GPs from this practice expressed the following concerns:

A

- **Technical issues:** The effect of computer use in the patient and doctor relationship
- **The work environment:** Trialing programs before use
- **Training and education:** A forum to discuss ideas about computers

The following comments taken from these interviews show a very positive attitude to computerization in this division and that the quantitative data previously provided shows only half the picture.

- "Don't be afraid, take a step. The only way to go is forward, unless you want to be anxious or depressed."
- "Electronic information is much easier to transfer from system to system than ink on paper. Lock-in isn't the problem it's thought to be, and the software industry has committed to fight it."
- "Plan for a useful life of computer hardware and software of around three years. The tax man says you can depreciate computers at 36%. If your system lasts functional longer than three years, you have earned a bonus."
- "Get a computer for home, connect it to Internet, and use it. There's no excuse, either for the kids, for yourself, or for your partner."
- "Home computers and modems are at commodity prices. Learn in the privacy of your own home."
- "Network with GPs who can share their computing experiences. Knowledge in this field has a very short shelf life. Anything in print with a cover is out of date. Your absolute best resource is the grapevine. The Internet is a superb grapevine."
- "Computerise your records if there is opportunity. Major opportunities include starting a new practice, changing from cards to the RACGP record system, and implementing health summaries. If your apple cart is stable, it may be best to let it be for a little while."

This small snapshot makes use of an actor-network analysis of the data gained through interview, observation, and discussion, and through a short survey. The information sought related to the experiences of the individual GPs rather than to their ability to use computers. As software and hardware issues are not clearly listed in these concerns, it is suggested that there has been an improvement in both since earlier days of computer introduction These concerns might imply that there is still a lot to be achieved by GPs, and that there may be logical steps in the adoption of computers into a practice (if steps are taken in a logical process, some of the concerns may be eliminated). The comments we have included indicate that use of information technologies does not develop in isolation, and similarly, these technologies do not develop free from social influence. The research indicates that the two shape each other, and that GPs and their practice staff will continue to struggle with the pace of change.

CONCLUSION

In this chapter, we have described how, by use of an actor-network theory, we are one step closer to a more detailed understanding of the relationships between information technology and its use in general practice. This choice was motivated by the way the actor-network theory offers a language and vocabulary for describing the many small, technical, and nontechnical mechanisms that go into the building and use of information infrastructures in rural general practice. The actor-network theory goes a long way to describe how actions are enabled and constrained. Information technologies do not develop in isolation free from social influence, and we have discussed how the two shape each other and how GPs and their practice staff continue to struggle with the pace of change.

KEY TERMS

Actor-Network Theory: An approach to research in which networks associations and interactions among actors (both human and nonhuman) and are the basis for investigation.

Australian Divisions of General Practice Ltd: The peak national body representing 121 local groupings of GP, known as Divisions of General Practice, across Australia.

Essentialism: The philosophical view that for some specific entity there is a finite list of characteristics that determine its nature.

General Practitioner (GP): A General Practitioner (known in some countries as a Family Physician) is a medical doctor who provides primary care, treats acute and chronic illnesses, and provides preventive care and health education.

Innovation Diffusion: A theory of innovation in which the main elements are characteristics of the innovation itself, the nature of the communication channels, the passage of time, and the social system through which the innovation diffuses.

Innovation Translation: A theory of innovation in which, instead of using an innovation in the form it is proposed, potential adopters *translate* into a form that suits their needs.

Practice Manager: The administrative (i.e., non-medical) manager of a medical general practice.

Advances and Trends in Tissue Engineering of Heart Valves

INTRODUCTION

Improvements in health care and treatment of diseases have led to an increase in life expectancy in developed countries. However, this achievement has also inadvertently increased the prevalence of chronic illnesses such as cardiovascular disease, adding to the growing burden of health care cost globally. Unfortunately, this trend is expected to escalate in the foreseeable future. Cardiovascular disease remains one of the main problems in contemporary health care worldwide, accounting for approximately one third of the world's total death (Poole-Wilson, 2005). This article focuses on a subgroup of cardiovascular disease known as valvular heart disease whereby abnormalities or malfunctions of the heart valves are detected. It is estimated that 93,000 valvular surgeries were conducted in the United States in 2002 (American Stroke Association & American Heart Association, 2005) and valve replacement surgeries accounted for 75% of the surgery performed for valvular defects in Australia and, of that, 56% were for aortic valves (Davies & Senes, 2003).

BACKGROUND

Currently, there are two types of artificial heart valves used in valve replacement surgeries: mechanical and tissue valves. However, these prostheses are not without limitations. Mechanical valves are usually made from pyrolytic carbon attached to a PET-covered metal such as titanium frame. Although more durable than tissue valves, patients implanted with mechanical valves are subjected to long-term complications such as thromboembolism, leading to a life-time administration of anti-coagulant (Bloomfield, Wheatley, Prescott, & Miller, 1991; Oxenham et al., 2003). Alternatively, tissue valves created from biological tissues from human or animal (porcine or bovine) may be used. While tissue valves do not require long-term anticoagulants, they undergo progressive deterioration such as calcification and tearing of cusps, leading to structural failure (Hammermeister, Sethi, Henderson, Oprian, Kim, & Rahimtoola, 1993; Schoen & Levy, 2005). Moreover, these clinically used prostheses are incapable of growth or remodelling. Hence, extensive research and development is being conducted worldwide to explore the potential of an emerging field, Tissue Engineering (TE), as a solution for addressing the shortcomings of current prosthesis used in valve replacement surgeries.

TE is a multidisciplinary area that amalgamates the principles of engineering and biological sciences to create functional tissue which can be ultimately used to repair, regenerate, or replace diseased or damaged parts of the body. A general approach of TE involves utilising temporary porous three-dimensional (3D) scaffolds to: (i) define the complex anatomical shape of the tissue, (ii) guide the proliferation and differentiation of seeded cells, and (iii) provide mechanical support for the cells (Ang, Leong, & Chua, 2006; Yang, Leong, Du, & Chua, 2001). While conventional techniques such as solvent casting and particulate leaching can be used to manufacture scaffolds, their applications to create scaffolds for heart valves are largely restricted by their limitations such as lack of mechanical strength and use of toxic organic solvents (Ang et al., 2006; Sachlos &

Czernuszka, 2003). The creation of scaffolds for heart valves require specific characteristics and precision of the tissue to be captured and ideally these scaffolds should be tailored to individual patients.

RAPID PROTOTYPING TECHNOLOGIES

Recently, an increased interest has been generated for Rapid Prototyping (RP) techniques as powerful tools for fabrication of scaffolds. RP techniques may be able to address some of the limitations encountered in the conventional techniques. There are three types of RP techniques discussed in this article: fused deposition modeling (FDM), 3D printing, and bioprinting.

FDM is a material deposition process which uses a computer-aided design (CAD) model to generate 3D scaffolds (Masood, Singh, & Morsi, 2005). The scaffolds are generated through the extrusion of thin rods of molten polymer using a computer-controlled XYZ robotic dispenser (Figure 1). The layers of polymer are deposited in an interconnected manner, thus improving the mechanical stability of the scaffold. FDM enables complex yet accurate characteristics to be reconstructed from CT scans, which leads to the ability to create scaffolds customised to patients' needs. Scaffolds demonstrating the complex geometry of the aortic valve which incorporated the exact dimensions of the sinuses of Valsalva (required to preserve the flow characteristics of the valve) were successfully manufactured using FDM (Figure 2) (Morsi & Birchall, 2005). This technique offers a high degree of control over the shape, pore interconnectivity, and porosity of scaffolds as individual process parameters can be defined and improved (Ang et al., 2006). A high resolution of 250 μm can be achieved with the FDM. An added advantage of the FDM technique is that the process does not utilise toxic solvents and porogens for the manufacturing of scaffolds (Leong, Cheah, & Chua, 2003; Yang, Leong, Du, & Chua, 2002). The flexibility of this technique lends itself to produce scaffolds of varying designs and complexity, thus expanding its application to other areas of TE aside from heart valves.

The 3DP is a layered fabrication process whereby sliced 2D profile of a model determined by CAD file is transform to a STL file and printed on a fresh layer of powder via deposition of a suitable binder from the inkjet printhead (Figure 3). The powders used are natural polymers such as starch, dextran, and gelatin in conjunction with water-based binder so that the scaffolds can be used in medical applications, as toxic solvents can be omitted from the manufacturing process. The 2D profiles are then successively printed on freshly laid layers of powder until the entire scaffold is printed. These printed layers are held together through

Figure 1. Diagram demonstrating the fabrication process of FDM. The ABS filament is fed through the FDM head via the drive wheels and melted at the appropriate temperature in the liquefier. The polymeric fibres of 250 μm are then deposited layer by layer in an XYZ direction to produce a 3D scaffold.

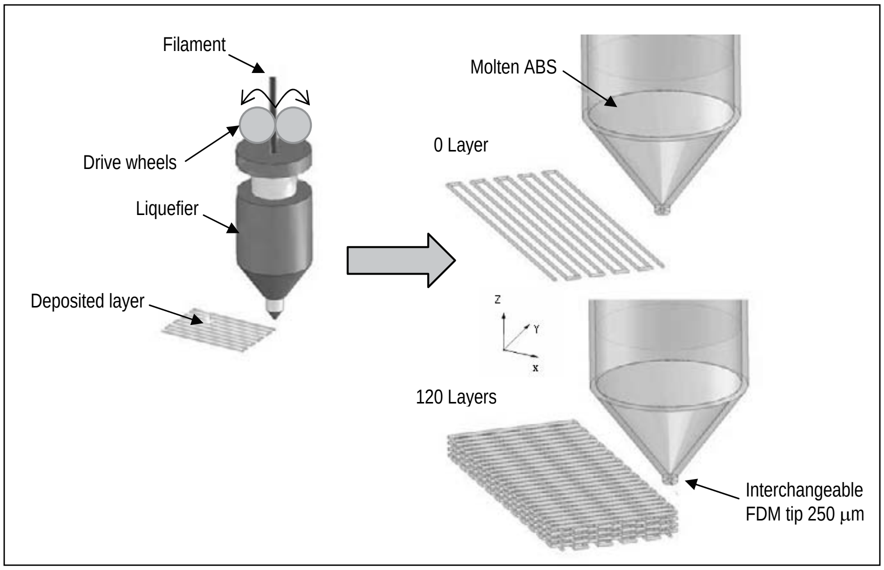

Figure 2. (a) FDM machine which produces 3D scaffolds using a deposition process; (b) model of an ovine aortic heart valve including the sinuses of Valsalva manufactured using FDM

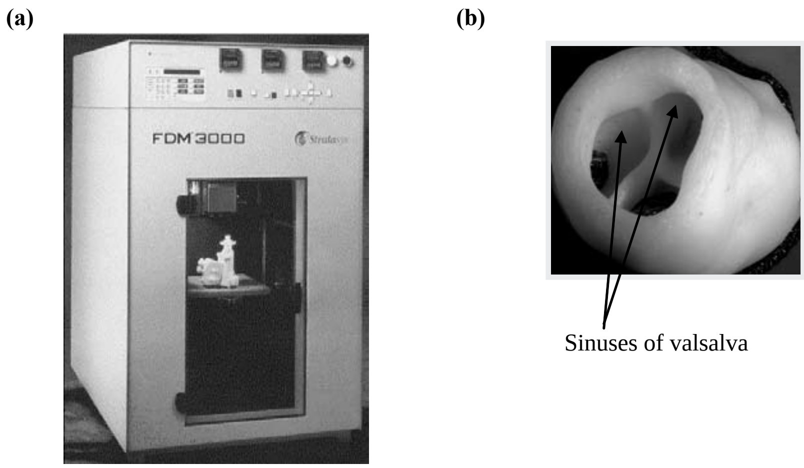

the binder and the completed model then undergoes post-processing to improve its water resistance and mechanical strength. This is because models created via 3DP are weak and easily damaged. The post-processing involves the printed scaffolds being dried at 100°C and impregnated with molten wax or polymeric solutions such as polycaprolactone and poly-L-lactide acid, followed by drying at room temperature (Lam, Mo, Teoh, & Hutmacher, 2002). Shrinkage of scaffolds can occur during post-processing and the proportion is dependent on the shape of the scaffold. Scaffolds with circular pore designs have been shown to have the highest shrinkage (Lam et al., 2002). The 3DP techniques enable scaffolds to be made at a fast pace and are cost-effective as compared to the FDM process. This technique is advantageous for producing scaffolds that do not require precision with regards to dimensions and mechanical strength, for example, as a prototype for conceptualisation purposes.

Bioprinting is a form of RP technology that incorporates biological components such as living cells into the scaffold produced. Typically, standard inkjet printers are modified so that cells suspended in liquid can be sprayed onto biodegradable, thermosensitive gel based on computer generated templates (Mironov, Boland, Trusk, Forgacs, & Markwald, 2003; Ringeisen, Othon, Barron, Young, & Spargo, 2006). The gel is then printed layer by layer to create the 3D model. Currently, a resolution of approximately 100 μm can be achieved (Mironov, Reis, & Derby, 2006). Recent improvements on the bioprinting technology have enabled aggregate of cells to be deposited in droplets via a micropipette within the printing head, as shown in Figure 4 (Jakab, Damon, Neagu, Kachurin, & Forgacs, 2006). This would increase the density of cells being "printed" onto the scaffold and possibly accelerating the formation of tissue.

It is essential that the printing process does not affect the viability of the cells; therefore, generation of scaffold within a short period of time is advantageous. Other factors that need to be considered include the heat generated by the inkjet system, shear stress experienced by cells during ejection from the printer head, and the impact upon contact with the scaffold. Furthermore, the printing process should not be toxic to the cells and the scaffold generated should be well interconnected. Printed chicken heart cells have been shown to survive the process and after 19 hours demonstrated normal heart cell characteristics such as beating synchronously (Jakab et al., 2006). An electrostatically driven printing system that generated less heat than the conventional system was recently demonstrated to be conducive to bovine endothelial cells (Nakamura et al., 2005). Bioprinting has the potential to create viable tissue such as blood vessels by, for example, printing consecutive circular layers of smooth muscle cells lined with endothelial cells to form a tube serving as replacements for arteries and veins. Since the cells are already incorporated in or onto the scaffold, the time required for investigating cellular growth and characteristics such as functionality *in vitro* can be reduced. A better understanding of the mechanism will ensure effective implementation of the technology to produce 3D scaffolds.

RP techniques are increasingly being used in the area of prosthetics. While TE of organs requires the creation of an anatomically correct scaffold, the mechanical properties of the scaffold also play an important role in tissue regeneration. The mechanical strength of the scaffold should be comparable to that of the organ or tissue of interest. For example, scaffolds for heart valves must be able to withstand the haemodynamic pressures experienced *in vivo*. Factors that influences mechanical properties include porosity of the scaffolds, strength and elasticity of the materials used (Yang et al., 2001). The technologies of RP have the flexibility to produce scaffolds with varying porosity to accommodate specific requirements. This is because the parameters of the RP techniques can be modified and controlled using softwares that drive the machine, giving rise to numerous possibilities. The flexibility offered by RP technologies is important as the optimal porosity differs between cell types with respect to cell attachment and proliferation, which in turn affect the mechanical properties required. Consequently, a balance or compromise is needed between these factors to produce a scaffold that can carry out a particular function satisfactorily.

CURRENT RESEARCH AND FUTURE TRENDS

RP is a technology that is developing rapidly, diverging from its traditional role in engineering to being used as a powerful tool in medicine, for example, in the area of prosthetics, surgical planning, and medical instrumentation. The transition from a technology mainly used in engineering to medicine was eased by the fact that computed tomography (CT) techniques used to scan various parts of the body operate via similar layer-based technologies as RP. Data obtained from the CT scans can be interpreted and translated to the RP system accurately.

RP techniques have been used in hip replacements and maxillofacial prostheses where models are created so that the resulting implant can be fitted onto the patient precisely (Eggbeer, Bibb, & Evans, 2006; Sanghera, Naique, Papaharilaou, & Amis, 2001; Sykes, Parrott, Owen, & Snaddon, 2004). Complex and challenging tasks such as sculpting an ear cast have also turn to RP so that an accurate model of the patient's ear can be generated in a time-efficient manner (Al Mardini, Ercoli, & Graser, 2005). Moreover, these techniques have been implemented to aid surgeons in their surgical planning for reconstruction procedures and act as guides during the procedure so that optimal outcomes, both clinically and aesthetically, were obtained, as well as for education purposes such as improving the understanding of trainees (Muller, Krishnan, Uhl, & Mast, 2003; Poukens, Haex, & Riediger, 2003; Toso et al., 2005).

Research into TE of heart valves has utilised RP in an attempt to address the aforementioned limitations of currently used prosthetic heart valves. Generally, a polymeric scaffold of heart valves is produced using RP and then seeded with cells of interest such as endothelial cells, valvular cells, and stem cells (Morsi, Birchall, & Rosenfeldt, 2004; Sodian et al., 2005). Research into stem cells in the recent years has presented itself as an exciting area in TE due to the potential of being undifferentiated cells that have the capability of developing into cells with specialised functions such as heart, liver and kidney cells. This suggests that given the right conditions, stem cells seeded onto scaffolds of heart valves may develop into valvular cells required to produce a functioning organ. However, the mechanisms of stem cells are yet to be fully understood and it is beyond the scope of this article to explore this area further.

Currently, RP technology in the form of FDM does not support the direct fabrication of scaffolds using biocompatible and biodegradable polymers. This is because initially, FDM machines utilise acrylonitrile butadiene styrene exclusively as its source of polymer. Subsequent modifications to the system enabled limited polymers, for example, polycaprolactone to be used by the FDM machine to create scaffolds for TE of bone (Chim et al., 2006). The success of modifying FDM systems to accommodate polymers other than acrylonitrile butadiene styrene has encouraged research into these systems to support other biocompatible and/or biodegradable polymers so that the models produced are clinically applicable. However, through FDM technology, a precise mold of a heart valve can be fabricated which in turn facilitates the creation of scaffold with polymer of one's choice. This indirect technique enables the design of heart valve scaffolds to be optimised, geometrically and biologically. The complex geometry of heart valves was successfully reproduced by RP technology and scaffolds of trileaflet heart valve created using synthetic polymers such as poly-4-hydroxybutyrate were demonstrated to be capable of opening and closing synchronously (Sodian et al., 2002). Other polymers such as polyglycolic and polylactic acid have also been used to create scaffolds for heart valves (Kim et al., 2000; Shinoka, 2002). Moreover, it is feasible to create heart valve scaffolds from natural polymers such as collagen using indirect RP techniques (Rothenburger et al., 2002; Sachlos, Reis, Ainsley, Derby, & Czernuszka, 2003; Taylor, Sachlos, Dreger, Chester, Czernuszka, & Yacoub, 2006).

CONCLUSION

RP is being increasingly used in medical research due to its flexibility in creating a variety of complex shapes which can be custom made to the patient's specifications. This ensures that implants will be optimally positioned in individual patients, thus improving the quality of treatment. Manufacturing scaffolds using RP technology also enable the transformation from design to a 3D model in a time-efficient and cost effective manner. Additionally, the operation of RP systems requires minimal human resources as most of the processes are automated. The ultimate goal is to refine existing RP technology so that it is applicable to medical research whereby scaffolds of heart valves fabricated from biocompatible and biodegradable polymer can be achieved using direct RP techniques. Such an achievement will not only produce heart valve scaffolds that are anatomically correct but ones that will degrade as extracellular matrix and tissue gradually takes over the scaffold, taking it a step closer to the generation of a true living tissue.

ACKNOWLEDGMENT

The authors would like to thank Mr. Toby Lai for his assistance in creating the diagrams.

KEY TERMS

Biocompatible Polymer: Polymer that does not produce toxin or harmful products and stimulate an immune response in biological systems. This is essential so that during implantation, the material does not induce a rejection response.

Biodegradable Polymer: Polymer that can be broken down into nontoxic by-products through biological processes. Biodegradation can occur physically or chemically via enzymes or bacteria. Examples of biodegradable polymers are polyglycolic acid and polycaprolactone.

Cell Proliferation: An increase in the number of cells due to cell growth and cell division. In the area of tissue engineering, proliferation of cells would enable cells attached to the scaffold to gradually cover the surface area of interest, producing a layer of live cells.

Computer Aided Design: Also known as CAD. A computer based software program which is commonly used to assist engineers and architects in designing detailed 3D models. CAD is also a useful tool for conceptualisation of designs and visualisation of models prior to production.

Fused Deposition Modeling: Commonly known as FDM. A type of RP technique. FDM produces 3D scaffolds by heating the material in the extruder and depositing them in a horizontal and vertical direction (XYZ direction), which is controlled by CAD.

Rapid Prototyping Technique: An advanced manufacturing technique that produces 3D models in an automated manner through sequential layering of the material. Models can be created in a time frame ranging from 3 to 72 hours, depending on size.

Scaffold: A supporting structure for cells and tissue to grow on; a scaffold will provide the physical structure, which guides the cells to grow to the correct anatomical shape.

INTRODUCTION

Millions of patients experience bone loss as a result of degenerative disease, trauma, or surgery (Xu, Othman, Hong, Peptan, & Magin, 2005). Healthy bone tissue constantly regenerates itself and remodels its architecture to meet the mechanical demands imposed on it, as described by Wolff's "Law of Bone Remodeling" (Wolff, 1986). However, this capacity is severely limited when there is insufficient blood supply, mechanical instability, or competition with highly proliferating tissues (Pinheiro & Gerbei, 2006). Furthermore, severe bone losses can be detrimental to individuals, because they reduce the bone's ability to remodel, repair, and regenerate itself (Luo et al., 2005; Nordin & Franklin, 2001), ultimately resulting in the deterioration of a patient's health, and, in some instances, death (Luo et al., 2005).

Because the repercussions of bone loss are severe, it is important to replace lost bone in patients. The current *gold standard* for specific-site structural and functional bone defect repair is autologous bone grafts (Mauney, Volloch, & Kaplan, 2005) or autografts. While autografts do not present the problem of immune rejection, since the bone tissue is being transplanted from another region of the patient's own body (Rahaman & Mao, 2005), they present certain complications such as significant donor site morbidity (death of tissue remaining in the region from which the donor tissue was removed), infection, malformation, and subsequent loss of graft function (Mauney et al., 2005).

Another established and widely employed technique for the treatment of bone loss is the transplantation of allograft bone or bone tissue from a donor (Mauney et al., 2005). Although allograft bone is effective in treating bone loss, there are several common problems associated with it: first, a compatible donor must be found (Jones, Erhenfried, & Hench, 2006) in order to minimize the possibility of immune rejection by the patient; second, there is a risk of potential disease transmission from the donor to the patient; third, donor site morbidity can occur (Jones et al., 2006); and, finally, there is a limited supply of donor tissue (Mauney et al., 2005). Therefore, patients often experience long waiting periods before receiving the transplant, due to the scarcity of tissue donors, and this can exacerbate bone tissue loss (Jones et al., 2006).

The development of the field of bone tissue engineering has expanded the solutions available to the problem of bone tissue loss. Arguably, implants developed via tissue engineering applications may be a more viable solution to the problem of bone loss than conventional solutions. In contrast with transplants, such implants are not subject to patient-donor tissue biocompatibility issues, because donor tissue is unnecessary. Also, morbidity of the site of extracted tissue is not as great of a problem, since implants can be developed from less tissue. Additionally, implants are generally more readily available to patients than transplants, which reduces the time for initiation of bone loss treatment (Jones et al., 2006). Therefore, bone tissue engineering may very well be the future gold standard treatment for bone loss.

BACKGROUND

One basic scheme of the bone tissue engineering process currently employed is illustrated in Figure 1. Briefly, mesenchymal stem cells are obtained from the patient, generally from the bone marrow (Stock & Vacanti, 2001). After a period of cellular expansion, the cells are seeded on biodegradable and biocompatible scaffolds (Stock & Vacanti, 2001). Poly-DL-lactic-co-glycolic acid (PLGA), gelatin, and collagen scaffolds are frequently employed as surfaces for bone tissue development (Wu, Shaw, Lin, Lee, & Yang, 2006; Xu et al., 2005; Zhang et al., 2006). These scaffolds are supplemented with bone differentiation promoting factors such as bone-morphogenic protein, dexamethasone, and ascorbate-2-phosphate that enable the stem cells to differentiate into osteoblasts (bone-forming cells) (Kim et al., 2005). After a substantial period of culturing, implantation of the scaffold into the patient occurs, leading to bone restoration (Xu et al., 2005).

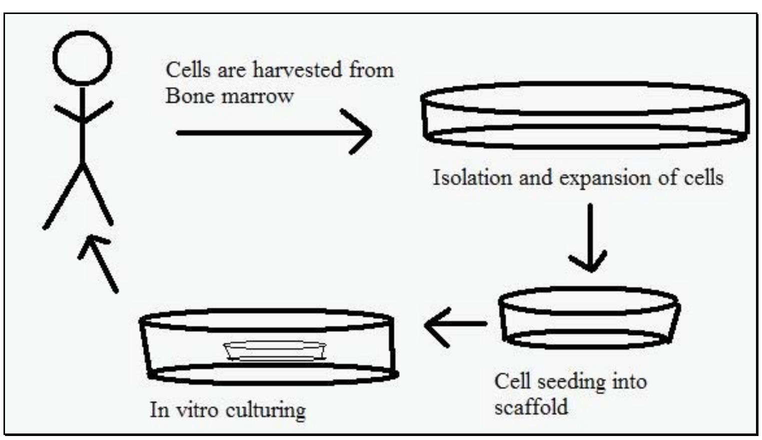
Although this process has the potential to treat bone loss, it is far from optimal. Formation of engineered bone tissue currently takes several weeks (at least 3 to 4 weeks), resulting in extensive waiting periods for patients (Cartmell et al., 2005). Since time is of the essence for patients with bone loss, reducing the culture time of stem cells is necessary for implants to be effective. In addition, a portion of the engineered tissue is destroyed during invasive histological assessment conducted to confirm the formation of bone tissue. This form of assessment can further increase patient waiting periods, as the portion of engineered tissue used for testing is no longer available for implantation. A need exists for a bone tissue engineering process that overcomes these problems.

Reducing the culture time of stem cells is necessary to increase the effectiveness of engineered implants. The use of electrical and mechanical stimulation devices to accelerate stem cell differentiation into osteoblasts has been implicated.

Electric and electromagnetic fields may be effective in accelerating stem cell differentiation. Aaron, Ciombor, and Simon (2004) demonstrated that electric and electromagnetic fields can accelerate bone formation and healing, particularly in osteotomies and spine fusions, both *in vivo* and *in vitro*; osteotomy is a procedure in which bone is surgically cut to improve alignment (ASBA Glossary, 2005). Electric fields can be generated either invasively in bone, by placing electrodes directly into the healing site, or noninvasively, through capacitive or inductive coupling. Osteogenesis, or bone formation, is usually stimulated at the cathode (Aaron et al., 2004).

"Electrical Properties of Bone" by Lakes (2005) describes another type of stimulation that can be achieved by means of a piezoelectric actuator. It has been demonstrated by several researchers that bone is piezoelectric. The piezoelectric nature of bone indicates that any mechanical stress applied to bone can produce

Figure 1. A current process of bone tissue engineering is depicted



an electric polarization of the tissue, and any electric field applied to bone can cause mechanical strain of the tissue. Piezoelectric effects occur in the kilo-hertz range, well above that of physiologically significant frequencies.

Pilla (2002) describes how low-intensity electromagnetic and mechanical modulations of bone growth and repair are equivalent. To explain that, there is a time-varying electric field, E(t), associated with both types of stimuli, which serves as a main messenger regulating cellular activity, therefore acting as a growth stimulus. This electric field can be either directly induced with electric and electromagnetic devices, or indirectly induced by an applied mechanical stress. One way to generate the latter is to use a piezoelectric actuator as described previously, and another way, which has also been demonstrated to work effectively for both *in vivo* and *in vitro* bone formation and repair by Nolte et al. (2001), is to use low-intensity ultrasound waves. Bone repair is significantly enhanced by both electromagnetic fields and ultrasound signals (Pilla, 2002).

In tissue engineering involving osteoblasts seeded onto scaffolds and grown *in vitro*, a recent study by Cartmell et al. (2005) has proven that mechanical forces, when applied within a certain dosage, influence osteoblast activity, by accelerating their growth. The solution for stimulation used in this study was "magnetic particles" that were coated with RGD peptides (adsorption-promoting proteins), and then attached to the human osteoblasts. Exposure to a magnetic field would cause the magnetic particles to move or vibrate, thus creating mechanical stimulation.

The various stimulation methods cited above demonstrate the recent trend towards developing technologies that improve established tissue engineering processes. Yet, the optimized usage of such stimulation devices has yet to occur (Zhang et al., 2006), and is dependent upon further research.

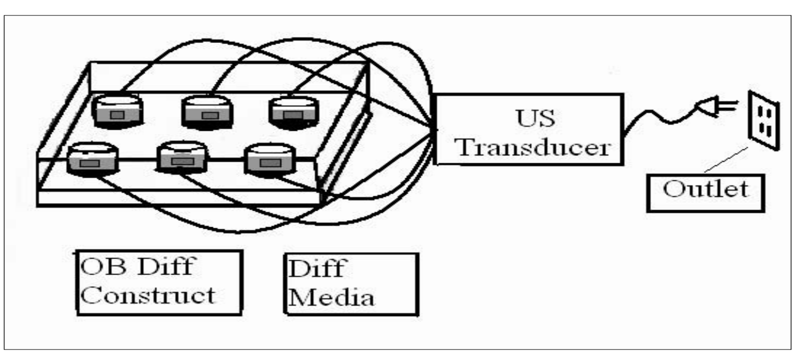
DEVELOPMENT OF A FEASIBLE BONE TISSUE ENGINEERING PROCESS

The development of a feasible bone tissue engineering process calls for a combination of a noninvasive stimulation device to reduce stem cell culture time, and a noninvasive method for monitoring the growth of the engineered constructs.

Of the various methods available to reduce the culture time of engineered bone tissue, ultrasound (US) stimulation may be the most promising one. This is because US is well known to be a noninvasive technique (Buckwalter & Brown, 2004), which is very relevant to bone tissue engineering because it insures the integrity of the engineered constructs, which are generally small and delicate. Moreover, previous studies have indicated that low-intensity pulsed US, administered with a dose as short as 20 minutes per day, activated ossification *in vitro* via a direct effect on osteoblasts and ossifying cartilage, after other animal and clinical studies showed that low-intensity US accelerated bone healing *in vivo* (Xu et al., 2005).

Magnetic resonance microscopy (MRM) has been proven to be an efficient, quantitative technique that could be applied to noninvasively monitor the bone tissue engineering process. This technique entails the application of a radiofrequency (RF) pulse to excite a tissue or specimen at resonance, and the acquisition of signal in the form of RF energy during subsequent relaxation of tissue magnetization. This method provides quantitative parameters that are directly dependent on the tissue properties, such as the spin-spin T_2

Figure 2. Ultrasound stimulation setup



relaxation time, which describes the time it takes for one of the magnetization components, the transverse component, to relax back to its equilibrium condition following excitation (Nishimura, 1996). Currently, magnetic resonance imaging (MRI) is widely used *in vivo* to assess connective tissue degeneration (Cartmell et al., 2005), and also to investigate the regeneration of engineered tissue (Carnegie Mellon University, 2005). A recent study showed that MRM can be used to monitor osteogenesis in tissue-engineered constructs (Xu et al., 2005), indicating that MRM and related technologies may be feasible for replacing the conventional, invasive histological assessment of engineered bone tissue.

With these considerations, in a recent work (Moinnes, Vidula, Halim, & Othman, 2006), we explored the usage of US stimulation for reducing the culture time of stem cells, and also the use of MRM for monitoring the growth of engineered bone tissue. Working off the conventional bone tissue engineering scheme, we isolated mesenchymal stem cells from human bone marrow, and then seeded these cells on collagen scaffolds; these scaffolds were grown *in vitro* for 3 weeks and were divided into three groups: control constructs, differentiated, nonstimulated constructs, and differentiated, ultrasound stimulated constructs, with the latter two groups exposed in culture to bone differentiation promoting factors. Ultrasound (Figure 2) was administered using a sonic accelerated fracture-healing system device and transducers delivering pulsed ultrasound waves with an intensity of 30 mW/cm^2, operating frequency of 1.5MHz, pulse width of 200 μsec, and pulse repetition rate of 1 kHz for 20 minutes per day throughout the growth period.

At 1 week intervals, we conducted both MRM and histological assessment of growth of the engineered constructs. MRM experiments were conducted at 11.74 T (500 MHz for protons) using a 56 mm vertical bore magnet (Oxford Instruments, Oxford, UK), and a Bruker DRX Avance Spectrometer (Bruker Instruments, Billerica, MA, USA) controlled by a Silicon Graphics SGI2 workstation (Mountain View, CA, USA). MR images were acquired using a Bruker Micro 5 imaging probe with triple axis gradients (maximum strength 2 T/m), and a 10 mm diameter RF saddle coil was used to transmit/receive the nuclear magnetic resonance signals. Our MRM analysis included the determination of the spin-spin relaxation time (T_2) for specific regions of interests localized at the periphery of each construct. Histological assessment, for correlation with the MR T_2 determination, included hematoxylin and eosin staining for the detection of cell nuclei, von Kossa staining for examination of mineralization due to calcium deposition by newly formed bone, and osteocalcin (bone matrix protein) for confirmation of bone tissue differentiation.

Using these methods, we drew several conclusions, which may help justify the usage of ultrasound stimulation and MRM construct monitoring in enhancing the current scheme for bone tissue engineering. First, we demonstrated a good correlation between the MR and histological/immunocytochemical results; we saw a reduction in the T_2 relaxation time values for differentiated ultrasound stimulated constructs after 2 weeks of growth, indicating an increase in construct stiffness due to bone formation, which we correlated with increased bone tissue formation determined through histological analysis (Figures 3, 4, 5, & 6). Thus, we demonstrated the feasibility of MRM for replacing histological assessment of the growth of engineered tissue. Moreover, we established the effectiveness of low intensity pulsed

(a) *(b)* *(c)*

ultrasound stimulation in accelerating the mineralization of osteogenic constructs *in vitro*; we noted a faster decrease in the T_2 relaxation time values for ultrasound stimulated osteogenic constructs in comparison with the nonstimulated osteogenic constructs.

To our knowledge, this combination of US stimulation and MRM as a monitoring technique has not previously been explored. All the works presented in the preceding section were uniquely exploring either a single aspect of bone growth stimulation or a technique to monitor the growth process (Aaron et al., 2004; Cartmell et al., 2005; Lakes, 2005; Nolte, 2001; Pilla, 2002; Xu et al., 2005). Though our major focus was not the improvement of the tissue engineering methodology by itself (the scaffold features, the biochemical agents, etc.), our work is unique in two aspects. First, it shows that MRM is sensitive enough to characterize the acceleration of osteogenic constructs growth, by sensing the difference in T_2 values between the US stimulated and nonstimulated constructs. Second, it shows that US is effective in accelerating osteogenesis *in vitro*; therefore, our study makes a valuable contribution towards the advancement of bone tissue engineering.

FUTURE TRENDS

Our recent work (Moinnes et al., 2006) made a giant stride in enhancing current bone tissue engineering processes, and also lends support to the conjecture that a combination of stem cell stimulation and noninvasive construct monitoring will increase the efficacy of bone tissue engineering processes. Yet, our work still leaves room for advancement. Notably, the optimized ultrasound parameters have yet to be determined. For instance, the optimal duration or frequency of ultrasound treatment and the critical stage in the cell differentiation process where it would have the greatest effect must be established; knowledge of this type could significantly reduce the net duration of ultrasound administration.

Also, future researchers can study and quantify the effect of various ultrasound operating frequencies on accelerating bone tissue formation in the engineered constructs, and therefore deduce the optimal one for this type of tissue engineering; this would require constructing specifically customized US transducers which would have variable frequencies, since they are not available in the market. Additionally, the optimal MRM parameters for tissue development monitoring must also be determined. These examples of future research directions demonstrate the need for greater knowledge on the optimization of enhanced bone tissue engineering processes.

Another trend which may emerge is the application of conclusions derived from works such as ours in the tissue engineering of other types of biological tissue, such as cartilage and muscle. With regards to the market, a trend which may emerge is that engineered bone tissue may be developed in the manner depicted by us in order to make this type of implant available to patients in a quicker manner, and therefore reduce the waiting periods of patients suffering from bone loss.

Other researchers are currently focusing on different aspects of bone tissue engineering and stimulation methods. For instance, Pinheiro et al. (2006) discussed photoengineering of bone repair processes. Jones et al. (2006) suggested improving the bone tissue engineering process by optimizing bioactive glass scaffolds. Hence, it is through the collaborative efforts of researchers worldwide, who individually and deeply study a given aspect of bone tissue engineering or a certain growth monitoring procedure, that substantial progress in this field may be achieved, the ultimate goal being the ability to provide patients suffering from bone loss with implants that are convenient for them right when they need them.

CONCLUSION

The specific techniques described in this work are not expected to be the ultimate ones that are to be utilized in future bone tissue engineering processes. Several major parameters are to be modified when it comes to the actual application of such techniques in a clinical setting, in order to completely substitute for the traditional autografts and allografts, which are widely employed today. Those parameters are mainly dependent on time and cost, among other constraints. Thus, it is undeniable that we are currently in the very early stages of what is sure to be a long path towards restoring bone tissue in humans using tissue engineering. Much time and research is still needed to progress from these simple experimental preparations, where all environmental and physical conditions can be utterly controlled, to human and clinical settings where unexpected physiological fluctuations introduce uncontrollable variations. Notwithstanding, these experiments are a good starting point on the path to complete bone restoration via tissue engineering.

KEY TERMS

Bone Differentiation Promoting Factors: Bone differentiation promoting factors are compounds such as dexamethasone, ascorbic acid, and β-glycerophosphate that cause the differentiation of mesenchymal stem cells into osteoblasts.

Bone Tissue Engineering: Bone tissue engineering focuses on the development of bone tissue *in vitro* (using osteoblasts, scaffolds, and bioactive molecules) generally for *in vivo* implantation.

Magnetic Resonance Microscopy: Magnetic Resonance Microscopy is a technique that entails the application of a radiofrequency (RF) pulse to excite a tissue or specimen at resonance, and the acquisition of signal in the form of RF energy during subsequent relaxation of tissue magnetization. This method provides quantitative parameters that are directly dependent on the tissue properties.

Mesenchymal Stem Cells: Mesenchymal stem cells are multipotent stem cells capable of differentiating into cells such as osteoblasts, adipocytes, chrondroblasts, fibroblasts, and muscle cells.

Osteoblasts: Osteoblasts (bone-forming cells) produce osteoid, a component of the bone matrix, and cause mineralization of the matrix.

Scaffold: In bone tissue engineering, a scaffold is a biomaterial surface used for the development of new bone tissue *in vitro*.

Ultrasound Stimulation: Ultrasound waves are sound waves with frequencies greater than 20,000 Hz. Low intensity pulsed ultrasound has been found to be effective at stimulating the differentiation of mesenchymal stem cells into osteoblasts.

Agent-Based Patient Scheduling

Einar Jakob Hovland
Agder University College, Norway

Even Åby Larsen
Agder University College, Norway

INTRODUCTION

Agent-oriented software engineering has, by many researchers, been dubbed the new paradigm in software development, and from its original concepts in the early '80s, agents and agent systems are now active research areas in computer science.

This evolution offers a promising approach to the development of patient scheduling systems. Coordinating and processing a vast amount of complex variables, such a system should be designed to stock and schedule a wide range of resources based on the patients' health condition and availability, drawing on the advantageous data control and optimization abilities of agent technologies.

This article presents the design of a working agent-based patient scheduling system prototype.

BACKGROUND

Agent Systems Definitions

A software agent is an autonomous entity capable of performing actions and interactions typically based on notions of beliefs and goals. In addition to autonomy and pro-activeness (Wooldrige & Ciancarini, 2001), typical characteristics of agents are anthropomorphism, situatedness, and social ability.

Agent systems can consist of just one such agent or a collection of agents performing different tasks based on individual or common goals. Due to the individualistic characteristics described above, an agent system can collectively draw on further advantages, including mobility, dynamic sizing, and complex cooperation through negotiation.

Historical Context

The term agent can be traced back to the *Actor Model* first presented by Hewitt, Bishop and Steiger (1973). This early concept simply defined agents as entities with a memory address and computational behavior to help solve common tasks.

In the late '80s, the Belief-Desire-Intention (*BDI*) model was proposed (Bratman, Israel, & Pollack, 1988). The model represented a novel approach of giving human properties to digital agents. Through available information about the environment (beliefs), the agents are given a set of certain possible actions (desires) which are activated based on agent goals (intentions).

With sophisticated communication, agents can interact to cooperatively achieve global tasks and goals. But this coordination needs more than sufficient shared semantics. It also requires planning and scheduling techniques to govern the order and partition of tasks. Roughly, there are two general frameworks developed over the last decades to deal with these challenges; namely, the partial global planning (PGP) algorithms, and the joint intentions framework.

PGP (Durfee & Lesser, 1991) was an early attempt at planning in a distributed dynamic environment. By sharing and communicating intentions globally, the framework allowed agents to make optimal decisions locally.

Joint intentions present another approach in coordinating and planning node actions. Instead of passively collecting information to decide on optimal actions, the joint intentions frameworks is mainly focused on reaching common goals through agreement (Jennings, Sycara, & Wooldridge, 1998). The model is that of a team's intention, rather than the individual agent's goals. As the main focus of communication in these frameworks is reaching agreements, a natural consequence is *negotiation*.

Almost all negotiation in agent systems is based on some notion of auction (e.g., Luck, McBurney, Shehory, & Willmott, 2004). The bids used in auctions are often based on game theory mechanics and utility functions. Basically, game theory is the study of decisions in environments where several players interact (Vlassis, 2003). Game theory frameworks include the Nash Equilibrium solution concept (Nash, 1950) and Operations Research (Phillips, Ravindran, & Solberg, 1976), amongst others.

Application to Patient Scheduling Systems

Decision support systems and patient scheduling systems in particular, have become an increasingly important factor in many hospitals and medical institutions (Manansang & Helm, 1996). The primary goal of patient scheduling systems is to treat as many patients as possible in the shortest possible time (Bartelt, Lamersdorf, Paulussen, & Heinzl, 2002).

The examination and treatment process for patients involves a high degree of uncertainty regarding time spans and the resulting diagnosis, thus patient scheduling systems have been deemed complex (ibid.). Modern patient scheduling system design focuses on patients, rather than specific tasks or resources (Guo et al., 2004).

Hence, patient scheduling systems exhibits many of the same characteristics as those recognized in the agents and agent systems literature. Characteristics like entity-focused design, and high complexity and abstraction levels are well-founded identifiers in agent-oriented literature

Some earlier proposals exist—most noteworthy, the MedPage project (e.g., Bartelt, Wagner, & West, 2002), which is an ongoing attempt to introduce agent planning and scheduling systems at German hospitals.

AGENT SCHEDULING SYSTEM DESIGN

Following the theories presented, this article proposes a patient scheduling technique founded on software agents. Using well-established optimization theories from various fields of science, including optimal decision processing and game theory, this section will present an agent system labeled *AgentMedic* to effectively schedule patients in a medical institution.

The following four subsections will describe this system in detail. First, we define the three distinct agent types used in the system, focusing on their tasks and goals. Second, the communication and utility data flow between these agents are introduced. The third subsection defines the optimal decision functions used to determine the relevant value of patients and their position in the treatment cycle. And lastly, the optimization and scheduling processes are presented.

Agent Specifications

When choosing the types of agents needed in such a system, it is convenient to remember the typical agent characteristics presented earlier in this article. The design should allow for the agents to make use of their anthropomorphic and pro-active nature, so as to represent a live entity in the best possible way (Foner, 1993). Furthermore, autonomous entities requiring both social and flexible behavior must, in particular, be considered for agent abstraction (Wooldridge & Ciancarini, 2001).

This in mind, *AgentMedic* contains three distinct types of agents, each representing different roles in the context of a treatment process and the actions performed in a medical institution:

- A patient agent is responsible for coordinating the full examination and treatment process of the patient it is representing. The agent must, at all times, keep track of the progress of the patient, his/her health condition, and the management of upcoming examination or treatment tasks.
  - **Goals:** *Get examined/treated as fast as possible*
  - **Possible actions:** *Apply for appointment*
- A personnel agent represents a member of the hospital staff. Its tasks involve keeping track of the personnel competence as well as availability. Further, a personnel agent must use these properties to optimize and coordinate examination and treatment tasks with the patient agents.
  - **Goals:** *Treat/examine patients as fast as possible*
  - **Possible actions:** *Grant/deny appointment, examine/treat patients.*

- An equipment agent is, in the same manner as the personnel agents, responsible for keeping track and coordinating the usefulness and availability of hospital equipment. The agent is involved in optimizing and coordinating the assignment of equipment to treatment tasks, taking patient and personnel into account.
  - **Goals:** *Support treat/examination process effectively*
  - **Possible actions:** *Grant/deny participation, support treat/examination process of patient.*

Communication Patterns and Utilities

The figure below show the general communication patterns for the agents defined above. A patient requests an examination or treatment within some field of expertise. The information from all patients is then dealt with by the equipment and personnel agents to reach the optimal scheduling for a particular timeslot cycle. The results are sent back to the patient agents who at the next timeslot can move on to next step in the treatment cycle (Figure 1).

To fulfill the optimization potential of an agent system, every agent—whether it represents a patient, a representative from the personnel, or a piece of equipment—constantly needs to argue their position and usage in the system. For example, a patient argues for urgent treatment or examination based on his or her health condition, a doctor argues for using his or her competence, and equipment argues for being used in suitable tasks.

To represent values for this type of argumentation, we introduce the notion of utility. A utility value is a comparable measure, which in our case is used to weight the health condition of patients, the competence of personnel and the usefulness of equipment. In addition, and in a similar manner, *AgentMedic* use an availability value (either 1 for available or 0 for not available) to represent the availability of personnel and equipment. This value denotes whether a piece of equipment or a member of personnel is present at the institution.

Patient Agent Task Generation

Assuming we know the health condition of patients and the probability of possible diagnostic results, we can introduce a simple example using two patients: John and Mary. For simplicity, only two patients are considered, and they both undergo exactly three cycles in a treatment process: a preliminary examination, a secondary examination, and a treatment process.

Figure 1. Communication patterns amongst agents

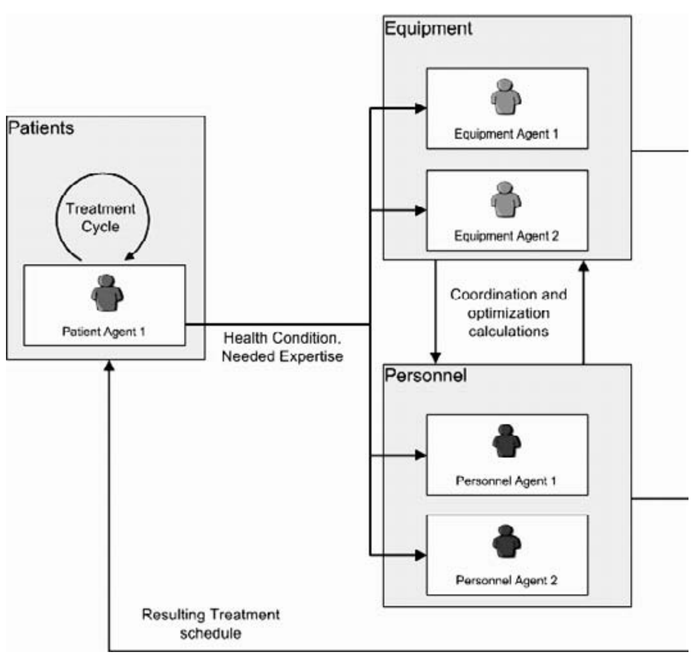

Figure 2. John and Mary parallel patient agent treatment processes

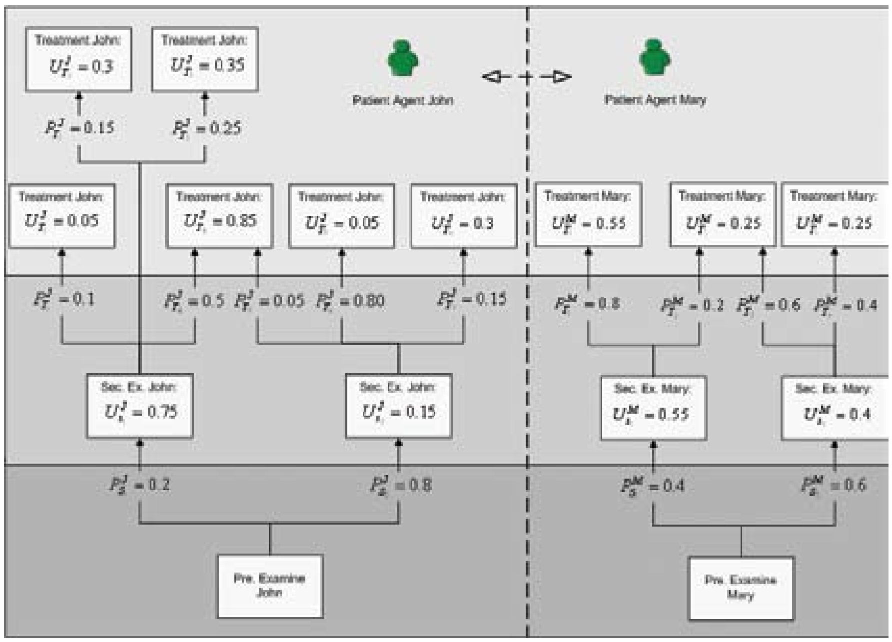


Combining all three stages and including example utilities *U* and probabilities *P*, the two patient agents can be presented in Figure 2.

The figure above shows the process path tree of two patient agents: one representing John, and one representing Mary. Assuming there is only one doctor available, the two agents should cooperate and bargain to obtain effective scheduling for the different stages of the two patients.

The scheduling is decided by using the relevant probability *P* and utility *U* values at each stage. By knowing the utility value *U* and the probability *P* of reaching all achievable states *s*, an optimal action α_t^* can be calculated by using the Bellman equation:

$$\pi^*(s) = \arg\max_{\alpha} \sum_{s^1} P(s^1 \mid s, \alpha) U^*(s^1) \qquad \text{(i)}$$

In words, for each state a related utility is calculated by finding the max return value of all possible actions obtainable in this state. The max return value is the utility multiplied by the probability for each new obtainable state. In our medical institution context we need to find these temporary utilities to be able to prioritize one task over another so that resources like personnel and equipment can be used effectively.

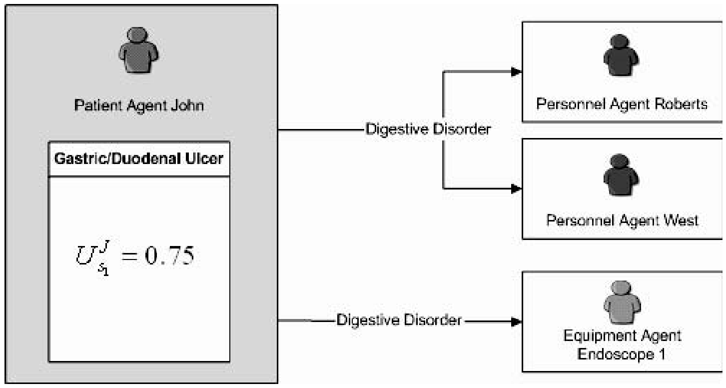
Using our example from Figure 2, the two agents need to agree on which patient goes first for their preliminary examination. Using the formula in (i), we can calculate the total utility values for John and Mary:

$$\alpha_{pre.ex.John} = (0.2 * 0.75) + (0.8 * 0.15) = 0.27$$
$$\alpha_{pre.ex.Mary} = (0.4 * 0.55) + (0.6 * 0.4) = 0.46$$

Hence, the results indicate ($0.27 < 0.46$) that preliminary examination of patient Mary should be prioritized before preliminary examination of John. Again, this is based on the possible outcomes of the examination. After the preliminary examination, we assume Mary was diagnosed with migraines ($U = 0.4$) and her agent now has to calculate the new temporary utility and argue for being prioritized at the next stage. By applying this formula for each patient on each stage, task priorities can easily be measured, compared, and prioritized.

As explained in the communication section above, the patient agents distribute the utilities to personnel and equipment agents for evaluation. When a utility is distributed, we may consider this action as a task generation, proposing a new task for the personnel and equipment agents. Naturally, many such task generations may occur within the same timeslot, generating the need for comparing and prioritizing tasks. The next section will take a closer look at this process.

Figure 3. Example: John's role assignment



Optimization and Scheduling

Before personnel and equipment agents can be assigned to the various treatment tasks presented by the patient agents, we need to investigate their competence and usefulness utilities in order to filter out unrelated personnel and equipment from our scheduling process equations.

This is done by relating the competence and usefulness of personnel and equipment to the general medical field of the task at hand. As an example, the symptom *heartburn* and the condition *ulcer* are both assigned to the more general condition of *digestive disorder*. Further, digestive disorder is part of the competence field for some of the personnel agents and has a usefulness factor in some of the equipment agents. Hence, the tasks involving the symptom heartburn or the condition ulcer are linked with personnel having competence in—and equipment with—a usefulness factor for digestive disorders.

The result of this process is patient agent tasks connected to "wish lists" containing desirable personnel and equipment.

Figure 3 shows patient agent John's resource wish list for the upcoming examination task. To decide the allocation of available personnel and equipment to patients, *AgentMedic* uses concepts from game theory, and more specifically the Nash Equilibrium (NE) model. The NE formula allows a consideration of all available agents and their respective utility and availability values at once, ensuring effective optimization:

$$u_i\left(\alpha_{-i}^{*}, \alpha_i^{*}\right) \geq u_i\left(\alpha_{-i}^{*}, \alpha_i\right) \qquad \text{(ii)}$$

In words, the formula state that a *joint action* (for example, "John treated by Smith" and "Smith treats John") is NE if no agent can improve utility by choosing a different action. Thus, NE represents optimal distribution for the two agents involved.

For example, consider a timeslot generating four tasks by four different patient agents: John, Mary, Chris, and Sarah. As shown, the four agents define medical field for their tasks and add personnel to their list in Figure 4.

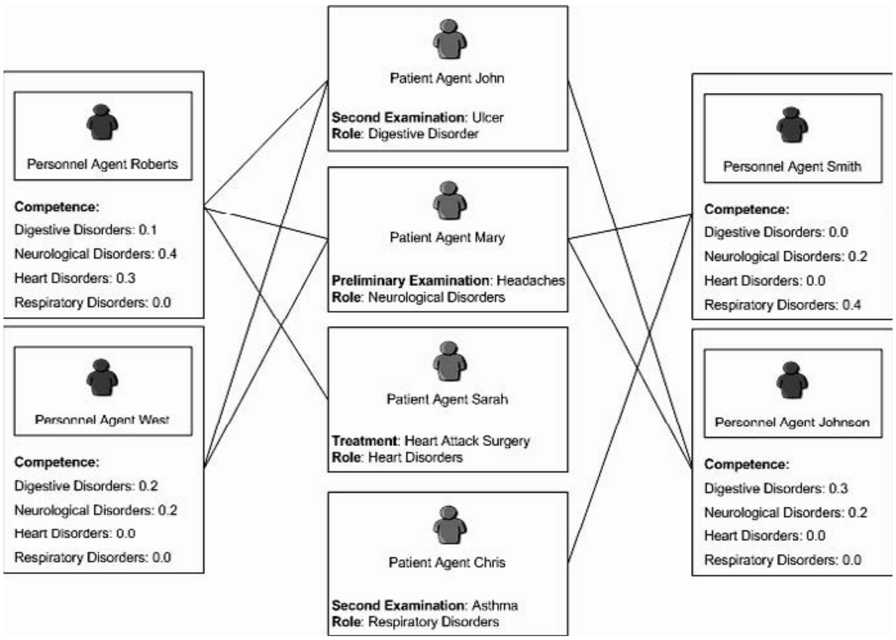
The diagram above shows that each patient agent finds all personnel agents that have some competence within the role that is assigned to their next task. For example, John would, in this example, make a sorted list with the following personnel agents: {Johnson, West, Roberts}.

Now that related tasks and personnel have been tied together, we can use a matrix to find NE. The matrix shows both the competence utility and a relative availability factor:

	Roberts	**West**	**Smith**	**Johnson**
John	*0.1 , 0.0*	*0.2 , 0.85*	*0.0 , 0.85*	*0.3 , 0.85*
Mary	*0.4 , 0.3*	*0.2 , 0.3*	*0.2 , 0.3*	*0.2 , 0.0*
Sarah	*0.3 , 0.15*	*0.0 , 0.15*	*0.1 , 0.15*	*0.0 , 0.0*
Chris	*0.0 , 0.5*	*0.0 , 0.5*	*0.4 , 0.5*	*0.0 , 0.0*

Note that the availability factor (1 for available or 0 for not available) has been multiplied with the patient utility. The three factors (utility, competence, and availability) are now part of the same matrix, and can be calculated using the NE formula. To calculate optimal distribution, we apply (ii) to each matrix cell.

Figure 4. General role assignment example



This produces the following set of NE joint actions:

{(John, Johnson), (Chris, Smith), (Mary, Roberts)}

With the correct personnel assigned, the patient agents should connect to the appropriate equipment agents in the exact same manner. Only patients that have been assigned a personnel representative may look for a piece of equipment however, as with no personnel, there will be no examination or treatment. We find the following results when applying the NE formula to each joint action:

{(John, Endoscope), (Mary, Surgery Equipment)}

Hence, all three patients but Chris were assigned relevant and available equipment for their task. As we can see, the NE does not always give fully satisfactory results. This is due to having two stages of NE, first for personnel then for equipment. As no equipment was available for Chris, we need to check if our last patient, Sarah, can be assigned to the now-available personnel Smith. As this can be the case for several patients, we run the NE matrix again with the remaining patients and personnel:

{(Sarah, Smith)}

Finally, we run the last NE equation, checking if the necessary equipment for Sarah is available. We achieve the following result:

{(Sarah, Blood Test Set)}

As a result of this, patients John, Mary, and Sarah are scheduled for examination/treatment in this timeslot. Chris will have to wait for the next timeslot where the necessary equipment hopefully is available.

Prototype Implementation

The ideas above have been implemented in prototype form to investigate the feasibility of the concepts and to verify that such a system will possess the robustness and flexibility claimed to be properties of agent-based systems (Hovland, 2006).

We have simulated the dynamic nature of hospitals by adding and removing agents from a running system. This represents changes in staff, equipment, and patients. We have also simulated mobility between institutions by moving agents from one running system to another. The tests have been mostly successful. The problems encountered can be attributed to shortcomings in the prototype, rather than the concept itself (ibid.).

FUTURE TRENDS

In accordance with the evolution of information systems in general, modern, health-specific systems have increased in both size and complexity. Typical modernizing trends within this field include globalization of system structure, emerging technologies, new complex data types, ubiquitous computing, and inclusion of strategic and administrative data (Haux, 2005).

Patient scheduling systems being part of this step to the future require, at the same time, a sharp focus on the patient (Guo et al., 2004). We have seen that agent technologies represent a promising approach in dealing with both the increase of complexity, while keeping this focus at bay.

CONCLUSION

Agent-based systems is an emerging approach in dealing with modern complex information systems. Furthermore, agents are well suited to deal with large amounts of variables, using negotiation to deal with complex planning procedures. As such, this article presents an agent-based patient scheduling system based on planning and optimization algorithms from game theory.

While the developed prototype from Hovland (2006) shows that such an approach is feasible, it is still a long way from real-life application. The presented approach demonstrates the core scheduling operations of such a system, but assumes some simplifications especially in regards of utility functions of the patients.

KEY TERMS

Agent: "A computer system that is capable of flexible autonomous action in dynamic, unpredictable, typically multi-agent domains" (Luck et al., 2005).

Agent System: "A group of agents that can potentially interact with each other" (Vlassis, 2003). "In multi agent systems, applications are designed and developed in terms of autonomous software entities (agents) that can flexibly achieve their objectives by interacting with one another in terms of high-level protocols and languages" (Zambonelli, Jennings, & Wooldridge, 2003).

Anthropomorphism: The attribution of human characteristics to software agents, including personalizability, learning and reasoning (Foner, 1993).

Dynamic Environment: Agent systems allow agents to enter, leave and change at runtime.

Mobility: The ease of transferring agents to other systems with the same characteristics, due to their autonomous nature and the dynamic property of agent systems.

Negotiation: Often used amongst agents as a means of optimal decision making. Agents can exhibit the ability to perform an optimal individual action, which contributes to the goals of the system as a whole.

Situatedness: Agents are in close relationship to its environment. Agents optimally have awareness capabilities, supervising their domain through sensors and performing reactive actions through effectors accordingly (Jennings & Wooldridge, 2000; Weyns, Steegmans, & Holvoet, 2004).

Social Ability: Agents communicate and reach mutual decisions through conversation and negotiation (Foner, 1993; Wooldrige & Ciancarini, 2001).

Analytics: Unpacking AIDS Policy in the Black Community

Fay Cobb Payton
North Carolina State University, USA

INTRODUCTION

With advances in information technology analytics applications, society stands to benefit greatly from health care innovation. The ability to link physicians, hospitals, pharmacies, clinics, and patients to health information networks and clinical and financial data management and analyses can prove to be invaluable in the diagnosis and treatment of chronic episodes of illnesses such as AIDS/HIV.

This access to data is a necessity in order for hospitals and physicians to provide the highest level of safety and quality of care. Providing the correct diagnosis and procedures is critical for the patient's utmost care. With the high costs associated with AIDS/HIV procedures, medications, and physician consultants, the integration of IT can offset these costs and improve the efficiency of the organizations. Factors such as cost of care and length of stay continue to drive health service delivery, resource availability, and quality of care.

Business analytics (BA), often termed business intelligence (BI), applications can carefully provide insight into the (in)significance of these factors in health care systems' abilities to treat AIDS/HIV in general. In particular, demographic variables that relate to cultural, socioeconomic status and community dimensions of those most impacted (namely, Black Americans in the United States, which is the focus of this writing) by the AIDS/HIV epidemic are often disregarded. For the broader community, the questions to address are diverse. What can business analytics inform us about Black Americans infected by AIDS/HIV? What are the broader cultural issues that often are not modeled by analytical tools? How do these findings stand to impact public policy and how the health care community can better assist those living with the disease? In this chapter, I take on these questions by first reviewing major issues and trends in AIDS/HIV and IT literatures by focusing on health disparities in one historically underserved group; namely, Black Americans. Next, I present public health conceptual framework that augments this discourse by depicting those factors uncovered in traditional information technology/systems works. This chapter concludes with recommendations for future research opportunities for examining AIDS/HIV public policy issues.

BACKGROUND

According to *Data Bulletin* (2003), between 1991 and 2003, per capita spending on health care in the United States rose almost 95%, with little improvement in national health metrics. Among policymakers, well-regarded media outlets, and others (Kovak, 2005), there is widespread disagreement about a final solution to the problem of rising health care costs. Moreover, there is equally widespread agreement that one element must be a large-scale, systemic change in the uses of information technology for health care management and delivery.

Comprehensive IT systems have improved efficiency and productivity in virtually every major industry, with the conspicuous exception of health care, based on recent RAND reports (Fonkych & Taylor, 2005). Used primarily for administrative tasks such as billing and scheduling, IT offers great promise for use in Electronic Medical Record Systems (EMR-S) or as a clinical diagnostic aid.

The AIDS/HIV epidemic continues to have a riveting impact on the United States. In order to slow the epidemic, analytics enables the field to improve upon its understanding of the dynamics behind the disease. There are an estimated 800,000 to 900,000 people currently living with AIDS/HIV in the United States, with approximately 40,000 new AIDS/HIV infections occurring in the United States every year. More recently, gender has become a significant factor to pay attention to when identifying new cases each year. For several years, men dominated the estimates of new infections; women, in general, are now also significantly affected, and Black women, in particular. Adopted from the

Centers for Disease Control and Prevention (CDC), Figure 1 shows that 70% of new HIV infections each year occur among men, although women are also significantly affected and hold the other 30%.

With regard to race, more than half of newly affected AIDS/HIV cases occur among Black Americans, although this subpopulation only represents 13% of the total population of the United States. Hispanics, who make up about 12% of the United States population, are also disproportionately affected. Figure 2 shows the estimates of annual new infections according to race. Blacks lead with more than 50%, while White and Hispanics trail behind with significantly lower percentages.

An even more astounding statistic shows that Black women accounted for 72% of all new diagnosed AIDS/HIV cases in the United States. The AIDS diagnosis rate for Black men was nearly 11 times greater than their white male peers, and this rate is 23 times greater for Black women in comparison to white women (CDC, 2005; LaVeist, 2005).

Business analytics (BA) focuses on effective use of these data and information to drive positive business actions such as those already noted. The body of knowledge for this area includes both business and technical topics, including concepts of performance management; definition and delivery of business metrics; data visualization; and deployment and use of technology solutions such as OLAP, dashboards, scorecards, analytic applications, and data mining (http://www.tdwi.org/). Analytics technologies reduce uncertainty, predict with precision, and optimize performance, and can be inclusive of forecasting, text and data mining, and statistical methods, just to name a few. These technologies can enable health care organizations to effectively use:

- **Electronic medical records (EMR).** Stores all patient information in a centralized location and allows physicians, nurses, patients, and other clinical staff to access clinical and financial data spontaneously.

Figure 1. Estimate of annual new infections by gender (N = 40,000)

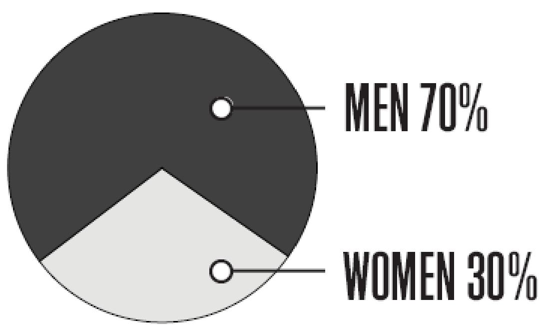

Figure 2. Estimate of annual new infections by race

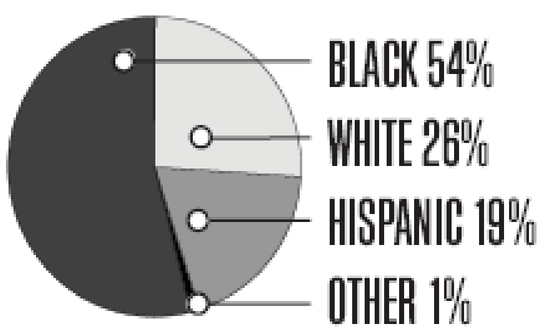

- **Computerized physician order entry systems (CPOE).** Manages order and fulfillment of medical actions, including prescriptions, lab orders, discharges, transfers, and referrals.
- **Clinical decision support systems (CDSS).** With the increased use of evidence-based medicine and the need for currency among clinical professionals, innovative knowledge can impact patient outcomes. These systems provide information on diagnosis, treatments, and recommendations given the situation.
- **Wireless networks and remote care.** This technology allows valuable information and observation beyond a hospital bed.
- **Aggregate database on treatment outcomes.** Placing data in databases allows faster assessments and analysis of the data. The data can be quickly filtered to show procedures, treatments, medications, and costs. Valuable information can be pulled much more quickly from electronic sources than hard copies.

BUSINESS ANALYTICS: HOW IT (UN)INFORMS US

Business analytics (BA) can better inform hospitals, insurers, and providers of two critical factors in the wake of managed care and capitation: cost of care (COC) and length of stay (LOS) for HIV/AIDS cases. Factors such as a patient's age, race, gender, and high-risk behaviors are significantly influential in determining COC and LOS. Moreover, geographic location has emerged as a critical factor in the equation. Recent reports by Newsweek (2006), UNAIDS (2004), and the Centers for Disease Control and Prevention (2005) confirm the notion that HIV/AIDS cases have spiked disproportionately in rural United States (particularly the South) and sub-Saharan African countries (particularly Kenya, Tanzania, and South Africa) where people of color comprise significant proportions of the total population.

Using stepwise regression models, SAS Enterprise Guide software (see www.sas.com) and a patient de-identifiable dataset of nearly 90,000 hospital encounters, the author sought to determine how many African American persons had HIV/AIDS. Table 1 shows that roughly 75% of the cases in the dataset represented Blacks, while 23% were whites. Figure 3 plots these figures along the normal curve to illustrate the vast differences in the number of cases between the two groups.

Within the framework of business analytics, these findings, along with other relevant statistics, can be used to inform performance management applications. Within a health care domain, these applications can measure, monitor, and evaluate performance relative to physician, nursing, and other clinical staff retention, internal operations, and clinical care; process performance is relative to disease intervention and diagnostic related groups (DRGs) and productivity enhancement. Hence, these data enable health care organizations to fuse typically disparate clinical and financial data and result in evidence-based medicine/practice.

Balanced scorecards can be generated with these objectives: decrease cost of care, decrease length of stay, and reduced averages by 10% among HIV/AIDS cases in general and Black Americans in particular. Figure 4 shows a snapshot from the SAS Strategic Performance Management (SPM) application to help health care providers meet these objectives. SPM offers graphical representations with diagrams, color-coding, and key

Table 1. Frequency of HIV/AIDS cases found in medical dataset

Race (uniform)				
RACE	**Frequency**	**Percentage**	**Cumulative Frequency**	**Cumulative Percentage**
1	375	23.99	375	23.99
2	1175	75.18	1550	99.17
3	6	0.38	1556	99.55
5	4	0.26	1560	99.81
6	3	0.19	1563	100.00

performance indicators (KPIs) functionality to aid in and enhance decision-making.

While BA applications and methods inform of valued statistics in the plight against AIDS/HIV, the numbers do not tell the full story. This is particularly the case in the Black community. In its May 2006 article, "Does Class Trump Race? DiversityInc suggested that to understand health outcomes and disparities, one must not ignore socioeconomic status (SES). This translated into those who have the highest propensity to be uninsured or underinsured; namely, Blacks, Latinos, and those living in impoverished rural areas. Hence, according to Isaacs' article in the *New England Journal of Medicine* (2004), many of those living in lower SESs are Black or other ethnic minorities.

Further, much of the health care system is based largely on one's educational training and the ability to navigate treatment, service delivery, and a host of payer guidelines and policies, all of which warrant some degree of adequate financial and educational resources. Oftentimes, this is not the case of underrepresented groups who are infected and affected by AIDS/HIV in the Black community. Health care policy experts (LaVeist, 2005; Shi & Stevens, 2005) liken these outcomes to race/ethnicity disparities where "adequate measures, such as cultural factors and measures of discrimination have not been developed or implemented, so we are left with race/ethnicity measures serving as relatively inaccurate proxies" (p 35).

Much of the demographics captured in the 90,000 records dataset extends beyond the scorecard in Figure 4 and includes ICD-9 codes, total hospital charges incurred by the patient, diagnoses (as many as 16 per record), medical record numbers, and attending physician codes. While BA applications can stimulate increased comprehension of the correlations among these variables to improve process improvement, forecasting, causal modeling, and resource utilization, just to name a few, clinical and financial systems often do not capture community determinants of vulnerability among chronic disease episodes as classified by Aday (1994). These vulnerable diseases or health conditions link to both the community and individual levels of resources. The community resources encompass cohesiveness among people and neighborhood characteristics (e.g., presence/absence of violence, unemployment rates, access to physical recreation) while the individual level encompasses social and human capital, social status, and health needs. Aday (1994) suggests that there are nine subpopulations that comprise vulnerability. Persons living with AIDS/HIV fall into one of these vulnerable subgroups.

Moreover, Stevens and Shi (2003) offer a conceptual model linking race and ethnicity with health care experiences. Their model encapsulates family characteristics that denote societal and environmental drivers and health system characteristics capturing health and social policy. While socioeconomic status or income

Figure 3. Normal curve showing Whites (case 1) and Blacks (case 2)

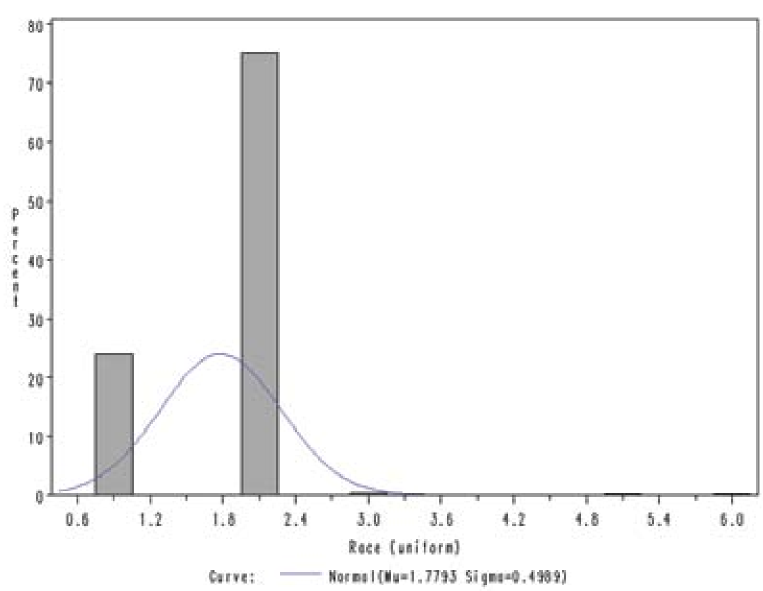

Figure 4. Example of scorecard used to minimize cost of care and length of stay, and reducing these averages among AIDS/HIV cases

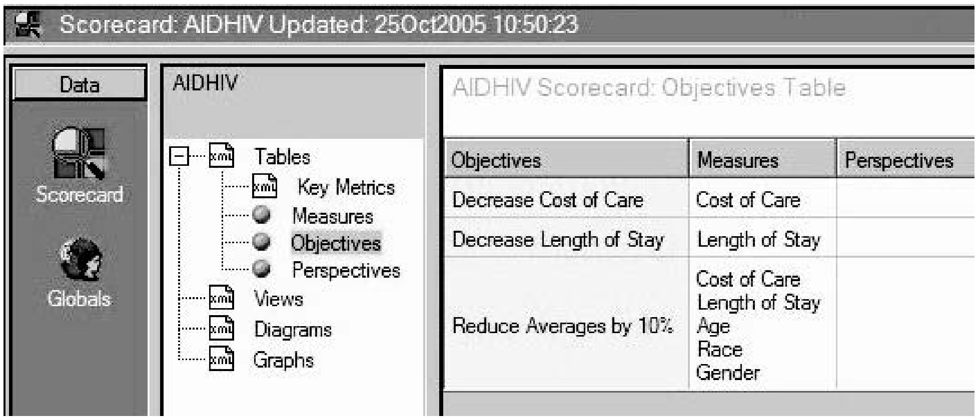

can trump race, as suggested by the Kim (2006) article, other dimensions of discourse cannot be ignored; namely, cultural factors, discrimination, health needs, provider factors, and health system factors. Cultural factors rest largely on family structure norms or beliefs and language that impact care delivery, behaviors, and health decision-making and seeking. Discrimination provides the pathway to link race to (un)intended motives, practices, and care delivery, thereby resulting in negative consequences associate with the medical system in general. Health needs influence services sought and implementation of recommendations by patients. Provider factors examine how patients interact with physicians and vice versa. It has been well documented that "physician perceptions and beliefs about patients are affected by race, ethnicity and socioeconomic status" (Shi & Stevens, 2005, p. 43) and do impact physicians' delivery of services and treatment plans. Lastly, health system factors examine the availability of health care resources and insurance coverage.

Furthermore, each of these dimensions can be linked to health disparities, particularly among Black Americans living with AIDS/HIV and dwelling in vulnerable scenarios of low social and human capital and high unemployment. Among the most vulnerable are those residing in the rural South (USA) where AIDS/HIV inflection rates are increasing at alarming rates while literary rates are often less than 30% for completing a high school education. These areas are characterized by the presence of high unemployment rates, incarceration among Black men, drug trafficking, and migrant workers.

FUTURE TRENDS AND CONCLUSION

Business analytics are applications and methodologies that can augment our understanding of a phenomenon in question. In this case, BA was used to analyze a de-identifiable set related to medical encounters or visits to a teaching hospital. BA offers statistical analyses, forecasting, and scorecards to describe the AIDS/HIV cases discovered in the dataset. However, BA is only as sound as the data provided to its users. Oftentimes, this will require that health care researchers analyze more than one dataset or examine findings from other reference disciplines to enrich their interpretation of results. The goal here is to offer the reader the opportunity to step back and reflect on the discourse at hand and recognize that chronic diseases such as AIDS/HIV in vulnerable populations (e.g., Blacks in rural South or in significantly vulnerable scenarios) are not monolithic. A deeper understanding of broader public health frameworks can shed auxiliary viewpoints on the data, thereby affecting one's interpretation of the results.

Hence, critical to this dialogue is the awareness of health literacy, cultural competency, and health communications in this domain. While there are numerous Internet resources that cover Black Americans' health, disparities, and AIDS/HIV, the current system is best exemplified by the absence of adaptive structuration (DeSanctis & Poole, 1994). That is, unintended community structures and human action can and often do emerge under the conditions of advanced technologies' designs where IT designers and sponsors are not void of predefined notions of structuration. Health care Web sites can lack the presence of cultural competency and a substantial degree of effectiveness in disseminating AIDS/HIV and other pertinent medical information to the Black community. To this end, Healthy People 2010 (2006) concluded:

Often people with the greatest health burdens have the least access to information, communication technologies, healthcare, and supporting social services. Even the most carefully designed health communication programs will have limited impact if underserved communities lack access to crucial health professionals, services, and communication channels that are part of a health improvement project.

Lastly, how AIDS/HIV issues are communicated to targeted groups could augment findings from clinical and financial applications that serve as input into BA applications. Health communication scholars argue that the media do not simply report on health issues, but rather play a major role in setting the agenda of health issues for the general public (Pitts & Jackson, 1993). This school of thought agrees with scholars that have analyzed the influence of the media in setting the public agenda on political issues (McLeod, Kosicki & McLeod, 1994; McCombs, 1994; Walker and Kiwanuka-Tondo, 2003). These areas offer promising research opportunities in the context of AIDS/HIV nationally and globally and can help define public policy discourse.

KEY TERMS

Business Analytics/Intelligence: Use of data and information to drive business actions, including concepts of performance management, definition and delivery of business metrics, data visualization by using online analytical processing (OLAP), dashboards, scorecards, analytic applications, and data mining.

Capitation: Typically associated with managed care; a fixed payment or reimbursement plan that physicians receive based on care delivery to patients.

Cultural Competency: The ability of an organization, group, or individual to work crossculturally in an effort to administer health care services and treatment; this is critical to the patient-physician relationship along with access to appropriate care and quality outcomes.

Diagnostic Related Groups (DRGs): A classification of hospital case types into groups expected to have similar hospital resource use. The groupings are based on diagnoses (*using* ICD), procedures, age, sex, and other attributes.

Health Disparities: Differences in the incidence, prevalence, mortality, burden of disease, or other adverse health conditions that exist among specific population groups.

Healthy People 2010: Objectives for the United States to achieve specified health care status, based on a 10-year timeframe. These objectives include extensive discussion on vulnerable populations, community groups, providers, and so forth, in an effort to improve overall health.

ICD-9 Codes: International Classification of Diseases–9th Division

Managed Care: An arrangement of specific health providers that are contracted through a structured plan for managing service delivery and cost of care.

Socioeconomic Status (SES): A measure of social and economic position that is a function of occupation, income level, and education.

Vulnerability: Propensity of poor health and/or lack of access to health care services.

Application of Wireless Data Grids for Health Informatics

Omer Mahmood
Charles Darwin University, Australia

INTRODUCTION

Distance and inaccessibility create special challenges for health practitioners in rural and remote areas. Health professionals in rural and remote areas face problems such as prescription concerns due to lack of information. This occurs due to a gap in knowledge regarding medications, as health practitioners do not have access to medical history of their patients. Frequent migration of patients in rural and remote communities results in the loss of patients' medical records. In addition, doctors have limited access to therapeutic information, as searching the Internet from most remote communities is expensive and slow. In addition, frequent migration of patients in remote communities results in the loss of patients' histories. This chapter proposes a refined conceptual health information management model based on the model presented by Mahmood (2006). The discussed model is based on the use of Data Grid technology and Data Recharging techniques employed in conjunction with wireless communication technologies to overcome the problems and challenges faced by health practitioners. The model categorizes the health establishments in remote areas into two categories on the basis of geographical characteristics and data access requirements. The discussed model aims to meet information and communication technology (ICT) requirements of health practitioners operating in each recognized category.

INFORMATION SOCIETY, E-HEALTH, TELEMEDICINE, AND HEALTH INFORMATICS

An information society is one in which the main product or a prerequisite to other products is information. In essence, in an information society, the workers' outputs and organizations' successes depend on their ability to utilize information (Knight, 2004). The main recognized sections of information society are information economy, electronic commerce, and e-health (Walsh, 2001).

Mitchell defined e-health as "a new term needed to describe the combined use of electronic communication and information technology in the health sector—the use in the health sector of digital data-transmitted, stored and retrieved electronically—for clinical, educational and administrative purposes, both at the local site and at a distance" (Mitchell, 1999). E-health includes the use of ICT to enable or improve health care service in both clinical and nonclinical sectors. It is composed of telemedicine and health informatics. Telemedicine is direct or indirect delivery of health care or health information. The direct means could include videoconferencing, and the indirect means could include Web sites. In telemedicine, physicians examine patients at a distance by using ICT (Preston, 1993). In relation to telemedicine, health informatics or medicine informatics deals with the resources and devices used to acquire, store, move, and retrieve data to support health care (Wang, Turner & Scott, 2003). So in essence, the application of health informatics is telehealth. This relation is presented in Figure 2.

CATEGORIES OF REMOTE HEALTH ESTABLISHMENTS

The ICT requirements and conditions for health informatics are very different in urban, rural, and remote areas. To set up effective health informatics, it is required to identify and categorize the rural and remote health establishments. The division should be based on the geographical location, mobility requirements of health service providers, current state of ICT infrastructure, and the migration habits of the patients in the recognized establishments. In this case, rural and remote area health establishments are divided into two categories: fixed and mobile remote establishments (Mahmood, 2006). Characteristics and ICT requirements of each establishment are outlined next.

Figure 1. Components of information society (Walsh, 2001)

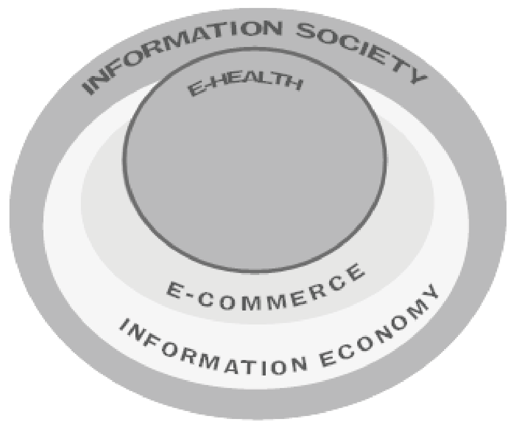

Figure 2. The e-health ICT impact model (Wang et al., 2003)

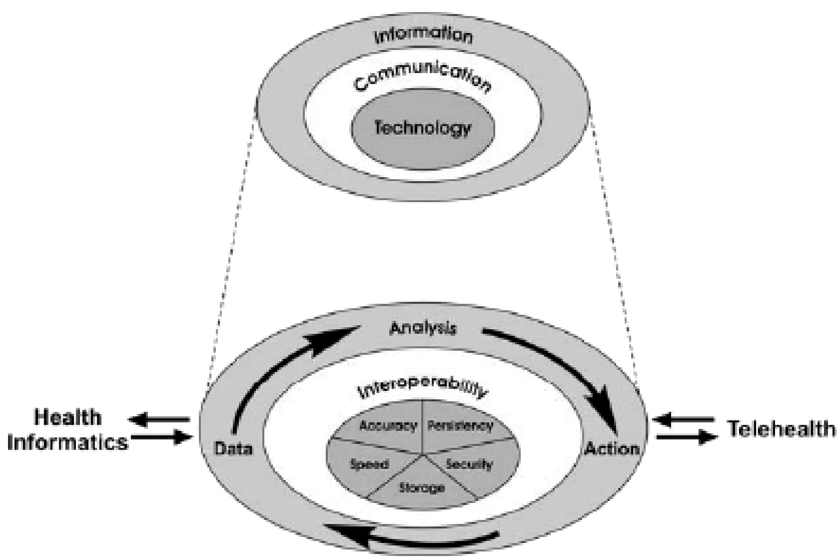


Fixed Establishments

Fixed remote/rural health care establishments consist of permanent health clinics that cater to the specific but limited health-related needs of local communities. Such establishments require access to limited data set, as the treatments and health services they provide are limited. These establishments do not require frequent synchronization of patient records between rural and urban health establishments due to lower migration of local community members. Semisupportive preestablished ICT infrastructure, such as phone lines, also exists at such establishments.

Portable Establishments

Portable health establishments generally consist of doctors, health practitioners, and district medical officers (DMOs) who visit relatively small communities in remote/rural areas. In such establishments, health practitioners take mobile electronic devices such as a laptop or a pocket PC to access and record the prescription information when undertaking consultations. Practitioners require highly filtered information as they offer limited health services. They have well-defined and limited patient base because of the community size. The data synchronization requirements of such establishments are quite high in relation to fixed establishments due to the high mobility of staff and migration habits of local community members.

The following section discusses the conceptual model. The discussed model targets to meet the requirements of both categories of remote establishments defined previously. It is divided into data grids, data recharging, and wireless Internet service modules (Mahmood, 2006).

HEALTH INFORMATION MANAGEMENT SYSTEM

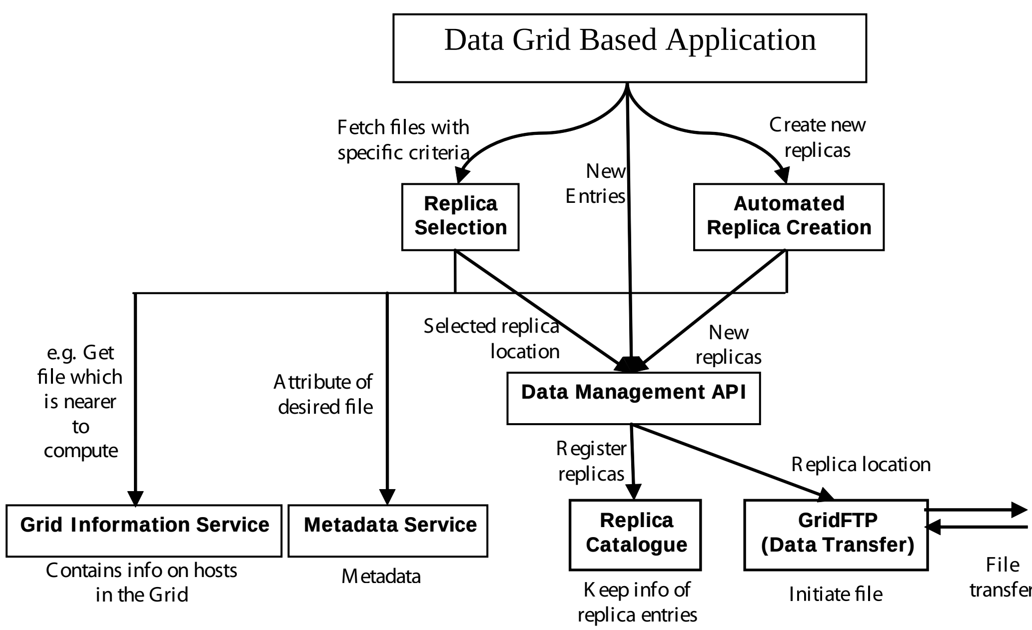
Health information management systems for health informatics need to maintain patients' health information and medical records of diagnosis, treatments, and procedures. Data grids have been proposed to meet data storage, movement, retrieval, and replication requirements. Data grids provide flexible infrastructure to share Internet-connected resources including computers, data storages, software applications, sensors, and instrument resources and wireless equipment (Tian, 2003). It is proposed to use data recharging techniques based on user profiles for information filtering, customisation, and prefetching. The application of data prefetching and filtering assists to reduce the record management and migration overhead (Mahmood, 2005). For cost-effective, robust, and easily maintainable networking, a combination of commercially available wireless LAN, GPRS (GSMWorld, 2006), and satellite-based connections is suggested.

Data Grids

Data grids enable the exchange of data from different sources. Existing in physically diverse locations, they hide all the differences from the users by enabling them to access data as if the data are on the local disk. Due to inbuilt features such as replication management and security, data grids offer a number of advantages over the traditional data access methods. These features of data grids make them most suitable for data exchange and sharing. Such features play a pivotal role if the data are distributed over a wide geographical area, as in case of health service providers operating in remote/rural communities where the patient's records exist at varied diverse location.

Drug researchers are currently using data grids to gain access to comprehensive patient records that meet designated characteristics such as age, race, geographical areas, and so forth. Such data could come from large disparate databases located in hospitals at many geographic places (Tian, 2003; Kermani, 2003). The

Figure 3. GridFTP and data selection scenario (Kim, 2002)



main internal services of data grids include GridFTP, a high-performance, secure, robust data transfer mechanism; Replica Catalogue, a mechanism for maintaining a catalogue of dataset replicas; and Replica Management, a mechanism to bind Replica Catalogue and GridFTP components. Replica Management service enables grid applications to create and manage replicas of datasets. Modules of replica management include creating new copies of complete or partial collection of files, registering these new copies to replica catalogue, and enabling users and applications to query and search the catalogues to locate all existing copies.

Data Recharging

Data recharging or data prefetching enables any device to plug into the wired or wireless network at any location for any amount of time and, as a result, end up with more useful data than it had before. The data recharging service constitute of a network of profile managers is located throughout the system network. Profile managers are responsible for retrieving required data from data sources for delivery to specific devices based on their recharging profiles (Cherniack, Franklin & Zdonik, 2001). In the discussed system, the profile managers interact directly with the underlying data grid system, requesting and, if necessary, reformatting or transforming the data (e.g., to XML, WML, or XHTML formats).

The system utilizes two types of profile managers: user profile and device profile managers. The user profile manager is used to filter the information in accordance with the expertise and requirements of the user; in this case, the health practitioner (Mahmood & Zomaya, 2006). The user profile manager builds and maintains the user's profile on the basis of job description of the user, offered services description by the health establishment from where the user operates, and the filters deployed by the user. This prefiltering technique is used to save time and to better utilize the limited network resources. The user profiles evolve over time and are somewhat static. Once the user profile manager filters the data, it is sent to the device profile manager. The device profile manager uses user mobile profile (UMP) to further filter the contents on the basis of capabilities of the mobile device the user is currently using. These two profiles are used to prefetch the information on a user's mobile device so the user can operate even in the absence of network coverage.

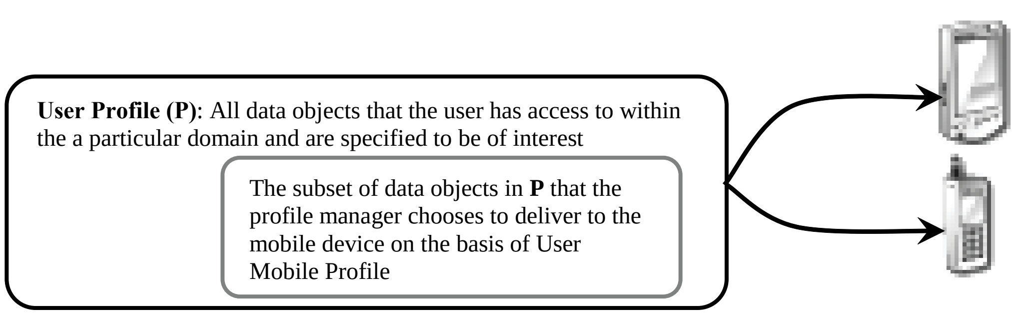
Striped Data Transfer (SDT) module of data grids can automatically strip defined data types resulting in smaller file sizes. SDT can also better utilize the available bandwidth by applying parallel transfers (Allcock et al., 2001). Moreover, STD, with the replica catalogue and replica management components, can also move the data closer to a user's geographical location. This feature significantly reduces bandwidth requirements, as the system can be configured to move the data when the network load is less, resulting in better use of network resources.

Hardware Based System Components

Within an ICT domain, the main characteristic of urban health establishments is the existing availability of stable telecommunication infrastructure supporting the availability of high network bandwidth. However, a new challenge arises if it is required to exchange data between urban and remote/rural fixed or between rural/remote fixed and portable establishments, since preestablished ICT infrastructure usually lacks in such geographical areas.

To meet the bandwidth requirements and share information with both types of health establishments,

Figure 4. Use of profiles for data recharging (Cherniack et al., 2001)



two networking solutions are discussed that implement and make use of a combination of different wireless communication technologies. For information exchange between remote/rural fixed and portable establishments, wireless local area network (WLAN), GPRS, or satellite connection could be used. The unique blend of communication technologies for each category of establishment is tailored to keep the setup, running, and maintenance costs low while providing dynamic, robust, secure, scalable, and customized architecture.

Fixed establishments. The choice of technology primarily depends on the aerial distance between the establishments. If the distance between fixed establishments is less than 23 kilometers, then it is proposed to use wireless bridges to extend the range of 802.11g WLAN network. Wireless bridges can connect locations up to 23 km apart, and can carry voice and data traffic at speeds up to 200Mbps. Wireless bridges use Radio Frequency (RF) wireless technology that can be secured by using encryption at each end. Table 1 outlines the data transfer speed and area coverage for each IEEE 802.11 WLAN standard when used in conjunction with range extenders (Long Range Team, 2006).

Portable establishments. In geographical areas covered by cellular networks such as Global System for Mobiles (GSM), EDGE, UMTS, TDMA, or Code Division Multiple Access (CDMA), data-added services could also be used. CDMA supports high-quality voice clarity and a bandwidth up to 14.4Kbps for data transfer, GPRS support up to 171.2Kbps of data transfer rate, while 3G supports up to 2Mbps for stationary systems. Like CDMA, GPRS and 3G enable users to use FTP service to transfer files, browse the Web, send and receive e-mails, and synchronize information with the server. It is recommended to use cellular data-added services only if the distance between the fixed and portable remote establishment is more than 23km, as the running cost would be much higher and the available bandwidth is significantly lower than WLAN.

However, in situations where the distance between urban, rural/remote fixed and portable establishments is greater then 23km and the establishment is not serviced by a cellular network, then it is recommended to use satellite connection. Mobile Packet Data Service (MPDS) supports digital voice, fax, and data exchange anywhere, anytime, and securely by using satellites. Such services provide up to 128Kbps inbound and up to 2Mbps outbound data transfer rate. The data transferred over a satellite network incur high running costs. In case of a doctor visiting a remote community, a Point-to-Point connection can be established where satellite is used to interconnect the fixed establishment with portable establishment. Use of satellites to transfer data is the most expensive method; therefore, this should be engaged only if no other networking method can be implemented.

CONCLUSION

This chapter proposes a conceptual model to meet data management and communication challenges faced by health practitioners operating in rural and remote communities due to lack of ICT infrastructure and frequent movements of patients. A blend of wireless communication technologies along with data grid applications and data recharging techniques are proposed to meet the health practitioners' requirements. In the model, the rural and remote health establishments are divided into two categories on the basis of their geographical characteristics and data access requirements. The model recommends using different wireless networking technologies on the basis of geographical characteristics of health establishments. It is proposed

Table 1. Comparison of 802.11 standards with range extenders

IEEE	Speed	Indoor Range	Outdoor Range*
802.11b	11 Mbps	100 meters	up to 23 km
802.11a	54 Mbps	100 meters	up to 5 km
802.11g	54 Mbps	100 meters	up to 23 km
802.11n (Draft)	200+ Mbps	150 meters	up to 23 km

*Note: * By using amplifiers, range extenders, bridges, and repeaters* to use Data Grids to create data backups, replications, and movements. Moreover, because of the built-in replica management feature of Data Grids, the patient's records can be replicated and moved automatically in response to his or her physical movements. The discussed model relies on the use of data recharging and data filtering techniques to cache and prefect the most relevant information to the user's device, thus enabling the user to operate efficiently even in the absence of network availability.

KEY TERMS

E-Health: A collective use of electronic communication and information technology in the health sector to electronically transmit, store, and retrieve digital data, both at the local site and at a distance, for clinical, educational, and administrative purposes. It is composed of telemedicine and health informatics.

Health Informatics: The use of devices and resources to collect, store, move, and retrieve data to support health care. One application of Health Informatics is telehealth.

Health Information: Recorded information in any form or medium about the health of a particular individual. It is created or received by a health practitioner or provider. It consists of past and present health condition of as well as past, present, and future treatments conducted on an individual.

Health Information Management System: An information system consisting of computer hardware and software, procedures, and processes that are specifically designed and implemented to store, maintain, collect, process, represent, and manage information specific to the health care domain.

Information Society: One in which the main product or a prerequisite to other products is information. In essence, in information society, the workers' outputs and organizations' successes depend on their ability to utilize information.

Telehealth: The distribution of health-related information or services by using telecommunication methods such as health-related advice over the phone; distribution of health-related information by using the Web; use of videoconferencing, online chat, online discussion boards, and exchange of medical records over the Internet or by using fax.

Telemedicine: Direct or indirect electronic delivery of health care or health information.

Applications of Data Mining in the Healthcare Industry

John Wang

INTRODUCTION

The workflow of health care organizations involves the generation and collection of various kinds of data relating to clinical practices, clinical trials, patient information, resource administration, policies, and research. Traditionally, statistical techniques are used to derive some operational information from the data. Data mining, a new method, provides the opportunity to derive, in an exploratory and interactive manner, valuable health care knowledge in terms of associations, sequential patterns, classifications, predictions, and symbolic rules. Such inductively-derived health care knowledge can provide strategic insights into the practice delivery of health care.

As the medical field expands, it is the duty of each physician to evaluate and protect each patient from diseases, side effects, and medical mishaps. Armed with a scalpel, stethoscope, and other accruements, physicians are now armed with data mining as a tool for expanding their knowledge base. Data mining is available to every aspect within the health care industry. It is multifaceted and used in areas like insurance to detect fraud, the pharmaceutical industry to evaluate side effects of drugs, and even detection of certain diseases based on genetics.

BACKGROUND

The progress of data mining has been around for decades. Although data mining is an evolution of a field that can be traced back many years, the terminology itself has been only been introduced in the 1990s. By using pattern recognition technologies and statistical and mathematical techniques to sift through warehoused information, data mining helps analysts recognize significant facts, relationships, trend, patterns, exceptions, and anomalies. The use of data mining can advance a company's position by creating a sustainable competitive advantage. Data mining is the science of managing and analyzing large datasets and discovering novel patterns (Davenport & Harris, 2007; Olafsson, 2006; Wang, 2006).

Data mining is becoming more prevalent in the health care industry because of the vast quantities of data stored in a multitude of medical systems, more specifically systems of health care providers, hospitals, and other medical institutions (Veletos, 2003). Recognizing patterns of data in order to discover valuable information, new facts, and relationships among variables are important in making business decisions that would best minimize costs, maximize returns, and create operating efficiency without compromising the quality of patient care.

The growth in data mining and its advantages over the traditional methods of collecting data in the industry, both for reducing costs and providing patient care, will be discussed. The bulk of the material focuses on various applications of data mining in the health care industry under three major areas. These areas include: data mining in health insurance plans; data mining in clinical care, and data mining in health care administration. Also, emerging future trends in data mining in the health care industry will also be explored.

MAIN FOCUS

Data Mining in Health Insurance Plans

Financially oriented applications, such as the actuarial cost-risk models utilized by health insurance companies, as well as models used to track and identify potential claim fraud, have been the primary focus of data mining in the health care industry. Along with these applications, predictive models have also been applied to issues that impact cost, such as predictions of length of stay, forecasting treatment costs, total charges, and even mortality. These applications contribute significantly to the driving force that has helped this industry evolve to the gigantic sector that it is in the market: how can health care organizations minimize cost, raise its quality of service, and maintain its competitive edge at the same time.

Fraud Detection

Research indicates that health care fraud and abuse costs the U.S. as much as $100 billion per year. That equates to about 10% of annual spending on health care. Numbers like that represent a huge red flag for action in this industry. Fraudulent and abusive behavior has become a serious problem. It is an area that requires significant attention and insight in order to prevent the unnecessary expenses associated with fraudulent transactions. Fraud detection takes on many forms including: claim fraud, premium avoidance fraud, and indemnity fraud (as in the case of disability or workers compensation insurance).

Claim fraud is currently the most predominant form of fraudulent activity and is a major concern of health care organizations. Medical claim fraud takes place when medical providers deliver unnecessary treatments and services or file claims to the insurance companies for services that have not been rendered in actuality. Due to the bulk of medical claims being processed side by side with a great multitude of insured patients and medical providers, detection of fraudulent claims poses a great challenge to health insurance companies. There is a considerable degree of difficulty involved in discerning whether a particular transaction is valid or illegitimate due to the enormous quantity of claims being processed.

Another type of medical fraud mentioned above is *premium avoidance fraud* which can occur under a variety of circumstances. Some examples include: (1) A policy holder attempting to reduce premiums by providing misinformation to the insurance carrier, such as fewer employees or lower payroll; (2) A policy holder submits incorrect classification to qualify for lower premium rates; (3) A policy holder changes insurance to cover injured employee and falsifies accident date; or (4) An employee changes a date-of-birth for a dependent that would otherwise not qualify for coverage.

Indemnity fraud, on the other hand, occurs when an insured customer receives workers compensation indemnity benefits (exemption from paying incurred liabilities) when in reality, they are no longer qualified to do so due to reasons such as capability of returning to work or discontinuation of medical treatments.

All of the forms of fraudulent activities mentioned above represent a consequential opportunity for high-value data mining applications in the insurance industry.

Yang and Hwang (2006) proposed a process-mining framework that uses clinical pathways to distinguish fraudulent and abusive cases from normal ones. The framework for their research consisted of first breaking the health care industry down by service groups. Then, for each care service, a set of features is identified and an inductive model is developed to detect suspicious claims for each particular service group. All of these methods reduce the workload of human experts.

Policy Holder Retention

In order to sustain desired revenues, programs desired to retain current members are vital to a medical insurance organizations. A significant threat to the insurance industry is a reduction in the number of policy holders. It has been recognized that retention of existing customers is about 5-10 times more cost effective than acquiring new ones (Haux, Elske, Werner, & Knaup, 2002). Therefore, it is considered wise for insurance companies to distinguish members who are at risk of switching their membership to another provider.

Data mining can be used to identify the potential loss of clients switching to other companies. Historical data contains usage patterns and other important customer characteristics that when discovered can be used to identify satisfied or unhappy policyholders. These correlations between historical data values are very complex. Predicting policyholders who are at risk of changing their service to another provider with a high level of accuracy is extremely complicated, and it requires a lot of experience. These, nonetheless, are very powerful profiling techniques.

New Policy Holders

Data mining can also be used to help identify potential new customers. By using historical data to predict future behavior, the marketing departments of insurance companies can determine potential policyholders whose behavior will be less risky then others. These high value, low risk potential policyholders can be approached with special packages developed for them in the hopes of attracting these customers from other companies.

Liability Profiling

Being able to predict the payout amounts that insurance companies would have to make is extremely important for both the long term financial health of the company, as well as being able to pay the company's current obligations. By predicting policyholders' behavior and risk, insurance companies can use these data mining models to construct the overall risk of a policyholder. Once the policyholder has a risk rating, the appropriate premium can be charged and the fee can be collected. Also, if the insurance company determines that the company, as a whole, will be paying out more than originally estimated, the company can adjust rates and assets to avoid any capital short fall.

Customer Service

Data mining is also used to predict when the call center will experience an increase or a decrease in volume. This allows for better staffing and better allocation of resources. Data mining is also used for the planning of resources when certain scenarios occur. For example, after an earthquake or wild fire, the insurance company can increases the call center staff to handle the increase in the volume caused by the disaster (Silver, Sakata, Su, Herman, Dolins, & O'Shea, 2001).

Cross Product Marketing

Once an insurance company has a profile on a customer, they often use the information to market other products that the insurance company provides, to the same customer. For example, once an insurance company provides health insurance for a customer, the company will often try to sell life insurance to the same customer. Data mining allows for greater predictability of the client's future needs.

Data Mining in Clinical Care

Data mining provides the ability to correlate differences in treatment with significant impact on the clinical outcomes. These tools can automatically identify the subgroup within a population, and provide descriptive statistics regarding how each subgroup compares with the population as a whole or with other subgroups.

Epidemiology

Interactive data mining, also known as *knowledge discovery* tools, can be used to identify critical variation and define priorities (Friedman & Fisher, 1999). Data mining in clinical care also uses pattern recognition to identify significant variations. This process allows doctors to identify the types of drugs that are associated with adverse effects. By combining data mining with statistics such as hypothesis testing, clinical researchers are able to improve clinical outcomes. This is achieved by comparing the sample result to the population, which can thereby determine the overall effectiveness of the drugs.

Patient Profiling

Using data mining techniques such as pattern recognition, physicians and patients can learn useful clinical trials of new treatments. Pattern recognition can also be used to prevent diseases before they occur. For example, a physician can identify patients who are at a great risk for having a heart attack before they even show any signs of the disease. This can be determined just by the pattern of the lifestyle. This test can be performed, and if there is an issue found, then heart disease medication could be prescribed to prevent a heart attack (Kathy, 1998).

The most popular data mining techniques used by physicians and pharmaceutical companies are *neutrality* tests, also known as *market based* tests. Market based tests utilize information from numerous local regions to construct a null distribution based on the variability characteristics of certain samples (Vasem & Primmer, 2005). This allows many variables to be considered especially when the size of the sample is small, large, or evaluated over time against the use of other drugs.

When long term side effects are considered, many faults or issues may arise. Since 1999, many vaccines, which are preventative and necessary in children, were pulled from the market. As vaccination increases paralleled increases in population many side effects would be noticed. Iskander, Pool, Zhou, and English-Bullard (2006) discovered that during 1991 and 2003, vaccinations tripled along with a proportionate number of adverse effects. With the use of market based data mining techniques, physicians are able to evaluate syndromes, symptom interactions, and intervaccine interactions, and evaluate potential adverse conditions with vaccinations. Medical data divided items into two categories: procedure and diagnosis. Unlike market base data, the association between procedure and diagnosis reveal cause and effect relationships (Doddi, Marathe, Ravi, & Torney, 2001).

Disease Management

Data mining applications are used to analyze treatments for particular diseases in order to visualize its possibility for further clinical enhancement. One scenario where data mining techniques could be applied would be a study of the relationships between two ailments and finding the most effective treatment. For example, a given health care provider could set up a regional test to examine all occurrences of asthma and allergies, find the connections between these two diseases, and look for the most efficient and effective way to combat them. The data which would be collected, studied, and compared could include types of over-the-counter (OTC) drugs or prescription medication such as antihistamines, as well as more holistic treatments such as taking a spoonful of honey daily while carefully taking into consideration the placebo effect. In line with Borok (1997), monitoring environmental factors such as pollution, pollen count, and airborne microorganisms, to name a few, would also be crucial to the study since they are also causes of the specified ailments. Through a thorough examination of these factors and their relationships to the different treatment regimes (pattern recognition), data mining could render a best treatment alternative.

Data mining could also be used in preventing the spread of a contagious ailment and forestalling the diffusion of an impending epidemic. According to the Centers for Disease Control and Prevention, the recurrence and resurgence of a disease which otherwise would have been completely eradicated stems from the tendency of patients to discontinue medication (even though the dosage has not been completed) the moment symptoms of the illness cease to exist (Srivastava & Singh, 2004). Through a rigorous analysis and careful monitoring, data collected from the study can be used to graphically represent the spread and progress of the disease. Hence, researchers would be able to discern patterns of the illness and take the necessary actions to address them.

Milley (2000) pointed out that along with the prevention of diseases, data mining can also be used to minimize the effect of many diseases before they progress further. For example, if there is a strong correlation between people with high blood sugar and blindness, doctors could require more frequent exams of those patients with high blood sugar level and check for blindness, than for those other patients who do not have high blood sugar level. This predictive model will keep doctors ahead of the disease and improve the overall quality of life fore most patients.

Data Mining in Health Care Administration

Data mining models are often used to support health care administration functions by predicting the following:

- Staff recruiting and staff retention
- Length of time an operating room will be required
- Number of beds that will available
- Expected return on investment per procedure
- Amounts and types of medicines on hand
- Number of ambulances
- Mortality rate per procedure and by doctor

Hospitals use this information for allocating resources and making decisions. As in most data mining models, validating data, testing algorithms, and clearly understanding methods make for accurate models. In addition to the standard method of data mining tools, according to Biafore (Biafore, 2003), hospitals often use utilization predictors. These tools allow hospitals the ability of knowing ahead of time which health care resources will be needed (both from the point of view of an entire member population and each individual member). These predictive solutions offer the capability of combining disparate data sources including both financial and clinical data to achieve accurate forecasts of resource utilization, across a wide variety of resource types.

Besides being able to utilize their facility optimally, hospitals and clinical organizations are often plagued by unpaid bills, collection agency fees and outstanding medical testing costs. Scheese (1998) estimated that, as a matter of fact, hospitals typically end up paying 30% to 50% of recovered bad-debt revenue to outside collection agencies.

FUTURE TRENDS

More Specific Package

Nowadays, many data mining packages available on the market are mainly for business use and are either too expensive or not specific enough to handle medical information (Liao & Lee, 2002). Characterized by a multitude of records and numerous attributes, health databases have become a challenge for data miners in their pursuit of developing applications and utilizing methodologies which would cater specifically to the health care industry. Applying more specific data mining to the entire health care industry would be the best way for physicians to evaluate the probability of patient interactions or reactions to certain treatments or diagnosis.

Appropriate Information Infrastructure and End-user Tools

The bottleneck for effective application of data mining in health care industry is lack of appropriate information infrastructure and end-user tools (Augen, 2003; Olafsson, Li, & Wu, 2006). Building infrastructures to support the free exchange of valuable health care data is vital for health researchers. By creating such infrastructures, there will be more data available to more researchers who can use data mining techniques to nugget out valuable hidden knowledge. With the proper infrastructure in place, doctors can use historical data and learning technology to find the best treatments for their patients. We believe in the near future, data mining software will become a major component of tomorrow's medical kit and a leading ally in the fight against illness and disease.

CONCLUSION

Data mining has definitely made an impact in the health care profession. Through the many data mining techniques discovered, medical experts have been able to improve the quality of care and service they provide to their patients. Data mining has become so popular that it can be used on the business side of health care to help reduce costs as well as the theoretical side in finding hidden knowledge in medical records. Experts have identified future trends and what needs to be done in order for them to be realized.

With data mining, hospitals would be able to monitor the data in a more sophisticated and intelligent way so that they can look at events that are occurring and find things they might not have thought of before. This new way of tracking data is more advanced than traditional analysis because they can find patterns that indicate problems to come. Hospitals have the chance to stay one step ahead of problems. Moreover, if they can be proactive, hospitals can avoid bigger problems. After all, timely information and early intervention is the key for preventing diseases. Considering the vast progress data mining is already responsible for in the medical field, one can only be excited to wonder what other great benefits will come about because of it.

KEY TERMS

Classification Regression Trees (CART): A mapping of observations about an item to conclusions about the item's end value.

Clinical Pathways: Integrated care pathways are multidisciplinary care plans where diagnosis and treatment are performed by medical teams.

Data Mining: Also known as knowledge discovery in databases (KDD), data mining is the process of automatically searching large volumes of data for patterns. Data mining is a fairly recent and contemporary topic in computing.

Data Mining Surveillance System (DMSS): Uses data mining techniques to discover unsuspected, useful patterns of infections and antimicrobial resistance from the analysis of hospital laboratory data.

Machine Learning: Concerned with the development of algorithms and techniques, which allow computers to "learn."

Neural Networks: Also referred to as artificial intelligence (AI), which utilizes predictive algorithms.

Pattern Recognition: The act of taking in raw data and taking an action based on the category of the data. It is a field within the area of machine learning.

Applying Cross Approximate Entropy to Blood Oxygen Saturation and Heart Rate from Nocturnal Oximetry in Screening for Obstructive Sleep Apnea

INTRODUCTION

Obstructive sleep apnea (OSA) syndrome is a major sleep-related breathing disorder, affecting 1% to 5% of adult men in western countries (Young, Peppard, & Gottlieb, 2002). This disease is now the most common respiratory referral to many sleep units (Douglas 2002). OSA syndrome is associated with excessive daytime sleepiness, neurocognitive deficits, and psychological problems. A significant number of patients with suspicion of OSA present mild to severe symptoms of depression (Schwartz, Kohler, & Karatinos, 2005). OSA syndrome is also a risk factor for cardiovascular disease morbidity and mortality (Leung and Bradley 2001). People with OSA have higher risk of sudden death due to cardiac causes during sleep than the general population (Gami, Howard, Olson, & Somers, 2005). Furthermore, subjects with OSA present an increased risk of being involved in traffic and work accidents (Barbé, Pericas, Muñoz, Findley, Anto, & Agustí, 1998).

The recommended diagnostic test for OSA is overnight polysomnography (PSG) (Polysomnography Task Force, 1997), which records neurophysiological and cardiorespiratory signals to analyze sleep and breathing. However, its relative high cost and complexity, along with the large number of people suspected of having this disease, limit its capacity as a diagnostic test for OSA (Whitelaw, Brant, & Flemons, 2005). Due to its simplicity and low cost, *portable monitoring* has been proposed as an alternative method to PSG in the diagnostic assessment of patients with suspected sleep apnea (Flemons & Littner, 2003).

Nocturnal oximetry provides different quantitative indexes commonly used by physicians in screening for OSA. Oxygen desaturation indexes (ODIs), which measure the number of dips in the oxygen saturation signal below a certain threshold, and the cumulative time (CT) spent below a certain saturation level, are the most widely used (Chaudhary, Dasti, Park, Brown, Davis, & Akhtar, 1998; Netzer, Eliasson, Netzer, & Kristo, 2001). However, their diagnostic sensitivity and specificity vary in a wide range between different studies and there is not a consensus on their definition (Netzer et al., 2001). Although oximeters usually provide both blood oxygen saturation (SaO_2) and heart rate (HR), classical indexes like ODIs or CTs are defined exclusively for SaO_2. Few studies have assessed the diagnostic accuracy of HR from nocturnal oximetry to diagnose OSA (Zamarrón, Gude, Barcala, Rodríguez,

& Romero, 2003; Zamarrón, Pichel, & Romero, 2005; Zamarrón, Romero, Gude, Amaro, & Rodríguez, 2001). The study developed by Zamarrón et al. (2003) showed that frequency characteristics from HR signals improved results obtained processing SaO_2 individually. In a later research by Zamarrón et al. (2005), both signals were processed together to quantify the relationship between oscillations in SaO_2 and HR by means of the frequency coherence function. In the present study, we estimate the *asynchrony* between SaO_2 and HR from nocturnal oximetry by means of a nonlinear measure called *cross approximate entropy (cross-ApEn)*. Previous studies have demonstrated the usefulness of nonlinear analysis in the diagnosis of OSA syndrome (Álvarez, Hornero, Abásolo, del Campo, & Zamarrón, 2006; Hornero, Álvarez, Abásolo, del Campo, & Zamarrón, 2007).

BACKGROUND

Similarities between two signals or variables have been traditionally quantified by means of linear methods, like the cross-correlation function or spectral estimates based on cross-spectrum, especially *coherency*. The magnitude squared coherence is a normalized cross-spectral density function that gives a measure of the degree of linear correlation between each of the individual frequency components of two signals (Hampson & Mallen, 2006). It has been widely applied to quantify functional interactions between different brain areas (Nunez et al., 1997). However, these classical estimates are often inadequate to satisfactory identify visually apparent instances of significant association or correspondence between paired series (Liu, Pincus, Keenan, Roelfsema, & Veldhuis, 2005). Statistical estimation methods are nontrivial and their interpretation could be problematic. Moreover, standard spectral estimators can be inconsistent and biased, especially in the presence of outliers and nonstationarities (Pincus, 2000). Particularly, coherency estimates are not suitable to characterize nonstationary signals and only capture linear relations between time series (Porta, Baselli, Lombardi, Montano, Malliani, & Cerutti, 1999; Stam & van Dijk, 2002).

A recently developed measure of asynchrony between time series, the *cross-ApEn*, has demonstrated to be complementary and often superior to both spectral and correlation based methods (Pincus, 2000). *Cross-ApEn* provides substantially more general or robust measures of feature persistence than both correlation and spectral based methods (Pincus, Mulligan, Iranmanesh, Gheorghiu, Godschalk, & Veldhuis, 1996). Cross-ApEn is a family of statistics proposed by Steven M. Pincus, suggesting its application to physiological signals like HR and respiratory rate (Pincus & Singer, 1996). It has been mainly applied to study hormone time series dynamics, like luteinizing and follicle-stimulating hormones (Veldhuis, Iranmanesh, Mulligan, & Pincus, 1999), luteinizing hormone and testosterone (Veldhuis, Pincus, García-Rudaz, Ropelato, Escobar, & Barontini, 2001), or adrenocorticotropic hormone and cortisol (Liu et al., 2005). Other entropy-based measures of asynchrony have been also applied to cardiovascular variability signals, pointing out their advantages over the linear approach (Porta et al., 1999; Porta et al., 2000).

This study was aimed to assess whether a measure of asynchrony between SaO_2 and HR from nocturnal oximetry using *cross-ApEn* could help in the diagnosis of OSA syndrome.

CROSS APPROXIMATE ENTROPY ANALYSIS TO HELP IN THE OSA DIAGNOSIS

Polysomnography and Oximetry Studies

A total of 187 patients with suspicion of OSA syndrome were studied. Sleep studies were carried out in the Sleep Unit of Hospital Clínico Universitario in Santiago de Compostela, Spain. The Review Board on Human Studies approved the protocol, and all subjects gave their informed consent to participate in the study. A nocturnal oximetry study (pulse oximeter Criticare 504, CSI, Waukesha, WI, USA) was performed simultaneously with a conventional PSG (Polygraph Ultrasom Network, Nicolet, Madison, WI, USA). If a subject had less than 3 hours of total sleep, the sleep study was repeated.

The PSG register was analyzed according to Rechtschaffen and Kales rules (Rechtschaffen & Kales, 1968). An *apnea event* was defined as a cessation of airflow for more than 10 seconds, whereas hypopnea was defined as the reduction of respiratory flow for at least 10 seconds accompanied by a 4% or more decrease in the saturation of hemoglobin. An average apnea-hypopnea index (AHI) derived from the PSG study was calculated for hourly periods of sleep. Subjects with an AHI greater than or equal to 10 were diagnosed as OSA positive. SaO_2 and HR signals from oximetry were simultaneously recorded using a dual wavelength-based finger probe with a sampling frequency of 0.2 Hz (one sample every 5 s).

We randomly divided the population under study into a training set (74 subjects, 44 patients with a positive diagnosis of OSA and 30 with a negative diagnosis of OSA) and a test set (113 subjects, 67 patients with a positive diagnosis of OSA and 46 with a negative diagnosis of OSA). The training set was used to perform the methodology and to select the optimum decision threshold. Finally, *cross-ApEn* was applied without further alteration to the data from the test set. Table 1 summarizes the demographic and clinical features of the patient groups.

Cross Approximate Entropy

The c*ross-ApEn* is a two parameter family of statistics introduced as a measure of asynchrony between two paired time series (Pincus, 2000). Its definition was proposed by Pincus as a method to compare correlated sequences, suggesting its application to physiological signals like HR and respiratory rate (Pincus & Singer, 1996).

Cross-ApEn is generally applied to compare sequences from two distinct yet intertwined variables in a network. It allows the assessment of system evolution

Note. Data are presented as mean ± SD or n (%). OSA Positive: patients with a positive diagnosis of obstructive sleep apnea syndrome; OSA Negative: subjects with a negative diagnosis of obstructive sleep apnea syndrome; BMI: body mass index; AHI (n/h): apnea/hypopnea index calculated for hourly periods.

characteristics such as feedback and control avoiding the requirement to model the underlying system (Pincus, 2000). *Cross-ApEn* evaluates subordinate as well as dominant patterns in data, quantifying changes in underlying episodic behavior that do not reflect in peak occurrences and amplitudes (Veldhuis et al., 1999). For two paired time series $u(i)$ and $v(i)$, *cross-ApEn* measures, within tolerance r, the (conditional) regularity or frequency of v-patterns similar to a given u-pattern of window length m. Greater asynchrony indicates fewer instances of (sub)pattern matches, quantified by larger *cross-ApEn* values (Pincus, 2000).

Formally, given two length-N sequences $u = [u(1), u(2), \ldots, u(N)]$ and $v = [v(1), v(2), \ldots, v(N)]$, and fixed the input parameters m and r, *cross-ApEn* could be computed as follows (Pincus, 2000):

1. Form the vector sequences $x(i) = [u(i), u(i+1), \ldots, u(i+m-1)]$ and $y(j) = [v(j), v(j+1), \ldots, v(j+m-1)]$. These vectors represent m consecutive u and v values respectively, commencing with the ith point.
2. Define the distance between $x(i)$ and $y(j)$, $d[x(i), y(j)]$, as the maximum absolute difference in their respective scalar components:

$$d\left[x(i), y(j)\right] = \max_{k=1,2,\ldots,m} |u(i+k-1) - v(j+k-1)| \quad (1)$$

3. For each $x(i)$, count the number of j ($j = 1\ldots N-m+1$) so that $d[x(i),y(j)] \le r$, denoted as $N_i^m(r)$. Then, for $i=1\ldots N-m+1$, set

$$C_i^m(r)(v \,\|\, u) = N_i^m(r)/(N-m+1) \quad (2)$$

The $C_i^m(r)$ values measure within a tolerance r the regularity, or frequency, of (v–) patterns similar to a given (u–) pattern of window length m.

4. Compute the natural logarithm of each $C_i^m(r)$, and average it over i,

$$\phi^m(r)(v\|u) = \frac{1}{N-m+1} \sum_{i=1}^{N-m+1} \ln C_i^m(r)(v\|u) \quad (3)$$

5. The cross approximate entropy is defined by:

$$cross\text{-}ApEn(m,r,N)(v\|u) = \phi^m(r)(v\|u) - \phi^{m+1}(r)(v\|u) \quad (4)$$

Typically, *cross-ApEn* is applied to normalized $\{u^*(i), v^*(i)\}$ time series, where $u^*(i) = [u(i)\text{–mean}(u)]/\text{SD}(u)$ and $v^*(i) = [v(i)\text{–mean}(v)]/\text{SD}(v)$.

Two important issues must be taken into account when computing *cross-ApEn* (Richman & Moorman, 2000):

a. *Cross-ApEn*$(m,r,N)(v||u)$ will not be always defined, because of $C_i^m(r)(v\|u)$ in equation (3) are equal to 0 in the absence of similar patterns between u and v. To solve this, we used two correction strategies proposed by Richman & Moorman (2000): bias 0 and bias max. Both strategies assign non zero values to $C_i^m(r)(v\|u)$ and $C_i^{m+1}(r)(v\|u)$ in the absence of any matches. The bias 0 strategy, sets the bias towards a *cross-ApEn* value of zero by setting

$$C_i^m(r) = C_i^{m+1}(r) = 1 \quad \text{if originally} \quad C_i^m(r) = C_i^{m+1}(r) = 0 \quad (5)$$
$$C_i^{m+1}(r) = (N-m)^{-1} \text{ if originally } C_i^m(r) \ne 0 \text{ and } C_i^{m+1}(r) = 0.$$

The bias max correction sets the bias towards the highest observable value of *cross-ApEn* by setting

$$C_i^m(r) = 1 \text{ if originally } C_i^m(r) = 0 \quad (6)$$
$$C_i^{m+1}(r) = (N-m+1)^{-1} \quad \text{if originally} \quad C_i^{m+1}(r) = 0$$

In this research, both correction strategies were implemented, and their influence in the diagnostic ability of *cross-ApEn* were studied in the training set.

b. There is a direction dependence. Because of the logarithm in equation (3), $\phi^m(r)(v\|u)$ will not generally be equal to $\phi^m(r)(u\|v)$. Thus, *cross-ApEn*$(v||u)$ and its direction conjugate *cross-*

ApEn($u||v$) are unequal in most cases. In the present study, both *cross-ApEn*($v||u$) and *cross-ApEn*($u||v$) were estimated, and the influence of the direction dependence in the diagnostic accuracy of *cross-ApEn* was tested in the training set.

In this research, we divided SaO_2 and HR signals in 200 sample epochs before *cross-ApEn* was applied. The input parameters were fixed to m = 1 or 2, and r was varied from 0.1 to 1.0 in steps of 0.1.

Results

Training Set. *Cross-ApEn* was applied to both OSA positive and OSA negative groups in the training set. Different combinations of the input parameters m and r were assessed, as well as the correction strategies bias 0 and bias max and the two possible directions (SaO_2||HR) and (HR||SaO_2). Student t-test was applied to check for significant differences. Firstly, a great difference was found between the directions (SaO_2||HR) and (HR||SaO_2). *Cross-ApEn*(m,r,N)(HR||SaO_2) achieved lower accuracies with all combinations of m and r in terms of the p-value. This fits well with the nature of SaO_2 and HR signals. SaO_2 signals are more regular than HR in both OSA positive and OSA negative subjects. The number of SaO_2 patterns similar to a fixed HR pattern when computing $C_i^m(r)(SaO_2\|HR)$ will be greater than the number of similar patterns when comparing a HR record to a fixed SaO_2 pattern. Hence, *cross-ApEn* will be statistically better estimated in the first case (Pincus & Goldberger, 1994), increasing the differences between OSA positive and OSA negative groups. With respect to the correction strategies, no significant differences were found between bias 0 and bias max ($p >> 0.01$).

Figure 1 displays mean *cross-ApEn*(m,r,N)(SaO_2||HR) values with bias 0 correction for both the OSA positive and the OSA negative groups in the training set. All the suggested combinations of the input parameters m and r were computed. For a fixed m and r pair, the OSA negative group achieves higher values of *cross-ApEn* than the OSA positive group. Hence, we could say that OSA negative SaO_2 and HR paired records are more asynchronous than OSA positive oximetric recordings. This behavior demonstrates the relative consistency of *cross-ApEn* applied to oximetry signals with r varying from 0.1 to 1.0 and m equal to 1 or 2.

Finally, an optimum decision threshold was derived from the training set by means of receiver operating characteristics (ROC) plots. The ROC curve is obtained representing sensitivity vs. 1-specificity for different thresholds, depending on the nature of the values provided by the method. The sensitivity of a test is the percentage of patients in the OSA positive group correctly diagnosed, whereas the specificity is the percentage of subjects in the OSA negative group rightly classified by the test. The optimum decision threshold was selected looking for a compromise between sensitivity and specificity. This value is graphically determined from

Figure 1. Mean cross-ApEn (SaO_2||HR) for both the OSA positive and OSA negative groups in the training set varying cross-ApEn input parameters

Note. Th: Optimum threshold; S: Sensitivity; E: Specificity; A: Accuracy; AROC: Area under the ROC curve.

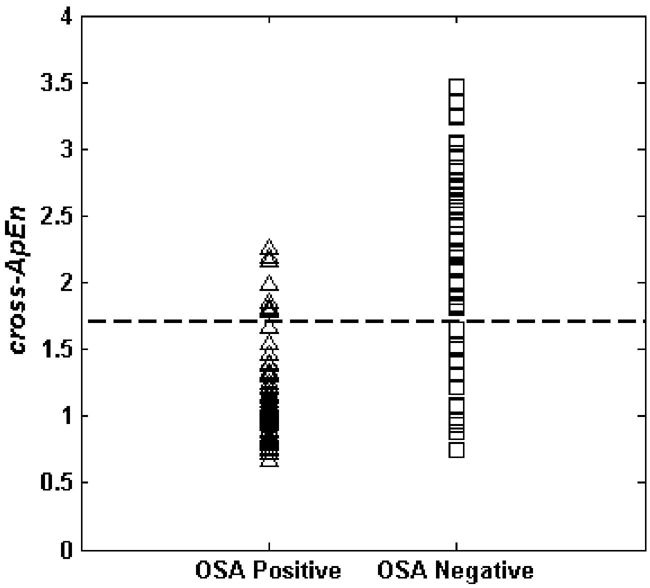
the ROC curve as the closest point to the left top corner (100% sensitivity and 100% specificity). Table 2 shows the statistics for the optimum threshold from the ROC analysis for *cross-ApEn*(*m*,*r*,*N*)(SaO_2||HR) with bias 0 correction. The best diagnostic accuracy was achieved with m = 2 and r = 0.6. The optimum threshold was selected at 1.7, where we achieved 95.5% sensitivity, 73.3% specificity, 86.5% accuracy and an area under the ROC curve of 0.87.

Test Set. We applied *cross-ApEn* to the test set using the optimum parameters derived from the training set: m = 2, r = 0.6, (SaO_2||HR) direction and bias 0 correction. Figure 2 displays the mean *cross-ApEn* values for the OSA positive and the OSA negative subjects in the test set. The dashed line represents the optimum decision threshold derived from the training set. Patients in the OSA positive group were characterized by lower *cross-ApEn* values (1.16 ± 0.38), according to the greater synchrony between their SaO_2 and HR recordings. On the other hand, OSA negative subjects were characterized by higher *cross-ApEn* values (2.18 ± 0.73). Finally, the diagnostic ability of *cross-ApEn* in screening for OSA syndrome was assessed computing the sensitivity, specificity and accuracy values in the test set with the optimum decision threshold provided by the training set. We achieved 86.7% sensitivity, 73.9% specificity, and 81.4% accuracy.

Discussion

In the present study, we analyzed the oximetric recordings of a sample of 187 patients (111 with a positive diagnosis of OSA and 76 with a negative diagnosis of OSA) looking for an alternative method to PSG in the diagnosis of OSA. The whole data set were randomly divided in a training set (44 OSA positive patients and 30 OSA negative subjects) and a test set (67 OSA positive patients and 46 OSA negative subjects). The training set was used to define different methodological issues and to select an optimum decision threshold, whereas the subsequently use of the test set provided a higher generalization of the results. A nonlinear method called *cross-ApEn* was applied to paired SaO_2

Figure 2. Mean cross-ApEn (SaO_2||HR) values from nocturnal oximetry for patients in the OSA positive and the OSA negative group in the test set. The horizontal dashed line, set at 1.7034, represents the optimum decision threshold between both populations derived from the training set.



and HR signals from nocturnal oximetry to quantify their asynchrony. A shorter value of c*ross-ApEn* indicates greater instances of (sub)pattern matches, so the sequences are more synchronous (Pincus, 2000). We found that the recurrent *apnea events* in OSA positive patients lead to a significant decrease in the c*ross-ApEn* values. Oxygen desaturations associated with apnea events typical of OSA, cause coordinate fluctuations in both SaO_2 and HR signals, leading to low c*ross-ApEn* values. Furthermore, we found a great direction dependence of the method. *Cross-ApEn*(SaO_2||HR) is better estimated than *cross-ApEn*(HR||SaO_2) ($p < 0.01$). On the other hand, no significant differences were found between the correction strategies bias 0 and bias max ($p >> 0.01$).

Previous studies assessed the relationship between oscillations in SaO_2 and HR as a sign of periodic breathing (Keyl, Lemberger, Pfeifer, Hochmuth, & Gesiler, 1997; Zamarrón et al., 2005). The study developed by Zamarrón et al. (2005) showed that the average level of SaO_2 and HR coherence in OSA positive patients was significantly higher than in OSA negative patients. Their results fit well with those obtained in our study, indicating higher synchrony between oximetry signals from OSA subjects. A sensitivity of 86.6%, a specificity of 73.9%, and an accuracy of 81.4% were obtained with the test set, using the optimum threshold of 1.7 derived from the training set.

We should take into account some limitations of our study. The sample size could be larger and OSA positive patients were predominantly studied. Moreover, a drawback in the applicability of our method should be mentioned. Oximetry signals were recorded simultaneously with PSG, eliminating potential confounders such as night to night variability of AHI, as well as ensuring that oximetry data were collected in exactly the same environment as the PSG data. Further analyses using unattended nocturnal oximetry in home are necessary. An additional difficulty lies in the estimation of the HR from the distal pulse obtained from pulse oximetry, instead of measuring the elapsed time between consecutive R waves. An overestimation of the high frequencies must be taken into account.

FUTURE TRENDS

Last years has shown an increasing interest in assessing portable monitoring as an alternative to PSG to study patients with suspicion of OSA syndrome. Its simplicity and low cost have made nocturnal oximetry an excellent screening method previous to PSG. However, research studies typically record nocturnal oximetry and PSG simultaneously in a sleep laboratory. Hence, the cost effectiveness of unattended monitoring at home would need to be evaluated prospectively in a controlled trial (Whitelaw et al., 2005). Moreover, additional work is required to apply our methodology to larger data set with a wide spectrum of sleep-related breathing disorders, as well as to study groups of especial interest, such as patients with lung diseases and young snorers.

Several quantitative indexes derived from nocturnal oximetric recordings are widely used by physicians, especially ODIs and CT. However, there is not a standardized definition or consensus on its use. Our research group has recently assessed the usefulness of nonlinear analysis in the diagnosis of OSA syndrome. We have shown that regularity, variability, and complexity measures from SaO_2 could improve the diagnostic accuracy of classical oximetric indexes (Hornero et al., 2007; Álvarez et al., 2006). Moreover, in the present study, we have found that HR could provide additional information to SaO_2 using *cross-ApEn*. However, it would be necessary to assess additional nonlinear methods, mainly those oriented to analyze the relationship between various signals. Further work is needed to assess nonlinear analysis and to verify its advantages over classical oximetric indexes and the linear approaches.

CONCLUSION

In summary, we found that the recurrence of apnea events in patients with OSA determined a significant decrease in the *cross-ApEn* values of the SaO_2 and HR oximetric recordings. This suggests that the apnea events cause synchrony fluctuations in SaO_2 and HR, affecting both respiratory and circulatory systems and their relationship. A sensitivity of 86.6%, specificity of 73.9%, and accuracy of 81.4% were achieved. With this research, we verified that the analysis of SaO_2 and HR jointly by means of *cross-ApEn* could provide useful information to help in the OSA diagnosis.

KEY TERMS

Apnea Event: The omplete cessation of airflow for at least 10 seconds.

Blood Oxygen Saturation (SaO_2): A percentage of hemoglobin binding sites in the bloodstream occupied by oxygen.

Cross Approximate Entropy (Cross-ApEn): The nonlinear measure of asynchrony between two paired time series.

Heart Rate (HR): The frequency of the cardiac cycle equal to the number of contractions of the heart (heart beats) in 1 minute commonly expressed as beats per minute (bpm).

Hypopnea Event: The partial reduction of respiratory flow for at least 10 seconds accompanied by a 4% or more decrease in the saturation of hemoglobin.

Nonlinear System: A system whose behavior is not subject to the principle of superposition, that is, its behavior is not expressible as the sum of its parts.

Obstructive Sleep Apnea (OSA) Syndrome: A sleep disorder characterized by repetitive obstruction of the upper airway despite the presence of respiratory effort, resulting in oxygen desaturations and arousals during sleep.

Oximetry: The noninvasive indirect measure of the percentage of arterial oxygen combined with the hemoglobin blood oxygen saturation (SaO_2), usually accompanied by an estimation of the heart rate (HR).

Polysomnography (PSG): A multiparametric test used in the study of sleep and breathing usually performed during the night in a specialized sleep unit. PSG records biophysiological and neurophysiological data, including electroencephalogram (EEG), electrocardiogram (ECG), electrooculogram (EOG), electromiogram (EMG), measurement of chest wall movement and airflow, and oximetry.

Applying Independent Component Analysis to the Artifact Detection Problem in Magnetoencephalogram Background Recordings

INTRODUCTION

The analysis of the electromagnetic brain activity can provide important information to help in the diagnosis of several mental diseases. Both electroencephalogram (EEG) and magnetoencephalogram (MEG) record the neural activity with high temporal resolution (Hämäläinen, Hari, Ilmoniemi, Knuutila, & Lounasmaa, 1993). Nevertheless, MEG offers some advantages over EEG. For example, in contrast to EEG, MEG does not depend on any reference point. Moreover, the magnetic fields are less distorted than the electric ones by the skull and the scalp (Hämäläinen et al., 1993). Despite these advantages, the use of MEG data involves some problems. One of the most important difficulties is that MEG recordings may be severely contaminated by additive external noise due to the intrinsic weakness of the brain magnetic fields. Hence, MEG must be recorded in magnetically shielded rooms with low-noise SQUID (Superconducting QUantum Interference Devices) gradiometers (Hämäläinen et al., 1993).

Unfortunately, the external noise is not the only undesired signal in MEG data. In these recordings, noncerebral sources (i.e., artifacts) appear mixed with the useful brain signals. The artifacts could bias the brain activity analyses, since both kinds of signals may have similar power and share the same frequency band. In MEG data, the main artifact is the cardiac one, whose amplitude is usually high enough to be visible in raw recordings (Jousmäki & Hari, 1996). Similarly, the ocular artifacts can be evident in MEG data (Antervo, Hari, Katila, Ryhänen, & Seppänen, 1985), and they can disguise the actual brain activity in long recordings. Finally, power line noise may also be present in MEG signals (Hämäläinen et al., 1993).

Diverse approaches have been used to detect and reject artifacts from EEG and MEG data, such as epoch rejection, regression methods (Croft & Barry, 2000), or principal component analysis (PCA) (Sadasivan & Dutt, 1996). In the early 1990s, a new method to obtain a blind source separation (BSS) became available: the independent component analysis (ICA) (Comon, 1994; Jutten & Herault, 1991). Since then, ICA has been increasingly used in the artifact rejection problem (Delorme, Makeig, & Sejnowski, 2001; Escudero, Hornero, Abásolo, Poza, Fernández, & López, 2006; James & Hesse, 2005; Jung, Makeig, Humphries, Lee, McKeown, Iragui, & Sejnowski, 2000; Sander, Wübbeler, Lueschow, Curio, & Trahms, 2002; Vigário, 1997; Vigário, Jousmäki, Hämäläinen, Hari, & Oja, 1998). One of the main advantages of ICA over other approaches is that artifacts must not be orthogonal to brain signals, and reference channels are not needed, although they can help to detect the artifacts (Barbati, Porcaro, Zappasodi, Rossini, & Tecchio, 2004; Flexer, Bauer, Pripfl, & Dorffner, 2005; Joyce, Gorodnitsky, & Kutas, 2004).

BACKGROUND

The use of ICA in the artifact rejection problem can be summarized as follows. Firstly, ICA finds a separating matrix, which decomposes the multidimensional input data (the EEG or MEG channels) into several independent components (ICs). Next, the ICs which account for artifacts are marked by visual inspection (Vigário, 1997; Vigário et al., 1998) or automatic methods (Barbati et al., 2004; Escudero et al., 2006; Flexer et al., 2005; Joyce et al., 2004; Li, Ma, Lu, & Li, 2006; Ting, Fung, Chang, & Chan, 2006), and they are removed. Finally, the pseudo-inverse of the separating matrix is used to build the output data (i.e., the signals without artifacts) from the retained ICs.

In this process, the main open issue is the artifact recognition. Several automatic criteria have been proposed. For instance, Delorme et al. (2001) used kurtosis and entropy to identify artifacts in EEG data. Adding a correlation criterion to these parameters, Barbati et al. (2004) proposed a semiautomatic approach to detect various artifacts in MEG signals. Similarly, Joyce et al. (2004) used a correlation metric, together with other simple procedures to remove ocular artifacts from EEG data. Recently, three criteria based on amplitude thresholds, power in frequency bands, and scalp distributions of the ICs were used by Ting et al. (2006) to deal with muscular and ocular artifacts in EEG. Moreover, Escudero et al. (2006) showed that a criterion based on the skewness of the IC amplitude distributions could detect the cardiac-related ICs better than kurtosis in MEG data.

In addition, it is important to select the number of ICs correctly. Whereas some papers set a power threshold (Ting et al., 2006), other studies set this parameter to the number of available channels (Flexer et al., 2005; Joyce et al., 2004; Jung et al., 2000; Li et al., 2006; Sander et al., 2002). Nevertheless, few statistical criteria have been used (Cao, Murata, Amari, Cichocki, & Takeda, 2003; Escudero et al., 2006; Ikeda & Toyama, 2000).

As it can be noted, very different approaches have been proposed to remove artifacts from EEG and MEG data with ICA. However, none has been generally adopted. This could be due to the intrinsic complexity of the MEG signals and the ICA algorithms. Because of this reason, straightforward artifact detection criteria might be preferred to complex ones, in order to keep the whole artifact rejection process at a suitable level of complexity. Therefore, in this study, we evaluated the usefulness of three criteria based on higher order statistics and spectral properties to detect the cardiac, ocular, and the power line artifacts in MEG data.

MAGNETOENCEPHALOGRAM RECORDING

Seven elderly subjects without past or present neurological disorders—age = 65.6 ± 7.9 years; mean ± standard deviation (SD)—participated in this study. They were asked to stay awake with closed eyes, and to reduce eye and head movements while they were lying on a patient bed to record the MEG signals. These conditions are similar to the recording protocol used in diagnostic studies. All subjects gave their informed consent for the participation in this study, which was approved by the local ethics committee.

For each subject, five minutes of MEG data were acquired at a sampling frequency of 678.17 Hz with a 148-channel whole-head magnetometer (MAGNES 2500 WH, 4D Neuroimaging) in a magnetically shielded room. The recordings were downsampled to 169.549 Hz. Fourteen epochs of 50 s (8,477 samples) with artifacts were selected for off-line analysis. All of them had cardiac artifacts, and some also presented ocular and/or power line ones. The epochs were digitally filtered using a band-pass filter with cut-off frequencies at 0.5 Hz and 60 Hz.

ARTIFACT REJECTION METHOD

Independent Component Analysis

The ICA model assumes that the n MEG channels, $\mathbf{x}(t) = [x_1(t), \ldots, x_n(t)]^T$, are a linear mixture of m ICs, $\mathbf{s}(t) = [s_1(t), \ldots, s_m(t)]^T$, with $m \leq n$ (James & Hesse, 2005). In order to represent the external additive noise, an n-dimensional vector of spatially uncorrelated Gaussian noise, $\mathbf{v}(t)$, can also be included in the model (Barbati et al., 2004; Cao et al., 2003; Ikeda & Toyama, 2000; Ting et al., 2006):

$$\mathbf{x}(t) = \mathbf{A}\mathbf{s}(t) + \mathbf{v}(t) \quad (1)$$

where the means of $\mathbf{s}(t)$, $\mathbf{x}(t)$, and $\mathbf{v}(t)$ are zero and $\mathbf{A}$ is a full rank $n \times m$ mixing matrix.

In this problem, only $\mathbf{x}(t)$ is known. Therefore, $\mathbf{A}$, $\mathbf{s}(t)$, and $\mathbf{\Psi}$—the covariance matrix of the external noise—have to be estimated blindly from $\mathbf{x}(t)$. To achieve this BSS, ICA makes several assumptions about the data (Cichocki & Amari, 2002; Comon, 1994): the ICs are statistically independent and have non-Gaussian distributions, and the mixing process is linear, instantaneous, and stationary. All these hypotheses have been previously validated for EEG and MEG data (James & Hesse, 2005; Vigário & Oja, 2000).

ICA provides a separating matrix, $\mathbf{W} = \mathbf{A}^{+}$ (apex "+" denotes a pseudo-inverse matrix). Using $\mathbf{W}$, we can compute:

$$\mathbf{y}(t) = \mathbf{W}\mathbf{x}(t) = \mathbf{W}[\mathbf{A}\mathbf{s}(t) + \mathbf{v}(t)] = \mathbf{s}(t) + \mathbf{W}\mathbf{v}(t) \quad (2)$$

where $\mathbf{y}(t) = [y_1(t), \ldots, y_m(t)]^{\mathrm{T}}$ is the m-dimensional vector which estimates $\mathbf{s}(t)$ (i.e., the ICs).

To calculate $\mathbf{W}$, we have used the cumulant-based iterative inversion (CII) algorithm (Cruces-Alvarez, Cichocki, & Castedo-Ribas, 2000). This ICA algorithm is robust to external Gaussian noise, in the sense that it is able to find an asymptotically unbiased estimation of $\mathbf{W}$, when calculations are carried out with enough samples (typically ≥ 5000) (Barbati et al., 2004; Cruces-Alvarez et al., 2000; Escudero et al., 2006).

Preprocessing

When high-density recording equipment is used, it may be necessary to reduce the data dimensionality (James & Hesse, 2005; Vigário & Oja, 2000). However, there is no information about the real m value. This dimensionality reduction is usually carried out with PCA (James & Hesse, 2005; Vigário & Oja, 2000), but this approach has some drawbacks, since it assumes that all the MEG channels have the same noise power (Barbati et al., 2004; Ting et al., 2006), and it does not set an objective criterion to estimate m (James & Hesse, 2005). To avoid these drawbacks, we have implemented the preprocessing using the unweighted least squares method (Cao et al., 2003) of factor analysis (FA) (Reyment & Jöreskog, 1993), which considers $\mathbf{\Psi}$. The model for this preprocessing is:

$$\mathbf{x}(t) = \mathbf{A}_{\mathrm{Pr}}\mathbf{z}(t) + \mathbf{v}(t) \quad (3)$$

where $\mathbf{C}$ is the covariance matrix of $\mathbf{x}(t)$, and $\mathbf{A}_{\mathrm{Pr}}$ as the preprocessing mixing matrix that relates the preprocessed data, $\mathbf{z}(t)$, to $\mathbf{x}(t)$.

$\mathbf{A}_{\mathrm{Pr}}$ and $\mathbf{\Psi}$ can be estimated from $\mathbf{C}$ using an iterative procedure (Cao et al., 2003, Escudero et al., 2006). Then, the matrix $\mathbf{Q}$ used to preprocess the data is calculated as the pseudo-inverse of $\mathbf{A}_{\mathrm{Pr}}$ taking into account the external noise power (Cao et al., 2003, Escudero et al., 2006). Finally, the preprocessed data are obtained by:

$$\mathbf{z}(t) = \mathbf{Q}\mathbf{x}(t) \quad (4)$$

This procedure assumes that m is known. However, m must also be estimated from the data. In order to determine it, we used a method derived from FA and based on statistical model selection with information criteria: the minimum description length (MDL), which was computed according to (Ikeda & Toyama, 2000) (Box 1),where $\mathrm{tr}(\cdot)$ denotes the trace of a matrix and N is the number of data points.

Artifact Detection Methods

Power Line Noise Artifacts. ICA can isolate most power line noise into one IC (Jung et al., 2000). Hence, the spectrum of such IC should be centered at the power line frequency (50 Hz in Europe). A spectral parameter, P_{50Hz}, which measures the fraction of the power spectral density (PSD) contained between 49.5 Hz and 50.5 Hz, may be useful to mark this kind of ICs. Therefore, we

Box 1.

$$MDL = \frac{1}{2}\mathrm{tr}\left[\mathbf{C}\left(\mathbf{\Psi} + \mathbf{A}_{\mathrm{pr}}\mathbf{A}_{\mathrm{pr}}^{\mathrm{T}}\right)^{-1}\right] + \frac{1}{2}\log\left[\det\left(\mathbf{\Psi} + \mathbf{A}_{\mathrm{pr}}\mathbf{A}_{\mathrm{pr}}^{\mathrm{T}}\right)\right]\cdots$$
$$\cdots + \frac{n}{2}\log(2\pi) + \frac{\log N}{N}\left[n(m+1) - \frac{m(m-1)}{2}\right]$$

marked for rejection the ICs with P_{50Hz} values larger than a threshold (th_{50Hz}).

Cardiac Artifacts. Skewness (Skw) is defined as:

$$Skw = \frac{m_3}{(m_2)^{3/2}}, \qquad (6)$$

where $\mathrm{E}\{\cdot\}$ is the expectation value, and m_n is the nth central moment of a statistical distribution: $m_n = \mathrm{E}\left\{\left(x - \mathrm{E}\{x\}\right)^n\right\}$. *Skw* measures the asymmetry degree of a distribution. It is zero only if the distribution is symmetrical. Thus, large absolute values of *Skw* should be related to asymmetrical ICs amplitude distributions, which are typical of cardiac artifacts (Escudero et al., 2006).

Ocular Artifacts. The spectrum of the ocular artifacts is usually focused in lower frequencies than in cardiac or brain activity (Joyce et al., 2004). It follows that the ICs whose energy is mainly gathered in a very low frequency band could be due to the ocular artifacts. Therefore, we calculated the fraction of the PSD, which every IC has from 0.5 Hz to 2.5 Hz (P_{LF}), and we set a threshold (th_{LF}). An IC is considered an ocular artifact when $P_{LF} > th_{LF}$.

RESULTS

Fourteen epochs of 50 s were processed to detect the cardiac, ocular, and power line artifacts. Firstly, the optimal *m* value for every MEG was estimated in the preprocessing stage. From the 148 MEG channels, the average estimated number of ICs was 30.14 ± 7.51 ICs (mean ± SD). Once the epochs had been preprocessed, we performed the ICA decomposition using the CII algorithm. The estimated ICs were visually inspected in both time and frequency domains, and they were compared to the raw MEG recordings. By this procedure, the ICs were classified into four groups: cardiac ICs, ocular ICs, power line ICs, and other signals. In all epochs, one IC was responsible for the cardiac artifact. Since the MEG was recorded with closed eyes, only 10 of the 14 analyzed MEG epochs had ocular artifacts. From these 10 epochs, 17 ICs were associated with ocular artifacts. Finally, 12 of the 14 MEG epochs had power line interference. In these epochs, the major line noise component was isolated into one IC.

Afterward, we used three straightforward metrics to detect the artifact ICs. First, we used the P_{50Hz} parameter to assess the line noise in every IC. Setting $th_{50Hz} = 0.500$, all the power line ICs were automatically recognized. Figure 1(a) illustrates this kind of IC. Actually, there was a large difference between the P_{50Hz} values for the power line ICs, which provided P_{50Hz} values larger than 0.586, and for any other IC, with values lower than 0.041, except for an IC with P_{50Hz} = 0.146.

We also used the *Skw* of the IC amplitude distributions to mark the cardiac artifacts. The IC that provides the maximum absolute value of *Skw* for every MEG epoch could be related to the cardiac artifact. We found that this criterion marked this artifact correctly in all cases. Figure 1(b) shows this artifact recognition principle. It can be noted that this artifact has an asymmetrical distribution, which produces large *Skw* values.

Finally, we used the spectra of the ICs to detect the ocular artifacts. Since a MEG epoch with ocular artifacts may produce more than one ocular-related IC, we evaluated the performance of the P_{LF} parameter using the 17 ocular ICs and the 17 nonocular ICs which had the largest P_{LF} values. We used this group of 34 ICs to find the optimal value for th_{LF}, which was 0.349. With this threshold, 16 of the 17 ocular ICs were correctly classified (94.12%), although three nonartifact ICs were erroneously marked as ocular artifacts. Figure 1(c) plots the spectra and amplitude distribution of an ocular IC.

DISCUSSION

Although MEG can provide useful information about the brain, it is usually polluted by several artifacts, which could bias the analyses (Hämäläinen et al., 1993). Diverse approaches, such as epoch rejection, regression techniques (Croft & Barry, 2000), or PCA (Sadasivan & Dutt, 1996), have been traditionally used to remove the artifacts. However, these approaches present certain drawbacks (Jung et al., 2000; Vigário & Oja, 2000). ICA has been proposed as an alternative to these methods, since the hypotheses ICA makes about the data seem sensible for EEG and MEG recordings (James & Hesse, 2005).

We aimed to remove the cardiac, ocular, and the power line artifacts from MEG recordings with ICA. Firstly, we preprocessed the MEG epochs to automatically select the number of ICs for each of them (Cao et

Figure 1. Examples of different kinds of ICs extracted from the same MEG epoch. The normalized PSD and amplitude distributions of the ICs are shown. (a) Power line IC. (b) Cardiac IC. (c) Ocular IC.

al., 2003; Escudero et al., 2006; Ikeda & Toyama, 2000). The mean number of ICs was 30.14 ± 7.51. This method contrasts with other criteria which involve a certain degree of subjectivity, such as setting $n = m$ (Flexer et al., 2005; Joyce et al., 2004; Jung et al., 2000; Li et al., 2006; Sander et al., 2002) or using a power threshold (Ting et al., 2006). Afterwards, the CII algorithm was applied to estimate the ICs, which were inspected and classified. Finally, three straightforward parameters were used to detect the studied artifacts.

To identify the ICs that account for the power line interferences, we calculated the fraction of the signal PSD centered at 50 Hz. Setting a threshold $th_{50Hz} = 0.500$, we could detect the 12 power line ICs. Moreover, the largest P_{50Hz} values were always found in this kind of ICs. This confirms that ICA can isolate most power line noise into only one component (Jung et al., 2000).

The results also showed that *Skw* could detect all the 14 cardiac-related ICs, since *Skw* marks asymmetrical distributions, which are typical of the cardiac signal. On the other hand, other higher-order statistics, such as kurtosis or entropy, do not distinguish between cardiac and ocular artifacts (Barbati et al., 2004; Escudero et al., 2006).

Finally, setting a threshold on the power contained between 0.5 Hz and 2.5 Hz ($th_{LF} = 0.349$), we could identify 16 of the 17 ocular ICs (94.12%). However, three nonartifact ICs were incorrectly marked as ocular ICs. This kind of error should be avoided, as it can lead to remove part of the brain activity. Due to the high rate of ocular ICs correctly classified by P_{LF}, this criterion may be supplemented with another parameter to avoid those false artifacts, similarly to (Joyce et al., 2004), who used three criteria together to remove ocular artifacts from EEG recordings.

Certain limitations of our study merit attention. Firstly, the sample size was small, and further analyses have to be performed to confirm our findings. Moreover, evaluation of artifact detection is difficult, since the true unmixed signals are not known. Thus, it is impossible to completely validate the physiological meaning of every IC.

FUTURE TRENDS

In the last years, ICA-based approaches have been used to extract and analyze ICs from brain activity off-line. However, some applications, like brain-computer interface, need real-time algorithms. To deal with these applications, online artifact removal algorithms have been recently proposed (Shayegh & Erfanian, 2006), although they are only a first step toward this aim.

In addition, the application of ICA and, more generally, BSS techniques in brain recording analysis should not be limited to the artifact rejection. These methods might be applied to transform the complex EEG and MEG recordings into simpler components, which could provide a better understanding of the brain dynamics. For example, Jin, Jeong, Jeong, Kim, and Kim (2002) applied ICA to analyze the effect of sound and light stimulation on the ICs of the EEG. They found that ICA could improve the interpretation of the changes that occur in the EEG before and after stimulation. Moreover, Cichocki, Shishkin, Musha, Leonowicz, Asada, and Kurachi (2005) decomposed the EEG from mild cognitive impairment patients and control subjects. Their results showed that this EEG filtering—based on a BSS and a projection of the components which are more sensitive to the disease—could improve the rate of correctly classified patients and controls.

CONCLUSION

Our analysis of the ICs which composed 14 MEG epochs from seven elderly subjects suggests that all the major power line interferences could be rejected, setting a threshold on the fraction of their PSD at 50 Hz. Moreover, skewness could also detect all cardiac ICs. In addition, the fraction of the energy that an IC has between 0.5 Hz and 2.5 Hz could be a useful parameter to recognized ocular-related ICs, although this parameter may incorrectly mark nonocular ICs. Therefore, it should be supplemented with another criterion, which could avoid those false positives.

KEY TERMS

Artifact: Signal not produced by the brain, which appears in EEG or MEG recordings, and could bias the analyses of the neural activity. Some examples are the cardiac, ocular, muscular, and power line artifacts.

Blind Source Separation (BSS): The estimation of a set of unknown signals which have been mixed to produce a set of observed signals, with very little information about the former. Some common methods of BSS are ICA and PCA.

Electroencephalogram (EEG): Neurophysiologic recording of the voltage differences between different parts of the brain.

Higher-Order Statistics: Central moments of a statistical distribution with order higher than two.

Independent Component (IC): Each of the inner components into which ICA decomposes a multivariate signal.

Independent Component Analysis (ICA): A linear transformation for separating a multivariate signal into inner components, which are supposed to be as statistically independent as possible.

Magnetoencephalogram (MEG): Neurophysiologic recording of the magnetic fields produced by the currents of the pyramidal neurons that flow parallel to the skull.

Principal Component Analysis (PCA): A linear transformation for separating a multivariate signal into inner components in such a way that the greatest variance by any projection of the data lies on the first component, the second greatest variance on the second coordinate, and so on.

Applying Social Network Analysis in a Healthcare Setting

Salvatore Parise
Babson College, USA

INTRODUCTION

The people-to-people relationships where knowledge work actually gets performed in organizations are called social networks, and they may be in complete contradiction to the information flows expected, based on looking at the organizational chart of formal roles or titles. These informal or social networks are playing an increasingly important role in the healthcare industry, as medical and clinical knowledge needs to be shared effectively between people within and among healthcare organizations. Social network analysis (SNA) is a research methodology to analyze networks between people, groups, organizations, and systems within and across organizations (Wasserman & Faust, 1994). The results of the analysis inform the researcher of both the structure of the network, as well as the positions of nodes or people in the network. This article provides a description of how SNA can be applied in a healthcare setting.

Organizations are increasingly relying on networks of people, groups, and other institutions collaborating with each other to perform knowledge-based work. This is especially true in knowledge-intensive industries, such as business consulting, technology, research, and petroleum, where work is project-based in structure and sharing information within and between teams is essential to performance. Also, much of the critical work in businesses today requires tacit knowledge, which, by definition, is difficult to codify and resides in the key experts of the organization (Polanyi, 1983). Therefore, connections to these experts are required in order to leverage their expertise, past experiences, and institutional memory.

These informal or social networks are playing an increasingly important role in the healthcare industry. With the continued advancements in medical treatments, the rapid dissemination and sharing of this information becomes vital. While treatment descriptions can be codified and put into a database that physicians can access, often physicians will call on their personal relationships to understand the relevance, risks, and benefits of the latest medical knowledge. Physicians are turning to Web-based communities, such as sermo.com, to exchange, comment on, and rate others' postings on medical insights. Social networks are also vital to understanding the communication patterns, both between and within healthcare organizations. While traditionally operating as silos, these organizations recognize the need for improved access and sharing of clinical and medical research knowledge across their organizational boundaries. Within healthcare providers, social networks can reveal who are the key decision-makers or influencers pertaining to medical treatments, and the adoption of medical technology and information technology (IT), as well as determining if certain physicians are a bottleneck (or overburdened) when it comes to answering questions and disseminating information. Therefore a network perspective is vital to understanding how work gets performed in the healthcare industry.

BACKGROUND

There has been a dramatic rise recently in social network research in the management field (Borgatti & Foster, 2003). Network research has grown as a result of the importance of connections between people, groups, organizations, and IT systems. Network research has been used to study leadership (Brass & Krackhardt, 1999), entrepreneurship (Baron & Markman, 2003), knowledge management (Parise, Cross, & Davenport, 2006), individual performance (Mehra, Kilduff, & Brass, 2001), and team performance (Hansen, 1999). Social network analysis (SNA) is a structured methodology to analyze networks within and across organizations. The results of the analysis inform the researcher of both the structure of the network as well as people's positions within the network. Based on these findings, organizations can then develop interventions to produce the desired network effects. There has been limited research in the healthcare setting, using SNA as a methodology. SNA has been used to study the interaction patterns in primary care practices (Scott, Tallia, Crosson, Orzano, Stroebel, DiCicco-Bloom, O'Malley, Shaw, & Crabtree, 2005), identify influential individuals who are critical to the successful implementation of medical informatics applications (Anderson, 2005), and study the relationship between communication density and the use of an electronic medical record system by nurse practitioners and physicians' assistants (Tallia, Stange, McDaniel, Aita, Miller, & Crabtree, 2003).

SNA allows us to analyze the relationships among actors or nodes in a network. Nodes can be people, organizations, and IT systems. Connections between nodes are called links and determine the relationships between nodes. Two common representations of networks are bounded networks and ego networks (Wasserman & Faust, 1994; Scott, 2000). In a bounded network, the nodes in the network are predetermined. When using bounded networks, the researcher will often look for silos or fragments in the network. This occurs when there is a breakdown in communication between structures, such as between departments or divisions. Attribute data, such as current job tenure, company tenure, job level, location, and functional area are often collected for each node in the network. This allows the researcher to analyze the structure of the bounded network, and determine if any of these dimensions are having a significant impact on its structure. Ego networks are those generated based on the perspective of an individual node or person in the network. Typically, in an ego network analysis, each respondent is asked to list nodes or actors pertaining to them specifically. The SNA researcher can then derive the network, based on the nodes listed by all respondents, as well as study any biases or gaps in an individual's personal network.

SNA researchers will typically analyze both the structure of the network as well as the role of individual nodes within the network. Density and centralization are two common metrics used to describe the entire network. Density is defined as the ratio of observed links or connections in a network to the maximum number of links possible if every node in the network was connected (Wasserman & Faust, 1994). Centralization refers to the degree to which links are concentrated in the network. The centralization metric is very useful in analyzing the degree to which there are "dominant" nodes in the network.

In addition to analyzing the network structure, the other major insight from doing an SNA analysis is to understand a node's role. Certain nodes in the network may be more central resulting in a more advantageous position. Individuals who are more central in the network have been found to have greater influence (Brass, 1984; Brass & Burkhardt, 1992), and have greater access and control of relevant information (Brass & Burkhardt, 1993; Krackhardt, 1990; Umphress, Labianca, Brass, Kass, & Scholten, 2003). In terms of identifying nodes with power or influence, central degree, and central betweeness metrics can be used. Degree centrality refers to the number of links going into ("in-degree") or coming out of ("out-degree") a node in a network (Freeman, 1979). Brokers in the context of SNA are used to describe nodes in the network that connect different subgroups. They may not have the most direct links, but they act as a conduit between departments, locations, and hierarchies. One common way to identify brokers is the betweeness centrality metric. Betweeness centrality for a particular node refers to the number of links that each other node in the network needs to go through that particular node to reach any other node in the network (Freeman, 1979).

SNA USE IN HEALTHCARE

Researchers can apply both a network perspective and the SNA methods to better understand the healthcare setting. In particular, there are two areas in healthcare that can benefit from a network approach: (1) analyzing medical and clinical information flows within and between healthcare organizations, and (2) identifying key "influencers" with respect to adopting medical treatments, medical technologies, and IT, or recommending referrals.

SNA can be used as an analytical tool to study interaction patterns within medical practices. It is critical to understand who the medical staff turn to for help regarding medical treatments, unstructured and complex problems, or decision-making. Great variations in organizational design exist in primary care practices (Tallia et al., 2003). Scott et al. (2005), for example, used SNA to study the decision-making patterns in two different medical practices, and found two vastly different organizational structures: one practice had a hierarchical structure where the practice leader had final decision-rights, while the other practice had a much more collaborative decision-making process where staff had the authority to make decisions on their own. Also, physician-to-physician communication is critical to the success of outpatient referral (Gandhi, Sittig, Franklin, Sussman, Fairchild, & Bates, 2000). This process requires the transfer of relevant clinical information in both directions between the physician and specialist. Furthermore, primary care physicians are often regarded as an obstacle or gatekeeper with respect to referring patients to specialist care (Scherger, 2002). An SNA could determine if any bottlenecks exist between the primary care physician and the specialist in the referral process.

SNA can be very effective at identifying influential individuals in the implementation of medical informatics applications and in the patient referral process. Suppliers of medical equipment face new challenges as new players are having a more active role in the assessment and purchase decision process (IBM E-Health Transformation report, 2002). Also, in terms of assessing the effectiveness of the referral process, one would need to know if there are only a few physicians making most of the referral decisions. For example, Anderson (2005) found that a group of physicians controlled the referral process, and were then enlisted in the planning and implementation of a new IT system.

CASE STUDY: SNA AT A MEDICAL CENTER

An SNA study was conducted at a medical center to analyze the collaboration between primary care physicians and specialist physicians. The center provided comprehensive adult and adolescent primary care. It consisted of several departments and practice areas, including primary care and major specialty areas, such as cardiology and gastroenterology. Most of the staff resided in two buildings located a few hundred feet apart in a campus setting. The research sample consisted of two practice areas: the primary care practice and a large specialist practice. A total of 57 respondents took the survey, including primary care physicians (PP), specialist physicians (SP), office managers (OM), administrative staff (ADM), nurses (N), physician assistants (PA), and lab personnel (LAB). All survey network data was analyzed using UCINET VI (Borgatti, Everett, & Freeman, 2002).

Three bounded networks were used that focused on information sharing, advice regarding complex medical problems, and the referral process. The questions used in the survey include:

- **Information:** *Please indicate the extent to which the people listed below provide you with information you use to accomplish your work.* A “0” response indicated the respondent did not know the person. A “1” (very infrequent) to “6” (very frequent) likert scale was used.
- **Advice:** *Please indicate the extent to which the people listed below provide you with advice regarding unstructured, complex medical problems.* A “1” (very infrequent) to “6” (very frequent) likert scale was used.
- **Referrals:** *Please indicate the extent to which the people listed below provide you with patient referrals.* A “1” (very infrequent) to “6” (very frequent) likert scale was used.

The information, advice, and referral networks were dichotomized at responses greater than “4,” so as to only use strong responses as links in the networks. All 57 respondents answered the Information network question, and only the 35 physicians were given the Advice and Referral network questions.

Ego networks were also examined to get a sense of where physicians obtained critical knowledge and what expertise areas were critical to perform their job. Each physician respondent was asked to:

- *Identify (up to 10) critical sources of information that help you with your job.* These sources can be individuals (inside or outside the medical center) as well as IT systems (such as on-line medical communities).
- *Identify the major (up to 10) expertise areas that are critical for you to perform your job.* For each expertise area, the respondent was asked to associate any of the sources of information to the expertise area.

Table 1 shows the overall network densities, as well as the dominant employees in the information and advice networks. The information network had an overall density of 12.7%. The top central connectors were PP4 and PP8, as 23 people in the network sought out PP4 for information, while 20 respondents relied on

Table 1. Key influencers () indicate in-degree scores

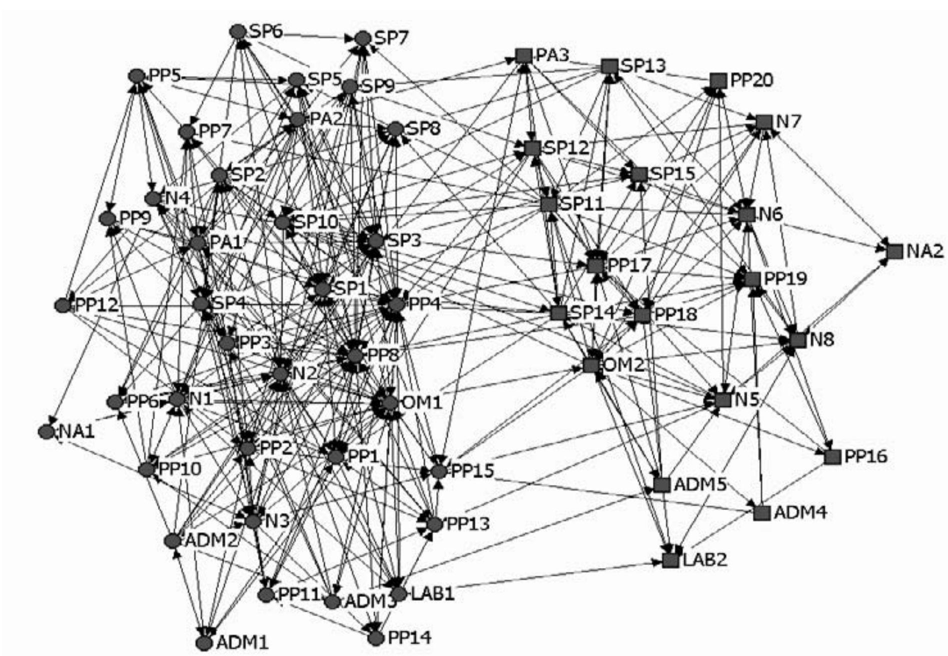
Network	Density	Central Connectors	Brokers
Information	12.7%	PP4 (23) PP8 (20) SP3 (16) OM1 (15)	OM1 OM2 PP4 SP10
Advice	8.5%	SP3 (17) SP12 (13) PP8 (11)	SP12 PP8 SP14 SP3 PP18

PP8 for information. The top brokers in the information network (as measured by betweeness scores) were the two office managers (OM1 and OM2) and PP4. The most surprising find was the fragmentation caused by building location. Figure 1 depicts the information network, and there is a clear divide in information sharing among employees between the two buildings. Of the 670 total links, 592 were within buildings, and only 78 links existed across the two buildings.

Figure 2 depicts the advice network in solving complex medical problems. The arrows in the network point to the source of the advice. The advice network was much less dense (8.5%) than the information network, and was much more concentrated with 43% centralization, compared with 28% for the information network. In other words, many of the respondents relied on three physicians to help solve complex problems: two specialists (SP3 and SP12), and one primary care physician (PP8).

Figure 3 depicts the referral network. The arrows in the network point to the source of the referrals. The source of the referrals was dominated by three primary care physicians: PP4, PP8, and PP17. These three physicians knew most of the specialists and their specific

Figure 1. Information network (the arrows in the network point to the source of work-related information)



Building 1

Building 2

Figure 2. Advice network (the arrows in the network point to the source of advice regarding complex medical problems)

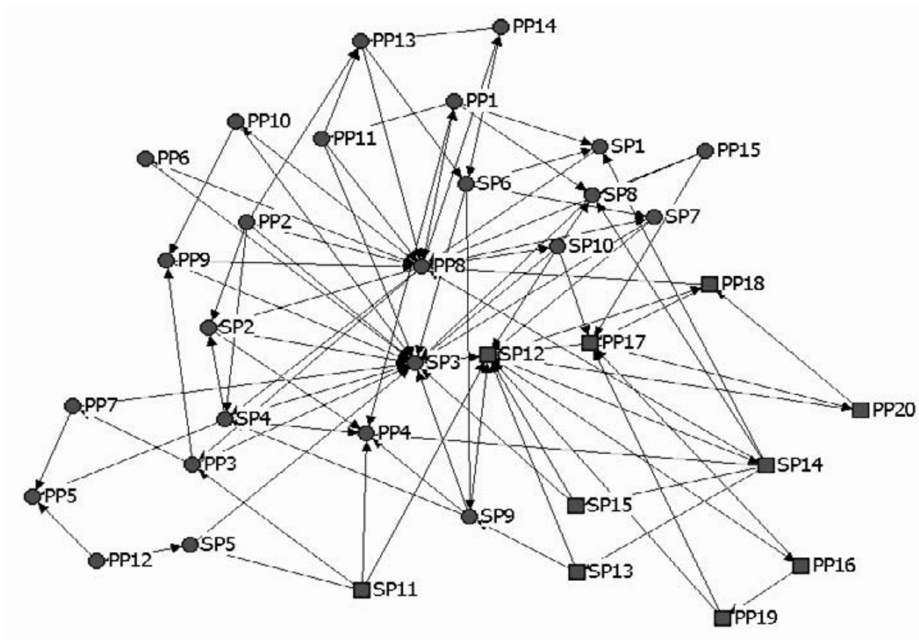


Figure 3. Referral network (the arrows in the network point to the source of the referrals)

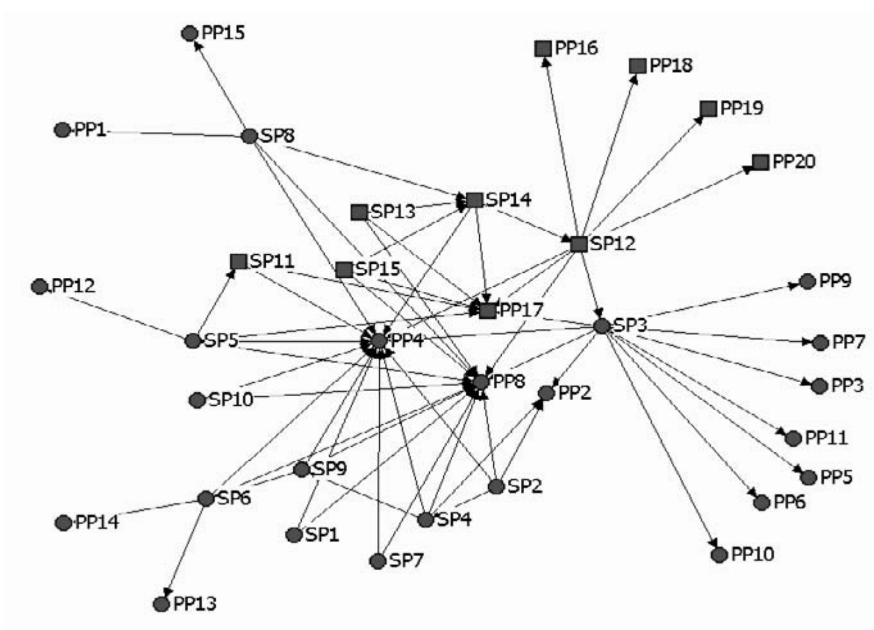


areas of expertise. Specialists indicated all three were effective in both deciding when a referral was needed, as well as providing effective content in the referral letter itself. Other primary care physicians often relied on PP4, PP8, and PP17 for advice regarding referrals. Follow-up interviews clearly revealed other physicians were not as effective in the referral process and most referred patients to only a single specialist with whom they were somewhat familiar and comfortable communicating, but was not necessarily the ideal specialist, based on the patient's condition.

Finally, the ego network yielded interesting findings, especially when comparing the personal network of the well-connected physicians with those that were on the periphery. Several of the well-connected physicians had listed many diverse sources of information, and for each of their expertise needs, they had several knowledge sources from which to choose (including physicians from other hospitals). Meanwhile, many of the peripheral physicians had personal networks that resembled primary care physician PP12's personal network. PP12 had been with the medical center for just about one year. She listed the following expertise areas as critical to her job:

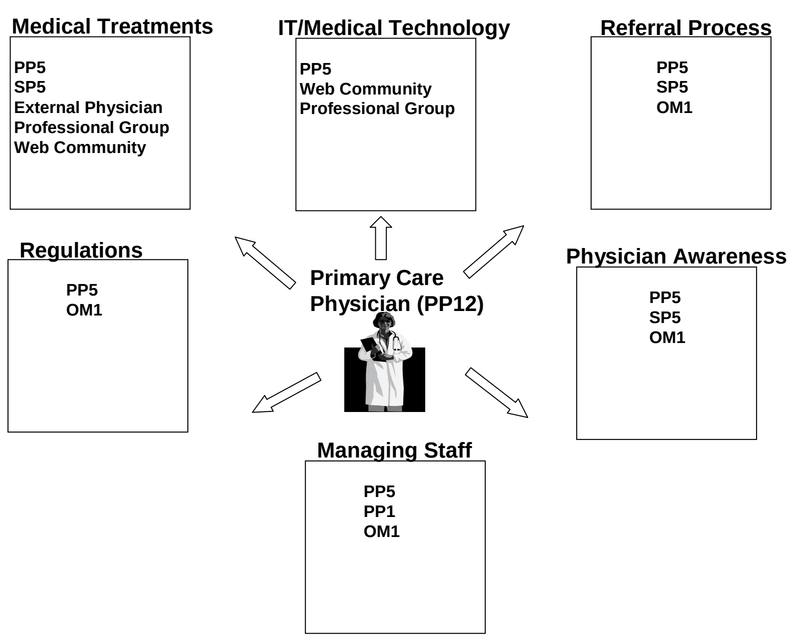
- Latest medical treatment knowledge
- IT systems and medical technology knowledge
- Referral process understanding
- Regulations/legal issues knowledge
- Awareness of other physicians' expertise areas
- Managing staff

As seen in Figure 4, her personal network was very limited and insular, as she relied too heavily on PP5, SP5, and OM1 to get her work done. She indicated in interviews that she was frustrated with doing too much "busy work," and did not feel well-connected with other physicians at the center. She admitted she was unaware of the specific areas of expertise of many of the physicians, so as a result, she relied heavily on only a few people at the center.

From these SNA findings, the office managers developed some interventions to improve collaboration and information sharing among the staff:

- It was clear from the SNA study that PP4, PP8, SP3, and SP12 were very influential at the medical center, since each of them held very central positions in the information, advice, and referral networks. All four of these physicians had over 10 years of tenure at the center. They all had built relationships with doctors throughout the industry, and they were well represented at professional conferences, and were members of professional

Figure 4. Physician PP12's personal network



groups and communities. However, they indicated that one source of frustration was they thought too many physicians and nurses came to them for routine questions or medical information, which could easily be handled by other staff members. Therefore, one action item was to free-up time for these physicians by delegating decision-rights for certain procedures and tasks to other physicians and nurses. In this way, they could focus on the complex medical problems.

- Another way to leverage these four influencers (PP4, PP8, SP3, and SP12) was to help them develop staff, especially new doctors coming into the center. Periodic meetings (e.g., once a month) could be scheduled between a newcomer and an appointed influencer physician. The meetings could be used as a forum for the newcomer physicians to: ask any questions about medical treatments and procedures; help build their awareness of the other doctors and their expertise areas; better understand the referral process, specifically which specialists should be contacted for what procedures and how to best communicate with certain specialists; help build their personal network by having experienced physicians introduce them to their own personal contacts and professional groups/communities; and create a trusting and sharing community with other doctors at the center.
- The office managers also realized they needed to leverage the influencer physicians in terms of planning and implementing their IT plans for the center. The goal was to have an interactive Web site and intranet for the center. The center staff would use the intranet to send emails, to do prescription refills, to schedule patient appointments, to access medical databases and communities, and to create expertise profiles for each of the staff members. The hope was that physicians could also use the intranet to develop their own content and to share their own experiences regarding the latest medical technologies and treatments. The office managers also wanted to make the center a "paperless" office by digitizing clinical records and making all patient information available either through the intranet or handheld computers. But, to achieve this vision, the office managers now realized they needed to get the influencer physicians to be a strong proponent of their IT plans, so they were invited to be part of this IT steering committee. This would also be a good opportunity to get some of the new doctors (who were more familiar with using IT) to be part of the IT committee.
- The referral network clearly showed the need for better communication between the primary care physicians and specialists, as that network was dominated by only three of the 20 primary care physicians. Part of the problem stemmed from a lack of awareness of what each of the specialists did, and the other part of the challenge was an understanding of what clinical information was expected to be transferred between the primary care and specialist physician. The hope was that IT could aid the referral process. Having an expertise profile for each of the physicians on the intranet could help build awareness. Specialists could also post information about their expertise areas, including information regarding a disease, its treatment, and caring for the patient. IT could also help automate the referral process by generating referral letters that could be sent via email.
- Finally, one of the most surprising findings was how much fragmentation there existed in the information network as a result of the staff's building location. One idea was to rotate work assignments across the two buildings, especially for the primary care physicians and their staff. For example, primary care physicians (especially newcomers) could work certain days of the week in each of the two buildings. The physical proximity would help the physicians build awareness and relationships with other doctors, including specialists.

FUTURE TRENDS

SNA continues to be a popular research methodology in understanding information flows among people in knowledge-intensive organizations. Going forward, there are many opportunities to incorporate a network perspective, and to leverage SNA in the healthcare setting. One specific area is to understand the information flows between healthcare organizations, such as hospitals, medical centers, pharmaceutical companies, and insurers. As the healthcare industry continues to evolve and change to be more efficient and effective in delivering patient care, both medical and clinical information need to be more transparent and accessible across organizations. SNA could be an effective means to map collaboration and information flows at an industry-level.

Another area that could benefit from incorporating a network perspective is to understand how physicians are using online medical communities to gain access to medical knowledge. Physicians today are able to tap into a larger network of physicians through blogs, wikis, and discussion threads on specific medical topics. These communities can exist both within and outside organizational affiliations. An ego network could be used to analyze a physician's personal network in terms of using electronic medical communities as a source of their medical knowledge. In this way, popular or effective communities could be shared with other physicians. Or, a network map could be created that identifies physicians as nodes, and comments or responses to physicians in these communities as links between physicians. In this way, central physicians could be identified based on their frequency of postings, and to which physicians they are responding to. The effectiveness of the postings (based on a user rating system) could also be incorporated as part of the network map.

CONCLUSION

This article has provided a description on how a network perspective, and in particular, a social network analysis (SNA) methodology could be applied in a healthcare setting. As illustrated in the case study, SNA allows the researcher to identify areas of fragmentation in the network as well as central people in the network. Based on this analysis, interventions can then be developed to improve the network structure and network roles, ultimately resulting in more effective collaboration. Going forward, incorporating a network perspective to understand the healthcare setting is important as collaboration among different stakeholders and sharing of medical and clinical knowledge remains a critical strategy.

KEY TERMS

Broker: In the context of SNA, brokers are used to describe nodes in the network that connect different subgroups.

Degree Centrality: Refers to the number of links going into ("in-degree") or coming out of ("out-degree") a node in a network.

Information Network: Information networks map who people turn to for information regarding work-related activities.

Network Fragmentation: In the context of SNA, network fragmentation occurs where silos exist in the network and information is not being transferred across functional, hierarchical, cultural, or geographic boundaries.

Social Network: The people-to-people relationships in organizations where knowledge work actually gets performed. The social network may be in complete contradiction to the information flows expected, based on the organizational chart of formal roles or titles.

Social Network Analysis: A research methodology to analyze networks between people, groups, organizations, and systems within and across organizations.

Tacit Knowledge: Knowledge that is difficult to codify, and often resides in the key experts of the organization.

Applying the Quality Loss Function in Healthcare

Elizabeth Cudney
Missouri University of Science and Technology, USA

Bonnie Paris
University of Wisconsin-Madison, USA

INTRODUCTION

Using the quadratic loss function is one way to quantify a fundamental value in the provision of health care service: we must provide the best care and best service to every patient, every time. Sole reliance on specification limits leads to a focus on "acceptable" performance rather than "ideal" performance. This chapter presents the application of the quadratic loss function to quantify improvement opportunities in the health care industry.

The quadratic loss function (QLF), also known as the quality loss function, is a metric developed by Genichi Taguchi, which focuses on achieving the target value rather than focusing on performance within the wider specification limits. Using the quadratic loss function allows the Six Sigma team to quantify improvement opportunities in monetary terms, the language of upper management. The quadratic loss function translates variability into economic terms by calculating the relationship between performance and financial outcome. The general quadratic loss function is shown in Equation 1.

(1)

*Loss at any point (L) = (monetary constant) * (average – target)*^{2}

The quadratic loss function is used to determine the average loss per product or encounter, and it enables Six Sigma teams to focus on performance relative to target and avoid the goal-post mentality. The loss function approximates the long-term loss from performance failures and encourages continuous improvement. The quadratic loss function is helpful both as a philosophical approach and as a quantitative method. Figure 1 illustrates the quadratic loss function.

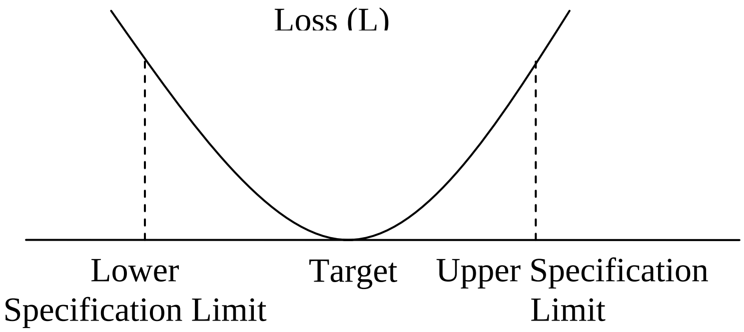
BACKGROUND

Many attempts have been made to make a business case for quality by examining cost, but a thorough review of literature shows no evidence of a sustained cost of quality system implementation in health care. Several researchers have commented on the paucity of information on this topic (Palladoro, 1997; Bozanich White, 1999), and in 2003, a collaborative, including Donald Berwick, M.D., president and CEO of the Institute for Healthcare Improvement, "sought to erase the notion that quality doesn't pay by setting up five case studies that would establish a 'business case for quality.'" All five failed to do so (Robeznieks, 2003).

One reason for this failure may be the fragmented information sources from which health care quality data are derived. Campanella (1990) cautions that "a real danger lies in finding and collecting only a small portion of the costs involved and having it represented as the total." This has likely been the case with previous attempts to cost-justify preventive measures. Getting the resources to collect the right data requires leadership commitment and technical expertise, especially in situations where data must be harvested from several sources and brought together for analysis. When performing a cost of quality analysis, it is preferable to use an activity-based cost (ABC) approach to gathering data because the ABC costs are analyzed in terms of work activities (Cokins, 1997), but hospital accounting is a tangled web of allocations developed to support cost reimbursement and was not designed to assist managers in decision-making (Bozanich White, 1999).

Many models consider the costs and benefits of providing care that is given, but do not address the cost associated with failure to provide care. There is a great deal of work remaining in the comprehensive application and adoption of cost of quality techniques to health care, and there is some indication that the current state

Figure 1. Quadratic loss function



of quality cost thinking in health care is similar to that of industry 60 years ago. The traditional view holds that high quality care costs more because it was seen as doing everything possible for the patient, whether or not the additional tests or extended hospital stays improved the clinical outcome (Burda, 1992).

In order to discuss the cost of quality in measurable terms, one must first have agreement on what is meant by quality. Safety is another aspect of quality, where patient safety is the avoidance of accidental harm to the patient (Kohn, Corrigan, & Donaldson, 2000). Some define safety more broadly to include avoidance of all harm to the patient. David Aquilina (1992) developed a framework for understanding health care quality that looks at health care quality as multidimensional, overlapping concepts. Industry usually defines quality in terms of customer requirements, but this can prove difficult in health care due to the complexity of the customer relationship and the complexity of the service (Aquilina, 1992).

The relationship between health care quality, however defined, is not easily related to the health care industry's bottom line. As in other industries, cost, revenue, and quality are codependent. However, in the current health care environment, even the link between throughput and revenue is indirect. There is a disconnect between the provision of service and payment of service due to a myriad of factors, such as government intervention and ability to pay vs. professional obligation to provide care.

The loss function makes the point that if performance is off-target in any way, there is a loss to society as a result. The loss may be experienced by the provider, the consumer, the environment, and so forth, but there is a cost associated with imperfection. At the point where total cost is minimized, quality is highest. In other words, the highest quality care is also the care with the lowest overall cost, when all costs are accounted for.

Although there are different opinions as to how quality and cost of quality relate to achieve an optimal level, there is agreement that money spent on prevention yields the highest return compared to any other quality cost component. This may be especially true in health care, where the prevention of an error may be possible, but once made, there is no opportunity to correct the error. An example of this is wrong site surgery, where a surgical procedure may be performed on the wrong limb. As a corrective action, the "right" surgery may be done, but the "wrong" surgery cannot be undone. Unlike other service industries, this "extra" service can cause permanent, irreversible harm to the patient (customer).

Empirical measurement of the care provided in terms of improved patient outcomes on a case-by-case basis is a labor-intensive but accepted method of evaluating the effectiveness of care. Controlling for measures such as type of illness, severity of illness, and other clinical factors on a case-by-case basis and evaluating the cost/risk and benefit of providing the care in each circumstance allows clinicians to develop evidence-based practice patterns. Even when evidence-based medicine is used and clinical outcomes are measured, these pieces of information do not add up to a picture of systemwide performance.

Evidence-based medicine is one standard; "care maps" for certain patient populations developed by interdisciplinary teams, specifications by government, health plans, and the like are growing in number. Standards in health care are not static, and the bar is always rising as medical knowledge increases. However, it is not always inappropriate to violate one standard in favor of another, so long as the standard is violated in the best interest of the patient (Laffel & Blumenthal, 1992).

An "ideal" cost of quality for health care could be estimated based on the principle that where total cost to society as a whole is the least, quality is the highest. Access to care, or the ability to obtain health care services, may have a significant impact on the "hidden" costs of "poor" quality health care. Likewise, individual participation in taking preventative measures, such as healthy diet and exercise, may also contribute significantly to overall demand and cost of health care. From a societal standpoint, these are individuals who may have prevented the onset of or complications of disease with earlier intervention but have instead been "reworked" through the health care system.

QUALITY LOSS FUNCTION

Genichi Taguchi, a Japanese engineer, developed the quality loss function based on the economic consequences of not meeting target specifications. Taguchi defined quality as the "[avoidance of] loss a product causes to society after being shipped, other than any losses caused by its intrinsic functions" (Evans, 1999). Losses to society encompass costs incurred by the manufacturer, the customer, and anyone affected by product deficiencies.

The quality loss function unifies quality and cost to drive on-target engineering. It also relates economic and engineering terms in one model. The function enables optimization of costs through the production and use of a product (Fowlkes & Creveling, 1995).

The loss to society includes costs incurred due to a product or service not meeting customer expectations, not meeting performance characteristics, and having harmful side-effects. The quality loss function associates a dollar value to the current state of quality for a product or process. The quality loss function approximates losses due to scrap, rework, poor performance, lack of customer satisfaction, and so forth. This dollar amount can be used to identify areas for improvement and evaluate improvement efforts.

Taguchi relates the monetary loss to quantifiable product or service characteristics. This translates the language of an engineer into management terms. The quality loss function focuses on target values rather than specifications for process output. When nominal specifications are achieved, the products are consistent, and there is no loss to society (Breyfogle, 2003). Any deviation from target incurs a loss to society. The loss increases as the measured responses move further away from the target value. The measured loss L(y) for a single product is estimated as shown in Equation 2.

$$L(y) = k(y - T)^2 \qquad (2)$$

where,

- L(y) is the loss in dollars,
- y is the measured response,
- T is the target value of the product's response, and
- k is the quality loss coefficient.

The quality loss coefficient, k, is determined using customer tolerance and the economic consequence. The economic consequence, A_0, is the cost to replace or repair the product. The associated costs include losses incurred by the manufacturer, customer, or third party. The customer tolerance is the point at which the product reaches unacceptable performance.

$$k = \frac{A_0}{\Delta_0^2} \qquad (3)$$

where,

- A_0 is the economic consequence of failure, and
- Δ_0 is the functional limits or customer tolerance for the measured response.

The quality loss function can also be used to determine the average loss per product. The expected loss, E(L), is used to depict the average loss. To reduce the expected loss, the variability and deviation from target must be reduced (Kiemele, 1999). Equation 4 shows the expected loss.

$$E(L) = k\left(\sigma_y^2 + (\bar{y} - T)^2\right) \qquad (4)$$

where,

- σ_y^2 is the variation,
- $\bar{y}$ is the response average,
- T is the target value, and
- k is the quality loss coefficient.

FUTURE TRENDS

Six Sigma is a customer-focused continuous improvement strategy and discipline that minimizes defects and variation toward an achievement of 3.4 defects per million opportunities. However, this target of 3.4 defects per million may create a "goalpost mentality" that everything within specification limits is equally good. In this traditional thinking, quality is achieved through conforming to specifications. However, the reality is that products just within the specification limits are not just as good as products that are directly on target. The quality loss function also addresses the concern that a defect rate of 3.4 per million opportunities may not be an appropriate goal for all processes, such as compliance with the medical library book check-out procedure.

Specifications have no value for the customer. The customer expects performance and does not care about specifications. Specifications use the old quality mentality to create "goalposts" for product acceptance for the supplier. Specification limits create a natural tendency to create products inside the limits and assume that all products inside the limits are equal. Specifications do not address the associated loss for not meeting the target.

In a hypercompetitive market with highly educated and discerning customers, companies cannot afford a uniform distribution of products. By only focusing on zero defects, companies will also go out of business because they are not using metrics that correlate to customer satisfaction.

These concepts have been used extensively in manufacturing, but they also apply to health care processes. For example, a focus study finds that patients are willing to wait 15 minutes to be seen by the physician for routine appointments. One approach is to look at the percentage of wait times of 15 minutes or less and consider these experiences to meet the customer expectation. However, a wait time of 14.9 minutes is considered as acceptable as a wait time of 2 minutes with this traditional approach.

Consider a hypothetical example of a surgical procedure with a typical hospital stay of two to five days with an average length of stay of 2.5 days. The target length of stay is 3 days because patients staying less than 3 days have an increased readmission rate, and patients staying longer than 3 days had complications and a prolonged recovery period.

A simulated data set containing 30 observations was developed to illustrate the differences between the traditional approach and the quality loss function approach. Using the traditional approach, the lower specification limit and upper specification limit would be two and five days, and 20% of the observations were considered outside of the target with 10% below the lower specification limit and 10% above the specification limit. This is shown in the Figure 3.

However, using the quality loss function approach, it is determined that only 16.7% of the observations are on target with a three-day length of stay. Using the quality loss approach, we are not meeting target more than 80% of the time.

Traditional thinking looks at stays less than three days as a cost savings, but due to increased patient

Figure 2. Perception of quality through meeting specifications

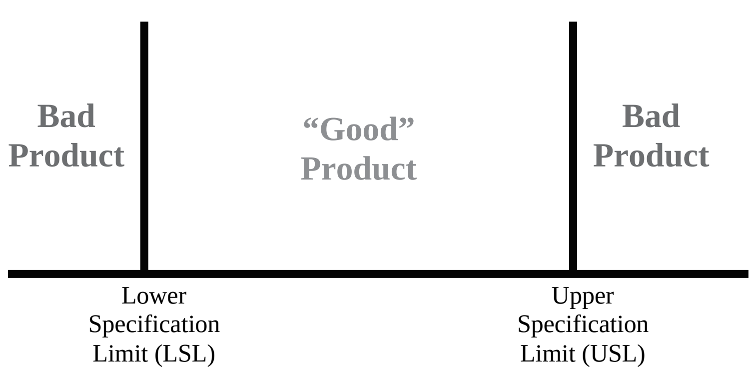


Figure 3. Traditional approach using CpK

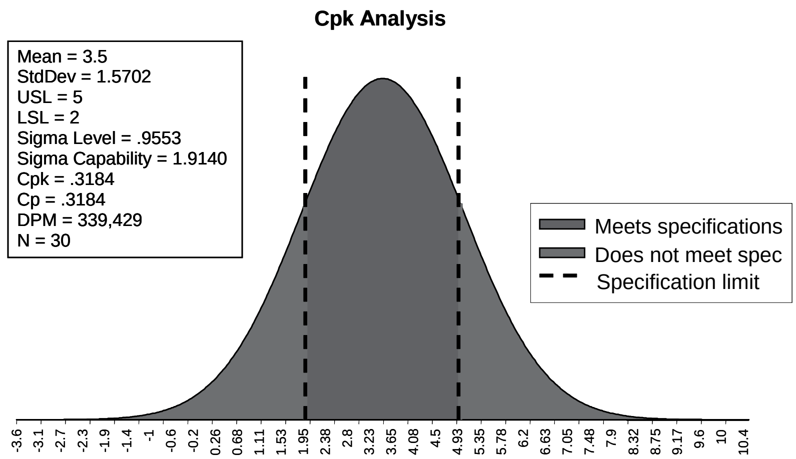

readmissions, this is not the case. There is a cost associated with early release, and this becomes apparent when we expand our focus from the patient encounter to the episode of care and case management of the patient's health, whether in or out of the hospital.

Suppose we calculate the monetary constant for the quadratic loss function as \$212.50, based on the average loss per patient and the patient's tolerance for a length of stay that is too short or too long. The average length of stay is known to be 2.5 days with a standard deviation of 1.57 days, and the target is three days. The average loss for the sample set can be found using Equation 4.

$$E(L) = k\left(\sigma_y^2 + (\bar{y} - T)^2\right)$$

E(L) = \$212.50 [(1.57*days*)2 + (2.5*days* - 3*days*)2] = \$576.92

We can calculate the total loss by multiplying the average loss by the case volume. If there are 350 procedures per year, then the total loss is \$201,922 per year.

Currently, use of the quality loss function is restricted to situations where quantitative information about product or service performance is available. To use the quality loss functions in situations where only qualitative data are available, a numeric measure of effectiveness or ranking can be used.

CONCLUSION

Quality is based on achieving a target value set by the customer, and any time there is deviation from the target, there is a loss. This loss can take many forms, including customer dissatisfaction, poor or unreliable performance, and rework, which are equated with monetary loss. Using the quality loss function can assist in quantifying and understanding this loss, in support of continuous improvement.

There is a great deal of work remaining in the comprehensive application and adoption of the quality loss function health care. However, the work will provide valuable information to decision makers and therefore assist in improving the cost and quality of care provided.

KEY TERMS

Fragmented Information Sources: Separate sources of data and information that require significant effort and skill to combine in a meaningful way.

Goalpost Mentality: The thought that performance between targets is always and equally acceptable.

Health Care Quality: Attributes of output of the health care process, including clinical outcomes, access to care, satisfaction with care, and cost of care.

Hidden Costs: Nonobvious costs of providing or failing to provide care, including the value of lost patient and provider time.

Tolerance: An acceptable level of imperfection in service received as defined by the customer.

Appreciation Level and Organizational Performance

Murako Saito
Waseda University, Japan

INTRODUCTION

Corporate environment changing with the advent of information technology and with diversified organization has been inquired to redesign to transform into an intelligent and innovative organization so that corporate vision and organizational goals in the subsystem of corporate are provided for being shared by multidisciplinary workers and other stakeholders, and corporate social responsibility can also be shared by all the participants. System matching between developing levels in technological systems and also cognitive fit in the levels of individual, team/group, and organization are required not only to maintain good balance, but also to enhance operational and organizational resilience in making appropriate shifts to adapt to a changing social environment. To make the shift successfully, cognitive fit or value alignment between individuals and collectives in the environment of advanced technologies is to be studied, so that corporate social responsibility or corporate prosperity is shared by all the stakeholders.

Organizational performance and the performances in the level of heterogeneous team/group of an organizational subunit will be improved by aligning cognitive incongruence or misfit between leaders and followers, or among different disciplinary members. Established discipline guides to manage technological procedures but does not appropriately lead to align value consciousness or appreciation among heterogeneous members. Methodology should be developed in enhancing collaborative work and in improving operational flexibility and organizational resilience.

BACKGROUND

Organizational effectiveness is assessed by the degree of appreciation on organizational context as well as by the degree of job skill and disciplinary knowledge related. The relationship of job skill with task performance has been studied, but there are few studies on contextual performance and very few on human performance, which is influenced by the practical process in the workplace or by the recursive learning process in organizational environment. Human performance emerges in the recursive information processing of organizational learning in which cognition and action are inseparably coupled with each other. Hence, whole system approaches or holistic approaches to identify what cognition-action coupling process of organizational learning necessitates for the evaluation of a human performance by treating a human as a social being. The theories on the continuous or recursive process of organizational learning in the field we have referred to in our surveys are appreciation system theory (Vickers, 1965, 1983), soft systems methodology (Checkland, 1993; Checkland & Holwell, 1998; Checkland & Scholes, 1999), knowledge creation process (Nonaka & Konno, 1998; Nonaka & Nishigihi, 2001)The author found later on that the essence of Vickers' theory was quite similar to the "pure experience" that emerged in practical field and that was the essence of Nishida's (1911) theory. Appreciation processes in the field, in addition to the already mentioned theories such as seven stages of internal and external thinking process in soft system methodology (Checkland, 1993), four stages of socialization, externalization, combination, and internalization in knowledge creation process (Nonaka, & Kanno, 1998), and many other processes, were reported by researchers in the past (Deming, 1982; Gomez, 1999; Kaplan & Norton, 2006; Maruyama, 1992, 1994; Mingers & Gill, 1997; Ulrich & Probst, 1991; Probst & Gomez, 1992). In this chapter, the degree of appreciation rather than the recursive process of appreciation on working conditions and organizational context is focused to assess human performance in the level of individuals and collectives.

MAIN FOCUS OF THE CHAPTER

The main focus of this chapter is on the relation of the degree of appreciation with organizational performance of the participants in a health care organization. Cognitive or value congruence among individuals and collectives leads to increased organizational effectiveness, while value incongruence leads to increased withdrawal behaviors, such as absenteeism and turnover. In this chapter, some empirical evidences provided are to positively identify significant effects of appreciation degree on organizational performance and to compare multiple causal relationships between the higher and the lower groups of appreciation.

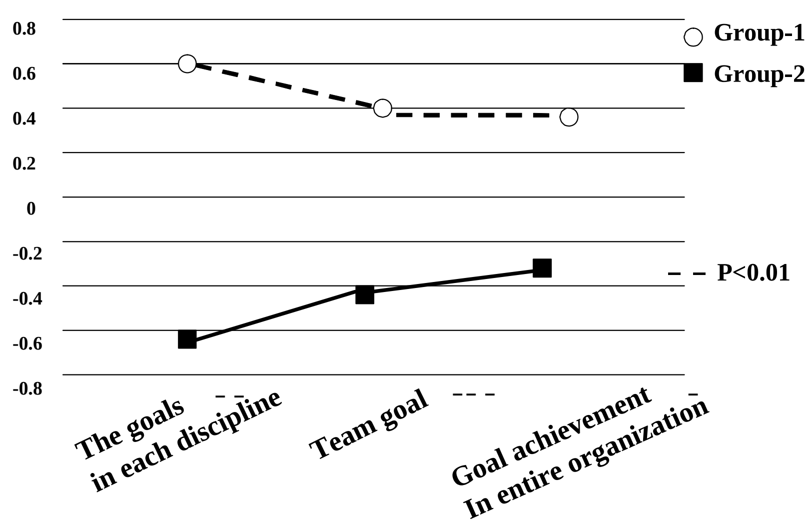
A total of 175 nurses engaging in a hospital, their average age and SD 32.1 ± 9.1, were investigated for the purpose of identifying the relation between organizational performance and individual appreciation of organizational environment. All the subjects were asked to respond to the self-administered questionnaires on work environment, learning type, fairness, and job satisfaction prepared for the survey using a four-point Likert-type scale. The most important indicators in evaluating performance of hospital nurses are performance reliability and team coherence or reciprocity. Performance reliability was measured by the common performance conditions (CPCs) developed by Hollnagel (1993, 1998). Human error is predicted by using performance reliability measured by nine items of work environmental conditions, which are called the CPCs, asking how do you cognize each working condition in operational, strategic, and normative levels; namely, asking how do you cognize the (1) adequacy of an organization, (2) working conditions, (3) adequacy of Man-Machine Interface and operational support, (4) availability of procedures/plans, (5) number of simultaneous goals, (6) available time, (7) time of day/circadian rhythm, (8) adequacy of training and preparation, and (9) crew collaboration quality, which are developed by Hollnagel (1998). Subjects are requested to select one of four answers: very efficient, efficient, inefficient, deficient.

Team coherence was measured by using the team-member exchange construct (TMX) developed by Seers (1989) and Seers, Petty, and Cashman (1995), which was designed to address an employee's exchange relationship to the peer group as a team. The TMX assesses the reciprocity among team members with respect to the members' contribution of ideas, feedback, and assistance to other members, made up of 34 questionnaire items with a five-point scale of -2, -1, 0, +1, and +2.

CLASSIFICATION OF APPRECIATION LEVEL

Subjects consisting of 175 hospital nurses were classified into two groups: higher and lower groups in the appreciation level of disciplinary goals in individual goals, team goals, and goal achievements of the organization. As shown in Figure 1, significant differences between the two groups was observed in terms of the goals in the discipline, team goal, and goal achievement in the organization (Saito, Murakami, Nishiguchi & Seki, 2006). In the higher group, Group 1, the

Figure 1. Comparison of appreciation on disciplinary goal, team goals and goal achievement of organization



degree of appreciation in achieving disciplinary goals appeared slightly higher than the appreciative degrees in team goals and organizational goals, while in the lower group, the degree of disciplinary goals appeared slightly lower than the degree of appreciation in team goals and organizational goals. These results suggest that development of individual disciplinary knowledge and skills seems important for professional workers like nurses in the higher level of appreciation, while nurses in the lower level of appreciation seem uninterested and nonchalant in individual development as well as achievement of team and organizational goals.

COMPARISON OF TEAM COHERENCE, AND PERFORMANCE RELIABILITY BETWEEN TWO GROUPS

Organizational performances such as team coherence or team reciprocity and performance reliability as two important indicators assessing organizational performance were compared between two groups clustered with appreciation on goals.

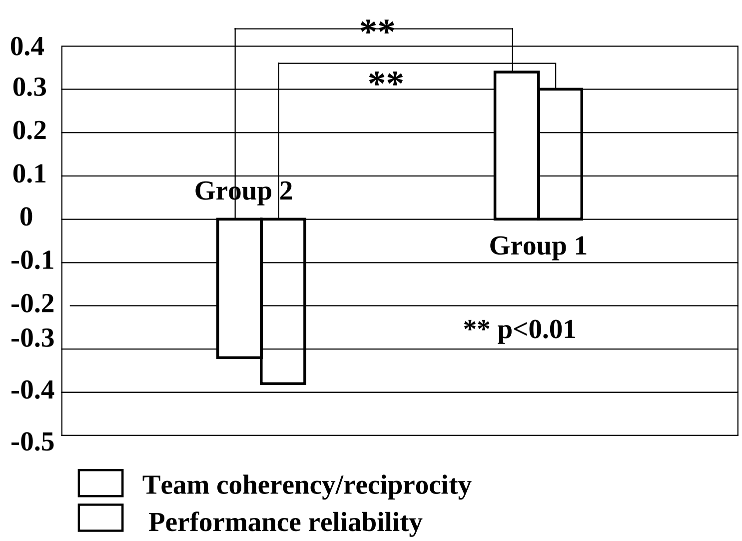
As shown in Figure 2, organizational performances represented by team coherence and performance reliability significantly ($P<0.01$) differed between two groups of the higher and the lower groups in appreciation (i.e., Group 1 and Group 2). Nurses in Group 1 are expected to provide care in security and safety more than the ones in Group 2. Incidence experience and accidental occurrence caused by human error is predicted by performance reliability according to the CREAM (Cognitive Reliability and Error Analysis Method) (Hollnagel, 1998). Average weighing factors of error occurrence for four control modes, such as scrambled, opportunistic, tactical, and strategic, are 2.3E+01, 7.5E+00, 1.9E+00, and 9.4E-01.

Nurses in Group 1 who marked higher factor loadings in team reciprocity are able to maintain better interpersonal relations among team members than the ones in Group 2. Group 1 might be engaging in a recursive process of organizational learning for keeping team coherence and performance reliability higher. Individual and organizational performance in Group 1 might be leveraged by communication through organizational learning and might be more effective and cooperative than in Group 2.

COMPARISON OF ORGANIZATIONAL PERFORMANCES, FAIRNESS AND JOB SATISFACTION

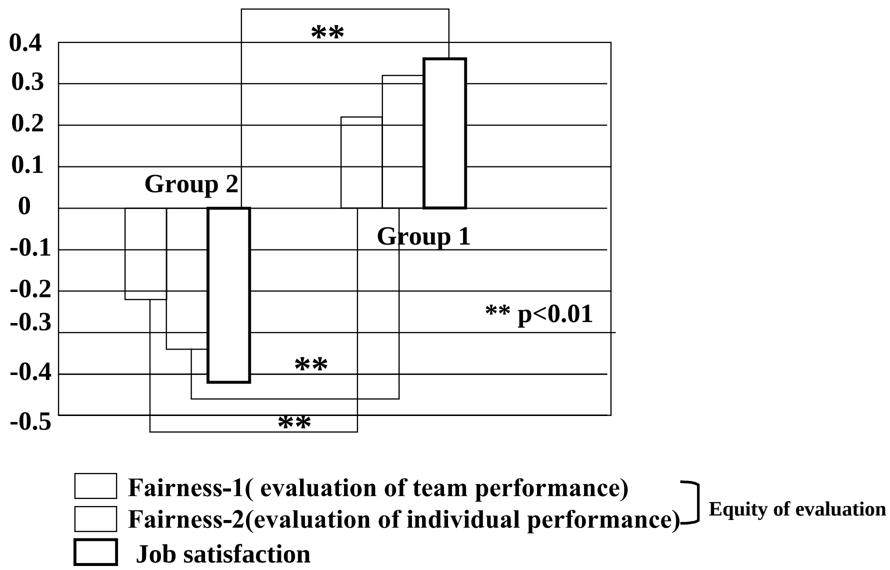
Organizational performances represented by fairness-1 and -2, and job satisfaction significantly ($P<0.01$) differed between two groups of the higher and the lower

Figure 2. Comparison of organizational performance of team coherency and performance reliability between higher and the lower in appreciation of organizational goal



A

Figure 3. Comparison of organizational performance of fairness -1 and -2 and job satisfaction between the higher and the lower in appreciation of organizational goal



degrees in appreciation of team care goals and organizational goals, as shown in Figure 3. Fairness-1 signifies how subjects feel about team performance evaluation, and fairness-2 means how subjects feel about individual effort-demand fairness (Janssen, 2001; Siegrist, 1996). Job satisfaction represented by satisfaction about the work allotted, meaning of work, and work pride significantly differed between the two groups, the higher and the lower degree of appreciation. The result suggests that the degree of appreciation on organizational context plays a significant role in improving the feeling of fairness and job satisfaction.

COMPARISON OF MULTIPLE CAUSAL RELATIONSHIP AMONG WORK DEMAND, ORGANIZATIONAL ENVIRONMENT, AND ORGANIZATIONAL PERFORMANCE

Causal relationship in the lower group was constructed by the factors representing physical and extrinsic factors, such as work time and frequency of patient visit for caring, while causal relationship in the higher group was constructed by the factors representing intrinsic factors, such as work discretion, mutual understanding, and work cooperation. As shown in Figure 4, the meanings of structural variables on work demands, organizational environment, and fairness evaluation were different between the two groups. As to fairness evaluation, work cooperation representing work demand and team work atmosphere representing organizational environment in Group 1 of higher appreciation linked to criterion variable of fairness in the evaluation of individual effort, while in Group 2 of lower appreciation, working time, and time for patient care representing work demand and organizational environment linked to criterion variable of overall evaluation by the hospital. These linkages were testified by good fit index (GFI=0.968, AGFI=0.903, RMR=0.024 in Group 1; GFI=0.931, AGFI=0.825, RMR=0.018 in Group 2). Direction and strength in causation among three variables such as work demand, organizational environment, and fairness as a criterion variable and the meaning of the structural variables, were different between the two groups.

As shown in Figure 5, in the causal linkages among work demand, organizational environment, and job satisfaction as a criterion variable, the meanings of each structural variable and criterion variable were different between the two groups, work cooperation representing work demand, understanding among staff representing organizational environment and pride for job representing job satisfaction in Group 1, while in Group 2, the meanings of all the structural variables

Figure 4. Casual relationship among environment, work demand, and fairness of evaluation in Group 1 and Group 2, the higher and the lower groups in work appreciation

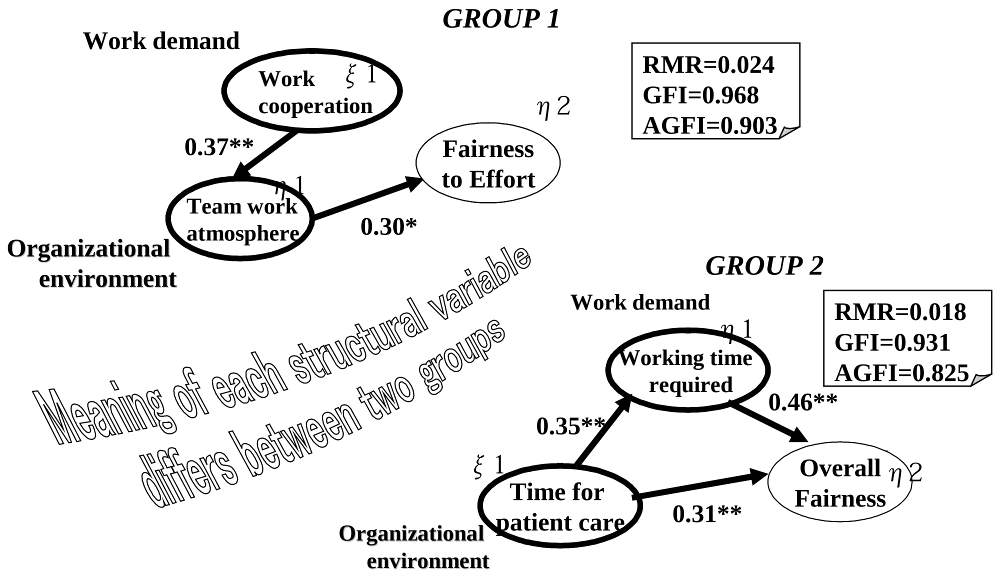


Figure 5. Casual relationship among environment, work demand, and job satisfaction in Group 1 and Group 2, the higher and the lower groups in work appreciation

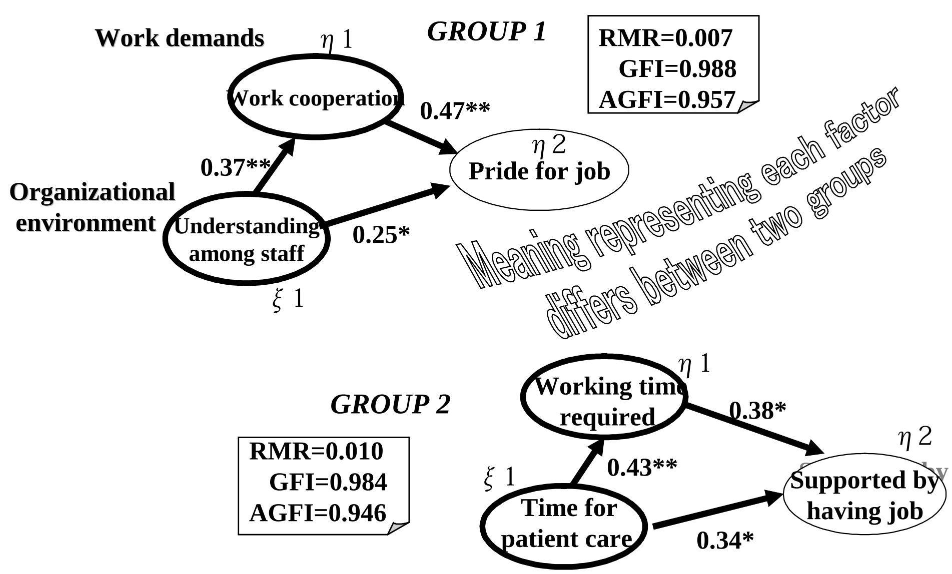

were physical, such as working time representing work demand, time required for patient care representing organizational environment, and satisfaction by having job. Both models of causation were testified by good ft index (GFI=0.988, AGFI=0.957, RMR=0.007 in Group 1; GFI=0.984, AGFI=0.946, RMR=0.010 in Group 2).

FUTURE TRENDS

Limitation of this chapter is classification of appreciation on organizational context in terms of goals in each discipline, team goals, and organizational goals. Organizational contextual factors other than the factors adopted in this chapter exist in the workplace. Typology and classification should be tried by including management strategies and their implementation processes, and also members' characteristics (i.e., knowledge, skills, attitudes, and others (the KSAOs). Appreciation in the workplace may be different by the degree of cognitive alignment between individuals and collectives, and also alignment of cognition and action on the individual level. Individual cognition on job responsibility and reciprocity among superiors, peers, and other stakeholders give a critical effect on job performance. Individual job competences might play crucial roles as moderators or mediators between organizational constraints as antecedents and consequences of organizational performances. Job competence of emotional regulation in the workplace is one of the influential factors as far as we have surveyed. Future studies are expected to identify interactive relations between individual and collective competences. Integrated value management approaches, whole system approaches, or holistic approaches are left for future study.

CONCLUSION

1. The degree of appreciation in an organizational context gave significant effects on team coherence, performance reliability, fairness perception, and job satisfaction. The higher degree of appreciation on organizational environment played a significant role in keeping a higher perception of team coherence/team reciprocity, performance reliability, fairness both in individual and team performance, and job satisfaction.
2. Multiple causation between the higher and lower groups of appreciation differed in the intensity and direction of causation among three variables of work demand, organizational environment, and fairness perception or job satisfaction as shown in Figure 4 and Figure 5. In the higher group of appreciation, work cooperation and understanding among staff members led to admitting equity of evaluation and keeping pride for job, while in the lower group of appreciation, working time and time required for patient care are strongly related to overall or vague feeling of fairness and acceptance feeling as a job. The result suggests that having higher appreciation signifies substantiality a cognitive world, while keeping lower appreciation signifies just following daily work without any development.

KEY TERMS

Appreciation: Value consciousness or understanding in organizational environments in which subjects engage. The degree of appreciation in organizational contexts has an effect on individual and organizational performances. In this chapter, appreciation was measured by clustering subjects into two groups, the higher and lower groups, in terms of the degree of appreciation on individual disciplinary goals, team goals, and organizational goals.

Fairness: Fairness in this chapter is defined in two aspects: fairness-1 signifies how subjects feel about team performance evaluation; and fairness-2 means how subjects feel about individual effort-demand fairness (Janssen, 2001; Siegrist, 1996) by preparing 14 questionnaire items with a four-point scale: totally disagree to totally agree.

Job Satisfaction: Measured by preparing six questionnaire items representing satisfactions about the work allotted, meaning of work, and work pride with a four-point scale: strongly disagree to strongly agree.

Performance Reliability: In this chapter, concept and methodology of performance reliability developed by Hollnagel (1998) were applied in predicting human error during work, measured by using nine common performance conditions (the CPCs) with a four-point scale: very efficient, efficient, inefficient, and deficient. Improved reliability and reduced reliability are also measurable by using the CPCs.

Team Coherence: Measured by applying the TMX (Team Member Exchange Quality) developed by Seers (1989). Team coherence was evaluated in this chapter to define mutual support, group cohesiveness, trust, responsibility for team goals, and team reciprocity as defined by the developer.

Arrhythmia Detection and Classification Using Wavelet and ICA

INTRODUCTION

The classification of an electrocardiogram (ECG) into different pathophysiological disease categories is a complex pattern recognition task. Computer-based classifications of the ECG can achieve high accuracy and offer the potential of an affordable mass-screening for cardiac abnormalities. Successful classification is achieved by finding the characteristic shapes of the ECG that discriminate effectively between the required diagnostic categories. Conventionally, a typical heart beat is identified from the ECG, and the component waves of the QRS, T, and possibly P waves are characterized using measurements such as magnitude, duration, and area. Datasets that are used for heart diseases involve different features. Some of them are based on laboratory experiments, while others include clinical symptoms. However, one of the most popular and useful databases is the MIT-BIH (http://physionet.fri.uni-lj.si/physiobank/database/mitdb/). Researchers have used this database to test their various algorithms for arrhythmia detection and classification. Two of the most popular methods are artificial neural networks (ANNs) and wavelet transforms, and their variations. For example, Lee (1990) classified three types of cardiac arrhythmias with accuracies of 99.55%, 97.75%, 57.1%, respectively using ANNs. Chi and Jaberi (1992), using triple neural networks, classified ventricular arrhythmia with the average accuracy of 95.1%. Karlik and Ozbey (1996) were able to classify 10 types of arrhythmia with average accuracy of 95%. Hu (1997), using self-organizer neural networks and the Linear Vector Quantization, was able to classify heart beats with average accuracy of 91.3% and 90.3%, respectively. Gholam Hosseini, Rainolds, and Powers (2001) implemented a multistage neural network with two MLPs, and were able to classify five kinds of arrhythmia. At the first stage, they achieved an average accuracy of 81.8%, and at the second stage, 88.3%. The algorithms developed in these works are based on analyzing the ECG signals, which requires a large simulation time.

Selected examples of using wavelet transforms and their variations for arrhythmia classification include the following. Yang, Hu, and Shyu (1997), using dyadic wavelets to extract features, and Kohonen self-organizing neural networks for classification, were able to obtain an average precision of 97.77% for heart disease diagnosis. Dokur, Olmez, and Yazgan (1999) used discrete wavelet transforms to classify ten types of arrhythmias with a precision of 97%. De Chazal, Celler, and Reilly (2000), using a set of 500 records with 345 abnormal cases, classified arrhythmias by using 15 feature sets of three Daubechies wavelets decomposition level and reached the maximum precision of 74.2%. Finally, Dokur and Olmez (2001), using wavelet transforms and ANNs trained by genetic algorithms back propagation, were able to classify 10 types of arrhythmia with a precision of 96%.

The goal of this article is to optimize the feature extraction process by using ICA and wavelet transform, apply the obtained set to several different machine learning schemes, and compare their performances. The article is structured as follows. Section 2.0 describes our proposed method for cardiac arrhythmias detection. Section 3.0 covers an overview of different classifier types that were used in this work. Sections 4.0 and 5.0 summarize our simulation scheme and results. Finally, section 6.0 presents the concluding remarks.

PROPOSED METHOD

Figure 1 presents the block diagram of the proposed detection and classification process. First, the appropriate components of the ECG signal are obtained by using the ICA algorithm. Next, these components are used to calculate the coefficients of the Daubechies wavelets. Based on this step, proper features are selected and fed into the classifier. For comparison purposes, three different machine learning methods have been implemented—namely, radial basic function (RBF), multilayer perceptrons (MLPs), and K-nearest neighbor (KNN).

Next, we will present an overview of the ICA and wavelet transform.

Independent Component Analysis with a Time Structure Method

To rigorously define ICA, we can use a statistical "latent variables" model. We observe n random variables $x_1,\ldots,x_n$, which are modeled as linear combination of n random variables $s_1,\ldots,s_n$:

$$x_i = a_{i1}S_1 + a_{i2}S_2 + \ldots + a_{in}S_n \quad i = 1,\ldots,n \qquad (1)$$

Where a_{ij}, $i,j=1, \ldots, n$ are some real coefficients. By definition, the s_i are statistically and mutually independent.

This is the basic ICA model. The ICA model is a generative model, which means that it describes how the observed data are generated by a process of mixing the components s_i. The independent components s_i (often abbreviated as ICs) are latent variables, meaning that they cannot be directly observed. Also, the mixing coefficients a_{ij} are assumed to be unknown. All we observe are the random variables x_i, and we must estimate both the mixing coefficients a_{ij} and the ICs s_i using the x_i.

Here, we have dropped the time index t, because in this basic ICA model, we assume that each mixture x_i, as well as each independent component s_i, is a random variable, instead of a proper time signal or time series.

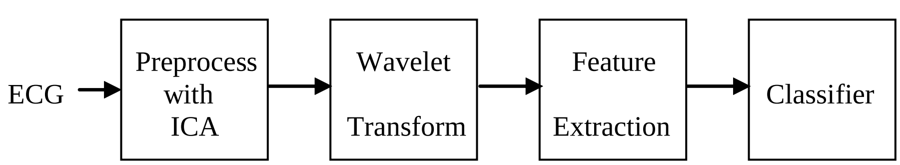
If the independent components (ICs) are time signals, the situation is quite different. In many applications, however, what is mixed is not random variables, but time signals, or time series. This is in contrast to the basic ICA model in which the samples of x have no particular order; we could shuffle them in any way we like, and this would have no effect on the validity of the model. In fact, if the ICs are time signals, they may contain much more structure than simple random variables.

In this research, we consider the estimation of the ICA model when the ICs are time signals, $s_i(t), t=1,\ldots,T$, where t is the time index. Here, t has a more precise meaning, since it defines an order between the ICs. The model is then expressed by:

$$x(t) = As(t) \qquad (2)$$

where A is assumed to be square as usual and the ICs are of course independent. We shall make some as-

Figure1. Block diagram of the proposed detection-classification system



sumptions on the time structure of the ICs that allow for the estimation of the model. First, we shall assume that the ICs have different autocovariances (in particular, they are all different from zero). Second, we shall consider the case where the variances of the ICs are nonstationary, as described by Hyvarinen, Karhunen, and Oja (2001).

In this article, we have implemented the "Fast ICA" algorithm to calculate ICs, similar to the work done by Hurri, Gavert, Sarela, and Hyvarinen (2005). According to the previous research done in this area, Rieta, Castells, Sánchez, Zarzoso, and Millet (2004), and Castells, Rieta, Millet, and Zarzoso (2005), at least three factors make ICA suitable for ECG signal analysis. These factors are as follow:

1. A trial and ventricular activity (AA, VA) are generated by sources of independent bioelectric activity;
2. AA and VA present non-Gaussian distributions; and
3. The generation of the surface ECG potentials from the cardioelectric sources can be regarded as a narrow-band linear propagation process.

Figure 2 shows results of the ICA processing and the original signal, which was generated by two independent sources of atrial and ventricular electrical activity (in such a ventricular arrhythmia). As shown in this figure, ICA with time structure successfully described these two sources that are characterized by "o" and "+" symbols in this figure.

Wavelet Analysis

Wavelet Analysis of a signal consists of breaking up a signal into a translated (shifted) and dilated (scaled) version of a reference (mother) wavelet. A wavelet is a signal of effectively limited duration that has an average value of zero. In determining the wavelet (decomposition) coefficients of a signal, the correlation of the mother wavelet at different translations and dilations with the signal is computed. Hence, the wavelet coefficients represent measures of similarity of the local shape of the signal to the mother wavelet under different translations and dilations. We utilize the feature extraction ability of this analysis for ECG. In this work, we have used Daubechies wavelets; this choice is explained in the Simulation section.

CLASSIFIERS

The results obtained from the previous section were fed into three different machine-learning algorithms—namely, (Multilayer Perceptron) MLP, (Radial Basis Function) RBF, and K-nearest neighbor. An overview of each of these methods follows.

Multilayer Perceptron

The most widely used neural classifier today is a Multilayer Perceptron network, which has also been extensively analyzed, and for which many learning algorithms have been developed. The MLP belongs to the class of supervised neural networks. The network has a simple interpretation as a form of an input-output model, with the weights and thresholds (biases), the free parameters of the model. Such networks can model functions of almost arbitrary complexity, with the number of layers, and the number of units in each layer, determining the function complexity. Multilayer networks use a variety of learning techniques, the most popular being back-propagation. Here, the output values are compared with the correct answer to compute the value of some predefined error-function.

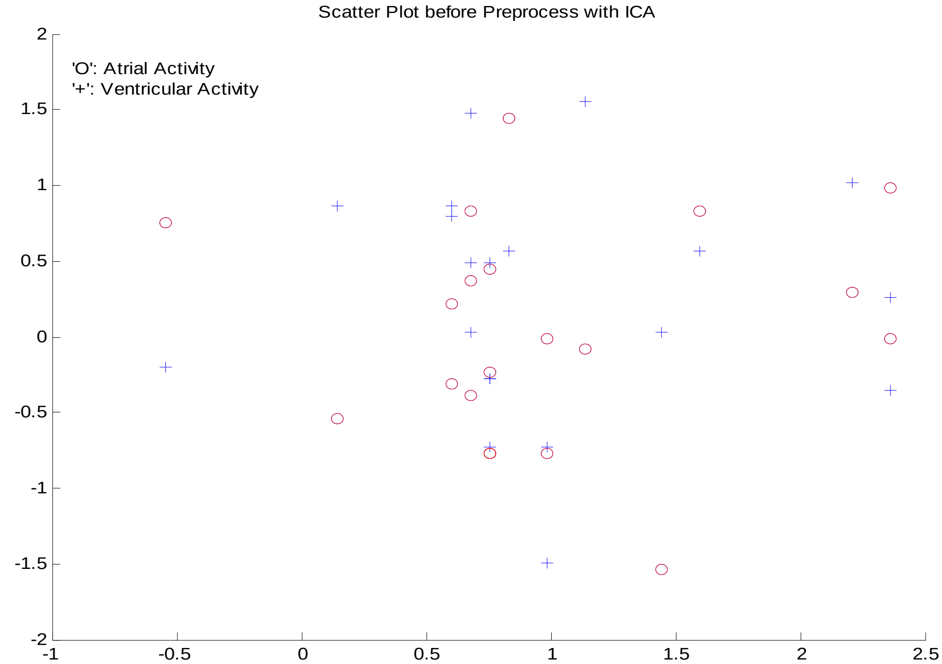
Radial Basis Function

Radial Basis Function Networks used for pattern classification are based on Cover's theorem on the separability of patterns. It contains an input layer, a hidden layer with nonlinear activation functions and an output layer with linear activation functions. The RBF network is a popular alternative to the MLP, which, although it is not as well-suited to larger applications, can offer advantages over the MLP in some applications. The RBF network has a similar form to the MLP, in that it is a multilayer, feed-forward network. However, unlike the MLP, the hidden units in the RBF are different from the units in the input and output layers: they contain the "Radial Basis Function," a statistical transformation based on a Gaussian distribution from which the neural network's name is derived.

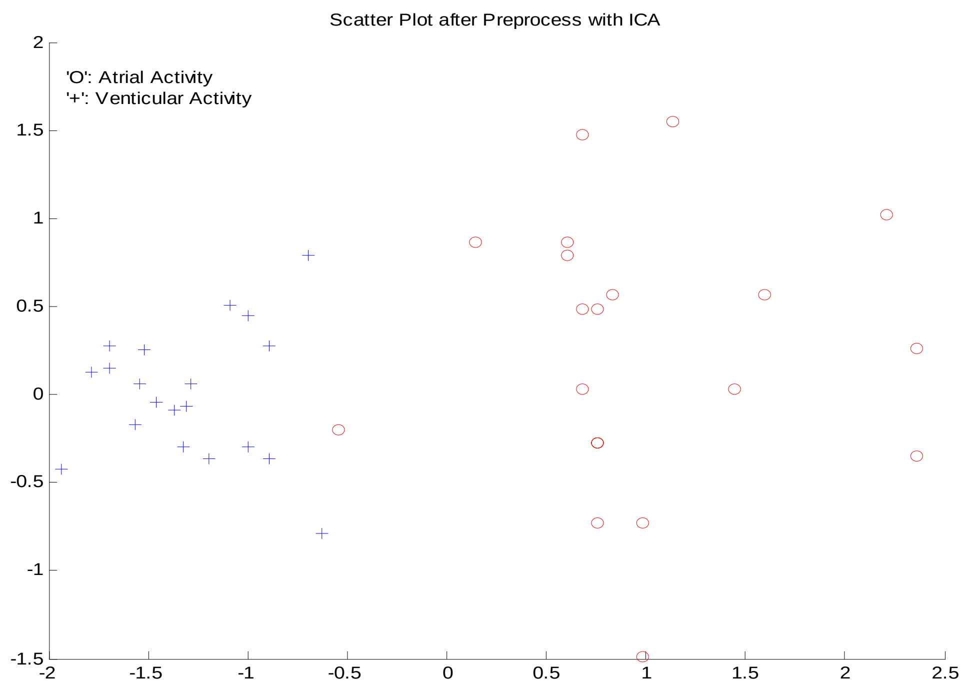
K-Nearest Neighbor Classifier

The nearest neighbor classifier algorithm is a method for classifying phenomena based upon observable features. In this algorithm, each feature is assigned a

Figure 2. Scatter plots (a) before denotation of independent sources by ICA; and (b) after denotation by Matlab ICA pack



(a)



(b)

dimension to form a multidimensional feature space. A training set of objects, with a priori-known class are processed by feature extraction and plotted within the multidimensional feature space. The offsets in each dimension are referred to as the feature vector. This is the training or learning stage. The geometric distance is computed between the new feature vector, and each a priori-feature vector from the training set. The shortest distance thus computed is to the nearest neighbor. The a priori class of the nearest neighbor is now assigned to the phenomena to be classified.

The simulation results of using the aforementioned profilers showed that the MLP provides the best classification. Details of the MLP classifier are presented in the next section. Table 1 summarizes the comparative simulation results:

Table 1. A comparison of the different profiler performance

Method	Overall Accuracy
RBF $(s = 0.3)$	70.80%
KNN (k=5)	84.80%
MLP (3 layers)	98.40%

SIMULATION

For the simulation part, we have used MATLAB's Neural Networks and Wavelet toolboxes, along with its Fast ICA package for pattern recognition and classification.

Five data sets, one normal and four abnormal, with modified lead II (MLII) and lead V1 from MIT-BIH were used in training and testing stages. The first set was from the NSR (Normal Sinus Rhythm), the second set from PVC (Premature Ventricular Contraction), the third set from LBBB (Left Bundle Branch Block), the fourth set from RBBB (Right Bundle Branch Block) and finally, the fifth set from P (Paced Beat) data bases. Dilation coefficients of Daubechies wavelets levels 6, 7, 8 of MLII and dilation coefficient levels 6, 7 of V1 samples after denotation by ICA were implemented as features. Next, the wavelet coefficients were normalized, and then fed into MLP, and the classification results were obtained. Table 2 illustrates the data distribution, and the number of records used for this part of the simulation.

The MLP, which is implemented in this article, is a three-layered neural network. The optimum topology was obtained with the following structure: five input neurons, eight hidden neurons, five output neurons, and the Levenberg-Marquardt as the training algorithm. The desired error was set at 0.01. The system was tested for 1–10 hidden neurons, and four different discriminator functions (activation functions).

Table 2. Data set descriptions and numbers used in the simulation

Description	No. of beats used in testing	No. of beats used in training	No. of records in MIT-BIH	Class No.
Normal Beat	50	100	101,105	1
PVC	50	100	200,213	2
LBBB	50	100	207,214	3
RBBB	50	100	118,212	4
P	50	100	107,217	5
	250	500	Total =750	

SIMULATION RESULTS

Table 3 illustrates the comparison of different activation functions that have been used in the MLP network that was described in the previous section. An entry such as "tansig-logsig" means that "tansig" is the activation function of the hidden neuron, and "logsig" is the activation function of the output layer. As the table indicates, optimum results can be obtained with the "tansign-tansig" activation functions with an overall accuracy of 98.4%, during testing. This is an improvement in comparison to the ones obtained in Shyu, Wu, and Hu (2004).

The performances of the MLP classifier are also expressed in terms of specificity, sensitivity, and overall accuracy. The specificity is defined as the fraction of correctly classified normal rhythms. The sensitivity of an arrhythmia is defined as the fraction of that specific arrhythmia correctly classified. The overall accuracy is the fraction of the total ECG beats correctly classified. The specificity and sensitivities of different ECG beat types are summarized in Table 4 for comparison.

Table 3. The overall accuracy in testing of MLP for different activation function (100% accuracy in training)

MLP Accuracy (%)	Activation functions
98.40	tansig-tansig
91.20	logsig-tansig
90.00	tansig-logsig
92.80	logsig-logsig

Table 4. Classification results of the proposed method

100.00	Specificity (%)	
98.00	PVC	Sensitivity (%)
96.00	LBBB	
98.00	RBBB	
100.00	P	
98.40	Accuracy (%)	

CONCLUSION

In this article, we have shown a new method for cardiac arrhythmias detection and classification, based on using Independent Component Analysis and wavelet transforms to extract important features. The extracted features were then fed to an MLP with the Levenberg-Marquardt back propagation algorithm. For the simulation part, 750 instances of MIT-BIH database from five disease categories were used and a 98.4% accuracy was obtained, which is an improvement with respect to similar works

According to the simulations, the type of activation function and the number of hidden nodes are the important factors in the topology of neural networks. We note that for extending these results, we need to use a larger number of samples from the database.

KEY TERMS

Artificial Neural Network (ANN): An interconnected group of artificial neurons that uses a mathematical model, or computational model, for information processing, based on a connectionist approach to computation.

Cardiac Arrhythmia: A group of conditions in which the muscle contraction of the heart is irregular, or is faster or slower than normal.

Independent Component Analysis: A computational method for separating a multivariate signal into additive subcomponents supposing the mutual statistical independence of the non-Gaussian source signals.

K-Nearest Neighbor Algorithm (K-NN): A method for classifying objects based on closest training examples in the feature space.

Multilayer Perceptron: A class of networks consists of multiple layers of computational units, usually interconnected in a feed-forward way.

Radial Basis Function (RBF): A real-valued function whose value depends only on the distance from the origin. In artificial neural networks, radial basis functions are utilized as activation functions.

Wavelet Transform: Representation of a signal in terms of a finite length or fast decaying oscillating waveform (known as the mother wavelet). This waveform is scaled and translated to match the input signal.

Assessing the Information Content of Microarray Time Series

INTRODUCTION

While the rise of microarray**s** has heralded a new era in molecular biology with its ability to measure the expression level of thousands of genes at once, the usefulness of microarray**s** is exigent upon the ability to obtain accurate gene expression data for the individual genes (Bowtell, 1999; Brown & Botstein, 1999; Cheung, Morley, Aguilar, Massimi, Kucherlapati, & Childs, 1999). However, there has been significant criticism as to how meaningful the information derived via microarrays is. In cases where one has attempted to find genes that correlated to types of cancer or survival rate, it was found that different analysis techniques would often times yield radically different set of genes, calling into question the validity of the overall experiment itself (Dupuy & Simon, 2007). It is our contention that part of the problem associated with microarrays is that there does not exist a coherent method for dealing with data quality, and if a coherent method for dealing with data quality existed, many of the criticisms of microarrays could be addressed.

BACKGROUND

"Fishing Expedition" is normally used in a negative connotation in the legal field. The negativity has carried over to the scientific field and describes an experiment in which the researcher does not know precisely what one is looking for. However, the promise of microarrays is the fact that they allow for just such experiments, and coupled with different algorithms allow for a data driven approach to science (Nakai & Vert, 2002). By identifying the possible targets of gene regulation, researchers can then formulate more specific experiments to validate such a hypothesis. While the technology behind microarrays consistently advances in terms of the density of microarrays as well as the repeatability between each individual microarray, there still exists the major issue of noise. Whilst the technological improvements themselves are able to minimize the technical noise, there still exists significant *biological noise* which for complex multitissue organisms cannot be easily overcome with technology. For instance, despite the standardization of rat/mice lines, there still exists significant variation in any reading taken from a population of animals. Due to this noise, it is difficult to identify the genes which actually respond to a given treatment, and those genes whose fluctuations are due to random noise.

Therefore the most important algorithms for the processing of microarray data are those that select meaningful genes from the thousands that are measured via the microarray. The most common metric used by these algorithms is that of *statistical significance* (Smyth, Yang, & Speed, 2003). There is one caveat with the use of statistical significance primarily in the fact that not all genes that are statistically significance are biologically relevant. The set of biologically relevant genes is dependent wholly upon the biological ground truth, whilst the set of statistically significant genes are dependent upon the number of replicates, the quality of the microarray platform, inherent SNR, as well as biological significance. This is a recognized problem which has been addressed by many researchers as a *feature selection* problem under the assumption that the set of biologically relevant genes ought to be able to work as classifiers between the different states being tested (Wu, 2005).

While not all genes that are statistically significant are biologically relevant and vice versa, there does exist a tendency for biologically relevant genes to be statistically significant as well. Therefore, by selecting statistically significant genes, one increases the likelihood of identifying biologically relevant genes as well. However for one to have confidence in these initial results, care must be taken in the selection of statistically significant genes, paying special attention to normalization and the setting of statistically significant cutoffs.

STATISTICAL SELECTION OF GENES FROM MICROARRAYS

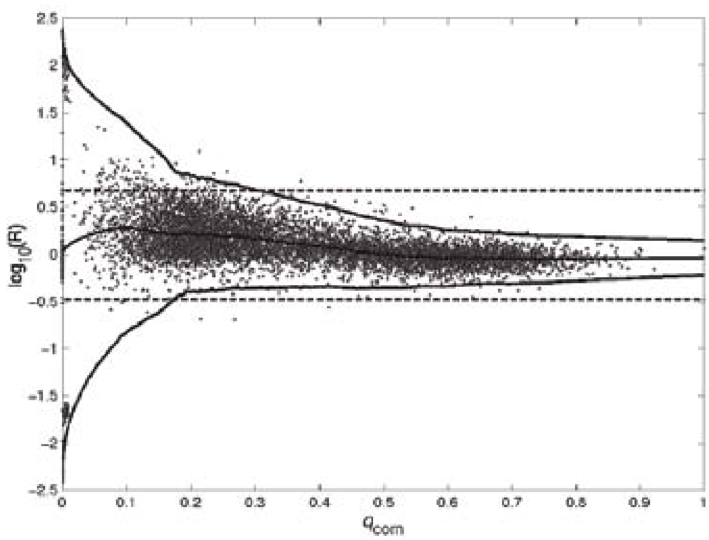
Normalization

The use of normalization is important because many of the selection algorithms that look for over/under expressed genes in a two state experiment base their assumption off of the fact that the initial distribution log is normalized and compute their confidence intervals according to that distribution. Therefore by transforming the data so it does conform to the log-normal distribution, one is able to use standard statistical tests such as the t-test to ascertain whether or not the variations are due to noise or due to some intrinsic change in the expression level of the gene.

One of the challenges with analyzing microarray data is the problem of translating the recorded intensity level obtained by the detection equipment and determining the true expression value of the given probe. Generally, for genes which show a high intensity value, there exists a good correlation between the intensity between the two samples follows a roughly linear trend. However, at low intensity levels, the correlation between the two samples deviates from this (see Figure 1). The justification for the majority of genes being linearly correlated is that under most situations, only a small fraction of genes are responding to the overall treatment and even with the addition of noise, they should be consistent over multiple chips in *temporal gene expression* experiments. The small fraction of genes that do deviate from this linear relationship are then the ones that deviate by a given statistically significant level. Techniques such as the LOESS, dCHIP, and PDNN (Cleveland, 1979; Li & Hung Wong, 2001; Millenaar, Okyere, May, van Zanten, Voesenek, Peeters, 2006; Nielsen, Gautier, & Knudsen, 2005), attempt to normalize the data in such a manner in which the correlation between two samples becomes consistent, thereby allowing for easier identification of statistical outliers.

LOESS (Cleveland, 1979) is a local nonparameter method which attempts to fit a low order polynomial, normally linear or quadratic, to the scatter-plot attempting to minimize the random variations in the data. It is most often used for the *normalization* of two dye experiments, primarily to account for the slight difference in affinity between the two dyes at low expression levels, but can be used generally to correct for the nonlinearities found at lower intensity levels. It is similar to a nonlinear regression fit, except it performs a local regression upon blocks of data. The blocks of

Figure 1. The deviation from the log normal distribution at low intensity levels. The LOESS curve centers the distribution and forces log-normality (Wang, Hessner, Wu, Pati, & Ghosh, 2003)



overlapping data used are determined via a smoothing parameters which is set by the user under the constraints given in Equation 1**.** The size of the data block used for each local fit is then given as nq.

$$\frac{(d+1)}{n} \le q \le 1 \tag{1}$$

where d is the degree of the polynomial used.

Since LOESS is a local fitting method, the number of points used in each fit is nq, where q is the selected smoothing factor which satisfies the constraint in Equation 1 and n is the total number of points in the dataset. There is an additional weighting function given in Equation 2 which forces points closer to the point of estimation to contribute more to the local fit than those that are further away. The distance of the points to the point of estimation are calculated, and then normalized, so the data-point at the point of estimation has a value of 0, and the point furthest away has a value of 1. The primary advantage of loess is the fact that it is a non-parametric normalization and henceforth can be used when an *explicit model* of the data is not available.

$$w(x) = \begin{cases} \left(1-|x|^3\right)^3 & \text{for } |x| < 1 \\ 0 & \text{for } |x| \ge 1 \end{cases} \tag{2}$$

While the LOESS method is a nonparametric normalization of the data, dCHIP and PDNN (Position Dependent Nearest Neighbor), on the other hand, are model based approaches. In dCHIP (Li & Hung Wong, 2001), the primary normalization method creates a model of chip variability through the use of invariant marker genes, whilst PDNN (Nielsen et al., 2005) uses a nearest neighbor model to describe the physical binding of mRNA to the probes. The different relative binding of each probe to its exact match is then used to normalize the intensity value to obtain an expression level given the intensity. This method has the advantage of normalizing multiple probes for the same gene to roughly the same expression level. This is important because it was observed that oftentimes for time series, probes that had a different sequence that targeted the same gene had significantly different expression levels, despite being well correlated with each other. The problem with this issue is that oftentimes, one probe set will show statistically significant differential expression, whereas the other probe-set would not.

PDNN works by assuming that the observed signaling intensity comes from three sources, Binding, Non-Specific Binding, and background. It calculates the expected intensity via Equation 3

$$\bar{I}_{ij} = \frac{N_j}{1+e^{E_{ij}}} + \frac{N^*}{1+e^{E^*_{ij}}} + B \tag{3}$$

Where I is the expected signal intensity, i is the probe index, j is the gene index, N_j is the number of mRNA copies in the sample, N^* is the number of mRNA copies that contribute to Nonspecific Binding, E_{ij} is the free energy of formation for the specific binding and E^*_{ij} is the average non-specific free energy, and B is the background intensity.

E_{ij} and E^*_{ij} are calculated as the sum of the stacking energy for the binding which is calculated via the nearest neighbor model given in Equation 4.

$$E = \sum w_k \varepsilon(b_k, b_{k+1}). \tag{4}$$

The w_k represents the individual weights for each nearest neighbor pair given by ε. All of the parameters are computed by minimizing the following Equation 5.

$$F = \sum_i \sum_j \left(\ln \bar{I} - \ln I\right)^2 \tag{5}$$

The normalized expression for each gene then consists of N_j which would then be the predicted number of mRNA copies given the intensity values. This value of N_j is useful because it provides a method for reconciling probe sets which target the same gene, but due to variation in their mRNA sequence show different intensity profiles. This allows for the acquisition of a more accurate measure of mRNA activity than by just relying on intensity. Furthermore, genes represented by multiple probe-sets can have their predicted gene expression averaged to further reduce the contribution of noise in the overall signal, something which cannot be done when using intensity data only.

Comparisons to the different normalization methods (Millenaar et al., 2006; Ryden et al., 2006) have suggested that while they show some difference, it was found that the set of genes that were selected as differentially expressed show a significant level of concordance.

Selection of the Statistical Cutoff

In the selection of genes that show a statistically significant chance of being non-random, there is the question of p-values. Many researchers utilize a p value of $p < .05$, or $p < .01$(Lee, Kuo, Whitmore, & Sklar, 2000). However, it is important to consider the overall sample size. In a representative array, the Affymetrix RAE230A, there are over 15K probe spots on the array. With a p-value of .05, it still leads to the possible random selection of 750 genes, which represents a significant reduction in the number of genes being analyzed but may lead to results which would be difficult to justify statistically. Instead, the p-value ought to be set a p-value of $p < 1/N$ where N is the number of probes on the chip. For microarrays, we term this the "Natural" p-value since it directly relates the p-value to the sample size.

Gene Selection

The simplest filtering technique which researchers use to select for statistically significant genes is the 2-fold test. This test essentially selects for genes that have shown either a two fold up/down regulation, and is widely used because of its inherent simplicity. This test is essentially an approximation of the t-test with three samples at a confidence interval of $p < .05$. It tends to work poorly at low expression levels due to the greater variability vs. the mean, that is, a lower signal to noise ratio (Novak, Sladek, & Hudson, 2002) as well as the fact that the log normal distribution breaks down at the tail end corresponding to low expression levels. Therefore, before the use of the 2-fold selection method, there is usually a normalization step performed such as LOESS, as well as a filter for sample data quality to filter out the gene with a low expression level. However, despite the mathematical transformations to correct for the deviations from the log-normal distribution as well as the loss of the SNR, the 2-fold test represents a very weak filtering method because there is no explicit control as to what the confidence level of the selected genes are.

The problem with utilizing any sort of fold measure whether it be 2 fold, or n fold for greater or lesser stringency is that one is unable to report the confidence level of the selection because of the dependence of the confidence interval upon the variation between the different replicates. As a general rule, there are two competing trends with utilizing this selection:

1. The repeatability of the gene chips is increasing due to improvements in quality and technological improvements such as the use of 60 base pair recognition sequences(Hardiman, 2004), making the 2-fold test more stringent now than in the past.
2. The number of spots per array has increased, thereby increasing the natural p-value needed to separate out random changes in expression levels.

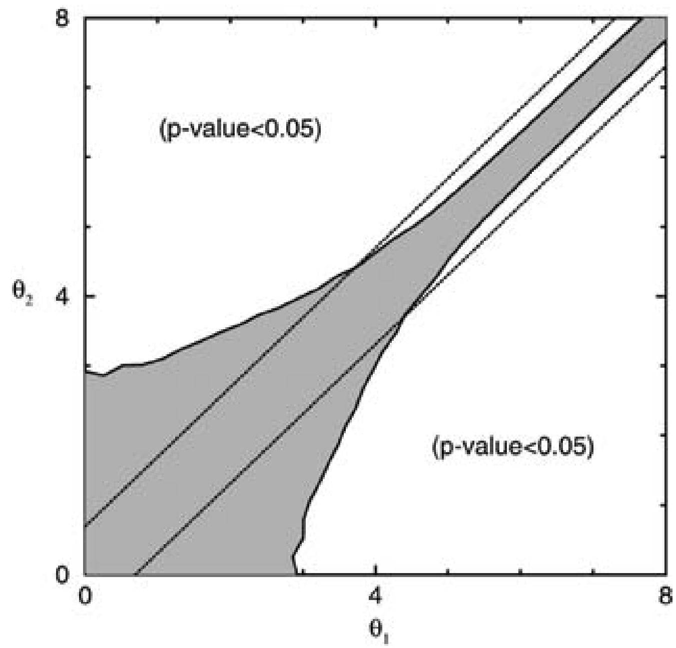
Both of these can be rectified with the use of the t-test which is give in Equation 6.

$$t = \frac{\overline{X_a} - \overline{X_b}}{\sqrt{\frac{\mathrm{var}(X_a)}{size(X_a)} + \frac{\mathrm{var}(X_b)}{size(X_b)}}} \tag{6}$$

The benefit of the utilizing the standard t-test is that the "Natural" p-value can be used as the cutoff for stringency as well as the fact that the metric is tailored for each individual gene with their attendant means and standard deviation. This method also has the added benefit of being able to handle the higher SNR found at the lower expression levels, Figure 2, because it does not assume the fact that there is a strict linear cutoff at all measured expression levels. Again as in the two-fold test, it is imperative that proper normalization take place before the use of the t-test, for without proper normalization, the any systematic errors that take place at lower expression levels tend to overwhelm the t-test.

A more sophisticated method for determining the quality of a gene's expression data is the Significance Analysis of Microarrays (SAM) method (Tusher, Tibshirani, & Chu, 2001). This method utilizes similar statistical metric to the t-test Equation 7. The primary difference between SAM and the standard t-test is the presence of an S_0 term which is calculated form the data that is designed to minimize the coefficient of variance of d(i) between the genes with low expression level and those with high expression levels. Additionally, instead of focusing on a statistical distribution such as the one

Figure 2. The variability between two chips. It is evident that as the expression level is lower, the linear trend between the two chips breaks down, and henceforth the 2-fold threshold does not become applicable. However, the t-test is able to correctly compensate for this change at lower expression level. Note however, that we do not advocate the use of the confidence interval of p < .05 for outlier detection(Tu, Stolovitzky, & Klein, 2002).



used for the t-test, the cutoff is determined arbitrarily by looking at a sorted plot of the d(i) values, Figure 3. Despite the fact that it is slightly different than that of the t-test, it satisfies the same goal which is primarily the assessment as to whether or not the difference measured between two samples has been reliably captured. The primary advantage of this method is that due to the normalization term S_0, there is increased sensitivity at lower expression levels, that is, it is less sensitive to SNR than the simple t-test.

$$d(i) = \frac{\overline{x_I}(i) - \overline{x}_u(i)}{\sqrt{a\left\{\sum_m [x_m(i) - \overline{x_I}(i)]^2 + \sum_n [x_n(i) - \overline{x_U}(i)]^2\right\}} + s_0} \quad (7)$$

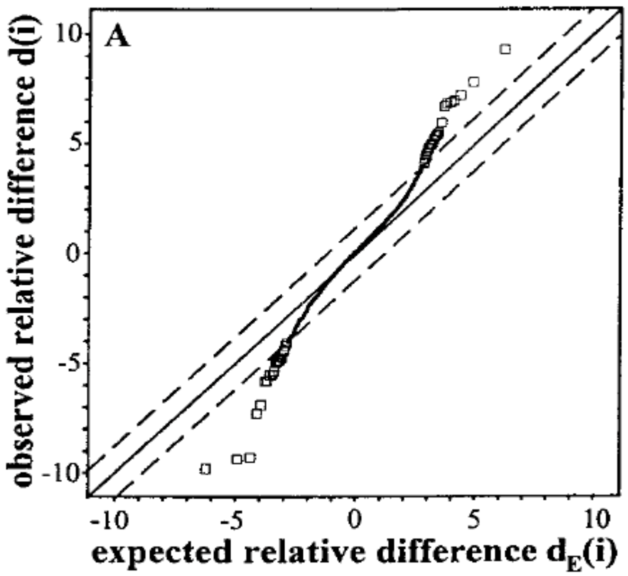
FUTURE TRENDS

One of the major pushes recently with *microarrays* is the use of temporal expression data. On a fundamental level, the same problem applies, namely the selection of statistically significant genes from the microarray. However, at this point it is not clear as to what a statistically significant temporal expression profile is. Some work has been done with the use of statistical over-representation of possible expression profile templates (Ernst & Bar-Joseph, 2006; Yang, Maguire, Yarmush, Berthiaume, & Androulakis, 2007) and future work has been proposed to make use of the replicates to identify those genes whose SNR in terms of *biological noise* is low enough where one can place high confidence in the overall shape of the obtained expression profile.

CONCLUSION

While microarrays have been hailed as a revolutionary advance in molecular biology, skeptics have pointed out the fact that there exists maddening inconsistencies in the results derived from microarray data (Kothapalli, Yoder, Mane, & Loughran, 2002). The primary problem with microarrays is the fact that at the same time, they are able to provide too much and not enough information. In the too much information realm, they provide the expression levels of thousands of genes at once, most of which are not related to the underlying phenomenon

Figure 3. The threshold's for SAM allows for the differentiation between genes that show differential expression as compared to the base state



being investigated. In the too few information realm, they are expensive enough where oftentimes there aren't sufficient replicates to deal with the inherent problem of technical and *biological noise*, making the selection of a set of genes questionable.

While technical noise is progressively being decreased through technological improvements via the makers of microarrays such as Affymetrix and Agilent, the problem of *biological noise* still remains. However, in either case, the ability to find experiments, genes, and probes whose intrinsic property remains despite the noise is still important. We feel that many of the criticisms of microarrays and the conclusions can be addressed with proper statistical evaluation of the data. This is not to say that conclusions that have not passed statistical muster do not contain important information; however statistical robustness adds another method of verification of the results. By utilizing experiment data quality assessments, one can determine whether an unknown process has indeed been captured in the context of both the biological response as well as technical issues such as the number of replicates, and the length of the time series. Proper analysis of the genes themselves will allow for the identification of genes that can be used for further analysis, and, finally, the analysis of the probes themselves ought to give an insight into the overall confidence in the values obtained from the technology as well as providing information as to whether or not the gene is actually expressed in vivo.

KEY TERMS

Biologically Informative: This is different from the notion of statistically significant because this set of genes is consistent over multiple experiments, replicates, and microarray platforms and reflects the underlying ground truth.

Locally Weighted Normalization of a Scatter Plot (LOESS; LOWESS): LOESS seeks to find a low order polynomial that best describes the overall variation in a scatter plot. This is used to normalize for the nonlinearities found in two state experiments.

Natural P-Value: The p-value a researcher should set in determining statistical significance. It is wholly reliant upon the number of samples in a given trial. Therefore, in a microarray, the natural p-value should be set to 1/N where N is the number of samples

Position Dependent Nearest Neighbor (PDNN) Model: A normalization technique by Zhang, Miles, and Aldape (2003), which makes the assumption that the signal intensity is dependent on both the probe sequence being used and the number of mRNA copies. It performs the normalization by calculating the number of mRNA copies and an expected signal intensity by optimizing for various parameters such as base stacking energy.

Significance Analysis of Microarrays (SAM): A selection algorithm which is nominally very similar to that of the t-test. It is, however, more robust to mRNA signals of lower SNR and hence gives more reliable filtering for genes of low expression levels.

Statistically Significant: The ability for the variability of a sample to be attributed by a factor other than through random noise. This is dependent first upon the overall distribution of the samples, though most researchers assume that the random variations are gaussian. Due to systematic factors such as dye binding affinities as well as the nonlinear binding behavior in microarrays, normalization is required before the use of this gaussian assumption

Signal to Noise Ratio (SNR): In the context of microarrays, the noise comes from two sources, technical and biological. This is, however, the primary determinant of how many replicates are required but is complicated via the fact that different probes have different SNR.

INTRODUCTION

Telephone companies are finding themselves confronted with a very basic problem: multiple networks. The solution that was devised is a unique new network for the future that will replace the entire telephone system and all the specialized networks with a unique completed network for all types of transport of information. This new network will support enormous rhythm of data compared to all the existing networks and services, and will render possible the offer of a large variety of new services.

The new service network for a wide region is called Digital Network of Completed Services of Wide Area broadband integrated services digital network (B-ISDN). The technological infrastructure that renders it feasible is called asynchronous way of transport: asynchronous transfer mode (ATM) because the transmission is not modern; that is, attached in a being first clock.

GENERALLY FOR THE ATM

The ATM was materialized initially in order to be used in the WANs, however, its value quickly appeared for the LANs. The topology that is used is that of aster. The stations are connected via an ATM Switch. Each Switch can now be connected, with his line in some other hierarchically superior Switch that plays the role of backbone. It should be noted that these appliances allow the transfer of data of concrete breadth of area; however, capacities today reach 10Gbps.

The flexibility of ATM springs from the segmentation of parcels in smaller departments that are named cells. Each cell has a length of 53 bytes from the five constituting the heading (header).

The ATM Switch undertakes the promotion cells to the recipient after decoding the address of the destination from the heading of each cell.

BASIC IDEA

The basic idea behind the ATM is the transport of all information in small determined length parcels that are named cells.

The reasons for cell choice are many. Some of them selectively are:

- The cell transfer is exceptionally flexible and it can easily handle the movement of constant rhythm (e.g., sound, video) and the movement of variable rhythm (data).
- In the very high speeds that are expected, the digital cell transfer is easier than the use of traditional multiplex techniques.
- With regard to television distribution, the possibility of emission is essential. The cell transfer can support it, while the transfer of circuit cannot.

The ATM is based on protocols of virtual connection (e.g., virtual paths, virtual circuits). The user of the ATM has the possibility of accessing in entirety the breadth of area of channel whenever he or she wants for as long as he or she wants. The ATM ensures that services such as voice and moving pictures are transmitted in priority, while the longest time of waiting in the tail of transmission is the time of transmission of cell 53 bytes (roughly 3m sec in rhythm 155 Mbps).

The means of transmission for the ATM is usually the optical fibres, but for connections under 100 meters, coaxial cables or double conductor category 5 can also be used. The fibers can have a length of many kilometres. Each junction is extended between a computer and a transporter ATM or between two transporter ATMs. Each junction from point to point is one way. For completely bidirectional communication, they need two parallel junctions for the movement to each direction.

That is to say, the ATM Connections can become:

- Point to point (point-point)
- Point to a lot of points (point-multipoint)
- Points-to-points (multipoint-multipoint)

The forecasted speeds for ATM networks are 155 Mbps and 622 Mbps, with the possibility of speeds a Gigabit later. The speed of 155 Mbps became in order to be compatible with the system of transmission SONET. The speed of 622 Mbps was selected so with this can be sent four channels of 155 Mbps.

CATEGORIES OF SERVICES OF ATM

Category of constant rhythm bit constant bit rate (CBR) has as its aim to assimilate the cupreous cable or the optical fiber.

The next category of variable rhythm bit variable bit rate (VPR) is divided to subclasses for real time and not real time, respectively. Real-time variable bit rate (RT-VPR) is intended for services that have variable rhythm bits and is combined with strict requirements of real time, as the dialogic video. The other subclass, non-real-time (nrt-VBR) serves the movement; the convenient delivery is important, but a certain small quantity is bearable from the application.

Finally, we reach the unspecified bit rate (UBR), which does not promise anything and does not provide retroaction for the congestion.

USES OF ATM

The widespread deployment of high-speed networks has spurred the development of multimedia applications such as voice and video. In the medical domain, the transmission of medical images over networks opens up the possibility of improved education by allowing remote participation in clinical conferences, or improved and more cost-effective diagnoses by allowing remote consultations with experts. This development is aligned with trends such as the rise of managed health care organizations and the increased pressures for cost reduction in medical care. For example, the Hamad Hospital in Dubai (1998) has signed an agreement in order to organize the installation of a health care network based on asynchronous transfer mode (ATM) technology. This network would enable the hospital to take up a pioneering role in providing innovative telemedicine solutions throughout the whole of the region for many years to come. ATM can be used in:

- **LAN:** Network ATM can function as LAN that connects separate users or as bridges that connect more LAN.
- **WAN:** The ATM offers important faculties for the WAN networks:
    - efficient management
    - control of network
    - the ATM does not face problems with the distance
    - the integrity of a transmitted signal is even ensured when different types of movement are presented in the same network
    - it can offer different services in various speeds and a lot of levels of output
- **MAN:** The movement in a MAN network is limited in distances of certain kilometers.
- As network of trunk

The ATM had big success as a network. It supports a lot of different technologies such as:

- DSL
- IP Ethernet
- Frame Relay
- SONET

OTHER PARAMETERS THAT SHOULD BE EXAMINED

Extension of Network

The ATM:

a. It is capable of supporting services in a lot of different rhythms of transmission, and hence can be used in each part of a network.
b. It can transport each type of service in all the breadth of the network; after this, it is also the aim of his initial designing.
c. It has failed until now to prevail or be extended in an important degree in the desktop part of networks.

Cost

The ATM presents cost, which results because it is for a high quality technology that is used mainly by a limited crowd of institutions for high specifications and objectives networks.

Complexity

The ATM:

- Has complex and complicated products
- Has difficult installation
- Provides difficult management of network from the Ethernet
- Finds mistakes but also the comprehension connection—oriented ATM of networks very often constitutes a real headache

Quality of Service in the ATM

There are three types of ATM services: permanent virtual circuits, SVC, switched virtual circuits, and without connection. The quality of service is an important subject for network ATMs, partly because they are used for movement of real time as the sound and the video.

Safety in the ATM

An element that was not reported until now and constitutes an important factor of the reliability of the network is safety.

The ATM can and it precisely provides safety in the connections because the “circuit” that is installed with a connection is virtual and is decomposed immediately after the end of the connection.

Advantages of ATM

The ATM offers:

- A high control in the elements of transmission and their easy management
- Constant connections
- Guaranteed breadth of area
- Low and constant latency
- A high output via the transformation of material
- Evolution in the speed and the size of networks
- Support LAN/WAN technology
- International conformity of models
- Can be used in near or far distances

The services that the ATM network offers are:

- Video on demand
- Tile-education
- Telemedicine
- Virtual telephony
- Video conferencing
- Desktop conferencing
- Videophone
- Picture/sound at order (audio/video being demand)
- Virtual local networks (VLANs: Virtual LANs)
- Communications ATM of big capacity with mobile nodes (usually with satellite junctions)
- Interconnection of local networks
- Unification of voice and data (VoATM)

A

CONCLUSION

Numerous telcos have implemented wide-area ATM networks, and many ADSL implementations use ATM. However, ATM has failed to gain wide use as a LAN technology, and its great complexity has held back its full deployment as the single integrating network technology in the way that its inventors originally intended.

http://www.hoise.com/vmw/articles/LV-VM-03-98-10.html

KEY TERMS

Asynchronous Transfer Mode (ATM): A cell relay network protocol that encodes data traffic into small fixed-sized (53 byte; 48 bytes of data; and 5 bytes of header information) cells instead of variable sized *packets* (sometimes known as *frames*) as in packet-switched networks (e.g., Internet Protocol or Ethernet).

Computer Networking: The scientific and engineering discipline concerned with communication between computer systems.

Data T ransmission: The conveyance of any kind of information from one space to another.

LAN: Local area network.

Safety: The state of being safe, the condition of being protected against physical, social, spiritual, financial, political, emotional, occupational, psychological, or other types or consequences of failure, damage, error, accidents, harm, or any other event that could be considered undesirable.

Transmission (telecommunications): The act of transmitting electrical messages.

WAN: Wide area network.

INTRODUCTION

Atrial fibrillation (AF) is the most frequently occurring sustained cardiac rhythm disturbance (Wolf, Mitchell, Baker, Kannel, & D'Agostino, 1998). Although relatively easy to diagnose by analysis of the surface ECG, AF has modalities, mechanisms, and predisposing conditions that still remain poorly understood.

AF is not a direct life-threatening arrhythmia. However, because of the associated strong symptomatology, it frequently results in hospitalisation, physician visits, and drug therapy, hereby limiting the physical and social activities of many patients. It not only affects the quality of life, but it also increases the likelihood of prothrombotic effects and the risk for mortality because of cerebrovascular events or progressive ventricular dysfunction (Wolf et al., 1998).

AF is also a frequent post-cardiosurgery complication that results in an increase of length of hospital stay and of the associated costs (Kannel, Wolf, Benjamin, & Levy, 1998). Even though several underlying pathophysiological conditions might predispose to AF, no reliable method exists as yet to stratify the relative risk for AF development from a patient's clinical state, or by analysis of the available bedside data (Gang, Hnatkova, Mandal, Ghuran, & Malik, 2004). It is not possible to predict episode recurrence in paroxysmal patients, since AF can often be asymptomatic, nor does a method to identify patients at risk for post-cardiosurgery AF by pre-operative clinical investigations exist.

In the last decades, several studies have focused on finding reliable methods for the prediction of atrial fibrillation by analysis of surface electrocardiographic records. The ECG is a simple and widely available noninvasive technique used in the diagnosis of various cardiac diseases. The P-wave represents the sequential atrial activation of right and left atria, and it reflects the atrial conduction properties. Indeed, individuals with a clinical history of paroxysmal AF have a longer inter-atrial and intra-atrial conduction time, shown as a P-wave prolongation on the surface ECG. Moreover, the regional differences in atrial activation time in AF patients might be reflected in temporal variations across the leads of an orthogonal ECG (Villani, Piepoli, Rosi, & Capucci, 1996).

These findings have lead to an increasing interest in time domain P-wave analysis as a tool for AF risk stratification. Maximum P-wave (i.e., longest P-wave in a 12-lead ECG) and P-wave dispersion (difference between the longest and the shortest P-wave duration in 12-lead ECG) are currently the most sensitive indexes for AF risk assessment (Dilaveris & Gialafos, 2001). However, time domain methods are limited by the lack of a standard and accepted definition of P-wave duration. P-wave boundaries are difficult to detect, both because of the small amplitude of the atrial signal on the ECG, and because of the gradual slope of the atrial waveform from the baseline. For this reason, its determination is mainly attributed to the cardiologist's opinion and experience. Obviously, this reduces the applicability of time domain indexes in AF risk stratification, since cut-off values result to be dependent on the particular study group, the patient population investigated, and also the technological equipment used.

Nevertheless, irregularities of P-wave morphology have been detected in patients with paroxysmal atrial fibrillation (Dilaveris & Gialafos, 2002), and different shapes of P-wave may represent the presence or absence of an underlying pathophysiological condition in patients prone to AF attacks (Carlson, Johansson, & Olsson, 2001). Indeed, P-wave morphological analysis can help detecting interatrial blocks, which predispose to this cardiac rhythm disturbance, even in patients who develop AF despite the absence of particular alterations in echocardiographic parameters (Bayes de Luna, Guindo, Vinolas, Martinez-Rubio, Oter, & Bayes-Genis, 1999).

BACKGROUND

Morphological analysis of P-wave has been extensively used to assess interatrial conduction defects and abnormalities of the left and right atrium (Dilaveris & Gialafos, 2002; Michelucci, Bagliani, Colella, Pieragnoli, Porciani, Gensini, Padeletti, 2002; Platonov, Carlson, Ingemansson, Roijer, Hansson, Chireikin, & Olsson, 2000). Changes in P-wave polarity, as well as subtle differences in P-wave morphology, are believed to reflect abnormal activation patterns in the atria (Michelucci et al., 2002). Irregularities in the orthogonal P-wave morphology have been detected in AF patients and associated with local interatrial conduction delay (Platonov et al., 2000). Different shapes of P-wave have been shown to represent the presence or absence of an underlying pathophysiological condition in patients prone to AF attacks (Gang et al., 2004). In the presence of a partial inter-atrial conduction block, P-wave shape changes have been demonstrated to depend on the direction of the activation wavefront. The studies on P-wave morphology are usually performed by visual inspection of shape changes. However, abnormalities of left or right atrium are likely reflected in subtle morphological changes beyond visual classification.

We hereby present a P-wave model, based on a linear combination of Gaussian functions, to perform an automatic and reliable quantification of the morphological features of P-wave in patients with paroxysmal atrial fibrillation (Censi et al., 2007). In addition, given the importance of multichannel electrocardiography for the extraction of quantitative parameters, we used a 32-lead mapping ECG system, to increase the spatial sampling on the body surface and to enhance low amplitude signals (Trobec, 2003).

MORPHOLOGICAL ANALYSIS OF THE P-WAVE

In order to overcome the limitations related to the time-domain analysis, an automated morphological analysis of the P-wave can be obtained by a model based on a Gaussian fit of averaged P-wave. Such a model can numerically and automatically quantify, beyond visual inspection, morphological aspects of P- wave in AF patients.

By describing a P-wave as a linear combination of up to eight Gaussian functions, the number of Gaussians that explain 97.5% of the signal variance is used as representative of that specific wave. The fit, in a way, acts as a filter that eliminates high-frequency noise.

Since more than one Gaussian function can be used by the model to cover steep portions of the signal, without really fitting a peak or valley, a better morphological description of the wave is obtained by evaluating the number of *maxima, minima,* and *zeroes* of the extracted fit. The P-wave morphology is then evaluated by the following parameters: the model order at which AdjRsq≥97.5%; the minimum (σ_{min}) standard deviation of the Gaussians included in the model; the maximum (σ_{max}) standard deviation of the Gaussians included in the model; the number of relative maxima and minima (max+min); and the number of zero crossings of the model (zeros). The Gaussian fitting of two P-waves with different morphology is shown in Figure 2. The P-wave on the left achieves an AdjRsq = 98.93% with a second first order model (two Gaussian functions), while in the second case, AdjRsq higher than 97.5% is only reached with a 6th order Gaussian fit. Lower panel shows the values of the five parameters extracted from the Gaussian fit to quantify the morphological features.

The parameters chosen synthesise the main morphological characteristics of the original waveforms: the order of the model is the number of Gaussians required; the number of maxima and minima provides information on the number of 'bumps' included in the waveform; the number of zeros accounts for the phase changes of the P-wave.

Figure 1. Electrode positioning scheme

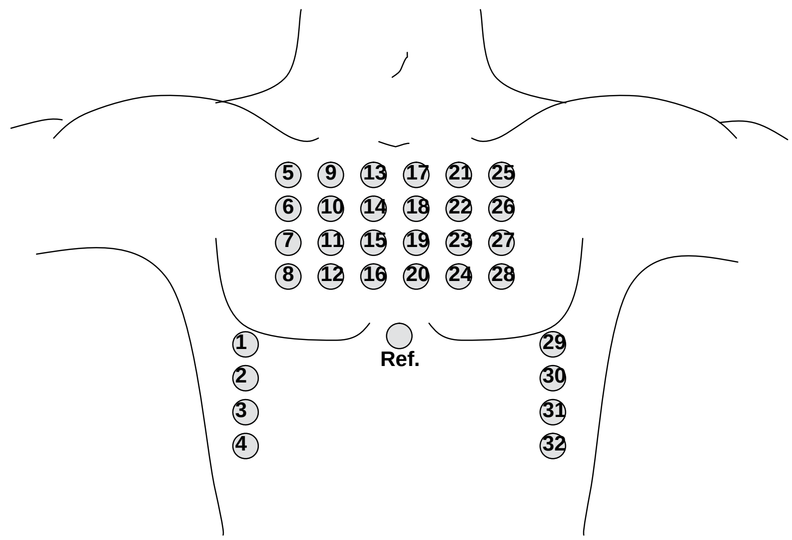

Figure 2. Gaussian fit of two P-waves with different morphology. Upper panel – left: two Gaussian functions fit the P-wave with AdjRsq =98.93%. Upper panel – right: AdjRsq higher than 97.5% is only reached by a 6th order model. Lower panel: values of the five parameters extracted from the Gaussian fit to quantify the morphological features.

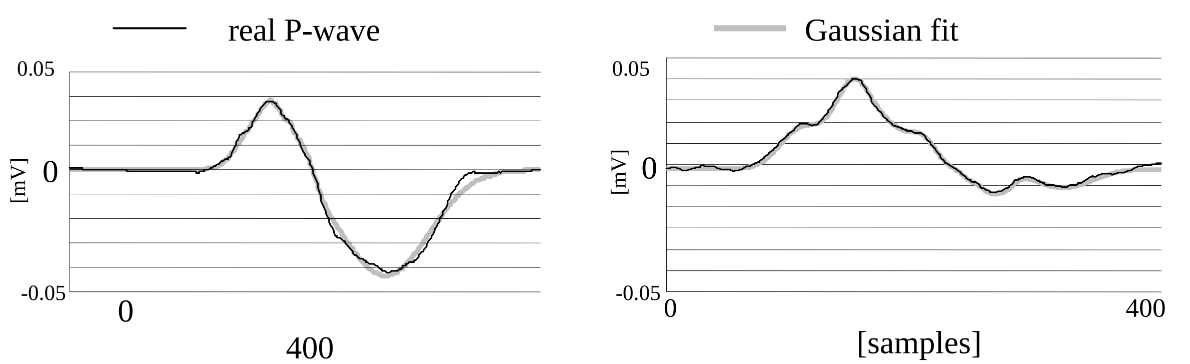

Best order: 2	*Best order: 6*
Zeros: 1	*Zeros: 1*
Max+min:2	*Max+min:4*
σ_{max}: *53.53*	σ_{max}: *53.78*
σ_{min}: *30.69*	σ_{min}: *23.20*

Table 1. Results for the morphological analysis expressed as mean values ± standard deviations and p-value obtained according to the statistical analysis explained in the text

	N	LR	HR	population *p*-value	N vs. LR *p*-value	N vs. HR *p*-value	LR vs. HR *p*-value
best model order	2.7±0.2	5.7±0.7	6.6±0.7	<0.01	<0.01	<0.01	<0.01
zeroes	0.7±0.3	0.9±0.34	1.8±0.7	<0.05	<0.05	<0.01	<0.05

sigma_min	24.5±2.2	22.2±10.7	23.5±9.6	0.5	0.2	0.6	0.5

ECG signals were acquired using a 32-lead mapping system for high-resolution biopotential measurement (ActiveTwo, Biosemi, the Netherlands), sample frequency 2 kHz, 24 bit resolution, 0-400 Hz bandwidth. The system is made of a battery powered AD box that digitises the signals and transfers them to a PCI receiver on computer through fiber optic connection. The 32 leads guarantees spatial sampling on the body surface. The leads were strategically positioned as shown in Figure 1, to allow accurate recordings of atrial signals. ECG recordings were acquired as single-ended signals, with respect to the common reference.

Twenty-five patients with permanent dual chamber pacemakers (AT500-Medtronic, Inc. Minneapolis, MN, USA) were recruited at South Filippo Neri Hospital, Rome, Italy. The AT500 device combines the monitoring of atrial tachyarrhythmias with both intervention therapies and pace-termination therapies. Intervention therapies aim at suppressing atrial tachyarrhythmia trigger mechanisms by using three programmable pacing algorithms. In addition, three pace-termination algorithms recognize treatable atrial tachycardias and delivers antitachycardia pace-therapies to restore sinus rhythm.

The study population consisted of 12 females and 13 males, aged 73 ± 8, affected by paroxysmal atrial fibrillation and bradycardia. Four healthy subjects, with no history or sign of cardiac disease, were recorded as a control group. Five-minute ECG recordings were performed for each subject, with the pacemaker programmed in VVI mode (i.e., in single-chamber ventricular pacing mode), set at 40/min. in order to have spontaneous beats. To compare the morphological parameters extracted from different type of patients, three classes of risk have been defined, according to the number of AF episodes recorded by dual chamber pacemakers in the last six months preceding the acquisition: class N: normal, no episodes and no risk associated (i.e., control subjects); class LR (low risk): number of episodes=0; class HR (high risk): number of episodes≥1.

Every lead signal was preprocessed and analysed to extract the average P-wave characteristic of the specific lead. The first step is to detect P-waves from the acquired signals. P-waves are isolated, considering 200ms windows triggered from the R wave of the QRS complexes. R-waves are detected using an algorithm similar to that proposed by Pan and Tompkins, which actually acts as a high pass filter on the ECG signals, enhancing the high frequency QRS complexes (Pan & Tompkins, 1998). Secondly, a beat-by-beat linear piecewise interpolation was used to remove baseline wander on each P-wave. Then, a coherent averaging procedure has been implemented. In order to take into account the variations in PR interval and/or the inaccuracy in R-wave detection, care had been paid to align the P-waves before the averaging procedure; particularly, P-waves were aligned according to the lag at which the cross-correlation function between the current averaged P-wave, and each single P-wave shows its maximum.

Mean values of these parameters over the 32 leads have been considered (Table 1). P-waves from the control group can be described by lower order models (2.7±0.2), compared to both LR (5.7±0.7) and HR patients (6.6±0.7). Also, morphological differences between LR and HR, evaluated in terms of model order, resulted to be significant ($p<0.01$). The number of relative maxima and minima from the Gaussian fit is significantly higher in HR class (7.3±1.5), compared to both LR (6.1±1.0) and N (3.1±0.4). The number of zeroes is also significantly increased in HR, compared to LR. No particular differences have been observed for σ_{max} and σ_{min} parameters.

These parameters might all be markers of the fractionated electrical activity that characterises paroxysmal AF patients in sinus rhythm. P-waves in control group, as expected from visual inspection, appear smoother than those from AF patients.

To our knowledge, no previous studies have performed a similar analysis in paroxysmal AF patients, thus no comparisons are possible. Gang and colleagues have recently proposed some complex morphological descriptors of the P-wave for prediction of AF risk in post-CABG patients, based on singular value decomposition of the ECG signal (Gang et al., 2004). These descriptors take into account global shape abnormalities and dissimilarities between shapes in individual leads. These parameters increased in AF patients, showing morphological alterations in this group, but failed to independently predict postoperative AF. A polynomial representation of P-wave was implemented by Clavier and colleagues, who developed a method for automatic analysis of the P-wave based on the use of a hidden Markov model and wavelets transformation (Clavier, Boucher, Lepage, Blanc, & Cornily, 2002).

A polynomial interpolation can only partially represent details in P-wave morphology that are thought to reflect the atrial conduction abnormalities, and degrees higher than the fourth generate waveforms that do not have a limited temporal extension, a characteristic that is indeed preserved by a linear combination of Gaussians. In addition, the Gaussian functions-based model of P-wave proposed in this study has the great advantage of being independent on the definition of P-wave boundaries, thus it can provide useful information in AF risk assessment.

FUTURE TRENDS

A fully automated analysis and quantification of P-wave morphological features could be useful for AF risk stratification, and could improve the sensibility and specificity of screening methods based only on the time-domain approach. Further studies are necessary to confirm the predictive value of the proposed descriptors of P-wave morphological characteristics using bigger population including control patients and prospective follow up of patients with different number and duration of AF episodes.

Electrocardiographic potentials recorded from multiple sites on the torso seem to help in yielding more diagnostic content by extracting information from anatomical regions not interrogated by the most common 12-lead ECG (Yamada, Fukunami, Shimonagata, Kumagai, Sanada, Ogita, Asano, Hori, & Hoki, 1999). The problem of optimal electrode positioning has not an unique solution, since it may depend on the kind of analysis to be performed (e.g., surface map, inverse problem) as well as by the pathology/population to be investigated, as reported by Finlay et al. (2006). However, there is general agreement and there are evidences that more electrodes should be placed on the anterior surface around the precordial area close to the heart. Given our necessity to record the electrical activity of the atria, we decided to place 24 out of 32 electrodes in the upper part of the torso, more concentrated in the area close to the heart; we also provided leads from the lateral zones by placing electrode A1-A4 and A29-A32. Whether this configuration is the optimal lead set for our population was not an objective goes beyond the aim of this study, and will be the objective of future investigations. We found that in many patients, the morphological parameters obtained from vertically aligned electrodes (e.g., A1-A4, A5-A8, and so on..., see figure 1) were rather similar. Interestingly, we found that the most discriminant leads for the morphological parameters are those placed on the right of the torso. Specifically designed configurations could thus be tested, with electrodes distributed also in the lower part of the torso and on the posterior surface, in order to investigate how the morphological parameters depend on the number and location of the leads.

Whether similar results can be obtained using conventional 12-lead ECG or Frank leads may be of clinical interest. Although the method itself can be applied to any lead configuration, our results were obtained using a wide-band, DC coupled, 24 bit resolution acquisition system with active electrodes. The impact of these technical features on the extracted parameters needs a deeper investigation.

CONCLUSION

Standard approaches for P-wave analysis deal mainly with the analysis of the duration of the P-wave. However, there is the lack of good and accepted definitions of P-wave onset and offset, whose determination cannot be automatic, and has a high interobserved variability.

Indeed P-wave morphology can be effectively modeled by a linear combination of Gaussian functions (i.e., by a Gaussian fitting). In addition, the morphological parameters extracted from the Gaussian function-based model of the P-wave can identify patients having low and high risk of developing AF.

KEY TERMS

Atrial Fibrillation: Cardiac arrhythmia involving the atria, which are exited by irregular disorganized electrical impulses, causing atria not to regularly contract.

Automatic Quantification: Extraction of numerical information by an algorithm, without the intervention of an operator.

Gaussian Fit: Fitting procedure using Gaussian functions.

Morphological Quantification: Extracting numerical information associated to the morphology of the signal examined.

Multisite ECG Mapping: Electrocardiographic acquisition from multiple sites.

P-Wave: ECG wave associated to the atrial depolarization.

P-wave Abnormalities: Irregularities on the P-wave normal morphology.

Balancing the Capacity in Health Care

Lars Odd Petersen
Danish Institute for Health Services Research, Denmark

INTRODUCTION

Diagnostics and treatment of patients often involve several different clinics. When improving quality and efficiency in health care we therefore need to consider the entire pathway from the patient's first contact with a health institution until the final discharge from the hospital and rehabilitation after the end of treatment. A system view is needed to consider the stochastic nature of acute patient arrivals, the variety of pathways through the clinics, and the stochastic time needed for diagnostics and treatment.

A balancing of the capacity at the different clinics, in order to deliver health care services in due time, to improve the overall productivity or use of capacity, calls for a reallocation of resources. A successful accomplishment of such a process requires a common insight and agreement by the clinics and therefore representatives from the clinics participating in the analytical process. The clinician participation enables elucidation and use of information on organisational behaviour of importance for the daily operations. This type of information does not appear from the registered patient data and implies analytical tools, which are both simple and intuitive and capable of handling and displaying the type and amount of information needed in a trustworthy and consistent way.

BACKGROUND

Different concepts for organisational improvements developed in an industrial environment have been introduced to—and applied in—the health care sector over the years. We shall briefly comment on four of them.

In Business Process Reengineering (Hammer & Champy, 1993), a fundamental rethinking and radical redesign of business processes is in focus. The word processes is the keyword. It is also the word that gives corporate managers the greatest difficulties. Most business people are not "process-oriented." They are focused on tasks, on jobs, on people, on structures, but not on processes. A business process is defined as a collection of activities which takes one or more kinds of inputs and creates an output of value to the customer.

An indispensable tool in Business Process Reengineering is process mapping (Johanneson, McHugh, Pendlebury, & Wheeler, 1993). Competitive realignment through identifying and exploiting "Break Points" is achieved by reengineering core business processes. This, in turn, requires an extensive understanding of the activities which constitute the core business processes and the processes which support them, in terms of their purpose, trigger points, inputs and outputs, and constraining influences. This understanding can be achieved by "mapping," "modelling," and then measuring the processes using various techniques that have been developed and refined over the years from simple flow diagrams to advanced simulation modelling charts.

With total quality management (TQM), inspired by Deming's "Out of the Crisis" (Deming, 1982) followed a systematic work describing goals for quality, preventing adverse events, monitoring quality, and constant improvements in quality. In health care many efforts to improve the quality are based on developing care pathways (deLuc, 2001), which specify how the patients' flow through the health organisation should be in order to achieve good quality. From mapping the pathways for the various types of patients, good quality is specified, actually delivered quality is monitored and ways to improve the quality are constantly considered. Mapping and diagramming are important ingredients here too. In TQM, the system's view is in focus as well. It is a mistake to assume that if everybody does his job, it shall be all right. The whole system may be in trouble. In much of the TQM activity in health care, the aim is to specify good quality in standard pathways. However, the capacity needed to deliver the desired quality is very seldom brought into focus.

The concept of the Learning Organisation (Senge, 1990) is to a considerable extent based on systems thinking and mapping tools such as the "Causal Loop

Diagram (CLD)" and the "Stock and Flow Diagram" (SFD). Both types of mapping are core elements in the modelling theory called System Dynamics (Sterman, 2000). According to the ideas of the Learning Organisation, the diagrams play an important role in involving the managers and employees in the efforts to improve the organisation. Its abilities to elicit peoples' mental models of how things are run in their part of the organisation, to share information and different views and to clarify necessary conditions for organisational improvements is stressed. With the CLDs and SFDs it is possible to pick up most of the soft and hard data (information) about how the organisation works. In relation to the SFDs, several simulation programmes have been developed to handle and apply the organisation's knowledge consistently in simulating the consequences of organisational changes before their implementation.

In Lean Thinking (Womack, Jones, & Roos, 1990), there is a focus on the value stream, for example, the flow of patients from the contact before diagnosing to the end of treatment. If the work in the organisation does not create value for the patients, it is regarded as waste and should be eliminated or at least reduced to a minimum. The same goes for obstacles preventing a continuous flow of patients in the process of diagnosing and treating.

Despite the differences explained in this short and not necessarily exhaustive list of concepts for organisational improvements, they have much in common when it comes to the mapping tools and techniques. When dealing with changes in health care organisations, I agree with those (Hsieh, Tan, & Lin, 2003; Reidd, Compton, Grossmann, & Fanjiang, 2005) who stress the importance of using a system approach and selecting tools which enable the analyst to work with a system rather than independent entities, that is, departments and processes.

The need in health care to do analysis from a systems perspective, implying the use of hard, soft, and stochastic data, in a coherent and consistent process of analysis and the involvement of clinicians in the modelling process, lead us to focus on the systems thinking (system dynamic) tools.

One can find recommendations from clinical professionals for using systems thinking as a tool for development in the health care sector in general (Beirema 2003; Nolan 1998), and system dynamic is applied in various health care contexts such as accident and emergency departments (Lane, Monefeldt, & Lund, 2000), queuing problems (Waaler & Iversen, 1998), waiting lists (Gonzales-Busto & Garcia, 1999; Van Ackere & Smith, 1999), and in the development of new health care initiatives (Homer, Hirsch, Minniti, & Pierson, 2004; Wolstenholme, 1999). The documentation of the applicability of system dynamics in health care is increasing. In a resent publication from the U.S. Academy of Science System Dynamics is on the list of systems engineering tools recommended for use in the process of improving the health care sector in the country (Reidd et al., 2005).

THEORY AND METHODOLOGY

As a modelling approach system dynamics has three characteristics (Lane, 2000). First is the use of "feedback loops." They are present in every system and often identified and visualised in simple causal loop diagrams. In health care, it is often reasonable to let these diagrams show the flow of patients and the variables or information controlling the flow—such as the capacity or the utilisation of capacity. In general terms, they show how information is followed by controlling action based on policies, followed by a new information collection. These closed loops of causal links involve delays and nonlinear relationships.

The second characteristic is computer simulation. Although humans can conceptualize system structure and loops, they lack the cognitive capability to deduce the consequent dynamic behaviour of the system without assistance. Computer simulation is therefore used rigorously to deduce the behavioural consequences over time of the hypothesized causal network (flow of patients). Such behaviour sometimes turns up to be counterintuitive, and may be explored further using simulations models.

The third and last characteristic is the need to engage in mental models. The most important information about social institutions is only held as "mental models," and is not written down. These mental models are complex and subtle, involving hard, quantitative information, and more subjective or judgemental aspects of a given situation. Such models are the basis for organisational decision-making. Hence eliciting, debating, and facilitating change in the mental models of decision-makers can result in improved ways of managing a system. Modelling work must therefore be carried out in close proximity to problem owners, who are then able to see that their mental models are reflected in a computer model.

A distinguishing feature of system dynamics is the use of various methods for mapping to conceptualise, represent, and communicate the underlying models. Although there is a range of mapping approaches in use in the world of system dynamics, two methods are overwhelmingly accepted by the international system dynamics community. First, broad representations of variables and feedback structure of a model are conveyed using "causal loop diagrams" (CLD). In contrast, "stock/flow diagrams" (SFD) are more detailed, discriminating both state and flow variables.

"System dynamics" uses models to explore the link between system structure and time evolutionary behaviour. The aim is to elicit and develop the mental model of the system in focus, to explain system behaviour by providing a causal theory, and to use that theory as the basis for interventions into the system structure which will then change the resulting behaviour mode.

In Figure 1, an example of CLD is shown. An increase in the arrival of planned and acute patients makes the number of beds occupied increase ("+"). With a certain number of beds available, the use of beds will increase too and when beds used reaches the number of beds usually available, extra beds from other wards are asked for. In case of extra beds available, the total bed capacity is increased and the use of bed capacity decreases ("-"). If no extra beds are available, there is an opportunity either to decrease the number of planned patients called in for treatment or to force the discharge of patients, that is, by decreasing the average length of stay.

Figure 1 represents a typical example of the use of hard and soft data. The soft—but still quantitative part—is the specification of how they react in the bed ward when the use of capacity is above an acceptable level. In Figure 1, three loops are marked with the symbol "(-)" expressing that the loops are stabilising or balancing. Here it means that when the bed ward is under pressure (a high use of bed capacity), they react in one or several ways to compensate for that pressure.

In system dynamics there are two types of causal links ("+", "-") and three types of variables. Some variables are changed only by "flows" accumulating into or draining out of them. Such variables are the "state variables" of the model (called "stocks" or "levels"). In contrast, the quantities of the flows (called "rates" or "flows") are instantaneously causally established by "information links" from "ordinary variables" and other state variables.

Figure 2 shows a stock and flow diagram of the system mapped in Figure 1. The dynamic simulation software package I think is applied in making the diagram. Planned and acute patients flow into the department treating the patients. After staying there for a while—determined by the actual length of stay—the patients are discharged. The length of stay can change when the use of capacity is too high. The other two options for system stabilising reaction are also shown in Figure 2.

Beds occupied and the total bed capacity are both represented by a stock symbol (rectangular). The flow

Figure 1. Example of causal loop diagram (CLD)

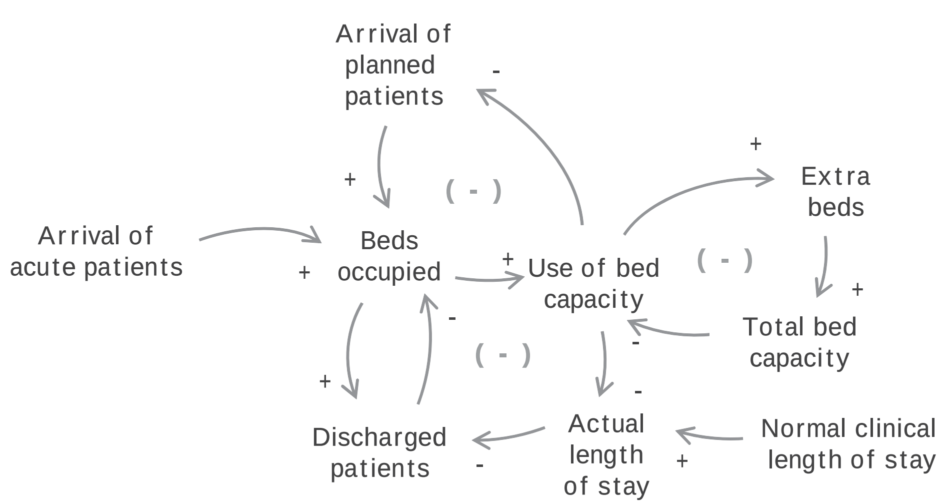

Figure 2. Example of stock and flow diagram (SFD)

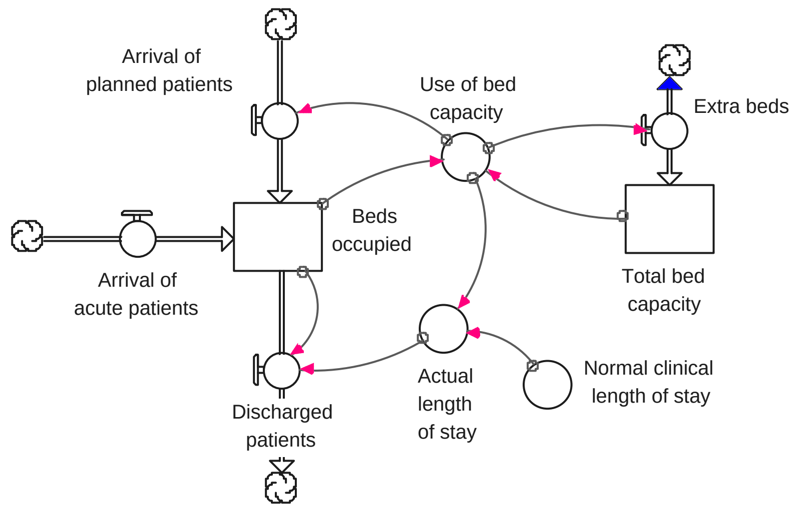


symbol (valve) is applied to represent the flow of patients in and out of the bed ward. Extra beds are also shown as a flow variable that either increase or decrease the total capacity. The other (auxiliary) variables shown in Figure 2 are represented by a circle and hold the logic or information needed to make the system of stocks and flow running.

The advantages of CLDs are the very limited library of symbols and the concentration on loop structure. As conceptualisation tools they are simple, easy and enjoyable for nontechnical people to use.

The SFDs offer a much sounder basis than CLDs for the rigorous deduction of dynamic behaviour.

In this section, it is argued for the choice of System Dynamics as the methodological basis in the analysis of the capacity in health care organizations. The System Dynamic tools—CLD and SFD—are introduced and their applicability in a health care context is illustrated.

In the following section, we describe how System Dynamics tools are applied in a case. Afterwards, the use of SD in the analysis and in health care analysis in general is evaluated and discussed.

CASE

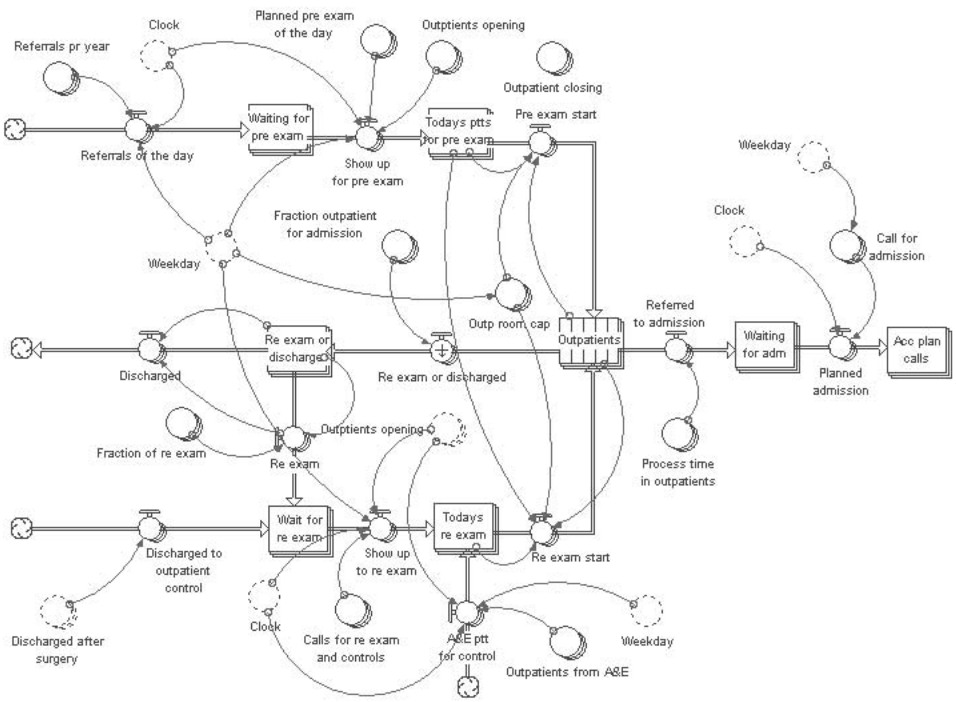
The mapping presented above was applied at a local hospital in the Copenhagen Metropolitan Area in an analysis of the surgical capacity with the intention to find out the extent to which the daily operations in the surgical departments could be improved. A benchmarking process had indicated a potential for improvements. The hospital had two surgical specialities—orthopaedics (O) and gastroenterology (G)—both sharing the same surgical department with four theatres (operating rooms) and a recovery section with four beds.

The analysis was carried out in collaboration with representatives from the surgical departments, anaesthetics, the operation theatres, and administration and assisted by an external consultant. Together they formed a working group. A small group of secretaries prepared the information for clarification in the working group and other specific tasks during the process such as data processing, mapping and computer modelling.

At a number of meetings in the working group during the autumn of 2004 the mapping of the surgical operations was done. This included drawing diagrams, going through quantitative data describing the operational details and deciphering the qualitative information about the behaviour in the system. During the process the daily operations were evaluated, and through the use of a simulation model, proposals for changes were described.

Figure 3 is a visual representation of one part of the model—the outpatient clinic—built up by using stock and flow symbols. Wards, Operating Theatres, Recovery and Accident, and Emergency are modelled in the same way but not shown in Figure 3. The stocks represent the number of patients in a certain stage in the patient flow—for example the number of patients waiting to be admitted, the number of patients in a ward or the

Figure 3. Visualisation of the outpatient clinic part of the simulation model



accumulated number of patients admitted. The large arrows (flows) represent the flow of patients going from one stage to another—for example, patients referred to the waiting list for admission. The circles represent variables in the model influencing the flow or logical relationships between internal variables such as stocks and flows and external parameters. Dashed symbols are copies of other variables. These are useful when one wishes to split the model into sections.

The flow of planned patients is seen as incoming referrals. All of them are called in for a pre-examination when capacity in the outpatient clinic allows it.

At first the model is used to calculate the actual figures describing the daily operation at the surgical departments. Comparing the recorded numbers with the simulated data of the actual operation showed a satisfying similarity.

From going through the operational details, numbers, and from modelling the actual daily operations, it was concluded that it should be possible to obtain a better balance in the use of capacity through

1. An improved flow of patients in theatres
2. A more flexible allocation of theatre capacity between specialities
3. A reduced length of stay on recovery
4. More beds in recovery
5. Accelerating the patient flows in department O by implementing Joint Care

From these initiatives, the model showed that it should be possible to increase the number of planned admissions of O patients by 36% and reduce the number of periods in recovery with more patients than allocated beds by approximately 25%.

FUTURE TRENDS

Concepts for organizational development emerge and many almost vanish after some years. Though the changes follow the fashion of management in appearance, some of the interior parts in shape of tools for mapping and analysing seem to recur in new versions often due to the PC development.

For decades examples has shown how health care can benefit from using operational management tools such as queuing theory and simulations in determining the level of capacity, improving the use of capacity, and many other managerial challenges (Bolling, 1972;

Schmitz & Kwak, 1972). Years of experiences tend to point to simulation as the tool that best can handle models that are able to contribute to the solutions of the managerial challenges in health care (Elkhuizen, van Sambeek, Hans, Krabbendam, & Bakkar, 2007; Koizumi, Kuno, & Smith, 2005).

When the U.S. Academy of Sciences reported from a committee's work where health care professionals together with engineers have identified systems engineering tools and technologies that could help the health system to overcome the poor performance in health care, they came up with a list where both queuing methods and simulations figured on the list (Reidd et al., 2005).

The health care sector as a whole has been reluctant to embrace these tools, even though they have been shown to yield valuable returns to the small but growing number of health care organisations and clinicians that have applied them. Relatively few health care professionals or administrators are equipped to think analytically about health care delivery as a system. Widespread use of systems-engineering tool therefore will require efforts such as the following from the Academy report:

- Incentives for health care providers to use system tools to improve the quality of care and the efficiency of care delivery
- Dissemination efforts by organizations that have used or promoted system-engineering tools in the health care delivery
- Support in the form of textbooks, instructional software, and other tools to train individual providers in the use of system-engineering tools
- Support for research to advance the application and utility of systems engineering in health care delivery
- Health care providers should ensure that current and future health care professionals have a basic understanding of how systems-engineering tools work and their potential benefits
- Support programs to educate and train present and future leaders and scholars in health care, engineering, and management in health systems engineering and management.

CONCLUSION

Although the case concerns a Danish hospital, it should be stressed that the problem of balancing the department capacities in a hospital is general. The numerous reports from using Operations Management in health care (Visser & Beech, 2005) show that even though modern hospitals around the world are not identical, they have very much in common. All over there are surgical and medical departments with various specialities, outpatient clinics, operations theatres, recovery rooms, intensive care units, and clinical service departments such as x-ray and laboratory. And they all face the challenge of balancing the capacity across departments in order to make a maximum flow of patients without local departmental bottlenecks. Therefore the use of SD illustrated by the Danish hospital case is relevant and applicable in hospitals in general.

An analysis, like the one described in this article, does require a lot of information and hard data about the daily operations. Clinicians often find it time consuming, and sometimes they doubt that it is necessary to go through all the data. Approaching the business of hospital employees from slightly new angles induces a natural scepticism among clinicians in particular. Especially when the data bring forward a picture of the daily operation that in some cases differs from their own mental models. This raises a lot of questions and time is needed to go through it thoroughly. If the analysis is aimed at achieving a common view of what can be improved and how, then those who will be responsible for implementing the recommendations from the analysis have to make sure that the analysis is based on the best information available. Therefore, very often, it does take time to bring out relevant data for this type of analysis.

The lack of available specific operational data also points out that something is missing in the management information and balanced scorecard at hospitals today. It is a little worrying to realise that many decisions about reorganising hospitals are made without the necessary operational data available. This local observation is a problem of a much larger proportion according to, for example, the American Academy of Science (Reid et al., 2005) that stress the lack of a system view in health care.

Regarding the use of models in balancing the surgical capacity in a hospital and many other important decisions to be made in health care, the clinicians' scepticism may be justified. Can these kinds of models be trusted? Should not the model be validated even further to make sure that it can handle all types of changes in a hospital? Our answer to a great extent follows Sterman (Sterman, 2000, p. 890),

All models are wrong, so no models are valid or verifiable in the sense of establishing the truth. The question facing clients and modellers is never whether a model is true but whether it is useful. The choice is never whether to use a model. The only choice is which model to use. Selecting the most appropriate model is always a value judgment to be made by reference to the purpose. Without a clear understanding of the purpose for which the model is to be used, it is impossible to determine whether you should use it as a basis for action.

System Dynamics is a general method for analysing and obtaining insight of systems and systems behaviour (Sterman, 2000). Therefore the tools (mapping and modelling), as mentioned, are very much applicable in other cases, where the flow of patients is in focus. The U.S. Academy of Science stresses that the health care sector is in need of system engineering tools in an effort to make improvement and System Dynamics is one the of tools recommended (Reidd et al., 2005).

What we seek when doing the modelling is consistency and the opportunity to evaluate the different proposals for improvement in broader terms rather than to derive an estimate of the expected effect with a probability of 95%.

As mentioned, it seems that the different concepts for organisational improvements have much in common when it comes to the tools and techniques for mapping. System Dynamics modelling techniques are presented as tools for making Business Process Reengineering (Spurr, Layzell, Jennison, & Richards, 1993), and there are similarities in the way we have used the ideas from System Dynamics and The Learning Organisation and the presentation of Lean Production (Bicheno, 2004).

Mapping is emphasized as an important tool in Lean. Nevertheless, Womack et al. (1990) (Rother & Shook, 2003) report that many well-intended initiatives get a poor result because the mapping exercise is skipped. A glance on some of the Lean references in the Health Care Sector (Jimmerson, Weber, & Sobek, 2004; Laursen, Gertsen, & Johansen, 2003; Lean), in our view, confirm the evaluation of Womack et al. (1990). There is room for improvements in the mapping part of Lean implementation. System Dynamics offers tools for mapping that integrate the visual clarification and mutual understanding of the system (value chain or patient flow) with the succeeding collection of data and modelling. This is an integration that secures a consistent use of organisational knowledge in suggesting and implementing proposals for improvements.

KEY TERMS

Balancing Health Care Capacity: Coordinating the capacities for the operational units involved in flow of patient in order to avoid bottlenecks and to secure a high rate in capacity usage.

Simulation: Calculating systems or health care organizations operational behaviour based on a mathematical model describing the system and with varying values for central parameters in the model.

System Dynamics: A methodology for studying and managing complex feedback systems, such as one finds in business and other social systems.

System View: An expression that is meant to remind you that you should focus on the whole system and to prevent you from (sub-) optimizing parts of it.

Visualization: Making maps showing the patient flows and central variables controlling the flows. Through the maps, different actors in the health care organizations elicit their common mental model of the system under consideration.

B

Biomedical Data Warehouses

Jérôme Darmont
University of Lyon 2, France

Emerson Olivier
University of Lyon 2, France

INTRODUCTION

With the growing use of new technologies, health care nowadays is undergoing significant changes. The development of electronic health records will indeed help enforce personalized, lifetime health care and presymptomatic treatment, as well as various analyses over populations of patients. Information-based medicine has to exploit medical decision-support systems and requires the analysis of various, heterogeneous data, such as patient records, medical images, biological analysis results, and so forth (Saad, 2004).

Data warehousing technologies (Inmon, 2002; Kimball & Ross, 2002) are now considered mature and can form the base of such a decision-support system. Although data warehousing primarily allows the analysis of numerical data, its underlying concepts remain valid for what we term *complex data*. To summarize, data may be qualified as complex if they are (Darmont, Boussaïd, Ralaivao & Aouiche, 2005):

- **Multiformat:** Represented in various formats (databases, texts, images, sounds, videos) and/or
- **Multistructure:** Diversely structured (relational databases, XML document repositories, file collection) and/or
- **Multisource:** Originating from several different sources (distributed databases, the Web) and/or
- **Multimodal:** Described through several channels or points of view (radiographies and audio diagnosis of a physician, data expressed in different scales or languages) and/or
- **Multiversion:** Changing in terms of definition or value (temporal databases, periodical surveys with evolving items)

In this context, the warehouse measures (although not necessarily numerical) remain the indicators for analysis, and analysis is still performed following different perspectives represented by dimensions. Large data volumes and their dating are other arguments in favor of this approach (Darmont, Boussaïd, Bentayeb, Rabaseda & Zellouf, 2003). Data warehousing also can support various types of analysis, such as statistical reporting, online analysis (OLAP), and data mining.

The aim of this chapter is to present an overview of the existing data warehouses for biomedical data and to discuss the issues and future trends in biomedical data warehousing. We illustrate this topic by presenting the design of an innovative, complex data warehouse for personal, anticipative medicine.

BACKGROUND

The first family of medical data warehouses we identify are repositories tailored for supporting data mining (Miquel & Tchounikine, 2002; Prather, Lobach, Goodwin, Hales, Hage & Hammond, 1997; Sun, Huang, Horng, Huang & Tsou, 2004; Tchounikine, Miquel & Flory, 2001). However, since data mining techniques take attribute-value tables as input, some of these warehouses (Prather et al., 1997; Sun et al., 2004) do not bear the multidimensional, starlike architecture that is typical in data warehouses. This modeling choice precludes OLAP navigation and is not very evolutionary; new analysis axes, or dimensions, cannot be easily plugged into the warehouse.

The most "canonical" medical data warehouse among these proposals is a cardiology data warehouse (Miquel & Tchounikine, 2002; Tchounikine et al., 2001). Its aim is to ease medical data mining by integrating data and processes into a single warehouse. However, raw sensor data (e.g., electrocardiograms) are stored separately from multidimensional data (e.g., patient identity, therapeutic data), while it might be interesting to integrate them all.

A second family is constituted of biological data warehouses that focus on molecular biology and genetics (Engström & Asthorsso, 2003; Eriksson & Tsuritani, 2003; Schönbach, Kowalski-Saunders & Brusic, 2000; Shah, Huang, Xu, Yuen, Ling & Ouellette, 2005; Sun et al., 2004), and bear interesting characteristics. For instance, some of them include metadata and ontologies from various public sources such as RefSeq or Medline (Engström & Asthorsso, 2003; Shah et al., 2005). The incremental maintenance and evolution of the warehouse is also addressed (Engström & Asthorsso, 2003). However, the particular focus of these approaches makes them inappropriate to more general needs, which may be both different and much more diversified.

Eventually, Boussaïd, Ben Messaoud, Choquet, and Anthoard (2006) recently proposed an eXtended Markup Language (XML) based methodology named X-Warehousing for warehousing complex data. This approach has been applied on a corpus of patient records extracted from the Digital Database for Screening Mammography[1]. The warehouse is a collection of XML documents representing OLAP facts that describe suspect areas in mammographies. It aims at breast cancer computer-aided diagnosis.

A COMPLEX DATA WAREHOUSE FOR PERSONALIZED, ANTICIPATIVE MEDICINE

Context and Motivation

Dr. Jean-Marcel Ferret, former physician of the French national soccer team, is the promoter of the personalized and anticipative medicine project. His aim is to extend results and empirical advances achieved for high-level athletes (not only soccer players) to other populations and to make the analyzed subjects the managers of their own health capital by issuing recommendations regarding, for example, life style, nutrition, or physical activity. This is meant to support personalized, anticipative medicine. In order to achieve personalized, lifetime health care and presymptomatic treatment, a decision-support system must allow transverse analyses of given populations of patients and the storage of global medical data such as biometrical, biological, cardiovascular, clinical, and psychological data. It also must be evolutionary in order to take into account future advances in medical research. More precisely, such a system must be able to store complex medical data and allow quite different kinds of analyses to support the following:

1. Personalized and anticipative medicine (in opposition to curative medicine) for well-identified patients;
2. Broadband statistical studies over given populations of patients.

We selected a data warehousing approach to answer this need. A data warehouse can indeed support statistical reporting and cross-analyses along several dimensions. Furthermore, dated personal data can be stored to propose full patient records to physician users. However, data complexity must be handled. For instance, multimedia documents such as echocardiograms must be stored and explicitly related to more classical medical data such as the corresponding patient or diagnoses. Users must be able to display and exploit such relationships, either manually (which is currently the case) or automatically (here, we anticipate the advances of multimedia mining and the development of advanced OLAP operators). The existing research proposals from the literature do not fulfill this requirement. In particular, Tchounikine, et al. (2001) store raw sensor data separately from multidimensional data, only as an archive. Finally, Dr. Ferret had quite an immediate need for an operational, efficient system. Hence, we chose to rely on the efficacy of a relational implementation. Although XML warehousing is particularly appropriate to complex, medical data, the performance of native XML Database Management Systems (DBMSs) is indeed currently not satisfactory for warehousing purposes, both in terms of storage capacity and response time.

In the remainder of this section, we present the global architecture of our medical data warehouse, two examples of simple datamarts (i.e., datamarts that store "simple" data), an example of complex datamart (i.e., storing complex data), as well as implementation issues.

Global Architecture

Our data warehouse is organized as a collection of interconnected datamarts sharing common dimensions. Each datamart stores the data related to a given medical field (e.g., biological analysis results, biometrical data, cardiovascular data, psychological data). These data are described by dimensions. Some are common to all the datamarts (e.g., patient information, dates), and some are specific to a given datamart. The warehoused data originate from diverse providers and are very heterogeneous (e.g., qualitative or numerical data, texts, medical images).

To make our solution evolutionary, we adopted a bus architecture (Firestone, 2002; Kimball & Ross, 2002) for our data warehouse. It is composed of a set of conformed dimensions and standardized definitions of facts. In this framework, the warehoused data related to every medical field we need to take into account represent datamarts that are plugged into the data warehouse bus and receive the dimension and fact tables they need. The union of these datamarts may be viewed as the whole data warehouse (Kimball & Ross, 2002).

Using conformed dimensions (i.e., dimensions that have the same meaning and the same modeling in all the fact tables to which they are linked) helps to guarantee that datamarts are not "stovepipes" that are independent from one another. Hence, when a new aspect of health care (e.g., chiropody) needs to be included in the warehouse, it is easier to plug it into the data warehouse bus.

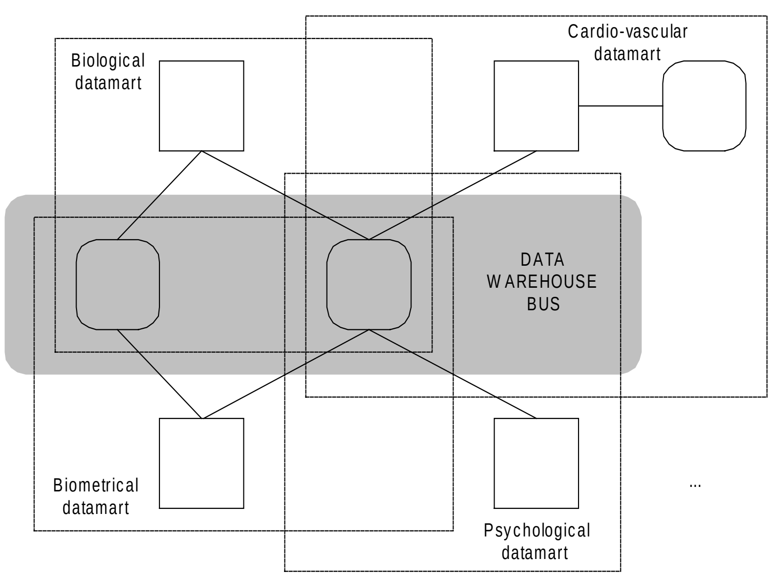
Figure 1 represents the global architecture of our data warehouse. Straight squares symbolize fact tables, round squares symbolize dimensions, dotted lines embed the different datamarts, and the data warehouse bus bears a gray background. It is constituted by dimensions that are common to several datamarts (and thus, fact tables). The main dimensions that are common to all our datamarts are patient, data provider, time, and medical analysis (that regroups several kinds of analyses) (see the next section). Of course, some datamarts (e.g., the cardiovascular datamart) do have specific dimensions that are not shared.

Simple Datamarts: The Biological and Biometrical Datamarts

Input biological data are actually the results of various biological examinations (e.g., biochemistry, protein checkup, hematology, immunology, toxicology, etc.), which are themselves subdivided into actual analyses (e.g., a hematology examination consists in reticulocyte numbering and a hemogram). These data are available under the form of unnormalized spreadsheet files from various sources. They are thus heterogeneous and often refer to the same examination using different terms or abbreviations, use different units for the same numerical values, and so forth. This heterogeneity is dealt with during the ETL (Extract, Transform, and Load) process (see the following implementation section).

Biometrical data are measured during medical examinations. They include weight, height, pulse rate, fat percentage, and blood pressure. Although their structure

Figure 1. Data warehouse global architecture



is simpler than that of biological data, they require a fine granularity that must be taken into account. For example, the weight of an athlete may be measured twice a day, before and after practice. This has an impact on data warehouse modeling. More precisely, it helps in defining the granularity of the time dimension hierarchy (see the following).

Figure 2 represents the architecture of our biological and biometrical datamarts. The biological fact table stores an exam result under the form of a numerical value (e.g., reticulocyte numbering). It is described by four dimensions: patient, time of the examination, data provider (typically the laboratory performing the analysis), and the analysis itself. The biometrical fact table stores numerical biometrical values (e.g., weight). It is described by the same dimensions as the biological datamart, the "analysis" actually representing a measurement. The patient, data provider, time, and medical examination dimensions are thus all shared, conformed dimensions. Attributes in dimension tables are not detailed due to confidentiality constraints.

Note that the medical analysis and time dimensions are further organized into hierarchies to take into account the particularities identified into the source data. Here, biological and biometrical data are distinguished; the simple biometrical data are not normalized nor organized in a hierarchy, while the biological data are. Hence, the description of biometrical facts only appears in the medical analysis dimension table, while biological facts are described further by a hierarchy of biological examinations and categories.

Each datamart is thus modeled as a snowflake schema rather than a simpler, classical star schema. Since the biological and biometrical fact tables share their dimensions, our overall data warehouse follows a constellation schema. In such an architecture, it is easy to add in new fact tables described by existing dimensions.

Finally, although this is not indicated in Figure 2, our data warehouse also includes metadata that help in managing both the integration of source data into the warehouse (e.g., correspondence among various labels or numerical units, the French SLBC biomedical nomenclature, etc.) and their exploitation during analysis (e.g., the interval between which an examination result is considered normal).

Complex Datamart: The Cardiovascular Datamart

Figure 3 represents the architecture of our cardiovascular datamart. The complex nature of source data, which are constituted of raw measurements (e.g., ventricle size), multimedia documents (e.g., echocardiograms), and a conclusion by a physician, cannot be embedded in a single standard fact table. Hence, we actually exploit a set of interrelated tables that together represents the facts, represented as dotted, straight squares in Figure 3.

Figure 2. Biological and biometrical datamarts' architecture

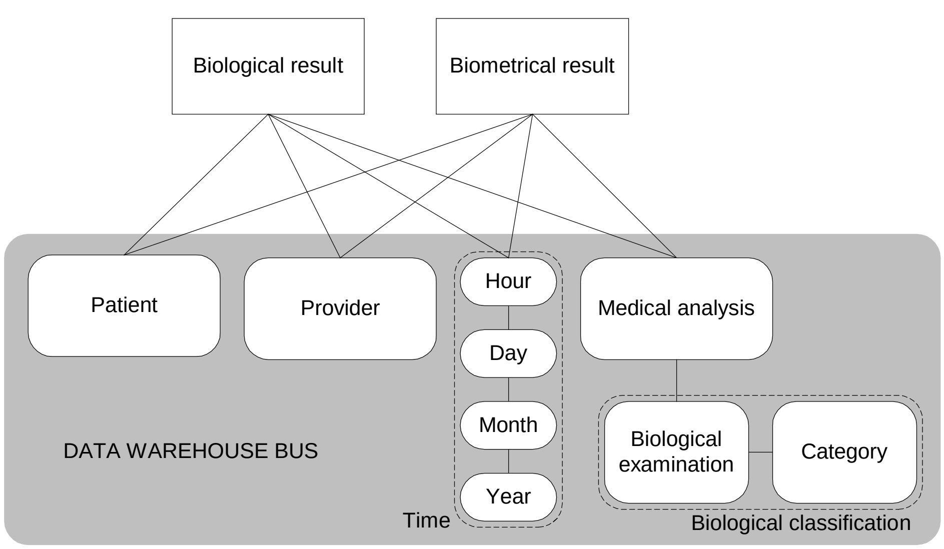


Figure 3. Cardiovascular datamart's architecture

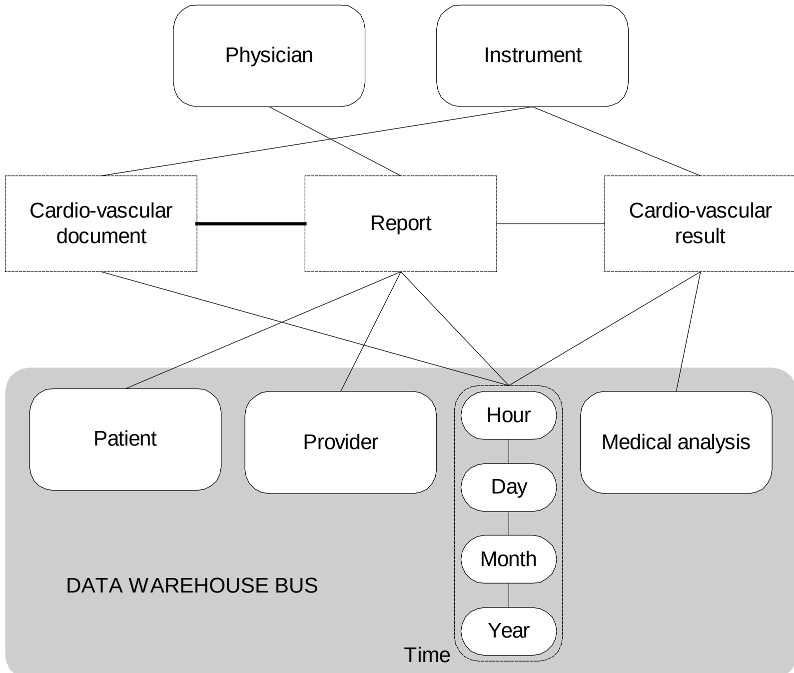

The report mainly contains the physician's conclusion. It is the central element in our "complex fact." It is linked to several numerical analysis results that help build the physician's conclusion. It is also related to multimedia documents such as medical images, which also help in devising the diagnosis. Note that this many-to-many relationship is represented as a bold line in Figure 3. Some documents may indeed be referred to by several reports; for instance, to take into account a patient's evolution over time, through distinct series of echocardiograms. Each component of our "complex fact" may be linked individually to the dimensions. Cardiovascular documents and results are indeed not descriptors of the would-be fact; they are part of a fuzzier fact that is composed of several entities.

Finally, note that cardiovascular documents currently cannot be exploited by OLAP technologies. However, we need to store them and have them accessible for medico-legal reasons. Furthermore, extensions to the usual OLAP operators should make this exploitation possible in the near future.

Implementation

Our data warehouse is meant to be used on an intranet. Hence, we developed a prototype using popular tools that are freely available; namely, the Apache Web server that implements the Secure Sockets Layer (SSL) protocol, which is important for the security of our solution; the MySQL DBMS that is fast and reasonably reliable; and the powerful PHP Web scripting language. This software configuration is sufficient for our prototype and very light and easy to deploy, but we can easily switch one component for a more robust one, if necessary. This is especially true for the DBMS component, since our data warehouse will have to store voluminous complex data.

At the ETL level, in order to achieve the integration of biological data into our data warehouse (biometrical data are much simpler to integrate), we developed a series of scripts that help in extracting the data from the source spreadsheet files, in transforming them so they are consistent with the data already present in the warehouse, and eventually in loading them into the data warehouse. This is currently only a semi-automatic process that proceeds in three steps/PHP scripts:

1. Remove doubles in the input files;
2. Check whether dimension data exist in the data warehouse and create them if not;
3. Transform the data whenever necessary (measure units, dimension key correspondence), and finally, load the data into the warehouse.

Eventually, the first analyses we implemented over our data warehouse are divided into two kinds that correspond to the goals we mentioned earlier: patient-oriented results and statistical analyses over groups of patients. For the first kind of output, our front-end tool includes a patient search engine; the display of a given patient's biological and biometrical data following the biological or biometrical examination dimension, respectively; the visual identification of out-of-norm values; and graphical representations of the evolution of any numerical measure over time.

To achieve the second kind of output, we implemented the notion of group of patients. The user can create, modify, and suppress such groups (e.g., soccer players, back and forward players, etc.); select group members according to various criteria; and eventually compare the various groups through numerical tables and graphs.

FUTURE TRENDS

The need for medical decision-support systems has grown very strong nowadays, and many such systems have been developed. However, most of them store, process, and allow the analysis of "simple" data. Taking complex data into account is now a pressing challenge (Saad, 2004).

We propose in this chapter a solution for warehousing (i.e., storing complex data). Many research perspectives still lie ahead, though. The multimedia data we store are indeed available for display, but we cannot truly analyze them. Developing OLAP and/or data mining techniques that operate on complex data is currently becoming a research field in itself. We could consider, for instance, medical images as a dimension in a medical warehouse. Aggregating such data with clustering-based OLAP operators (Ben Messaoud, Rabaséda, Boussaïd & Bentayeb, 2004) could help in rolling up and drilling down along this dimension.

To achieve this goal, integrating semantic information about the processed complex data is mandatory, and OLAP and data mining techniques must rely heavily on metadata and domain-specific knowledge. The integration of this knowledge into complex data warehouses and, most of all, its exploitation for data analysis, are also exciting challenges.

CONCLUSION

We have presented in this chapter an overview of biomedical data warehousing, particularly focused on the complex data warehouse for personal, anticipative medicine we propose. The aim of this tool is to support both patient-oriented analyses and broadband statistical studies over populations of patients. By adopting a data warehouse bus architecture, we designed our system to be global to take into account several medical fields, and evolutionary to take into account future advances in medical research. We also have briefly presented the prototype we implemented to achieve our analysis goals.

The direct perspectives over this work are twofold. The first one concerns the actual contents and significance of the data warehouse. It involves modeling and adding in new datamarts. The psychology datamart from Figure 1 is already implemented, and more are either currently developed (such as a medical background datamart), being developed, or scheduled. This helps in broadening the scopes of analyses. Other output than statistical reports also are envisaged. Since we adopted a dimensional modeling, OLAP navigation is also definitely possible, and "attribute-value" views easily could be extracted from the data warehouse to allow data mining explorations.

The second kind of perspective is more technical and aims at improving our prototype. This includes automating and generalizing the ETL process on all the datamarts, which is currently an ongoing task. We also follow other leads to improve the user-friendliness of our interfaces and the security of the whole system, which is particularly primordial when dealing with personal medical data.

KEY TERMS

Bus Architecture: Set of conformed dimensions and standardized definitions of facts (Kimball & Ross, 2002). Datamarts "plug into" this bus to receive the dimensions and facts they need (Firestone, 2002).

Complex Data: Data that are not numerical or symbolic (e.g., multimedia, heterogeneous data stored on multiple platforms).

Data Warehouse: Subject-oriented, integrated, time-variant and nonvolatile collection of data in support of management's decision-making process (Inmon, 2002).

Datamart: Logical and physical subset of the overall data warehouse, usually dedicated to a given activity.

ETL: Data warehousing process that includes extracting data from external sources, transforming them and finally loading them into the warehouse.

Information-Based Medicine: Utilizing information technology to achieve personalized health care (Saad, 2004).

OLAP (Online Analytical Processing): An approach for processing decision-support, analytical queries that are dimensional in nature.

INTRODUCTION

Digitization of biomedical signals has been used in several areas. Some of these include ambulatory monitoring, phone line transmission, database storage, and several other applications in health and biomedical engineering. These applications have helped in diagnostics, patient care, and remote treatment. One example is the digital transmission of ECG signals, from the patient's house or ambulance to the hospital. This has been proven useful in cardiac diagnoses.

Biomedical signals need to be digitally stored or transmitted with a large number of samples per second, and with a great number of bits per sample, in order to assure the required fidelity of the waveform for visual inspection. Therefore, the use of signal compression techniques is fundamental for cost reduction and technical feasibility of storage and transmission of biomedical signals.

The purpose of any signal compression technique is the reduction of the amount of bits used to represent a signal. This must be accomplished while preserving the morphological characteristics of the waveform. In theory, signal compression is the process where the redundant information contained in the signal is detected and eliminated. Shannon (1948) defined redundancy as "the fraction of unnecessary information, and therefore repetitive in the sense that if it was missing, then the information would still be essentially complete, or it could at least be recovered."

Signal compression has been widely studied during the past decades, and several references discuss this subject (Gersho & Gray, 1992; Jayant & Noll, 1982; Sayood, 1996).

Signal compression techniques are commonly classified in two categories: lossless and lossy compression. Lossless compression means that the decoded signal is identical to the original one. In lossy compression, a controlled amount of distortion is allowed. Lossy signal compression techniques show higher compression gains than lossless ones.

BACKGROUND

Lossless Compression

Lossless signal compression techniques are less efficient with respect to compression gains. They may be used in combination with lossy compression techniques, especially in cases where the maximum allowed distortion has been reached, and additional compression is needed. Among several lossless compression techniques, we highlight entropy coding (Gersho & Gray, 1992), Run-Length, Huffman (Huffman, 1952), arithmetic coding (Witten, 1987), and delta coding (Ken, 1985).

Run-Length Coding

Data files frequently present sequentially repeated characters (a character run). For instance: text files use several spaces to separate sentences and paragraphs. Digital signals may contain the same value, or the same character representing that value in its data file, repeated many times sequentially. This indicates that the signal is not changing, as in the isoelectric segments of ECG signals, for example.

Figure 1 shows an example of Run-Length coding of a data set that contains runs of zeros. Each time the coder finds a zero in the entry data, two values are written in the output data. The first of these values is a zero indicating that the Run-Length codification started. The second value is the amount of zeros in the sequence. If the run of zeros in the input data set is in average larger than two, then the Run-Length coder will achieve data compression.

Huffman Coding

In Huffman coding, the data are represented as a set of variable length binary words. The lengths depend on the occurrence frequency of the symbols used for representing each signal value. Characters that are used often are represented with fewer bits, and those that are seldom used are represented with more bits.

Figure 2 shows an example of how a Huffman code is generated, given a data set X and its characteristic probability of occurrence—p(X). The character codes are generated by combining the bits of a tree with ramifications, adding their probabilities and restarting the process until only one character remains. This process generates a three with ramifications linked to bits 0 and 1. The codes for each character are taken in the inverse path of these ramifications. Note that initial character arrangement is not relevant. In this example, we chose to encode the upper ramifications with bit 0 and the lower ones with bit 1. However, the opposite representation could have been used as well. Any decision criteria may be used in ramifications with equal probabilities.

Huffman coding has the disadvantage of assigning an integer number of bits to each symbol. This is a suboptimal strategy, because the optimal number of bits per symbol depends on the information content, and is generally a rational number. Arithmetic coding is a more sophisticated compression technique, based on Huffman coding concepts. It results in compression gains closer to the theoretical limits. In this coding, character sequences are represented by individual codes depending on their probability of occurrence. Huffman and Arithmetic codes are often used in combination with Run-Length coding, for further compressing biomedical signals that were first compressed using orthogonal transforms.

Delta Coding

Delta coding refers to signal compression techniques that store a digital signal as the difference between successive samples. Figure 3 shows an example of how this is performed. The first sample in the encoded signal is equal to the first sample of the original signal. Subsequent encoded samples are equal to the difference between the current sample and the previous sample of the original signal.

Using this technique, the encoded signal has a smaller amplitude dynamic range than the original signal. Therefore, it takes fewer bits to store or transmit the encoded signal. Delta coding is a particular case of Differential Pulse Code Modulation (DPCM). DPCM is used in combination with Huffman coders in several biomedical signal compression algorithms.

Lossy Compression

There are two major categories of lossy compression techniques used with biomedical signals: direct methods, and transform compression.

Direct Methods

Direct methods encode signals in time domain. These algorithms depend on the morphology of the input signal. In most cases, these methods are complex, and provide lower compression efficiency than transform coders (discussed in the next section).

Direct compression methods use sophisticated processes and "intelligent" signal decimation and interpolation. In other words, these methods extract K "significant" samples of the original signal x(n), such that:

$$(n, x(n)),\ n = 0,\ldots, N-1 \rightarrow (n_k, x(n_k)),\ k = 0,\ldots,K-1, \qquad (1)$$

where k<N. The reconstruction of values between significant samples is performed by interpolation, using the generic expression (Sörnmo & Laguna, 2006):

$$\hat{x}(n) = \begin{cases} x(n), & n = n_0,\ldots,n_{k-1}; \\ f_{n_0,n_1}(n), & n = n_0+1,\ldots,n_1-1; \\ \vdots & \vdots \\ f_{n_{K-2},n_{K-1}}(n) & n = n_{K-2}+1,\ldots,n_{K-1}-1; \end{cases} \qquad (2)$$

The process of selecting significant samples is based on the characteristics of the signal, and on a tolerance interval criterion for the reconstruction error. The interpolation function $f_{n_{k-1},n_k}(n)$ is generally a low order polynomial, of either zero or first order. These polynomials approximate the original signal with a series of lines connecting the K significant samples. The geometric parameters of these lines (length and inclination) are stored instead of the discarded sample values, resulting in a reduction in the amount of stored or transmitted data.

Transform Compression

Among the several methods for signal compression, the techniques based on transforms yield the best performance in terms of compression gain and fidelity of the waveform of the reconstructed signal.

Given a vector of data $x=[x(1)\,x(2)....\,x(N)]$, we can define an orthogonal transform as a linear operation given by a linear transformation T, such that:

$$y = Tx, \tag{3}$$

where $y=[y(1)\ y(2)\ ...\ y(N)]$ represents a vector of transformed coefficients, and T satisfies the orthogonality condition:

$$T^t = T^{-1} \tag{4}$$

Transform compression is based on a simple premise: when the signal is processed by a transform, the signal energy (information) that was distributed among all the samples in the time domain can be represented with a small number of transformed coefficients.

This can be observed in Figure 4, where an ECG signal is shown along with the correspondent coefficients in transformed domain. In this example, we use the discrete cosine transform (DCT). The DCT is used in the most popular standard for image compression, the *Joint Picture Expert Group* (JPEG).

Note that, in the transformed domain, the energy of the signal is concentrated in a small number of coefficients with high amplitude. Thus, if we store the high-amplitude coefficients, and discard the low-amplitude coefficients, the signal may be represented accurately enough, and can be recovered by inverse transformation. Figure 5 shows the same ECG signal in Figure 4, and the reconstructed signal after discarding 80% of the DCT coefficients. Note that, by storing only 20% of the DCT coefficients it is possible to reconstruct the original signal without visible distortions.

Currently, the most widely used transform for encoding biomedical signals is the discrete wavelet transform (Daubechies, 1988; Mallat, 1989). The wavelet transform is used for image compression—such as in the JPEG 2000 compression standard—and in more recent studies on biomedical signal compression. In this transform, a signal containing N samples is filtered by a pair of filters that decompose the signal into low- (L) and a high- (H) frequency bands. Each band is undersampled by a factor of two; that is, each band contains N/2 samples. With the appropriate filter design, this action is reversible. This procedure can be extended for two-dimensional signals, such as images. In Figure 6, we show an example of wavelet decomposition for a gray-scale image with 256 x 256 pixels. Similarly to what was observed using the DCT, many of the coefficients in the high-frequency subbands have amplitudes close to zero (very dark pixels), and it is possible to compress the image by discarding them.

Wavelet transform compression is evolving with respect to the way in which the coefficients are encoded. When a coefficient in a low-frequency subband is nonzero, there is a high probability that, at positions that correspond to high frequencies, the coefficients are also nonzero. Thus, the nonzero coefficients can be represented in a tree, beginning with a low frequency root. Figure 7 illustrates this concept. A single coefficient in the LL band of layer 1 has a correspondent coefficient in the other bands. The positions of the coefficients in layer 1 are mapped into four daughter-positions in each subband of layer 2.

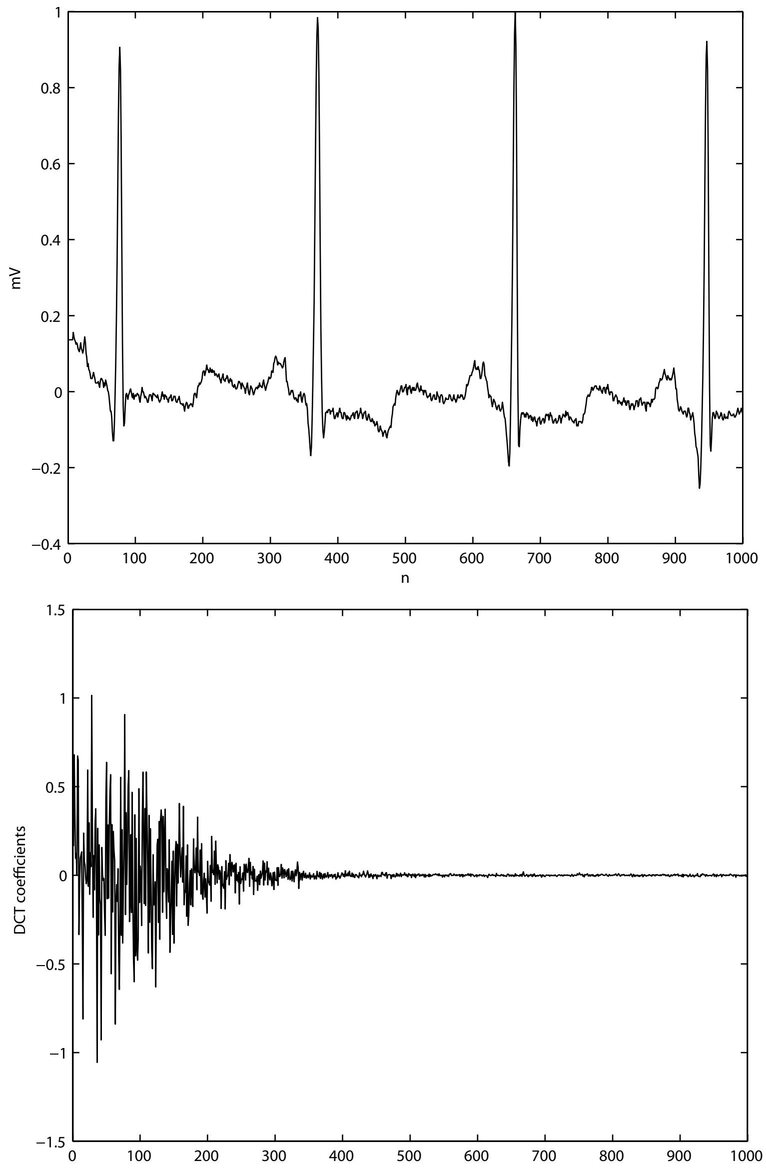
An efficient way of coding the coefficients that are non-zero is to code each tree of coefficients, beginning with the root decomposition level. The coefficients at the lower layers are encoded, and followed by their children coefficients in the higher layer, until a null coefficient is found. The next coefficients of the tree have great probability of also being null, and they are replaced by a code that identifies a tree of zeros (zerotree code). This method is called Embedded Zerotree Wavelet (EZW). Another method, similar to the EZW, and commonly used in the wavelet coefficients encoding, is the Set Partitioning In Hierarchical Tree (SPIHT) (Said & Pearlman, 1996).

COMMENTS ON CURRENT AND FUTURE RESEARCH

The compression of biomedical signals has been extensively studied by the scientific community. In this article, we discuss more thoroughly the compression of electrocardiographic (ECG) and electromyographic (EMG) signals.

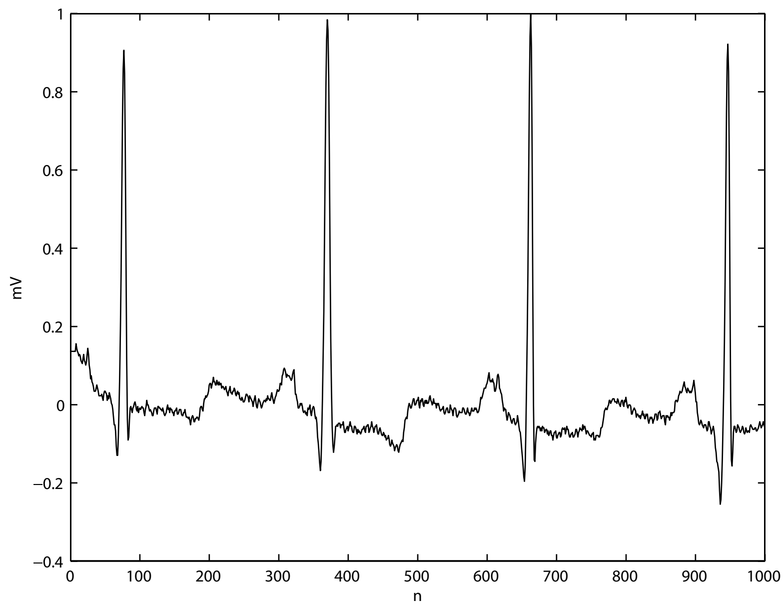
In general, we can group the techniques for compression of ECG signals in two main groups:

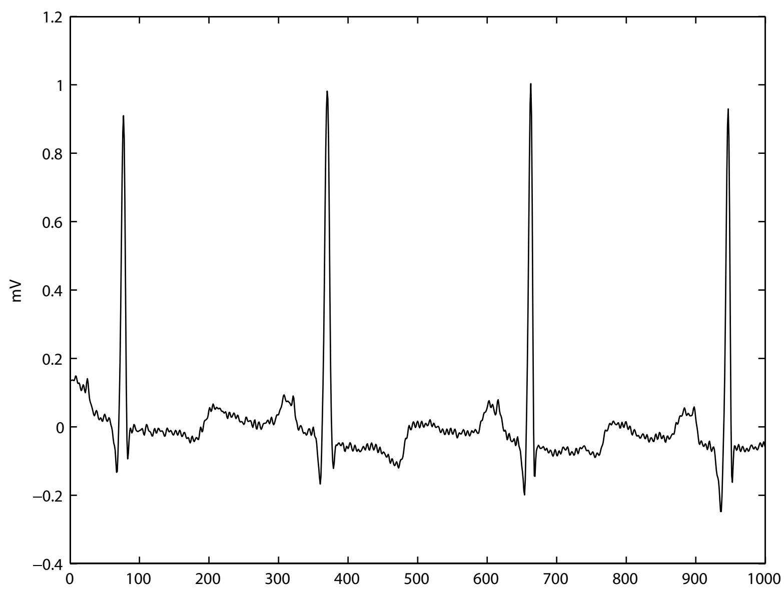
Figure 4. (a) ECG signal (top); (b) transformed coefficients (bottom)



1. Dedicated techniques:
   a. Direct Methods: Amplitude Zone Time Epoch Coding (AZTEC) (Cox, Noelle, Fozzard, & Oliver, 1968), Turning Point (TP) (Mueller, 1978), Coordinate Reduction Time Encoding System (Abenstein & Tompkins, 1982), FAN algorithm (Dipersio & Barr, 1985) and modified time domain coding algorithms, such as SLOPE (Tai, 1991) and Scan Along Polygonal Approximation (SAPA) (Shahein & Abbas, 1994).
   b. Optimization algorithms: Long-Term Prediction (LTP) (Nave & Cohen, 1993), algorithms based on analysis by synthesis (ASEC) (Jalaleddine, 1990), and the Cardinality Constrained technique (Nygaard & Hauglan, 1998).
2. Generic techniques: These techniques can be used with a great variety of signals, including voice, image, and video. This includes Differential Pulse Code Modulation (DPCM), Subband Coding (SC) and transform-based coding (Hilton, 1997; Istepanian, Hadjileontiadis, & Panas, 2002; Lu, Kim, & Pearlman, 2000; Rajoub, 2002).

Figure 5. (a) original ECG signal (top); (b) reconstructed ECG signal after discarding 80% of the coefficients (bottom)





Currently, the algorithms that provide the best ECG compression results use transform-based coding, and the most widely used is the wavelet transform. These algorithms can be grouped, with respect to coefficient encoding, into two main groups: algorithms with coefficient thresholding, and algorithms with tree-based coefficient encoding.

Coefficient thresholding algorithms follow a methodology that was presented in the previous section. The majority of these algorithms also apply lossless compression techniques to encode the wavelet coefficients. One example of this technique is the work by Rajoub (2002).

Tree-based coefficient encoding algorithms use hierarchic structures for encoding the wavelet coefficients, by exploiting the redundancy in the scales of the wavelet decomposition. Such algorithms provide results superior to traditional thresholding algorithms. Among recent works that use this paradigm, we can mention the works of Istepanian et al. (2002), Hilton (1997), and Lu et al. (2000).

Figure 6. Two-dimensional wavelet decomposition

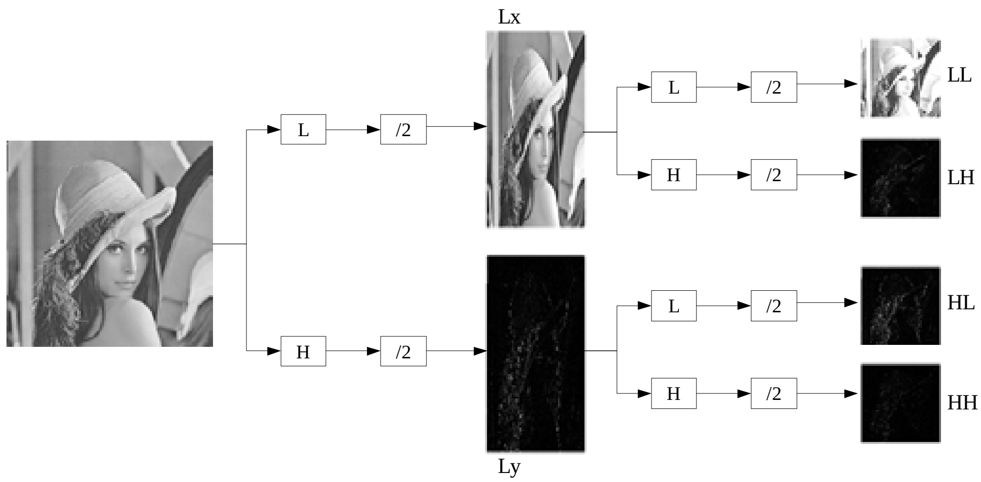


Figure 7. Wavelet coefficients tree

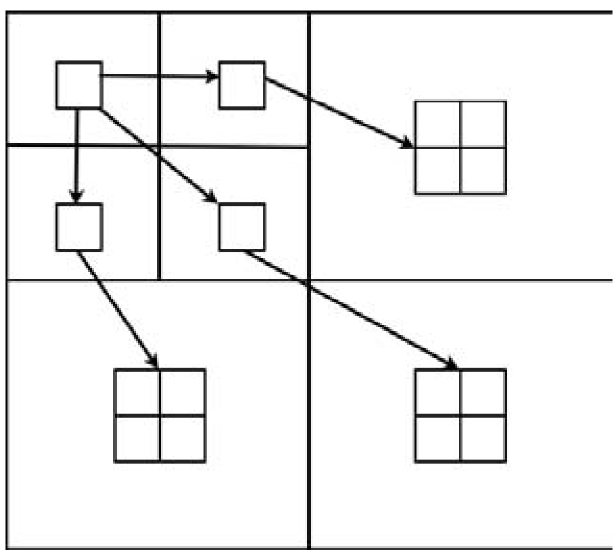

The main techniques described in the literature for EMG signal compression can be found in (Berger, Nascimento, Carmo, & Rocha, 2006; Guerrero & Maihes, 1997; Norris, 2001; Norris, Englehart, & Lovely, 2001; Wellig, Zhenlan, Semling, & Moschytz, 1998). Norris et al. (1995) investigates the compression of EMG signals using Adaptive Differential Pulse Code Modulation (ADPCM). Guerrero and Maihes (1997) compared different methods for lossless compression with methods based on orthogonal transforms. The orthogonal transform based showed better performance, with respect to compression ratio.

Recently, the use of wavelet transform for compression of EMG signals was studied by Wellig et al. (1998), Norris et al. (2001), and Berger et al. (2006). Wellig et al. (1998) and Norris et al. (2001) encoded the transformed coefficient using the EZW algorithm and compared their results with the traditional wavelet transform. Berger et al. (2006) used a scheme for adaptive dynamic bit allocation for encoding the coefficients. These methods provide performance equivalent or better than previously described methods.

Comparing different algorithms for EMG signal compression is difficult, because there is no standard database, such as the *MIT-BIH Arrhythmia Database*, which is used in most studies on compression of ECG signals. The studies on EMG signal compression usually use different test signals, involving different muscles, volume conductors, conduction velocities, loads, sampling rates and duration. Therefore, the comparison between different algorithms should always be analyzed with caution.

The algorithms mentioned in this article have the goal of guaranteeing the fidelity of the reconstructed signal after decoding. In this sense, the wavelet transform and the EZW and SPIHT algorithms are considered by the specialized public as the most promising lines of work, and future research tend to emphasize improvements in these algorithms.

However, reaching a good quality representation of signals with low bit rates comes with the cost of increasing the complexity of the compression algorithms. Few studies on low-cost real-time compression of biomedical signals have been published, even though the interest on telemedicine applications is growing. This is an important issue, which should be addressed in the future. The works by Alesanco, Olmos, Istepanian, and García (2003) and Kim, Yoo, and Lee (2006) proposed the first solutions for real-time ECG compression, and Carotti, De Martin, Merletti, and Farina (2006) a lossy coding technique for surface EMG signals that is based on the algebraic code excited linear prediction (ACELP) paradigm, widely used for speech signal coding. The algorithm was adapted to the EMG characteristics and tested on both simulated and experimental signals. This method is characterized by moderate complexity (approximately 20 million instructions/s) and an algorithmic delay smaller than 160 samples (~160 ms).

CONCLUSION

This article presented a review of techniques for compression of biomedical signals. Among the different techniques that were presented, the ones based on wavelet transforms had the best performance with respect to compression gain and reconstructed waveform fidelity. When the wavelet transform is used, a great challenge is to find effective alternatives for efficiently encoding the transformed coefficients. The most efficient methods for this are the EZW and SPIHT algorithms. An important line of future work is the search for real-time, low-consumption algorithms, which would be suitable for telemedicine applications.

B

KEY TERMS

Arithmetic Coding: A more sophisticated compression technique, based on Huffman coding concepts. It results in compression gains closer to the theoretical limits. In this coding, character sequences are represented by individual codes depending on their probability of occurrence.

Biomedical Signals: Refers to signals that carry useful information for probing, exploring, and understanding the behavior of biomedical systems under investigation.

Delta Coding: Refers to signal compression techniques that store a digital signal as the difference between successive samples. The first sample in the encoded signal is equal to the first sample of the original signal. Subsequent encoded samples are equal to the difference between the current sample and the previous sample of the original signal.

Direct Methods: Encode signals in time domain. These algorithms depend on the morphology of the input signal. Direct compression methods use sophisticated processes and "intelligent" signal decimation and interpolation.

Discrete Cosine Transform: A technique for expressing a waveform as a weighted sum of cosines. The DCT is central to many kinds of signal processing, especially video compression.

Embedded Zerotree Wavelet: A simple, yet remarkable effective, compression algorithm witch exploits the self-similarity of the wavelet transform coefficients at different scales, by structuring the data in hierarchical tree sets that are likely to be highly correlated, yielding a fully embedded code.

Huffman Coding: Refers to a compression technique where the data are represented as a set of variable length binary words. The lengths depend on the frequency of occurrence of the symbols used for representing each signal value. Characters that are used often are represented with fewer bits, and those that are seldom used are represented with more bits.

Lossless Compression: A signal compression technique where the original signal can be perfectly recovered from the compressed signal. The Morse code of telegraphy provides a classic example: by sending short patterns (dots and dashes) for frequent letters, and long patterns for rare letters, fewer bits are needed on the average than with the standard computer representation (ASCII), which assigns the same number of bits to all letters.

Lossy Compression: Compression is lossy if the original signal cannot be perfectly recovered from the compressed file, as a controlled amount of distortion is allowed. Lossy signal compression techniques show higher compression gains than lossless ones.

Run-Length Coding: A lossless compression. A set of symbols is represented as a sequence of RUN/LEVEL. RUN being the number of consecutive zeros and LEVEL being the value of the following nonzero coefficient.

Set Partitioning in Hierarchical Tree: A refinement of the Embedded Zerotree Wavelet algorithm. SPIHT requires partitioning the wavelet coefficients into a number of lists, with list membership changing as the execution proceeds, and in some cases involving dual membership of a coefficient in different lists.

Signal Compression: The reduction of the necessary amount of bits to represent a signal. In many cases, this must be accomplished while preserving the morphological characteristics of the waveform. In theory, signal compression is the process where the redundant information contained in the signal is detected and discarded.

Transform Compression: Compression technique that is based on a simple premise: when the signal is processed by a transform, the signal energy (information) that was distributed among all the samples in the time domain can be represented with a small number of transformed coefficients.

Wavelet Transform: Refers to a transformation where a signal containing N samples is first filtered by a pair of filters that decompose the signal into low and a high frequency bands. Each band is undersampled by a factor of two, that is, each band contains N/2 samples. With the appropriate filter design, this action is reversible.

Biosensors

Sourabh Bansal
Illinois Institute of Technology, USA

INTRODUCTION

Biosensor[1] is a diagnostic tool in which a biological element is used to sense a chemical and its amount in a given sample, and then the sensed information (i.e., data) is transferred to a transducer which converts this signal to electrical signal. In this way, it transforms a biological response into an electrical signal. It also detects, records, and transmits data generated due to physiological change or any chemicals presence in the area being analyzed. The analysis is accurate and reliable.

In other words, biosensor can be termed as a device used in a biological derived sensing element[2] integrated with a physiochemical transducer, producing an electrical signal (Turner, 1996). The resulting electrical signal is a measure of the amount of chemical or combination of chemicals being detected.

Sometimes Biosensors are referred as the living organisms, which are used as a sensor to detect the environmental change.

BACKGROUND[2]

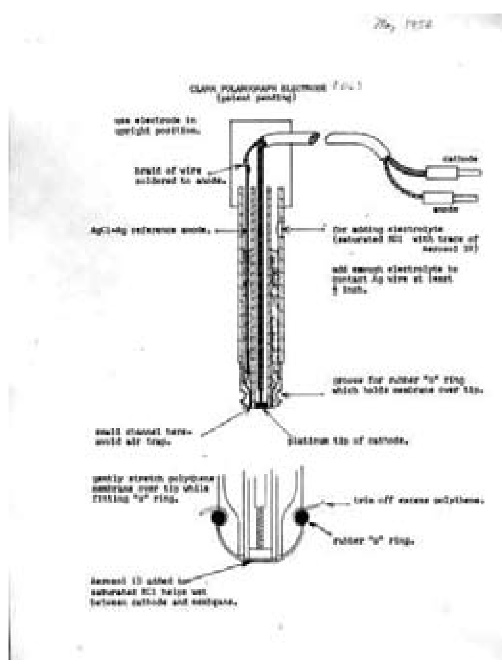
Professor Leland C. Clark Jr. led the foundation of biosensor concept. He was a pioneer in this field. His name will always remain embedded with the concept of *Artificial Blood*[3]. In 1956, Clark ignited the biosensor concept by publishing one of his revolutionary papers on the oxygen electrode (Figure 1).

Soon, Clark invented a device to rapidly determine the amount of glucose present in the blood at a given instant of time. In 1962, at the New York Academy of Sciences symposium, based on his experience and addressing his desire to expand the range of analytes that could be measured in the body, he made an ineffaceable mark by describing how to make electrochemical sensors more intelligent by adding enzyme transducers as membrane enclosed sandwiches. After that, Guilbault and Montalvo described a potentiometric enzyme electrode to sense urea, based on urease immobilized at an ammonium-selective liquid membrane electrode. In 1974, thermal transducers for biosensors were proposed, and were named as thermal enzyme probes and enzyme thermistors respectively.

Soon, Clark's spark was turned into fire in 1975 with the successful launch of Yellow Springs Instruments Company glucose analyzer, based on the amperometric detection of hydrogen peroxide. In the same year, a paper regarding utilizing bacteria as the biological element in microbial electrodes for the measurement of alcohol was presented by Divis. Later, during the same year, Lubbers and Opitz introduced the term "optode" to describe a fiber-optic sensor with immobilized indicator to measure Carbon dioxide or oxygen. Commercial optodes are very well used in vivo measurements of pH, pCO_2 and pO_2. After that, a lot of ideas were floating, but as the time passed, they sank.

In 1982, Shichiri was the first one to describe the first needle-type enzyme electrode for subcutaneous implantation. In 1984, Cranfield Biotechnology Centre, from Cranfield University, published a paper on the use

Figure 1. The Clark polarograph electrode



of ferrocene and its derivatives as an immobilized mediator for use with oxidoreductases in the construction of inexpensive enzyme electrodes. In 1987, based on this, MediSense (Cambridge, USA) launched screen-printed enzyme electrodes with a pen-sized mater for home blood-glucose monitoring. Today, 18.2 millions of diabetic people in USA[4] depend on Clark's original glucose sensor concept for self-monitoring.

BASIC STRUCTURE OF BIOSENSOR[5]

Biosensor comprises of a biological element which is connected to a transducer, which in turn is connected to electronics, which can process the received information, and then finally display it. The illustrated version has been demonstrated in Figure 2.

A most common example of a biosensor for the detection of glucose in a sample (blood) can be seen in Figure 3.

Glucose oxidase enzyme (GOx) in glucose molecule is converted to hydrogen peroxide (H_2O_2) and gluconic acid ($C_6H_{12}O_7$) within the biolayer. The H_2O_2 passes through all the layers in the path, and is detected at platinum electrode. The electrode senses it, and the current is thus produced, which is then processed further, and is passed on to the display unit to show the concentration of glucose in given sample.

CLASSIFICATION OF BIOSENSORS[5]

Broadly biosensors can be classified according to Transducers, bioactive components, or immobilization techniques used in the biosensor. Detailed classification of Biosensors has been illustrated in Figure 4, 5 and 6.

Transducer used can be Electromechanical, optical, piezo-electrical, or thermal. Bioactive components can be enzymes, antibodies, cells, nucleic acids, or lipids. Immobilization techniques can be physical or chemical.

CURRENT AND FUTURE DEVELOPMENTS IN BIOSENSORS

Biosensor is the one of the most rapidly growing fields now-a-days. Its current developments and focus is mainly towards the health care area. In spite of its tremendous potential, many of the developments in Biosensors are still not commercialized. As of now, mostly single analyte devices are present; however, in the future, multianalyte sensor will be there. Research and development in biosensor field is very rapid, and lot of potential is there in coming years:

- Routine analytical measurement of folic acid, biotin, vitamin B12, and pantothenic acid[6].
- Remote sensing of airborne bacteria (e.g., in counter-bioterrorist activities[6]).
- Most of the research is going on in the development of noninvasive devices strips to diagnose diseases[7].
- Medical telesensor is in development phase, consisting of an array of chips to collectively monitor bodily function such as blood pressure, oxygen level, pulse rate, and body temperature[8].

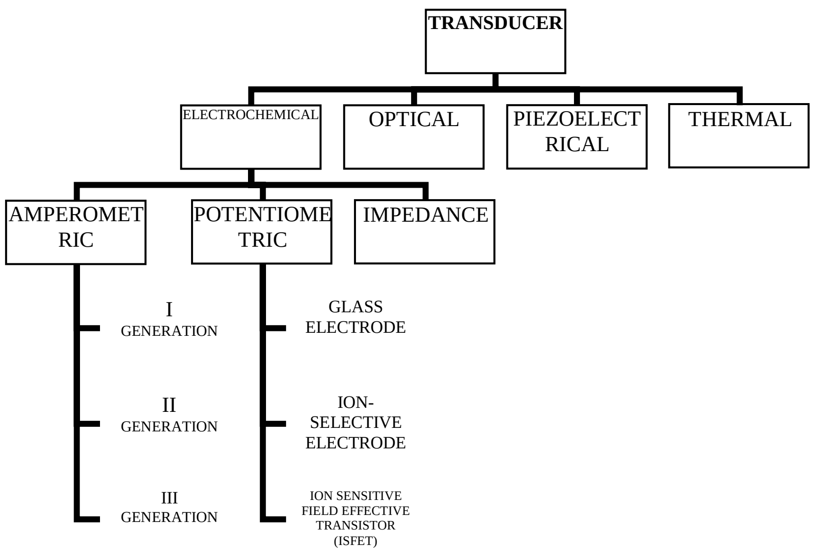

Figure 5. Classification of biosensor based on bioactive components used (Source: http://intel.ucc.ie/sensors/Biosens.htm)

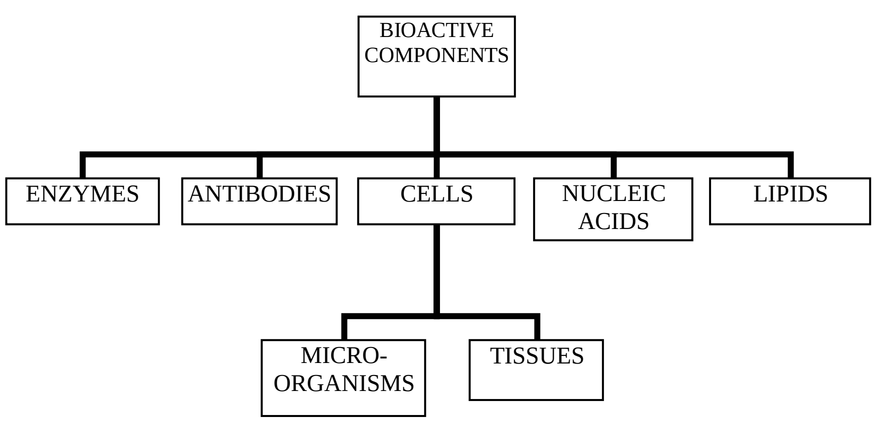

Figure 6. Classification of biosensor based on immobilization technique used (Source: http://intel.ucc.ie/sensors/Biosens.htm)

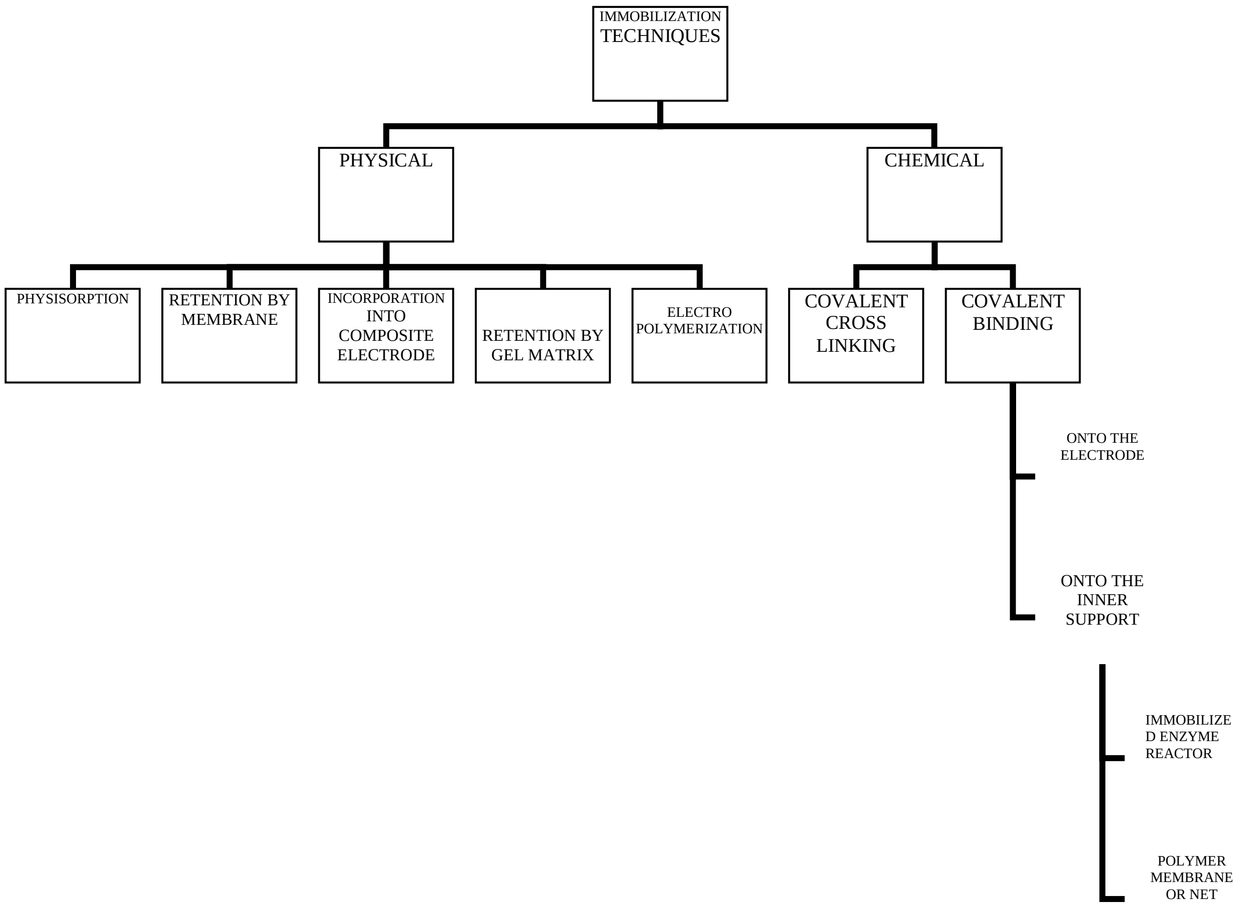

- In military, biosensors are being pursued to detect and analyze pathogenic microorganisms or any contaminates in food[9].
- Research is also being done in the field of environment monitoring. A biosensor with very high sensitivity and designed for real time analysis for contaminates (arsenic, lead, pesticides, phenol, and so on) in ambience is under development. This kind of device helps in field screening at given instant of time[10].
- ORNL (Oak Ridge National Laboratory) has been developing a lot of biosensors using sophisticated technology to detect a specific abnormality in living beings. The major one is the optical biopsy sensor developed by Vo-Dinh with researchers at Thompson Cancer Survival Center in Knoxville (Vo-Dinh, Kasili, & Wabuyele , 2006). This laser-based fluorescence sensor can depict whether a tumor is a cancerous or not. Its discovery has made the determination of cancer of esophagus easier by elimination of biopsy, reducing pain in patients[8]

CONCLUSION

Biosensors will bring a drastic revolution in health care and medicines. The Biosensor field is rapidly being developed. Biosensors have a lot of potential in the future, whether it is the area of defense, industrial, medical, environmental, or food related areas. Glucose monitoring has proved a great help for the people who are suffering from diabetes, or who are on the verge of it. A lot of research is going on in different areas around the globe.

KEY TERMS

Amperometric: Pertaining to or involving the measurement of an electric current.

Electrochemical: Of or relating to chemical reactions brought about by electricity; galvanochemical.

Electrode: A conductor, not necessarily metallic, through which a current enters or leaves a nonmetallic medium, as an electrolytic cell, arc generator, vacuum tube, or gaseous discharge tube.

Oxidoreductases: An enzyme that catalyzes an oxidation-reduction reaction.

Piezoelectrical: Of or relating to generation of electricity, or of electric polarity in dielectric crystals subjected to mechanical stress.

Potentiometric: Pertaining to or involving the measurement of an electromotive force, or potential difference by comparison with a known voltage.

Subcutaneous: Performed or introduced under the skin, as an injection by a syringe.

Blood Pressure Estimation with Considering of Stroke Volume Effect

Moha'med O. Al-Jaafreh
University of Technology, Australia

Adel A. Al-Jumaily
University of Technology, Australia

INTRODUCTION

The mean arterial pressure (MAP) is a very important cardiovascular parameter for physicians to diagnose various cardiovascular diseases. Many algorithms were used to estimate MAP with different accuracy. These algorithms used different factors, such as blood level, pulses, and external applied pressure, photo-plethysmography (PPG) signal features, heart rate (HR), and other factors. In addition, some natural-based techniques were employed to minimize the difference between estimated and measured blood pressure, as well as to measure blood pressure continuously.

This article presents an algorithm to estimate MAP, utilizing the HR, Stroke Volume (SV), and Total Peripheral Resistance (TPR), with considering SV changing influence; this consideration is investigated mathematically, and by the Particle Swarm Optimization (PSO) technique.

This new algorithm was implemented on 20 cases of mimic database (Mimic Database, http://www.physionet.org/physiobank/database/mimicdb); 10 cases for training to investigate the suitable values of these factors, and all cases for verification and examining the performance of these techniques. The achieved results of estimated MAP by these techniques are compared with real MAP, and illustrated in tables and figures.

BACKGROUND

The cardiovascular system consists of heart, vessels, and blood. In a healthy person, the heart pumps the blood in vessels with synchronous pulses (HR) and pulse wave velocity (PWV). The force of blood flux, which is caused by heart beating, forms a pressure against blood vessels' walls.

Blood pressure (BP) is a vital measurement used by the physicians for diagnosing the health situation of subjects, and saving them from critical diseases or some dangerous circumstances, such as hypertension, hypotension, artery stiffness, coma or heart attack.

Many models have used to estimate BP; these models rely on factors such as blood level, pulses, external applied pressure, PPG signal features, HR, artery volume changes, and many other factors.

The first model has been used to estimate BP, and depends on the blood level factor (O'Brien & O'Malley, 1981); blood level is related to BP, according to Equation 1:

$$P = \rho \times g \times h \qquad (1)$$

Where P is blood pressure,
ρ is blood density,
g is acceleration of gravity,
h is blood level.

The blood level is measured by inserting a catheter on the subject's artery; the blood level is elevated in the inserted catheter by BP affect, and this blood pressure is computed by Equation 1 and displayed on a monitor or drawn on paper. This method is known as the arterial cannulation method—it was first used by Ludwig on 1847. It is an accurate and reliable method, but it is very invasive, and causes limb ischemia, thrombosis, hemorrhages, and other bad affects (Kasirajan, Simmons, King, Shumaker, DeAnda, & Higgins, 2002).

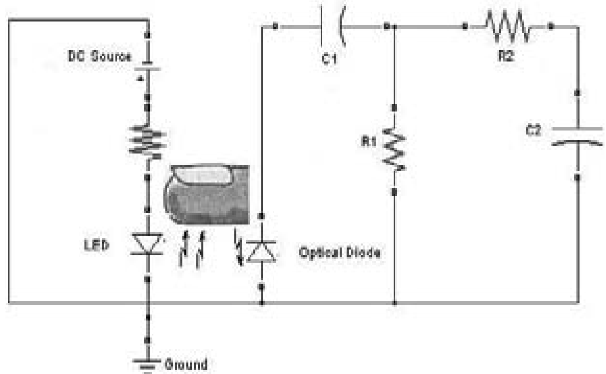
The second method to estimate BP is the Auscultatory method. It is first used by Korotkoff in 1905 (Beecher, 2003). This method depends on heart pulses and external applied pressure factors. First, the blood flow is obscured by applied external pressure on an artery by inflation of an air cuff; second, the pressure is reduced slowly. Finally, the blood pressure equals applied pressure when the blood starts flowing on the squeezed artery, and the heart pulse is heard by an expert physician or nurse, while reducing that applied pressure (Geddes, Hoff, & Badger, 1966).

This method has to be implemented by a physician or nurse by using sphygmomanometer, which consists of a cuff to apply pressure, and a mercury (Hg) meter to measure that pressure. The Auscultatory method is more widely used than the arterial cannulation method, because it is not invasive. But it is a discontinuous method, because of the inflation and defilation of the cuff, which is wrapped around the subject's arm. Also, it is uncomfortable, because of the affect of applied pressure.

On other hand, BP has been estimated depending on pulse arrival time and PWV (Bazett & Dreyer, 1922; Lansdown, 1957). Afterwards, Mackay (1964) estimated BP by piezoelectric pressure transducers, and developed the tonometry method. Soon after, depending on PPG and artery volume changes, some methods were developed to estimate BP, such as volume-compensation and local pressurization. In addition, pulse wave velocity and pulse arrival time have been used to estimate BP changes (Chen, Kobayashi, Ichikawa, Takeuchi, & Togawa, 2000; Geddes, Voelz, Babbs, Bourland, & Tacker, 1981; Piston & Stradling, 1998).

Finally, the cuffless and real-time measurement methods have been developed to estimate BP. Actually, these methods are noninvasive, continuous, and comfortable methods, because they relied on a PPG signal. The PPG sensor continuously emits light by a light-emitting diode, as a transmitter, through the subject's finger, and then the PPG signal is extracted by an optical diode as a receiver. A PPG sensor circuit is shown in Figure 1.

Figure 1. Circuit model



The cuffless and real-time measurement methods are used to estimate BP, by using the PPG signal's features through mathematical models, which depend on the relationship between BP and the PPG signal's features. The BP and PPG signal's features' relationship is complex and dynamic (Shaltis, Reisner, & Asada, 2005). This relation has been studied—Yan and Zhang (2005) stated that the normalized harmonic area of a discrete period transform of the PPG signal has a high correlation with BP. Moreover, the time interval between the peak of electrocardiograph (ECG) and the front foot of the PPG signal, also known as the PTT_f; has a high correlation with BP variability (Ma & Zhang, 2005).

Furthermore, a model has been found to estimate BP by using a weighted PTT (PTT_w); this feature is dependent on that specified subject. PTT_w depends on calibrating measurements of systolic and diastolic BP (Poon & Zhang, 2005).

Moreover, some work of PPG-based methods has established correlation between the frequency of the PPG signal, HR, and BP (Ganong, 2003). MAP is related to HR, as shown in Equation 2:

$$MAP = HR \times SV \times TPR \qquad (2)$$

Where MAP is mean arterial pressure,
SV is stroke volume,
HR is heart rate,
TPR is total peripheral resistance.

This correlation depends on constant factors SV and TPR. In reality, these factors are not constant, and the relationship between MAP and HR is nonlinear.

In our work, a new algorithm is developed to estimate MAP, utilizing the HR, stroke volume, and total peripheral resistance, and considering SV changing influence; this consideration is investigated mathematically, and by the Particle Swarm Optimization technique.

This new algorithm was implemented on 20 cases of mimic database (refer to Mimic Database Web site); 10 cases for training to investigate the suitable values of these factors, and all cases for verification, and examining the performance of these techniques.

METHODS TO ESTIMATE MAP

Practically, the relationship between MAP and HR is nonlinear (Shaltis et al., 2005) because of many reasons, such as SV changing, and TPR. Therefore, PSO is used to deal with this nonlinear research problem.

A new mathematical model was developed, considering SV changing, which depends on HR. Therefore, Equation 2 was written as:

MAP = HR × SV × TPR ---------- (2)

MAP = HR × (SV_0 + A × SV_0 ×HR) × TPR

MAP = SV_0 ×TPR ×HR× (A × HR+1) ------- (3)

where SV_0 is the constant stroke volume of the heart.
A is the coefficient of SV changing.

So how can A—coefficient of changing—be calculated? In this article, A is calculated mathematically, and by using PSO, by considering twenty cases of MIMIC database. The HR and MAP have been extracted from 20 cases of MIMIC database to investigate the relationship between them.

MIMIC database is available in Physio-bank database (refer to Mimic Database Web site), which includes continuous records for each case from the intensive care unit (ICU) every second over 10 hours; that means 36,000 records for each case, at least. In addition, these records include signals and interrupted measurements such as HR, MAP, Systolic BP, and Diastolic BP for each case, which are measured from a bedside monitor and clinical database extracted from patients' medical records.

First, the following procedure has been followed to calculate A mathematically by fit function:

1. The coefficient of SV changing percentage (A) was generated by using a fit function for 10 cases processed by developed formula, which is:

   MAP = SV_0 ×TPR ×HR× (A × HR+1) ------- (3)

2. The best A is when the mean of error for all cases is the smallest.

   where Error = Real MAP – Estimated MAP

3. The MAP was estimated for all cases' records by equation (3):

   Where TPR = 0.018 mmHg.min/ml (Klabunde, 2006)
   SV_0 = 70 ml (Klabunde, 2006).
   A = Achieved value of A by fit function

Second, A is calculated by the PSO technique—PSO is a new based nature technique, and has been invited by Russell Eberhart and Jim Kennedy in 1996. PSO deals with various types of nonlinear continuous problems. PSO is utilized to find an optimal solution for nonlinear continuous problems by simulating the social model and imitating the birds and other animals' movement within swarm topologies.

In general, PSO ties to artificial life, while in particular, it ties to bird flocking, fish schooling, and swarming theory. Also, PSO related to evolutionary computation, and had ties to both genetic algorithms and evolutionary programming (Kennedy, Eberhart, & Shi, 2001).

Particle Swarm Optimization fundamentals are the population of particles, interconnection topologies, search algorithms, and evaluation rules; these fundamentals cooperate to find the optimum solution of the problem.

The normal population of PSO is 20 to 50 particles, this number is determined depending on the problem size; however, this population is far less than usual for population of other evolutionary algorithms.

PSO particles have interconnection topologies describing the communication among them to move within problem domains to find optimum solutions. There are two topologies:

1. Sociometry topology, or global best topology, where every particle is connected with all particles of a population, and influenced by a particle which has found the best problem solution.
2. Ring lattice, or local best topology, where every particle is connected to previous and the next particles of the population array only.

Local best topology can converge separately on various optima solutions in problem space, and it has fewer connections between particles than global best topology. However, global best topology is faster to find an optimum solution of problems (Zomaya, 2006).

The main fundamental of PSO is the search algorithms, which change particles' positions through these equations:

$$xd\ (t + 1) = xd\ (t) + vd\ (t + 1) \qquad (4)$$

$$vd(t + 1) = \chi \times vd(t)\ \varphi \times rand \times (pi,d - xi,d(t)) + \varphi 2 \times rand \times (pg,d - xi,d(t)) \qquad (5)$$

v_d is the displacement of the particle's movement
x_d is the particle's position within the problem domain
χ is the constriction coefficient
$\varphi_{1,2}$ is the acceleration constants
$p_{i,d}$ is the local best within neighbor particles
$p_{g,d}$ is the global best within all particles

First, parameters' values of $v_d(1)$, $x_d(1)$, $\varphi_{1,2}$, χ, $p_{i,d,}$ and $p_{g,d}$ are initialized to start particles' movements within the problem space.

Acceleration constants' values $\varphi_{1,2}$ manage particles' movements, and the probability of finding optimum solution slowly with high fineness, or quickly with less fineness. On the other hand, construction coefficient χ balances between the effect of previous displacement, and the effect of interconnection topologies local and global best on current displacement.

Besides these algorithms and their parameters, maximum displacement (V_{max}) and maximum position (X_{max}) will be located to surround the positions' movement within the problem space, and stop particle searching out of the problem space.

Second, particles fly within the problem domain by updating their displacements v_d by Equation 4, then adjusting their positions x_d by Equation 5.

Third, the evaluation rules appraise the obtained solution success, and assist PSO search algorithms to achieve the optimum problem solution by adjusting $p_{g,d}$ and $p_{i,d}$ values according to new particles' positions.

Finally, this operation is reiterated till the search algorithm reached the optimum solution.

In summary, PSO search algorithms and interconnection topologies control the particles' movements within the problem domain to find the optimum problem solution, which is evaluated by evaluation rules.

IMPLEMENTING PSO

The PSO is implemented to find a good estimation for MAP, through calculating A by the following procedure:

1. The problem domain for the PSO is the database of 10 cases of MIMIC database.
2. The swarm population is 30 particles.
3. The two particles' topologies—gbest and pbest—have been employed to achieve the solution.
4. Set constant values for swarm parameters (χ, $\varphi_{1,2}$, X_{max}, V_{max}) to move the particles within the problem domain to find the best suitable value for the coefficient of SV changing (A) to minimize the difference between real MAP and estimated MAP.
5. Then, testing all 20 cases' database to ensure that this is the optimal value for A, which minimizes the difference between real MAP and estimated MAP by Equation 3 for all cases.

For comparison, the estimated MAP is compared with real MAP and the estimated MAP by Equation 2:

MAP = HR × SV × TPR ---------- (2)

Where TPR = 0.018 mmHg.min/ml. SV = 70 ml.

These results and comparison between all MAP estimated by three methods, and real MAP, are illustrated in tables and figures, as shown in the next section.

RESULTS

Each case of MIMIC database has 36,000 records, at least. To illustrate these results properly, MAP for all records of all cases is estimated by three methods:

1. Equation 3 by substituting A of Fit function (Method 1).
2. Equation 3 by substituting A of PSO (Method 2).
3. Equation 2 (Method 3).

Then the means of estimated MAP (mmHg), absolute difference |real MAP-estimated MAP| (AD) and absolute percentage difference (APD) for all subjects of all methods were calculated. Where APD

$$= \left| \frac{\text{Real MAP - Estimated MAP}}{\text{Real MAP}} \right| \times 100\% .$$

Moreover, the averages of means of estimated MAP (mmHg), AD, and APD for all cases of all methods are computed, and then all are tabled in Table 1.

From Table 1, the average of mean of estimated MAP for all cases by Method 2 estimated MAP by Equation 3 by substituting A of PSO, also the average of AD and APD between mean of real MAP and mean of estimated MAP for all cases by Method 2 are the best and closest values to the mean of real MAP for all cases. Therefore, PSO has a better ability to find the optimum solution than the other two methods.

To demonstrate the excellent performance of implementing the PSO to estimate MAP, the three parts of Table 1 are represented in Figure 2, Figure 3, and Figure 4, respectively.

From Figures (2, 3, and 4), the implementation of PSO in Method 2 achieves more reliable results of MAP than Method 1 and Method 3.

FUTURE TRENDS

The suitable values of stroke volume, total peripheral resistance, and the coefficient of SV changing (A) will be investigated to achieve high accuracy, by testing more cases, and by using the multiobjective PSO technique.

B

CONCLUSION

The relationship between HR and MAP is nonlinear (Shaltis et al., 2005). A lot of efforts were made to simplify this relation. In this article, a new algorithm was developed to estimate MAP, utilizing HR, stroke volume, total peripheral resistance, and considering SV changing influence; this consideration was investigated mathematically, and by the Particle Swarm Optimization technique. In addition, the suitable value of SV and TPR were investigated by PSO.

This new algorithm was implemented on 20 cases of mimic database (refer to Mimic Database Web site); 10 cases for training to investigate the suitable values of these factors, and all cases for verification and examining the performance of these techniques.

The estimated MAP by these mathematical models are compared with real MAP, and shown in tables and figures. The estimated MAP by Equation 3 with substituting A of PSO (Method 2) is achieved for best results.

In addition, Particle Swarm Optimization achieved an optimal value of stroke volume and total peripheral resistance, and the coefficient of SV changing percentage (A), which minimized the difference between real and estimated MAP.

The work of this article is part of our project to develop the Cardiovascular Parameters Long Term Monitoring System (CPLTMS), which depends on the PPG sensor.

KEY TERMS

Arterial Cannulation Method: The oldest method used to measure BP, by inserting a catheter on subject's artery.

Auscultatory Method: The most common method to measure BP by using sphygmomanometer.

Heart Rate: The rate of heart beating during a minute.

Mean Arterial Pressure: The mean of the force of blood flow against the artery walls.

Particle Swarm Optimization: A natural-based technique which relays on a certain insight concerning on persons actions and cognitions.

Photo-Plethysmography: The new method to measure the blood flow within the artery by PPG sensor.

Stroke Volume: The volume of the blood pumped by heart.

Total Peripheral Resistance: The summation of all body vessels' resistance against blood.

INTRODUCTION

In radiation therapy, especially using intensity modulated radiation therapy (IMRT), a high dose of ionizing radiation is delivered to the patient and, therefore, the bone health is a major concern for young patients. What is more, many tumors, like soft tissue sarcomas, are located in close proximity to bone. High energy radiation unavoidably exerts negative impacts not only on bone physiological properties, but also on its mechanical and structural properties. As a result, bone fracture risk for these patients is increased significantly. Thus, it is necessary to develop a quantitative noninvasive screening technique to identify these high risk patients.

BACKGROUND

Recently, IMRT has been increasingly used as an adjuvant treatment in conjunction with surgical resection for soft tissue sarcoma. Clinical studies have shown that wide excision followed by irradiation has resulted in excellent local control. Because most tumors extend to bones, particularly long bones, it is, therefore, necessary to perform excision of periosteum to obtain a clear margin. However, periosteal stripping destroys the nutrient vessels to bone and, thus, compromises the vasculature of the outer cortex. In addition, although IMRT is superior to conventional radiation techniques in critical organ sparing, for certain tumor sites such as soft tissue sarcoma, it still delivers a significantly high dose to bones. This affects bones negatively in many aspects. Hematopoietic cells of bone marrow are extremely sensitive to radiation. Clinical data have indicated that radiation dose at the level of ~ 1 Gy can produce bone marrow suppression. Lethal or sublethal damage to stem cells caused by radiation therapy prevents them from developing into differentiated myeloid and lymphocytic cells. Furthermore, osteoblasts and mesenchymal stem cells are also radiosensitive. Irradiation can reduce metabolic bone formative activity. It has been reported that as low as 8 Gy can inhibit the formation of heterotopic ossification.

The most common type of radiation treatment related to bone fracture is a stress fracture. The fracture risk rate may be as high as 24% in sarcoma patients who have undergone periosteal stripping and received chemotherapy. Thus, it is clinically relevant and significant to have a viable screening tool to identify those patients with high risk for IMRT treatment induced fracture. Since most sarcoma patients receive a follow-up CT scan upon completion of IMRT treatments to assess the treatment response, it would be very meaningful and cost-effective to develop a technique to assess bone fracture risk based on CT scans. Currently, bone densitometry is the most widely accepted method to detect bone fragility and to assess bone fracture risk. The established technique for measuring bone mineral density (BMD) is dual-energy X-ray absorptiometry (DXA). However, studies have shown that BMD is not the only determinant for bone fracture and other factors also contribute to bone fracture risk in other ways. *In vitro* experiments have revealed that bone strength depends not only on bone mass, but also on several mechanical and structural properties of bone, such as Young's modulus, bone microstructure, and geometric characteristics. These factors are not directly linked to BMD and, therefore, are not accounted for by dual-energy X-ray absorptiometry. In this article, we present a mathematical model for quantitatively assessing bone strength. The model, termed the spring-network model, takes these mechanical and structural factors into account and could provide a potential screening tool for predicting IMRT treatment related bone fracture risk.

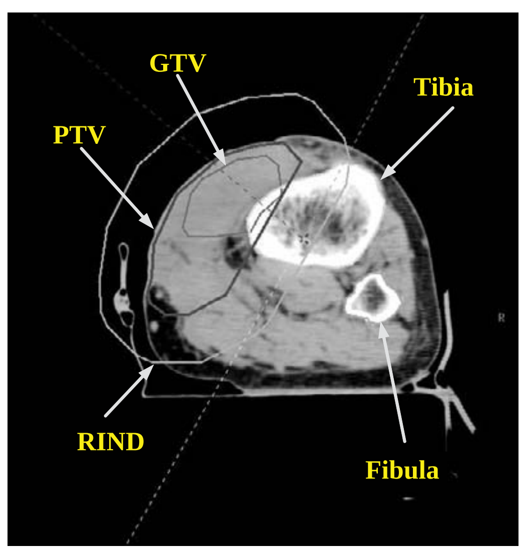
METHODOLOGY

IMRT

Since 2000, IMRT has emerged as the most important radiation therapy modality for soft tissue sarcoma treatment. Like conventional techniques, IMRT also employs the use of ionizing radiation to control and destroy malignant cells. The process of IMRT treatment planning consists of patient simulation, CT scan, target volume delineation, plan optimization, multileaf collimator (MLC) leaf sequence generation, and final dose calculation (Song, 2004; Xing, Wu, Yang, Boyer, 2004). The patient is first simulated on a simulator to determine the iso-center position and the possible treatment beam angles. In theory, the iso-center should be placed at the geometric center of the target. The goals are to fully use the central portion of the beam that posses most desirable beam properties and to minimize the probability of violating the MLC hardware constraints. Once the simulation is completed, the patient is CT scanned in the same position as in the simulation in a customized thermoplastic mold to minimize patient movement during the imaging process. At our cancer center, CT images of 2.5 mm slice thickness are acquired over the entire treatment region for treatment planning purpose. The planning target volume (PTV) is delineated on the CT images by the radiation oncologist. The PTV is created by adding a certain amount of margin around the gross tumor volume (GTV) to account for microscopic extension of the disease and treatment setup uncertainty. To achieve a better target dose coverage, a new structure named PTV_X is created by extending PTV superiorly and inferiorly one slice. In addition, a tuning structure, RIND, is also generated by expanding PTV_X by 2 cm axially to fine tune the dose distribution and to remove radiation hot spots from normal tissues. The treatment planner delineates the involved bones because they are the organ at risk in this setting and need to be spared.

Based on our clinical experience, a four or five-beam plan is necessary to create a concave dose distribution around the long bones. In selecting beam angles, all the beams enter the target from one side of the leg to spare a longitudinal strip of soft tissue. In addition, efforts are made to ensure that no beams enter or exit through the uninvolved leg. Furthermore, all beams should not pass through or be close to genital organs for patients with a tumor in the upper thigh and pelvic region. The collimator of each beam should be rotated to conform to the contour of the PTV for the best beam shaping. Figure 1 shows the volume definitions for a representative soft tissue sarcoma IMRT plan. The IMRT plan is computed using an in-house treatment planning system. Given a set of dose constraints, each IMRT plan is optimized based on a quadratic objective function. Once optimal beam intensity profiles or maps are obtained, MLC leaf sequences are generated using the

Figure 1. Structure definitions used in IMRT inverse treatment planning optimization. In this particular case, the tumor was in the right leg



dynamic MLC (DMLC) technique. Based on these leaf sequences, the final dose distribution is then computed using a pencil beam algorithm. If the criteria for plan acceptance are not met, a trade-off between the target dose coverage and normal tissue constraints would have to be made. The patient shown was treated with six MV photons on a Varian Clinac 21EX (Palo Alto, CA) equipped with a 120-leaf MLC. Figure 2 shows the MLC aperture projected on the digitally reconstructed radiograph (DRR) at a beam angle of 210^0.

Spring-Network Model

The quantitative assessment of bone strength is based on a novel mathematical model called spring-network model (Song, 2004), where the bone specimen is constructed by many elastic elements (or called occupied cubic voxels in the 3-dimensional CT image space with a grid of 512x512xslice number). Every voxel consists of 24 springs (Ladd & Kinney, 1997; Ladd, Kinney, & Breunig, 1997). Twelve of them have an elastic constant k along 12 sides of the cubic voxel, the remaining 12 have an elastic constant 2k along face-diagonals (Ladd et al., 1997), as shown in Figure 3. Under this construction scenaior, the spring network is isotropic and stable in configuration, although no cubic-like network is precisely isotropic mathematically (Ladd & Kinney, 1997).

The following boundary conditions are applied to this model: when the network is subjected to a vertical compression ς, all nodes on the top surface are free to move in horizontal direction uniformly in their displacement; vertical motion is not allowed. All nodes on the bottom surface move within horizontal plan and no

Figure 2. A representative MLC aperture at a beam angle of 210^0. The open area was part of the leg that needed to be treated. The other areas were blocked by the MLC.

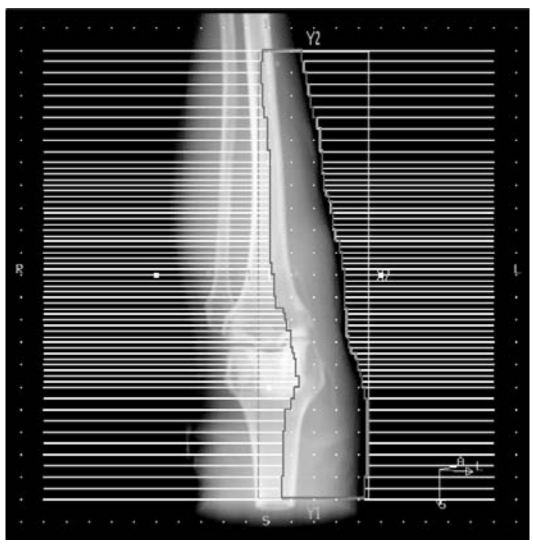


Figure 3. A bone specimen is represented by microscopic cubic building blocks through a series of modeling, where each block (or voxel) is described as a 24 linear spring system positioned in the CT image Cartesian coordinator

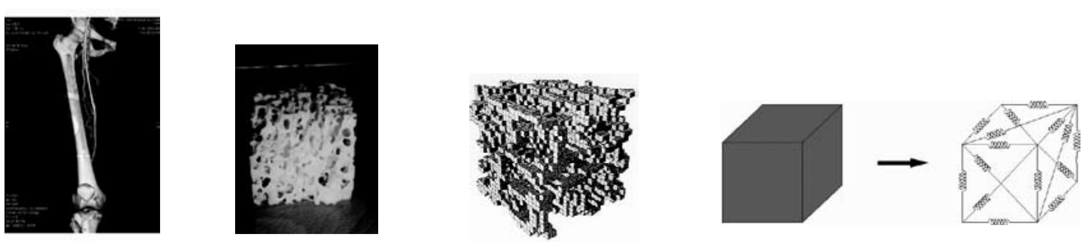

vertical motion is permitted. All other nodes in the bulk can shift in the way determined by all the elastic forces exerted by all its neighbors through linear mechanical law. The dynamical behavior of the network under external compression ς is described by classical particle in each node with mass *m* and viscosity constant κ. The mass *m* is one eighth of the total mass of each voxel if this node is at one of the vertices with 8 neighbors. If this node is at the edge or boundary of the lattice network, the number of occupied voxels in neighbor is less than 8, the mass *m* is then scaled by a factor $s < 8$ from voxel mass $sm/8$. In the same consideration, the elastic modulus kg_{ij} connecting nodes *i* and *j* should be scaled by a factor, depending on whether its neighbor is 8 or less. The Hamiltonian of the network is

$$H = \sum \frac{p_i^2}{2m_i} + \frac{k}{4} \sum g_{ij} [(u_i - u_j).\hat{x}_{ij}]^2$$

where p_i denotes the momentum of the mass at node *I*, u_i its displacement, and $\hat{x}_{ij}$ the unit vector in the direction from node *i* to node *j*. The equilibrium configuration of the nodes in the network subject to a compression ς is determined by minimizing potential energy *H* given above. This minimization is realized by the conjugate-gradient method under the certain choice of initial conditions and model parameters, otherwise, the equilibrium configuration can not be reached within finite steps of calculation.

The network fracture is simulated by the failure of individual elastic elements when a threshold strain η is reached: when the strain of a voxel is bigger than η, this voxel will be set to 0 for its mass and elastic modulus and this voxel is no longer occupied. We set a constant fracture-strain threshold for every voxel in this model because experiments indicated that for a given anatomical location of human trabecular specimen, the fracture-strain is nearly independent of human age (Gao, Jager, Artz, & Fratzl, 2003; Liebachner, 2005; Rajapakee et al., 2004), thus independent on the level of mineralization. The strain is calculated from the largest eigenvalue of the strain tensor (all direction components are included in this tensor), thus, in this model, the failure strain is independent of the degradation of the network model. It is shown that if the network contains large porosity, the fracture strain will reduce because of the large likelihood of fracture size (Gao et al., 2003; Rajapakee et al., 2004). If there is enough amount of new stress pathway, the network exhibits certain plasticity no matter how individual voxels are assumed to be brittle in the model assumption.

Bone Strength Assessment

To assess the bone strength, CT images with bone cross section are converted from DICOM format to TXT format to obtain the voxel information, such as voxel size and CT number. A three dimensional Cartesian coordinator is constructed with a resolution of 512 x 512 x *h*, where *h* is the number of CT slices. If a voxel value is not zero, its position is identified as (*x*, *y*, *z*) and it is replaced by an elastic element (24 linear spring boxes). Since a voxel value is directly related to its CT number, thus, it is proportional to the mass at that point of bone specimen. We assign a voxel value as its mass and elastic modulus to the corresponding elastic element in the assessment.

As a given model parameter, all nodes on the top surface vertically shift a constant value. It represents a mechanical load applied to the network and all nodes on the bottom layer are allowed to move in a horizontal plane. The vertical motion is not allowed. The displacements of all the other nodes in the bulk are adjusted accordingly and finally a stable configuration is reached with minimized Hamiltonian. If the network is not uniform, for example, if some porosity exists, or some voxels have a small elastic modulus, the local strain will be larger than the threshold that we preselected in model parameter. This voxel will be eliminated. Consequently, the neighbor voxel will adjust its strain until a stable configuration is reached again. In the stable configuration, a response force proportional to the displacement of position on top layer nodes is derived according to Hooke's Law. If vertical compression h increases step by step, a series of response forces are derived and a strain-stress curve is obtained. In this process, if more and more voxels are eliminated, eventually an avalanche occurs and the response force will drop rapidly until the network completely elapses. Figure 4 shows two representative CT images used in the calculations. Figure 5 shows the four 3-D bone specimens reconstructed from a series of 2-D CT images. Figure 6 shows the response stress under the external loading for four soft tissue sarcoma cases prior to IMRT treatment. The slopes indicate the stiffness (Young's modulus) of the bones.

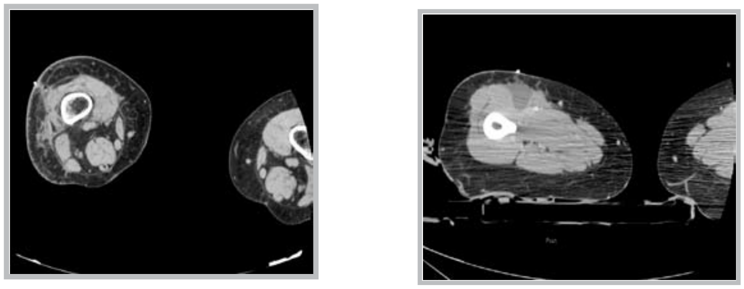

Figure 5. Bone specimen of the four representative cases used in the study. The bone specimens were reconstructed from the 2-D CT images as shown in Figure 4.

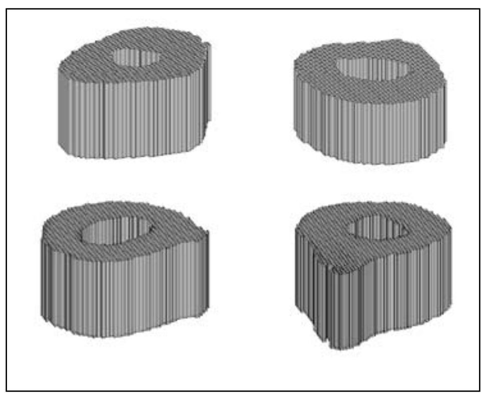

Figure 6. Mechanical response as strain applied at the top layer of the network. The slop indicates the stiffness of the bone specimen.

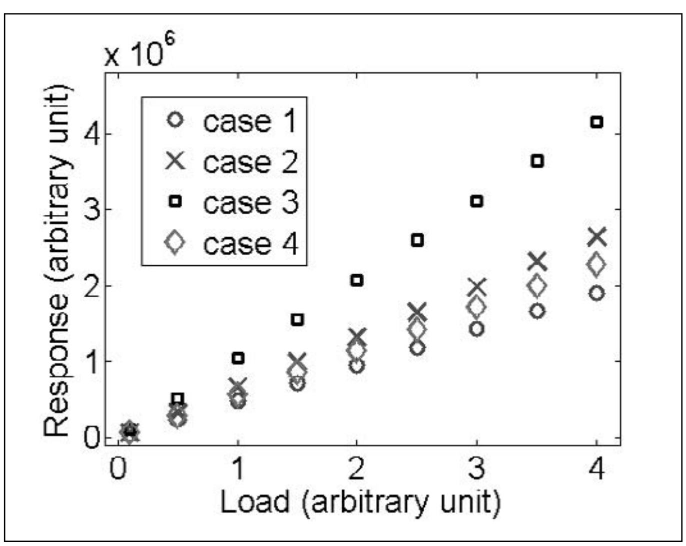

FUTURE TRENDS

Despite significant technological advances in computed tomography, anatomic definition of bone at a microscopic level remains limited. Currently, commercial diagnostic CT scanners have a nominal 512x512 in-plane resolution and a millimeter slice thickness. With a smaller field of view (FOV), a submillimeter in-plane resolution is achievable. However, it is still insufficient for quantitatively imaging the microstructure of bone at the micrometer level. As the detector size becomes smaller, the detecting efficiency improves, and faster reconstruction algorithms are developed, commercial ultra-high resolution CT scanners will eventually become available, leading to CT Microscopy. Indeed, high-resolution MicroCT has been developed and used in ultrahigh resolution imaging in the research laboratory on small animals and pathologic specimens. With CT Microscopy, the spring-network system will be able to model the mechanical properties and geometric structure of bone more precisely, thus providing a more accurate quantitative estimate of bone fracture risk. In addition, *in-vitro* experiments will be performed to calibrate our model system so that an absolute bone fracture factor can be calculated.

CONCLUSION

Based on the results of our preliminary study, we find that the spring-network model is an easy and practical approach to assessing bone strength. As shown in Figure 6, the mechanical response (stress) of the bone sample is linearly proportional to the applied load (with increment of one unit displacement at the top layer). The units in Figure 6 are arbitrary, so only the change in the curve direction or the change in the slope between the pre- and post-radiation treatments is important. By determining the slope difference between the pre- and post-radiation treatment loading-response curves, we will be able to tell the effects of IMRT treatment on the bone strength and its fracture risk. We believe that this model is a useful screening tool for bone strength assessment and has potential applications in radiation oncology as an increasing number of cancer patients receives IMRT treatments.

KEY TERMS

Intensity Modulated Radiation Therapy (IMRT): A new radiation therapy technique based on the concept of inverse treatment planning. By optimizing a set of dose-volume constraints and dose limits, the radiation intensity can be finely modulated so that the dose distribution matches the geometrical distribution of the target volume. Therefore, the maximum dose of radiation can be delivered and the side effect can be minimized.

Strain: The relative deformation (size or shape) of a material under stress.

Stress: The internal distribution of force over a unit area. It is the interaction response to the external loading.

Voxel: The smallest volume element in a 3-dimensional image space determined by the image resolution. It is the basic image element of the object reconstructed from a series of 2-D CT images.

Young's Modulus: The ratio of material stress to strain (when strain is not very large). It is a measure of material stiffness.

The Canadian Health Record Interoperability Infrastructure

Jens H. Weber-Jahnke
University of Victoria, Canada

INTRODUCTION

Countries around the globe are struggling with the rising cost of delivering health care. In the developed world, this trend is enforced by aging demographics and emerging forms of expensive medical interventions. Disease prevention, early disease detection, and evidence-based disease management are key for keeping health care systems sustainable. Electronic information management has been recognized as a central enabler for increasing the quality of health care while controlling the cost of delivering it. Secondary care facilities (e.g., hospitals) and laboratories have made use of electronic information systems for decades. However, the primary care sector has only recently begun to adopt such systems on a broader scale. The benefit provided by each system in isolation is limited since citizens generally receive their care from a multitude of providers. Health care information systems need to interoperate in order to enable integrated health information management and consequently attain the declared qualitative and economic objectives. Many industrial countries have begun to create common infrastructures for such an integrated electronic health record (EHR) (Blobel, 2006). Different approaches exist, ranging from centralized databases to highly distributed collections of mediated provider-based systems. This chapter describes the architecture of the Canadian infrastructure for health information management, which can be seen as a compromise between a fully centralized and a fully distributed solution. While in Canada the delivery of health care is a matter of provincial territorial authority, the health ministers of all provinces and the federation have created a joint organization called Health Canada Infoway with the mandate to develop an architecture for and foster implementation of a joint interoperability infrastructure for EHRs in Canada. The second major version of this architecture has now been released, and provinces have begun to implement it. The solution is based on the paradigm of a service-oriented architecture (SOA) (Erl, 2004) and embraces a range of domain-specific and technical standards. It leverages and integrates existing investments in health information systems by making them available through interface standards-conform interface adapters. The Canadian EHR architecture has received attention beyond the Canadian context. This chapter reports on this architecture, its enabling technology paradigms, experiences with its implementation, and its limitations.

THE CANADIAN HEALTH CARE SYSTEM

Canada is a federation of 10 provinces and three territories. Funding and administration of health care services falls under the jurisdiction of these individual provinces and territories. Federal legislation (the Canada Health Act) provides a common set of conditions under which provinces and territories receive funding for health services. These conditions include *universal access* to health care for all Canadians independently of their income. Moreover, they require portability of insurance coverage among provinces such that Canadians remain entitled to medical care while moving among provinces. The Canada Health Act covers basic health services only, including primary care and hospital services. Many other services such as dental care, optometry, and prescription medications are excluded. Private insurance plans are available for purchase to cover these services. They are also a typical component of employee benefit packages.

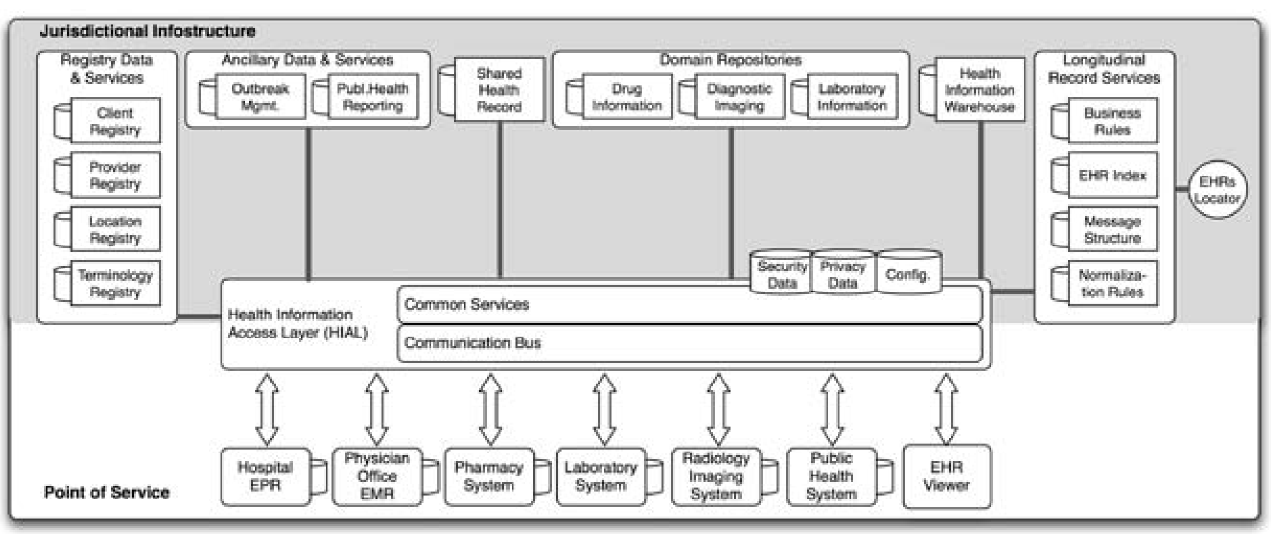
There are approximately 60,000 physicians practicing in Canada, half of them in primary care, the other half as specialists. The Canadian health care system has been slow to adopt new information and communications technologies (ICTs) (Newbery, Gelhorn, Gutkin, Renaud & Challis, 2000). This is particularly the case for the primary care sector. While ICTs are increasingly being used for administrative services such as billing, scheduling, and managing basic demographic data, the majority of medical records is still kept in paper files. At the turn of the millennium, Canada launched initiatives focused on removing the barriers of making the transition to a more efficient and modern health care system. An example is the *Primary Care Transition Fund*, which has invested $800 million over six years (2000–2006) for renewing the health care systems across the country. The Canadian Health Accord released in 2004 recognizes that "electronic health records and telehealth are key to health system renewal, particularly for Canadians who live in rural and remote areas."

The decentralized nature of the Canadian health care system has contributed to the development of a large number of heterogeneous medical information systems. A recent estimate puts this number at 40,000 (Allas, 2006). Integrating all these systems to achieve more efficient and effective use of medical information poses a significant challenge. In order to facilitate this integration, the health ministers of all provinces, territories, and the federal government have jointly formed an organization called *Health Canada Infoway* (Infoway, 2006) with a mandate to facilitate the development and adoption of interoperable electronic health (EHR) record solutions. Founded in 2001, Infoway has the goal of connecting at least 50% of all Canadians to an interoperable EHR by the end of 2009.

ARCHITECTURE

The Canadian strategy for achieving an interoperable EHR pivots on a joint information system reference model called the EHR solution blueprint architecture (EHRs blueprint). Infoway published the first version of the EHRs blueprint in 2003. Its second and final major version update was released in 2006 after extensive consultation with various stakeholder groups. This major revision adds concepts for *Telehealth* and *Public Health Surveillance* as well as extensive requirements and design specifications for security and privacy concerns. According to Richard Alvarez, Infoway's president and CEO, the EHRs blueprint provides the Canadian framework for accessing and consolidating health information and presenting it in a way that meets the needs of health care professionals such as GPs, specialists, nurses, and pharmacists across various care settings, including hospitals, emergency rooms, clinics, home care, and geographical distances (Infoway, 2006). The EHRs blueprint is based on the *Service-Oriented Architecture* (SOA) paradigm, which promotes loosely coupled and standards-based component interfaces (Erl, 2004). The following diagram gives a conceptual overview of the EHRs blueprint architecture, which consists of the *jurisdictional infrastructure* part (also called the *EHR Infostructure – EHRi*) and the actual application components used at the *point of service* (PoS).

Figure 1.



The EHRi consists of the following:

- **Registry services** to manage and provide directory information about actors, resources, and terminology in the EHRs, including a registry of health care providers, patients, and locations, as well as standard terminologies to describe diseases, acts, and other clinical information.
- **Domain repositories** to store and provide clinical information about patients pertinent to a particular domain (e.g., diagnostic imaging, laboratory data, drugs).
- A **shared health record** to manage and provide information about patient health histories.
- **Longitudinal record services** to orchestrate and track distributed care processes, including access, updates, and location of health data.
- A **health information data warehouse** for collecting health information for the purpose of public health surveillance.
- A **health information access layer** (HIAL) that forms the middleware between the EHR infostructure and individual point of service (PoS) systems, including a communication bus and common services (e.g., for privacy and security).
- A generic class of **ancillary services** that rely on, need, or complement EHR data (e.g., communicable disease reporting, outbreak management, and wait-list monitoring).

The EHRs blueprint architecture can be considered a compromise between a fully decentralized federation of autonomous medical record systems and a fully centralized information system concept. It recognizes that the individual PoS information systems will keep most of their autonomy hosting patient-centric health information. However, the Shared Health Record (SHR) component of the EHRi assumes the role of the *definitive* medical summary that is shared among medical service providers. Moreover, the SHR forms a longitudinal record that should cover a patient's health history "from womb to tomb."

Geographically distributed EHRs implementations subscribe to a common *EHRs Locator* service component, which enables them to locate other EHRs implementations that maintain health data about a particular patient. For example, a patient who has accessed health services provided by four health authorities (running their own EHRs) will have his or her clinical information residing in four EHRs implementations. However, any such storage fragmentation of personal health information is hidden from the point of view of the individual PoS applications accessing any EHRs. The Longitudinal Record Services (LRS) of each EHRs use the EHRs Locator to automatically locate all relevant storage locations in order to assemble a cohesive health record.

While the HIAL facilitates integration of existing PoS applications, their integration still requires adaptation effort. Therefore, providers can also use a dedicated *EHR Viewer* to access the EHR data while their PoS application is not yet fully integrated with the HIAL or when their practice does not yet use an electronic medical record system.

INTERACTION MODEL

Various PoS systems communicate updates to patient health records by means of the SHR. The EHRi does not support direct peer-to-peer communication between different PoS applications. The EHRi plays a passive role when it comes to interacting with PoS applications. This means that it does not actively *push* any information to or *pull* information from connected PoS applications. Rather, PoS applications use the EHRi to retrieve health data or push local updates to the shared infrastructure. When a patient accesses the health care system at a particular PoS, the information system installed at that location queries the SHR for the most up-to-date health record for this patient. If the patient has never accessed the health care system at this particular PoS, a new local health record is created based on the record provided by the SHR. Otherwise, the local record is updated by any SHR updates since the patient's last visit at this location, or the local data and the SHR data are presented side by side to the clinician. Clinical data captured at the PoS application may be promoted to the EHRi level in order to update the SHR as a result of the new patient encounter.

INTEROPERABILITY STANDARDS

The interoperability standards used in the EHRs blueprint are based on the Health Level Seven (HL7) V.3 messaging architecture (Beeler, 1998). Some messages use coded data, while others use unstructured information (i.e., free text). The standard uses coded messages for updating registries (e.g., service delivery locations) as well as messages for recording clinical observations and (potentially composite) professional services. Semistructured (partially uncoded) messages are used to record referrals, clinical documents (observations), discharge and care summaries, and general health conditions, and to retrieve a patient's SHR summary. Coding systems used are SNOMED-CT, ICD-10 (with Canadian enhancements), and the Canadian Classification of Health Interventions (CCI) (Chute, 2000).

SECURITY AND PRIVACY

Infoway released a detailed specification of privacy and security requirements in 2005 that considered and complied to national, provincial, and territorial privacy legislations, policies, and standards. These requirements are partially of a technical and partially of an administrative nature. They are also categorized regarding their scope (i.e., whether they pertain to Point of Service (PoS) applications connecting to an EHRi, or whether they pertain to organizations hosting EHRi components). While Canada has federal privacy legislation (*Personal Information Protection and Electronic Documents Act*), most provinces have their own legal frameworks. Therefore, EHRs requirements are defined conditionally. For example, certain aspects of dealing with consent are not consistently defined in the requirements specification. As such, it is not defined whether participation in the EHRi is mandatory or whether there are choices to opt in or opt out. In 2005, Infoway further published a conceptual architecture of privacy and security services that are considered necessary and sufficient to enable implementation of the specified requirements. These services include anonymizing filters, encryption services, services to ensure integrity and perform authorization, authentication, and auditing. One important principle of the privacy and security architecture is that it uses separate repositories for storing medical information and personal identifiable information. Both data sets are linked up only by a reference identifier that has no other purpose or semantics.

IMPLEMENTATION EXPERIENCES

Different jurisdictions may implement different technical realizations of the aforementioned EHRs architecture according to their needs. The Infoway blueprint defines the EHRs architecture only on the conceptual level and logical levels, but leaves the definition of the physical level up to the individual jurisdiction. It is expected that as long as different EHRs implementations use the same standards, they will be interoperable to ultimately create the envisioned pan-Canadian EHR. At the same time, Infoway has funded and actively worked with public and private partners to develop *reusable* components for this architecture with the objective to "*build once but use many times.*"

Several components of the EHRs blueprint architecture have been developed in various jurisdictions throughout Canada. Early implementation efforts have concentrated on developing registry services (e.g., patients, providers, locations, drugs, etc.) and domain repositories (e.g., digital imaging, laboratories). Infoway has started funding initiatives for developing the infrastructure components that integrate this information. Currently, Infoway is funding and actively working with more than 150 projects.

Several Canadian provinces have already developed infrastructures for particular aspects of the planned EHR (e.g., shared drug information systems). These projects have influenced and have been influenced by the two subsequent versions of Infoway's national EHRs blueprint. They provide a first limited evaluation of the EHR blueprint. To date, the arguably most difficult component, the component that provides the *Longitudinal Record Services* (LRS), still remains to be implemented in most jurisdictions. While the current second version of the EHRs blueprint is considered final when it comes to the publication of a cohesive document, Infoway has created a joint artefact repository for sharing experiences made with implementing the EHRs blueprint and for refining the specifications on an ongoing basis.

DISCUSSION AND COMPARISON

The Canadian EHR infrastructure is most similar to the Australian *HealthConnect architecture*, which is expected to be implemented by 2010 (Wooding, 2003). Both models advocate a federated model leveraging existing PoS applications and implement a distributed repository for shared health record data. They also use a similar set of standards. Patient participation in HealthConnect is voluntary on an opt-in basis.

In Europe, the *NHS Care Records Services* project in the United Kingdom and the *Dossier Médical Personnel* (DMP) in France implement a more centralized notion of the shared health record. The core database of the NHS project, called the *Spine*, went live in 2005, while the DMP is expected to go online in 2007 (Cross, 2006). These projects defer from Canada's EHR project in that they represent fully centralized repositories for all citizens rather than specifying a blueprint standard that is implemented separately across different jurisdictions. The different approaches reflect on the general differences in the countries' health care systems. There have been significant concerns regarding privacy and security of these centralized solutions. Both systems make a default assumption of citizen participation. Privacy advocates demand for the right to opt out.

Other European countries such as Germany are using a different approach to tackle the interoperability challenge. They provide citizens with "smart" health cards to store and share health data. Germany started a trial run involving 10,000 patients in December 2006. Over the course of the project, the card will gradually store an increasing amount of information, including prescriptions, medications, and allergies, up to the complete electronic medical record. Patient participation in this system is mandatory, but patients can decide how much information is kept on their cards (BMG, 2006).

Countries lacking a cohesive public health care system have seen developments of various disparate EHR initiatives. In the United States, the most notable system on the national level has been developed by the Department for Veteran Affairs. The *Veterans Health Information Systems and Technology Architecture* (VistA) is a client-server system maintaining care records of approximately 4 million veterans. Being developed for a single organization, VistA puts more emphasis on developing the PoS application user interface than the EHRs, which mainly focuses on infrastructure. VistA includes an extensive GUI client called the *Computerized Patient Record System* (CPRS) (Fletcher, Dayhoff, Wu, Graves, & Jones, 2001). Other implementations of EHRs exist for separate American health care organizations.

KEY TERMS

Domain Repository: A component of an EHR Infrastructure that stores, manages, and persists a clinical subset of data pertaining to a specific domain.

EHR Infrastructure: A collection of common and reusable components in support of a diverse set of health information management applications. It consists of software solutions, data definitions, and messaging standards for the EHR.

Electronic Health Record (EHR): Provides a secure and private lifetime computer-based record of a patient's key health history and care within a health system.

Health Information Access Layer: A gateway that acts as an abstraction layer to separate PoS applications from the EHR Infrastructure. It is made up of service components, service roles, information models, and messaging standards required for the exchange of EHR data and the execution of interoperability profiles among EHR Services.

Health Information Data Warehouse: An information system to compile, aggregate, and consolidate EHR data for reporting and statistical or research analysis.

Point of Service (PoS) Application: PoS applications are used by authorized caregivers to view and navigate the EHR of a patient/client.

Registry: A directorylike system that focuses solely on managing data pertaining to one conceptual entity.

Challenges with Adoption of Electronic Medical Record Systems

Morgan State University, USA

INTRODUCTION

Among health care information systems, past research has credited Electronic Medical Records (EMR) systems with offering the greatest potential for improving quality within health care environments. Benefits range from reducing errors to cutting overall health care costs. For instance, the utility of an EMR system will allow physicians' enterprise wide access to a patient's entire medical chart, monitor patients' care for possible drug interaction, proactively prompt doctor(s) with recommended treatment, provide clinical decision support, simplify record keeping, e-prescription, documented referrals, and reminders to patients and health care providers.

Despite these benefits and a defined movement to integrate EMR systems in medical outfits, adoption of EMR systems by health care professionals has been very slow (Audet, Doty, Peugh, Shamasdin, Zapert, & Schoenbaum, 2004; Burt, Hing, & Woodwell, 2005; Miller & Sim, 2004; Simon & Simon, 2006). According to the National Ambulatory Medical Care Survey Report (2005) only 25 % of office-based physicians are recorded as partial or fully using EMR systems. Nevertheless, interest to adopt EMR systems continues to be significant (Miller & Sim, 2004).

What accounts for the slow adoption of EMR systems? To answer, we must identify and address challenges associated with this process. A review of the recent practitioners, academic health informatics literature, and provisions of HIPPA Act of 1996 (Adler & Edsall, 2005; Audet et al., 2004; Baharozian, 2005; Edsall & Adler, 2005; Hough, Chen, & Lin, 2005; Lenhart, Loomis, Criswell, & Meggs, 2000; Miller & Sim, 2004; Retchin, Wenzel, &, 1999; Swartz, 2005; Valdes, Kibbe, Tolleson, Kunik, & Petersen, 2004) cite several barriers faced with the adoption process. Further analysis also suggests that the promises of successful EMR deployment will not be fully realized unless concerns linked to the EMR implementation process are alleviated. We investigated EMR adoption by conducting open ended interviews with EMR managers, vendors, and physicians to explore their experiences with their EMR implementation.

In this article, we present the results from our study. The next section highlights challenges associated with EMR adoption and use. We conclude by suggesting solutions geared towards lessening these challenges thereby clearing the path for successful EMR adoption and use.

CHALLENGES

Our meta-analysis identified several barriers experienced by professionals regarding EMR adoption and use. These challenges include: cost, difficulty in calculating return on investment, lack of education, physicians' and staff concerns, technology related concerns, inadequate complementary changes to organizational processes, lack of IT support, and lack of incentives.

Costs

EMR systems are costly. Many health care institutions cite cost as a primary prohibitive factor with adoption of EMR. There are high up-front installation costs and recurring expenses for operation and maintenance. During our interviews, the interviewees clarified that up-front costs range from $15,000-$60,000 per physician.

Initial set-up costs include purchase cost of hardware, software, network infrastructure, trainin, and workflow reorganization. Operation and maintenance costs include data conversion, ongoing training, hardware and software, and specialized IT support staff.

With such exorbitant costs and uncertainty regarding return on investments, we can assume that small companies may not find adoption of EMR systems feasible thus prohibiting implementation (Audet et al., 2004; Miller & Sim, 2004; Retchin et al., 1999; Winn, 2002).

Additional expenses are incurred during the EMR transition period due to physicians attending to fewer patients translating to decreased revenue.

Difficulty in Calculating Return on Investment

One of the major concerns with new projects for upper level management is financial payoff. Is this worth the investment? As mentioned earlier, the level of initial investment is high. There is an uncertainty over the size of financial benefits that may accrue over time (Audet et al., 2004; Miller & Sim, 2004).

Benefits obtained from EMR can be complex to measure with long pay back period. Most health care institutions lack the financial and operational analysis tools for an "uninformed" EMR buyer to make a competent decision on behalf of their organization.

Lack of Education

Most health care institutions lack knowledgeable personnel capable of evaluating and managing implementation EMR system for their organizations. EMR systems are complex with several modules and requiring special expertise.

During the implementation phase there is a need for a champion. The literature states projects without a champion are most likely to fail. A champion is one that promotes the benefits of EMR within the organization. He or she is a person capable of aligning the systems' functions with the needs of the health care organization. A champion can properly assist in defining the scope, allocating resources and preparing the organization for the transition that will come with EMR implementation.

Concerns of Physicians and Staff

The concerns of physicians and staff to use and manage EMR systems remain another major challenge. Physicians are very reluctant to adopt and use EMR systems. Physicians view their role primarily about patients, with automation secondary. Many fear the use of EMR systems will take them away from their primary duties.

Physicians and nurses also fear that managers could measure, compare, and evaluate the amount of time each professional spends on each task. Physicians and other medical staff are apprehensive that they may be reprimanded for "slacking off" or deviating from predetermined practice sequence. These concerns act as an impediment for adoption and use of EMR systems (Bar-Lev & Harrison, 2006). During our interviews, however, this factor did not emerge as one of the areas of concerns.

Physicians and staff are also reluctant to use EMR because they need to take time off their schedule for training on coding, documentation, and e-prescription capabilities of EMR systems (Berkowitz, 1997; Lenhart et al., 2000). Training requirements erode the initial enthusiasm for use among some users. During our interviews, a few physicians expressed that they spent a significant amount of time meeting the training requirements.

Physicians are also resentful with receiving clinical recommendations from EMR. They believe that after years of medical training, accepting recommendations from a computer information system is demeaning and a threat to their independent thinking.

Technology Related Concerns

There are several concerns related to EMR technology.

Technophobia

There are people within the health care clinics that are intimidated by technology. They simply panic when interacting with technology. Fears range from care providers perceiving that their jobs are at stake (EMR will replace or outperform them) to "what if I hit an incorrect key stoke and erase critical data from the system?" Such fears have crippling effects on EMR implementation.

Other Technology Concerns

Interoperability is another major concern. Interoperability refers to the ability of EMR system to facilitate exchange of patients' medical records across medical institutions such as hospitals, polyclinics, independent testing labs, and medical centers. This factor is important because there are more than 264 different software programs currently used in the U.S. and most of these programs are not compatible with each other (Retchin et al., 1999; Valdes et al., 2004). Poor interoperability results in poor electronic data exchange across institutions. Support staff and physicians get frustrated as they are forced to spend more time to manually enter data from external systems.

System difficulty is another technology related concern. This issue pertains to the difficulty associated with conversion of old paper based documents into electronic medical records (Berkowitz, 1997; Retchin et al., 1999). This factor need to be considered because many documents involve extensive handwritten content, some of which may have been generated by different health care professionals over the life span of the patient and some of the content is illegible for conversion. Moreover, the digital scanning process involved in conversion of these physical records to electronic documents is an expensive, time-consuming process, which must be done to exacting standards to ensure exact capture of the content.

Usability remains as a major concern. There are multiple screens, options, and navigational aids in the EMR system. Problems with EMR usability, especially documenting progress notes cause physicians to spend extra time learning effective ways to use the EMR (Audet et al., 2004; Miller & Sim, 2004). This issue is compounded by the fact that smaller medical institutions often lack financial resources to train physicians on usability.

Health care information is sensitive. There are concerns pertaining to data security and privacy (Baharozian, 2005; Rind & Safran, 1993). HIPPA Act (1996) mandates that all health care providers adhere to national standards while conducting electronic exchange of health data and emphasis should be laid on the security and privacy of health data. Even though it is recognized that EMR systems are better than paper based systems in terms of data security and privacy, these concerns still persist (Baharozian, 2005; Hsieh & Lin, 2006). There is a persistent fear that hackers can destroy sensitive patients' records.

Inadequate IT Support

With the implementation of any major information system as EMR, there is a need for IT support. Factors range from hardware, software, or network ongoing issues to training. EMR is also considered a reengineered process. Most professionals found in health care environments are medical professions with limited technology expertise. Many care providers express being more at ease using the system with IT support close by.

Inadequate Complementary Changes to Organizational Processes

EMR hardware and software cannot simply be used as "out of box" to reap superior business value. As Wade and Hulland (2004) point out, managers should effectively use outside-in and spanning resources such as IT management practices, IT change management, business systems thinking together with inside-out IT resources such as basic IT infrastructure and IT technical manpower. This simply means that information technology innovations and organizational process changes in tandem. Complementary changes needs to be done to the hospital processes such as patient registration, diagnosis, medical/surgical process, prescription generation and billing, and so forth. These complementary changes exact a great deal of time from physicians, nurses, front-office staff, and hospital managers. Physicians have to redesign their workflows (i.e., how they work in the exam room). Managers and support staff have to redesign office workflows. Practitioners' literature (Miller & Sim, 2004) point out that office-based physicians and solo physicians do not spend enough time in redesigning workflows. It is well known that hospitals that install sophisticated EMR systems before they have done the necessary organizational process changes are not going reap benefits from EMR investments. In our interviews, EMR managers agreed that extensive changes are needed in the management of work flow while trying to implement EMR systems.

Lack of Incentives

It is agreed upon that EMR systems are expensive and most medical professionals require extensive training to reap full benefits. The evidence from the literature suggests that given a choice many physicians will not use EMR systems. They view use of this system as time consuming and distracting from their primary duties. Without incentives by their institutions or government many health care professionals will not implement EMR systems.

SOLUTIONS

There are no simple anecdotes to overcome the challenges referenced above. We therefore propose a multifaceted solution. To expedite the process of EMR implementation, barriers experienced by health care professionals must be addressed at the individual, organization and governmental levels. On one hand we have risks feared by health care professionals and institutions. On the other hand we have a lack of incentives to entice businesses to adopt EMR.

We believe that interventions at the governmental and institutional levels can play a role in stimulating the adoption process. Each intervention increases the attractiveness of EMR use by hospitals and medical institutions.

Governmental Level Interventions

Certain interventions could be undertaken at the governmental level in order to spur the EMR adoption and use.

a. Federal and state governments could provide financial incentives, subsidies, and tax breaks to hospitals and medical institutions that adopt and use EMR systems. As we mentioned before, lack of financial resources is one of the major challenges faced by medical institutions and hospitals. This scheme of providing financial incentives would promote medical institutions and hospitals to invest and effectively use EMR systems. Audet et al. (2004) report that in European countries such as the UK and Sweden, physicians who invest in EMR systems receive government subsidies, which has spurred adoption of EMR systems. Such policies could be adopted by the U.S. federal government also. This scheme would also benefit the patients as EMR systems improve the overall efficiency of health care service providers.
b. As we mentioned before, system interoperability is one of the major technology related concerns. In order to address this concern, the U.S. Department of Health and Human Services could develop a process to harmonize EMR system applications and create industry-wide standards for operation and maintenance of EMR systems and exchange of health data. Vendors who sell EMR systems would be forced to come up with software applications that are compatible with each other. This would promote better standardization of the product, interoperability of EMR systems and information sharing of health records across medical institutions, hospitals and testing centers. This scheme would in turn promote usage of EMR systems. Miller and Sim (2004) report that the government has initiated some data exchange standards such as HL7, LOINC, and provisions of HIPPA Act of 1996 also mandate use of data exchange standards. We hope that more organizations use these data exchange standards so as to improve system interoperability.

Institutional Level Interventions

Hospitals and medical institutions could undertake the following interventions in order to promote adoption and effective usage of EMR systems by physicians and other staff.

a. **Provide performance incentives to physicians and other staff:** Hospitals and medical institutions could consider providing performance improvement based financial incentives to physicians and other staff. As mentioned before, many hospitals and clinics have reported that EMR systems have improved the throughput for diagnosis, treatment, and consultation, reduced the time taken for delivery of services, improved the speed and accuracy of medical insurance claims registration, reduced the number of medical coding and transcription errors, and improved the data integrity of patient's medical records and the institution's overall responsiveness to patient's needs. Hospitals could come up with a set of process based metrics (such as diagnosis throughput, number of medical errors, number of correct insurance claims registered, etc.) and evaluate the performance improvements associated with the use of EMR systems. Based on the extent of performance improvements achieved, physicians and other staff could be provided extra financial incentives. This would motivate the physicians and other staff to use EMR systems.

b. **Consider temporal aspect of technology payoff:** As IT business value studies (Brynjolfsson & Hitt, 2000; Devaraj & Kohli, 2000, 2003) suggest, top management of hospitals and medical institutions should consider the temporal aspect of technology payoff; that is, payoffs may not be realized instantaneously, but only after certain periods of time, which is usually 2-3 years. Hence it becomes important for top management to consider the lag effect when they conduct cost-benefit analysis of EMR systems.

c. **Top management support for use of advanced capabilities of EMR systems:** As mentioned before, the capability of EMR to document progress notes and facilitate audit trails create fear in the minds of physicians and nurses that managers could measure, compare and evaluate the amount of time each professional spent on each task. Physicians and other medical staff also fear that they might be reprimanded for "slacking off" or deviating from predetermined practice sequence. These fears act as an impediment for usage of EMR systems. Top management should lend its support to physicians and work to alleviate these fears. Top management should develop strong channels of communication and co-operatively work with physicians and other staff members. Also, physicians should be made to understand that coding, documentation, and audit trail capabilities should be viewed as positive features as they provide the required checks and balances in the health care delivery system.

d. **Increase thrust on training:** In order to work around technology usability issue, hospital management should place increased emphasis on training of system users (i.e., physicians and other office staff). Users should be given time off their regular work schedules so that they can be trained to use EMR systems effectively.

e. **Emphasize complementary process changes:** Managers and physicians should stop viewing EMR as a "mere technology." To derive value out of EMR, it has to be viewed as "Joint EMR-organization" endeavor. It is important to recognize that information technologies such as EMR interact with key organizational processes in order to bring about business value. Swanson (1994) calls such a joint endeavor as Type III innovation (Swanson, 1994). Complementary changes needs to be done to hospital processes such as patient registration, diagnosis, medical/surgical process, prescription generation and billing, and so forth.

f. **IT support:** Technical support is critical when implementing complex computer information systems. Problems can arise from hardware, software, network or user initiated failure. The provision of adequate IT support is essential to achieving maximum results of EMR with minimal downtime. Medical personnel also report feeling more comfortable transitioning to EMR when IT support is available. Health care institutions should never underestimate the value of IT support. During IT planning, institutions should consider acquiring IT support from EMR vendors and independent consultants, as well as establishing an in house support center.

CONCLUSION

Implementation of EMR systems can be a daunting task. Many health care advocates as well as the government are promoting EMR to become a standard in health care. The promised benefits of EMR are enticing. This process is also accelerated by changes in health care and reporting demands from the influx of managed care plans. We reviewed the existing literature as well as conducted our own study to unearth key barriers that affect EMR adoption. In this article, we highlighted these challenges and proposed solutions.

We urge researchers to continue this line of research. Several interesting topics still need to be explored. Is cost really the main inhibitor of EMR adoption? What organizational factors affect the success or failure of EMR adoption? Initial evidence suggests that the size of a practice matters with EMR; more work is needed to confirm this. What demographics data affect EMR adoption; for instance, does age or medical school education of physicians affect EMR adoption/use. The literature reports that many of the benefits of EMR will be realized later. As such, this gives us a need to conduct longitudinal studies at health care organizations.

Additionally, researchers should seek to evaluate EMR adoption research with the theoretical lenses of transaction cost economics, resource based view, social network theory, digital options theory, diffusion of innovation, and other grounded IT adoption theories.

KEY TERMS

Electronic Medical Records System: An interorganizational information system that captures the essential components of a patient's medical encounter with the medical provider, including storage and retrieval of subjective, objective patient information, assessment, and plans for patient care (Lenhart et al., 2000).

EMR Challenges: Any factor that would impede the adoption and use of EMR.

Health Care Information System: An arrangement of information technology, people, data, and processes that interact to gather, process, store, and disseminate health care information (adapted from Whitten & Bentley, 2007).

IS Adoption: The deployment of information systems within an organization.

Challenges, Systems, and Applications of Wireless and Mobile Telemedicine

Mieso K. Denko
University of Guelph, Canada

INTRODUCTION

Telemedicine can be defined as the delivery of healthcare, and the sharing of medical knowledge over a distance, using information and communication technologies (Pattichis, Kyriacou, Voskarides, Pattichis, Istepanian, & Schizas, 2002). Telemedicine aims at providing expert-based medical care to any place where healthcare is needed. It was introduced about three decades ago, where the only available communication technologies were telephone and fax machines. However, in recent years, many telemedicine applications have been developed over wired telecommunication technologies, wireless telecommunication technologies, as well as integrated wired and wireless networks.

Wireless communication and networking technologies such as 2.5G, 3G, 4G, and 802.11 Wireless LANs and Bluetooth have allowed the provision of wireless telemedicine systems, thus freeing the medical personnel and the patient from being bound to a fixed location. The wireless communication technology provides more flexible access to doctors and patients with the use of mobile stations. Mobile computers are gradually gaining more interest as the point of care tools used by many physicians and healthcare professionals. Since their introduction in the early 1990s, Personal Digital Assistants (PDAs) are increasingly becoming more and more popular for a large variety of medical applications. PDAs can be used in many areas of medicine as off-line reference tools, risk estimation for specific diseases, off-line diagnosis code databases, drug reference databases, and many more useful emerging applications. Some of these applications are stand-alone mobile applications, while many others are networked.

There are many benefits which wireless and mobile telemedicine can provide to healthcare and medical applications. Some of the specific benefits are outlined as follows. First, it can provide rapid responses to critical medical care, regardless of geographical barriers. It can be quickly deployed in disaster recovery areas, where existing communication links may have been disrupted. Second, it can provide flexible and reliable access to expert opinion and advice at the point of care with insignificant delay, and with improved management of medical resources. Third, it can allow patients to remain in their communities and receive medical services. This significantly reduces the costs of healthcare through improved healthcare management systems and reduced travel expenses. Fourth, it can provide interactive medical consultation and communication of medical records, image and video data in mobility scenarios, and with global coverage and connectivity, and fifth, it can support the empowerment and management of medical expertise in rural and underserved areas through the use of wireless infrastructureless networking technologies.

CHALLENGES IN MOBILE AND WIRELESS TELEMEDICINE

Mobile and wireless telemedicine faces a number of technical challenges emanating from various sources, including design and application scenarios. In this article, we will discuss the challenges related to image and video transmission, wireless signal quality, design, and standards. These challenges are briefly described in the following section.

Image and Video Transmissions

A telemedicine system would require the transmission of digital images as well as digital video. There are no set bandwidth requirements for the transmission of medical images. Some medical images, like a chest cardiogram, can take up to 50 MB of space, and would require longer transmission times. The transmission of medical images would require the use of compression algorithms. There are two types of medical image compression techniques: lossless, and lossy compressions (Kivijarvi, Ojala, Kaukoranta, Kuba, Nyul, & Nevalainen, 1998). Lossless techniques restructure the image exactly from its compressed format, preserving original quality, but providing limited compression ratios. On the other hand, lossy compression ratios provide an approximate reconstruction of the original image. The use of lossy compression in wireless telemedicine would require a careful evaluation of the effect of the compression on different medical diagnostic scenarios. When appropriate, the background of an image could be ignored, since it may be of no diagnostic value. Adapting such techniques can avoid compression of the background and other insignificant regions, providing substantial improvements of compression ratios (Young, Whiting, & Foos, 1999).

A reliable wireless telemedicine system also requires optimal transmission of digital video. In telemedicine, video transmission can be segregated into several categories, namely: real-time video transmission, off-line video transmission, medical video and audio for diagnostic applications, and nondiagnostic video and audio. Real-time diagnostic audio transmission includes transmission of stethoscope audio, as well as audio that accompanies diagnostic video (Pattichis et al., 2002).

There are a number of research projects investigating various techniques of video compressions. One possible technique for achieving acceptable video compression for diagnostic proposes the use of object-based encoding and decoding. Here, the video is segregated into different segments of diagnostic, and then assigned a corresponding bit rate, according to the predetermined significance. This technique significantly reduces the bandwidth, while retaining high-quality video images of regions with diagnostic interest (Pattichis et al., 2002). The difficulty of using object-based encoding is the uncertainty over which part of the video is diagnostically significant. Using interactive video may be enough in overcoming this uncertainty.

Many applications often transmit different types of streams simultaneously, such as medical images, vital signs, real time video, and other readings from various medical sensors. Depending on the application, the wireless transmission requirements for each stream can be quite different. Thus, a challenge when implementing a wireless telemedicine application would be to establish policies to coordinate, prioritize, and compress the various media streams to eliminate signal impedance and congestion problems.

Wireless Communication

The actual throughput of current commercially available cellular wireless links is fluctuant (Chu & Ganz, 2004). For example, CDMA provides data rates of about 153.6 kbps. However, the actual throughput of such cellular wireless links is fluctuant with an average throughput of about 70 kbps. Hence, the implementation of a mobile telemedicine system over such a link will have to take this limitation into account. Other forms of wireless communication technology also have their share of concerns. The use of satellite communications demands the procurement of expensive equipment, dedicated links, as well as skilled operators. Short range wireless technologies, like wireless local area network (WLAN) and Bluetooth, offer data rates that can support multimedia information—unfortunately, over short distances and with degrading results with increasing distance. The 802.11 WLANs offer data rate of 54 MBPS, while Bluetooth offers rates of up to 723 kbps. The 2G and 3G Cellular technologies offer the advantage of distance, but with lower maximum data rates. The maximum theoretical data rates for global system for mobile communications (GSM), general packet radio service (GPRS), EDGE, and universal mobile telecommunications system (UMTS) are 9.6 kbps, 171.2 kbps, 384 kbps, 2 mbps, respectively. The choice of the type of wireless communication technology to be employed depends on several factors, including deployment location, desired quality of transmission, and security level.

Design Challenges and Standards

One of the major challenges for the adoption of mobile data applications is getting the right form factor. This is also true in telemedicine, where it is significant to build the right device to handle the need of the healthcare service it provides. The challenge here is in getting the devices to a manageable size, thus minimizing inconvenience to the user (patient or the practitioner) (Tachkara, Wang, Istepanian, & Song, 2003). Patient confidentiality during use of a handheld device is an area of concern. Security should be factored into the design of the application, since the reliability and quality of patients' information that is stored are dependent on this. The most common solution is password protection. Automatic lockout after a user-defined period of time can also be used. There is also the problem of mapping free text notes into the handheld's understandable codes and structure. Physicians typically store their notes in computers via dictation and transcription. The translation of these notes into digital format by hand notes is costly. Tools to automate this translation are needed. Unfortunately, computer programs still cannot accurately interpret unconstrained text. The alternative would be having the physician coding his/her own data as they enter it through selection menus and other GUI controls (McDonald, 1997).

Each healthcare location may use a different primary computer system, and very likely different laboratory, pharmacy, and radiology service. Each location carries a part of that patient's medical information. Even within a single organization, like a hospital, many separate sources of information exist, containing different data formats and levels of granularity with different coding systems to identify similar clinical concepts. External healthcare sites may contain even more discrepancies than those within the hospital—employing different ways for representing patient data, drugs codes, and image formats. Such differences present information barriers to combining patient data from many sources in a single electronic medical record (EMR) system. The solution to this problem lies in the standards which have started to develop in the recent years (Tachkara et al., 2003), linking the differences between the many sources of electronic patient data, so that the data can be seamlessly combined and transferred with little cost. These standards allow vendors to create telemedicine systems, which can incorporate data from various sources like laboratories, pharmacy, and many more.

Some of the existing medical standards should be used when designing a mobile and wireless telemedicine system. The key standards are: Health Level 7 (HL7), Digital Imaging and Communications in Medicine (DICOM), Systematized Nomenclature of Medicine (SNOMED) and the International Classification of Diseases, Clinical Modification, Ninth Revision (ICD-9-CM) (Bidgood, Horii, Prior, & Van Syckle, 1997; McDonald, 2005; NCHS, 2000).

HL7 is the message standard of choice for communicating clinical information, like diagnostic results, notes, referrals, scheduling information, nursing, problems, clinical trial data, and so on, among heterogeneous computer systems. It is an international standard, in use in countries like the U.S., Canada, New Zealand, Japan, and many countries in Europe. HL7 provides the structure for interchanging patient information between source systems like laboratory, dictation, and pharmacy systems data repositories performance databases and medical record systems (Kurtz, 2002). DICOM is the standard of choice for transmitting diagnostic images. It is supported by all medical imaging vendors, and is tightly coupled to the HL7 standard (Bidgood et al., 1997). Universal code systems are now available for subject matter such as Logical Observation Identifiers Names and Codes (LOINC) for identifying laboratory observations. Other standards such as SNOMED exist for device classifications, organism names, symptoms, and pathology. ICD-9-CM is used in assigning codes to diagnoses associated with inpatient, outpatient, and physician office utilization in the U.S. It is maintained by the National Center for Health Statistics (NCHS) and the Centers for Medicare and Medicaid Services in the United States (NCHS, 2000).

All of the above standards are becoming more and more in use with various telemedicine systems, wired, wireless, mobile, or stationary. There are still a large number of systems in use that do not comply with them. The sooner every one of them adopts these standards, the faster and easier it will be to build interoperable telemedicine systems and applications.

MOBILE AND WIRELESS TELEMEDICINE SYSTEMS

A number of applications and systems have been proposed and developed for mobile and wireless telemedicine in recent years. They can be grouped according to the type of wireless technologies they employ, such as cellular or IP-based, and the type of services they provide, such as emergency healthcare, telecardiology, teleradiology, or remote monitoring. In this section, some existing mobile and wireless telemedicine systems are discussed.

Ambulance Emergency Services

Mobile telemedicine systems have been developed and tested for ambulance emergency services. Such a system consists of two main components: a mobile unit installed within the ambulance, and a base station for receiving hospital Internet connections (Tachkara et al., 2003). Using wireless digital cellular communications technologies, the mobile unit transmits to the trauma center real-time patient vital sign data, audio, and video images of the patient within the ambulance. It uses a video system with a patient monitoring interface to automatically capture images using a lossy JPEG image format, and then transmitted to the base station. The spectrum uses up to four bonded digital wireless phone lines to transmit voice, images, and data. In the hospital, a server receives these signals, and then forwards the transmitted data to a computer monitor to be viewed in an Internet browser setting by the doctor. One major limitation of this system is that it does not support real-time digital video. The video system is a movable camera mounted in the ceiling of the ambulance above the patient head, capturing images at 30 frames per second. In emergency situations, the system allows on-the-fly tradeoff between motion handling and resolution. There is a special button that lets the ambulance personnel capture video clips at 5 fps, which are sent in a store-and-forward fashion.

An ambulance system that supports real-time transmission of critical biosignals (electrocardiogram (ECG), blood pressure, heart rate, temperature, and SpO2) and still images of the patient has been in Europe (http://www.biomed.ntua.gr/emergency112/). The system utilizes a GSM link for transmissions. Originally, the system allows telediagnosis and teleconsultation with mobile healthcare providers by experts located at emergency coordination center or a specialized hospital. At a later point in time, the system was extended to provide a more integrated solution. This system, EMERGENCY-112, enables the transmission of critical biosignals and still images from the emergency site to an emergency call center. It is designed to operate over several communication links, including satellite, GSM, and Integrated Services Digital Network (ISDN). EMERGENCY-112 comprises of two modules: a patient unit operating automatically over several communication links, and a physicians unit located near the expert doctor in the hospital. The physicians unit can also operate over several communications links, depending on the expert's location. Given its ability of use of both wireless and wired communications, EMERGENCY-112 can be used to provide healthcare from ambulances, rural hospital centers, or any other remotely located health center, and even navigating ships.

Another ambulance system is the Teletrauma system (Chu & Ganz, 2004). The system is comprised of two units: a trauma-patient unit, and a hospital unit. The trauma-patient unit resides in an ambulance laptop or tablet PC. Through its connection to devises such as vital sign monitoring devices, portable ultrasound, and video camera, the unit collects patient's information, processes (i.e., compresses) it, and transmits it over 3G wireless link to the hospital unit PC in the trauma center, where it is processed and viewed. At the hospital, the physician has access to visual information like ECG, medical images and real-time video. Because the three media streams are transmitted simultaneously, congestion becomes a factor. To minimize the effect of congestion, the system effectively utilizes different transmission protocols to the different streams. The reliable transmission control protocol is used for the ECG and images to guarantee their transmission integrity. Due to video's tolerance to frame loss, its communication is managed using UDP, coupled with a frame rate adjustment policy.

Telemedicine in Space

National Aeronautics and Space Administration (NASA) has been at the forefront in the field of telemedicine, since the 1970s (Jones, McGinnis, Hamilton, D'Aunno, Simmons, Melton, & Armstrong, 2002). NASAs interest in telemedicine stems from the potential of using telemedicine in care of astronauts operating beyond Earth's orbit in the future. A telemedicine program developed by NASA comprises the astronaut patient, a consultant, data acquisition and handling hardware/software, and telecommunication connection. A device called Telemedicine Instrumentation Pack (TIP) collects medical audio, video, and data from the patient in space. TIP collects data like heart rate, blood oxygenation, blood pressure, and EKG, and it transmits medical video of eye, skin, ear, nose, and throat. The system contains an electronic stethoscope that collects heart, lung, and bowel sounds to ground flight surgeons. TIP data is output via the space stations or shuttle communication network back to earth.

Telecardiology System and Ultrasound

Telecardiology is concerned with diagnosis and treatment of diseases of the heart and circulatory system at a distance. One proposed system for telecardiology consists of a mobile van that houses a whole-body computed tomography (CT) scanner, and a second van that houses satellite communication equipment (Takizawa, Sone, Hanamura, & Asakura, 2001). This system features CT scanning, online two-way transfer of image data, and teleconferencing with a consultation center with various medical experts. The system personnel are the drivers, and a radiology expert that operates both CT scanner and the telecommunication unit. The van hosts a PC that manages CT data transmission teleconferencing equipment, an image printer, a facsimile machine, and resuscitation equipment. Communication between the mobile and stationary unit is done at 155 mbps in asynchronous transmission mode (ATP) via satellite or ISDN. Image communication uses a DICOM 3 protocol.

TeleCardio-FBC is a Web-based telemedicine system developed and deployed in Brazil that enables cardiologists at the unit of cardiology and cardiovascular surgery to cooperate with other physicians (Monotoni et al., 2002). The system provides cardiology care for patients living in remote areas, reducing costs and allowing better follow-up services for discharged patients. This system was designed for use with desktop computers as the only computational platform. Telecardio Mobile was later developed with the purpose of taking full advantage of 3G technology, adding mobility to the original system. It provides online access to the information in the TeleCardio-FBC system through PDAs and mobile phones (Monotoni, Villela, Rocha & Rabelo, 2002). This system consists of two subsystems: M-TeleCardio, and WapCardio. M-TeleCardio allows access to full functionality offered by TeleCardio-FBC to the mobile device (Laptop, PDA, palm, mobile phone) that is wirelessly connected to the Internet. WapCardio subsystem utilizes wireless application protocol (WAP) technology to supply medical information like remote consultation requests and results of medical procedures to physicians on mobile.

Adding a wireless capability to ultrasound would enable image scans directly from the patient rooms, and immediate doctor consultation from distant locations. The purpose of a wireless ultrasound application is to create an electronic archival system for ultrasound images for retrieval through wireless medium at remote locations (Kazmi, Arslan, Tulgar, Pedersen, Pahlavan, Cengiz, & Arslan, 2000). The doctors will take an ultrasound scan of the patient, save it on the wireless laptop, and then transmit it to a centralized server for future references. The application also includes an option for the doctor to annotate voice and text files to the ultrasound image file. Unique to the wireless ultrasound application is that it can handle three different file formats, including image, voice, and text, which are all transmitted and received as a single object between the laptop and the server archive.

PDA-BASED MOBILE AND WIRELESS TELEMEDICINE APPLICATIONS

PDAs are increasingly becoming more popular in use within the field of medicine. Physicians are showing interest in computer-based information about medications, patient education material, and treatment recommendations. Such interest has motivated a lot of software vendors in developing various types of medical applications for the PDA platform (Fisher & Steward, 2003). Current PDAs do not have the functionality to manage a complete electronic medical record system, nor are they capable of storing large graphics. Regardless of these limitations, they have been identified by physicians as excellent tools for managing clinical information and accessing it at the point of care (Bates, Ebell, Gotlieb, Zapp, & Mullins, 2003). This section presents an overview of current literature regarding the applications of handheld devices in medicine.

Basic PDA Applications

A PDA comes with many basic functions that are built into the operating system. These functions can be quite valuable for the medical practice and healthcare. Some of these include: scheduler, address book, a to-do-list, and memo functionality. A physician uses the scheduler to set up alarms alerting him of upcoming appointments with patients or other medical practitioners. The latest version of Windows CE5 operating system comes packaged with such basic applications (Ebell, Gasper, & Khurana, 1997).

Another basic functionality is the ability to read text files, such as medical books, references, and documents downloaded from the Internet. Several vendors offer such reader applications for PDA platform. Adobe has a PDA version of its reader, while AportisDoc Mobile and TealDoc (http://www.tealpoint.com/softdoc.htm) are two other document reader applications.

Voice dictation applications have been proven to be very useful for the physician. As the physician speaks, the dictation software automatically writes it as text, that is saved as a text file that can be retrieved later for analysis by the same doctor or another. Many PDAs come equipped with voice recognition or dictation software that can be used for this purpose.

Medical Information Access

It is important for the doctor at the point of care to have access to medical information. Access to medical information is becoming more important when considering the rate and amount of newly added medical information, and the increase in expectations to follow medical guidelines. There are several applications allowing access to internet-based literature. AvantGo is a free program that allows the mobile user to download Web sites on his handheld PDA on a daily basis for off-line viewing (http://www.avantgo.com). During synchronization, medical journal Web sites that the doctor subscribes to are downloaded into it (or updated if the content is out of date). This allows the doctor to have up-to-date abstracts as well as full articles in relevant medical journal on their PDA, at any time.

Drug information databases and pharmacopoeias can be formatted onto a handheld device. Studies have shown that drug applications can save physicians valuable time during information retrieval, and that it easily incorporates into their workflow, making improvements in drug-related decision making. Inquiries about drugs at the point of care provide prescription information at the patient's bedside, potentially reducing the information search time, as well as mitigating the risk of incorrectly prescribing a harmful drug (Rothschild, Lee, Bae, & Bates, 2002).

There are several mobile applications for handheld devices. A very popular handheld drug database is ePocrates. This free medical reference guide provides a comprehensive drug list, dosing guidelines, drug interaction guidelines, retail pricing of drugs, and common side effects. Another popular free database, the ABX Guide (http://hopkins-abxguide.org/show_pages.cfm?content=siteinfo_content.html), was developed at the division of Infectious Disease at the John Hopkins University. It allows searches for antibiotic information with respect to diagnosis, pathogen, or antibiotic type. The database is always up to date, and it can be transferred to a Palm-based handheld to be used at the point of care. Another mobile drug reference system is the *mobilePDR* (mobile Physician's Desk Reference) (Bojovic & Bojic, 2005). The *mobilePDR* consists of several components: an application and a corresponding database on a PDA device, desktop software for backing up data and synchronization over the Internet with Medec Web server that delivers updates to drug data.

Patient Tracking Applications

PDAs also play a very significant role in areas where patient tracking is needed. Handheld devices can be used to monitor patients' health, and to keep medical staff informed of his/her condition. Recently, many patient tracking programs have become available. Patient Track, which is available for both Palm OS and Windows CE PDAs, allows the user to enter patient records, including demographics, medication/allergy lists, test results, and radiology reports. Another application of interest is the Ward Watch (Palm OS). This application aids medical staff involved in ward rounds by recording investigations, medications, dosages, and consultations (Duncan & Shabot, 2000; Fischer & Steward, 2003). The TelePatient System assists healthcare providers in monitoring patient's information at all times (Chu & Ganz, 2004). The system involves two networks: a wireless personal area network that contains the medical data acquisition units, and a wireless network for transmitting the data to the healthcare provider. Here, a PDA is used as a gateway between the two networks. Medical data acquired by the various medical acquisition units (i.e., cardiac monitor, camera) is passed through the PDA to the healthcare provider.

There are risks in the areas of patient data management and sign-over between physicians, with respect to propagation of errors, when done by hand using pen and paper means. PDAs may play a paramount role in mitigating these human errors. Documents containing patient information can be transferred from the desktop computer to the PDA or created on the PDA. Changes to the data made on the database can be transferred to the PDA during synchronization. Similarly, data manipulated on the PDA can be sent to the desktop application or database in order to update its out-of-date information. Infrared beaming or Bluetooth communication can be used to transfer information between the PDAs of different physicians, allowing them to exchange patient information between shifts.

Medical Research and Education Applications

The medical education environment is using PDAs for electronic data collection to manage information. Various medical education institutes are utilizing PDAs for the evaluation of training of medical students, and in the monitoring of student's clinical experience. The University of Minnesota Medical School has equipped its students with PDAs loaded with clinical references and tools to collect information about the patients they see and the seminars they attend during their clerkship (Speedie, Pacala, Vercellotti, Harris, & Zhou, 2001). A survey to program directors of all U.S. Medical Schools found that two thirds of the schools were using handheld devices in their residency programs (Fischer & Steward, 2003). A PDA application that logs and tracks resident's procedural experience has been shown to be a useful tool for ensuring adequate educational experience.

PDAs outfitted with tailored application for data collection have been used for research data collection. A case in point is the use of a PDA for the evaluation of craving and withdrawal symptoms of patients in a smoking cessation program. Instead of asking the patients to remember their experiences looking back, they can enter this information in real-time at their natural environment. This type of point of care data collection, using a handheld device, has been shown to be quite efficient—23% faster than traditional hand recording (Fischer & Steward, 2003). The size advantage of a PDA, being small and handy, is that it can easily be carried in the briefcase or a pocket, and data entry can be carried out at any time.

Business Applications

PDAs can play an important role in increasing medical business efficiency. Business processes are improved by utilizing PDA's basic applications like schedulers, to-do-lists, and remainders. Another way to improve business efficiency is by handling the billing process. Billing information can be entered to the PDA by the physician during rounds in the hospital, and then transferred to a central database (later on during synchronization) and viewed by office staff. This approach provides quicker billing and improves the business cash flow.

Prescription and Pharmaceutical Applications

Using a handheld computer to do electronic prescription is becoming increasingly popular. Many physicians are now writing prescriptions electronically and transmitting them to the pharmacy without manual intervention. Using this approach mitigates the number of errors that may have been otherwise introduced by illegible handwriting or dictation, as well as saving time for the physician, pharmacist, and patient (Embi, 2001; Fischer & Steward, 2003).

FUTURE TRENDS IN MOBILE AND WIRELESS TELEMEDICINE

The next generation mobile and wireless communication technologies coupled with heterogeneous network tremendously improve the future mobile and wireless telemedicine services. There is an increasing research for a mobile telemedicine system that can rapidly be deployed in remote areas, or in disaster recovery situations where telecommunication infrastructure is lacking or destroyed. One such system is the Tele-Emergency system, which is based on mobile ad hoc networks (MANETs) (Husni, Heryadi, Woon, Arifianto, Viswacheda, & Barukang, 2006).The basic requirements for such systems are the capability to work in remote areas with little or no existing communication infrastructure, and provide both basic and extensive medical services. The system is designed to manage medical record data, as well as deliver real-time multimedia and geographical information system data wirelessly. In MANETs, mobile nodes communicate directly with one another in a peer-to-peer manner, where each mobile node also acts as a router for any other node. The healthcare practitioners will use mobile nodes to transmit patient data to the healthcare center or mobile ambulance. The mobile ambulance is a mobile node equipped with a local server and optional communication devices. Every mobile node within the subnetwork can route information through a MANET routing protocol. Mobile and wireless telemedicine can also be deployed in heterogeneous networking environment, which includes wireless mesh networks (with infrastructure or hybrid architectures). Recent advances in wireless mesh networking that allows multiradio and multichannel transmission will significantly improve the performance of the future mobile and wireless telemedicine.

CONCLUSION

Wireless technologies can provide promising solutions in the future healthcare and medical applications. Current applications vary with respect to the wireless technology they employ and the type of service they provide. Whether they utilize 3G, 4G, or WLANs communication technologies, their wireless capability adds a much-needed dimension to existing wired and stationary healthcare services that result in the fast and successful delivery of healthcare services in remote areas. Mobility, coupled with wireless connectivity, has the advantage of providing more flexible healthcare services at the point of care. In many medical situations, the ability to provide such services saves lives in danger, or significantly mitigates the severity of medical conditions by offering a quicker alternative. Moreover, the use of PDAs in telemedicine can provide basic services like scheduling and medical billing. It provides a convenient way to wirelessly retrieve medical information on the go, and to make information immediately available at the palm of the physician's hand. The existing systems and applications can be further improved while the new ones emerge, making use of the advances in medical, communication, and networking technologies.

KEY TERMS

Bluetooth: Wireless technology that enables data connections between electronic devices—such as desktop computers, wireless phones, electronic organizers, and printers—within a short communication range, typically about 10 meters.

Electrocardiogram (ECG): It measures heart's electrical activity.

General Packet Radio Service (GPRS): It provides mobile and wireless data services.

Digital Imaging and Communications in Medicine (DICOM): A set of standards for handling, storing, and transmitting information in medical imaging.

Health Level 7 (HL7): It is a standard for healthcare, and is the interface standard for communication between various systems employed in the medical community.

Mobile Ad Hoc Network (MANET): It is a self-configuring network of mobile nodes connected by wireless links.

Personal Digital Assistant (PDA): A hand-held computer device which manages personal information and interacts with other computers and telecommunications systems.

SpO2: A measurement of the amount of oxygen attached to the hemoglobin cell in the circulatory system.

Wireless Application Protocol (WAP): It is an application that allows users to access information instantly via handheld wireless devices such as mobile phones, pagers, two-way radios, smart phones, and PDAs.

Wireless Local Area Network (WLAN): WLANs are defined in the IEEE 802.11 standard.

Classification of Waste in Hospitals

Victoria Hanna
University of Melbourne, Australia

Kannan Sethuraman
Melbourne Business School, Australia

INTRODUCTION

The health care industry today is a complex web of ever-changing relationships among patients, physicians, hospitals, insurers, employers, communities, and government. A combination of factors, including the emergence of intense, dynamic competition (and consolidation) and increasing expectations of demanding patients, has generated a challenging environment for hospitals. Today, spending on health care in the United States has risen to $1.3 trillion, which almost equals 14.5% of the United States GDP. The cost of providing health care in OECD countries ranges from 7% to 9% of GDP (Folland, Goodman & Stano, 1997) and is expected to rise due to the aging population, an increasing number of chronic health conditions, soaring drug costs, and costs of new technology. With health care costs continuing to rise faster than general inflation, a theme that resonates throughout the health care field today and receives increasing attention from policymakers, academia, and industry is the necessity to contain costs without compromising quality of care. Here we interpret the quality of care as how cost effectively the hospital organizes its resources to meet the medical requirements of its patients.

Hospitals have to focus their efforts on identifying and eliminating waste of all forms if they are to succeed in today's competitive landscape. A recent study by the Murphy Leadership Institute (Murphy, 2003) concluded that wasteful work consumes more than 35% of hospital employees' time. This wasteful work includes activities such as completing multiple forms for the same task, filing inefficient shift-to-shift departmental reports, waiting for medications, and searching for misplaced records. Jimmerson warns that the actual amount of waste in health care lies closer to 60% (Panchek, 2003).

In this chapter, we briefly review principles of lean philosophy for improving performance and then present a classification of waste that is relevant to hospital management. This classification is aimed at directing hospital initiatives toward understanding and controlling waste in its health care delivery processes. Through several examples from real-life hospital case studies that we have investigated, we trace much of the waste to various types of variability (both natural and artificial) and offer prescriptions to control variability. We then provide some guidelines for streamlining processes and show how this would benefit various stakeholders. We conclude the chapter with some directions for further research.

BACKGROUND

Since the 1980s, hospitals have borrowed concepts and ideas that have helped transform manufacturing industries for decades. These include ideas from total quality management, lean thinking, and six sigma approaches. Although there are some overlaps among these principles, in this chapter, we focus primarily on lean principles and their applications in hospitals.

Lean Thinking in Hospitals

Toyota Production System principles, popularized by Womack, Jones, and Roos (1990) as lean production concepts, have helped turn around many manufacturing firms. Although Womack and Jones (1996b) state that the principles of lean production can be applied equally in every industry around the globe, the adoption of lean principles has largely remained limited to the manufacturing industries, and there is sparse evidence to suggest the effective "crossover" of these principles to nonmanufacturing settings. However, some recent research holds promise for the transferability of these principles to the service sector; in particular, to the health care sector. Lean patient care is all about creating more value for patients through the elimination of all nonvalue-adding steps in the health care delivery process. Wysocki (2004), Miller (2005), and Weber, Jimmerson, and Sobek (2004) have documented initiatives highlighting how lean thinking is helping to transform hospitals around United States.

In the following sections, we investigate how waste manifests in hospitals and offer prescriptions for its reduction/elimination.

MANIFESTATION OF WASTE IN HOSPITALS: CLASSIFICATION, REASONS, AND CURES

Drawing on the vast literature that exists on the Toyota Production System (Liker, 2004; Monden, 1993; Womack & Jones, 1996a; Womack et al., 1990), we offer a classification of waste, highlighting how waste propagates in hospitals. This classification is expected to assist both hospitals and other players in the health care value chain in their pursuit of the elimination of waste.

Waste Classification

Ohno (1988) identified and popularized the notion of seven wastes in manufacturing that include overproduction, waiting, unnecessary transport or conveyance, over-processing or incorrect processing, excess inventory, unnecessary movement, and defects. We provide a revised classification of waste that adapts each waste in Ohno's classification to fit the health care context.

1. **Over-servicing.** This waste identifies situations in which patients are being processed or served at a stage earlier or faster than their actual needs in subsequent stages. This is a symptom of patients being pushed through the system. Such an approach appears logical and cost-effective when batching economies or other constraints due to poor coordination are present. However, this push approach often creates greater congestion and larger queues. For instance, in many of the hospitals we have studied, patients scheduled to have surgery in the morning session in a theater were all requested to arrive between 6.45 and 7.15 A.M. Our investigation found that this practice was followed to allow anesthetists to complete their preassessment of patients prior to the commencement of surgery on the first patient. This practice is largely motivated by their need to be physically present in the theater for the complete duration of surgery, poor information transfer of patient medical records between surgeons and anesthetists, and the pressure from surgeons to ensure fast turnaround between surgical cases. As a consequence, there is a glut of patients undergoing preoperative assessment much ahead of their scheduled need, overburdening the subsequent stages resulting in chaotic movement of patients, staff, and information and long wait times.
   Another example of over-servicing is when diagnostic tests are performed much ahead of their actual requirement, causing redundancies and wastage of resources. In addition, requesting more diagnostic tests than what is required for accurate assessment, is an example of over-servicing patients.
2. **Waiting.** In hospitals, one can observe two kinds of waits—one experienced by patients and another by staff and doctors in the system. Under lean philosophy, both of these waits are categorized as waste. Patient waits correspond to poor service and are undesirable. Resource waits result in reduced utilization and increased costs for the hospital. Hospital practices focus on minimizing the wait for doctors and its staff and resort to batching strategies, which result in higher waits for patients. Lack of coordination across stages also results in excessive patient waits and doctor waits. Patient waits have other costs that are normally not well recognized by hospitals. For instance, you need more room to hold them, more resources to engage and monitor them, and more resources to progress them through the system.
   To improve performance on this measure, hospitals need to understand the implications of queuing and the causes and costs of congestion. Little's law from queuing theory provides a useful framework, illustrating the linkage between average patient wait time, the average number of patients in progress, and patient throughput rate.
3. **Unnecessary transport or conveyance.** Historically, hospitals have been designed by specialty rather than around the patient. As a result, we often find patients who are in the middle of their treatments moved a long distance, creating

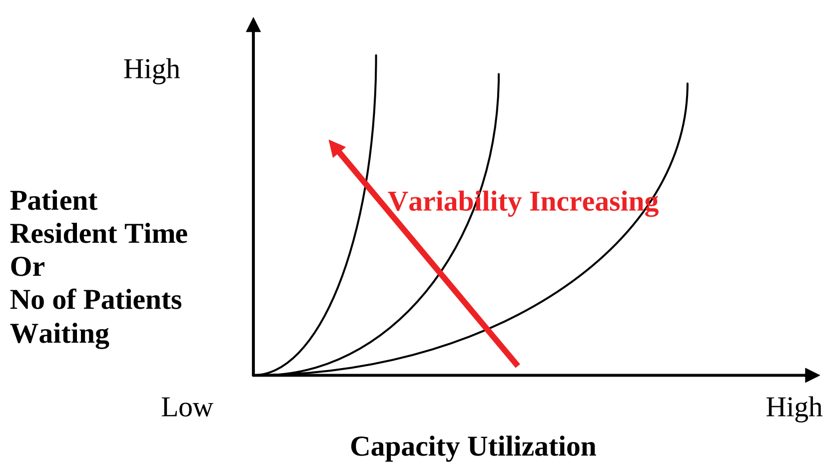
unnecessary transport. Also, they are moved in and out of waiting bays or postoperative wards to accommodate capacity restrictions elsewhere. To prevent such redundant transport, a coordinated approach to patient process flow is a must. Specialty hospitals such as Shouldice Hospital (Heskett, 1983) in Toronto have streamlined their process flows around patient needs, minimizing movement of patients through the system.

We have also witnessed a convoluted flow of documents (between doctors and hospitals), medication, and other shared ancillary equipment and staff, which often result in a waste that can be categorized as unnecessary transport.

4. **Unnecessary movement.** Unnecessary motion is caused by poor workflow, poor layout, and inconsistent or undocumented work methods. Any wasted motion that nurses, surgeons, or orderlies have to perform during the course of their work, such as looking for reports, reaching for reports or patients, can be classified as unnecessary movement. Also, any unnecessary walking that they perform will fall into this category.
5. **Over-processing or incorrect processing:** In hospitals, processes evolve over time and are typically not optimized in a holistic manner. Each specialty focuses its effort on enhancing patient care from its own perspective. As a result, you have unnecessary or over-processing and sometimes incorrect processing. Unnecessary surgeries and diagnostic tests are well-known examples of this type of waste. Rother and Shook (1999) provide a technique called value stream mapping that enables hospital officials to document and understand the steps that are essential for serving their patients more effectively. From a clinical perspective, the development of pathways has enhanced the quality of care and has facilitated earlier detection of deviation from expected treatment paths.
6. **Excess Inventory.** This waste is easily identifiable in hospitals. There is plenty of evidence for excess stock of medical supplies, pharmacy items, and other medical equipment resulting from uncoordinated purchasing policies.

In a hospital environment, patients in progress (PIP) also represent a form of inventory, and the level of PIP is determined by batching considerations and variability. Litvak and Long (2000) identified four forms of variability that occur in health care systems; namely, clinical, flow, professional, and artificial variabilities. Clinical variability captures the degree of illness, choice of treatment alternatives, and response that patients with the same disease exhibit. The flow variability is illustrative of the randomness inherent in patient arrival rates, and professional variability illustrates the heterogeneity in the ability of medical practitioners and health care delivery systems to provide the best treatment. The fourth form of variability was branded as artificial, and is an artifact of dysfunctional management and inefficient health care delivery practices. These variabilities increase PIP and the average patient resident time in the system. The relationship between PIP or patient resident time and variability

Figure 1. The ill effects of variability and capacity utilization



is conceptually shown in Figure 1. Based on this relationship, we can conclude:

i. Increased variability (either in the patient arrival process, the patient service process, or both) will essentially cause patient queue length and average patient resident time to increase.
ii. In a highly utilized environment, increased variability will result in the patient queue length and average patient resident times increasing in a highly nonlinear fashion.
iii. With higher levels of variability, the system will have to operate at lower levels of utilization to achieve target responsiveness (measured in terms of patient resident times).

It is critical for hospitals to get a better handle on various types of variabilities that cause havoc on patient responsiveness. Clinical and professional variabilities are virtually impossible to manage; however, flow variability can be managed though improved scheduling practices that attempt to level out the workload. Artificial variability arising from dysfunctional practices has to be minimized if not eradicated completely.

7. **Defects.** Medical service errors such as wrong medication or wrong procedures performed on a patient constitute defects in a hospital context. These errors can be life threatening, and the costs of such errors should not be measured only in terms of dollar value. They also waste resources in at least four ways. First, the materials (e.g., medical supplies and other inputs) that were consumed to provide the service cannot be recovered; second, the labor (e.g., doctor and other personnel time) used to provide this service is wasted; third, you require labor to perform the rework; and last, labor is required to address any forthcoming patient complaints (e.g., litigation, etc.) and word-of-mouth adverse publicity. Some medical errors occur because the concept of error proofing is less prevalent in health care, and due to problems not being tackled at their source. Unless hospitals build a culture of empowering its workforce to stop and fix problems at their source, it is very hard to eliminate this type of waste. For example, Wysocki (2004) emphasizes the need to empower workforce through an example of a nurse who was empowered to bring immediate attention to a situation that otherwise might have been life threatening to a patient.

   In a recent book, Liker (2004) extended Ohno's waste classification to include an eighth waste—unused employee creativity.

8. **Unused employee creativity.** This refers to the time, ideas, skills, improvements, and learning opportunities that a hospital foregoes by not engaging or listening to their employees. People who are closest to their processes know the finer details of the processes and how they can be improved. Few hospitals have tapped this resource meaningfully.

Waste Minimization Strategies

In this section, we prescribe approaches that would help minimize the occurrence of waste in hospitals. See Table 1 for a summary.

1. **Standardize work procedures and reduce variability:** Standardization of work procedures would help minimize artificial variability created through dysfunctional processes and facilitate building in quality. If the errors persist in spite of following standardized work, then it is important to continuously strive to improve the standards.
2. **Streamline patient flow:** The smooth flow across stages of the treatment process would ensure that processes are connected meaningfully with one another without any loss of information from one stage to another. A tightly coupled process would help highlight bottlenecks and imbalances in the system more effectively. As Minoura, a former president of Toyota Motor Manufacturing, North America, mentioned (Liker, 2004), problems in single-piece flow manufacturing forces everyone to solve the problem immediately and enables everyone to become better team players. Similarly, coordinated patient flow has the potential to not only build in quality but also improve the responsiveness of the system.
3. **Improve coordination across stages in the health care value chain:** It is not only important that the hospital manages the value creation process within its boundaries effectively, but it is also critical to coordinate its interface with external parties involved in the treatment process. When the information flow is disrupted between

Table 1. The causes, contributing factors, and countermeasures for different types of waste in the health care industry

Types of Waste	Contributing Factors	Countermeasures
1 Over-servicing	Batching economies Poor coordination and information sharing Lack of goal congruence	Modify the measurement and evaluation systems to facilitate the use of systemwide objectives Adopt pull approach as opposed to the push approach to manage patients through the system Have a common database that can provide real-time updated information to all concerned parties
2 Waiting	Floating bottlenecks Imbalance in capacity across stages Variability in patient arrival and service processes Unexpected disruptions Lack of information sharing across different stakeholders	Minimize the variability in patient mix and schedule in elective surgeries Keep buffer capacity during instances of increased uncertainty as in emergency cases Align incentives to improve data sharing
3 Unnecessary transport or conveyance	Poor facility layout Lack of real-time updating of patient information	Design layouts around patient flow when possible Ensure centralized real-time updating of information
4 Unnecessary movement	Undocumented or poor work methods Inefficient design of workflow Poor layout of facilities	Apply value stream mapping to eliminate nonvalue-added activities
5 Over-processing	Inefficient design of work flow Undocumented procedures	Standardize work methods and procedures
6 Excess Inventory	Batching economies Bulk discounts Imbalances in capacities across stages Uncertainty in supply Variability in patient service process Artificial variability introduced through dysfunctional practices	Develop strategic partnerships between surgeons, hospitals, and other stakeholders Initiate vendor-managed inventory for medical suppliers where possible Initiate collaborative planning and forecasting methods for managing demand
7 Defects	Lack of error proofing Batching and demand surges create a pressurized environment, leading to increased errors Lack of worker empowerment to fix problems at source	Empower employees and ensure quality at the source at all opportunities Develop KPIs to reflect strategic priorities
8 Unused employee creativity	Lack of appreciation for human potential to innovate	Provide forums to give employees opportunities to share their ideas for improvement

the surgeons and the hospital staff, it can create multiple opportunities for propagation of waste through the system. Hence, all efforts need to be made to ensure smooth flow of real-time information across the different entities.

4. **Align incentives:** While the effective treatment of patients is the overarching objective, the priorities of various parties involved in the treatment process can be divergent, and meaningful incentives will help align the priorities.
5. **Adoption of consistent information technology:** In today's rapidly changing technological world, it is imperative for hospitals to invest in information technology that can take advantage

of centralized information. This would minimize duplication of efforts and clerical errors and achieve higher levels of data consistency and improved responsiveness.

6. **Build quality at the source:** Jidoka (building quality at the source) will ensure that the errors occurring at a particular stage do not flow downstream unattended and thereby cause even more waste or distress. Also, it facilitates the identification and rectification of root causes right at the source.
7. **Level out the workload:** Although it sounds harder to level out a work schedule in the service setting, it is not far fetched to see how this concept can be applied in hospitals. This is easier to do in case of activities that can be planned ahead of time. The key principle here is to minimize the unevenness in workload that may result due to an unleveled schedule. Also, Sethuraman and Tirupati (2005) have recently documented the evidence of the bullwhip effect in the health care sector. If the workload is not leveled out, then it has the potential to amplify the demand variation as one travels up the health care value chain.
8. **Use visual control to highlight problems:** Fujio Cho, president of Toyota Motor Corporation (Liker, 2004), said, "Mr. Ohno said one must clean up everything so you can see problems. He would complain if he could not look and see and tell if there is a problem." Visual control aids in noting whether the work is being performed in accordance with the standard, and it highlights any deviation from the standard. This will be very much applicable in case of hospitals, and it would refer to the design of visual cues and communication that enable fast and proper execution of operations and processes.
9. **Empower workforce:** People closest to the process have the most creative ideas to solve problems or improve the process. Hence, it is vital for hospitals to harness this resource meaningfully as manufacturers have done in the past.

CONCLUDING REMARKS AND DIRECTION OF FUTURE RESEARCH

The taxonomy of waste we have provided should aid hospitals and hospital management in their quest to eradicate waste from their business processes. However, the question still remains whether it is truly possible to translate concepts that have benefited the manufacturing sector into health care. Consider "single patient flow" as akin to single piece flow in the case of manufacturing—is it ever achievable in a hospital setting, and if so, would it deliver the same benefits that it has to manufacturing organizations, such as the elimination of waste, achievement of higher quality, improved safety and better productivity? More research is required to fully understand the benefits and consequences of translating useful principles from manufacturing into a language and form that the health care sector can easily understand and apply.

KEY TERMS

Artificial Variability: The poor management of the processes used to provide care. This type of variability (dysfunctional management and policies) can be reduced.

Lean Principles: Lean principles were originally developed in Toyota's manufacturing operations, known as the Toyota Production System. The term was popularized in the seminal book, *The Machine that Changed the World* (Womack et al., 1990), which clearly illustrated for the first time the significant performance gap between the Japanese and Western automotive industries.

Natural Variability: A source of great waste in the health care delivery system is excessive variability in the processes used to provide care. Natural variability is largely outside the control of a hospital. It includes clinical variability (patients differ in the type and severity of their diseases, and similar patients respond differently to treatment), patient demand variability (patients arrive for treatment randomly over time), and professional variability (different providers treat similar patients in different ways), which has given rise to the development of approaches like practice guidelines and clinical pathways.

Patients in Progress (PIP): In a hospital environment, patients in progress (PIP) represent the number of patients in the system at one time. PIP is a form of inventory, and the level of PIP is determined by batching considerations and variability.

Patient Resident Time: The amount of time a patient spends in the health care system, typically measured from the moment he or she enters the system until time of medical discharge.

Wasteful Work: Wasteful work is the fraction of the total time and effort in any organization that *does not* add value for the end customer. By clearly defining value for a specific product or service from the end customer's perspective, all the nonvalue activities, or waste, can be targeted for removal step by step. For most production operations, only 5% of activities add value; 35% are necessary nonvalue-adding activities, and 60% add no value at all. Eliminating this waste is the greatest potential source of improvement in corporate performance and customer service.

Examples of waste:

- Overproduction
- Waiting
- Transporting
- Inappropriate processing
- Unnecessary inventory
- Unnecessary movement

Clinical Decision Making by Emergency Room Physicians and Residents

INTRODUCTION

Clinical decision-making is a complex process that is reliant on accurate and timely information. Clinicians are dependent (or should be dependent) on massive amounts of information and knowledge to make decisions that are in the best interest of the patient. Increasingly, information technology (IT) solutions are being used as a knowledge transfer mechanism to ensure that clinicians have access to appropriate knowledge sources to support and facilitate medical decision-making. One particular class of IT in which the medical community is showing increased interest is clinical decision support systems (CDSSs).

CDSS is "any program designed to help healthcare professionals make clinical decisions" (Musen, Shahar & Shortliffe, 2001). Decision models used in CDSS, especially those providing patient management and diagnostic advice, are normally based on expert knowledge, either discovered from past data or elicited from medical books or practice guidelines. The quality of any patient-specific CDSS is reliant on the quality of the underlying decision model(s). These models have to reflect clinical expertise, which implies that clinicians using such systems have to provide values for the CDSS input variables that can be correctly elicited only with an appropriate level of expertise. That is, only experienced clinicians will be able to provide CDSS input variables in a reliable and comprehensive manner, while inexperienced clinicians will be forced to gather information and make assessments for activities that they may lack the clinical acumen to do accurately. This may diminish the usefulness of the CDSS and the validity of the advice generated by the system, and lead to the rejection of the system by novice clinicians as forcing them to evaluate a patient in a way in which they are not accustomed.

CDSS users can be categorized using the classical taxonomy of novice or expert decision-makers. Differences between these two classes of decision-makers have been widely documented in the decision-making and medical literature. In complex domains such as medicine, it typically takes 10 years of training before one can be considered an expert (Prietula & Simon, 1989). Over time, experts develop a capability to systematize information and to form complex networks of knowledge that is stored in long-term memory (Arocha, Wang & Patel, 2005; Prietula & Simon, 1989). Novices lack these knowledge networks, and thus, when faced with new informational cues, they need to produce more hypotheses than experts (Kushniruk, 2001) and are unable to filter out irrelevant cues (Patel, Arocha & Kaufman, 1994), thus taking a longer time to make their decisions.

The purpose of this chapter is to explore how two classes of CDSS users representing different levels of expertise consider expert-generated CDSS inputs in their clinical decision-making. In this study, staff physicians are considered expert decision-makers and residents are considered novice decision-makers. Our study is based on the empirical results of a clinical trial of a CDSS that was developed for helping with triage decisions of pediatric abdominal pain in an emergency department (ED) (Farion, Michalowski, Slowinski, Wilk & Rubin, 2004). On the basis of collected data and other established literature on expert/novice decision-making, we evaluate differences between these two groups of CDSS users and draw more general conclusions for supporting clinical decision-making with technology.

The research question we seek to answer is:

What importance do residents and staff physicians place on expert-generated CDSS input variables in making their clinical decisions?

This chapter is organized as follows. First, background about the Mobile Emergency Triage (MET) CDSS is presented, along with an explanation of the input variables that are used by the system. Next, descriptions of the sample and data collection procedures are provided, along with the analysis techniques used. This is followed by a discussion of the results, future trends in CDSS design, and a conclusion.

BACKGROUND

The MET system was designed and developed to support ED physicians in making triage decisions about children with abdominal pain. The MET system consists of a server that interfaces with a hospital's electronic patient record system using the HL7 protocol and a client that resides on a PDA. The client facilitates the collection of clinical data during examination by physicians and also supplies a triage support function. The client is used directly at the point of care.

The MET client provides a series of interfaces to collect 11 out of 13 input variables shown in Table 1 that are used by the abdominal pain triaging algorithm (the remaining two variables, gender and age, are extracted automatically from the electronic patient record system). The collected data get transferred to the server for persistent storage and usage in the electronic patient record system. Discretizations for numerical input variables were based on medical practice, and the triage decision-making model was developed using retrospective chart analysis and knowledge discovery techniques based on rough set theory (Pawlak, 1991; Slowinski, 1995). The decision model is represented as decision rules that are easy to comprehend and interpret by physicians, and therefore are well accepted in clinical practice.

Based on the values of the input variables, the client uses the rule-based decision model to offer a suggested triage decision, which can be one of the following three options:

Table 1. Abdominal pain triaging input variables

Input Variable Name and Description	Possible Values
Age	number, discretized to 0-6, >= 7 years
Gender	male, female
Duration of pain	number, discretized to <=24 hrs, 1-7 and >7 days
Site of maximal pain	right lower quadrant (RLQ), lower abdomen, other
Type of maximal pain	continuous, other
Vomiting	yes, no
Previous visits in the ED for abdominal pain during the last 48 hours (irrespective of site)	yes, no
Temperature	number, discretized to <37, 37-39, >= 39 Celsius
Site of maximal tenderness	RLQ, lower abdomen, other
Localized guarding: localized muscle sustained contraction noted when palpating the abdomen	absent, present
Rebound tenderness: pain felt at site of maximal tenderness, produced by altering intra-abdominal pressure	absent, present
Shifting of pain	absent, present
WBC (white blood cells)	number, discretized to <=4000, 4000-12000, >=12000

- **Discharge.** Patient can be discharged to home, as their pain is caused by a nonserious problem.
- **Observation/Investigation.** Further in-hospital evaluation is required to determine the cause of the pain, as a serious cause (other than appendicitis) is likely.
- **Consult.** Surgeon is called because acute appendicitis is suspected.

Abdomen location input variables (site of maximal pain, site of maximal tenderness) were collected by clicking on an abdomen pictogram on the PDA. A screen capture showing the interface for "site of pain" is provided in Figure 1. The resulting input variable values (RLQ, lower abdomen, other) and corresponding areas on the abdomen were defined by surgeons and ED physicians. Figures 2 and 3 show MET screen captures for "type of pain" and "temperature," respectively.

METHODS AND RESULTS

This study of staff physician and resident decision-making was part of a larger clinical trial that was designed to evaluate MET-AP clinical accuracy with physicians' triage predictions. Results of that study can be found in Farion, et al. (2007).

Sample and Data Collection

A convenience sample of 574 eligible children, aged 1 to 16 years, with acute AP were enrolled with consent between July 2, 2003, and February 29, 2004, at the Children's Hospital of Eastern Ontario (CHEO) ED.

Figure 1. MET-AP screen capture for site of pain

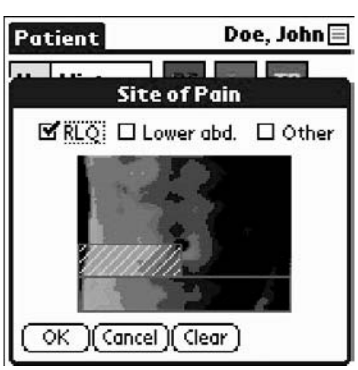

Figure 2. MET-AP screen capture for type of pain

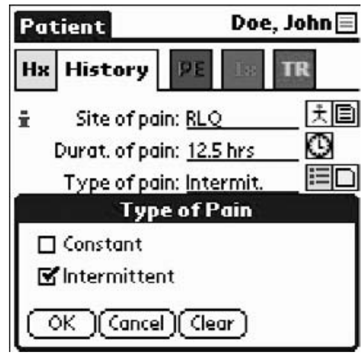

Figure 3. MET-AP screen capture for temperature

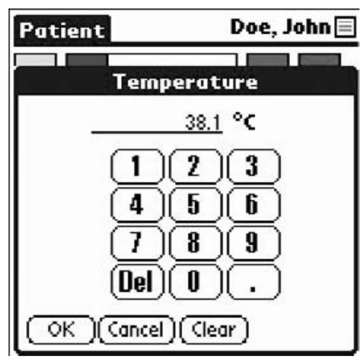

The treating ED resident or staff physician recorded their findings using MET-AP's electronic structured data screens. Blinded to the CDSS recommendation, the clinician entered his or her prediction of which triage category into which the patient was most likely to fit. This prediction was made at the time of initial assessment prior to obtaining an abdominal ultrasound or surgical consult, if required. A clinician of the opposite level (i.e., resident, staff physician) completed an independent interrater assessment within one hour of the original assessment, when possible.

Forty staff physicians and 110 residents enrolled patients. The ED clinicians had varying degrees of experience with handheld computers before entering the trial. All clinicians received in-depth orientation and training sessions, and as a result, all could use the system easily before the trial began. Two hundred and twenty two of the patients were seen by both a resident and a staff physician.

Analysis

The analysis focused on determining which of the CDSS input variables were being used in the clinicians' triage decisions. Since our independent variable (triage decision) is categorical, logistic regression was used to determine significant decision-making input variables. While triage decision initially had three categories, we have collapsed the observation and discharge result into a single category. We have done this because we are primarily interested in the input variables that are used to arrive at a consult decision, as this represents the most important clinical decision of the three possibilities.

Full main effects models were run independently for patients who were seen by residents and patients who were seen by staff physicians. All input variables except white blood cell count were included in the model. White blood cell count was removed from the study because of extensive missing data.

Results

The logistic regression results for residents and staff physicians are shown in Tables 2 and 3, respectively. The Nagelkerke's R^2 are .568 and .699 for the residents' and staff physicians' regression models, respectively. Overall, staff physicians have a higher number of significant CDSS input variables in their triage decision models than do residents. Specifically, pain site, pain type, vomiting, localized guarding, and rebound tenderness are significant for staff physicians. Alternatively, residents only had tenderness site, localized guarding, and rebound tenderness as significant variables. In terms of the "number of significant variables," these results are consistent with literature on strategic experts, which

*Note: *p < 0.05, **p < 0.01, ***p < 0.001* states that experts have complex structures that assist in the recognition and interpretation of environmental signals and events (Lyles & Schwenk, 1992) and that these structures are more complex, contain more links among elements, and hence contain more elements then the cognitive structures of less experienced strategists (Day & Lord, 1992; Lurigio & Carrol, 1985).

Of note is the significance of input variables that are "most dependent" on physical examination (localized guarding and rebound tenderness) in residents' and staff physicians' regression models. This result is not surprising, given the educational focus of these input variables as being primary determinants of acute appendicitis. However, research has shown that residents often have deficiencies in their physical examination skills (Mangione, Burdick & Peitzman, 1995) and that novice physicians have generally weaker information gathering and decision-making skills than more experienced physicians (Johnson & Carpenter, 1986). We know from past empirical studies that clinicians with different levels of expertise exhibit differences in their abilities to collect and interpret information from physical examinations (Pines, Uscher Pines, Hall, Hunter, Srinivasan & Ghaemmaghami, 2005; Yen, Karpas, Pinkerton and Gorelick, 2005). In comparing abdominal examinations of ED pediatric patients undertaken by residents and attending physicians, it was found that all parts of the examination had less than moderate agreement (Yen et al., 2005). Similar results were found in studying abdominal examinations of nonminors by residents and attending physicians (Pines et al., 2005). While the "correctness" of eliciting the input variables was not explicitly validated in this study, the implication is that residents rely on input variables that they may be deficient at eliciting, in making their clinical decisions.

FUTURE TRENDS

In evaluating the use of a CDSS for abdominal pain ED triage, we found that staff physicians used more of the CDSS input variables in their triage decision than did residents. The importance of the input variables that required physical examination was underlined by their significance in both staff physicians' and residents' regression models, even though past research suggests that residents have trouble accurately eliciting variables dependent on physical examination.

In order to take into account differences in clinical experience and to ensure appropriate support is available to these various user groups, we propose that the CDSS designers should (a) differentiate between information values provided by the data coming from expert and novice assessments, and (b) implement logical variable patterns that warn users when a single variable or a combination of variables is out of the expected range.

To design and implement aids that consider information value of the inputs, the input variables used in CDSS models must be categorized. Required variables could be logically categorized based on how difficult they are to elicit; to what extent they are reliant on tacit, explicit, and declarative knowledge; and subsequently be possibly labeled as "low confidence" and "high confidence" variables. This broad categorization reflects the ability of various physician user groups to accurately elicit values for the different attributes. A typical novice physician would have elicitation difficulty with "low confidence" attributes. Therefore, the user interface for the "low confidence" attributes should provide extensive explanations and guidelines to assist the process of collection. Further, provision for recording imprecise or uncertain information (e.g., selecting several values instead of a single one, entering some "confidence factor" associated with a value, or having a discrete option for "uncertain") should be provided.

In clinical decision-making, values of selected attributes form a pattern that is indicative of an underlying health condition. For example, for pediatric abdominal pain, certain pain location in concert with presence of guarding is indicative of possible acute appendicitis. It is possible to use information about such patterns to develop context-sensitive thresholds for values of individual attributes and their combinations. If values entered by a physician would significantly deviate from these logical thresholds, a CDSS would issue a specific warning alerting the physician to this situation. While this will provide additional support for novice physicians, it will also help to minimize the potential error between user and technology, which recently has been identified as an important source of clinical error (Kohn, Corrigan & Donaldson, 2000).

CONCLUSION

Many decision models implemented into CDSS encapsulate knowledge that relies on evaluating input variables that require experience and significant clinical acumen. This creates uncertainty about the quality of the recommendations produced by the CDSS. Customized decision support, taking into account the level of clinical expertise of a physician of a given specialty, is required to ensure that inputs into CDSS are accurate. Such expanded support is as important for the acceptance of a CDSS by physicians as the quality of the underlying decision model and user interface.

ACKNOWLEDGMENT

Research described in this chapter was supported by grants from NSERC-CHRP and Physician Services Inc. Foundation. A longer variation of this chapter was presented at the 12th Americas Conference on Information Systems; a longer version exists in the Conference Proceedings.

KEY TERMS

Clinical Decision Support Systems (CDSS): Software that assists clinicians in making health care decisions.

Emergency Department (ED): The department responsible for providing immediate medical care to patients arriving at the hospital.

Logistic Regression: Technique for making predictions when a dependent variable is a categorical dichotomy, and the independent variable(s) are continuous and/or categorical.

Pediatric Abdominal Pain Triage: A process of sorting children with abdominal pain into categories that reflect the treatment they require

Personal Digital Assistant (PDA): A handheld computer device.

A Collaborative Approach for Online Dementia Care Training

INTRODUCTION

There are several reasons why university-based researchers and community groups may choose to collaborate together on research projects. Involving the end-users of the research data in the research process often motivates them to integrate the results into new policies, procedures, and education programs. Research outcomes therefore become more relevant to the community members than would be the case using a more traditionalistic approach to research (Morrison & Lilford, 2001; Patton 1997). Community-based partners fully immerse themselves in a collaborative research process as they strive to underpin their interventions with other complementary concepts or evidence-based theories. They are then better positioned to promote social change.

Furthermore, collaborative projects provide an educational opportunity for partners to develop a collective consciousness in addressing the issues at hand (Gallagher, Easterling, & Lodwick, 2003; Karim, 2001; Minkler & Hancock, 2003). The problem is viewed from multiple perspectives as university-based researchers and community professionals contribute unique strengths and share research-related responsibilities within the social and cultural dynamics of the partnership (Gibbon, 2002). Simultaneously, university-based researchers are able to come to a better understanding of the community of interest and its changing realities. The cultural differences of both groups are acknowledged, and sensitive strategies can be collaboratively developed in which the roles and expectations are clearly outlined (Agency for Healthcare Research and Quality, 2003). Full advantage can be taken of the knowledge, experiences, and perspectives of professionals in the community as they provide input on all aspects of the research project. Thus, the research process becomes a collaborative, co-learning, community-building experience.

There are obvious benefits to working in collaboration. However, real collaboration takes time; time to engage in meetings, complete accountability processes, and resolve problems. The delicate balance between democracy and efficiency can be compromised when you have to choose between equal participation and looming deadlines (Stoecker, 2003). Weaver and Cousins (2004) described this dilemma as assessing manageability or having to make a choice between achieving complete diversity on the researcher-community team and the unwieldiness of working with a large committee. Compromise is often necessary.

This article describes our experiences using a collaborative approach involving university-based researchers and community professionals—in this case, long-term care (LTC) managers, administrators, and hospital-based educators and researchers—to create an online dementia care training program.

BACKGROUND

The Sisters of Charity of Ottawa Health Service (SCOHS) is a corporation with a teaching chronic care hospital and two LTC facilities. Community professionals at SCOHS recognized that their healthcare providers were facing challenging behaviours from persons suffering from dementia, which has been known to lead to staff burnout, distress, and high turnover rates. The community professionals felt that this problem could be partially ameliorated with staff education through e-learning. They contacted a professor in the Faculty of Education at the University of Ottawa who was conducting research on e-learning. Together, they agreed that conducting a project involving frontline workers in LTC facilities that addressed this issue would be mutually beneficial. Additional experts were recruited to join the project, including psychologists as content experts, e-learning course developers and pedagogy experts, and evaluators experienced in online course evaluation. Six pilot LTC facilities were identified, and representatives from each facility were included in the research team.

THE ONLINE DEMENTIA CARE TRAINING PROJECT

The research group used the Demand-Driven Learning Model (DDLM) (MacDonald, Stodel, Farres, Breithaupt, & Gabriel, 2001, see Figure 1) to guide the design, development, delivery, and evaluation of the bilingual dementia care training program. The program was targeted towards frontline healthcare providers (registered and nonregistered) who care for persons experiencing dementia in LTC facilities.

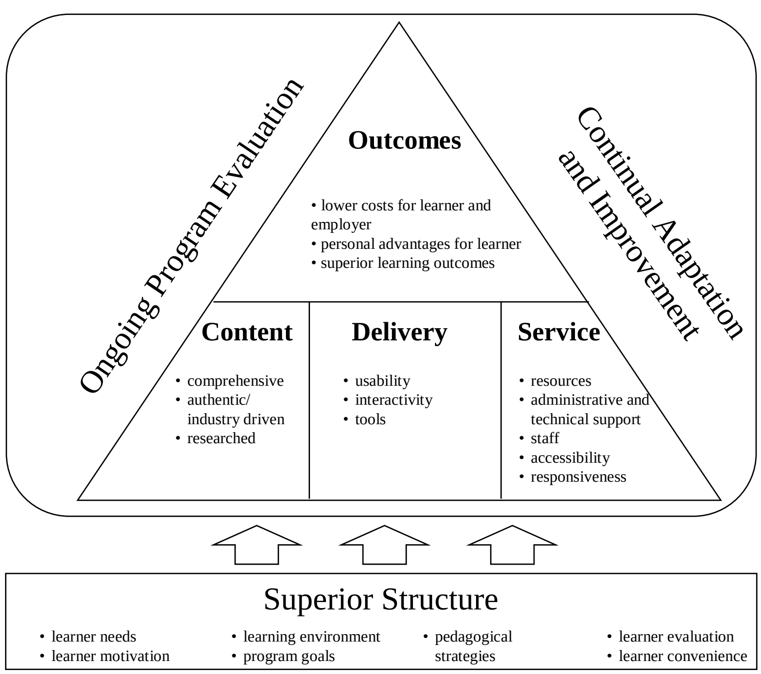
Conducting the Needs Assessment

As advocated in the DDLM, the first step of the project involved identifying the needs of the learners. The university-based researchers conducted three in-depth focus group interviews with seven healthcare providers (prospective learners) and two site coordinators who would serve as the on-site support persons for the learners during the implementation of the program. Through the needs analysis process, community-based stakeholders were able to provide input regarding the design, development, and delivery of the dementia care training program. The results of the needs analysis are published elsewhere (MacDonald, Stodel, & Coulson, 2004).

Designing and Developing the Program

The course facilitator, a content expert and psychogeriatric nurse with no e-learning experience, was responsible for putting together the first draft of the program content and learning activities. To ensure the

Figure 1. The demand-driven learning model (MacDonald, Stodel, Farres, Breithaupt, & Gabriel, 2001)



content was authentic to the community experience, as recommended by the DDLM, the course facilitator drew on her experiences working with frontline personnel who provide care to individuals with dementia. Once she developed the content, the pedagogy team reworked it into an appropriate format for e-learning. This was a time-consuming process, but one the academics felt strongly about as they were concerned with respecting online pedagogical principles and the quality of the online course design.

The pedagogy team encountered competing tensions as they developed the content using a collaborative approach. Ensuring the content was comprehensive, another DDLM component, was difficult to achieve due to time limitations. The content had to be chunked into sections that could be completed in 30-minute learning sessions, which limited the amount of content that could be included. Thus, content experts were advocating for the inclusion of a wide range of content, while other stakeholders wanted to reduce the amount of content, as they were aware of the limited time the learners would have to engage in the program.

Other issues related to time also affected the collaborative process. The pedagogy team had limited time to develop the content and adapt it to an online format, due to deadlines imposed by the funding agency and delays in hiring qualified project staff. Once the content was approved, it was given to the instructional designer to be put online. The instructional designer developed the online program using WebCT, the online course management system adopted by the University of Ottawa. However, the pedagogy team quickly realized that, while having many advantages, this system limited certain aspects of course design and evaluation. Time constraints and the initial decision to work with the University of Ottawa's Centre for E-Learning prevented the research team from exploring alternatives to WebCT.

The instructional designer questioned the efficiency of the collaborative process adopted in this project. He felt there were too many people trying to reach consensus. He postulated the lack of efficiency was because "the roles of the people involved were not well-defined." Similarly, not all stakeholders felt they were heard when they contributed expertise. One team member stressed that learners must be honestly informed about the time commitment required to participate in this project, prior to their consent and participation. Another found the program hard to navigate, and suggested changes be made in the online layout. However, despite these warnings, neither the amount of content was reduced to meet the learners' expectations and needs, nor the navigation improved before the program was offered, and both were identified as weaknesses of the program in the evaluation (MacDonald, Stodel, & Casimiro, 2006). These changes did not occur due to time constraints and/or lack of project ownership. Compromise, rather than consensus, became the decision method of choice, especially as the deadlines loomed closer.

A significant factor in the lack of project ownership was that the principal investigator had to leave the project suddenly at the beginning of the production phase. This temporarily compromised the project's leadership. Leadership is necessary for the smooth running of a project. This leader should bring expertise in optimizing group functioning, such as defining roles and orienting the group towards action. This person should also ensure equality among members and aim for consensus.

Delivering the Program

The completed program was delivered to 95 learners at six sites in three provinces across Canada. Forty-nine (52%) enrolled in the French language program, and 46 (48%) enrolled in the English language program. Learners were expected to spend two hours each week, at their convenience, reading the content and completing the learning activities and evaluations. Each site had a coordinator whose role was to support the learners in their learning and with the technology. These site coordinators were an integral part of the pedagogy team.

Throughout the delivery of the program, the site coordinators met with the pedagogy team for 30 minutes each week via teleconference. These meetings enabled site coordinators to keep track of the timelines set out for the learners, and allowed them to provide feedback to the pedagogy team regarding the learners' experiences and progress with the program. These meetings were instrumental to the success of the program. Because of the regular feedback from the site coordinators, the pedagogy team was able to address problems and concerns that arose in an expedient fashion. For example, when it became apparent that the program required significantly more than two hours a week to complete, and that some of the learners felt frustrated and overwhelmed, the pedagogy team promptly adapted the program by reducing the number of required exercises and extending the deadlines to complete the program. A number of site coordinators attested that the learners immediately felt less pressure once the amount of work was reduced.

Evaluating the Program

One of the reasons the community created a partnership with academics was to help develop strategies for evaluating the program. The university-based researchers had specific knowledge of evaluation and online data collection procedures. Using the DDLM evaluation tool (MacDonald, Breithaupt, Stodel, Farres, & Gabriel, 2002) as a guide, they drafted the evaluation instruments and invited the pedagogy team to provide input. As a result, survey questions were added, deleted, or modified. This collaborative process resulted in the development of relevant evaluation tools tailored to the needs of learners in LTC facilities. Further, the evaluation team conducted in-depth semistructured interviews in order to obtain a rich description of the stakeholders' experiences with the program, specifically in terms of the DDLM components. Interviews were conducted with ten learners, all six site coordinators, the course facilitator, and the instructional designer. Knowing the importance of management buy-in for this program to be viable in the future, the pedagogy team also interviewed the higher management of the six LTC facilities to gather their impressions of the value of the program for their organizations.

The evaluation team conducted, transcribed, and analyzed all the interviews, compiled and analyzed both the quantitative and qualitative data (French and English), and wrote the final report (MacDonald & Stodel, 2004). The evaluation continued to be a collaborative process as both community professionals and university-based researchers were part of the evaluation team. Moreover, the evaluation team received input from the pedagogy team. This decision making process worked well; the group weighed the importance of outcomes relevant for the learners' practice—a reality best understood by the community—against the outcomes related to the e-learning experience—a reality best understood by the university-based researchers.

Disseminating Findings

The university-based researchers took the lead role in the dissemination activities. However, input received from community members was critical to ensure the quality and relevance of the final products. Input from community members allowed the university-based researchers to create a PowerPoint presentation and two professional posters comprising an overview of the project and its findings that could be used by the community to share details of the project at conferences or in their local healthcare communities. While these individuals may not have had the time or the interest to prepare the presentation material, they were able to actively participate in the dissemination process by using materials created by the university-based researchers. This highlights another benefit of taking a collaborative approach.

Writing this article involved a collaborative effort between three university-based researchers and one community member. The collaborative approach added to the amount of time necessary to complete the manuscript, yet it added to the quality and accuracy of the article on several fronts. First, both the university- and community-based members' perspectives were reflected. Second, perceptions of the process of running the project were shared and elaborated. Lastly, the workload was shared between the authors. In the end, the process of collaborating in the publication process was a positive experience in which co-learning took place, and a stronger article resulted.

FUTURE TRENDS

The implications and lessons learned from this research are important to consider when conducting future research in this area. Although several of the community members were experienced at and capable of conducting research and disseminating the findings without the assistance of the university-based researchers, they felt a partnership with academics would strengthen their research position in the field of e-learning, and they would gain information on quality e-learning design. In turn, the academics wished to apply their knowledge to the healthcare field, but lacked the intimate knowledge of this group of learners. Consequently, they benefited from the input of the community members and gained valuable knowledge of the content area (dementia care) and healthcare culture. Even though the university-based researchers had much to gain from the partnership, this project was instigated and led by members of the community.

Our experience suggests that taking a collaborative research approach significantly increases the amount of time required to complete a project, though the research team felt it was a worthwhile trade-off, given the contributions made by each member. We acknowledge that failure, at times, to reach consensus and the pressure of timelines to complete this project by a specific date compromised the quality of the design. From an e-learning perspective, it is critical that the content be developed early in the process. A common fallacy is that once the content is developed, it can be put online quickly.

Stoecker (2003) suggested that it is an unrealistic expectation that those involved in a collaborative project be equal partners in all aspects of the process. His claim appears to be grounded in concerns for the time demands on community members. Indeed, as Israel, Schulz, Parker, Becker, Allen, and Guzman (2003) have suggested, efforts were made to involve community members in the publications resulting from the research process, but few had the time to do so. Sullivan, Chao, Allen, Koné, Pierre-Louie, and Krieger (2003) recommended that communities receive concrete benefits in return for their involvement in research partnerships, noting that without such tangible benefits, the partnership may not be advantageous to the community.

We also realized how important communication is to successful collaboration. Working in a large team means that many relationships need to be developed and maintained. In this project, constructive criticism about the program was sometimes taken as a personal affront by the individual responsible for that aspect of the program, and hard feelings resulted. This point becomes even more poignant when communication between members is conducted via e-mail where tone, emotion, and other nonverbal cues are lost. In the case of this project, misunderstandings in communication caused some minor conflicts, but effective communication also allowed the rifts to be resolved.

Clarification of members' roles at the beginning of the project is also critical. In writing this article, it emerged that the evaluation team was ill-defined; each of us had a different view of whom the evaluation team comprised. Further, one of the pedagogy team members who had experience in online pedagogy and e-learning applications in healthcare felt that her expertise was not used as much as it could have been. Not only was this a frustrating experience for her, but she also predicted many of the problems reported during program delivery.

In the end, the project resulted in an educational opportunity for all involved (Minkler & Hancock, 2003). The community of program personnel succeeded in offering a generally well received e-learning program to help healthcare providers manage persons with dementia. They also enhanced their skills for designing, developing, delivering, and evaluating a successful e-learning program by using the DDLM. The university-based researchers learned more about healthcare in general, and dementia care specifically, obtained further appreciation for healthcare providers' needs for learning online, and became aware of the values and complexities of collaboration. Further, the university-based researchers also profited by gaining access to data for research purposes.

CONCLUSION

In sum, the adoption of a collaborative research approach with a community of professionals is not only beneficial but also desirable. Collaboration allowed multiple views, attitudes, and experiences to strengthen the program. By describing the complexities involved in this process, we reveal both the challenges and achievements inherent in designing a quality online learning event through collaboration. Moreover, by addressing some of the details involved in this process, we hope that our experiences help others plan collaborative partnerships with community professionals, and develop collaborative e-learning programs for healthcare providers.

KEY TERMS

Collaborative Research Approach: A research approach that uses the strengths of both researchers and community-based practitioners to increase the quality of the research process and the impact of the research outcomes.

Demand-Driven Learning Model: An e-learning model that is grounded within a constructivist framework and defined by five interrelated dimensions that, in concert, create a high-quality e-learning experience: superior structure; three consumer demands of content, delivery, and service; and learner outcomes.

E-Learning: Learning that takes place via the Internet.

Long-Term Care Facility: A licensed residence for individuals who require personal support and nursing care, and who cannot remain in their family home, because support at home (from family or agencies) is insufficient or unavailable. While funding sources may differ, LTC facilities and nursing homes can be categorized together under this definition.

Instructional Designer: Person who uses technology (media) to design optimised learning events. Instructional design is historically grounded in cognitive and behavioural psychology.

Pedagogy: The profession, art, science, theory, principles, or methods of education, instruction, and teaching.

Psychogeriatric Nurse: A nurse whose practice is focused on older people (usually 65 years of age or older) with mental illness and/or cognitive impairment.

Web Course Tools (WebCT): An e-learning platform and online course management system used extensively in colleges, universities, and other educational institutions. WebCT supports online tools such as discussion forums, e-mail, live chat, and whiteboarding, as well as content in various formats (e.g., html documents, Web pages, and so on). WebCT recently merged with Blackboard, another leading provider of educational software.

Combining Technology with Tradition to Effect Superior Pain Management Strategies

Choong Khean Foo
RMIT University, Australia

INTRODUCTION

"Pain is a very good servant but a bad master."
- Author unknown

Everybody knows what pain is, but no one really knows how to switch it off, especially when it becomes persistent and annoying.

Pain is not just from physical disorders but also from combinations of physiological, pathological, emotional, psychological, cognitive, environmental, and social factors. The keys to successful pain control are the mechanisms that initiate and maintain pain. … Now, the public and health professionals expect to control pain by using preventive and active strategies, including drugs and physical and psychosocial interventions. (Holdcroft & Power, 2003)

Have we lost sight of the real pathophysiology that underlies the phenomenon of pain? Are we concentrating on the end point rather than the cause of the malady? Drugs and physical therapies don't have all the answers to pain management. Is there another way? Maybe we should take a broader look at why the pain started in the first place, and then we can work out the solution to the health challenge.

BACKGROUND

Pain arises when a living tissue is injured, and the tissue responds with inflammation. Inflammation involves a cascade of events involving cells, enzymes, cytokines, chemokines, and other substances, which will initiate other secondary responses by other cells and blood vessels. Inflammation is the beginning of the process of repair and healing. Ancient civilizations used various modalities to manage pain. They used physical therapies, medicinal foods, and herbs where appropriate.

Over the past century, pain and its management have changed dramatically. In this chapter, I propose to discuss the reasons for the change in pain experience and will explore the practical aspects of pain management using the best from the East and West. While scientists are dwelling deeply on the complex issues of pain and inflammation, patients in pain need help and advice now. Drugs alone cannot relieve all pain and suffering; surgical and psychological treatment may help some, but for most, a holistic approach may help to reduce or relieve the pain and suffering.

MAIN FOCUS OF THE CHAPTER

"We are what we eat."

If we supply our body with inappropriate or inferior quality materials, the tissues and structures so made will be of inferior quality. Deficiency diseases like scurvy and rickets have been known to cause deformed tissues and cause pain with different characters. By correcting the deficiencies, these maladies can be cured. In our modern society, it seems that more people are experiencing and suffering from pain. Is it because the newer generations are made of "weaker" materials, or is it that the pain threshold is reduced or the background inflammation in the body system has heightened? The fact that we have not been able to quantify and identify the missing ingredients in chronic pain should not deter us from searching for an answer by going "back to basics." Our body is created to function efficiently and effectively when it is provided with all the nutrients it needs.

MODERN MEDICAL MODEL OF PAIN MANAGEMENT

In modern medicine, pain is treated with analgesics and nonsteroidal anti- inflammatory drugs. If pain persists, stronger narcotics and anti-inflammatory corticosteroids are used. Other drugs like antidepression and anti-epilepsy drugs often are used in pain clinics to help modulate the pain experience. Unfortunately, all these medications have unwanted side-effects. There is a growing awareness in the community that drug therapy is not the only way. People are looking for more natural alternatives and less harmful treatment modalities with more self-help involvement. They want to participate actively in the healing process. People are turning more and more to alternative and natural therapies such as physical therapies, (e.g., physiotherapy, osteopathy, chiropractic) with stretching, mobilization, manipulations, heat/cold packs, and acupuncture/acupuncture-related techniques, along with diet and nutritional supplements, to help manage their painful conditions.

TRADITIONAL MEDICAL MODEL OF PAIN MANAGEMENT

In traditional Chinese medicine (TCM), diseases develop when the flow of Qi (energy, prana, life force) is blocked or interrupted. The basis of TCM treatment is to reestablish the flow of Qi. The TCM practitioners use needle acupuncture and/or herbal remedies to alter or reestablish the flow of Qi to reestablish homeoestasis in the body (Chinese acupuncture and moxibustion, 1990; O'Conner & Bensky, 1983).

The Qi or Life Force is also derived from the air we breathe and the water and food we drink and eat. Proper breathing and nutrition form part of the total management in TCM to help bring the body back into balance. It is well known that the food we eat determines how we feel. There are certain foods that will initiate or aggravate the painful situation. Food sensitivities and intolerance can trigger inflammatory response and cause pain (Author's clinical observation and treatment protocol).

ALTERNATIVE THERAPIES

Acupuncture, LLLT, & TENS

Since 1974, acupuncture has been an accepted treatment method in pain clinics around the world. There is only one slight drawback with acupuncture. Not many people, given a choice, would like to have needles stuck into them. So scientists did intensive research for a noninvasive acupuncture-point stimulation methods. In the East, traditional health practitioners used manual massage—Shiatsu, AnMo, and Tui Na—to stimulate the tissues and acupoints. Scientists discovered two modalities that can stimulate acupoints through the skin without inflicting pain by using Low Level LASER Therapy (LLLT) (Oshiro & Calderhead, 1990; Wong & Fung, n.d.; Baxter, 1994) and Transcutaneous Electrical Nerve Stimulation (TENS). Both these techniques are well accepted by the patients, as needles are not used. There is evidence that these methods of acupoint stimulation may give some of the benefits of needle acupuncture treatment. Although TENS was introduced more than 30 years ago as an alternative therapy to pharmacological treatments for chronic pain and in spite of its widespread use, the effectiveness of TENS is still rather controversial. A meta-analysis was carried out by scientists in 2001, and the results were published in the *Cochrane Database Systemic Reviews*, which showed that there was no evidence to support the use of TENS in the treatment of chronic low back pain, while the results for chronic pain were inconclusive.

Convention TENS stimulation has its limitation because of habituation from repetitive monotonous stimulation over the same points (Godfrey, n.d.; Carroll et al., 2001; Milne, et al., 2001). However, the Canadian research scientists were able to overcome this habituation by using a novel machine called Codetron®, which uses six negative electrodes and one positive electrode. At any one time, a pair of electrodes is stimulated. The sequence of stimulation is randomized so the brain will not filter out the stimulation and will accept each individual stimulation as a novel one. Controlled studies were done comparing Codetron with Sham Codetron therapy (Fargas-Babjak, Rooney, & Geretz-Simon, n.d.) and Codetron with Electroacupuncture (Richard & Cheng). The findings were very favorable toward Codetron therapy.

DIET, NUTRITION, AND PAIN MANAGEMENT

In recent years, many reports have been published stating that certain types of food cause or aggravate arthritic or rheumatic pain. Childers and Margoles (1993) in their article "An Apparent Relation of Nightshades (Solanaceae) to Arthritis" suggested that Solanaceae can cause pain in at least two known ways. First, the alkaloids in these foods can act alone or with other *cholinesterase inhibitors* (caffeine or food impurities containing systemic cholinesterase inhibiting pesticides) and can cause muscle spasms, aches and pain, tenderness, inflammation, and stiffness of body movements. Second, Solanaceae can develop the very active metabolite of vitamin D3 (1a25 dihydroxycholecalciferol), which can cause calcinosis of soft tissues, ligaments, and tendons, mineralization in walls of major arteries and veins, and osteopetrosis and related pathology in livestock. Over a period of time, these cause progression to lameness and extended uselessness, with eventual death of livestock (Childers & Margoles, 1993).

It was reported that 28% of arthritis sufferers had a "marked positive response," and another 44% had a "positive response' when they eliminated nightshades from their diet over a period of a few months (Childers & Margoles, 1993). In my clinical practice, a high percentage of rheumatic and arthritic patients improved just by avoiding the nightshade plants in their diet. The response can be as quick as a few weeks (Author's clinical observation and treatment protocol).

Although rheumatoid arthritis (RA) is listed as an autoimmune disease, it may be linked to food allergies and sensitivities (Zeller, 1949). In some RA patients, the pain is made worse when they eat foods to which they are allergic or sensitive, and vice versa, when these foods are avoided, the patients feel better (Author's clinical observation and treatment protocol; Beri et al., 1988; Panush, 1988; Taylor, 1983; Darlington & Ramsey, 1991). It is estimated that one-third of RA patients can control the disease completely through allergy elimination (Darlington & Ramsey, 1991).

Inflammation and Foods

Inflammation, with the accompanying features of redness, swelling, warmth, and pain, is the basic way living tissues react to injury, irritation, or infection. This is a form of nonspecific immune response.

The foods we eat have a powerful bearing on our health and, specifically, inflammation. Some foods we eat are pro-inflammatory, while others are anti- inflammatory. With the advent of fast food industries, our normal balanced inflammatory index diet has shifted toward 30 times more pro-inflammatory when compared with our forefathers' diets. As a consequence, nowadays it is not surprising to note that more people are suffering from various rheumatic-type pain. One of the contributing factors could be the types of foods we eat and how we prepare our foods. To win the war against inflammation, we have to turn the tide and go back to eating what Mother Nature wants us to eat—fresh living natural foods!

Fats, Oils, and Anti-Inflammatory Foods

Extremely low-fat diets have been reported to help people with RA (Lucas & Power, 1981), and very low-fat, pure vegetarian diets have also proved helpful (Skoldstram, 1987; Nenonen, Helve & Hanninen, 1992). While polyunsaturated fats like n-3 fatty acids and n-6 fatty acids of evening primrose oil are helpful, oily fatty greasy fried foods are known to be pro-inflammatory and can aggravate inflammation and intensify pain. Vegetable oils heated to high temperature can turn into pro-inflammatory oil. There are many foods that are known to be pro-inflammatory in nature, and whenever possible, they should be avoided by people who suffer from aches and pains. Some of the common foods are milk products, wheat and wheat products, red meat, eggs, preservatives, additives and colorings, sugars, and caffeine drinks (Author's clinical observation and treatment protocol; Warmbrand, 1974; Kjeldsen-Kragh, 1991).

In a laboratory experiment, Tall & Raja demonstrated that rats fed with soy protein diet had significantly less inflammation in their paws following an injection of Freud's adjuvant as well as having a higher tolerance to heat compared with those rats fed with casein-fed animals. These results are consistent with previous research showing consumption of a soy-containing diet suppressed the development of pain following nerve injury (Shir, Raja, Weissman, Campbell & Ze'ev Seltzer, 2001).

Preliminary evidence suggests that consumption of olive oil rich in oleic acid may decrease the risk of developing RA (Linos et al., 1999). One trial in which people with RA received either fish oil or olive oil, found those olive oil capsules providing 6.8 g of oleic acid per day for 24 weeks produced modest clinical improvement and beneficial changes in immune function. However, as there was no placebo group in that trial, the possibility of a placebo effect cannot be ruled out (Kremer et al., 1990).

Our forefathers used to eat food containing a higher proportion of n-3 fatty acids. It was suggested that the ratio of n-3 fatty acids—n-6 fatty acids—was in the region of 1:1. Nowadays with intensive farming and chemical fertilization, the ratio of n-3 fatty acids—n-6 fatty acids—is closer to 1:30. Possibly because of the skewed ratio, more people are suffering more aches and pains in our society. To help correct this imbalance, it will be prudent for us to eat more n-3 fatty acids, which are found in deep-sea fish and flaxseed oil.

Omega 3 fatty acid is used by the cells to keep cellular and nuclear membranes soft and pliable in order for the cells to function properly. Omega 3 fatty acid is also converted into Prostaglandin E(3) (PGE 3), a potent anti-inflammatory eicosanoid. Omega-6 fatty acid, which is found in vegetable oil, is converted to either Prostaglandin E (1) (PGE1) or Prostaglandin E (2) (PGE2). PGE1 is a strong anti-inflammatory eicosanoids, while PGE (2) is pro-inflammatory eicosanoids. Through proper diet and supplements of flaxseed oil and fish oil, it is possible to improve the n-3:n-6 fatty acids ratio and increase anti-inflammatory eicosanoids in the body (Author's clinical observation and treatment protocol; James, Gibson & Cleland, 2000).

Free Radicals and Antioxidants

Many painful conditions such as arthritis, fibrositis, and fibromyalgia are oxidative disorders due to free radical attacks. Increased free radical levels may be responsible for the development of many painful inflammatory conditions such as rheumatoid arthritis, fibromyalgia, osteoarthritis, and various rheumatic painful conditions (Packer, Hiramatsu & Yoshikawa, 1999; Bagis et al., 2005).

There is a wide range of antioxidants found naturally in the foods we eat and the herbs and spices we use for cooking. The most well known ones are Vitamin C and Vitamin E complex, which play a major role in supporting the other antioxidant activity in the body. Free radical attack causes damage to the cell structure by disrupting the stable cellular membranes. Inherently, a free radical is an unstable molecule with one or two missing electrons. Free radicals will try to snatch an electron from another stable molecule, and by so doing will cause a chain reaction of free radical attacks on the tissues, leading to damage to the tissue structure. The body tissues have an endogenous antioxidant system and will try to repair the free radical tissue damage. When DNA is damaged by the free radicals and it cannot be repaired, the disrupted genetic coding will duplicate without any central control. This is how cancer cells develop and multiply.

Supplements with vitamins, minerals, and phytonutrients such as carotenoids, flavonoids, and cruciferous, which contain potent antioxidants, have proved to be very effective in quenching the free radical attacks. When we eat a wide variety of fresh colorful fruits and vegetables, we are providing our body with a basket of antioxidant that will help neutralize the free radical activities and protect the cells from further damage (Packer, Hiramatsu & Yoshikawa, 1999).

In recent years, scientists have been looking at various phytonutrients in foods and plants that we consume in our diet. One such product is Pygnogenol (Procyanidins and Catechin) extracted from the French maritime pine bark. It is a very potent antioxidant and is also a strong anti-inflammatory agent, which will help to relieve many painful conditions. Anthocyanins, procyanidins, and quercetins are also found in grape skins and grape seeds. Another antioxidant that has proved to have both anti-oxidant and anti-inflammatory properties and has given great relief to people with various pain conditions is Xanthones. Xanthones are flavonoids and are found in some fruits and bark of trees, but the highest concentration is found in the pericarb of the mangosteen fruit. There are 200 known Xanthones; 44 of them are found in the pericarb of the mangosteen fruit.

Personal communication from Dr. Vaughn T. Johnson, DO told of his open study on patients who had elevated C-Reactive Protein CRP), an inflammatory marker. After putting them on the whole mangosteen fruit puree for one month, 29 out of 30 of the patients' CRPs returned to normal. This suggests that the phytonutrients in the Mangosteen fruit puree containing Xanthones have a potent anti-inflammatory property. Many diseases are caused by inflammation, and if there are substances in nature that will help reduce inflammation, people should consider taking these food-source phytonutrients to help reduce inflammation in order to prevent the development of medical diseases.

Traditional health practitioners also use herbs and spices to treat painful conditions and reduce inflammation. Herbs such as bupleurum, ginseng, licorice, ginger, cat's claw, guggul, curcumin, and bromelain have potent anti-inflammatory action and, hence, have helped patients with painful conditions (Bermejo Benito, 1998).

FUTURE TREND

It is heartening to note that patients and health practitioners are looking at alternative ways to help manage their illnesses, including pain. Combining technology and tradition for pain management is moving in the right direction. Present modern treatment methods have leveled off. Using stronger drugs to control pain is not the way to go. Taking a closer look at what is causing the seemingly increased number of people suffering from aches and pains may help us to find a less invasive and maybe more effective solution to the pain problem.

Inflammation holds the key to the pain problem. If we can reduce the background inflammation by changing our lifestyle, our diet, and nutrition to a more inflammatory neutral living, pain will be similarly reduced to a soft background tingle. More and more people and a growing number of health practitioners are looking at alternative ways to help relieve pain. Using scientific knowledge and modern technology and integrating them with some old fashioned remedies from Mother Nature will see us winning the war against pain.

CONCLUSION

We live in an exciting but challenging time. The evolution of technology is outstripping the slow Darwinian's process of evolution. Things are moving too fast, background noise is too loud, light and color are too dazzlingly bright. The poor body is trying to cope with the massive changes. The body, so to speak, is not ready for the 21st century!

As a consequence of these massive changes, a new group of medical diseases has evolved. Pain, an unpleasant sensation, has grown louder and stronger in modern society. People are relying on stronger drugs, more intensive physical therapy, and the latest technology to combat pain. Technology-driven solutions alone are not necessarily the optimal answer, but a combination of both old and new from the East and West may affect superior pain management strategies.

Holistic medicine is the wave of the present and the future. It is good medicine to "first do no harm" and to encourages patients to be actively involved in the healing process using healing foods and herbs provided by the benevolent hands of Mother Nature. This integrative approach will ultimately lead to better practice of medicine and a superior quality of outcome.

KEY TERMS

Antioxidants: Antioxidants are chemical substances that donate an electron to the free radical and convert it to a harmless molecule.

Autoimmune Disease: Normally, the immune system protects us from disease and infection, but if our immune system turns around and mistakenly attacks ourselves, an autoimmune disease ensues. Autoimmune diseases can affect many parts of the body such as connective tissues, nerves, muscles, endocrine system, and digestive system.

Codetron: Codetron has been classified as acupuncture-like TENS. The effect of this machine is equal to or better than electroacupuncture therapy.

Eicosanoid: Eicosanoid is a lipid mediator of inflammation derived from the 20-carbon atom arachidonic acid (20 in Greek is "eicosa") or a similar fatty acid. The eicosanoids include the prostaglandins, prostacyclin, thromboxane, and leukotrienes.

Free Radical: A free radical is an atom or molecule that has an unpaired electron in the outer ring. An unpaired electron will also always mean that there is an odd number, since pairing of electrons goes by 2s. Free radicals are highly reactive molecules and cause damage to nearby cells, causing a cascade of chain reactions of free radical damage to other cells and tissues.

Inflammation: Inflammation is a basic way in which the body reacts to infection, irritation, or other injury, the key feature being redness, warmth, swelling, and pain.

LLLT or Low Level Laser Therapy (also known as Low Power Laser Therapy): LLLT is the application of red and near infrared light over injuries or lesions to improve wound/soft tissue healing and give relief for both acute and chronic pain, nonhealing wounds, post-op pain, and acupoint stimulation. First developed in 1967, it is now commonly referred to as LLLT. The red and near infrared light (600nm-1000nm) commonly used in LLLT can be produced by laser or high-intensity LED. The intensity of LLLT lasers and LEDs is not high like a surgical laser. There is no heating effect.

Nightshade Plants: Solanaceae (nightshade family) has been highly cultivated over the years and includes potatoes, tomatoes, eggplant, sweet peppers, chili peppers (but not black pepper), tobacco, and petunias. Some plants have great medicinal value, and some are quite poisonous. The calyx and corolla are 5-lobed, and usually there are 5 stamens. The fruit is partitioned into 2 or 4 seed-producing divisions, and may be dry or a fleshy berry.

Pygnogenol: Pygnogenol is the patented trade name for a water extract of the bark of the French maritime pine (Pinus pinaster ssp. atlantica). Pygnogenol contains *oligomeric proanthocyanidins* (OPCs) as well as several other Bioflavanoids: *catechin, epicatechin, Phenolic fruit acids,* and *taxifolin*. Procyanidins are oligomeric catechins found in red wine, grapes, cocoa, cranberries, and apples. Pygnogenol helps the integrity of the blood vessels, skin, and mental function, as well as being a potent antioxidant.

Qi (pronounced "chee"): Qi is proposed to regulate a person's spiritual, emotional, mental, and physical balance and to be influenced by the opposing forces of Yin (negative energy) and Yang (positive energy). Disease is proposed to result from the flow of Qi being disrupted and Yin and Yang becoming imbalanced.

TENS (Transcutaneous Electrical Nerve Stimulation). TENS produces neuromodulation through the following pathways: (1) presynaptic inhibition in the dorsal horn of the spinal cord; (2) endogenous pain control (via endorphins, enkaphalins, and dynorphins); (3) direct inhibition of an abnormally excited nerves; and (4) restoration of afferent input. The results of laboratory studies suggest that electrical stimulation delivered by a TENS unit reduces pain through nociceptive inhibition at the presynaptic level in the dorsal horn, thus limiting its central transmission. The electrical stimuli on the skin preferentially activate low-threshold myelinated nerve fibers. The afferent input from these fibers inhibits propagation of nociception carried in the small unmyelinated C fibers by blocking transmission along these fibers to the target or T cells located in the Substantia Gelatinosa (laminae 2 and 3) of the dorsal horn.

Xanthones: Xanthones are close cousins to the polyphenols family and have strong antioxidant effects on the nervous system. They are found in several botanical tonics, including St. John's wort, gentian root nectar, and mangosteen. Current research on Xanthones suggests that they are beneficial in helping with many conditions, including allergies, infections (microbial, fungus, viral), cholesterol levels, inflammation, skin disorders, gastrointestinal disorders, and fatigue. Xanthones have also been found to support and enhance the body's immune system and exhibit strong antioxidant activity, which is beneficial for neutralizing free radicals in the body.

A Comparison of Lossless Image Compression Algorithms for Colour Retina Images

Gerald Schaefer
Aston University, UK

Roman Starosolski
Silesian University of Technology, Poland

INTRODUCTION

Diabetic retinopathy is the leading cause of blindness in the adult population. In order to effectively identify patients suffering from the disease, mass-screening efforts are underway during which digital images of the retina are captured and then assessed by an ophthalmologist. In order to identify features such as exudates and microaneurysms, which are typically very small in extent, retinal images are captured at high resolutions. This in turn means large file sizes and, considering the archival of typically thousands of records, a high demand on computational resources, in particular storage space as well as bandwidth when used in a Picture Archiving and Communications System (PACS). Image compression therefore seems a necessary step. Image compression algorithms can be divided into two groups: lossy techniques where some of the visually less important image data is discarded in order to improve compression ratios, and lossless methods which allow the restoration of the original data. As the features that indicate retinopathy are very small in size and following legislation in several countries, only lossless compression seems suitable for retinal images.

In this article, we present experiments aimed to identify a suitable compression algorithm for colour retina images (Schaefer & Starosolski, 2006). Such an algorithm, in order to prove useful in a real-life PACS, should not only reduce the file size of the images significantly but also has to be fast enough, both for compression and decompression. Furthermore, it should be covered by international standards such as ISO standards and, in particular for medical imaging, the Digital Imaging and Communication in Medicine (DICOM) standard (Mildenberger, Eichelberg, & Martin, 2002; National Electrical Manufacturers Association, 2004). For our study, we therefore selected those compression algorithms that are supported in DICOM, namely TIFF PackBits (Adobe Systems Inc., 1995), Lossless JPEG (Langdon, Gulati, & Seiler, 1992), JPEG-LS (ISO/IEC, 1999), and JPEG2000 (ISO/IEC, 2002). For comparison, we also included CALIC (Wu, 1997), which is often employed for benchmarking compression algorithms. All algorithms were evaluated in terms of compression ratio which describes the reduction of file size and speed. For speed, we consider both the time it takes to encode an image (compression speed) and to decode (decompression speed), as both are relevant within a PACS.

Experiments were performed on a large dataset of more than 800 colour retinal images, which were also divided into subgroups according to retinal region (nasal, posterior, and temporal) and images size. Overall, JPEG-LS was found to be the best performing algorithm as it provides good compression ratios coupled with high speed.

LOSSLESS IMAGE COMPRESSION ALGORITHMS

In this section, we give a brief overview of the lossless compression algorithms that we have evaluated. For further details on the algorithms, we refer the reader to the original references.

- **TIFF PackBits:** A simple RLE compression algorithm (Adobe Systems Inc., 1995). The Tag Image File Format (TIFF) standard specifies this simple runlength (RLE) coding technique; we used the LibTIFF implementation by Leffler (version 3.6.1, http://www.remotesensing.org/libtiff/).
- **Lossless JPEG:** Former JPEG (Joint Photographic Experts Group) committee standard for lossless image compression (Langdon et al., 1992). The standard describes predictive image

compression algorithm with Huffman or arithmetic entropy coder. We used the Cornell University implementation (version 1.0, ftp://ftp.cs.cornell.edu/pub/multimed/ljpg.tar.Z) which applies Huffman coding. The results are reported for the predictor function SV7 which resulted in the best average compression ratio for the dataset.

- **JPEG-LS:** The standard of the JPEG committee for lossless and near-lossless compression of still images (ISO/IEC, 1999). The standard describes low-complexity predictive image compression algorithm with entropy coding using modified Golomb-Rice family. The algorithm is based on the LOCO-I algorithm (Weinberger, Seroussi, & Sapiro, 1996). We used the University of British Columbia implementation (version 2.2, ftp://ftp.netbsd.org/pub/NetBSD/packages/distfiles/jpeg_ls_v2.2.tar.gz).
- **JPEG2000:** A more recent JPEG committee standard describing an algorithm based on wavelet transform image decomposition and arithmetic coding (ISO/IEC, 2002). Apart from lossy and lossless compressing and decompressing of whole images, it delivers many interesting features such as progressive transmission, region of interest coding, and so forth (Christopoulos, Skodras, & Ebrahimi, 2000). We used the JasPer implementation by Adams (version 1.700.0, http://www.ece.uvic.ca/~mdadams/jasper/).
- **CALIC (Context-based Adaptive Lossless Image Compression):** A relatively complex predictive image compression algorithm using arithmetic entropy coding, which because of its usually good compression ratios is commonly used as a reference for other image compression algorithms (Wu, 1997). We used the implementation by Yang. In contrast to the other algorithms, CALIC is designed for grayscale images only. We therefore apply CALIC to each of the individual channels separately.

Lossless JPEG, JPEG-LS, and JPEG2000 are covered by international ISO standards whereas TIFF represents an industry standard. All algorithms except CALIC are incorporated into the medical imaging DICOM (Mildenberger et al., 2002; National Electrical Manufacturers Association, 2004) standard.

RETINAL IMAGE DATASET

A large set of over 800 colour retinal images captured at various ophthalmology centres was used in our experiments. The set is large both with regards to the number of images as well as with regards to the actual sizes of individual images. All images were initially obtained in uncompressed 24-bit RGB format. Images contain between 1.4 and 3.5 millions pixels and hence require between 4 and 10 MB of storage space.

In order to verify whether there are certain image classes that are especially susceptible to compression (or especially hard to compress), we divided the dataset into categories according to the following criteria:

1. **Retinal region:** The whole set is divided into three groups: *nasal*, *posterior*, and *temporal*. Evaluating the compression performance for individual subgroups will highlight whether any algorithms work especially well on any of these categories.
2. **Image size:** Here the images fall mainly into two categories: those images with about 1.4 million pixels (*small*) and those with about 3.4 million pixels (*large*). Compression ratios and compression speed are sometimes dependent on the image size, evaluating the individual size categories will hence confirm whether any such dependency exists for retinal images.

The two criteria are independent of each other (i.e., there exist both *small* and *large* images of all three regions in the dataset) and are hence tested separately. Details on how the images are divided into the individual categories are given in Table 1.

EXPERIMENTAL RESULTS

Experimental results were obtained on a HP Proliant ML350G3 computer equipped with two Intel Xeon 3.06 GHz (512 KB cache memory) processors and Windows 2003 operating system. Single-threaded applications of algorithms used for comparisons were compiled using Intel C++ 8.1 compiler. To minimise effects of the system load and the input-output subsystem performance, the algorithms were run several times; the time of the first run was ignored while the collective time of other runs (executed for at least 1 second, and at least three times) was measured and then averaged. The time measured is the sum of time spent by the processor in application code and in kernel functions called by the application, as reported by the operating system after application execution. The speed of implementations is reported in megabytes (uncompressed) per second (MB/s), where 1 MB = 124 bytes, both for compression and decompression speeds. We note that we actually measure the speed of the specific implementation of the given algorithm on the particular computer system, not the absolute speed of the algorithm itself. The computer system we used, in terms of the processor speed, amount of the installed memory, and so forth, is similar to machines currently employed in PACS. The compression ratios are reported as bitrates, expressed in bits per pixel (bpp) $8e/n$, where e is the size in bytes of the compressed image including the header and n is the number of pixels in the image. We note that smaller bitrates mean better compression and that uncompressed images are stored using 24 bpp.

As mentioned above, all algorithms were evaluated in terms of compression ratio, compression speed, and decompression speed. Results were obtained both for the full dataset and for the individual categories outlined above and are given in Tables 2 to 4. The numbers are calculated as the averages for all images contained in a category; since not all groups contain the same number of images the average results for all images are slightly different from the average over all groups.

Table 2 lists the compression ratio results for all categories. From there we can see immediately that the compression performance of the PackBits methods is very different from those of the other algorithms. Considering that uncompressed images require 24 bits per pixel, the 19.36 bpp achieved by PackBits is fairly feeble yet not surprisingly so, as runlength coding is only suitable for images with large uniform patches to produce reasonably compressible runlengths of pixels. As this is not the case for retinal images (apart from the fairly uniform black background), the achieved compression ratios alone disqualify PackBits as a suitable method for compressing retinal images. Among the remaining algorithms, Lossless JPEG is consistently the worst performing algorithm, which again is expected as it is based on relatively simple predictive coding. The best performing algorithm is CALIC with an average bitrate of 6.60 bpp. That CALIC provides the best

Table 1. Test dataset of retinal images

Category	Number of images	Average size (pixels)
nasal	252	2214864
posterior	301	2203523
temporal	250	2213720
small	468	1383184
large	335	3365689
all	803	2210257

Table 2. Compression ratio results

Category	PackBits	L-JPEG	JPEG-LS	JPEG2000	CALIC
nasal	19.38	8.12	6.83	7.14	6.61
posterior	19.25	8.08	6.80	7.11	6.56
temporal	19.48	8.10	6.84	7.16	6.63
small	18.32	7.92	6.49	6.84	6.25
large	20.78	8.34	7.26	7.53	7.07
all	19.36	8.10	6.82	7.14	6.60

Table 3. Compression speed results

Category	PackBits	L-JPEG	JPEG-LS	JPEG2000	CALIC
nasal	51.2	16.4	14.7	3.3	2.7
posterior	51.4	16.5	14.7	3.2	2.7
temporal	51.0	16.4	14.6	3.3	2.7
small	50.2	16.5	15.3	3.4	2.8
large	52.6	16.4	13.8	3.0	2.6
all	51.2	16.5	14.7	3.3	2.7

Table 4. Decompression speed results

Category	PackBits	L-JPEG	JPEG-LS	JPEG2000	CALIC
nasal	68.7	24.3	14.4	3.1	2.4
posterior	69.1	24.5	14.4	3.0	2.4
temporal	68.4	24.3	14.3	3.1	2.3
small	64.8	24.3	15.0	3.2	2.4
large	74.2	24.5	13.5	2.7	2.2
all	68.7	24.4	14.4	3.1	2.4

compression ratio was to be expected and was indeed the reason for including the algorithm in the evaluation in the first place. However, JPEG-LS performs only slightly worse than CALIC with an average bpp value of 6.82. Somewhat worse than JPEG-LS is the performance of JPEG2000 with a compression ratio of 7.14 bits per pixel.

Looking at the variation of results between the image categories we see that there is very little difference between the compression ratios for the *nasal*, *posterior*, and *temporal* image groups. This suggests that these groups share similar image characteristics. Inspecting the *small* and *large* image categories we can see that all algorithms are more effective for smaller images. The larger images of about 3.4 million pixels are compressed with an on average about 10% higher bitrate compared to the smaller 1.4 megapixel images; the highest differences are observed for PackBits while Lossless JPEG is the algorithm that performs most constant across different image sizes.

We now turn our attention to Table 3 which lists the compression speeds expressed in terms of MB/s of all algorithms. Here, PackBits is clearly the best performing technique affording compression speeds more than three times higher the next best competitor. However, as has been pointed out above, this high speed comes at the expense of an unsatisfyingly high bitrate which rules out the algorithm as being useful in practise. Lossless JPEG is the next fastest algorithm with an average compression speed of 16.5 MB/s which is again due to the relatively simple compression technique. Only slightly slower is JPEG-LS with 14.7 MB/s, which hence provides fast compression coupled with good compression ratios. JPEG2000 and CALIC are much slower than the other algorithms with compressions speeds of only about 3 MB/s which is about five times slower than Lossless JPEG and JPEG-LS. This low speed results from the relatively complex compression paradigms involved which are based on wavelets and complex predictive and arithmetic coding respectively. Looking at the individual image groups, the results across the different region category images are again very uniform while larger images allow higher compression speeds with PackBits but lower speeds with JPEG-LS, JPEG2000, and CALIC.

While the compression speed is obviously of importance at the time of image capture, in a PACS the decompression time might be of higher interest as medical images are typically stored (and hence compressed) only once whereas they are read (and hence decompressed) several times, in particular in the context of medical image retrieval applications (Mueller, Michoux, Bandon, & Geissbuhler, 2004). In Table 4, we therefore list decompression speeds, again expressed in terms of MB/s, for the algorithms on all image categories. Since there is always a certain symmetry in the operations involved in encoding and decoding images, it is not surprising to see that overall the decompression speed results are not very different from the compression speed ones. Lossless JPEG represents a notable exception as for this algorithm the decompression speed is much higher (by about 2/3) than the compression speed. PackBits also decompresses faster than it encodes whereas for the rest of the algorithms encoding and decoding speeds are fairly close to each other. Hence, PackBits is by far the fastest algorithm in terms of decompression speed, followed by Lossless JPEG, JPEG-LS, JPEG2000, and CALIC. Again, there is no noticeable difference between the different region categories while PackBits decompresses larger images faster still, and JPEG-LS, JPEG2000, and CALIC have slightly higher decompression speeds for smaller images.

Integrating all experimental results, that is, compression ratios, compression and decompression speeds, should enable us to judge each algorithm's suitability for the task of being employed as a compression algorithm for colour retinal images in a medical Picture Archiving and Communications System. While TIFF Packbits provides by far the highest encoding and decoding speeds, its performance in terms of compression ratios is also significantly worse than those of all others. The fact that it reduces file sizes only by slightly more than 20% rules it out as an algorithm to be used in practice. CALIC on the other hand provides the best compression rates but is at the same time the slowest algorithm. In fact, both CALIC and JPEG2000 are significantly slower than the rest of the algorithms, both for compression and decompression. This slow decompression speed makes them unsuitable to be employed in PACSs; in addition CALIC is not covered by any standard, in particular not by the DICOM standard. The most suitable algorithm for lossless compression of colour retinal images hence seems to be the JPEG-LS standard. It provides good compression ratios (only slightly worse than CALIC) combined with fast compression and decompression performance. Furthermore, JPEG-LS represents an ISO standard and is included in the DICOM standard for medical imaging. In systems where decompression speed is significantly more important that compression ratio, Lossless JPEG might be an alternative as it decodes faster, yet at the expense of higher bitrates.

FUTURE DIRECTIONS

The presented study clearly indicates the suitability of various compression algorithms for the medical domain. Nevertheless, further insights can be gained by conducting "real-world" evaluation in a large PACS and measuring the retrieval times of various images based on different encodings.

In terms of compression ratios, only little improvements can be expected in the future. The reason for this is that current compression algorithms are very good at identifying and exploiting redundant information in images. Other factors however are likely to be improved further such as compression and decompression speed (though potentially at the expense of a small amount of compressibility). Also, other capabilities such as progressive image decoding or the possibility of midstream content access (Picard, 1994) are likely to prove useful in future applications.

CONCLUSION

We have analysed the performance of several standard lossless image compression algorithms, namely TIFF PackBits, Lossless JPEG, JPEG-LS, and JPEG2000, as well as the nonstandard "benchmark" CALIC algorithm for a large set of colour retinal images. The compression performance was measured in terms of compression ratio, compression speed, and decompression speed. JPEG-LS was found to be the best performing algorithm offering good compression ratios combined with high compression and decompression speed. In addition, apart from being a standard itself, JPEG-LS is also incorporated in the DICOM standard and is hence readily available to be employed in Picture Archiving and Communications Systems.

KEY TERMS

Diabetic retinopathy: A common complication of diabetes leading to progressive damage of the eye's retina.

DICOM: A medical imaging standard describing how image information can be exchanged.

Image compression: Reduction of the amount of memory used to store an image.

Lossless compression: Compression from which the original information can be recovered without loss.

Ophthalmology: The science of eye medicine.

Retina: A thin layer of neural cells which lines the inner eyeball.

Screening: Checking for a disease in people without symptoms.

Comparison of Step Length Estimators from Wearable Accelerometer Devices

INTRODUCTION

Video-based gait analysis, and other measurement devices such as force-plates, electrogoniometers, or electrodes to measure EMG signals are adequate for laboratory studies but are not designed for usability in ambulatory applications.

Conversely, accelerometers provide easily portable systems that supply real-time data, which is why they are widely used in ambulatory diagnostic devices. However, such systems do not provide direct measure of several spatio-temporal parameters of interest such as step length, walking distance, or walking velocity. Instead, they have to be estimated with a mathematical model from indirect sensor measurements. Specifically, in this chapter we are concerned with the accelerometry-based estimation of the step length in straight-line human walking.

BACKGROUND

Gait analysis is frequently made by means of video-based recording of markers placed at end-points in a subset of some body segments. However, such equipment is not easily portable and requires off-line digitizing that can be time-consuming and automated real-time acquisition systems, which can be costly. Because of that, nonspecialist users cannot use these systems in ambulatory applications. Other measurement devices such as force-plates, electrogoniometers, or electrodes to measure EMG signals (Grasso, Zago & Lacquaniti, 2000) are also not designed for usability.

Conversely, accelerometers provide easily portable systems that supply real-time data. In addition, these systems come at a decreased cost when compared to video motion analysis systems, making them easily available to a wide range of clinics. Precision and repeatability characteristics of accelerometry make it adequate for gait analysis (Henriksen, Lund, Moe-Nilssen, Bliddal & Danneskiod-Samsoe, 2004), and it has been widely used recently, mainly in ambulatory diagnostic (Auvinet et al., 2002; Kavanagh, Barrett & Morrison, 2004; Moe-Nilssen, 1998a, 1998b; Najafi, Aminian, Paraschiv-Ionescu, Loew, Bula & Robert, 2003).

For instance, there exist empirical relations between the step length and the maximum and minimum vertical acceleration of the body's center of mass (COM) (Analog-Devices, 2000). More frequently, it is accepted as a linear relation of the step length with the step frequency (Ladetto, Gabaglio & Seeters, 2003). Finally, clinical studies show that an inverted pendulum model can describe the displacement of the body's COM while walking, and the model can be applied to estimate the step length from this displacement (Brandes, Zijlstra, Heikens, van Lummel & Rosenbaum, 2006; Zijlstra & Hof, 1997). All these estimators had in common that they require a previous parametric adjustment or calibration from experimental walking data for every individual. After that, they all provide comparable estimation results, as will be shown in this chapter.

In the following, we compare these common step length estimators reported in the literature. Also, modifications to these estimators are proposed, based on biomechanical considerations. Results show that these modifications lead to improvements of interest over previous methods.

EXPERIMENTAL COMPARISON OF STEP LENGTH ESTIMATORS

Participants

Measurements were taken from a group of four adult men, ages 32 to 38. Height of subjects varied from 168cm to 186 cm. None of them presented vestibular or neurological disorders that could affect the experiments, and all of them gave their signed consent.

The step length was estimated from a three-axial accelerometer placed close to the L3 vertebral position, accepted as a fine approximation of the COM position during normal walking (Moe-Nilssen, 1998b). The device is fixed to the lower lumbar spine with an adjustable corset to avoid movement artifacts.

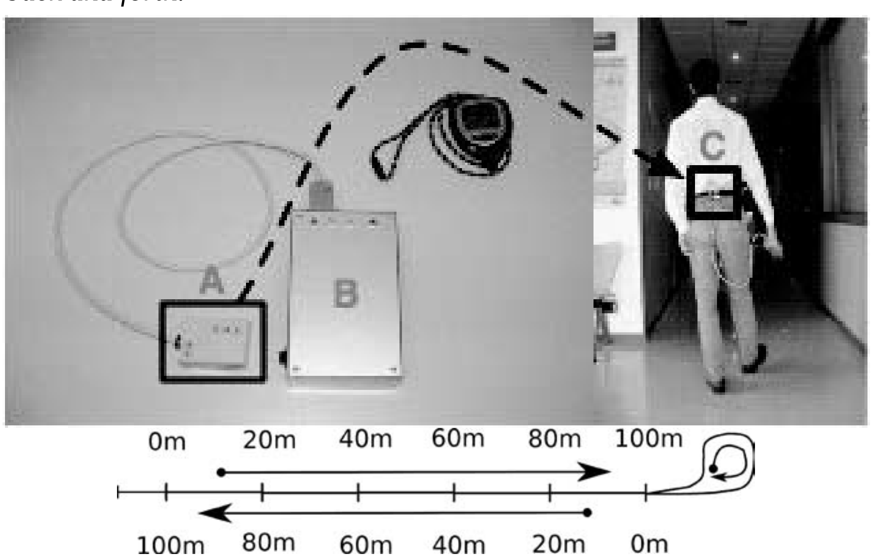
Apparatus

The device prototype (see Figure 1) is built over two biaxial accelerometers AXL202AE from Analog Devices (Analog-Devices, 2000) mounted to form a three-axes frame with a measuring range of ±2*g* being *g* the gravity acceleration. A calibration procedure takes into account offset and scale factors and the orthogonality of the axes (Krohn, Beigl, Decker, Kochendorfer, Robinson & Zimmer, 2005). A PIC16F877 Microchip micro-controller has been used as interface and data logger. Signals are sampled at 50Hz using a 10-bit A/D conversion. Data gathered during the experiments are stored in an internal memory and transferred to an external computer through a serial communication link for further processing. A total of 64K samples can be stored in memory, so we were able to extend the experiments over 20 minutes.

Procedure

During test procedures, subjects were asked to walk along a 100-meter-long corridor following a straight path, back and forth (see Figure 1). The first 10m of walking were discarded for the analysis, as gait is not stable during initial phases of displacement. Each individual completed four independent excursions, and they were asked to maintain a constant velocity for each walk: "preferred" (first excursion), "fast" (second excursion), "low" (third excursion), and "medium" (a velocity between preferred and fast velocities, last

Figure 1. Experimental setup: (Up) Accelerometer device and data acquisition system. The triaxial accelerometer (A) is sampled at 50Hz with the data logger (B) and is fixed to the lower lumbar spine (C) with an adjustable corset (not shown in figure) to avoid movement artifacts. (Down) Procedure: individuals walk a 100m distance at different paces, back and forth.



excursion). This adds up to a total of 800m per individual. Subjects were allowed to turn freely between both 100m segments, and to walk freely or to rest on a chair between different excursions for a lapse of five minutes. Time laps were taken at 20m intervals with a stopwatch. Retest procedures were carried out similarly one month later with the same four subjects and procedure.

Estimators Tested

In its simpler form, human gait can be described by an inverted pendulum model (Zijlstra & Hof, 1997). From this mechanical model, necessary relations between the forward displacement *S* and various measurable step variables can be obtained. Here we will use the relationship between the vertical and the forward displacement, given by equation:

$$S_{M_1} = K2\sqrt{2lh - h^2}$$

where *l* stands for the leg length, and *h* stands for the vertical displacement of the center of mass during one step, as in Figure 2. We well refer to it as the M_1 estimator. The constant *K* has to be calibrated for each individual based on experimental data. The calibration procedure is as follows: for each individual, *K* is the ratio between the real and the estimated walked distance for a given trial.

The vertical displacement for each step is computed with a double integration of the vertical acceleration of the body center of mass. To avoid the integration drift error we need to reset the integral at any point of the step. This reset point was settled at the time of foot-flat, where the vertical velocity of the body is null. Notice that the forward acceleration cannot be used because the COM forward motion has no instants of null velocity, and consequently, the double integration drift error grows unbounded. Mediolateral acceleration, which is responsible of the lateral movement of the hip, presents also zero velocity points, but this signal is weaker than the vertical acceleration and therefore more sensitive to noise.

Estimator M_2 assumes that in the time of foot-flat, the velocity is zero and the vertical coordinate of the COM is the same as at the beginning of the step. Adding a constant offset term to the acceleration forces the final values of the integrals to be the desired ones in the following equations:

$$\int_{t_0}^{t_1} (a_y + c_1)dt = 0$$

$$\int_{t_0}^{t_1} \left(\int_{t_0}^{t} (a_y + c_1)\, dt \right) c_2\, dt = 0$$

being t_0 and t_1 two consecutive instants of foot-flat, and c_1 and c_2 two offsets. This method reduces the drift effects, and a more exact computation of the COM

Figure 2. Inverted pendulum model of human walking. The step length can be estimated as the addition of two factors: the horizontal distance traversed by the COM during the mid-stance phase and the distance traversed during the double-stance phase. Both can be estimated from the vertical maximum displacements of the COM at each respective phase.

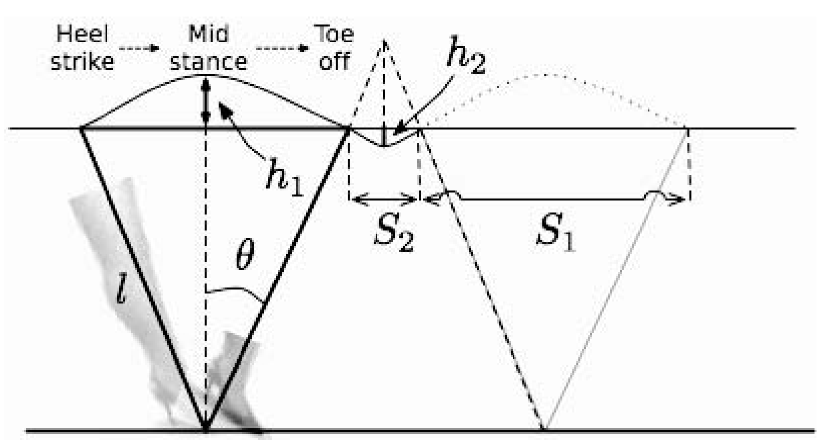


Figure 3. The modified estimator M_3 breaks each step in two phases: double-stance and single-stance. Heel-strike and toe-off events are detected in the measured accelerations. An inverted pendulum model will estimate the longitudinal displacement during the single-stance phase. The displacement during the double-stance phase will be assumed constant.

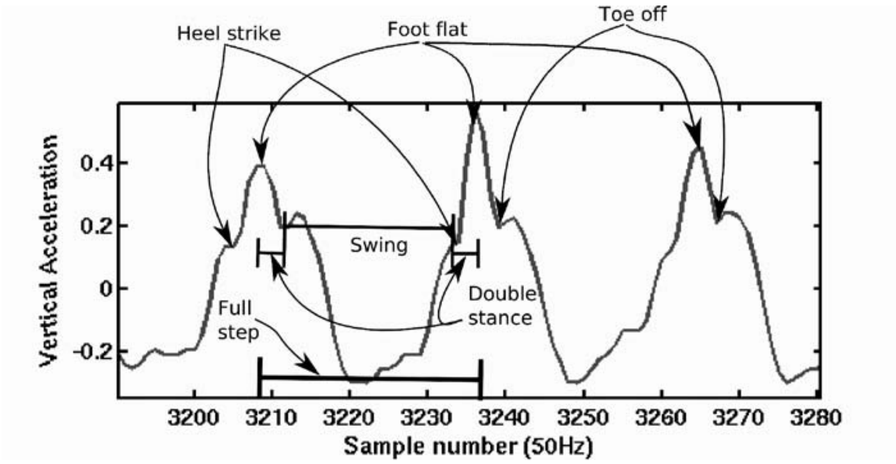

excursion can be done. This method needs the same calibration as the M_1 estimator.

Estimator M_3 assumes a more complex model (see Figure 3), as the displacement of the COM is related with two pendulums. There is an inverted pendulum with length equal to the length of the leg during the swing phase and a second pendulum (of unknown radius) during the double-stance phase.

$$S_{M_3} = S_1 + S_2 = 2\sqrt{2lh_1 - h_1^2} + S_2$$

The displacement is computed as the motion during the swing phase plus the displacement during the double stance phase. The first displacement can be computed according to the same equation M_1. The vertical excursion of the COM is computed by means of the double integral of the accelerations between the time of toe-off and the time of heel-strike. Detection of toe-off and heel-strike events is done using both the vertical and the antero-posterior accelerations. The same drift correction method used in M_2 is also applied here. The second displacement is set as a constant equal to the foot length, from the first metatarsal head to the calcaneal tuberosity. This method does not need any experimental calibration.

Instead of the double integral, there is an empirical relation of the vertical acceleration with the stride length that depends on the step count *n*:

$$S_{M_4} = Kn\sqrt[4]{a_M - a_m}$$

being a_M and a_m maximum and minimum values of the first harmonic of the vertical accelerations at every step, and *K* a calibration constant that has to be computed from experimental data in the same way as in methods M_1 and M_2. The first harmonic of the acceleration is computed by means of a low pass filter set at 3Hz. This estimator M_4 is claimed to measure distance walked to within 8% across a variety of subjects of different leg lengths (Weinberg, 2002).

The fifth method M_5 is based on the linear relation existing between the cadence and the step length. From experimental data at different speeds, a mean value of cadence and step length is calculated from the first 40m. Those data are fitted to a straight line for each individual. Using this linear model, an estimation of each single step is computed by mean of a linear regression:

$$S_{M_5} = \frac{K_1}{T_{step}} + K_2$$

being T_{step} the period of the step, and K_1 and K_2 two calibration constants.

Results

In Figure 4 there is a comparison among the first four estimators, M_1 to M_4. The vertical axis is the ratio between the estimated and the real walking distance. For each estimator, the most extreme values in the data set (maximum and minimum values), the lower and upper quartiles, and the median are plotted. The estimation has been done for each section of 20m, and the ratio between the estimation and the real ground value (20m) has been computed. The figures show aggregated data for all trials and all individuals. Two calibration procedures have been employed. In the first one (Figure 4-left), *K* was computed using the data from the first 40m walked at the preferred speed. In the second one (Figure 4-right), *K* was computed using the data from the first 40m at each velocity. In both cases, the method M_3 was not experimentally calibrated. Results were computed using the anatomical data of each individual (for methods M_1 to M_3). In Figure 5, all estimators are compared. Every method was calibrated using the data for the first 40m at each speed.

Methods M_1 to M_4 show a tendency to overestimate the step length, as their median values vary between 100% and 105% of the real value. The worst-case error was obtained with method M_1 using single speed calibration, and was almost a 40% higher than the real value. Method M_1 also has the highest variance. When data from multiple speeds are used, all the methods improve, both in median and variance. Method M_5 has the lower median of all (98%).

FUTURE TRENDS

Three methods of step length estimation reported in the literature, M_1, M_2, and M_4, present similar performance. According to the results of our study, there are no significant differences on average among them (see Figure 4). Method M_4 has the advantage that is easier to implement.

Method M_3, which does not need an experimental calibration, achieved similar results to previous estimators that were calibrated with a single velocity procedure (see Figure 4). This has an interesting potential application for wearable devices, as this method avoids unfriendly and time-consuming calibration procedures. Further research is required to define the optimal anatomical landmarks to use as the pendulum length in the swing phase and as the displacement constant during the double stance period.

CONCLUSION

In this chapter, five methods of estimation of step length were compared. Common methods reported in the literature, M_1, M_2, and M_4, present similar performance, with no significant differences on average among the three methods. Method M_1 had more variability for a given prediction. There is no statistical difference between methods M_2 and M_4. These results are consistent with the fact that methods M_2 and M_4 are intended to reduce the effect of the integration drift.

Figure 4. Walking distance estimation, using methods M_1 to M_4 compared to the real walking distance. For each estimator, the distribution (median, quartiles, and extreme values) is represented. (Left) Calibration made using data from the experiment at preferred speed. (Right) Calibration made using data from experiments at different speeds.

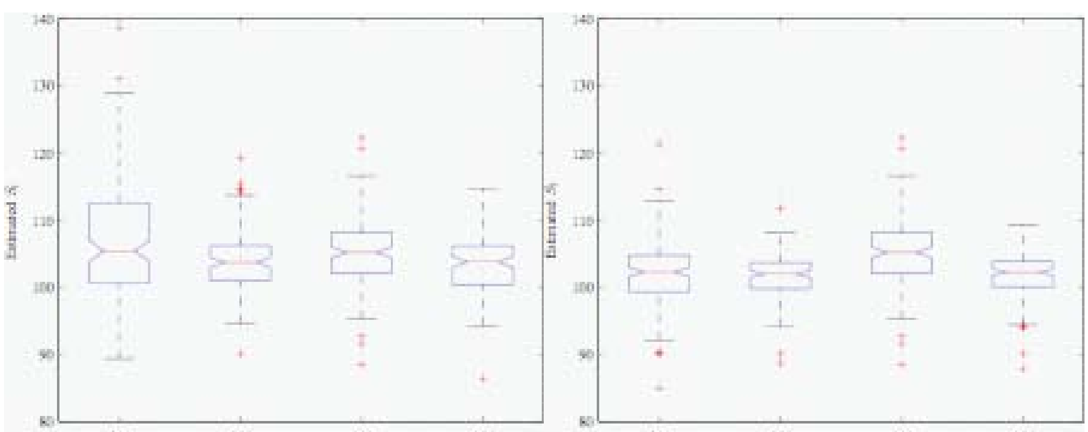

Figure 5. Estimation based on cadence requires data gathered at different velocities for calibration. The figure represents estimated to real walking distance, including the estimator M_5. The new calibration data set is used with all estimators.

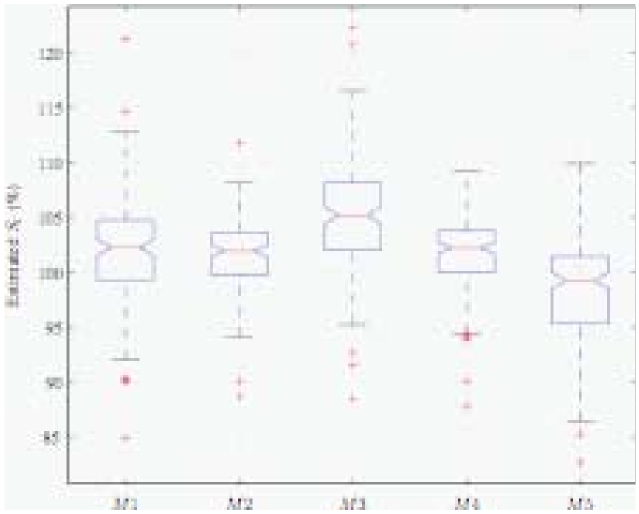

Multiple velocity calibration improves the performance of methods M_1, M_2, and M_4, mainly through a significant reduction in the standard deviation (see Figure 4). Median values are closer to 100% (unbiased estimation), compared to single velocity calibration, although the difference is not statistically significant. This result is consistent with the fact that walking speed is a relevant factor of the gait.

Method M_1 produces a closer estimation to the desired value, although it also presents a high variance. A possible reason for this is the low temporal resolution in the measurement of the step duration. Further experiments using a higher acquisition rate are needed to verify this hypothesis. Method M_3, without experimental calibration, achieved similar results to methods M_2 and M_4 calibrated with a single velocity.

INTRODUCTION

One of the major challenges that the human computer interface (HCI) faces nowadays is that of identifying a subject's state, in a real world environment, characterized mainly by its being: open-recorded, event-elicited, and internal *emotional state*-driven (Picard, Vyzas, & Healey , 2001). The main requirement for such system regards the noninvasive character of their working principle.

Subsequently, in order to improve communication in HCI systems or to asses the human state, the analysis of the *body language* could be a solution. Thus, a "sensitive computer" could use the body movements and the positions of the body in order to assess the state of a person (e.g., confusion, illness, nervousness, lack of attention, motor fatigue, agitation, etc.).

In the rehabilitation process, the measurements of the motion impairments are very important because they can quantify the patient's recovering between two consecutive medical sessions. Nowadays, this type of motion analysis is achieved by physicians through visual observation of the patient during some standard tests. As a result, the physician subjectivism is introduced and, much more, when different physicians evaluate the same patient, the reproducibility of the measurements becomes a difficult task.

To respond to the previously presented requirements in different application fields, a noncontact laser system was introduced by the authors (Cracan, Teodoru, & Dobrea, 2005; Dobrea, 2002; Dobrea, Cracan & Teodoru, 2005; Dobrea & Serban, 2005). Here, we present the implementation of an independent system constructed as a self-contained unit that can be further integrated in much more complex and intelligent structures, together with new possible applications.

This article proposes a new real-time, noncontact system able to:

- Acquire and interpret the subject's *body language*,
- Recognize static *hand signs*, and
- Provide physicians with a quantitative tool to monitor the evolution of the *Parkinson Disease.*

BACKGROUND

The proposed bio-instrumental system (BIS) was designed to be used in the medical field, in applications such as: rehabilitation, functional movement analysis, evaluation of the cognitive deficits, or motion and support offered to the vocally impaired subjects.

Nowadays, in order to evaluate and assess the severity of *Parkinson's Disease*, physicians use different rating scales. The method used to assess *Parkinson's Disease* is based on a questionnaire : Unified Parkinson's Disease Rating Scale, (MDSTF, 2003). The most important disadvantage of the rating scales is the lack of results reproducibility. Different physicians obtain different results on the same patient due to different medical experience and the possibility to observe, at one moment, only one cross-section of the patient. The BIS presented in this article will be used in the quantitative analysis of the head tremor movements. Even if, for this application, other methods exist to acquire the movement, based on accelerometer sensors (Keijsers, Horstink, & Gielen, 2003), optical data flow, and gyroscope (Mayagoitia, Nene, & Veltink, 2002), no method has imposed yet as a standard.

Recognition of the *hand signs* is a challenging task for the nowadays systems and it is very important for the vocally impaired people. Even if the research in this field fade in time, the first large recognized device for identifying the *hand signs* was developed by Dr. G. Grimes (1983) at AT&T Bell Labs. This device was created for "alpha-numeric" characters communication by examining hand positions like an alternative tool to keyboards; it was also proved to be effective as a tool for allowing nonvocal users to "finger-spell" words and phrases. In order to understand the *hand signs* language the hand gesture must be acquired. Mainly, the *hand signs* are acquired using video cameras (Cui & Wenig, 1999; Ho, Yamada, & Umetani, 2005) or some devices that directly determine the position of the hand parts (such as gloves) (Hernandez-Rebollar, Kyriakopoulos, & Lindeman, 2004).

There are strong relations between psychological states and the body movements, confirmed by the theories of Kestenberg-Amighi, Loman, Lewis, and Sossin (1999) and Hunt (1968) or by the analyses realized in the field of the *body language* investigation (Pease, 1992). Moreover, these relationships make the subject of the somatic theory. The health care efficiency in the activity related to the human-computer interaction is directly dependent on both the subject's state and the capability of the health care systems to recognize the specific needs of the user in order to change their response accordingly. Unfortunately, acquiring and interpreting this kind of information is very difficult and, as a consequence, all the actual systems have only a limited ability of communication. Current strategies for user's *emotional state* acquisition are either obtrusive (Picard et al., 2001) or the data captured by the systems consist in low level useful information.

A NEW TYPE OF NONCONTACT BIO-INSTRUMENTAL SYSTEM

The new proposed BIS was designed to determine, in a fast way and without any physical contact with the subject, the movements, the position, and the distance to an observation point. Using this information, the physiological and *emotional states* of the subject are estimated.

System's Architecture. Working Principle

The BIS is composed of a laser scanner, an interface unit, a video camera, and a software program, running on a DSP platform that controls the scanner, acquires the images, and extracts the distance/position information, as in section a of Figure 1. The BIS schematics and the system data flow are presented in section b of Figure 1.

The working principle of the whole system is based on a laser scanner that generates a laser plane at a constant angle from the horizontal plane. When the laser plane hits a target in the imaged area, a line of laser light appears on the body of the subject. See Figure 2 – Img_{t+1} image. The video camera acquires two images: first, with the laser diode off, Img_t, and second, with the laser diode on, with a line of laser light that appears on the target, Img_{t+1}. Subtracting the two images we get only the laser line projected on the people's torso, *OutImg* – Figure 2. In the ideal situation, all pixels for which $Img_{t+1}(x, y) \neq Img_t(x, y)$ describe the laser line which appears on the user's body torso. In real cases, the images are corrupted by noise. This problem was solved using an experimentally obtained noise model, σ. The criterion to extract the line of the laser light becomes now: $Img_{t+1}(x, y) – Img_t(x, y) > \sigma$. Other problems, such as shadows, slight body subject movements, light sources, video camera saturation, and background changes do not affect the reliability of the laser line feature extraction. This is happening because the time interval between the two images acquisition is less than 40 ms and the noise model presented above have been proven to be adequate. Based on this operating principle, the extraction of the laser line becomes a very fast task—a major advantage of this system.

If the object is far away, the extracted laser line will be farther from the bottom of the image, h_1. In the opposite situation, it will be closer to the bottom part of the resulting image, h_2. At this point, one knows the angle between the laser scanner and the horizontal plane, the position in space of the video camera and the extracted shape of the laser line on the subject body. The depth information of each point on the extracted laser line is calculated using some basic geometric formulae. Further on, having all these values, we exactly determine the real 3D subject body position with respect to the camera.

The hardware system has two components: the electro-mechanical scanner and the DSP system. The scanner has a low-power laser diode and a mechanical system with mirrors, section a of Figure 1 (Dobrea, 2002). The plate with mirrors is attached to an engine shaft. The DSP system interfaces with the engine control system only through a single digital line that can start/stop the engine.

Since this application deals with images and all these type of applications are considered data and computing-intensive, the TMS320C6416 DSP was chosen due to its: high computing power, large on-chip memory, and efficient data transfer mechanism.

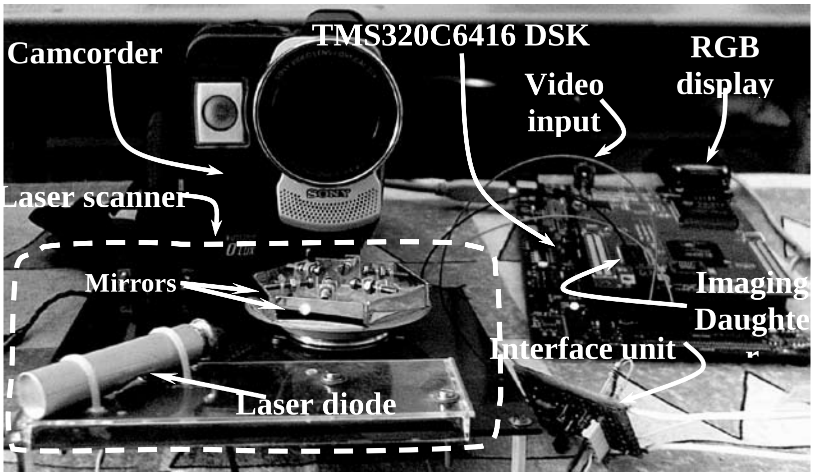
In order to have a *real time supervision* of the system evolution, an output image, containing both the acquired image and the resulting one (*OutImg*), is formed and displayed on a RGB monitor (the image data are moved in background using for this the EDMA controller, section b of Figure 1).

Movement-Based Subject State Identification System

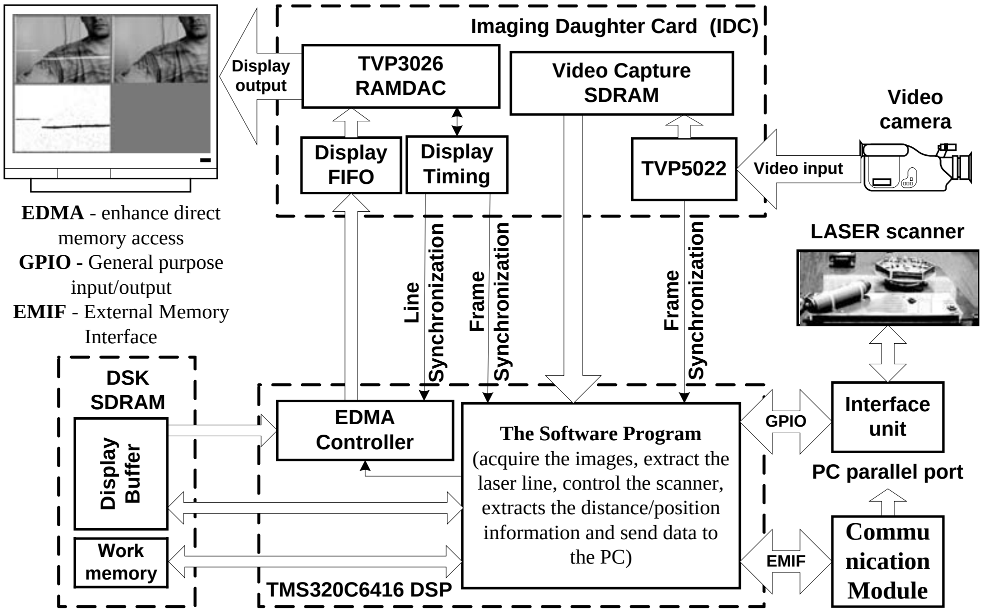
In order to test the BIS, we have developed an experiment intended to determine if there is a correlation between the *emotional state* of a person and the body torso movement of that person.

We admitted six subjects for this study. All of them were young healthy people (26.6±3 years, mean

Figure 1. The bio-instrumental system



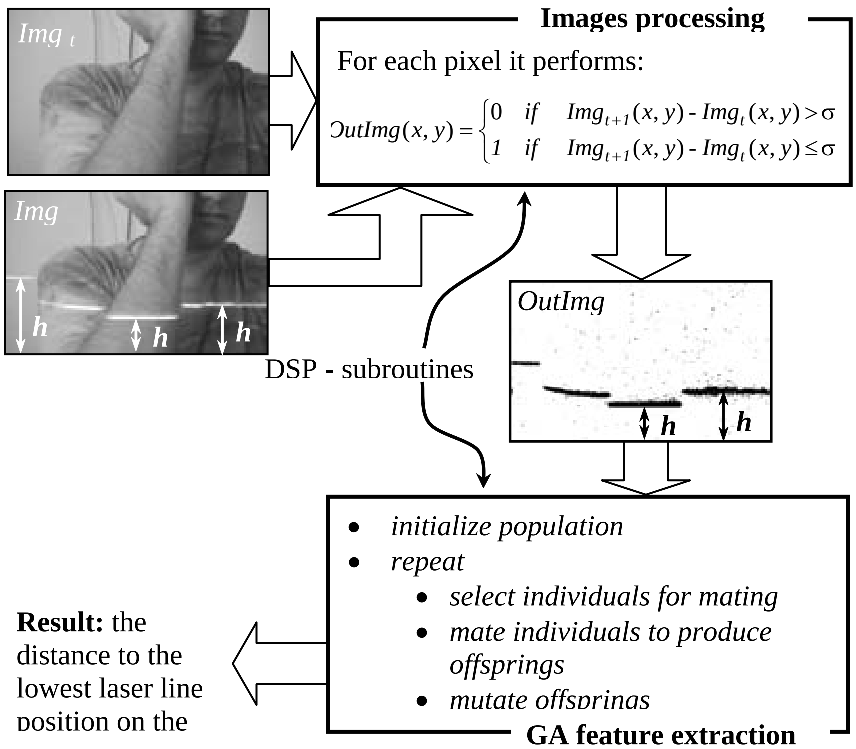
a) view of the implementation



b) BIS schematics and the system data flow

continued on following page

Figure 2. The data flow for the distance determination



± standard deviation) (Dobrea & Serban, 2005). But first, the *emotional state* must exist and must be manifested by the subjects. The emotion was induced by two films presented to the subjects: an action movie and a horror movie. At the end, an analysis was done on the recorded body torso movements to characterize common behaviors of the subjects during the movies associated with special time moments of the films. In this way, the system was validated and analyzed.

The movement of the subject was characterized by the position of the subject torso, determined by means of the distance between the closest point of the chest situated on the laser line and the video camera. This distance is proportional to the distance from the lowest point of the extracted laser line (projected on the subject torso) to the bottom border of the image, h_3 on Figure 2.

The Distance Determination

A special algorithm was designed in order to determine the distance between the subject and the laser diode. The algorithm use a standard genetic algorithm (GA), described by Goldberg (1989), Figure 2. For each generation, an entirely new population is created by selecting individuals for mating from the previous population, according to a specified selection method. In order to implement the GA we have adopted a philosophy inspired by GALib, a C++ library for GA objects (Wall, n.d.).

For our application, each chromosome has two genes, encoding the position of an image pixel (Dobrea, Sîrbu, & Serban, 2004). We have implemented the binary string format for chromosomes, concatenating the binary representations of the coordinates, on the *x* and *y* axis. The fitness function was designed to maximize the number of image pixels in the vicinity of the selected image pixel and to minimize the distance between the pixel and the bottom of the screen. In this mode, the chromosome with the best fitness value will characterize a point belonging to the laser line segment which is closest to the bottom border of the image. To reduce the influence of noise, the pixels having in their vicinity less than a specified amount of adjacent pixels are ignored. The population was initialized randomly, uniformly distributed in the four quadrants of the image, to ensure the rapid convergence of the GA.

In section a of Figure 3, we present two evolutions of the GA for an extracted laser line, displaying the fitness of the best individual and stressing two behaviors: medium and slow algorithm convergence. For the tests we have run, the mean number of generation for convergence is 200, for a population of 100 individuals, with no elitism, 0.9 probability of crossover, and 0.001 probability of mutation.

The Emotional State Detection

A problem this system must to deal with is given by the limbs movements that generate *artifacts*—for example, in Figure 2 the arm positioned in front of the body determines the GA to obtain the h_2 distance instead the correct distance h_3. These *artifacts* were removed using a special algorithm which takes into account the arm thickness.

The Pearson's Product-Moment *Correlation coefficient* was computed in order to characterize common behaviors of the subject's movements recorded during the movies and associated with special time events of the films. A time evolution of the distance between the view point (video camera) and the subject's chest position is presented in section b of Figure 3.

The six subject's traces, representing distance evolutions, are presented and marked in this figure with S1- S6. They correspond to a movie fragment able to impress the subjects.

c) The correlation coefficient

The Pearson's *correlation coefficients* computed for all pairs of two time segments, shown in section b of Figure 3, are presented in section c of Figure 3.

The obtained results support and demonstrate the system's ability to evidence a common subject *emotional state* reflected by the body movements. The subjects' different behavior as a response to the same emotional state (through the movements of the body, hands, etc.) and the time delay required to manifest the emotional state determine the spread of the computed correlation values. For other time fragment of the movies, similar results were obtained.

A Hand Sign Recognition System

The system able to recognize the static *hand sign* we propose is a combination of two methods described in the literature: video and special device-based. The *hand signs* can be formed using one or both hands. Five of the ten used *hand signs* are presented in section a and b of Figure 4.

The algorithm used for the extractions of the projected laser line image is similar to the one presented above. The laser trace signal ($H_s[n]$ resulted from the laser extraction algorithm) is modeled using the coefficients of an autoregressive (AR) filter, (Cracan et al., 2005), (Dobrea et al., 2005). The AR filter's coefficients are used to reduce the redundant input information passed to the classifier algorithm implemented on DSP.

A multilayer perceptron (MLP) neural network was used in the *pattern recognition* process (Cracan et al., 2005); Dobrea et al., 2005). The correct recognition rates for all the *hand signs* were in the range of 0.823÷1. The necessary time between the first image acquisition and the end of the entire classification process was less than 1.5 seconds, adequate for *real time supervision.*

FUTURE TRENDS

From the Subject's Body Language to Emotional State Identification

The identification of some particular postures like the arm position in front of the torso, as in Figure 2, or the torso position, as in section a of Figure 5, can be made by *pattern recognition*, in the manner presented above. Each of these postures or body positions can be related to different internal subject states, (Pease, 1992), that can guide a system in order to improve the human computer interaction. For example, in Figure 2, the subject posture can express boring if the subject keeps this posture for a long time.

Evaluation/Analysis of Parkinson Patients

Up until this moment there is no kind of standard method (either qualitative or quantitative) to evaluate the Parkinson symptoms. Moreover, in MDSTF (2003), one mentions a number of errors in the Unified Parkinson's Disease Rating Scale such as: some ambiguity in the text, inadequate instructions to rate some questioner rubrics, one deficiency in a unit of measurement, and the lack of questions other than motor aspects of Parkinson's disease.

Using two different laser scanner systems, the trajectory of the subject head (as in section b of Figure 5) can be recorded and easily quantified in order to assess the patient rehabilitation. In this mode, the proposed system is able to quantitatively evaluate the severity and the progress of the Parkinson's disease and to offer a reproducibility of the obtained results. Thus, all the above presented drawbacks are eliminated.

CONCLUSION

In this article, a DSP implementation of a new noninvasive BIS was presented. This project has a significant impact on the people's life reflected in:

- The natural form of subject's interaction and supervision by the health care systems, in order to determine the emotional and physiological state changing;
- The reproducibility of the evaluation and assessment of the severity in *Parkinson's Disease*—a way of helping the physicians to improve the quality of the medical act;
- The support offered to the vocally impaired subjects.

This system offers the possibility to use a new kind of information regarding the subject's emotional and physiological state, unexploited yet on the HCI systems, namely, the state of the subject expressed through *body language*.

The system is inexpensive, easy to manufacture and, hence, attractive for practical applications. In the end, last but not least, the entire system is very fast, being adequate even for *real time supervision*.

KEY TERMS

Biosensor: A device incorporating a biological sensing element (the recognition element is biological in nature).

Digital Signal Processor (DSP): A specialized, programmable computer processing unit that is able to perform high-speed mathematical processing. DSP refers to manipulating analogue information that has been converted into a digital (numerical) form.

Fitness: A measure of the suitability of a potential solution for the given application. Each individual is an encoded representation of all the parameters that characterize the solution. It has an associated value (fitness) which is a measure of its performances.

Genetic Algorithm (GA): An optimization and search technique based on the principles of Darwin's theory of natural selection and Mendel's work in genetics on inheritance: the stronger individuals are likely to survive in a competing environment. It allows a population composed of many individuals (possible solutions) to evolve under specified selection rules to a state that maximizes their suitability for the specific application.

Human Computer Interface (HCI): The process by which users interact with computers; based on HCI, one designs and implements human-centric interactive computer systems.

Neural Network: A system of programs and data structures that approximates the operation of the human brain.

Sensor: A device that measures or detects a real-world condition, such as an acoustic (microphone, hydrophone), electromagnetic (radar), or optical (camera) signal.

INTRODUCTION

The growing demand for a better quality of life is now the major motivation behind the recent focus on health care research. Current worldwide shortages in medical personnel have placed immense strain on present health care systems in the presence of a growing global population. Alarming statistics from the recent WHO 2006 report[1] depict critical shortages in health care providers with 57 countries possessing less than 80% coverage of health care providers for their citizens. It is estimated that training the health care workforce to cope with these shortages by 2015 would incur annual costs of \$1.6 to \$2.0 billion per country depending on its size. This predicament makes it paramount to look at alternative avenues for more effective health care technologies to ensure the sustainability of worldwide health care systems.

Computational intelligence (CI) is the implementation of artificial intelligence in computer science allowing for the design of powerful decision systems capable of processing and interpreting large volumes of data. This discipline has recently been applied to biomedical engineering problems, specifically those in which human intervention can be replaced by some form of automated response. As will be seen later, supervised learning formulations such as artificial neural networks (Haykin, 1994), support vector machines (Schlkopf, Burges, & Smola, 1999; Vapnik, 2000), and fuzzy classifiers (Abe, 1997) have been recently applied to diagnostic and prognostic biomedical applications. These techniques learn nonlinear relationships between patient data and disorders which could not otherwise be captured with standard statistical analysis techniques. Moreover, CI techniques are cost effective to implement, being fundamentally software-based in nature and thus requiring only a processor with mathematical functions and adequate memory, for example, personal computers.

Sensor networks (SN) is an emergent technology which combines small sensors outfitted with wireless transmitters to form a network with more powerful sensing capabilities (Akyildiz, Su, Sankarasubramaniam, & Cayirci, 2002; Chong & Kumar, 2003). The primary application for SN technology is monitoring environmental changes making it ideal for deployment in patient monitoring systems. In contrast to other monitoring technologies such as video, SN offers a potentially cheaper solution consisting of cost effective interconnected sensors which cooperatively sense the surroundings. Individual sensor information is then fused to derive an instantaneous description of the environment.

In this article, we review briefly the recent applications of CI and SN technologies in health care, mentioning some of the challenges in deploying these technologies. This is followed by an example of a biomedical system incorporating both technologies in a single paradigm. The state of current systems and their advantages over existing methods are highlighted with examples focusing primarily on intelligent automated diagnostic systems to augment clinician diagnoses and health care monitoring systems for continuous patient observation.

COMPUTATIONAL INTELLIGENCE FOR DIAGNOSIS AND DETECTION IN HEALTH CARE

In recent times, intelligent biomedical applications incorporating CI techniques have been investigated for detection and diagnosis of pathologies. The objective is to replicate the diagnostic capabilities of a medical specialist based on patient data and where possible provide a more reliable diagnosis. In this endeavour, two trends have emerged: the first being pathology detection and the second being biological system modeling. The former has enjoyed cautionary clinician acceptance as pattern recognition is becoming common while the latter is less accepted due to the "black box" model which makes them difficult to be directly related to the pathology and thus remains a major issue to be addressed.

A general intelligent system incorporating CI consists of biosignal inputs, preprocessing, feature extraction, feature selection followed by pattern recognition (Figure 1). Biosignal inputs consist of measured signals from organs such as the heart or muscle. The signals are recorded, amplified, and filtered before feature extraction is performed. Proper feature extraction is essential for the later recognition stage as features should represent the unique pathological characteristics as much as possible. Feature selection is optional but functions to reduce redundant information which could confuse the detection process. The function of CI in this system lies in the final pattern recognition stage, where the task is to learn the implicit relationship between features and the respective pathologies given the finite set of data. It is important to note that the success of the system lies in its ability to perform well on new data and minimize the risk of misdiagnosis.

One of the more successful systems has been the diagnosis of cardiovascular diseases based on the QRS wave complex recorded from electrocardiograms (ECG) (Julian, Campbell, Cowan, & McLenachan, 2005). The average peak-to-peak voltage of the QRS complex is considerably larger than electrical activity from neighbouring organs making filtering simple and subsequent QRS detection algorithms sufficiently accurate (Friesen, Jannett, Jadallah, Yates, & Nagle, 1990). QRS information such as ST segment length (Edenbrandt, Devine, & Macfarlane, 1993), peak amplitudes, number of waveform turns, and peak to peak intervals (Kundu, Nasipuri, & Basu, 1998; Lin & Chang, 1989; Marques, Goncalves, Ferreira, & Abreu-Lima, 1994) have been effectively used as discriminating features. More advanced processing methods such as wavelet transforms, autoregression, and principal components analysis have also been applied to extract better features (Baxt,1993; Strauss, Steidl, & Jung, 2001). Classification of cardiovascular disorders using CI techniques, for example, ectopic beat detection (Chow, Moody, & Mark, 1992), arrhythmias (Coast, Stern, Cano, & Briller, 1990; Silipo, Zong, & Berthold, 1999), myocardial infarctions (heart attacks) (Fricker, 1997), and ischemia (Vladutu, Papadimithou, Mavroudi, & Bezerianos, 2001) has been sucessfully demonstrated. Tests performed on a variety of publicly available databases, for example, MIT-BIH[2] have yielded on average high accuracies with neural networks being the major applied technique (Table 1).

The classification of neuromuscular diseases has been more complex. Unlike the QRS waveform the motor unit action potential (MUAP), waveforms measured via electromyography (EMG) are composite waveforms derived from superposition of nerve signals emanating from adjacent muscle fibres (Emly, Gilmore, & Roy, 1992). Direct measurement of a single MUAP using needle EMG may not yield clear isolated waveforms either because motor units in the muscle fibers produce comparably smaller action potentials (-35mV to -70mV) making them easily corrupted by electrical noise. Even though muscle mechanics and action potentials are well understood, motor neuron firing is still thought to be random and nondeterministic. Research has examined the physical measurement of a single MUAP such as the number of turns and peak to peak amplitudes similar to QRS analysis (Park & Lee, 1998). This could be adequate provided a single clear MUAP waveform

Figure 1. General flowchart of intelligent detection biomedical system

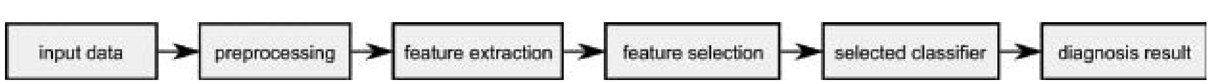

Table 1. Comparison of classification accuracies for ECG beat detectors using various classifier schemes

Classifiers	No.of Beats	Accuracy (%)
MLP1 (Hu, Thompkins, Urrusti, & Alfonso, 1993)	13	84.50
MLP2 (Izeboudjen & Farah, 1998)	12	90.00
SOM-LVD (Yu, Palreddy, & Thompkins, 1997)	4	92.20
MLP-LVQ (Oien, Bertelsen, Eftestol, & Husoy, 1996)	2	96.80
Hybrid Fuzz NN (Osowski & Tran, 2001)	7	96.06

could be obtained which is unfortunately rarely possible in practice. In this aspect, autoregressive (AR) models (Coatrieux, 1983; Pattichis & Elia, 1999) and independent component analysis (ICA) (Garcia, Martinez, Sornmo, Olmos, Mur, & Laguna, 2002) have been successfully employed. The former is based on a linear filter system and attempts to model the MUAP waveforms using a linear predictor model, while the latter performs MUAP decomposition but is highly sensitive to the final mixing matrix. The AR model performs better with higher model orders while ICA has been used in conjunction with template matching systems for the decomposition of MUAPTs (Garcia et al., 2002). Other methods such as the popular wavelet decomposition have also been applied, but it requires correct wavelet selection to extract meaningful information which is usually achieved through trial and error (Kumar, Pah, & Bradley, 2003). Much research is focused on finding more accurate signal processing techniques to interpret the MUAP trains (MUAPTs). Another issue is the type of features that should be extracted given that it may not be possible to recover the single MUAPs. In terms of classification, the literature has reported success in using neural networks (Pattichis, Schizas, & Middleton, 1995) while support vector machine (SVM) classifiers and hybrid models remain to be researched with few successful results. The emphasis for now is on using feature extraction methods to determine neuromuscular disorders for use in diagnosing diseases for example, myopathy and neuropathy from healthy subjects (Schizas, Pattichis, Schofield, Fawcett, & Middleton, 1990) (see Table 2).

In addition to neuromuscular diseases, EMG signals can be used with CI techniques in the development of prostheses and orthotics. Early myoelectric prostheses such as the Utah arm (Jacobsen, Knutti, Johnson, & Sears, 1982) possessed simple logic and few degrees of movement and depended on detecting a muscle posi-

Table 2. Comparison of classification accuracies of myopathy, motor neuron disease, and normal subjects. Note that the data set used is equivalent and the results are a comparison of the performance of these techniques and the corresponding features used.

Classifier Method	Feature Set	Accuracy (%)
BP-NN (Pattichis, Schizas, & Middleton, 1995)	MUAP time domain	80.00
NN-majority vote (Pattichis et al., 1995)	AR, cepstrum, time domain	80.00
Neurofuzzy hybrid (Christodoulou & Pattichis, 1999)	AR, cepstrum, time domain	88.58
Genetics Based Machine Learning (Pattichis & Schizas, 1996)	MUAP time domain	<95.00
Hybrid SOM-LVQ (Christodoulou & Pattichis, 1999)	MUAP time domain	97.61

tion after the user had flexed and held the position for some time. This approach was inadequate for situations requiring instant responses and a lot of time was spent on training the amputee to use the prosthesis. Recent research has concentrated on using CI to recognize limb positions (Karlik, Osman, & Alci, 2003; Katutoshi, Koji, & Takao, 1992; Peleg, Braiman, Yom-Tov, & Inbar, 2002) with very few studies of muscle activity when the limb is moving (Boca & Park, 1994). A more advanced prosthesis is the exoskeleton which provides mechanical strength either for everyday use or rehabilitative purposes. Kiguchi, Tanaka, and Fukuda (2004), for example, have developed an exoskeleton with three degrees of freedom (Kiguchi et al., 2004) and used a neurofuzzy system to detect the intended motion from EMG signals. More work, however, is required to improve the accuracy of translating and predicting the user's intention to move the exoskeleton, especially when detection errors can lead to injuries from unintended motion.

Electroencephalogram (EEG) signals from the brain provide important information regarding brain function and cognitive performance and can be detected based on their frequency bands, for example Alpha (8-12 Hz) and Beta (12-26 Hz) waves (Bylsma, Peyser, Folstein et al., 1994). Variations in these rhythmic sinusoidal signals can be used with CI techniques to detect various neurological disorders such as epilepsy (D'Alessandro, Esteller, Vachtsevanos et al., 2003), Alzheimer's (Cho, Kim, Park et al., 2003) and Huntington's (De Tommaso, Difruscoloand et al., 2003) diseases. Since these signals have small magnitudes, a major concern has been in noise reduction before CI detection. Another interesting area is the development of EEG-based communication links known as the brain controlled interfaces (BCI), which can restore functional activities in the disabled. CI techniques are proving very useful for classifying mental tasks from EEG signals which have subsequently improved the control of external devices and actuators (Deng & He, 2003; Felzer & Freisieben, 2003; Wang, Zhang, Li et al., 2004).

CI techniques have only recently been applied to research in human movement sciences and gait analysis upon the realization that locomotion is vital to our daily activities and our perceived quality of life (Whittle, 2002). Numerous gait variables such as joint angles (Oberg, Karsznia, & Oberg, 1994) and ground reaction forces (Begg, Sparrow, & Lythgo, 1998) can be recorded making feature selection an important aspect of gait data classification. CI has been recently used to study normal gait biomechanics (Barton & Lees, 1997; Barton, Lisboa, Lees, & Attfield, 2007), detect gait pathologies arising from lower extremity injuries and imbalance disorders due to cerebral diseases such as Parkinson's (Morris, Iansek, Matyas, & Summers, 1994) and Cerebral Palsy (Kamruzzaman & Begg, 2006). Falls in the elderly are another major health concern since they cause serious injuries and can be fatal, hence motivating the need for newer prediction and prevention techniques (National Safety Council, 2005). Recently CI techniques have been used to detect and predict elderly persons at risk of falling using gait variables such as the minimum toe clearance (Begg, Lai, Taylor, & Palaniswami, 2005; Khandoker, Lai, Begg, & Palaniswami, 2006). The uptake of CI approaches in gait analysis however has not kept pace with other biomedical areas and further research is required before these techniques become routine in clinical and rehabilitative settings.

WIRELESS SENSOR NETWORKS FOR HEALTH CARE

One emerging technology in health care is wireless sensor networks for patient monitoring systems aimed at reducing health care costs and addressing the shortage of medical staff in industrialized countries. The great advantage of a true wireless architecture is that there is little to no requirement for static infrastructure such as wires, cables, access points, and transmitting antennas to modems and routers. Wireless networks can be deployed using portable devices which communicate via radio frequency transmission with minimal infrastructure. We review briefly several existing research initiatives for sensor networks in health care.

Wireless Protocols and Standards

Several wireless technologies are currently in use such as wireless LAN (IEEE 802.11) and Bluetooth, which now come standard in personal computers, digital assistants (PDAs), and mobile phones. Wireless LAN has been used in hospitals for Internet access and to transfer patient data between departments, and now enjoys widespread acceptance due to its extensive coverage and ease of use. Unfortunately, wireless LAN requires high power consumption, large packet overheads, and requires static infrastructure support such as access points. Bluetooth on the other hand was designed as a short range protocol for communication between a small group of devices and is ideal for office spaces where data can be transmitted to devices within a 10m to 50m radius (Haartsen, 2000). It was envisaged that Bluetooth would be used in the deployment of Wireless Personal Area Networks (WPANs) in workplaces but was later found to be susceptible to degradation due to noise and multipath effects which reduced its effective range. This protocol nevertheless features prominently in mobile handsets and is sufficient for the local exchange of music, pictures, and data files. Both protocols look unlikely to be suitable for the design of wireless health care monitoring systems incorporating small sensor nodes due to a different set of requirements.

The key difference between wireless computing networks and sensor networks is that small low computing powered devices (sensors) are equipped with wireless capabilities to form a network. These devices are intended to collect data from the body in our case, and transmit it to a processing centre (such as a PC) usually called a mother node. Because the sensor nodes are small they do not possess substantial on board energy for transmission which restricts them to smaller volumes of data (low data rates) over shorter distances. Newer protocols, such as the IEEE 802.15.4 or Zigbee, have been proposed to address these design requirements. Zigbee was conceived in 1998 and completed in 2003 and is primarily designed for low powered devices over short ranges. This type of protocol is well suited to wireless monitoring systems for health care (Golmie, Cypher, & Rebala, 2004, 2005), for example, a wireless ECG monitor will allow a patient to move around the hospital while still being monitored. Rapid action can be taken if complications arise while providing more mobility and privacy for the patient. These networks are also known as Body Area Networks (BANs) comprising unobtrusive devices to monitor health signs such as heart rate or blood pressure (Guang-Zhong, 2006; Jovanov, Milenkovic, & Otto, 2005; Jovanov, Milenkovic, Otto, & Groen, 2005).

Another emerging technology is Radio Frequency Identification (RFID), a labeling technology in retail which has been increasingly deployed (Roy, 2006) for tracking. When combined with databases and globally linked systems, RFID can be used pinpoint patients or pharmaceuticals as they move in the hospital. These features are the driving force behind continued research into RFID technology for health care since a hospital could, for example, use RFID to tag blood samples to the patient thereby eliminating the need for paper records.

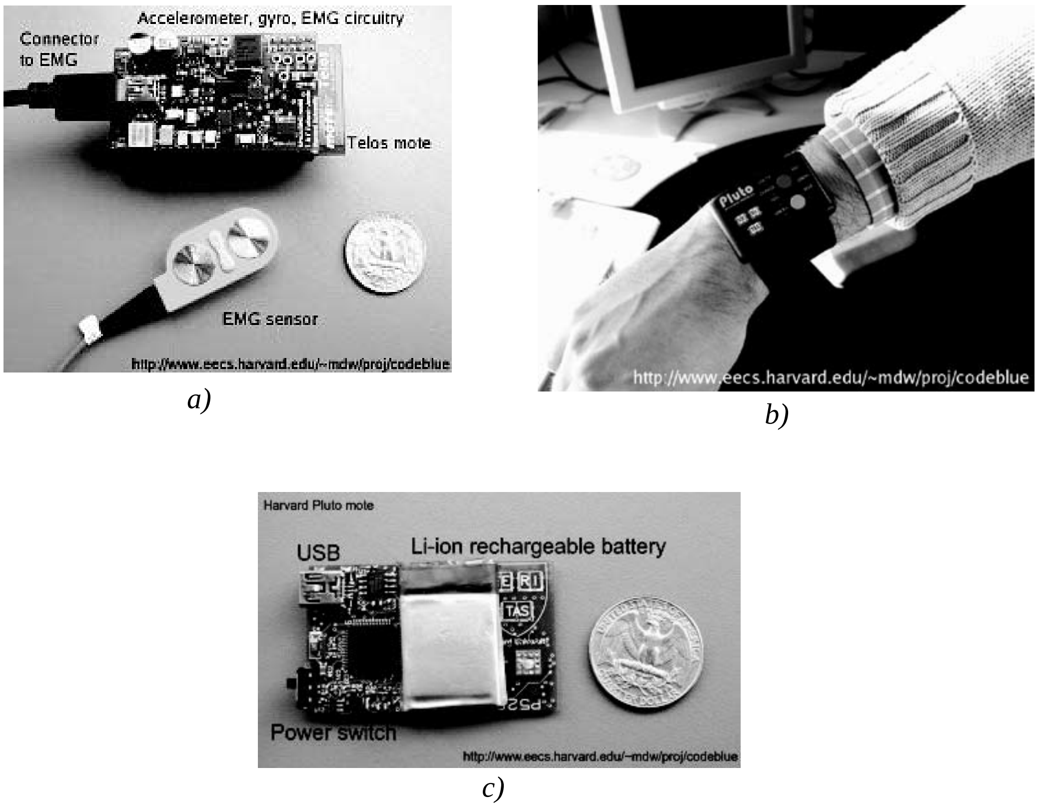
CodeBlue: Wireless Sensor Networks for Medical Care

Harvard University has initiated a wireless network project for health care called Codeblue (http://www.eecs.harvard.edu/ mdw/proj/codeblue/) in collaboration with hospitals (such as the Boston Medical Center) with support from national institutions such as the National Science Foundation (NSF), National Institutes of Health (NIH) and also companies such as Microsoft. The aim of the project, which began in 2003, is to explore applications of wireless sensor network technology to a range of medical applications, including prehospital and in-hospital emergency care, disaster response, and stroke patient rehabilitation.

Several small sensor devices with wireless capabilities such as a wireless pulse oximeter based on the Mica and Telos sensor motes from Crossbow and the University of Berkeley respectively have been developed. Other devices include a modified Telos mote known as the Pluto mote equipped with accelerometers, gyroscopes, and EMG circuitry (Figure 1). The mote is incorporated in a wrist-worn device and monitors vital health statistics such as heart rate. A Codeblue software platform provides routing, naming, discovery, and security for wireless medical sensors, PDAs, PCs, and other devices for health care monitoring (Lorincz, Malan, Fulford-Jones et al., 2004). A subsystem for this platform is MoteTrack, used for tracking the location of individual patient devices both indoor and outdoor using radio signals from beacons fixed in the surroundings. The group is focused on major issues in the integration of medical sensors with low-power wireless networks such as wireless routing, security, 3D location tracking, and adaptive resource management.

Other groups adopting Codeblue software include, for example, the Motion Analysis Laboratory in the Spaulding Rehabilitation Hospital[3] (and the AID-N project at the Johns Hopkins Applied Physics Laboratory,[4] which is investigating a range of technologies for disaster response. The AID-N wireless sensors are deployed on devices such as an electronic “triage tag” with pulse oximeter, LCD display, and LEDs for

Figure 2. (a) The combined accelerometer, gyroscope, and electromyogram (EMG) sensors for stroke patient monitoring, developed by the Codeblue project. (b) The Pluto mote can be mounted in a case which makes it easy for wearable wrist devices. (c) The Pluto mote designed at Havard. The architecture is based on the design of the Telos mote from the University of Berkeley and uses rechargeable Lithium ion batteries (http://www.eecs.harvard.edu/~mdw/proj/codeblue/ accessed 4/15/2007).



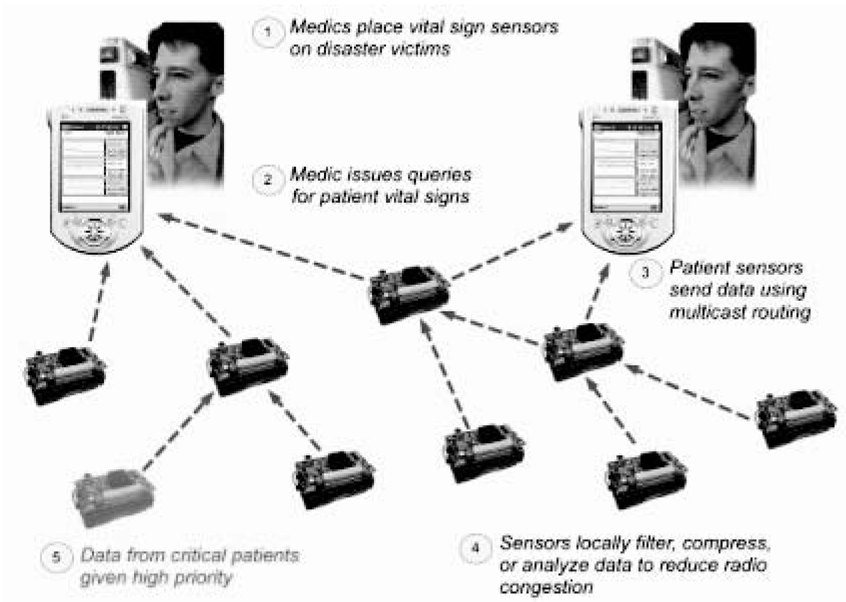
indicating a patient's status. There is also a packaged version of the two lead ECG mote developed by the Harvard group and also a wireless blood pressure cuff. Other collaborations include a wide-area event delivery infrastructure for medical care, with Harvard University, and a project integrating Vital Dust sensors into a PDA-based patient record database (iRevive). The iRevive system provides real-time monitoring of vital signs by emergency department personnel and clinicians through a variety of interfaces such as PDAs or Web-based PCs.

Mobihealth: Body Area Networks (BANs) using Wireless Mobile Phone Technology

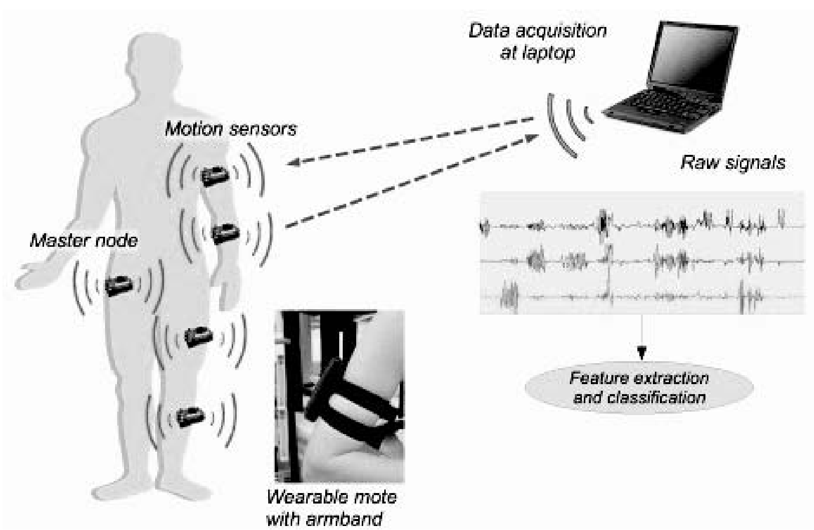
Mobihealth (2002) (http://www.mobihealth.org/) is a collaborative project based on a European initiative to create a generic platform for home health care. The platform defines a body area network (BAN) with low bandwidth GPRS/UMTS wireless protocols for communication. The BAN devices can be worn by patients and serve to monitor vital health statistics, being both low-powered and customizable. The technology is directed at providing new services to the remote monitoring of chronically ill patients (in hospital and at home), remote assistance in emergency and disaster situations, and the remote management of clinical trials (research augmentation). It is hoped that these developments will reduce health care costs while maximizing response times. Project designers have focused on developing a generic platform which could incorporate all these services.

From a CI perspective, Mobihealth presents an exciting new possibility to design a platform supporting intelligent plug-and-play devices. One example is to incorporate CI for early warning detection of high risk patients, for example cardiac health. This presents an

Figure 3. (a) The Codeblue architecture consisting of Telos or Pluto motes used for emergency response, (b) limb motion monitoring for rehabilitation in stroke patient. Photo courtesy of Codeblue homepage (http://www.eecs.harvard.edu/~mdw/proj/codeblue/ Accessed 4/15/2007).



a)



b)

opportunity for the application of CI techniques with BAN technology not only for abnormality detection but also for onset prediction of a serious pathology. Detection and prediction models can be placed on board the sensor devices to increase their advantages allowing immediate contact of emergency personnel and overall improved response times.

Other Health Care Sensor Research Initiatives

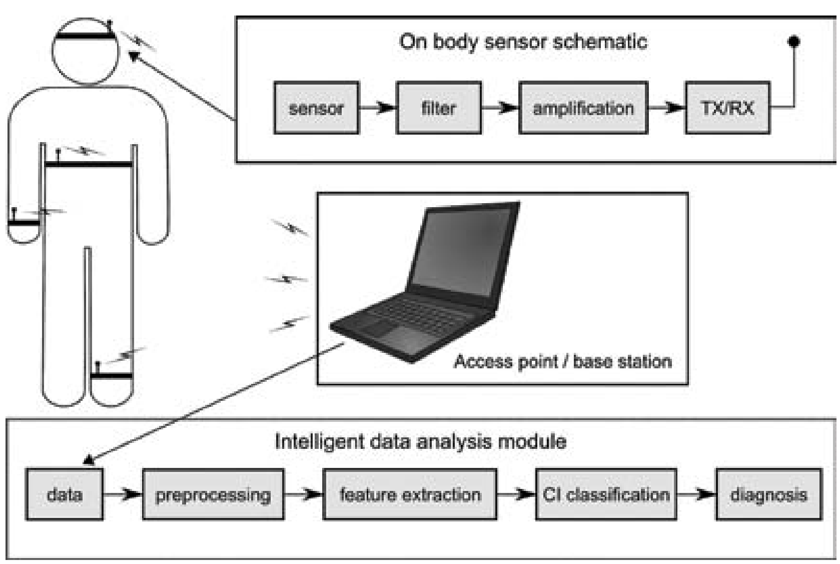
Several other projects have already commenced on using wireless technologies in health care, ranging from sensor deployment to the underlying transmission protocols undertaken by universities in collaboration with hospitals. The UPDATA project (http://www.sscnet.ucla.edu/issr/da/PDA/) was initiated by the biomedical library at the University of California Los Angeles (UCLA), with the objective of incorporating statistical analysis in medical data via a PDA. The project is attempting to create a central server with customizable searches, calculation tools (such as ratios and dosages), and a database of links to major health care sources all of which can be accessed by researchers using PDAs. Another project (Jovanov, Milenkovic, & Otto, 2005; Jovanov, Milenkovic, Otto et al., 2005) has investigated wireless sensor technology for ambulatory and implantable psycho-physiological applications. These devices are capable of monitoring the functioning of the heart, long time motion of prosthetic joints, and for monitoring other vital signs. Their main focus is wearable and implantable (or subcutaneous) biosensors, biomaterial technologies, modelling, and wireless communication. Further scope exists for deploying CI as backend software either for assisting diagnosis or for data interpretation.

Research initiatives involving personalized and non-hospital based care are also receiving significant attention. It has been estimated that two thirds of deaths due to cardiac disease occur outside hospital environments (Rubel, Fayn, Simon-Chautemps et al., 2004). This suggests the need for personalized diagnostic devices that can monitor ECG waveforms in the community and warn of any forthcoming cardiac events. Such a system will require intelligent information processing to analyse patient vital signs and alert the care providers. Rubel et al. (2004) reported the development of an intelligent Personal ECG Monitor (PEM) for early detection of cardiac events. Their system is equipped with in-built advanced decision making and can generate alarm levels and messages for care providers. This type of device demonstrates how effectively pervasive computing and CI-based intelligent information processing, combined with personalized and wearable ubiquitous devices, could improve health care.

INTELLIGENT SENSOR NETWORK SYSTEMS FOR HEALTH CARE MONITORING

In this section, we discuss the properties of a health care system incorporating computational intelligence and sensor network technology in a single paradigm. A general system (Figure 4) consists of the sensor network, first deployed either by attaching sensor nodes to a patient or placing them in the patient area. Once the network is setup, the actual measurements can be made, collected, and transmitted to a base node for further processing. Measurement data is generally corrupted by noise and must be filtered and preprocessed using signal processing techniques. The processed data can then be analysed with a selection of CI techniques and the appropriate decisions made based on the system outputs.

Figure 4. General schematic of an intelligent sensing system for patient monitoring



The advantage of sensor network monitoring compared to traditional bed care monitoring is that measurements can be continuously made and the patient need not be confined to the bed. This is advantageous for diseases such as diabetes (Klonoff, 2005) where patients still value their mobility. A recent example application successfully incorporating intelligent sensor network monitoring is the determination of levodopa-induced dyskinesias (LID) (Keijsers, Horstink, & Gielen, 2003). LIDs are characterized by involuntary muscle movements caused by levodopa medications used to treat Parkinson's disease. The long term side effect is involuntary muscle movements ranging from unnoticeable to severe. These movements are measured using the Abnormal Involuntary Movement Scale (AIMS) with score ranges from 0 to 4, with 4 being the most severe. Knowledge of the amount of LIDs is useful for estimating them accurately to improve the daily life of the patient. We now review the components in this system.

Sensor Measurements

The measurement system consists of six accelerometers attached to the patient's body: one on each foot, two on the shoulders, one on the chest, and one on the arm with the most severe LID. The small sensors can be quickly attached and do not interfere with patient mobility. The nodes serve to measure the linear acceleration which can be processed to obtain velocity and displacement measurements. Since the main symptom of LIDs is uncontrollable muscle tremors, the acceleration data is converted in to the amount and direction of low frequency vibrations (3 Hz or less). In general, signal processing algorithms such as wavelets (Adeli, Ghosh-Dastidar, & Dadmehr, 2007) and principal component analysis (Pawar, Anantakrishnan, Chaudhuri, & Duttagupta, 2007) could also be used to extract useful information giving a wider scope for this and other applications. Keijsers et al. (2003) derived 92 features in total, ranging from percentage of time the patient was sitting to various cross-correlations between different sensors.

Data Analysis

The system is fully off-line; data is logged and then processed on a separate PC similar to other processing techniques such as electrocardiogram (Paoletti & Marchesi, 2006), patient sleep state (Held et al., 2006), metabolism (Davies, Batholomeousz, & Andrade, 2003), and urea (Paoletti & Marchesi, 2006). This allows for a computer implementation of neural networks for supervised learning, specifically the multilayer perceptron (MLP) trained with the standard backpropagation algorithm. The size of the network was determined using forward selection as suggested by Laar, Heskens, and Gielen (1999). This classifier may be replaced with other computational intelligence methods such as the self-organizing map (Bonato, Mork, Sherrill, & Westgaard, 2003), support vector machines (Ubeyli, 2007), and spiking neurons (Rom et al., 2007).

Traditional LID measurements were previously done by asking the patient to remain still so that the measured movements could be assumed to originate from involuntary actions. Detection of involuntary motions becomes more complex when a patient is allowed every day motions such as cleaning or making coffee. The reliable detection of involuntary movements from voluntary ones would require more complex algorithms such as artificial neural networks. In addition, changes to the degree of these movements could depend on several other biomechanical factors which could be extremely difficult to explicitly model. Computational intelligence affords us a method to approximate these changes by learning the relationships between the effects and the system outcomes hence making detection easier.

System Performance

The performance of Keijsers et al. (2003) system was compared against two physicians who assessed the patient's AIMS score (0 to 4) from video tapes. Their classifications were considered as the true detection and the neural network was trained and tested against this. Results indicated that the system could consistently and reliably estimate LID value from sensor measurements. The predicted AIMS scores were never more than 1 off the physician scores and in 98% of the cases were correct. As the tests were cross-validated, they showed that the system could generalize to unseen samples of the same patient as well as to new patients which were encouraging because it demonstrated that sensor data could be reliably integrated with computational intelligence to design more intelligent monitoring systems.

CONCLUSION

In this article, we reviewed the applications of two emerging technologies in health care, namely computational intelligence and sensor networks. Both these technologies offer cheap and efficient alternatives to the current shortages in medical personnel faced by today's global health care systems. The combination of these technologies has been applied to the development of intelligent detection and patient monitoring systems, thereby reducing the patient attention demands on clinicians. Further research is required to develop more accurate and reliable systems which can provide similar or better qualities of care than current health care systems. The future looks promising as work moves to make both technologies ubiquitous in health care systems.

KEY TERMS

Classification: Assigning a class designation to a set of subject attributes.

Computational Intelligence: Mathematical formulations which simulate human learning and are implemented on computers.

Detection: Becoming aware of a present condition.

Diagnosis: Reaching a conclusion on a certain disorder based on observation and physical measurements.

Intelligent Monitoring Systems: Systems designed to monitor patient health signs and are capable to act on them.

Prognosis: The severity and future outlook of a disease and its progression.

Rehabilitation: The recovery process from a disorder after medical treatment.

Sensor Networks: A network of sensors which are each equipped with radio transceivers.

Computational Methods for the Early Detection of Diabetes

Herbert F. Jelinek
Charles Sturt University, Australia

David J. Cornforth
University of New South Wales, Australia

INTRODUCTION

The incidence of diabetes is increasing, and is expected to exceed one million people in Australia by the year 2010. Diabetes is currently diagnosed after the onset of symptoms. At this stage, detection of complications is a key intervention point in reducing the associated personal and community burden. These include eye, heart, kidney, and foot disease, which in many instances can be treated with good outcomes, provided the disease process is recognized early. In Australia, both national and state governments acknowledge the disadvantage faced by rural people in availing themselves of all aspects of diabetes management, from screening to regular assessment, education and health care (Colagiuri, Colagiuri, & Ward 1998). Therefore, the challenge that is the focus of this article is the early detection of diabetes complications associated with vision and cardiac function, with the eventual aim of providing a screening service that can be used in a rural or regional environment.

BACKGROUND

Complications associated with diabetes often remain undetected for quite some time, especially in rural regions, but are often what alerts health care providers to the presence of diabetes. Vision loss, cardiovascular disease, and foot amputations are the most often occurring outcomes of diabetes. Early detection of blood vessel changes associated with retinopathy, cardiovascular disease, and foot complications is important for timely treatment, to prevent or delay the occurrence of these complications and improve the quality of life for individuals with diabetes. Regular health screening that includes eye and cardiac function assessment has the potential to reduce the high costs on the health care system associated with diabetes, and to reduce the disparity in health care between rural and urban communities by providing timely feedback to those at risk.

Currently, regular screening provides an opportunity to discover people with unidentified diabetes and with subclinical eye and heart complications. Extrapolation from data obtained from eye health initiatives indicates that interventions that relieve or prevent complications associated with diabetes are highly cost effective (Lee, Lee, Kingsley, Wang, Russell, Klein, & Warn, 2001).

Universal screening is both feasible and cost effective. It delays complications, and younger patients have a longer time to benefit from early identification. In spite of this, diabetes screening is far from universal, especially among rural and regional populations. However, recent reductions in the cost of health technology and an increase in the availability of computing equipment, coupled with advanced data processing techniques, offer new opportunities. These include the ability to detect complications earlier, make screening faster, more accurate and cheaper, and to remove access barriers faced by those in rural and regional communities. This article focuses on two aspects of screening that could benefit from automation using computational techniques: diabetic retinopathy (DR), and cardiovascular disease.

DR is a condition in which the retina has suffered damage due to the complications of diabetes. DR could be significantly reduced by simplifying the procedure used to identify the condition and ensuring that early eye examinations become routine for diabetic patients. Damage to the eye associated with DR is the commonest cause of blindness in the working age population in developed countries. Yet, 98% of people with vision loss can be treated effectively provided the pathology is detected early (Lee et al., 2001). Automated assessment of retinal health allows community screening programs to be offered and operated effectively, utilizing community health professionals.

Cardiovascular disease includes a range of diseases, of which coronary artery disease (CAD) is the single most common cause of death in the western world. Cardiovascular complication is associated with diabetes, and on its own is the most common cause of death (Mathers & Penm, 1999). Cardiovascular disease affecting the larger blood vessels is a major complication of diabetes. People with diabetes are two to four times more likely to develop cardiovascular disease, and their prognosis is not as good as those without the disease. Cardiac autonomic neuropathy (CAN) is part of the cardiovascular disease spectrum, in part caused by CAD, which leads to reduced oxygenation of the nerves regulating the cardiac rhythm. The resulting morbidity and mortality can be reduced with regular screening and early recognition of nervous system damage affecting cardiac function in people with diabetes, which allow better treatment intervention.

Electrocardiology is still regarded as the most commonly used procedure for the assessment of cardiac function and identification of heart disease, and is utilized by numerous health care practitioners. The 12-lead electrocardiograph (ECG) is the kind of equipment most often used in regular general practice. In community health care, outreach nurses do not have the in-depth training to determine risk of a potentially dangerous cardiovascular condition, based on signs and symptoms, and are most often familiar with three-lead recordings. ECG interpretation is usually carried out by a specialist.

Screening for both cardiovascular disease and DR in rural areas is difficult because of health care barriers such as geographical isolation, the cost of visits to specialists, and the lack of cardiologists and ophthalmologists.

COMPUTATIONAL METHODS FOR THE EARLY DETECTION OF DIABETES IN A RURAL CONTEXT

Advances in computational methods that may be of use in rural settings involve two main areas: DR, and heart rate variability (HRV). Both of these rely on the fact that diabetes affects the cardiovascular system. Both aim to provide methods that can be applied easily and cheaply in a rural setting.

Analysis of Diabetic Retinopathy

The assessment of retinopathy has been enhanced by the ability of regional clinics to make quality photographs of the retina that can be then sent to remote ophthalmologists for assessment. This has recently been expedited using digital photography and improvements in digital communication. The best quality images are obtained using fluorescein photography, where the contrast is enhanced by using a dye injected into the bloodstream. This, however, is invasive, and much research has been conducted into processing of nonfluorescein color images using computational techniques.

The scope of DR covers a wide range of pathologies that are amenable to automated identification including:

- Microaneurysms (Jelinek, Cree, Worsely, Luckie, & Nixon, 2006; Cree, Olson, McHardy, Forrester, & Sharp, 1996).
- Hard exudates and cotton wool spots (Dua, Kandiraju, & Thompson, 2005).
- Haemorrhages (Singalavanija, Supokavej, Bamroongsuk, Sinthanayothin, Phoojaruenchanachai, & Kongbunkiat, 2006).
- New vessel growth (Soares, Leandro, Cesar, Jelinek, & Cree, 2006).
- Arteriolar narrowing and venous dilatation (Wong, Shankar, Klein, Klein, & Hubbard, 2005).

Automating the assessment of changes in the retina can be carried out using mathematical techniques. These techniques can be applied to the estimation of blood vessel diameter changes and quantify the appearance of microaneurysms and haemorrhages in the early stages of retinopathy, as well as new vessel growth in the advanced stages of DR. Of interest has been the correlation between blood vessel diameter changes in the eye that is not only associated with diabetes, but is also an early indicator for cardiovascular disease and stroke (Wong et al., 2005). For the automated assessment of most of these, the optic disk needs to be identified. This facilitates, for example, macula location, false positive localization of hard exudates, and vessel tracking.

Retinal Image Processing

Several computational operators have been utilized for retinal image processing. Morphological filtering simplifies a segmented image to facilitate the search for objects of interest. This is done by smoothing out object outlines, filling small holes, eliminating small projections, and other similar techniques.

Many image processing techniques use frequency filtering, based on the Fourier Transform. The form of the filter function determines the effects of the operator. A low-pass filter attenuates high frequencies, and retains low frequencies, so is used for smoothing and noise reduction. A high-pass filter yields edge enhancement or edge detection in the real domain (because edges contain many high frequencies), and therefore suppresses areas of constant grey level (which consists mainly of low frequencies). A band pass filter combines both of these functions. A suitable choice of filter enables the vessel pattern to be extracted. Further analysis can then be carried out by extracting shape descriptors that quantise the branching pattern of the vessels. These techniques can also be of use in detection of the optic disk.

Optic Disc Boundary Detection

The optic disk (OD) appears as a pale circular region in the human retina. It is the entry point of nerves and blood vessels into the retina. Its size and morphology are indicative of the general health of the retina, and distortions are indicative of disease leading to blindness. Many structures of the human retina are positioned in known relation to the optic disk.

The detection of the OD is not trivial, as the region appears bright, but crossed by dark blood vessels. This complicates identification of the boundary, which becomes fragmented. In addition, the size and the colour of the optic disk vary between individuals.

The method we have used for optic disk detection uses a high-pass filter to extract the edge of the OD, followed by a grayscale morphological closing operation with a flat disk-shaped structuring element. This is followed by applying Canny edge detection (Jelinek, Depardieu, Lucas, Cornforth, Huang, & Cree, 2005). We achieved an accuracy of 70% (14 correct out of 20 images), which can certainly be improved by adjusting the edge detection parameters, but compares favorably to previous work in this area. However it is to be noted that the result is excellent with respect to processing time and simplicity of the method (Figure 1).

Once the optic disk has been detected, the size and shape can be estimated, or it can be used as the starting point for vessel tracking, in order to determine the diameters of arterioles to venules, or it can be removed from the image by subtraction to simplify processing of the rest of the image.

ECG Assessment

In contrast to analysis of the retina, ECG assessment relies on processing of time series signals, of which an example is shown in Figure 2. Several automated classification systems for ECG assessment are in use, with the Minnesota code being the early de facto standard. This was followed by the NOVACODE (Rautaharju, Park, Chaitman, Rautaharju, & Zhang, 1998). For epidemiological studies, however, several individual ECG categories can be pooled into minor and major groupings to enhance statistical analysis, and are still in use (Klein, Klein, McBride, & Moss, 2005).

Figure 1. Retinal images showing application of the canny edge detector; left: good detection; right: detection with two errors

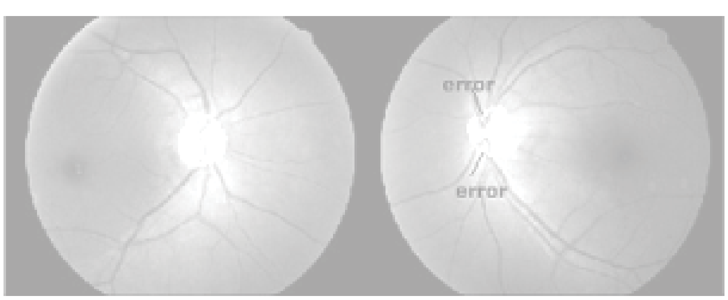

Figure 2. A typical three-lead ECG showing R peaks

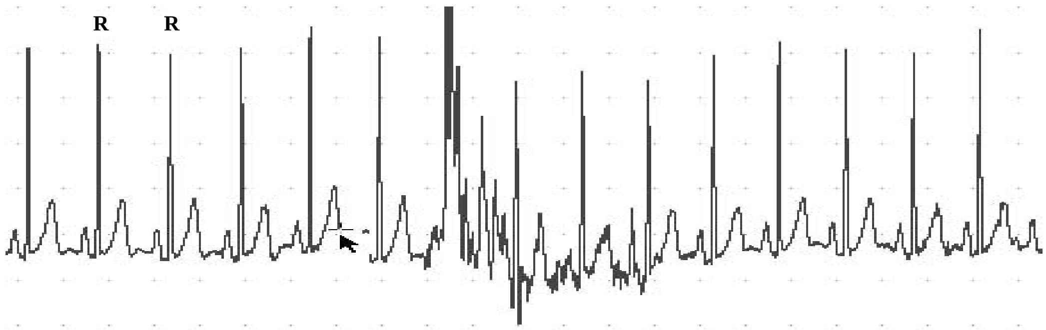

Figure 3. The R-R intervals are quantised and plotted against time to indicate HRV

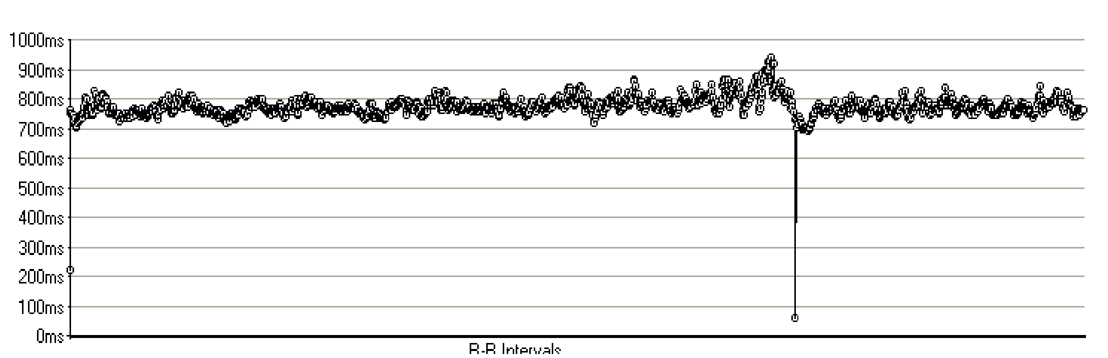

The Charles Sturt Diabetes Complications Group (CSDCG) has investigated the possibility of primary health care providers assessing heart function using an automated ECG assessment tool that differs from the traditional method, by evaluating HRV using a three-lead recording. This recording and interpretation tool adds two important features to heart assessment. First, it allows primary health care providers to record ECGs, as placing three-lead ECGs is simpler compared to placing a 12-lead ECG, and less invasive in community health settings. Second, it is able to identify asymptomatic changes in heart function associated with diabetes. HRV is based on observations that many cardiac anomalies including CAN, change the HRV before any overt ECG anomalies are detectable. Cardiologists with current methods cannot pick up preclinical cardiac anomalies, but newer methods such as HRV have the potential to do this. In addition, relatively short three-lead ECG recordings can be used in evidence-based health care and accountability for primary health care practice, showing a similar efficacy in identifying at risk individuals as 12-lead ECG recordings.

Heart Rate Variability

To assess CAN, the variation in the interval between successive beats can be analyzed in terms of HRV. An ECG obtained using the three-lead method is shown in Figure 2. The large peaks are referred to as the R portion of the ECG, and the time between subsequent R peaks gives the period of the ECG. From the raw ECG recording the R-R intervals are obtained as shown in Figure 3, and analysed.

HRV analysis has been shown to be effective in diverse clinical situations including risk assessment of future myocardial infarction, changes associated with hypertension, Parkinson's disease, eating disorders, and diabetes (Gerritsen, Dekker, TenVoorde, Kostense, Heine, Bouter, Heethaar, & Stehouver, 2001; Kallio, Haapaniemi, Turkka, Suominen, Tolonen, Sotaniemi, Heikkila, & Myllyla, 2000; Mont, Castro, Herreros, Pare, Azqueta, Magrina, Puig, Toro, & Brugada, 2003).

A study on automated classification of diabetes, based on HRV, used data from the CSDCG study, which consisted of 46 adult people, 22 with known diabetes, and 24 controls, which have not been diagnosed with diabetes (Cornforth, Jelinek, Teich, & Lowen, 2004). The feasibility of classification was investigated using a variety of classifiers. It appears that diabetes could be detected from an analysis of HRV, but further study is obviously required. Diagnosis of diabetes by this method is not 100% accurate, and depends upon careful selection both of the classifier algorithm used, and the feature subset. As each classifier has different properties, there may be some further benefit by combining the results of classifiers.

Nonlinear Analysis of HRV

HRV recordings contain an irregular (aperiodic) component in addition to the low frequency and high frequency components. Detrended fluctuation analysis (DFA) is a form of nonlinear analysis, which best allows for the detection of long-range correlations. DFA is able to distinguish between people with congestive heart failure (CHF) and controls, and is a prognostic indicator for CHF that may complement traditional HRV measures in assessing cardiac risk in patients with CHF (Ho, Moody, Peng, Mietus, Larson, Levy, & Goldberger, 1997).

The majority of studies conducted using DFA involve recordings of two hours or greater. However, more recent studies showed the utility of shorter ECG recordings (Flynn, Jelinek, & Smith, 2005). Although CAN may be present in people with no diabetes, the study group was a sample of people with diabetes attending the CSDCG study. All participants were screened for CAN using the HRV 30:15 ratio. DFA analysis determines the long range correlations between successive R-R intervals. Table 1 shows that controls can be distinguished from people with diabetes and from those with CAN. Although there was no significant difference between those with and without CAN, there was a trend for the mean DFA value to be lowest for people with diabetes and CAN, followed by people with diabetes but without CAN, and highest for the control group.

Table 1. Results of a t-test on people with diabetes, diabetic autonomic neuropathy (DAN) and CAN shows the power of DFA to distinguish the early signs of diabetes

Comparison	**p**	**significant?**
Control / diabetes	0.03	yes
CAN^{+}/ CAN^{-}	0.41	no
Control / DAN^{+}	0.02	yes

The benefit of nonlinear analysis is that it provides a numeric scale that allows identification of the extent of cardiac dysfunction using short ECG recordings, making the results easy to interpret for nonspecialists, such as general practitioners. Also, as this numeric scale is an objective outcome measure, it can be used to determine the efficacy of treatment and ensure best practice.

Considering cardiovascular complications in diabetes account for 65% of all diabetic deaths, automated screening using nonlinear analyses has the potential to reduce cardiac morbidity through the early identification of pathology changes in people with diabetes. Nonlinear analysis also provides a means of following any progression in pathology associated with diabetes or otherwise that leads to cardiac dysfunction.

FUTURE TRENDS

It is already clear that automated procedures based on nonfluorescein photography of retinal images, and ECG based on the simple three-lead ECG, hold potential for the early detection of diabetes. What is not yet clear is how these techniques can be combined. We would expect that in the next few years, there will be attempts to perfect these analysis methods, and to apply data fusion, in order to combine the data from these sources. This will of course only be effective if applied to a routine screening of the general population. This depends on raising the awareness of diabetes among people in the community, especially among those in rural and regional areas, as this is where the greatest incidence of the disease occurs. The greatest obstacle to overcome in development of these new techniques will not be the technical aspects, that are already well on their way to being perfected, but rather in community acceptance.

CONCLUSION

Diabetes has been well recognized as a significant threat to health in many regions. Although treatment options are available, it remains a chronic disease contributing significantly to morbidity and mortality. Detection of the disease during its early stages holds promise for better treatment, higher quality of life, and a reduced burden on health provider services. However, this remains difficult.

Recent advances in computational methods provide a new range of tools that can be applied to early detection of diabetes. Among these are the automated analysis of retinal images and HRV, and the concept of a mobile "one-stop shop" for diabetes screening in rural communities. It is likely that these concepts will be further developed and integrated, in order to provide a rapid and reliable diagnostic tool that will be used as part of screening.

INTRODUCTION: THE CORONARY FLOW RESERVE

The coronary flow reserve (CFR) represents an important functional parameter to assess epicardial coronary stenosis and to evaluate the integrity of coronary microcirculation (Kern, 2000; Sadamatsu, Tashiro, Maehira, & Yamamoto, 2000). CFR can be measured, during adenosine or dipyridamole infusion, as the ratio of maximal (pharmacologically stimulated) to baseline (resting) diastolic coronary blood flow peak. Even in absence of stenosis in epicardial coronary artery, the CFR may be decreased when coronary microvascular circulation is compromised by arterial hypertension with or without left ventricular hypertrophy, diabetes mellitus, hypercholesterolemia, syndrome X, hypertrophic cardiomyopathy, and connective tissue diseases (Dimitrow, 2003; Strauer, Motz, Vogt, & Schwartzkopff, 1997). Several methods have been established for measuring CFR: invasive (intracoronary Doppler flow wire) (Caiati, Montaldo, Zedda, Bina, & Iliceto, 1999b; Lethen, Tries, Brechtken, Kersting, & Lambertz, 2003a; Lethen, Tries, Kersting, & Lambertz, 2003b), semi-invasive and scarcely feasible (transesophageal Doppler echocardiography) (Hirabayashi, Morita, Mizushige, Yamada, Ohmori, & Tanimoto, 1991; Iliceto, Marangelli, Memmola, & Rizzon, 1991; Lethen, Tries, Michel, & Lambertz, 2002; Redberg, Sobol, Chou, Malloy, Kumar, & Botvinick, 1995), or extremely expensive and scarcely available methods (PET, SPECT, MRI) (Caiati, Cioglia, Montaldo, Zedda, Rubini, & Pirisi, 1999a; Daimon, Watanabe, Yamagishi, Muro, Akioka, & Hirata, 2001; Koskenvuo, Saraste, Niemi, Knuuti, Sakuma, & Toikka, 2003; Laubenbacher, Rothley, Sitomer, Beanlands, Sawada, & Sutor, 1993; Picano, Parodi, Lattanzi, Sambuceti, Andrade, & Marzullo, 1994; Saraste, Koskenvuo, Knuuti, Toikka, Laine, & Niemi, 2001; Williams, Mullani, Jansen, & Anderson, 1994), thus their clinical use is limited (Dimitrow, 2003). In addition, PET and intracoronary Doppler flow wire involve radiation exposure, with inherent risk, environmental impact, and biohazard connected with use of ionizing testing (Picano, 2003a).

In the last decade, the development of new ultrasound equipments and probes has made possible the noninvasive evaluation of coronary blood velocity by Doppler echocardiography, using a transthoracic approach. In this way, the peak diastolic coronary flow velocity reserve (CFVR) can be estimated as the ratio of the maximal (pharmacologically stimulated) to baseline (resting) diastolic coronary blood flow velocity peak measured from the Doppler tracings. Several studies have shown that peak diastolic CFVR, computed in the distal portion of the left anterior descending (LAD) coronary artery, correlates with CFR obtained by more invasive techniques. This provided a reliable and noninvasive tool for the diagnosis of LAD coronary artery disease (Caiati et al., 1999b; Caiati, Montaldo, Zedda, Montisci, Ruscazio, & Lai, 1999c; Hozumi, Yoshida, Akasaka, Asami, Ogata, & Takagi, 1998; Koskenvuo et al., 2003; Saraste et al., 2001).

Moreover, this parameter has been shown to be able to detect coronary stenosis (> 90%) in the LAD coronary artery (Voci, Pizzuto, Mariano, Puddu, Chiavari, & Romeo, 2002) with high sensitivity and specificity (90% and 93%, respectively). In particular, a value of peak diastolic CFVR<1.9 has been associated to severe coronary stenosis (Matsumura, Hozumi, Watanabe, Fujimoto, Sugioka, & Takemoto, 2003), while a peak diastolic CFVR≥2.5 is representative of normal coronary epicardial stream (Picano, 2003b).

BACKGROUND: TRANSTHORACIC DOPPLER ECHOCARDIOGRAPHY

Transthoracic Doppler echocardiography is usually performed using an ultrasound unit equipped with a broad-band, high-frequency (3.5 to 7 MHz) transducer, with the patients in the left lateral decubitus position. The conventional imaging approach consists first in obtaining a short axis of the left ventricular apex and anterior groove to search for middistal LAD coronary flow using the Color-Doppler flow modality. When a diastolic circular color-coded blood flow is visualized in the anterior groove area, the transducer is rotated clockwise to obtain the best long axis of color flow, as visualized in Figure 1. Alternatively, a modified foreshortened two-chamber view could be obtained by sliding the transducer superiorly and medially from an apical two-chamber position.

Then, a careful search for color-coded blood flow is made over the epicardial part of the anterior wall with simultaneous attempts to optimize the visualization of the anterior groove area by very slight counterclockwise rotation and medial angling of the probe.

To minimize artifacts due to systolic cardiac contraction, the sample volume is placed in correspondence to the diastolic position of the explored vessel cross-section, and maintained fixed for all the acquisition period. Pulsed-wave Doppler spectral tracings of LAD flow velocity is then recorded by fast Fourier transformation analysis (Caiati et al., 1999a).

Particular care has to be taken in maintaining the pulsed-wave Doppler aligned parallel to the blood flow. The achievement of this task can be confirmed by the fact that the spectral Doppler flow shows the characteristic biphasic flow pattern, with a larger diastolic component, and a smaller systolic one.

Once the image is optimized, multiple still-frame image acquisition is performed to obtain representative images of consecutive beats at baseline, digitally stored for off-line analysis. Then, the maximal stress condition is pharmacologically induced by injecting adenosine or dipyridamole. When dipyridamole is utilized (0.56 mg/kg i.v. in four minutes, and successively 0.28 mg/kg i.v. in two minutes, to induce vasodilation of the microcirculation), image acquisition is performed after two to four additional minutes from the drug subministration, depending on the patient response, with the same ultrasound settings of the baseline acquisition (Lim, Shim, Rhee, Kim, Hwang, & Kim,

Figure 1. Example of a diastolic frame acquired with the color–doppler flow modality activated

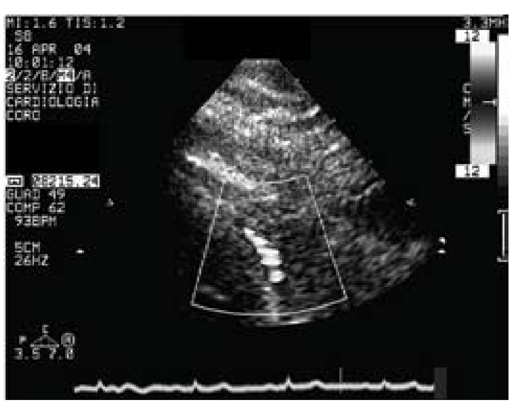

Figure 2. Example of the Pulsed-wave Doppler spettral tracings of flow velocity in the LAD coronary artery. The characteristic biphasic flow pattern can be observed.

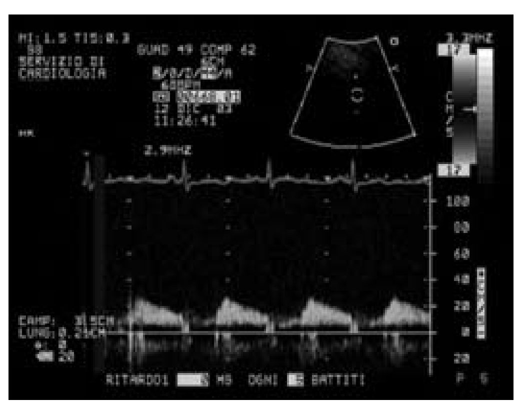


2000), and, at the end of the protocol, 125 to 250 mg of aminophylline are subministered to counteract the effect of dipyridamole. In addition, ECG is continuously monitored on the ultrasound screen (one lead) and by conventional 12-leads ECG.

Background: Transthoracic Doppler Echocardiography Limitations

Despite the advantages introduced by the transthoracic Doppler echocardiography, in clinical practice the off-line analysis of the Doppler flow velocity is based on manual identification, often performed on a single beat, of few fiducial points (systolic and diastolic peak velocities). From these points, both peak diastolic CFVR and the diastolic-to-systolic velocity ratio (DSVR) are computed (Picano, Sicari, & Varga, 1999). This time-consuming manual analysis introduces subjectivity in the measurements of the extracted clinical parameters, as well as limits the information which could be exploited from the coronary Doppler velocity signal with a more automated analysis.

As transthoracic coronary Doppler echocardiography is rapidly gaining appreciation as a popular tool for the noninvasive evaluation of peak diastolic CFVR, we hypothesized that the computerized analysis of the coronary Doppler velocity signal would reduce the subjectivity in the results and would allow the calculation of additional parameters, which could be potentially useful in the diagnostic process. Accordingly, we developed a technique for nearly-automated detection of Doppler coronary flow velocity profile, and validated this technique in comparison with the conventional measurements obtained by manual tracings.

COMPUTERIZED ANALYSIS OF CORONARY FLOW VELOCITY PROFILE

One hundred patients (67 males, mean age 62±9), referred to transthoracic echocardiographic examination at the Cardiology Unit of the Ortophedic Galeazzi Hospital in Milan, were retrospectively analyzed. All patients were studied by a Sonos 5500 (Philips) ultrasound machine equipped with a S8 high-frequency probe, according to the standard protocol described in the previous paragraph, using dipyridamole.

Image Preprocessing

To automatically quantify parameters relevant to the Doppler flow velocity profile, a specific custom software was developed using Matlab (The MathWorks, Inc.; Natick, Massachusetts).

The digitally acquired images were automatically cropped to extract the region of interest (ROI) containing the Doppler tracings, with the relevant time and velocity scales, and the ECG signal. A horizontal Sobel filter was then applied to automatically detect the zero velocity line, thus cropping the ROI to contain only positive velocity Doppler tracings. In fact, the negative velocity components of the Doppler tracings are not determinant in the calculation of the peak diastolic CFVR.

To properly scale the measurements which will be computed, otherwise expressed in pixels, the vertical velocity axis and its horizontal ticks were detected by Sobel filtering. The distance between two consecutive ticks was automatically computed and associated with the scale factor, manually inserted by the user.

To properly obtain the temporal information relevant to the duration of each consecutive beat, imaged in the same still-frame, the ECG signal, visualized in green at the top part of the ROI, was extracted exploiting the colour information. To prevent unambiguous detection of the R-wave peak for every cardiac cycle, a skeletonization operator was applied to thin the ECG trace at one pixel thickness. Finally, the fiducial points corresponding to the R-wave peaks were detected by a conventional threshold-derivative algorithm.

Detection of the Doppler Velocity Profile

To automatically detect the Doppler velocity profile from the Doppler tracings, a local adaptive thresholding algorithm was developed and applied. First, the ROI was divided in three partially overlapped equally sized rectangular regions. For each ROI, its inverse normalized cumulative videointensity histogram was computed as $\%\sum_{i=I}^{256} \#\, pixel(i)$.

The videointensity L, at which 25% of the pixels had an intensity greater than L, was assumed to be the threshold for that region (see Figure 3).

In the overlapped areas, the mean of the thresholds relevant to the two adjacent regions was utilized. The value of 25% was preliminary determined as the optimal choice as follows: first, the images acquired from a randomly selected subset of 20 patients, both at baseline and during stress, were analyzed with the proposed local adaptive threshold algorithm using different presettings for the automated threshold (from 10% to 40%, with a 5% step). Then, each automatically detected Doppler velocity profile contour was shown in random order, overimposed to the original image, to two expert cardiologists for visual evaluation. The cardiologists, blinded to the threshold value, had to reach a consensus on which of the presented images better visualized the true Doppler velocity profile contour. The images corresponding to the contour extraction using the 25% threshold value were selected in 90% of the cases.

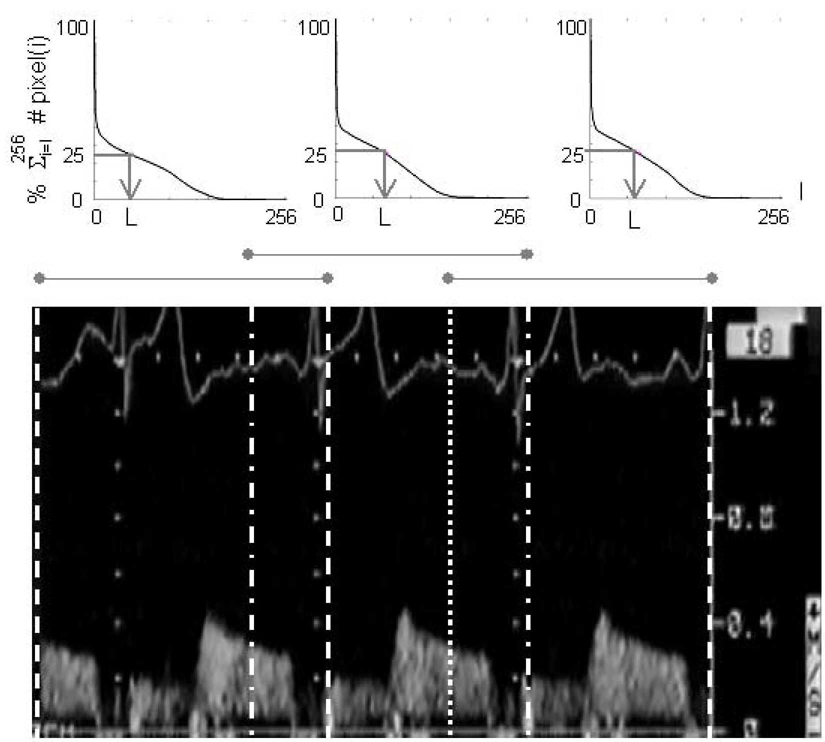
Each pixel column was scanned from the bottom to the top, to search for the first pixel with intensity lower than the corresponding threshold, thus obtaining a binary image representing the detected Doppler velocity profile. Finally, the 1-D velocity signal was extracted and filtered (median filter, order 15) to remove outliers and artefacts, and then overimposed to the ROI to allow visual verification of the reliability of the detected profile, and eventual manual correction of the thresholds. Subsequently, the detected Doppler profile was interpolated (cubic spline) to obtain a 1000 samples/sec oversampling; then, a low-pass FIR filter (150 coefficients, cut-off frequency 30 Hz) was applied, in order to reduce high frequency noise, and the first derivative was computed.

Parameters Extraction

In order to automatically obtain conventional clinical parameters from the detected Doppler velocity profile, some fiducial points needed to be identified in consecutive beats. From the detection of the R-wave peak positions, the beginning (R(i)) and ending (R(i+1)) points of the Doppler profile relevant to each consecutive cardiac cycle were automatically identified. Only the cardiac cycles that were completely represented in the still-frame image were considered in the further analysis.

Basing on the a-priori knowledge of the expected velocity profile morphology (biphasic pattern, with a systolic and a diastolic velocity components), for each

Figure 3. Bottom: doppler flow velocity profile image divided in three partially overlapped rectangular regions (black lines); top: the inverse normalized cumulative videointensity histogram, and the videointensity L at which the 25% of the pixels had an intensity greater than L, is shown for each region



C

cardiac cycle the following fiducial points were identified (see Figure 4): (1) peak diastolic velocity (PDV), as the absolute maximum in a temporal window ranging from ¼ to ¾ of the RR duration; (2) peak diastolic acceleration (PDA), as the first derivative absolute maximum in a temporal window ending at PDV, with a duration equal to 20% of the total beat duration; (3) the beginning of the diastolic phase (BD), as the absolute minimum of velocity in a temporal window ending at PDA, with a duration equal to 15% of the total beat duration; (4) peak systolic velocity (PSV), as the absolute maximum in the window ranging from R(i) to BD; (5) peak diastolic deceleration (PDD), as the derivative absolute minimum in a temporal window starting from PDV to R(i+1).

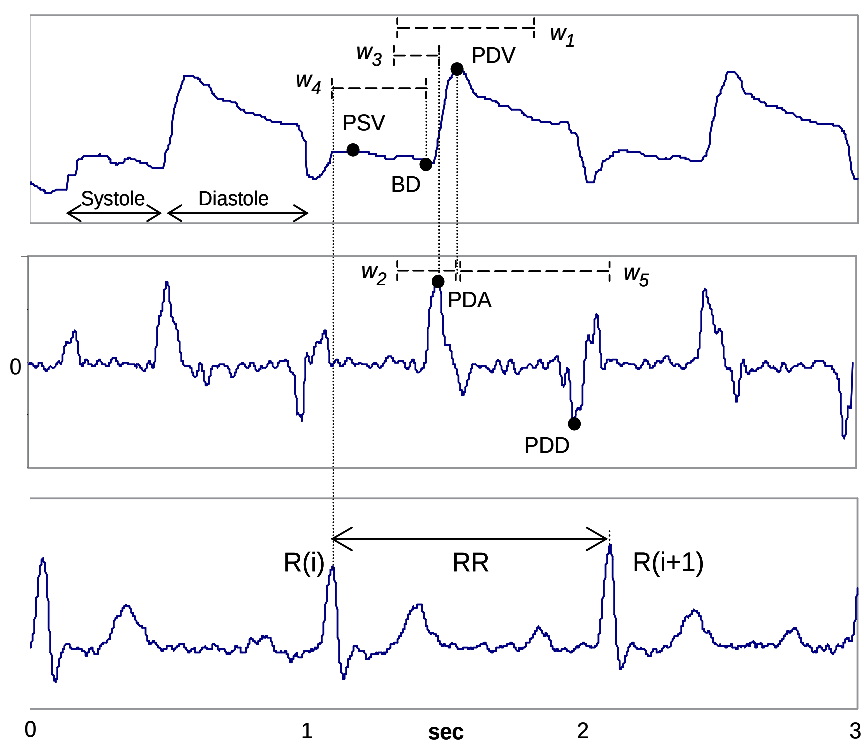
From these fiducial points, the following clinical measurements can be obtained: systolic and diastolic peak velocities (PSV and PDV), DSVR, peak diastolic CFVR. All the measurements obtained from three consecutive cardiac cycles were automatically averaged to reduce measure variability, and to take into account possible respiratory variations.

Validation Protocol

For each subject, still-frame images, including three to four cardiac cycles relevant to both baseline and stress, were independently analyzed by two observers (A1 and A2), using the developed custom software. To obtain a reference for comparison, the same images were manually evaluated by two expert cardiologists (M1 and M2), blinded to each other and to the results of the automated analysis, to extract the conventional clinical indices of PDV, PSV, peak diastolic CFVR and DSVR. For each index, the mean value was considered as the "independent standard" value.

The mean of the computerized measurements, obtained by A1 and A2, was compared to the manual "independent standard" by linear regression and Bland-Altman analyses. For each linear regression, the correlation coefficient was computed ($p<0.05$). For Bland-Altman analysis, the confidence interval was defined as ± 2SD, and the significance of the bias was tested by a paired t-test vs. null values ($p<0.05$). For both manual and automated measurements, the

Figure 4. Schematization of the automated detection of fiducial points from the doppler velocity profile (top), its first derivative (middle) and the ECG (bottom)



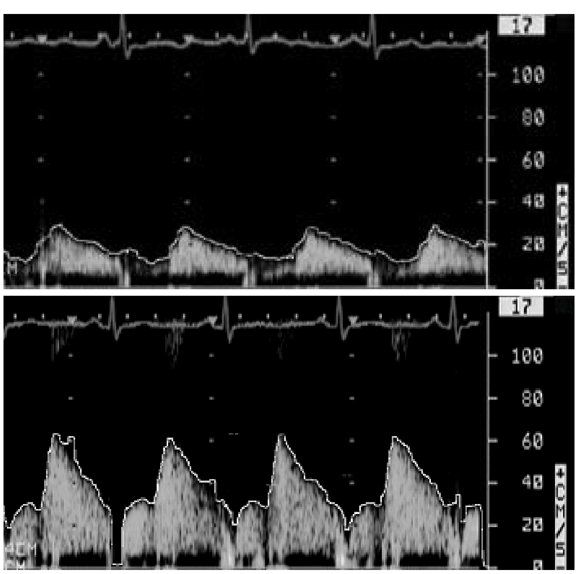
inter-observer variability was computed as the SD of the two respective measurements, and expressed as percentage of their mean.

Results

A set of 200 Doppler velocity images (100 at baseline and 100 at stress) from 100 patients was analyzed. In these images, the horizontal resolution was fixed and equal to 128 pixels/sec, while the vertical resolution varied according to the velocity scale settings, in a range between 150 and 300 pixels/m/sec.

The proposed method was able to correctly detect the Doppler velocity profile in 180/200 of the analyzed frames without the need of manual interaction, using the preset algorithm parameters. In the remaining 20/200, a manual adjustment of the threshold parameter was necessary to correctly identify the profile. The required time for analysing a single frame containing three consecutive beats ranged between 10 sec. (with automated threshold setting) and 40 sec (with manual correction of threshold setting), using a Pentium M 745 (1.8 GHz CPU) personal computer, including data retrieval. Conversely, conventional manual analysis of a single frame required about 5 min., including data retrieval and mean computations.

Figure 5. Doppler flow velocity images with good image quality, visualized with overimposed the corresponding automatically detected velocity profile contour; top: baseline; bottom: stress



In Figure 5, examples of the detected Doppler velocity profile obtained using the preset 25% threshold value are shown.

The results of the comparisons with the "independent standard" values showed excellent correlation in PSV (y=1.01x-0.17, r=0.986, p<0.0001), PDV (y=1.02x-0.86, r=0.998, p<0.0001), and peak diastolic CFVR (y=0.97x+0.07, r=0.987, p<0.0001). Also, a good correlation was found in DSVR (y=x+0.02, r=0.809, p<0.0001).

Bland-Altman analysis resulted in not significant biases (i.e., mean of the signed differences) and small confidence intervals in each of the examined parameters (bias±2SD, PSV: -0.2±5.0 cm/s; PDV: -0.4±3.2 cm/s; CFVR: 0.01±0.25; DSVR: 0.0±0.56).

Inter-observer variability between A1 and A2, resulting from the computed indices using the proposed computerized method, was low (baseline: PSV: 6.84±8.6 %; PDV: 1.65±2.4 %; DSVR: 6.64±9.4 %; stress: PSV: 3.71±5.2 %; PDV: 1.90±2.4 %; DSVR: 4.69±8.3 %; peak diastolic CFVR: 2.65±3.3 %) and comparable with that resulting from M1 and M2 conventional manual tracings (baseline: PSV: 3.77±3.8 %; PDV: 2.53±2.3 %; DSVR: 4.23±4.7 %; and stress: PSV: 5.20±7.0 %; PDV: 1.98±2.0 %; DSVR: 5.78±6.4 %; peak diastolic CFVR: 3.16±2.6 %).

DISCUSSION

The possibility to noninvasively obtain information about coronary blood velocity by transthoracic Doppler echocardiography opens new scenarios in the diagnosis and treatment of coronary artery disease. However, the need for manual analysis of the Doppler tracings introduces a limitation to the clinical applicability of this methodology. To overcome this limitation, computerized methods for analysis of the Doppler coronary flow velocity profile are needed. Accordingly, we developed an adaptive thresholding algorithm, capable to take into account artifacts (high frequency or speckle noise) potentially existing in the Doppler coronary flow velocity signal, and extract clinically useful parameters.

The choice to divide the image in three partially overlapping regions, and to compute for each region, based on its histogram, the videointensity value to be assumed as the local threshold, allowed the velocity profile detection to be reliable, even in presence of low quality images. The choice of the preset optimal dimension of the median filter was defined in order to obtain a good compromise between accuracy of the detection and suppression of local artefacts. When compared with manual tracing, the proposed computerized approach reduced the time necessary for the analysis, thus preserving the reliability of the results and their reproducibility. In fact, both linear regression and Bland-Altman analyses confirmed the high correlation, absence of bias, and narrow limits of agreement, pointing out the excellent correlation between the results obtained with both the techniques and the potential clinical applicability of the proposed method. Also, the interobserver variability measured in the clinical parameters by the proposed technique was low and similar to the results obtained by manual analysis. The largest variability was observed in DSVR: this parameter, representing the ratio between the peak diastolic and systolic velocities, probably reflects and amplifies the higher variability observed in the peak systolic velocity.

The availability of a reliable digitized Doppler flow velocity profile could allow in the future to extended the routine clinical analysis to the computation of additional amplitude and temporal parameters (i.e., mean velocities, phase durations, diastolic slope, peak derivatives) other than the conventional indices.

CONCLUSION

In conclusion, the measurements obtained with the proposed computerized approach were found accurate and reproducible compared with manual tracing, with a reduction of the time needed for the analysis.

The proposed method allows the computation of additional indices, which may be useful in the diagnostic phase. Moreover, it could potentially be applied to evaluate the coronary flow velocity measured by intracoronary devices (Doppler flow wire), or the Doppler flow velocity recorded in other arteries (i.e., brachial, femoral) or districts (aortic or mitral inflow). However, the preliminary phase of optimal threshold value assessment should be repeated for each specific application, to confirm if the 25% value could still be considered as the optimal one.

KEY TERMS

Bland-Altman Analysis: Statistical method which allows to compare measurements obtained in the same subjects by two different techniques. The Bland-Altman graph plots the difference between the two measurements against their average, for each subject.

Coronary Flow Reserve: Functional clinical parameter, computed as the ratio of maximal (pharmacologically stimulated) to baseline (resting) diastolic coronary blood flow peak, used to assess epicardial coronary stenosis and to evaluate the integrity of coronary microcirculation.

Dipyridamole: Drug that inhibits platelet aggregation and causes vasodilation. It is used in cardiac stress testing as a coronary vasodilator to induce the maximal stress condition.

Image Processing: The process of applying algorithms to images in order to improve their quality reducing artefacts, to enhance characteristics, to detect object contours.

Left Anterior Descending Coronary Artery: One of the two branches (together with the **circumflex (Circ)** coronary artery) in which the **left main** coronary artery divides into.

Local Adaptive Thresholding Algorithm: Technique based on the computation of a locally dependent threshold in a determined region of interest, by which the object contour is then detected by thresholding.

Thresholding: The process of detecting object contours based on the computation of a binary image in which pixel values are set to one, in correspondence to a videointensity value of the corresponding pixel position in the analyzed image greater than the threshold, and to zero if the videointensity is lower than the threshold. The threshold can be constant for all image, or can be adaptive and spatially dependent.

Transthoracic Doppler Echocardiography: Noninvasive evaluation of coronary blood velocity by Doppler echocardiography, using a transthoracic approach.

Costs and New Technologies in Healthcare Delivery

Marie-Christine Thaize Challier
University of Grenoble, France

INTRODUCTION

Reducing medical costs is one of the major policy questions. A well understanding of this issue requires specific insight into some domains. The three main points which must be clarified relate to: (1) the nature of the costs (production costs and transaction costs), (2) the nature of *new healthcare technologies* (the biotechnology and biomedical engineering vs. the e-healthcare system, the face-to-face communications between the primary care physicians or other providers and the patients vs. the non face-to-face communications), and (3) the nature of *information* (which can be asymmetric, incomplete, or imperfect). This article studies what differences there are when considerations about informational issues and types of medicine are taken into account in the modern health economy characterized by the generation and the implementation of new healthcare technologies. To do this, this article first clarifies and presents some concepts in the framework of the health economy. Then, from these issues, it discusses the cost containment in the current case of the development and adoption of new technologies, and contrasts the opinions and perspectives.

BACKGROUND: COSTS AND INFORMATION ISSUES

An approach for a better understanding of healthcare delivery requires particular insights into the nature and effect of new technologies, information, and costs.

Technologies, Information, and Costs

A first interest concerns the consequences of new medical technological innovations on medical costs. *(i)* On the one hand, biotechnologies (defined by technological applications using biological systems or living organisms to make or change products or processes), biomedical engineering (i.e., the application of engineering techniques and principles), and nanotechnologies (a variety of techniques to produce materials and devices on the scale of the nanometer, their societal implications being a controversial subject) are expensive. Nowadays, this healthcare industry represents one of the international largest and fastest-growing industries. Yet, accurate data on the genuine costs of such new healthcare technologies are not available. *(ii)* On the other hand, technological improvements based on e-healthcare technologies (over the Internet, e-mail, text messages, video conferences, and other ways) seem to reduce costs through efficient use of technology. For financial reasons, e-healthcare systems are becoming strategic necessities. Indeed, various networking technology and information have introduced major transformation in healthcare delivery in particular through telemedicine, electronic patient records, technology-mediated solutions, network design issues for healthcare operations, among others. Moreover, by introducing non face-to-face communications between the practitioners and the patients, the latter is empowered through better access to medical information and care.

The second point which deserves some details is relative to the term information. In the economic sense, it is usual to refer to three major concepts: asymmetric information, incomplete information, and imperfect information. *(i) Informational asymmetries* occur when one party to a transaction knows more information than the other parties either about his/her own position or about the environment. Such asymmetries in information lead to distortions when parties define strategies or assess a situation. Asymmetrical information can induce opportunistic behaviors and can be responsible for problems of contractual performance: the adverse selection problem and the moral hazard problem. "*Adverse selection*" refers to situations in which, *before* the transaction occurs, the ignorant party lacks information about some aspect concerning the characteristics of the other party or the object of the transaction (Akerlof, 1970). "*Moral hazard*" refers to situations where, *after* the transaction occurs, the informed party engages in activities that are undesirable from the other party (Arrow, 1963; Holmström, 1979). *(ii) Informational incompleteness* means that there is a lack of complete information between two parties, the actions or characteristics of one party being not observable by the other one. In other words, one party has private information about something relevant to his/her decision making. *(iii) Imperfect information* refers to situations where a party does not know the previous actions of the other party (Rothschild & Stiglitz, 1976). For example, a physician ignores the patients' behaviors with regard to their own health.

A third clarification concerns the tendency to adopt organizational modes that best reduce healthcare costs, specifically production costs and transaction costs. If the former are generally well-defined, the latter deserve more specific attention. Economists define transaction costs as the costs of running the system: costs of coordinating and of motivating (Milgrom & Roberts, 1992; Williamson, 1979). Coordination costs include, among others, search costs, communication costs, decision costs, and enforcement costs while motivation costs refer to informational situations and encompass costs associated with imperfect, incomplete, and asymmetric information (Milgrom & Roberts, 1992). Such transaction costs can be reduced in the three types of medicines: the preventive medicine (act of protecting, promoting, maintaining health, and preventing disease), the diagnostic medicine (act or process of identifying the cause and nature of the illness through the evaluation of patient history and the examination of laboratory data), and the curative medicine (which covers the actions and treatments correcting a harmful or troublesome situation).

Rising Costs and Medical Practices Faced to Moral Hazard, Supplier-Induced Demand, and Adverse Selection

Besides technological change and aging, most researchers and practitioners focus on three main causes of rising spending on medical care without proportionate increases in the quality of care: *moral hazard* and *supplier-induced demand*.

1. A first informational problem and source of inefficiency is due to "moral hazard," specifically here to an excessive demand by insured patients. Indeed, in this specific case, moral hazard reflects the state of mind and the change in behavior that can occur when a person becomes insured. Through their insurance, patients pay less out of their own pocket when they consume medical services, and consequently they can demand more of them. In other words, if insurance covers the full cost of care, policyholders may overuse medical services, leading to raise costs. Researchers distinguish *ex ante moral hazard*, which is relative to the absence or lack of preventive action by insured *and ex post moral hazard*, which refers to the insured behavior when the illness appears, such as medical nomadism—people seeking advice from various physicians for the same disease—or repetitive tests. Therefore, to prevent moral hazard, insurers—following the RAND Health Insurance Experiment—limit the incentives of patients to demand services. To do this, thinking that *price matters*, insurance companies share healthcare expenses by imposing a copayment, namely a fixed portion of the actual medical cost that an insured person must pay (Dranove, 2000, pp. 28–31). They use copayments in order to: (1) prevent unnecessary medical care, (2) rein in medical costs, and (3) lead to savings for insurance companies. However, this health-insurance policy, according to which insurers bear only an amount of the actual cost, can produce perverse effects. For example, copayments can cut appropriate and necessary office visits and medications. More broadly**,** they can reduce preventive and curative care (Keeler, Brook, Goldberg, Kamberg, & Newhouse, 1985; Lurie, Kamberg, Brook, Keeler, & Newhouse, 1989). Furthermore, insured people who make copayments can be healthier than those who do not, and therefore purchase fewer medical services; in that case, *price might not matter*.
2. A second informational problem and source of inefficiency is due to the phenomenon of "supplier-induced demand" (Evans, 1974; Pauly, 1994; Roemer, 1961). The demand inducement problem occurs when primary physicians use their superior knowledge and their influence to generate demand for personal gain, without health benefits. Due to this information gap between such physicians and patients, the former (who are both advisors to the patients and providers of services) can make

treatment recommendations and various clinical decisions that raise the costs, and are not in the best interests of their patients. It is worth emphasizing that this agency problem occurs because, not only physicians are more fully informed than patients, but also because they can have financial incentives to recommend costly treatments that are of little value to patients. Patient ignorance provides doctors with discretionary power to manipulate demand; clinical recommendations for medical treatment can be ambiguous, harming the patient's interest (Folland, Goodman, & Stano, 2001, chap. 10; Rice & Labelle, 1989). The supplier-induced demand is a controversial problem: while inducement theorists put forth that supply causes demand, other researchers develop different opinions or causalities. Reinhard (1989) considers as a matter of the utmost importance to know whether healthcare markets function according to the demand or supply side. Under fee-for-service payments, physicians can induce demand by overtreating their patients, who thus purchase more medical care; it results that such behaviors drive up medical costs, and increases unnecessary and inappropriate cares. Since the price paid by insured consumers when they apply for healthcare services can be set separately from the price paid to providers when services are supplied, the two alternative ways for controlling the spending are: *(i)* demand-side cost sharing (where patients must pay more in copayments), and *(ii)* supply-side cost sharing (in order to change the incentives of suppliers to provide certain services (for the development of such strategies, refer to Ellis & McGuire, 1993). Whatever the causalities, treatments seem more dependent on economic, rather than medical, criteria.

NEW MEDICAL TECHNOLOGIES FACED TO MEDICAL COSTS

Healthcare costs rise despite several techniques to limit them. New economic issues spring through the generation and implementation of new healthcare technologies and e-healthcare technologies; in particular, those developing solutions to cut healthcare costs and insurance costs.

Technological Change and Costs in the Healthcare System

Costs of Healthcare

Technological change may reduce costs when it increases the productivity of healthcare resources by providing less costly production methods for existing products (when less expensive inputs replace more costly inputs) or may increase costs when it promotes new and expensive products. Measuring the cost of a medical treatment when such "process innovations" and "product innovations" change the access to care, and the treatment is not easy. Scitovsky (1985) finds that technological change increases the cost of several diseases. Other researchers explain increasing costs of healthcare by highlighting the "medical arms race;" namely, the competition between hospitals for physicians and patients by supplying the latest medical technology and the largest staffing (Dranove, 2000; Robinson & Luft, 1985). Moreover, since physicians are both diagnosticians and clinicians, patients trust them to undertake the right decisions. Consequently, especially in the case of new treatments and technologies, patients are more vulnerable, having more difficulty to assess the value of the new care. This represents thus another source of inflation if physicians raise their incomes by unnecessary or inappropriate recommendations or other medical decisions. Such misbehaviors can be higher when physicians own diagnostic testing equipment (Dranove, 2000).

Costs of Health Insurance

Indemnity insurance is often considered as a source of the development of costly medical technology (Goddeeris, 1984a). Insurance coverage seems to increase costs through its weak direct effect on demand and its strong inducement of cost-increasing technological innovations. In this context, Newhouse (1988) and Peden and Freeland (1998) support the "induced-innovation hypothesis." Investigating the following question: does medical technological change make the average patient better off? Goddeeris (1984a, 1984b) finds that indemnity insurance increases the relative profitability of cost-increasaing technological innovations towards cost-cutting ones, insurance leading to "more costly mix of medical innovations than would otherwise occur" (pp. 530). He shows that the average patient pays the full cost of the new healthcare technologies since his/her insurance premiums increase in addition to out-of-pocket costs. This patient may be worse off after the introduction of such technological change than before its implementation.

Costs in New Healthcare Systems

Given the generation and implementation of high-cost technologies, healthcare is facing various challenges; in particular, the cost containment which is greatly connected with quality improvement, accountability, affordability, and the equitable access to care for all citizens and residents. Fuchs (1996) argues that "integrated healthcare systems" are the best way to deliver cost-effective care, physicians having "the *incentive*, the *information,* and the *infrastructure* needed to make […] decisions in a cost-effective way" (pp. 17). Fuchs contends that integrated healthcare systems cope with the following current and future major key challenges.

1. A first challenge consists in developing the physician's central position in medical decision-making, because the latter prescribes drugs, orders tests, and other procedures, admits patients to hospitals, and refers patients to specialists, among others. Through the promotion of a patient-physician relationship based on mutual recognition, accountability and acceptance of rights, patients become informed and can act cooperatively with thoughtful and careful physicians. Such measures may prevent patient moral hazard and physician malpractices.
2. With regard to the physician payment, the Fuchs's recommendation is to implement a reimbursement that promotes a good care and balances the obligations, rights, and income of physicians. Fuchs advocates capitation and adjustment for patient characteristics. This Fuchs's recommendation deserves the following details. Capitation is a system where a per capita amount is paid to a physician for each patient. Under its initial form, this amount is determined by a per member per month calculation. Clearly, under this per-member-per-month payment, the physician income depends on the *numbers of patients* to whom the healthcare service is delivered, which may lead to negligence. However, it is insightful to note that this system could give incentives to promote a *preventive* medicine since, receiving a fixed amount per patient, it is in the physician's interest to have healthy patients in order to decrease the numbers of their visits. Nevertheless, it is also worthwhile to note that a salary payment, characterized by a predetermined amount whatever the numbers of patients, may prevent carelessness and other malpractices.
3. Another Fuchs's recommendation relates to copayments at the time of use—except for the poor—and to a basic healthcare plan, plus a variety of options corresponding to services (choice of health providers, access to new experimental technologies, as well as to the older technologies not included in the basic plan) desired and paid by the patient. Fuchs specifies that such options are not alternative insurance plans, and do not create a separate plan between the poor and the rich.
4. Technologies used for diagnosis and treatment are characterized by expensive costs so that practicing in a costeffective way is not an easy task for physicians. Furthermore, this difficulty is increased by the great uncertainty of such technologies with regard to their merits. Consequently, Fuchs suggests the creation of a Center for Technology Assessment (CTA) to provide people and policy makers with independent, timely, and comprehensive assessments of technological impacts on society. Two main functions are recommended for such a center. First, it would develop knowledge about the costeffectiveness of medical technology, provide health professionals with information to measure, improve their clinical practices, and select the medical services that should be included in the basic integrated system. Second, it would give legitimacy for the costeffective medical practice. Recently, an international CTA emerged. It is worthwhile to note that, besides an "appropriate technology" (adaptable to local needs) for diagnosis and treatment, integrated systems do not forget the holistic medicines which are more time intensive than capital intensive (seeming thus favoring the salary payment than the capitation payment) and which also further affordability and accountability.

Healthcare Information Systems faced to Costs and Technological Change

New healthcare organizations meet the increasing demands of healthcare access and quality improvement as well as reduced costs. To reach such challenges and mitigate informational inadequacies (asymmetric, imperfect, and incomplete information), some new regulations and information systems are required. Various telecommunication networks—in particular, e-healthcare systems—promote patient-centric organizations and institutions which encourage patients' involvement in their own care, while providing relevant information for practitioners. Through such information systems, one can witness to the containment of various transaction costs such as: (1) the "search costs" and "communication costs" between the patients and the practitioners; (2) the "decision costs" since healthcare providers know immediately the patients' characteristics through the electronic medical records and the integrated information management systems; and (3) the "enforcement costs," since the practitioners can quickly prescribe a treatment and/or order laboratory tests.

On another level, such patient-centric healthcare systems can also cut the costs of the preventive, diagnostic, and curative medicines. (1) Indeed, by promoting investment in *preventive medicine*, such healthcare information systems may bring down medical costs, such a prevention averting the risk of disease. (2) With regard to the *diagnostic medicine*, electronic medical records and integrated information management systems, by reducing the spatial and temporal costs of a face-to-face care, may contribute also to rein in medical costs in the context of quality and safety clinical care. Diagnostics carried out immediately under full information about the patient history are major factors to improve quickly the quality of care and thus reduce medical costs. (3) Concerning the *curative medicine*, information systems may quickly order medications, laboratory work, and new diagnostic tests if necessary. Finally, information systems provide also an increased access to care for the poor and patients living in distant rural areas.

Through acts—such as the Health Insurance, Portability, and Accountability Act (HIPAA) enacted by the United States or directives (e.g., European Union Directives)—other various decisions have been recently taken for regulate the healthcare policy (for a presentation of the HIPAA's key elements, see Fadlalla & Wickramasinghe, 2004; Wickramasinghe, 2007). Recently, in the specific context of the Healthcare Information System (HCIS), Wickramasinghe (2007, pp. 8–9) contends that "information flowing within the HCIS and between […] key players must exhibit the attributes and the dimensions of the *information integrity* construct." Information integrity "should display the attributes of accuracy, consistency, and reliability of the content and processes as well as the dimensions of usefulness, completeness, manipulability, and usability" (Wickramasinghe, 2007, pp. 9).

FUTURE TRENDS

This article approaches some of the issues that must be considered when analyzing the relationships between healthcare costs and the introduction and implementation of new technologies. Efficient solutions exist to reduce transaction costs, defined as coordination and informational costs. However, our account of this topic is, of course, incomplete, and many questions still remain unanswered. Future studies could pay more attention on some important issues. (1) The relationship between the new technologies (biotechnologies and biomedical engineering, among others), and the cost containment needs to be scrutinized. (2) The relationship between such technologies and the insurance question requires further research. (3) With regard to e-health systems: *(i)* the study of their strengths and weaknesses on healthcare quality improvement requires more theoretical and empirical attention. The ways to increase social responsibilities and community values to increase such quality is a valued perspective; *(ii)* their impact on practitioner payments and health insurance need also further studies; *(iii)* however, in some contexts, such information systems must be particularly vigilant on the questions relating to prevention programs (early detection), holistic options, and affordability. Keeping in mind that all the countries do not have the same medical needs, nor the same resources and medical practices, creative solutions to promote healthcare quality improvement and cost containment must be continuously undertaken. The development of health prevention and cooperation between various organizations offer promising results.

CONCLUSION

The critical issues discussed in this article summarize many challenges to healthcare cost containment. This article studies connections between instruments and activities, the introduction and implementation of new technologies affecting healthcare processes. Nowadays, achieving more quality improvement and cost containment constitutes a challenge for healthcare systems. Thus, new e-healthcare systems succeed in internalizing many externalities, in particular those concerning the myriad of informational issues. How such systems will evolve and what consequences they have remain challenges for further research.

KEY TERMS

Agency Relationship: Situation in which one party relies on another party to make decisions.

Copayment: The fixed partial payment that a subscriber to a medical insurance must pay for the use of a medical service covered by his/her insurance company.

Curative Medicine: Actions and treatments correcting a harmful or troublesome situation.

Diagnostic Medicine: Act or process of identifying the cause and nature of the illness by its signs and symptoms.

Moral Hazard: In economic theory, moral hazard refers to the postcontractual opportunism that results from an asymmetric information. It occurs when the actions contractually required are not freely observable; for example, a party takes an inappropriate action or decision that can affect the outcomes of the contract. In insurance, moral hazard refers to the tendency of people to change their behavior when they are insured; it does not induce the insured to protect him/herself from the risk.

Preventive Medicine: Act of protecting, promoting, maintaining health, and preventing disease.

Transaction Costs: Costs incurred in making an transaction. They include costs of coordinating (search, communication, decision, enforcement costs) and costs of motivating (opportunity costs).

Cost-Sensitive Classification for Medical Diagnosis

Gerald Schaefer
Aston University, UK

Tomoharu Nakashima
Osaka Prefecture University, Japan

Yasuyuki Yokota
Osaka Prefecture University, Japan

INTRODUCTION

Medical diagnosis is often regarded as a pattern classification problem: based on a certain input, the task is to assign it to one of a set of classes. Often the number of classes is two: for example, malignant vs. benign, disease vs. no disease. The task of a pattern classification system is to assign as many input samples as possible to the correct class whereas the behaviour of the classifier is often optimised through the learning of some ground truth data. Conventional classifiers treat each sample of this learning set equally, yet in medical diagnosis this is often not desirable as different classes are associated with different costs. While the misdiagnosis of a malignant case as being benign can be very costly (e.g., when the time for effective treatment has passed), mistaking a benign case as malignant (though of course it should be avoided) will involve relatively lower costs (such as some further tests).

In this article, we present a cost-sensitive approach to medical diagnosis based on fuzzy rule-based classification (Schaefer, Nakashima, Yokota, & Ishibuchi, 2007). While fuzzy rule-based systems have been mainly employed for control problems (Lee, 1990) more recently they have also been applied to pattern classification problems (Ishibuchi & Nakashima, 1999; Nozaki, Ishibuchi, & Tanaka, 1996). We modify a fuzzy rule-based classifier to incorporate the concept of weight which can be considered as the cost of an input pattern being misclassified. The pattern classification problem is thus reformulated as a cost minimisation problem. Based on experimental results on the Wisconsin breast cancer dataset, we demonstrate the efficacy of our approach. We also show that the application of a learning algorithm can further improve the classification performance of our classifier.

FUZZY RULE-BASED CLASSIFICATION

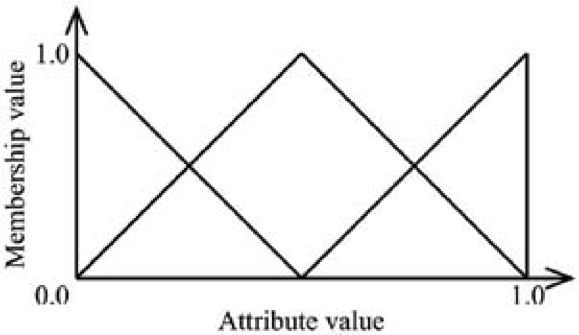
Let us assume that our pattern classification problem is an n-dimensional problem with M classes (in medical diagnosis M is typically 2) and m given training patterns $\mathbf{x}_p = (x_{p1}, x_{p2},...,x_{pn})$, $p = 1,2,...,m$. Without loss of generality, we assume each attribute of the given training patterns to be normalised into the unit interval [0,1]; that is, the pattern space is an n-dimensional unit hypercube $[0,1]^n$. In this study we use fuzzy if-then rules of the following type as a base of our fuzzy rule-based classification systems:

$$\text{Rule } R_j: \text{ If } x_1 \text{ is } A_{j1} \text{ and } \ldots \text{ and } x_n \text{ is } A_{jn}$$
$$\text{then Class } C_j \text{ with } CF_j \qquad j = 1,2,\ldots,N \qquad (1)$$

where R_j is the label of the j-th fuzzy if-then rule, $A_{j1},...,A_{jn}$ are antecedent fuzzy sets on the unit interval [0,1], C_j is the consequent class (i.e., one of the M given classes), and CF_j is the grade of certainty of the fuzzy if-then rule R_j. As antecedent fuzzy sets we use triangular fuzzy sets as in Figure 1 where we show a partition of the unit interval into a number of fuzzy sets.

Our fuzzy classification system consists of N fuzzy if-then rules each of which has a form as in Equation (1). There are two steps in the generation of the rules: specification of antecedent part, and determination of consequent class C_j and grade of certainty CF_j. Once the antecedent part of a rule is specified the consequent part (i.e., consequent class and the grade of certainty) is determined from a set of given training patterns (Ishibuchi, Nozaki, & Tanaka, 1992). In Ishibuchi and Nakashima (2001), it is shown that the use of the grade of certainty in fuzzy if-then rules allows us to generate comprehensible fuzzy rule-based classification systems with high classification performance.

Figure 1. Triangular membership function



Fuzzy Rule Generation

Let us assume that m training patterns $\mathbf{x}_p = (x_{p1},...,x_{pn})$, $p = 1,...,m$ are given for an n-dimensional C-class pattern classification problem. The consequent class C_j and the grade of certainty CF_j of the if-then rule are determined in the following manner:

1. Calculate $\beta_{Class\ h}(j)$ for Class h as:

$$\beta_{Classh\ h}(j) = \sum_{\mathbf{x}_p \in Class\ h} \mu_j(\mathbf{x}_p) \tag{2}$$

where

$$\mu_j(\mathbf{x}_p) = \mu_{j1}(x_{p1}) \cdot ... \mu_{jn}(x_{pn}) \tag{3}$$

and $\mu_{jn}(\cdot)$ is the membership function of the fuzzy set A_{jn}. In this article, we use triangular fuzzy sets as in Figure 1.

2. Find Class $\hat{h}$ that has the maximum value of $\beta_{Class\ h}(j)$:

$$\beta_{Class\ \hat{h}}(j) = \max_{1 \le k \le C}\{\beta_{Class\ k}(j)\} \tag{4}$$

If two or more classes take the maximum value, the consequent class C_j of the rule R_j cannot be determined uniquely. In this case, we specify C_j as $C_j = \{\}$. If a single class $\hat{h}$ takes the maximum value, let C_j be Class $\hat{h}$.

The grade of certainty CF_j is determined as:

$$CF_j = \frac{\beta_{Class\ \hat{h}}(j) - \bar{\beta}}{\sum_h \beta_{Class\ h}(j)} \tag{5}$$

with

$$\bar{\beta} = \frac{\sum_{h \ne \hat{h}} \beta_{Classh}(j)}{c-1} \tag{6}$$

Fuzzy Reasoning

Using the rule generation procedure outlined above we can generate N fuzzy if-then rules as in Equation (1). After both the consequent class C_j and the grade of certainty CF_j are determined for all N rules, a new pattern $\mathbf{x} = (x_1,...x_n)$ can be classified by the following procedure:

1. Calculate $\alpha_{Class\ h}(\mathbf{x})$ for Class h, j=1,...,C, as:

$$\alpha_{Class\ h}(\mathbf{x}) = \max\{\mu_j(\mathbf{x}) \times CF_j \mid C_j = h\} \tag{7}$$

2. Find Class h' that has the maximum value of $\alpha_{Class\ h}(\mathbf{x})$:

$$\alpha_{Class\ h'}(\mathbf{x}) = \max_{1 \le k \le C}\{\alpha_{Class\ k}(\mathbf{x})\} \tag{8}$$

If two or more classes take the maximum value, then the classification of **x** is rejected (i.e., **x** is left as an unclassifiable pattern), otherwise we assign **x** to Class h'.

COST-SENSITIVE FUZZY CLASSIFICATION

The standard fuzzy rule-based classifier as detailed above treats each class and hence each sample equally. In medical diagnosis however this is often not desirable. Misdiagnosing a malignant case as benign should be penalised more than diagnosing healthy patients as having a certain disease. While in the first case, the result might be that of late treatment in the best and missing of the treatable time in the worst scenario, the latter case will usually involve some further tests which should then identify the misdiagnosis. Clearly, the costs involved in the first case will exceed those of the latter.

We therefore wish to develop a classifier that incorporates this and reformulate the pattern classification problem as a cost minimisation problem. The concept of a weight is introduced for each training pattern in order to handle this situation where the weight of an input pattern can be viewed as the cost of misclassifying it. Fuzzy if-then rules are generated by considering the cost as well as the compatibility of training patterns.

In order to incorporate the concept of cost, we modify Equation 2 of the fuzzy rule generation to:

$$\beta_{Class\ h}(j) = \sum_{\mathbf{x}_p \in Class\ h} \mu_j(\mathbf{x}_p)\,\omega_p \quad (9)$$

where ω_p is the cost associated with training pattern p. A suitable overall cost function can be defined as:

$$Cost(S) = \sum_{p=1}^{m} \omega_p \cdot z_p(S), \quad (10)$$

where m is the number of training patterns, ω_p is the weight/cost of the training pattern $\mathbf{x}_p$, and $z_p(S)$ is a binary variable set according to the classification result of the training pattern $\mathbf{x}_p$ by S: $z_p(S) = 0$ if $\mathbf{x}_p$ is correctly classified by S, and $z_p(S) = 1$ otherwise (i.e., $\mathbf{x}_p$ is misclassified or rejected). We use this cost function as a performance measure as well as classification rate.

LEARNING ALGORITHM

A learning method that adjusts the grades of certainty CF_j can be employed to achieve improved classification performance (Nakashima, Yokota, Ishibuchi, & Schaefer, 2005). It is based on an error-correction learning approach where the adjustment occurs when classification of training patterns is not successful. When a training pattern is correctly classified, we do not adjust the grade of certainty. The main idea of the learning method is to adjust the degree of certainty CF_j of two fuzzy if-then rules: We decrease the degree of certainty of a fuzzy if-then rule that misclassifies a training pattern and in turn increase that of a fuzzy if-then rule that is supposed to correctly classify the training pattern.

Let us assume that we have generated fuzzy if-then rules by the rule-generation procedure detailed above. We also assume that a fuzzy if-then rule R_j misclassifies a training pattern $\mathbf{x}_p$. That is, R_j is used to classify $\mathbf{x}_p$ from Class c^* by using Equation (8) but the consequent class C_j does not agree with the true class of the training pattern $\mathbf{x}$. Let R_* be the fuzzy if-then rule that is selected by Equation (7). That is, R_* has the maximum value of $\alpha_{class\ c^*}(\mathbf{x}_p)$ among those fuzzy if-then rules with Class c^* but does not have the maximum value among all generated fuzzy if-then rules. The proposed learning method adjusts the grades of certainty of R_j and R_* as follows:

$$CF_j^{new} = CF_j^{old} - \eta \cdot \omega_p \cdot CF_j^{old} \quad (11)$$

$$CF_*^{new} = CF_*^{old} - \eta \cdot \omega_p \cdot (1 - CF_*^{old}) \quad (12)$$

where ω_p is the weight of the training pattern $\mathbf{x}_p$, and η is a positive constant value. We assume that $0 \le \eta \le 1$.

One epoch of the proposed learning method involves examining all given training patterns. Thus there will be $2m$ adjustments of fuzzy if-then rules if all m training patterns are misclassified. The learning process is summarised as follows:

1. Generate fuzzy if-then rules from m given training patterns.
2. Set K as K=1.
3. Set p as p=1.
4. Classify $\mathbf{x}_p$ by using the generated fuzzy if-then rules in Step.
5. If $\mathbf{x}_p$ is misclassified, adjust the grades of certainty using Equations (11) and (12). Otherwise no rules are adjusted.
6. If $p<m$, let $p:=p+1$ and go to Step . Otherwise go to Step.
7. If K reaches a pre-specified value, stop the learning procedure. Otherwise let $K:=K+1$ and go to Step.

Note that K in the above learning procedure corresponds to the number of epochs.

EXPERIMENTAL RESULTS

In order to evaluate our proposed cost-sensitive fuzzy classifier, we tested it on a standard medical classification dataset, namely the Wisconsin breast cancer dataset (Wolberg & Mangasarian, 1990) which comprises a collection of nine cytological attributes such as clump thickness, uniformity of cell size and shape, and so forth, for 444 benign and 239 malignant cases.

We used a standard fuzzy rule-based classifier to obtain a baseline benchmark to compare our algorithms to. We then applied our proposed cost-based classifier with two different cost setting: a ratio of 1:2 between benign and malignant cases and a ratio of 1:5 (though both are probably still conservative estimates). We also used the learning algorithms detailed above to improve upon the classification performance of our cost-based classification system. We investigate two different sets of parameters for the learning algorithm: a slower learning method with η=0.2 and *K*=50 and a faster approach with η=0.5 and *K*=20. In all experiments, we divide each attribute uniformly into three triangular fuzzy sets as shown in Figure 1. In order to arrive at statistically meaningful results, in all cases we perform 10-fold cross-validation where the patterns are split into 10 disjoint subsets and each subset is in turn used as an unseen test set while the other nine sets are used for training the classifier. We report the results in terms of sensitivity defined as:

$$SE = \frac{TP}{TP + FN}$$

and specificity defined as:

$$SP = \frac{TN}{TN + FP}$$

where *TP*, *TN*, *FP*, and *FN* correspond to true positives, true negatives, false positives, and false negatives respectively. All results are given as the average 10-CV scores for both training and unseen test data and are shown in Tables 1 and 2.

On the training data, the conventional classifier achieves a sensitivity and specificity of 97.49% and 98.65% respectively, which corresponds to six false negatives and six false positives. Our cost-based ap-

Table 1. 10-CV results on breast cancer training data

	Classifier	tot. cost	SE (%)	SP (%)	TP	FN	FP	TN
1:2	conventional	18	97.49	98.65	233	6	6	438
	cost-based	15	98.33	98.42	235	4	7	437
	cost+learning η=0.2,*K*=50	2	100.00	99.55	239	0	2	442
	cost+learning η=0.5,*K*=20	2	100.00	99.55	239	0	2	443
1:5	conventional	36	97.49	98.65	233	6	6	438
	cost-based	21	99.16	97.52	237	2	11	433
	cost+learning η=0.2,*K*=50	2	100.00	99.55	239	0	2	442
	cost+learning η=0.5,*K*=20	2	100.00	99.55	239	0	2	443

Table 2. 10-CV results on breast cancer test data

	Classifier	tot. cost	SE (%)	SP (%)	TP	FN	FP	TN
1:2	conventional	39	94.14	97.52	225	14	11	433
	cost-based	37	95.40	96.66	228	11	15	429
	cost+learning η=0.2,*K*=50	37	95.40	96.66	228	11	15	429
	cost+learning η=0.5,*K*=20	37	95.40	96.66	228	11	15	429
1:5	conventional	81	94.14	97.52	225	14	11	433
	cost-based	56	96.65	96.40	231	8	16	428
	cost+learning η=0.2,*K*=50	56	96.65	96.40	231	8	16	428
	cost+learning η=0.5,*K*=20	56	96.65	96.40	231	8	16	428

proach improves upon this by correctly identifying two more malignant cases (while increasing the number of false positives by 1). A further dramatic improvement is observed after we apply the learning algorithm achieving a sensitivity of 100% with a specificity of 99.55%.

On the test data the difference between the algorithms is still significant though not as pronounced as for the training data. Here, three more malignant cases are identified for a cost setting of 1:2 while six more cancer patients are detected with a cost setting of 1:5. The effect of the misclassification costs on the performance is hence readily observable here; also in all cases the cost-based variations produce lower overall costs compared to the conventional approach.

FUTURE TRENDS

As has been shown in this article, the application of costs and an associated cost-sensitive classifier can prove very useful for medical diagnosis. The main problem here, however, is that in most cases the costs are only estimated and hence do not necessarily represent the true costs. Consequently, the derived classifier might not perform as well as it could. A different approach would, hence, be to derive a classifier that does not take into account the costs directly but rather relies on an ordering of importance between the different classes (Nakashima, Yokota., Schaefer, & Ishibuchi, 2007).

Also, the fuzzy rule base derived in our work contains some redundancies and is hence not as efficient and compact as possible. To arrive at a smaller but equivalent rule base, rule pruning methods can be applied. A smaller rule base also has the advantage of better interpretability of the derived rules.

CONCLUSION

In medical diagnostic classification systems, classification performance is not always the only indicator for assessing classifiers. Rather, misclassification costs should be taken into account as well, as usually misclassifying a malignant case will prove much more costly than misclassifying a benign one. In this article, we have applied a cost-sensitive fuzzy rule-based classifier, which emphasises the importance of those classes which have high misclassification costs, to medical diagnostic classification datasets. We have also applied a learning algorithm to further boost the classification results. Experimental results have shown that our cost-based approaches perform better than conventional classifiers under the assumed conditions.

KEY TERMS

Cross Validation: A standard method of evaluating classifiers where data with known classes is divided into disjoint sets and the classifier tested on various combinations of these training sets.

Fuzzy Logic: A form of logic where variables can take on variable degrees of truth.

Fuzzy Set: An extension of the classical set whose memberships have degrees of membership.

Membership Function: A function that describes the degree of an element's membership in a fuzzy set.

Pattern Classification: Automatic transformation of input data into categories (classes).

Rule-Based Classifier: A pattern classification system in which the classification is expressed as a set of rules.

Creating and Marketing a Dental Supply Online Store

David Gadish
California State University, USA

INTRODUCTION

The dental supply company is family owned and operated. It was founded in the 1940s and currently serves approximately 1,000 dental offices and offers over 16,000 different products from over 200 manufacturers. Management did not consider the importance of information technology solutions that other firms have implemented to increase efficiency and cut costs. A decision to modernize came in 2003 as revenues started falling and existing clients started ordering dental supplies from competitors. This analysis covers the first 2 years of marketing from November 2004 to November 2006. The process was preceded with a 2-month campaign planning phase.

Understanding the Dental Supply Industry

The North American market size in 2005 was estimated to be $5.6 billion (Patterson, 2006). Two main players in the market are Patterson with 32% and Sullivan-Schein with 30% market share. Market growth is estimated to be 7% to 9% annually.

The Patterson Dental Company provides a range of consumable dental products, clinical and laboratory equipment, and value-added services to dentists, dental laboratories, institutions, and other health care providers. Patterson Dental has the largest direct sales force in the industry, totaling nearly 1,300 sales representatives and equipment/software specialists. Projected revenues for the fiscal year 2005 were 1.8 billion dollars (32% of the North American market share) (Patterson, 2006). Sullivan-Schein Dental has an extensive line of dental, medical, and pharmaceutical products (Sullivan-Schein, 2006), the company holds about 30% of the North American market in fiscal year 2005 (Patterson, 2006). Benco Dental serves 20,000 customers in 18 states and employs about 950 associates (Benco, 2006).

Pearson Dental Supplies offers dental supplies and dentist office equipment. The company was founded in 1945 and its supply catalog carries over 65,000 products, making it one of the big players in the dental supply industry (Pearson, 2006).

The other players in the Dental Supply Industry include but are not limited to AccuBite Dental Supply, Atlanta Dental, Applied Dental, Burkhart Dental, Conger Dental Supply Company, Darby Dental Supply, Discus Dental, and Eastern Dental Supply.

The North American dental market consists of about 156,000 U.S. dentists and around 18,000 Canadian dentists (Pearson, 2006). 65%-70% are sole practitioners. There are over 135,000 dental practices. The average revenue per dentist stands at $550,000 per annum. Dentists spend $0.05 – $0.07 revenue per dollar on consumables supplies, which means $25,000 to $35,000 of revenues per annum.

The international market has enormous possibilities for U.S. exports. The European Union will continue to be one the largest export markets for the U.S., but countries in Central and South America and India are becoming larger buyers of high quality dental supply.

The U.S. has historically accounted for roughly 50% of the global market for dental equipment and supplies. In 1998, the total export of dental products totaled $633 million. In 1998, exports to Europe rose to $277 million, which represented 44% of total exports of dental supplies. As Japan and China become world powers, their need for dental hygiene products increases. As of 1998, U.S. sales reached $28 million, which represented a 40% increase since 1996. This is attributed to economic growth, higher income levels, increased access to dental clinics, and great awareness of dental hygiene (Palmer, 2002).

The Internet, the World Wide Web, and other developments of the information revolution will redefine patient care, referral relationships, practice management, quality, professional organizations, and competition (Bauer & Brown, 2001).

THE DENTAL SUPPLY E-COMMERCE SOLUTION

The Web offers the advantages of both centralization of information and coordination (Marks, 2004). To survive, the company needed to increase revenues and reduce operating costs. They chose to accomplish this by automating business processes through the implementation of their online solution. The Web site provides customers with information online. It allows dentists to place orders online. It also allows prospective dentists to reach them. The company will become more accessible to their clients and prospects (Goff, 2002). It will also be able to further build on its brand.

The company uses their Web site to further inform its customers of new dental supplies and sell dental supplies to its customers. The company's Web site integrates three areas of commerce:

- The Products system includes product search and an online catalog system
- The Customers system includes a customer accounts systems, authentication system and links to the order and product systems
- The Orders system includes customer orders and delivery systems

Databases, Web servers, Web applications, and other computer technology were used to get the Web site up and running. Data about dental products was loaded from the company's existing ERP system. Product images were requested from a few hundred dental product manufacturers who's products the company resells, and were then incorporated into the e-commerce solution. The process is detailed in the following sections.

Planning of Dental Supply E-Commerce Infrastructure

In creating the e-commerce solution for ENG Dental Supply, the Systems Development Life Cycle process was utilized. It consists of seven phases. The planning phase covered project scope and budget. The analysis phase included research of the competition, analysis of employees and client requirements, research of ISPs, and research of e-commerce packages. The design phase included designing processes to add/remove/modify products and planning marketing strategies. The system build phase includes the purchasing and configuring test computer, purchasing the e-commerce package, and development and testing of an e-commerce Web site. The data build phase involved many activities including: extraction of product data from the DMS system, identification of products to list online, cleanup of product data, classification of products, data load, collection of product images, population of images into the e-commerce Web site, and finally testing the data in the e-commerce Web site. The deployment phase consisted of: creation of training materials, training employees, moving the site from test to production environment, and training clients online. The final phase is operations, which included activities; updating prices, adding/removing/modifying products, and marketing and supporting the e-commerce Web site. Once these activities were identified, a preliminary project budget was established (see Figure 1).

Determine Project Scope

ENG needed to catch up with their competitors almost immediately if they wanted to remain a viable dental supply company. In order to do so, ENG needed to provide its customers with an online product catalog that would have electronic commerce capabilities so the customers could compare products and place orders.

Determine Budget

The client allocated $45,000 for the initial implementation, and so the question facing the team was how to implement the maximum possible for the tight budget.

Figure 1. Dental supply e-commerce planning phase

To achieve that, the activities were prioritized and implemented selectivity.

Analysis of Dental Supply E-Commerce

The e-commerce site needed to be easy to use and maintain. An analysis study of the company's business processes was performed in order to identify ENG's requirements. Information about employees and their duties was collected, and a course of actions was formulated based on the analysis of the findings (see Figure 2).

Research Competition

Portals differed in many characteristics, such as the number of services, product pricing, discussion forum activity, navigability, reaction time in response to questions, and site responsiveness (Schleyer & Spallek, 2002). The online presence of the dental supply competitors including their e-commerce capabilities was analyzed. These companies included: Patterson Dental Company, Sullivan-Schein Company, Burkhart Dental, Inc., Darby Dental Supply, and Benco Dental, Inc.

Analyze Employees and Client Requirements

Meetings with management covered the employee and client requirements. The customer service department and the outside sales people were then utilized to determine their requirements for such a system. They were asked to review competitors systems, and recommend ways in which the ENG System could be designed to achieve their needs and be better then the competition.

Research ISPs

The information of the company's Internet Service Provider (ISP) was gathered. The company hosting the Web site relied on older technology and the ISP features did not allow for the usage of dynamic information. Several ISPs were studied for reliability, connectivity, and service to support the new Web site. A company by the name of 1and1 met all the requirements for the solution.

Research E-Commerce

Several e-commerce packages were tested before making a final purchasing decision. X-cart Gold was selected to drive the new e-commerce site. The price was also very competitive compared to other vendors. The main reasons why this package was chosen are shown in Table 1.

Design of the Dental Supply E-Commerce Web Site

The design phase consisted of designing an e-commerce site look and functionality, creation of the process to update prices, creation of the process to add/remove/modify products, and the planning for marketing campaigns (see Figure 3).

Design E-Commerce Site Look/Functionality

Two main actions were taken with respect to ENG's Web site, to improve its performance and usability:

Figure 2. Dental supply e-commerce analysis phase

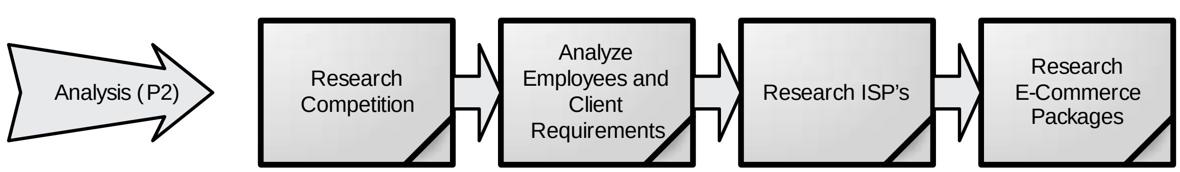

Table 1.

Free customer support for X-cart customers. Whereas most vendors provide technical support for their products at a cost, X-cart has free customer support with the purchase of the software.	Personal order history log gives ENG customers the ability to view how much and what they have ordered in the past.
Ability to print transactions.	Clients can search products by title, description and category.
The option to use discount coupon codes and gift certificates.	Full inventory control.
"Out of Stock" notifications.	Quantity discounts.
Retail and wholesale pricing.	Allow customers to choose delivery methods.
Ability to process credit cards using different known transaction companies.	Export sales and customer data for use in a spreadsheet.
Printable shipping labels.	Personalized greetings of regular customers.
Real-time order tracking for registered customers.	Encryption protection for secure transaction and customer data transmission.

Figure 3. Dental supply e-commerce design phase

- Minimize dynamic content; with careful performance analysis, it was determined that the usage of dynamic content on the site would decrease server performance. Budget constraints impeded the company to afford a high-end dedicated hosting server. Therefore, in order to improve performance on the Web site, dynamic content use would be minimized as much as possible.
- Increase the appeal of ENG's Web site. The main page of every Web site is critical in capturing the visitor's attention. Generally only 5 seconds are required to captivate the audience's attention. If the content does not convey the right message, the potential customer may be lost. The company's original Web site did not attract visitors.

The site was not sophisticated enough and e-commerce was nonexistent. A survey of 250 clients was performed in order to determine what needed to be changed. The results were very clear. The recipients agreed that the Web site needed to be thoroughly revised. Hence, the Web site was redesigned to maximize its appeal and functionality.

Create Process to Update Prices

Product prices were updated daily on the DMS environment. This was a manual process based on market prices of products offered by the competition. A new e-commerce solution meant that prices would need to be updated twice, creating possible inconsistencies between online and off-line ordering prices due to human data entry errors. To resolve this, a batch process would be created to copy all price changes from the DMS to a Microsoft Access document twice each month. This document would be manually imported into the new e-commerce environment, then updating the prices quickly and consistently.

Create Process to Add/Remove/Modify Products

A list of products added, removed or modified would be downloaded from the DMS environment twice per month. The changes to product descriptions, added products or removal records would then need to be manually recorded into the system by an operator.

Plan Marketing Campaigns

A plan and a schedule were created outlining the traditional and online marketing efforts that would take place to promote the e-commerce Web site. Some activities were planned for the prelaunch period, others for the initial operational period and for ongoing activities.

Build of the Dental Supply E-Commerce System

E-commerce software was purchased, customized, and tested (see Figure 4).

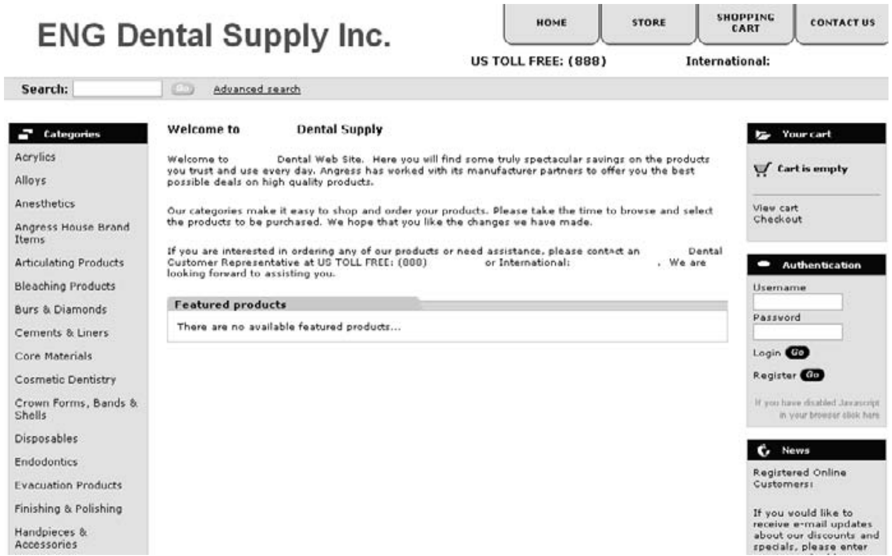
Purchase/Configure Test Computer

A dedicated computer was purchased in order to perform testing of the Web site by the company's staff. The computer was setup as a dedicated machine to perform intensive tests and identify any possible design errors. The investment of this system was a few hundred dollars.

Figure 4. Dental supply e-commerce system build phase

Figure 5. Screenshot of ENG's homepage

Figure 6. Screenshot of ENG e-commerce storefront page



Purchase E-Commerce Package

The software package chosen for the design and implementation of the e-commerce site is called X-cart Gold and was purchased from X-cart solutions (X-Cart). The basic package offered system capabilities such as querying, ordering and processing.

Create E-Commerce Web Site

The graphical user interface was customized for a more aesthetically appealing look. Features such as product search and thumbnail display were added (see Figure 5 and Figure 6).

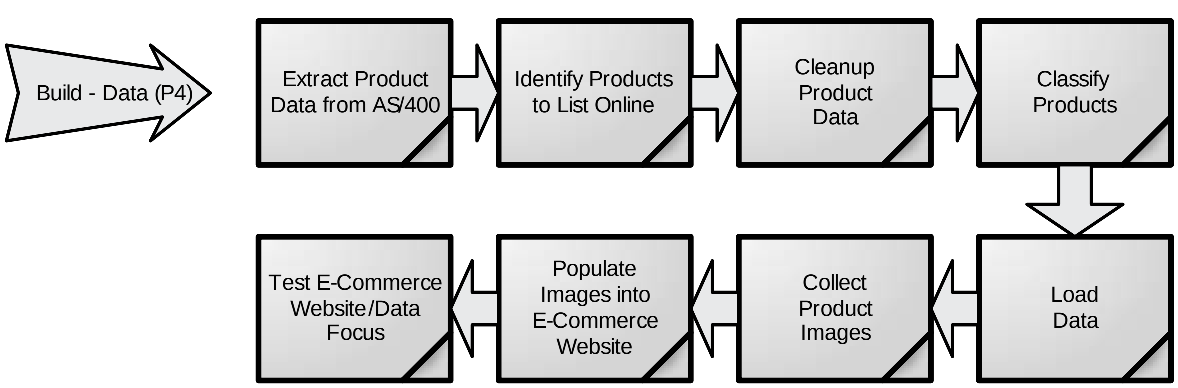
Test E-Commerce Web Site

A limited data set of product records and clients was entered into the system. Testing was performed to ensure online ordering, transaction recording, and reporting of other key functions worked flawlessly.

Build of the Dental Supply E-Commerce Data

The current database contained in the DMS was updated with detailed product descriptions and placed into a hierarchy in accordance with industry norms (see Figure 7).

Figure 7. ENG dental supply e-commerce data build phase



Extract Product Data from DMS

A script to extract all DMS data was created, tested, and executed. Data was extracted into an MS Access file.

Identify Products to List Online

The organization's purchasing manager reviewed each product item in the Microsoft Access file. Over 5,000 products were identified as being discontinued or no longer sold by the company. Records were uploaded into the e-commerce package and tested to ensure the system reflected the appropriate values.

Product Data Cleanup

Focus was placed into making sure that all products had full description including prices and tags. The data was extracted into Microsoft Excel.

Classify Products

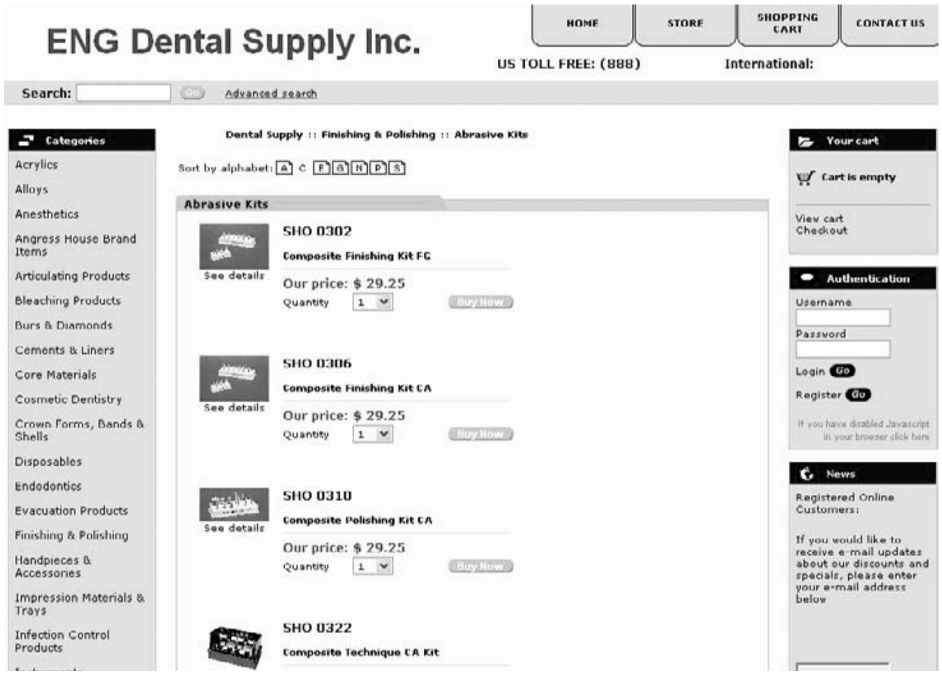
The DMS environment used only by ENG staff did not classify products in categories. Dental offices would require these to facilitate a more user friendly search. A list of ENG product categories was created by analyzing the categories of products available on competitors' Web sites (see Figure 8 and Figure 9). These categories

Figure 8. ENG's product categories

Acrylics	Cosmetic Dentistry	Infection Control of Products	Retration Materials
Alloys	Crown Forms, Bands and Shells	Instruments	Rubber Dam and Accessories
Anesthetics	Disposables	Matrix Products	Small Equipment
Articulating Products	Endodontics	Miscellaneous	Surgical Products
Bleaching Products	Evacuation Products	Orthodontics	Sutures and Suture Needles
Burs and Diamonds	Finishing and Polishing	Parts	Toys
Cements and Liners	Handpieces and Accessories	Pins and Posts	Waxes
Core Materials	Impression Materials and Trays	Preventative and Prophy Items	X-Ray Products

Figure 9. Screenshot of ENG's product categories

Figure 10. Screenshot of ENG's product listings



were subdivided into 638 subcategories to allow users to further refine their search of dental products.

Load Data

The e-commerce Web site uses MySQL to store the extracted records provided by the vendor in charge of retrieving the mainframe's information. The MS Access data was exported into a common separated value (CSV) file that would be recognized by the e-commerce package. These records were then carefully imported into MySQL to ensure data integrity (see Figure 10).

Collect Product Images

The image collection process caused major time delays due to difficulties entailed in obtaining the images from product supplier and manufacturers. ENG's suppliers and manufacturers were contacted in order to provide their images for the e-commerce environment. Manufacturers provided diskettes or CDs with the product data. These images were converted to low-resolution format using Advanced JPEG compression version 4.8 software. The images were named according to the ENG product codes. Images are in the JPG format, which is a standard format supported by the X-cart package.

Populate Images into E-Commerce Web Site

This manual process involved importing one image for the directory of images into the corresponding data record in the e-commerce environment (see Figure 11).

Test E-Commerce Web Site/Data Focus

Testing was performed for a period of one week. All departments of the organization were involved in the thorough testing of the new site. Feedback was provided for minor adjustments of the e-commerce environment. A full time person was assigned to search for the most popular products to ensure their descriptions would help locating them online. A second week of testing involved ten ENG clients. They were provided with written instructions and telephone support to help them register, and use the system to purchase dental products online.

Deployment of the Dental Supply E-Commerce Web Site

Deployment consisted of creating training materials, training employees, moving the Web site to the produc-

Figure 11. Screenshot of a dental product image

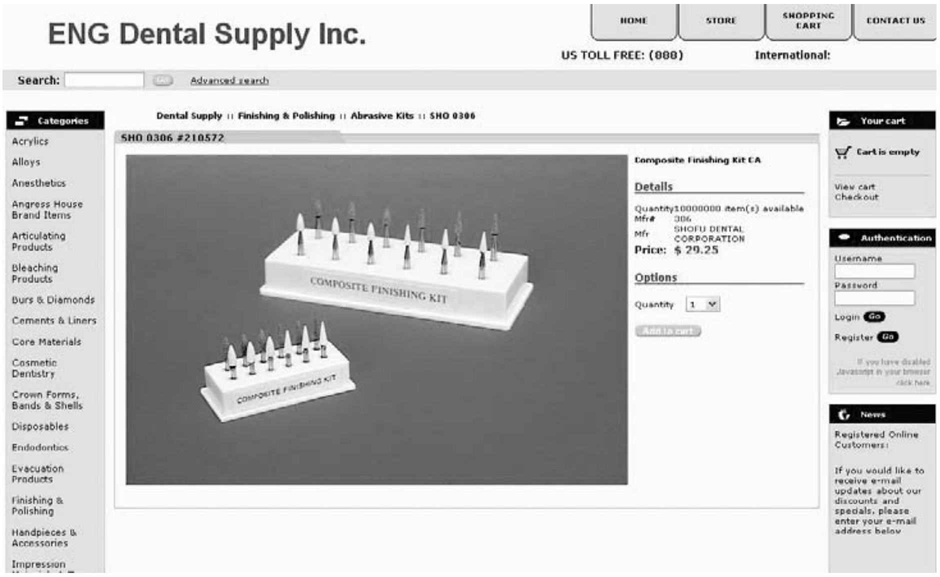


Figure 12. ENG dental supply deployment phase

tion environment, and then training ENG's customers (see Figure 12).

Create Training Materials

Two training programs were offered to ENG: one for its employees and another for its clients. Separate training materials were prepared to train customer service staff and employees supporting the system. The documentation included:

A document specifying the system's different features and capabilities; product search features, registering to the Web site, and so forth.

A document containing an overview of the architecture of the system, instructions of how to maintain and add basic features to the system.

A document containing a site map and information regarding product so as to assist customer service staff in supporting customers remotely.

Train Employees

The ENG customer service and sales department employees were trained on registering to the system, searching for products, reviewing transactions, and extracting transactions from the DMS environment for order fulfillment.

Move Site from Test to Production Environment

The new Web site had to be uploaded and promoted from testing to production once the required tests were performed.

Figure 13. ENG dental supply e-commerce operations phase

Train Clients Online

Two main options for client training support were offered:

- Phone support by the customer service department staff for those clients encountering difficulties ordering or searching products through the system.
- Personal visit by sales representatives - in extreme cases where phone support didn't resolve the clients' problems or for VIP customers.

Customers were trained to register online, to search for products, to order products, to change orders and to review the order history.

Operations of the Dental Supply E-Commerce Web Site

Ongoing operations of the e-commerce environment include price updates, adding, removing or modifying product information, marketing the e-commerce Web site, and supporting the site and the data (see Figure 13).

Update Prices

The customer service support department employees were trained in the process outlined earlier. The ongoing was then implemented.

Add/Remove/Modify Products

The customer support department employees were trained in the process to add, remove, and modify product information as outlined earlier. The ongoing process was then implemented.

Support E-Commerce Web Site

The ENG customer service department would be responsible for fielding client calls about the usage of the new e-commerce environment, about recommendations for changes or enhancements to the environment, as well as product search assistance to clients that cannot find the products they need. A list of proposed enhancements would be created to be incorporated into the planning on the next release of the site. Any data errors identified would be resolved within one business day.

MARKETING STRATEGY FOR THE E-COMMERCE SITE

The company was faced with a tight budget as it began to plan the marketing strategy for the new e-commerce site. Both online and traditional marketing campaigns were planned and implemented to maximize the exposure of the new dental supply Web site to its target audience segments. The company embarked on a low-budget creative marketing strategy to help increase its Web site exposure. Online activities included e-mail marketing, search engine advertising, cross linking, additional online store advertising, banner advertising, online article publication in online publications and newsgroups. Traditional marketing activities included a launch event, labels on merchandise, flyers, one-on-one meetings, phone calls, letters, and advertising in paper publications.

Target Dental Market Segments

This was the first time in the company's history that it embarked on a comprehensive marketing strategy. Engaging and returning customers required a focus on the following segments:

- Existing clients of the company that were not purchasing online should be encouraged to purchase online, trained to do so, provided assistance with the initial registration process, and encouraged to purchase online on a regular basis.
- As clients started purchasing online, they were targeted to purchase more, and/or more frequently.
- Clients that used to purchase from the company in past years, but then switched to purchase from competitors and their online stores, were encouraged to return to the company by exploring its online shopping option.
- Established dental offices in the traditional geographic coverage area of the company that have been purchasing from competitors were encourages to purchase products online.
- Established dental offices outside the traditional coverage area of the company that have not purchased from the company in the past were exposed to this new online shopping option. The majority of them were not familiar with the brand, have not had a relationship or purchased in the past. This marketing exposes them to a new option for dental supply shopping.
- Newly graduated dentists from dental school are key to the future success of the organization. These were encourages to become familiar with the company, and its online store, so that they can approach it once they start working at an existing practice or once they open their own practice.
- A high-level marketing plan was created to include both online and traditional marketing methods. Parts of the plan were implemented during the first two-year period. These are discussed next.

Online Marketing Campaigns: Descriptions and Costs

Different online marketing campaigns were planned, executed, measured and evaluated by the company.

E-Mail Marketing

E-mailing is a highly effective, targeted method of reaching the dental community. An initial e-mail was sent to current to encourage them to purchase online. Regular e-mails were then sent notifying them of weekly/monthly specials. Past clients were e-mailed to show them the benefits of returning to do business with the organization via its e-commerce site. This was effective with some clients since the reason they left in the first place was the lack of ability to make online purchases.

To reach prospects via e-mail, the company first needed to determine their e-mail addresses. It is possible to extract e-mail addresses from Web sites that include discussion about dental topics, as well as dental online forums, and newsgroups. There is no cost associated with such activity beyond human resources, and this is a way to generate thousands of e-mail addresses of dentists, dental assistants, dental hygienists and others in the dental industry. An alternative is to purchase an e-mail list of all dentists in a particular region. For example, e-mails of over 8,000 dentists in southern California can be purchased for $940. E-mails are sent once per month, and recipients have the option receive weekly specials via e-mail or to unsubscribe from the monthly e-mail list, if they choose the first option, they receive weekly notification of specials via e-mail. The monthly e-mail contains a reminder to shop online, and lists a few monthly specials (those available at a discount price throughout the month). The weekly e-mail contains those products available at a discount rate for the week. Online greeting cards are e-mailed during major holidays to the subscribed e-mail list.

Search Engine Advertising

The Google AdWords program was utilized to increase traffic to the e-commerce site. The site would appear on the top right hand side of search result screens, when searching for “dental products,” “dental equipment,” “cheap dental products.” The company advertised with MSN Sponsored Sites as well.

Web Site Cross Linking

Web site cross linking was set-up with other organizations in the dental industry. Web sites of service providers such as dental labs, repair dental equipment shops, and others that cater to dentists were approached. Web sites of organizations that sell dental software, dental equipment, and provide other noncompeting products were also approached. Both parties seeking to increase their memberships benefit from such cross linking. There are no costs to this approach beyond the cost of banner design and implementation, and placement on the other organization's Web site. Possible Web sites considered for cross linking and other advertising methods include: www.handpieceheadquarters.com, www.dentalproducts.net, www.dentalxchange.com, and www.edentalmall.com.

Additional Online Store Advertising

A dental supply store was created on E-bay to expand the sale of the goods. One reason for this approach was to sell a few select popular products. More importantly, this is a way to channel more traffic from e-bay to the e-commerce Web site of the company and to enhance the company's brand. Dental supply stores were created in other related portals and online shopping malls including Amazon.com

Banners in Online Dental Publications

Research conducted as part of the company's planning efforts shows that 11% of the traditional paper publications have online versions that offer additional advertising opportunities. The Web site was linked to online portals (vertical portals of the dental industry) by paying to place banners in these Web sites that lead prospects to the company's Web site. Banner prices range from $500 per month for on the American Dental Association's Web site, to $65 per month in regional publications.

Articles in Online Dental Publications

Articles were submitted to and published in dental organizations' online newsletters, announcing the launch of the company's Web site as a way to increase exposure. Organizations included different dental association, associations of dentists, associations of dental hygienists, and associations of dental assistants.

Article Posts to Newsgroups

A search of Google Groups and Yahoo! Groups yield hundreds of groups related to dentistry. The company posted messages on these boards on a regular basis. The messages are related to the topics discussed, and suggest that additional information can be found by visiting the company's Web site. The company has also started a number of dental groups to provide people in the industry additional forums for discussion.

Traditional Marketing Campaigns in Support Dental E-Commerce

Targeted traditional marketing campaigns for the Web site were planned, executed, measured, and evaluated.

Launch Event

Local current and past clients, as well as local dentists that have not been purchasing from the company, were invited to a special PR launch event where the new e-commerce system was presented. In order to provide incentives, discounts were offered for those clients ordering products using the new system the week following the event.

Labels on Merchandise to Existing Clients

The Company's shipping department places a large label on each shipment of products to clients with the Web site address and the words "Order Online" printed on them. This approach is effectively reminds existing clients to purchase additional products online.

Flyers with Mailed Invoices

A one-page advertisement is sent with each invoice to existing clients of the dental supply company. It lists a few "Monthly Special" items that are available at discount rates only via an online purchase.

Office Visits by Sales People

Current clients of the company were visited by their sales persons to inform them of the new e-commerce capabilities and the advantages of purchasing online. Follow-up meetings were arranged, to demonstrate the Web site's functionality and create accounts for them. Clients were told that they would continue to get the levels of support expected. Sales people were asked to visit past clients, and encourage them to register online and make an initial purchase at a substantial discount. Sales people were also instructed to visit offices in their geographic coverage that are not currently serviced by the company, assist with the online registration process, and offer a substantial discount on an initial purchase.

Phone Communications with Customer Service

Customer support representatives were instructed to inform each caller about the new online shopping environment that became available. They were trained in assisting clients to go through the registration, search and purchasing processes.

Letters to Past Clients

Letters were mailed to customers that used to purchase from the company but switched to purchase from competitors in recent years.

Advertising in Paper Publications

Ads were selectively placed in a number of paper publications. A survey of the paper publications of the dental industry was conducted by the company as part of its marketing planning effort. It shows that 34% of publications are published monthly, 20% are published quarterly, 9% are annual, and the remaining 37% consist of those published bi-weekly, 3, 5, 6, 7, 9, and 10 times a year.

The average back page of a publication costs $1,336, inside back page at $882, inside front $1,112, full inside page $1,110, two thirds of a page $947, half page at $700, one third page $610, quarter page $478, one sixth of a page $318, one eighth of a page $210. The publication of the American dental association which reaches dentists through out the USA charges substantially larger advertising fees, with full page ads reading $9,030, two thirds page $6500, one half page $5,690, one third page $4,030, one fourth page $3,030, one sixth page $2,740, and one eighth page $2,450.

The average cost of advertising per publication reader is $0.56 for the back page, $0.67 for the inside back page, $0.61 for the inside front page, $0.26 for a full page ad, $0.17 for two thirds page ads, $0.16 for half page ads, $0.10 for third page as well as quarter page ads.

ANALYZING WEB SITE USAGE

Web site usage was tracked over a 2-year period as the different marketing campaigns outlined earlier were implemented.

42% of customers of the Web site are California, 45% come from other U.S. states, and the remaining come from outside of the U.S., mostly Canada and Europe.

10% of the new customers were referred to the Web site by a sales person's visit and/or phone call, 4% were referred by a colleague, 2% from attending dental shows, 12% from banner advertising, 27% from search engines, 26% from direct e-mailing, 5% from newsgroups, 10% from ads in paper publications, and 4% from other referral sources.

Most dental offices purchasing from the site are small operations of a single dentist or a couple of dentists. In small dental offices, the dentist is more likely to order dental supplies then in larger dental practices. Of the visitors to the Web site, 74% have indicated that they are dentists, while 26% indicated they are dental office staff.

During the registration process of dentists on the Web site, 51% of dental visitors have asked to receive a monthly online dental newsletter.

Of the registrants to the Web site, 34% did not login to the site during a 30 day period following registration. A call to these dentists asking them to follow-up and visit the site, resulted in 56% positive response rate. Over 19% of Web site registrants began purchasing online only following human interaction.

During the 2-year period of this study, the number of Web site user increased from zero to over 3,400 registered users. The growth was almost even, with an average of 142 registrations per month. Weaker periods of growth are exhibited during the summer months of June, July, and August, as well as the holiday season of December.

Of the shoppers, 17% did not return to purchase again on the Web site during the period, in spite of an ongoing e-mail campaign to entice them to come back. Many of these indicated price to be the main reason for their decision.

CONCLUSION AND FUTURE WORK

The decision to implement an online shopping portal for dental practitioners that serves as a gateway for accessing over 16,000 products offered by the company was important to ensure the continued existence as well as the growth of the company. The objectives of the portal were to (1) lower the cost of operations for the company, (2) improve efficiency, and (3) increase revenues.

The number of customers quadrupled and the revenues more than tripled over this 2 year period with a very limited budget.

The ability to capture demographic information, shopping habits and other vital information was also implemented. Several kinds of reports were created through data mining to perform effective targeted marketing. These will be utilized over the next few years to take the company's marketing for existing and past clients to a new level.

We believe that a human touch must accompany each client to complement and enhance their online experiences. This encourages customers to purchase more, and more frequently.

Larger dental supply companies offer more services and more products to their clients, which is what sets them a part. The company is planning to transform part of its Web site into a dental services portal, linking its visitors with repair services for hand pieces, dental office design specialists, dental office software automation vendors that will offer their clients discounts. The portal will include: (1) Office design assistance: design the office from the equipment they need to work to the furniture, computer software programs they need to operate their facility. (2) Business rewards cards: Offer business cards to customers where on each purchase with the company, they can receive a certain percentage of money back or points towards other company products. (3) Demographic site analysis: Give business advice to new dentists. The company will provide business analysis for new dentists on the local economy, future growth potential and real estate potential. (4) List of conventions and seminars: The company will be prepared with a list of upcoming conventions and seminars for new dentists, veteran dentists, dental hygienist, dental assistants and dental students. (5) Jobs portal to attract those in the dental profession looking for a new job. The portal would provide the company with additional reasons to interact with prospective buyers, inform them of the company and its products, and convert them to shoppers of its online shopping environment.

Creating Patient-Centered E-Health

E. Vance Wilson
University of Toledo, USA

INTRODUCTION

As e-health applications have increased in number and variety, the generalized concept of e-health as "health services and information delivered or enhanced through the Internet" (Eysenbach, 2001) has lost much of its value as a mechanism for guiding development and research in this emerging field (Pagliari et al., 2005). E-health has expanded to comprise purely clinical applications (e.g., physicians consulting on a diagnosis) (Wiecha & Pollard, 2004), emergency health communication applications (e.g., for distributing information about SARS) (Rizo, Lupea, Baybourdy, Anderson, Closson & Jadad, 2005), disease-focused applications (e.g., diabetes self-management support) (McKay, Glasgow, Feil, Boles & Barrera, 2002), applications to support electronic communication between patients and physicians (Wilson, 2003), and commercial applications that have no association with a patient's own health care provider (e.g., WebMD) (Itagaki, Berlin & Schatz, 2002). It is clear that the needs of both users and researchers vary widely across these diverse applications, and I argue that both groups would benefit from development of finer-grained approaches to thinking about e-health.

BACKGROUND

Initial e-health applications were designed from a *consumer-centered* perspective, drawing upon an e-commerce business model in which vendors expected to profit from consumers paying directly for products and services they would acquire through the e-health Web site or from advertisers paying for exposure to consumers (Wilson, 2006). Most of these commercial e-health ventures failed during the dot-com bust (Itagaki et al., 2002). However, health care provider organizations have emerged to fill the void by supplying *provider e-health* to their own patients,[1] including generalized informational content as well as appointment scheduling, prescription refilling, and online communication with physicians and clinical staff (Lazarus, 2001; Wilson & Lankton, 2004).

Despite the goal of serving patients, most provider e-health has been developed from an *organization-centered* perspective that is based upon the provider's needs and economic interests. Patients' needs tend to be based on assumptions made by e-health developers and provider administration rather than being driven by patients themselves (Wilson, 2006). As a result, patients sometimes ignore e-health applications that providers assume will be the most essential to their interests. For example, Payton and Brennan (1999) describe e-health that provided Alzheimer caregivers a sophisticated, interactive, decision-support utility, e-mail communication with a nurse-moderator, an electronic bulletin board, and an online medical encyclopedia. The decision support system was considered by developers to be essential to caregivers and was substantially more expensive to deliver than other components. Yet monitoring over an 18-month period showed that decision support was used less than one-tenth as frequently as simple online communication services consisting of an electronic bulletin board and e-mail communication with a nurse-moderator.

CENTERING ON THE PATIENT

This chapter approaches e-health from a *patient-centered* perspective. Patients comprise a large and growing constituency of e-health users (Krane, 2005), and surveys indicate there is very high interest among patients in increased access to provider e-health for a variety of specific interaction needs (e.g., physician-patient communication) (Taylor & Leitman, 2002). Leaders in the medical community are coming to recognize that patients *expect* to be empowered in making health care decisions (Institute of Medicine, 2001), and that the expectation of personal control is especially strong for e-health applications (Lafky, Tulu & Horan, 2006; Markle Foundation, 2004). However, health care provider organizations have only recently begun to provide patients with online access to health care services, and numerous obstacles are present that can block development of effective patient-centered e-health applications. These include:

1. Financial disincentives for participation by outside parties (i.e., participants in e-health other than the patient, including physicians and provider administration)
2. Reduced work quality resulting from participation by outside parties
3. Reluctance of outside parties to relinquish control to patients
4. Restrictive interpretation of privacy and security regulations
5. Discomfort of patients and other key parties with computing environments.

A complete discussion of means for overcoming such obstructions is well beyond the scope of this chapter (for such a discussion, see Tan, Cheng & Rogers, 2002). Potentially, obstructions can be overcome as has been the case for other heavily regulated, traditional industries (e.g., banking and financial services), which have successfully transitioned to the online environment.

Guiding Principles for Creating Patient-Centered E-Health

In order to meet patients' expectations, it is essential for developers to focus on several guiding principles that are distinct from alternative approaches. Specifically, these are:

1. Focus on desired interactions in which the patient is an active participant
2. Incorporate only those services that meet the expressed needs of patients or are validated against patient needs
3. Be understandable to patients
4. Provide easy access for patients to completely manage and control functionality
5. Provide ready interoperability to support interaction with outside parties (e.g., physicians and pharmacy) and with other health information systems (e.g., hospital billing)

These principles correspond to a large extent with user-centered design principles that have proved important to the success of developing Web applications across numerous contexts outside the health care domain (Lazar, 2001).

The first principle emphasizes patient *involvement*, thereby distinguishing patient-centered e-health from other applications such as telemedicine, where the patient is primarily an object of the interaction rather than an active participant. The second principle addresses patient *interest* and specifically cautions against relying on untested assumptions about patients as a basis for e-health design. By emphasizing patients' involvement and interest, the first two principles help to ensure that patients will have inherent motivation to use related e-health applications. They also guide the process of eliciting patients' interaction needs and mapping these to e-health services. The remaining principles center on accessibility and source of control.

Principle 3 proposes that e-health information and communication should be understandable to patients. Some researchers argue that it is patients' own health literacy that must increase in order for e-health to succeed (Norman & Skinner, 2006). However, this type of idealistic mindset ignores first that patients' *need* for health care services is not dependent upon their literacy level, and second, that patients can benefit greatly if e-health designers make the effort to incorporate simple explanations and illustrations where these are practical. Many individuals who are only marginally literate have proved to be highly capable of interacting with online applications (e.g., banking) when they are provided with effective technological support. Further, requiring patients to be highly literate in order to use e-health is no more defensible logically than requiring high literacy in order to schedule exams or other health care services that the provider may offer. From the patient's perspective, e-health is simply an extension of the providers' other services; thus, it is reasonable for patients to expect e-health to be generally understandable and for the provider to offer mechanisms by which better explanations can be obtained if these are needed.

Principle four presents a clear statement that ultimate control of patient-centered e-health must flow to the patient. Increasing patients' involvement in e-health has been promoted recently as part of the U.S. plan for "delivering consumer-centric and information-rich health care" (Thompson & Brailler, 2004). However, achieving patient control faces two key obstacles. First, medical institutions are only slowly moving away from a firmly embedded authoritarian or "paternalistic" model of physician-patient relationships (Emanuel & Emanuel, 1992) in which physicians expect to control virtually all aspects of their interaction with patients (Eysenbach & Jadad, 2001). Embedded cultural practices can take significant time to change, even in the face of substantial social pressures. Therefore, it is likely in the foreseeable future that many physicians and other outside parties will resist allowing patients to exercise complete control over e-health or other aspects of health care. Second, health care provider organizations are reluctant to open up health information systems (HIS) to access by patients. Reluctance is based on several factors, none of which is necessarily unreasonable. Providers have the responsibility to maintain privacy and security of patient and provider data, which could be compromised by increasing accesses to HIS. Significant labor expenditures will likely be necessary in order to interconnect HIS with e-health, and it may be difficult for providers to identify ways that these expenses can be offset by increased income. Furthermore, access to HIS may be structurally blocked by disparate storage and communication formats among various proprietary systems. Lack of access to the provider's HIS or to specific parts, such as medical records and test results, leaves patients with relatively little to control, as the e-health application will not be able to offer direct interaction with key functions, such as billing and appointment scheduling. Therefore, it is important to develop strategies that can economically enhance access to HIS without compromising security or can establish alternatives to direct access (e.g., applying a data warehouse model where only duplicate data are accessible to patients). It also is key to promote among physicians and clinical staff that patients have the right to play a central role in their own health care decisions.

Principle five emphasizes that interaction with outside parties is essential for creating effective patient-centered e-health. Technical approaches can be important to achieve interoperability, as demonstrated by Wilson and Lankton (2003) in their proposal of a guided-mail system as an alternative to e-mail for patient-physician communication. However, social issues should not be overlooked in achieving interoperability, as these may be even more important than technical aspects in motivating outside parties to participate. For example, patients embrace the idea of having access to their own medical records, yet physicians are skeptical that patients would benefit from access and worry that their workload would increase if records became available (Ross, Todd, Moore, Beaty, Wittevrongel & Lin, 2005).

By addressing these five principles, developers can work to create e-health that is centered on patients' needs as well as accessible and meaningful in its capabilities. It may be anticipated that other design principles will also apply (e.g., requirements arising from privacy and security regulations). However, care should be taken to ensure that these do not unnecessarily obstruct any of the five principles of patient-centered e-health that are enumerated previously.

Analyzing Patients' Interaction Needs

This section demonstrates a method for analyzing patient interaction needs. Recall that the principles—*(1) focus on desired interactions in which the patient is an active participant* and *(2) incorporate only those services that meet the expressed needs of patients or are validated against patient needs*—are intended to guide the process of eliciting patients' desired interactions and mapping these to e-health services. Both principles require e-health developers to interview representative patients. Interviews may be conducted with individual patients or in facilitated focus groups. In both settings, the key objectives are (1) to establish what participants the patient desires to interact with regarding his or her own health care and (2) to list the specific types of interaction the patient needs to perform with each participant. A third objective is to discuss specific e-health services that could meet each interaction need and assess the patients' evaluations of these. This discussion typically is conducted at the end of the interview or focus group session.

The sample patient interaction chart shown in Table 1 illustrates results of a completed interview in which each of the objectives is represented by a column. Column 1 identifies the desired participants (other than the patient) involved in health care interactions. Column 2 describes the interaction need, and column 3 maps that interaction need onto an e-health service. Note that in several cases interactions map to the same type of e-health service. For example, most interactions that access generic information can be satisfied by linking to appropriate static Web pages (i.e., Web links). Other services may be shared, assuming that e-health interconnects with the specified other participant. Making

Table 1. Sample patient interaction chart

Other Participant	Interaction Need	E-Health Service
Self	Manage health information	Personal health record
	Set up and receive personal health reminders	Reminder system
Other patients	Participate in peer support groups	Discussion lists
Physicians and clinical staff	Access electronic medical record (EMR)	EMR interface
	Communicate with physicians and staff	Online mail
	Receive reminders and office visits follow-up	E-health mail
	Connect for remote diagnosis and monitoring	Instrumentation interface
	Order prescription refills	Prescription manager
	Request referrals	Referral request
Provider administration	Schedule appointments	Appointment scheduler
	Manage co-pays and financial accounts	Payment center
	Communicate with administrative staff	E-health mail
	View provider's promotional and educational materials	Web links
Pharmacies	Manage prescription ordering, delivery, and pick-up	Prescription manager
	Manage co-pays and financial accounts	
	Research medication instructions, side-effects, and	Payment center
	potential interactions	Online drug formulary
Supporting facilities (lab, rehabilitation center, in-home services, etc.)	View patient instructions and facility policies	Web links
	Schedule appointments	Appointment scheduler
	View test results	Web links
Employer health services	Manage health plan enrollment forms	Web links
	Research alternative insurers	Web links
	View employer's promotional and educational health materials	Web links
	Receive notifications of changes to health plan options	E-health mail
Insurers	Manage insurance forms	Insurance manager
	Manage financial accounts	Payment center
	Solicit pre-approvals for procedures and medications	Insurance Manager
	Research participating physicians	
		Web links
Governmental agencies	Manage school health forms	Web links
	Research government services	Web links
	Receive public health notifications and alerts	E-health mail

payments or sending/receiving health-related e-mail can be handled efficiently through a shared clearinghouse service, regardless of which other participants these involve.

It is important for developers to recognize that interaction participants and needs can vary widely among patients, depending upon socioeconomic class, health condition, and age. Patient needs should dictate how participants are categorized and what level of e-health services are provided. For example, geriatric patients who are dependent upon government programs may need detailed interactions with governmental agencies. In this case, the governmental agencies participant category in Table 1 may need to be expanded to represent several agencies.

Personal Health Informatics and Patient-Centered E-Health

Creating effective patient-centered e-health is an important goal, but as discussed previously, this goal faces numerous obstacles, including fears of financial disincentives and reduced work quality for outside parties who are called upon to participate. Key to these concerns is the current lack of a focused discipline in which creation of patient-centered e-health is a core responsibility. It will remain difficult to champion patient-centered e-health initiatives until such a discipline coalesces through establishment of training programs, identification of best practices, and development of a shared identity.

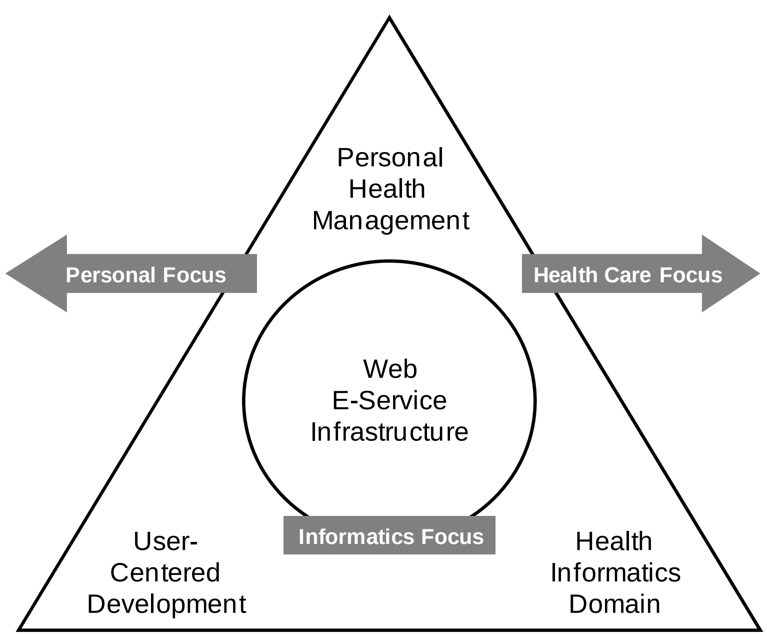
One training approach that satisfies the major goals and guiding principles of patient-centered e-health is the Personal Health Informatics (PHI) agenda proposed by Wilson (2006). PHI incorporates the knowledge, skills, practices, and research perspectives necessary to develop patient-centered e-health. As shown in Figure 1, four essential content areas support PHI, and these are applied within three focal areas. *Web e-service infrastructure* describes the hardware, software, and networking capabilities that support e-health functions. In recognition that e-health is primarily service-oriented, the *informatics focus* in PHI centers on infrastructure that is specialized for e-service presentation and delivery. *Personal health management* and *user-centered development* make up the *personal focus* that PHI presents to patients. User-centered development methods provide tools for eliciting user needs, designing solutions, and evaluating the utility of these solutions in meeting patients' needs. Personal health management addresses patients' individual practices as well as psychological, social, and cultural aspects of their management of personal health information. Personal health management and the *health informatics domain* combine in the *health care focus* of PHI. Content drawn from the health informatics domain addresses the skills and knowledge necessary to interface with HIS and related health care systems.

Development of a PHI discipline in which personnel train in these four essential content areas and share a joint focus on patients (personal), health care, and informatics would provide substantial leverage toward achieving effective patient-centered e-health. Patient surveys consistently show a groundswell of desire for e-health applications that meet patients' specific needs, including needs for electronic support for managing personal health information (Taylor, 2004), patient-physician communication (Taylor & Leitman, 2002), and high-quality online health information (Krane, 2005). Approaches such as PHI will be essential in concentrating the skills, knowledge, and patient-centered perspective that are necessary to meet these growing patient demands.

CONCLUSION

The emergence of e-health has been overwhelmingly beneficial to patients, who already conduct many types of transactions and information searches on the Internet and strongly wish to be able to access health care services and information in the same manner. I argued in this chapter that patients comprise a large and growing constituency of e-health users whose interests would be served by creating e-health from the patient's perspective. The guiding principles and interaction need

Figure 1. Conceptual model of key PHI structural components (Wilson, 2006)



analysis techniques I have outlined important steps toward achieving patient-centered e-health. However, there remains a need to develop an academic and professional discipline in which patient-centered e-health constitutes a core responsibility, as represented by the PHI agenda presented here.

KEY TERMS

Consumer-Centered e-Health: E-health applications created to generate profit through sales of products, services, and/or advertising.

e-Health: Health services and information delivered or enhanced through the Internet (Eysenbach, 2001).

Organization-Centered e-Health: E-health applications created to meet organizational needs and economic interests.

Patient-Centered e-Health: E-health applications created to support interactions that are desired and needed by patients.

Patient Interaction Needs: Interactions with other individuals or institutions that the patient desires and considers to be needed.

Personal Health Informatics: The knowledge, skills, practices, and research perspectives necessary to develop patient-centered e-health.

Provider e-Health: E-health applications supplied by a health care provider organization primarily for use by its own patients.

C

Critical Issues in Assessing Sustainability and Feasibility of E-Health

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

Santosh K. Misra
Cleveland State University, USA

INTRODUCTION

The cost of health care is increasing exponentially worldwide. The adoption and diffusion of e-health and the application of Internet and Communication Technology (ICT) in health care is growing at a rapid rate in an attempt to find cost-effective methods of providing quality health care. Both European and US governments are making e-health a priority on their agendas. However, few, if any, discuss the critical issues of the sustainability and feasibility of e-health models. We attempt to fill this critical void by presenting a macro framework that identifies the key components of a generic e-health system and identifying factors playing a role in the assessment of e-health sustainability.

BACKGROUND

During his State of the Union Address in January 2004, President George W. Bush affirmed the intention of the government to emphasize the role of technology in administration and delivery of health care in the United States (Bush, 2004). Similar sentiments have been voiced by European leaders (Global Medical Forum Foundation, 2005; Oslo Declaration on Health, 2003) and the World Health Organization (WHO) (e-health in eastern Mediterranean, 2005; A Health Telematics Policy, 1998). Both European and US authorities define their initiatives primarily in terms of medical information technology, centering on computerized patient records (CPRs) or, in more acceptable parlance, the EHR (electronic health record) (Brailer & Terasawa, 2003). WHO's platform statement (A Health Telematics Policy, 1998) speaks of a "health telematics policy," an all-inclusive term that incorporates not only EHR but also all health care services provided at a distance and based on the use of information and computer and communications technologies (IC^2T). Countries are now turning to various e-health solutions in order to stem the escalating costs of health care and yet provide superior health care delivery.

As any student of electronic business (e-business) knows, a number of dot.com companies went out of business in the early 2000s. Going out of business is also a fairly regular phenomenon in the brick and mortar world. Health care organizations have not escaped this "going out of business" problem. It is expected that e-health will face similar going out of business issues. At the same time, many businesses, including many health care organizations, have maintained continuity of profitable operations, and it stands to reason that e-health organizations can also do the same. Sustainability of businesses has been studied extensively by management theorists. However, to date, few studies, if any, have attempted to assess the sustainability and feasibility of e-health.

In this chapter, we attempt to study the sustainability of e-health. For this, we draw from our work on assessing the sustainability and feasibility of e-business models in general (Sharma, Wickramasinghe & Misra, 2002). Our proposed sustainability macro model also builds on our previous work in identifying the competitive forces facing e-health (Wickramasinghe, Misra, Vogel & Jenkins, 2006).

IDENTIFYING KEY ISSUES OF SUSTAINABILITY IN E-HEALTH

E-Business Models

The prime objective of a business model is to ensure that the organization is profitable (La Monica, 2000). E-businesses that offer products and services online must work efficiently and effectively to create profit margins. E-businesses, like any business, can compete in the marketplace by differentiating their products and services from their competitors and by providing unique and better customer value. A product or service can be differentiated if customers perceive some value in the firm's products and services that competitors cannot match. Differentiation also can be done by offering different product features, timing, location, service, product mix, and linkages among functions (Afuah & Tucci, 2000). One can judge the customer value by examining whether a firm is offering its customers something distinctive at a cost the customer is willing to pay, and whether the combination of distinctiveness and price is a better value than provided by the firm's competitors. The success of the business model would then depend upon how the firm sets a price for the value offered.

Pricing and profitability are factors of market shares and margins. A good business model can strive for high market share and devise strategies to maintain the market share. The cost and asset model of a firm also influences the product pricing decisions. The cost (fixed cost + variable cost) should be spread out in an appropriate fashion in order to maintain positive profit margins. For electronic businesses, profit margin is not only derived from product sales but also from many other revenue sources. Such revenue sources may include banner advertising, membership, and referral fees. In addition, a firm can have significant competitive advantage if it offers products and services that cannot be imitated easily. The sustainability of a firm can be judged by examining issues associated with maintaining and improving the firm's market share as well as sources of its competitive strength. For example, using a simple profit equation (Profits=(P-Vc)Q-Fc+OthRev), we can examine how each of the components of a business model impacts profitability. If a firm offers distinctive products, it can charge a premium price P and increase the margin. The firm also can increase profit by reducing the variable cost Vc by increasing the market share Q and other revenues (OthRev) such as banner advertising fees (Afuah & Tucci, 2000).

E-Health Business Model

Our previous work (Figure 1) (Wickramasinghe et al., 2006) (1) has served to map the key components of an e-business model into the health care domain. Specifically, this model incorporates all the key actors of health care, including suppliers, health care organizations, providers, regulators, payers, and, of course, the patient. It is important to note that the dynamics of health care are quite unique (Gargeya & Sorrell 2004; Wallace, 1997; Wickramasinghe et al.,

Figure 1. E-health business model components

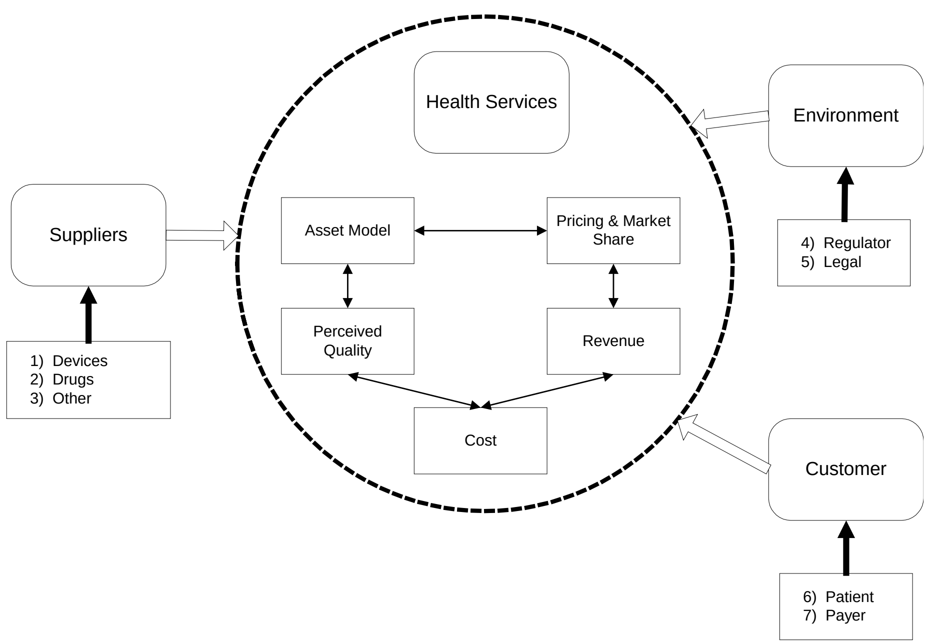

Table 1. Key areas of sustainability

Competitive Positioning	Product/Service Competition and Industry Structure Health care Consumer Value
Economic Positioning	Revenue Model Cost Model
Enterprise Resource	Asset Model People and Partners Processes Technology

2006) and that health care delivery by its very nature necessitates people-to-people interactions. E-health not only requires a physical organization (the brick-and-mortar component) but also a supporting e-health network. This idea of a netcentric perspective to health care already has been established by von Lubitz and Wickramasinghe (2006). Given the netcentric nature of e-health, sustainability of e-health is essentially the sustainability of the e-health network. We consider this distinction to be especially important since there is a near universal move to embrace various e-health initiatives in an attempt to offer superior, cost-effective health care delivery.

Key Elements of Sustainability

In an elementary sense, an enterprise is sustainable when it can maintain a stream of profit over a long period of time. As shown in the case of e-business, sources of profit are many and can be summarized into three primary areas: competitive positioning, economic positioning, and enterprise resources of a business (Afuah & Tucci, 2000; Wickramasinghe et al., 2006). Table 1 identifies a few of the important factors that influence each of these key areas. We argue that any sustainability model must take all these areas and their contributing factors into consideration (Sharma et al., 2002).

In addition, it is also prudent to consider health care service demand as a key area. If the demand for health care services through e-health does not exist or is very small, then an e-health network would find it much more difficult to sustain itself.

In Table 2, we examine in more details some of the primary components of the key areas: demand, revenue, cost, and asset.

E-Health Sustainability

Figure 2 proposes a macromodel for an e-health network's sustainability. The model components shown in Table 2 are mapped into the model of Figure 2. The macromodel of Figure 2 also shows interdependence among model components.

An e-health network can be sustained if it can maintain positive revenue margin. Other key measures of sustainability include market share, retained earnings, and growth rate. A positive margin is generated when revenues exceed cost. As we have shown in Table 2, there are many potential sources of revenue as well as many different cost drivers. The demand for e-health services is potentially global and has a significant impact on the revenue stream. The asset model as well as the cost model of e-health impact the products and services of the e-health network. Finally, the asset, cost, and revenue models themselves benefit from the positive revenue and market shares.

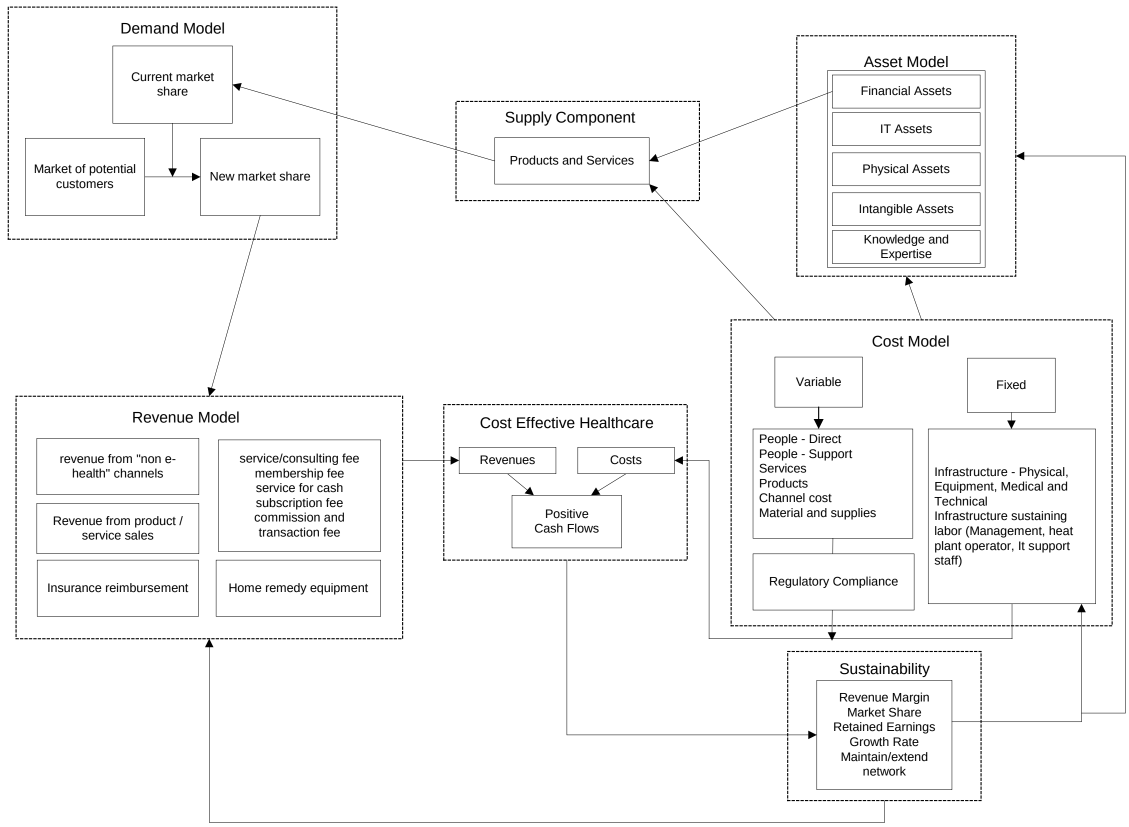
FUTURE TRENDS

Our e-health sustainability model in Figure 2 has many significant implications to health care. First, it is important to note that e-health sustainability links to sustainability of the country's health care model. This means that any e-health initiative must be considered within the context of the health care polices and structures of that country. The e-health sustainability model underscores the importance of e-health as providing a network for which superior cost-effective health care delivery can ensue. Moreover, the e-health sustainability model represents a macro sustainability model, and it is critical that in the development of any e-health initiative, a holistic systems perspective is adopted. Within this

Table 2. Key model components for assessing sustainability (adapted from Sharma et al., 2002)

Model Component	Description
Demand	
Demand Type	
Current Market Share	The market share enjoyed in a pre- e-health network state. An existing organization would have a market presence that defines the baseline from which growth can occur due to e-health.
Market of Potential Customers	The larger market that can be realized
New Market Share	The market share that results from entry into e-health segment of health care. This growth should occur since a health care consumer would be able to benefit from a complementary channel of service delivery. For those organizations with a brick-and-mortar presence, e-health is an additional channel; for purely e-health networks, any gain in market share is new market share.
Revenue	
Revenue Type	
Product or Services Sales	The revenue from the sales of goods or services.
Advertising	The fee for hosting other companies' advertisements
Subscription Fee	The fee from subscriptions to receive certain products or services
Membership Fee	The fee for memberships in interest groups
Commissions or Transaction Fee	The transaction fee or commission as an agent or broker for facilitating the selling of partner organizations' products and services
Insurance Fee	Reimbursement from insurance providers for services rendered
Cost	
Cost Type	
People	Salaries and other benefits of employees and consultants. This includes cost of hiring, developing, and training as well as operational costs.
Advertising or Marketing Expenses	Cost for identifying health care consumers and markets. This cost also includes all channel costs to deliver nonelectronic services.
Commissions or Transaction Fees Cost	Paying commissions or transaction fees to agents or brokers who are selling a company's products and services
Material and Supplies	Cost to procure materials and supplies
Physical infrastructure	Cost for facilities, equipment, buildings, utilities, etc.
IT Infrastructure	Cost of computer setup, network costs, Internet subscription, development costs, and operating and maintenances costs
Asset Model	
Asset Type	
Financial Assets	Balance sheet, cash flows
Physical Assets	Plants, equipment, etc.
IT Assets	Information technology infrastructure
Intangible Assets	Relationships with partner organization, agility and strength of brand, etc.
Intellectual Assets	Knowledge and expertise of key participants, patents and copyrights, tacit knowledge.

Figure 2. Macromodel of sustainability



network, each player who contributes to the network supplier, health care organization, provider, or payer must then look at its own organization's micro sustainability model, while the patient must make judicious and informed choices for the specific care treatment; the role of the regulator should be that effective governance of this system is maintained at all times.

The model presented in Figure 2 is a generic business model applicable to many e-health business scenarios. At this point, we have not made any distinction in terms of an e-health organization that operates as a stand-alone virtual organization or as an additional channel to an existing health care entity. While we argue that the sustaining factors would be present in both of these groups of e-health, we believe the intensity of contribution would be significantly different based on organizational structure for a specific e-health entity. In addition, we hypothesize that a trust and reputation relationship would play a significant role in the long-term sustainability of an e-health organization, even though this role is implied within the intangible asset and knowledge/expertise components of the asset model defined in Figure 2. In our opinion, these issues require further exploration.

CONCLUSION

Business sustainability is not a new concept. It has been studied by management theorists for a long time. The structure of an e-health network has many unique features not ordinarily associated with a typical business. Nevertheless, an atypical business such as e-health must still be sustainable. In this chapter, we analyze the factors that play a role in sustaining this atypical organization. A macromodel is proposed. Components of this model are identified, and their interdependence is mapped. Such a model is important as countries and health systems try to incorporate various e-health initiatives and also as health care infrastructures are rebuilt after devastation; for example, the tsunami affected countries of the Indian Ocean, or war affected countries such as Iraq.

We propose to refine this model in our future studies. We also propose to derive empirical relationships among model components so that predictive measures for sustainability of e-health can be developed.

KEY TERMS

Asset Model: Components of business model that define the assets owned by the business entity.

Cost Model: Components of business model that define the cost sources for the organization.

Demand Model: Components of business model that define the customer needs and wants.

E-Health: The offering of health care products and services using Web-based technologies.

E-Business Model: A business model where either the product or process or selling agent is partially or completely electronic.

Intangible Asset: Assets such as goodwill, reputation, and brand recognition.

Revenue Model: Components of business model that define the sources of revenue for the organization.

Sustainability: The long-term survivability of the business entity.

Critical Role of Bionanotechnology in Healthcare and Society

Shivani Choudhary
Illinois Institute of Technology, USA

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

Eliezer Geisler
Illinois Institute of Technology, USA

INTRODUCTION

Bionanotechnology is a combination of three terms: "bios" meaning "life," "nano" (origin in Greek) meaning "dwarf," and "*technologia*" (origin in Greek—comprised of "*techne*" meaning "craft" and "*logia*" meaning "saying"), which is a broad term dealing with the use and knowledge of humanity's tools and crafts. Bionanotechnology is a term coined for the area of study where nanotechnology has applications in the field of biology and medical sciences.

Healthcare is defined by the Oxford Dictionary as the "care for the general health of a person, community, etc., especially that is provided by an organized health service." Moreover, *Healthcare* can also be defined as the prevention, treatment, and management of illness and the preservation of mental and physical well-being through the services offered by the medical, nursing, and allied health professions[1].

BACKGROUND

The healthcare industry is one of the world's largest and fastest-growing industries[2]. However, since ages the gravest dilemma of the healthcare system has been its soaring costs. Healthcare forms a major part of a country's economy by consuming over 10 percent (Figure 1) of gross domestic product (GDP) of most developed nations. In 2003, healthcare costs consumed 15.3%[3] of the GDP of the United States, the largest of any country in the world. In 2001, for the Organisation for Economic Cooperation and Development (OECD) countries the average was 8.4%[4] with the United States (13.9%), Switzerland (10.9%), and Germany (10.7%) being the top three (See Appendix A).

Figure 1. U.S. healthcare costs[3]

1950	$12.7 billion	4.5 percent
1965	$40 billion (est.)	6 percent
1980	$230 billion	9 percent
2000	$1.2 trillion	14 percent

At present, the U.S. healthcare system has three prime goals: the provision of high-quality care, ready access to the system, and reasonable costs. Therefore, discovering or inventing new ways which would offer effective and efficient quality healthcare treatment is becoming a main concern, not only in the U.S., but also worldwide, as the expenditure in healthcare is increasing exponentially (Wickramasinghe, Choudhary, & Geisler, in press).

ROLE OF BIONANOTECHNOLOGY IN HEALTHCARE

Bionanotechnology deals with nanomaterials and their applications in life sciences. Bionanotechnology being one of the most promising and growing industry today, a large amount of work that is being carried out in this area. Bionanotechnology is currently in its prime with researches being carried out all over the globe in this field. The applications[5,6] of bionanotechnology are vast. The following outlines what is currently being done in this field:

- **Dendrimers:** (Svenson & Tomalia, 2005) It can act as a good *drug delivery agent* as well as a *time-release delivery agent*. It is normally used in therapeutic developments which are targeted to cancer cells (Baker, 2003). Dendritic polymers are also used for the development of nanosensor/NEMS systems for noninvasive, continuous monitoring of astronauts for the biologic effects of space travel.

- **Gold nanoshells:** They are nanoparticles made of silica (glass) which are completely coated with gold (Ha, Jeong, & Chung , 2005; Jain, 2005). Researchers are trying to make use of gold nanoshells for the detection as well as treatment of cancerous cells.
- **Patient-specific medicine:** (Baba, 2006) Personalized medicine or Patient-Specific medicine simply means the *prescription of specific therapeutics best suited for an individual*. Xiaolian Gao, professor of chemistry, has developed a chemical process for building a device that could help doctors predict a patient's response to drugs or screen patients for thousands of genetic mutations and diseases, all with one simple lab test—on a DNA chip. The ultimate vision of this research is the development of Patient-specific medicine.
- **BioNanosensors[7]:** Researchers in many universities and R&D laboratories are trying to develop sensors based on nanotechnology which, when implanted under the skin of a human being, will be able to detect the level of glucose, hormones or cholesterol. Nanosensors (Clark, Singer, Korns, & Smith, 2004; Jain, 2005; Kohli & Martin, 2005; Kvennefors & Persson, 2004) can play a vital role in the treatment of genetically-based diseases like sickle cell anemia, due to their characteristics of have high sensitivity and specificity.
- **Smart drugs[8,9]:** Drugs when injected inside the human body will be able to predict the specific location where the human cells have been contaminated, and then release a precisely targeted drug dose (Peppas et al., 2004).
- Biochemist Susan Hardin and four University of Houston colleagues are developing a new technology for direct molecular sensing that could be used to sequence an individual's entire genome—the gathering of all the genetic information contained in a person's DNA—in less than 24 hours, rather than 2–3 days.
- **Quantum dots[10]:** "Quantum dots" are nanoparticles made out of semiconductors having unique electrical and optical properties (Jiang, Papa, Fischer, Mardyani, & Chan, 2004; Jain 2005; Chan, 2006; Weng & Ren, 2006). They are specifically used for *imaging purpose* inside the human body. They demonstrate extremely high sensitivity.
- **Silver nanoparticles:** As the term suggests, they are nanoparticles derived from the silver atom. A study conducted by the University of Texas and Mexico University found that silver nanoparticles can kill HIV-1, and is likely to kill virtually any other virus.
- **Regenerative medicines:** (Emerich & Thanos, 2003; Rajangam, Behanna, Hui, Han, Hulvat, Lomasney, & Stupp, 2006; Yamato & Okano, 2006) Regenerative medicine helps natural healing processes to work faster, or uses special materials to regrow missing or damaged tissue. Scientists at Northwestern University are working towards the development of regenerative medicines. They have successfully *grown nerve cells* using an artificial three-dimensional network of nanofibers. They have also developed a liquid that forms a gel-like mass of nanofibres on contact with water, which could provide the most promising vehicle yet for the *regeneration of damaged spinal cords*. Many scientists working in the area of regenerative medicine are trying to develop *artificial scaffolds* that store or attract cells, and then control their growth and final identity.

With such great applications, bionanotechnology can help in the reduction of the soaring costs of healthcare. It can help the healthcare system in the production of better and smarter drugs. Expenditures can be highly reduced along with the improvement in the quality of healthcare by the inventions of smaller devices for healthcare purposes and better surgical interventions. Moreover, with faster curing time, the number of days a patient would have to stay in a hospital will lessen significantly, resulting in lower costs of healthcare.

Although most bionano products are currently under research or production, there number has been increasing exponentially in the market. Some of the bionano products that are currently available in the market are *Abraxane* developed by Abraxis Bioscience[11], *M-DNA* developed by Advance Technologies[12], *PuraMatrix*[13] is 3DM Inc.'s patented product line of synthetic self-assembling peptide hydrogels invented at MIT, *Opticell* developed by Bio Crystal Ltd.[14], *Nanosensors and NanoBiosensors* being developed by Bionano International Singapore Pte Ltd.[15], *The Verigene™ System* by Nanosphere[16], *Quantum Dots* by Evident[17], *Nanodisc*[18] developed by Nanodisc Inc., and many more. With such bionano products in the market, and more to be made readily available with the next three to five years of time frame, bionanotechnology shows a tremendous potential in lowering down the costs of healthcare system.

BIONANOTECHNOLOGY AND SOCIETY

In terms of bionanotechnology, the society has been divided into two major categories: one fraction of the society considers that bionanotechnology can prove to be a great benefit to mankind, while the other part raises issues and concerns relating to safety, moral, social, legal, and ethical behavior. Some of the major concerns[19] related to bionanotechnology are discussed below.

- *Will we be able to differentiate at nanoscale?* This is a very important issue raised by the advent of nanotechnology. How will we be able to distinguish between an infected cell and a good cell in our body at nanoscale where everything looks the same? According to Dr. Kevin FitzGerald:

  "We cannot easily define what a disease is at nanoscale. The same genetic sequence may be considered a mutation in one context and merely a difference or polymorphism in another context[…]Bionanotechnology is so reductionistic in this sense that one can even lose the biological concepts of health and disease when focusing on this scale alone."

- *Once in the body, can nanoparticles evade natural defenses of humans and other animals?* What is the likelihood of immune system recognition of nanomaterials? According to Dr. William Hurlbut, nanoparticles might have a subtle effect on the body that we should try to be attentive to. They might interact with basic cell mechanisms, block up pores or passages and change the mechanical forces that influence cell differentiation. Alterations at such a fundamental level of growth and development could have adverse consequences that remain unrecognized for years.
- *Where do we stop?* (Connelly, 2005) It has been brilliantly described by Dr. E. Geisler in his book—*Creating Values With Science & Technology*[20]—that once the Pandora's Box has been opened, it becomes impossible to put the evils back inside the box, meaning that it is impossible to reverse the advancements in the field of science and technology, and so is the case with bionanotechnology. Hence, we need to take care of what we are developing else the consequences can be disastrous.
- *Will genetic modifications that increase sustainability breech our current definition of being "human?"*[21] Humans by nature are supposed to be mortals while machines are considered to be immortals. Thus, by using devices and procedures to indefinitely lengthen human life are we not going to turn humans into machines? Dr. Nilmini Wickramasinghe thinks that Bionanotechnology can surmount the nature's rule of "survival of the fittest in the animal world." She gave an example of a premature baby who, according to nature, is suppose to perish, but because of various medical facilities, can easily survive. This is neither good for the baby nor for the nature's phenomena.
- How will liability and criminal statuses apply to the misuse of nanotechnology innovations?
- *Will it be just another way for rich nations to get richer, or should we take steps now to ensure the developing and underdeveloped countries can participate?* The technology required to genetically "improve" a human being is not going to be inexpensive. According to Dr. FitzGerald, as this technology will be very expensive, certainly at its inception, it will be primarily available to the wealthy to use it to their own benefit. In this way the gap between the "have"s and the "have-not"s will become even greater. So, *is bionanotechnology going to be the tool of the rich?* Also, there is already a wide divide between the various nations of the world, thus it can be an ethical concern to prevent the global "nanodivide" from further contributing to uneven power and wealth distribution.
- *Questions relating to privacy of an individual.* Imagine tiny sensors traveling through your bloodstream, sending constant signals to nearby

computers which relay information about you to your doctor, attorney, local fire or police station, grocer, creditor, or financial institution.[22]

- At present, very little is known about the *health and environmental effects of bionanotechnology* (Preston, 2005). The eventual proliferation and use of nanotechnology could cause unintended consequences, such as the creation of new classes of toxins or related environmental hazards[23]. According to Mr. Sourabh Bansal, MS student at Illinois Institute of Technology:

  "Regular use of bionanotechnology esp. bionanorobots in humans can decrease the immunity of our coming generations towards diseases as their cure will become highly dependent on bionanotechnology. The count of white blood cells in a human body will most likely extinct gradually due to the excessive use of bionanotechnology for curing purposes."

- Who should define these as needs, or judge whether the expense of research is better spent on other ends?

Moreover, some great scholars also believe that bionanotechnology is being greatly hyped. Among them is Dr. Michele Mekel, Associate Director at Institute on Biotechnology & the Human Future, IIT Chicago. According to her, *"nanobiotechnology's biggest problem is 'hype'"*. She believes, *"It has been hyped so much that it may fail. People are destined to be disappointed."* Moreover, Dr. Mekel also said, *"Companies are trying to capitalize 'nano' as a brand."* However, according to Dr. FitzGerald:

Nanotechnology is being hyped because the hype helps to generate more funding. It is good to inform the public about this hype because this situation raises important fundamental questions about the relationship between science and technology development and the public trust.

In addition, Mr. George Kimbrell, Staff Attorney at the Intenational Center for Technology Assessment and the Center for Food Safety, considers nanotechnology as a *"New Wonder Technology."* He said:

There has been cultural amnesia about stuff in the past, this is not the first time. Every time we discover something new it is always hyped[…]This area of nanotechnology is the least researched and regulated. There has been no cost benefit analysis and a significant amount of hype.

In spite of such intense arguments concerning the consequences of bionanotechnology, there is still another section of the society which believes that, if used wisely, bionanotechnology can open doors to great inventions and discoveries, which can help not only reduce the costs of healthcare, but also highly improve the quality of life of a human being. One such scholar who believes that bionanotechnology can prove to be a boon to mankind is Mr. Nik Rokop, President and CEO, nLake Technology Partners, LLC. According to him, *"Historically, people are skeptical of changes."* He stated a brilliant example of nuclear technology. When it was being discovered, there was a huge concern about its affects. However, as we see now nuclear science provides us with nuclear energy as the unlimited source of energy which is truly remarkable. According to Mr. Rokop, people do not really know much about what is really happening in the field of nanobiotechnology, and are hence making assumptions. He said, *"Discussions should be based on facts and not emotions."* When asked if it is correct to mutate a human being he promptly replied, *"Nature creates mutation in the form of evolution which is created due to the presence of certain external factors. A world with no technological progress is nothing but Stone Age. I would not like to be a part of such world."*

Dr. Jialing Xiang, assistant professor of Biology, IIT Chicago, also considers nanobiotechnology as a benefit to human society, due to its focus on detection and increase in sensitivity. She said, *"There is no problem if this technology is solely used for nano level detection. It is a very powerful tool, like an electronic microscope, which can give the minutest of the details inside a human being and help in the early and effective diagnosis of a disease."*

According to Dr. Ruthanna Gordon, assistant professor, Institute of Psychology, IIT Chicago, *"claiming all positive or negative effects of a particular technology is silly."* Hence, we need to understand that there is *nothing intrinsically good or bad about a technology, it all depends on how it is used*.

CONCLUSION

Nanotechnology shows a tremendous potential for exceptional works in the area of medicine and biotechnology. This area of nanotechnology which deals with biology and life sciences is also known as bionanotechnology. In future, bionanotechnology can help in the early and effective diagnosis of various diseases like cancer, Alzheimer's, and so on.

We discussed some of the most prominent and researched applications of bionanotechnology like dendimers, personalized medicines, bionanosensors, regenerative medicines, quantum dots, gold nanoshells, silver nanoparticles, smart drugs, and so on. Moreover, we also mentioned a number of products that are currently available in the market based on bionanotechnology. In addition, as discussed above bionanotechnology can also prove to be an excellent tool for the reduction in cost of healthcare industry as it can provide us with better and effective drugs, smaller devices, and better surgical interventions.

Discussions above also describe the views of the two divisions of the society in case of bionanotechnology. The ethical, social, moral, and legal concerns and issues of bionanotechnmology are also discussed, along with valuable opinions from various prominent scholars across the United States.

ACKNOWLEDGMENT

The authors would like to acknowledge the contributions of George Kimbrell (International Center for Technology Assessment[25]), Jialing Xiang (Assistant Professor, Illinois Institute of Technology), Kevin FitzGerald (Georgetown University), Michele Mekel (Institute on Biotechnology & the Human Future), Nik Rokop (nLake Technology Partners, LLC), Ruthanna Gordon (Assistant Professor, Illinois Institute Of Technology), Sourabh Bansal (MS Student, Illinois Institute of Technology), William B. Hurlbut (Stanford University Medical Center).

KEY TERMS

Drug Delivery Agent: Drug delivery agent is a medium which facilitates in the delivery of a pharmaceutical compound to humans or animals.

Healthcare Costs: Cost paid to hospitals, physicians, nursing homes, diagnostic laboratories, pharmacies, medical device manufacturers, and other components of the healthcare system.

Nanosensors: Nanosensors can detect either minute particles or miniscule quantities of something.

Nanobiosensors: Nanobiosensors are capable of penetration and location at specific sites within single living cells, which is made possible through developments in nanobiotechnology.

Nanoshell: A spherical core consisting of a particular compound, which is surrounded by a shell of a few nanometer of thickness.

Nanoparticles: A microscopic particle whose size is measured in nanometres (nm). It is defined as a particle with at least one dimension <100nm.

Society: An organized group of persons associated together for religious, benevolent, cultural, scientific, political, patriotic, or other purposes.

C

Critical Success Factors for Delivering M-Health Excellence

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

Steve Goldberg
INET International Inc., Canada

INTRODUCTION

Medical science has made revolutionary changes in the past decades. Contemporaneously, however, health care has made incremental changes at best. The growing discrepancy between the revolutionary changes in medicine and the minimal changes in health care processes is leading to inefficient and ineffective health care deliver and one, if not the most significant, contributor to the exponentially increasing costs plaguing health care globally.

Health care organizations can respond to these challenges by focusing on three key solution strategies (or the value proposition): (1) access—caring for anyone, anytime, anywhere; (2) quality—offering world-class care and establishing integrated information repositories; and (3) value—providing effective and efficient health care delivery. These three components are interconnected such that they continually impact the other, and all are necessary to meet the key challenges facing health care organizations today.

The application of mobile commerce to health care (i.e., m-health) appears to offer a way for health care delivery to revolutionize itself. However, little if anything has been written regarding how to achieve excellence in m-health. This chapter serves to address this major void by presenting an integrative framework for achieving m-health, developed through the analysis of longitudinal applied research conducted by INET in conjunction with academia. After presenting this framework and discussing its key inputs, we then illustrate how the mapping of case data to the model enables the attainment of a successful m-health application to ensue and the benefits of adopting such a methodology.

BACKGROUND

Currently, the health care industry in the United States as well as globally is contending with relentless pressures to lower costs, while maintaining and increasing the quality of service in a challenging environment (Blair, 2004; European Institute of Medicine, 2003; Frost & Sullivan, 2004; Kulkami & Nathanson, 2005; Kyprianou, 2005; Lacroix, 1999; Lee, Albright, Alkasab, Damassa, Wang & Eaton, 2003; National Coalition on Healthcare, 2004; National Center for Health Statistics, 2002; Organisation for Economic Co-operation and Development (OECD), 2004; Pallarito, 1996; Plunkett, 2005; Russo, 2000; Wickramasinghe & Silvers, 2003; World Health Organization Report, 2000, 2004). It is useful to think of the major challenges facing today's health care organizations in terms of the categories of demographics, technology, and finance. Demographic challenges are reflected by longer life expectancy and an aging population; technology challenges include incorporating advances that keep people younger and healthier; and finance challenges are exacerbated by the escalating costs of treating everyone with the latest technologies. Health care organizations can respond to these challenges by focusing on three key solution strategies: (1) access—caring for anyone, anytime, anywhere; (2) quality—offering world-class care and establishing integrated information repositories; and (3) value—providing effective and efficient health care delivery. These three components are interconnected such that they continually impact the other, and all are necessary to meet the key challenges facing health care organizations today.

In short, the health care industry is finding itself in a state of turbulence and flux (European Institute of Medicine, 2003; National Coalition on Healthcare, 2004; Pallarito, 1996; Wickramasinghe & Mills, 2001; World Health Organization Report, 2000, 2004). Such an environment is definitely well suited for a paradigm shift with respect to health care delivery (von Lubitz & Wickramasinghe, 2005). Many experts within the health care field agree that m-health appears to offer solutions for health care delivery and management that serve to maximize the value proposition for health care. However, to date, little if anything has been written regarding how to achieve excellence in m-health. This chapter serves to address this apparent void.

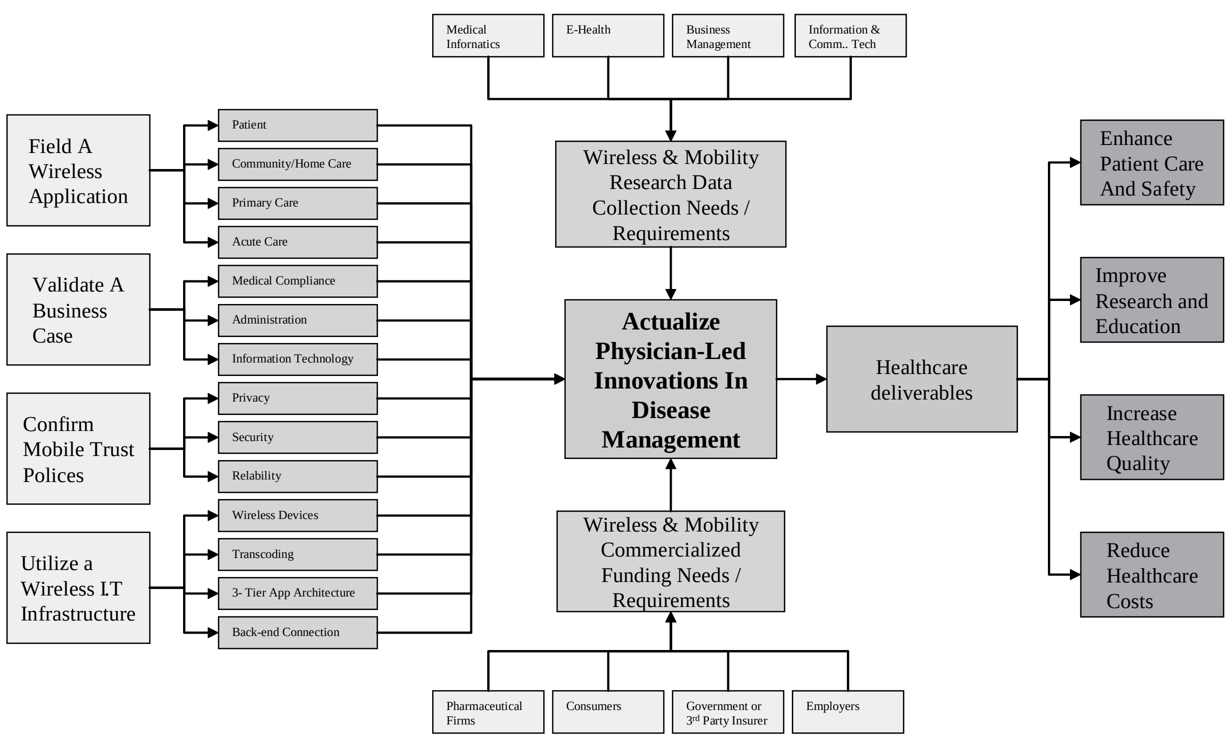
INTEGRATIVE MODEL FORM-HEALTH

Successful m-health projects require consideration of many components. Figure 1 provides an integrative model that serves to capture all the key factors we have identified through our research. What is highlighted by this figure is the need to address many aspects in order to achieve m-health excellence upon which we now expand.

Web of Players

The first consideration is the people component. Any health care initiative, be it wired or wireless, must first and foremost be aware of all key actors involved in the delivery of health care. It is useful to think of these various actors as a web of players, because they interact at different levels and degrees, depending on the specific action or procedure. Figure 2 depicts the web of players that must be considered for health care in general and m-health in particular. From this figure, it is possible to see that m-health requires input and coordination between and within suppliers, payers, health care organizations, providers, regulators, and the patient, if excellence is to truly ensue. Further, all these players are represented in Figure 1, where their specific roles regarding any m-health project are also

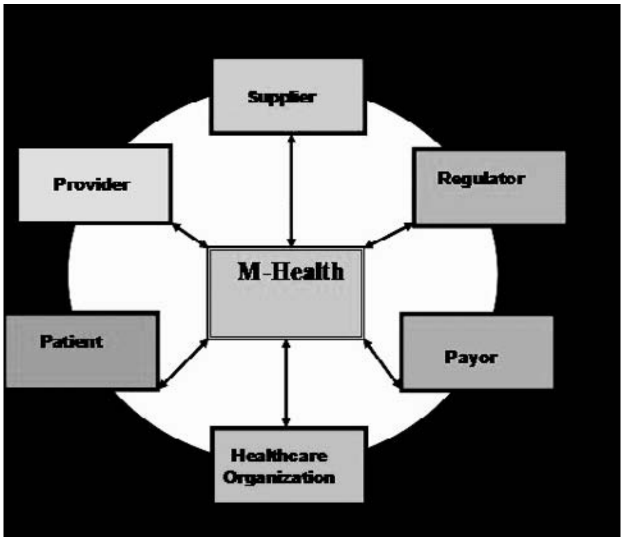
Figure 1. A mobile e-health project delivery model



* Information and Communication Technology

© Goldberg & Wickramasinghe, 2004

Figure 2. Web of healthcare players (Adapted from Wickramasinghe, et al., 2005)



noted. For example, patients, providers, and health care organizations are among the primary inputs, while payers and regulators as well as various suppliers are modifiers to the process of actualizing the physician-led solution.

IT Architecture

The next important consideration is concerned with the existing IT infrastructure and architecture. Any m-health solution must leverage off existing IT architecture, wired and wireless, at the respective locations of the web of key players. Typically, in today's technocentric world, this involves understanding the client-server computing paradigm as depicted in Figure 3. To support such a client-server architecture, special attention must be paid to the ICT infrastructure. The ICT infrastructure includes phone lines; fiber trunks and submarine cables; T1, T3, and OC-xx; ISDN, DSL, and other high-speed services used by businesses as well as satellites; earth stations; and teleports. A sound technical infrastructure is an essential ingredient to the undertaking of e-health and m-health initiatives. Such infrastructures should also include telecommunications, electricity, access to computers, number of Internet hosts, number of ISPs (Internet Service Providers) and available bandwidth and broadband access. Such IT infrastructure and architecture components form a key input into the designing and development of any m-health project, as can be seen in Figure 1.

IT Architecture and Standard Mobile Environment

By adopting a mobile/wireless health care delivery solution, it is possible to achieve rapid health care delivery improvements, which impact both the costs and the quality of health care delivery. This is achieved by using an e-business acceleration project that provides hospitals a way to achieve desired results within a standardized mobile Internet (wireless) environment. Integral to such an accelerated project is the ability to build on the existing infrastructure of the hospital. This then leads to what we call the three-tier Web-based architecture (Figure 4).

In such an environment, Tier-1 is essentially the presentation layer, which contains the Web browser, but no patient data are stored within this layer, thereby ensuring compliance with international security standards/policies such as HIPAA. Tier-2 then, provides the business logic, including but not limited to lab, radiology, and clinical transcription applications; Messaging of HL7, XML, DICOM, and other data protocols and interface engines to a Hospital Information Systems (HIS); Lab Information Systems (LIS); Radiology Information Systems (RIS); as well as external messaging systems such as Smart Systems for Health (an Ontario Health care IT infrastructure project). Finally, there is the Tier-3 architecture, which consists of back-end databases like Oracle or Sybase.

Figure 3. IT architecture (adapted from Wickramasinghe et al., 2005)

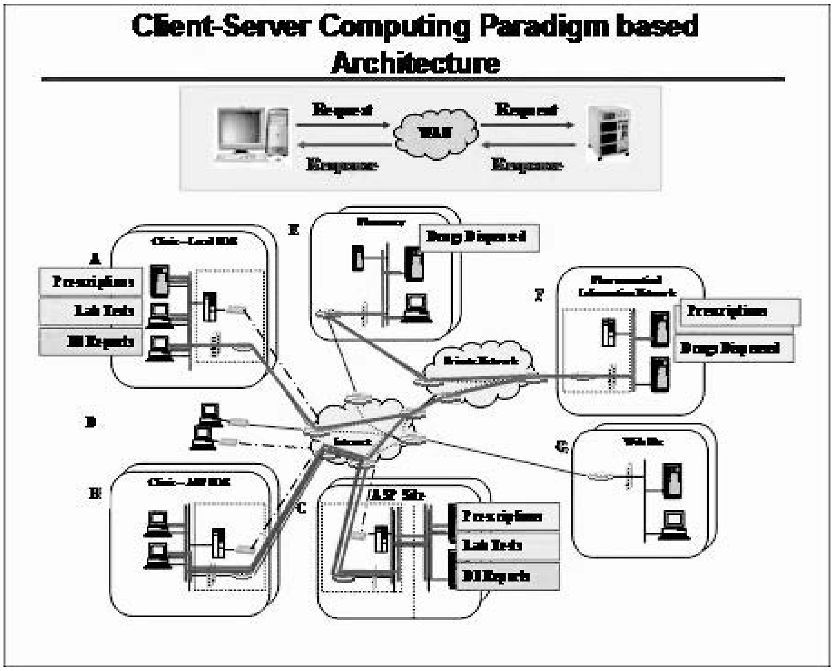


Figure 4. A Standardized Mobile Internet (wireless) Environment

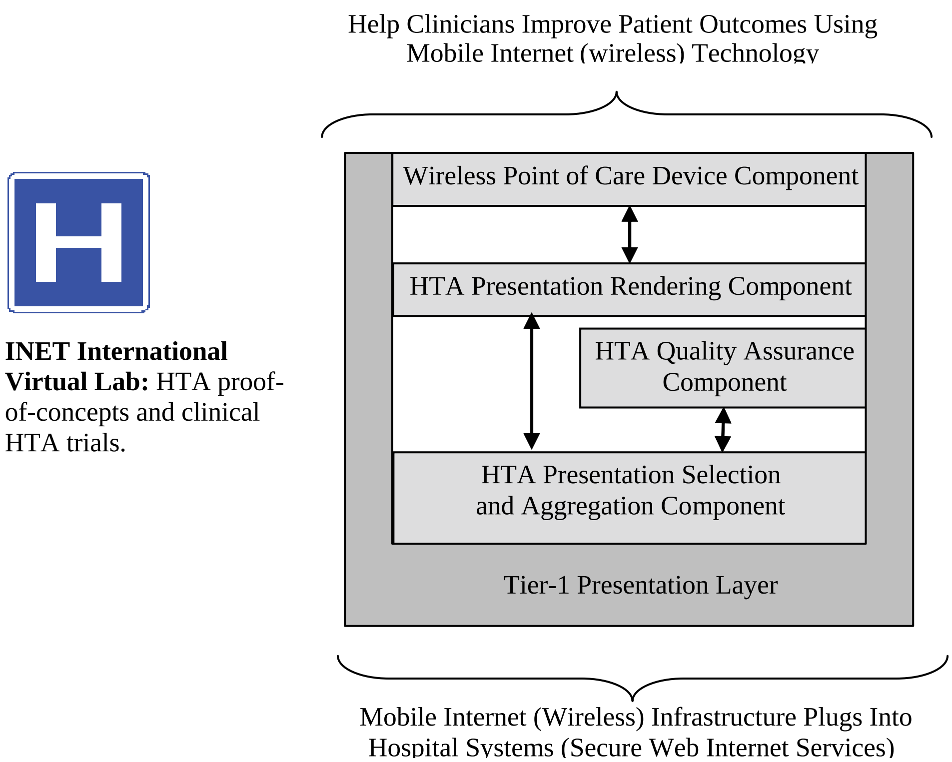

C

Security and Regulatory Conformance

The third primary input in Figure 1 is concerned with security, privacy, and reliability issues. Given the nature of health care data adherence to adequate standards, in this regard it is imperative to the ultimate success of m-health delivery. In the United States, security, privacy, and standards for electronic submissions and exchange of health care information are covered by HIPAA (the Health Insurance, Portability and Accountability Act) (2001) (Fadlalla & Wickramasinghe, 2004; Moore & Wesson, 2002). It is useful to conceptualize this as a HIPAA triangle (Figure 5), which highlights the fundamental elements of the HIPAA regulation; namely, security, transaction standards and privacy.

Security

According to HIPAA, a number of security criteria must be met by all electronic health care transactions. Some of these criteria directly affect how health care systems can be accessed as well as how the key players may interact with these systems. Table 1 details some extracts of the HIPAA security requirements (readers interested in the complete HIPPA security requirements are referred to HIPAA Security requirement matrix, 2002). Essentially, these security criteria fall into three main categories: administrative, physical, and technical. Table 1 summarizes the major issues and levers under each of these categories as well as identifying which are required and which are optional.

Transaction Standards

The Standards for electronic health information transactions cover transactions including claims, enrollment, eligibility, payment, and coordination of benefits. Succinctly stated, the aspect of HIPAA referring to transaction standards can be thought of in terms of practice standards and technical standards, as can be seen in Table 2.

Privacy

The final element of the HIPAA triangle deals with ensuring the **privacy of health care information.** Specifically, the Federal Register (Vol. 67, No. 157) details all the rules that must be adhered to with respect to privacy. The purpose of these rules is to maintain strong protections for the privacy of individually identifiable health information, addressing the unintended negative effects of the privacy requirements on health care quality or access to health care, and relieving unintended administrative burdens created by the privacy requirements. Thus, theses privacy requirements cover uses and disclosures of treatment and payment information and create national standards to protect individuals' medical records and other personal health information. Specifically, they do the following:

- Give patients more *control* over their health information.

Figure 5. HIPAA triangle (Adapted from Fadlalla & Wickramasinghe, 2004)

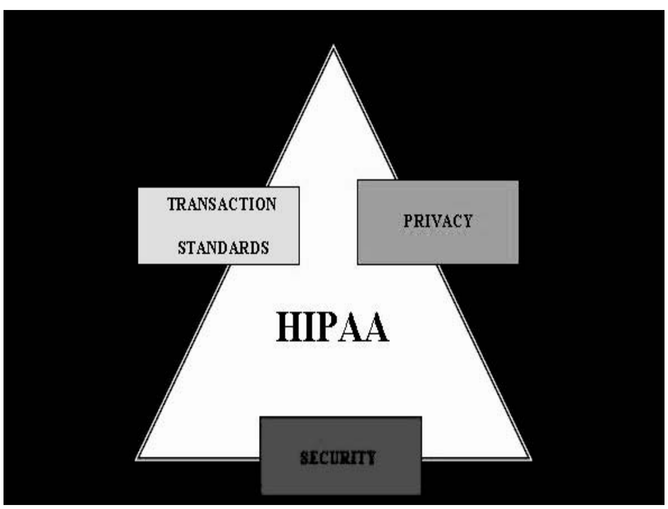

Table 2. Practice and technical standards

STANDARD SETS
Practice Standards
Health Care Common Procedure Coding System (HCPCS) This standard contains the Level II alphanumeric HCPCS procedure and modifier codes, their long and short descriptions. These codes, which are established by CMS's Alpha-Numeric Editorial Panel, primarily represent items and supplies and non-physician services not covered by the American Medical Association's CPT-4 codes. This standard does not contain the American Medical Association's CPT-4 codes.
ICD-9 – Diagnosis Codes International Classification of Diseases, 9th revision, Clinical Modification ICD-9-CM.
ICD-9 – Procedure Codes International Classification of Diseases, 9th revision, Clinical Modification ICD-9-CM.
Technical Standards
Technical Standards Adoption of electronic data interchange (EDI) using health care industry implementation guidelines and other standards such as XML and X12

Table 1. HIPAA security requirements (Adapted from Fadlalla & Wickramasinghe, 2004)

Extracts from HIPAA Concerning Security Requirements
• Establishment of trust partnership agreements with all business partners
• Formal mechanisms for accessing electronic health records
• Procedures and policies to control access of information
• Maintaining records authorizing access to the system
• Assuring that system users receive security awareness training and the training procedures are periodically reviewed and updated
• Maintaining security configuration, including complete documentation of security plans and procedures, security incident reporting procedures, and incident recovery procedures
• Communication and network control, including maintaining message integrity, authenticity, and privacy. Encryption of messages is also advocated for the open network transmission portion of the message.
• Data authentication to ensure that data is not altered or destroyed in an unauthorized manner

- Set *boundaries* on the use and release of health records.
- Establish appropriate *safeguards* that health care providers and others must achieve to protect the privacy of health information.
- Hold violators *accountable*, with civil and criminal penalties that can be imposed if they violate patients' privacy rights.
- Strike a balance when *public responsibility* requires disclosure of some forms of data; for example, to protect public health.

For patients, this means being able to make informed choices when seeking care and reimbursement for care based on how personal health information may be used. Specifically, privacy requirements do the following:

- Enable patients to find out how their information may be used and what disclosures of their information have been made.
- Generally limit release of information to the minimum reasonably needed for the purpose of the disclosure.

- Give patients the right to examine and obtain a copy of their own health records and request corrections.

For the average health care provider or health plan, the privacy regulations require activities, such as:

- Providing information to patients about their privacy rights and how their information can be used.
- Adopting clear privacy procedures for its practice, hospital, or plan.
- Training employees so they understand the privacy procedures.
- Designating an individual to be responsible for seeing that the privacy procedures are adopted and followed.
- Securing patient records containing individually identifiable health information so they are not readily available to those who do not need them.

A NEW ICT INFRASTRUCTURE TO SUPPORT E-BUSINESS ACCELERATION PROJECTS

INET's challenge was finding an ICT infrastructure to support the delivery of an accelerated e-business project. After five years of investigation and practical experience, INET has defined this new ICT Infrastructure as follows:

1. **Simple and low-cost technology.** Internet applications, wireless technology, cell phones, and/or personal digital assistants (PDAs)
2. **The next generation ICT professional.** Engage ICT players that have made the transition to a new cultural of meeting the highly responsive and evolutionary needs of end-users
3. **Demonstrable processes to accelerate ICT project delivery.** Demonstrate a rigorous project delivery process that reduces time cycles by 75% with a 50% reduction in project costs

For an in-depth look at INET findings, let us begin with a definition of an information and communication technology (ICT) infrastructure. It can be defined as a set of technologies such as computer hardware, devices, printers, applications, software, wired and wireless networks, and other technology components. The infrastructure is supported by ICT players that research, develop, deliver, service, and sell technologies to enhance information systems operations. These players also deliver new systems using a rigorous systems development life cycle methodology. In health care, an ICT infrastructure can be referred to as e-Health, and typically contains configurations similar to that depicted in Figure 3.

What is different today? In the past, many people resisted the use of technology to exchange and communicate information. It is well documented that they will not use technology if it is too complex or too costly. What is new today is the commercialization and acceptance of wireless technology. Wireless technology eliminates the costs and complexity in communicating and exchanging information at the point of need, regardless of location or time. This is evident by the widespread use of PDAs and cell phones, along with wireless data networks. Today, more than 33% of physicians use PDAs, and by 2005, it is predicted to grow to 50%[1]. In 2003, PDA usage among medical residents was 85%[2]. More than 172 million American consumers use cell phones[3] with the potential to access health care ICT systems anywhere, anytime.

Even with wireless technology removing the cost and usability barriers to enhance communications and exchange information, INET quickly discovered a new barrier when trying to engage the ICT industry in an e-Business Acceleration Project. This is manifesting itself as a user frustration with the responsiveness of the ICT industry to meet their demands. INET believes this is the result of a project engagement gap between the ICT one- to five-year system development cycle practices and users' demands for immediate and quick results. The e-Business Acceleration Project was design to bridge the gap between ICT and the user. From INET's experience, ICT needs a cultural change to meet the highly responsive and evolutionary needs of an e-business acceleration project. The INET experience clearly showed there was no consensus on an ICT infrastructure (people, process, and technology) to support both benefits of wireless technology and rapid project delivery achievements. INET spent four years researching and developing a roadmap to help the ICT industry make this transition. To release a solution and build consensus, INET founded and chaired the first wireless IT committee for the Information Technology

Association of Canada (ITAC). After the inaugural year, the group delivered the Wireless I.T. Infrastructure Procurement Guidelines in Health care[4].

At the same time of the ITAC Wireless IT Committee, INET started to gather evidence on an ICT infrastructure that can support the rapid and concurrent delivery of INET e-business acceleration projects. After a surveillance of Internet usage, INET selected health care market research in 2003. This industry is quickly shifting traditional quantitative research methods, such as face-to-face or telephone interviewing to online surveys using the Internet. The use of the Internet has shortened field time cycles by as much as 75% with the added benefit of reducing costs upwards to 50% when compared with telephone studies. To confirm these findings, INET completed more than 20 market research engagements involving the United States, the United Kingdom, Canada, Japan, Denmark, Italy, Spain, Australia, Germany, and France. To deliver these e-Business Acceleration Projects, INET assembled and used an ICT Infrastructure with the following key attributes:

- The heart of the INET ICT infrastructure is a form generation technology component(s) to create custom online surveys within three days. This an instrument with the programming capability to deliver custom surveys (forms) on demand; field multiple projects at the same time; integrate with many online panel methods; support, at a minimum, all standard survey question types, including single and multi-selects, grid and three-dimensional grid questions, open text/verbatim, and numeric entry; and able to securely integrate video/audio clips and other embedded technology objects.
- The INET hosting environment employs a fully redundant technical platform hosted in a state-of-the-art data center and capable of handling more than 50,000 surveys per hour. INET also assures these platforms are secure, and when required, can conduct a HIPAA-compliant audit.
- The technology hosting servers have redundant connectivity to the Internet and are managed on a 7-day/24-hour basis.
- When required, it can connect to wireless networks and devices using transcoding technology components. Transcoding component sits on top of a three-tier application architecture to redirect applications for use by a smaller screen, synchronize data, and support many types of wireless devices from laptops to cell phones (see Figure 5).

Using the INET ICT infrastructure, an INET e-business acceleration project for market researchers begins with a questionnaire written in an Microsoft Word document; it is then programmed and hosted for the Internet. When required, the survey is translated into another language to field non-English-speaking countries. Then INET fields the study with an online panel of physicians; for instance, INET sourced almost 200,000 physicians worldwide to participate in online research. An online panel process begins by e-mailing an invitation to the targeted respondent to participate in an Internet survey. With the use of an anonymous electronic ID, privacy is upheld and enhanced. There is no personnel information capture in the online survey. Once a panel member clicks on a unique URL, in the e-mail the member is immediately connected to a secure Internet site and completes the survey. Typically, an online panel response rate is 23% and upwards to 40%. Total time to program and test of a survey is three days. The timing in the field is approximately five to seven days, regardless if this is for N=100 or N=2000 completes, and delivery of the data file is within 24 hours.

In summary, INET reuses the lessons learned from delivering market research data collection projects and using wireless technology to show how an ICT infrastructure can support INET e-business acceleration projects. In this way, continuous improvement is achieved, and the future state is always improved through analysis and diagnosis of the current state outcomes and then implementation of appropriate prescriptive measures. The next step is to gain better acceptance of an e-business acceleration project in health care. This will occur as the industry embraces e-health and wireless possibilities.

ACHIEVING ICT PROJECT SUCCESS IN HEALTH CARE

In order to achieve ICT project success in health care, INET maps the e-business acceleration project to the mobile e-health project delivery model and then vets the model with a use case scenario. INET sees this model, combined with use case scenarios and a peer review process as a rigorous mechanism in the delivery of local and international mobile e-health projects.

For the past five years, the primary sponsors for a mobile e-health project are organizations looking to conduct studies on the use of wireless or mobile technology in health care delivery. These projects are typically funded through government research grants and the IT industry. In INET's case, an e-business acceleration project was used to deliver a mobile e-health project and was funded through the ICT industry sector. However, in 2003, INET began to quickly understand that it would be difficult for the ICT industry to continue the sponsorship of research-originated projects without a much faster commercial payback period. INET clearly saw this as the need to rebalance funding from research to commercial sources. With this in mind, INET started working in collaboration with others on a strategy to incorporate the e-business acceleration project as an INET mobile e-health project and accelerate commercial successes. The INET Mobile e-Health project objectives include the following:

1. Accelerate consensus building with an e-health solution focused on a disease state and driven by the medical model, with the primary objective to streamline communications and information exchange between patients and providers of community/home care, primary care, and acute care.
2. Acquire commercial funding early with a compelling business case. For instance, enhancing therapeutic compliance can improve patient quality of life with significant health care cost savings. It is well documented that in diabetes mellitus, this will have immediate and high impact benefits for health care consumers, pharmaceutical firms, governments, insurers, and employers.
3. Avoid risk by reengineering large-scale health care delivery processes in small manageable pieces. Today, organizations can harness a rigorous method to incrementally enhance a process one step at a time, a way to achieve quick wins early and frequently.
4. Rapid development of simple-to-use, low-cost, private/secure information and communication technology (ICT) solutions. Achieve these benefits through wireless Application Service Providers (ASPs). In addition to rapid development, a wireless ASP can easily connect and bring together many independent health care information systems and technology projects.

To actualize the mobile e-health project, INET is looking to the mobile e-health project delivery model as a framework (Figure 1). For INET, this will support a Mobile e-Health Project Management Office (PMO) to manage the costs, quality, and ICT vendors; deliver many small projects; and replicate projects for local and international distribution. As a first-case scenario for the model, INET is proposing an INET Diabetes Mobile e-Health project with leadership from a family physician. The INET PMO is provisioning a project manager to support this physician-led project to meet both research and commercial sponsors' interests and objectives in diabetes. A detailed description of the key attributes of the INET Diabetes Mobile e-Health project includes the following:

- **Problem statement:** There are many communication and information exchange bottlenecks between patients and their family physicians that prevent the effective treatment of diabetes. As background, a fundamental problem today is the ability to have a private and secure way to manage, search, and retrieve information at the point-of-care. In diabetes, physicians cannot quickly and easily respond to patients with high glucose levels. They need to wait for people to come to the office, respond to phone calls, or reply using traditional mail delivery; they may never receive the patient information.
- **Solution mandate:** Implement a diabetes monitoring program to enhance therapeutic compliance, such as releasing a program to enhance the usage of oral hypoglycemic agents (drugs), and/or the usage of blood sugar monitoring devices.

  As background, everyone wins when enhancing patients' abilities to follow instructions in taking prescribed medication. The patient's health, safety, and quality of life improve with significant health care cost savings. However, it is well documented that many patients do not stay on treatments prescribed by physicians[5]. This is where wireless technology may have the greatest impact to enhance compliance.

  One solution may be as simple as using a cell phone and installing a secure wireless application for patients to monitor glucose levels, and provisioning a physician to use a PDA (personal digital assistant) connected to a wireless network to confidentially access, evaluate, and act on the patient's data.

- **Business case:** In Ontario, Canada, the cost savings may represent almost $1 billion over three years. INET uses a simple calculation to determine the $1 billion savings. This can be found at www.inet-international.com (select the INET mobile e-health project section to review the calculations.

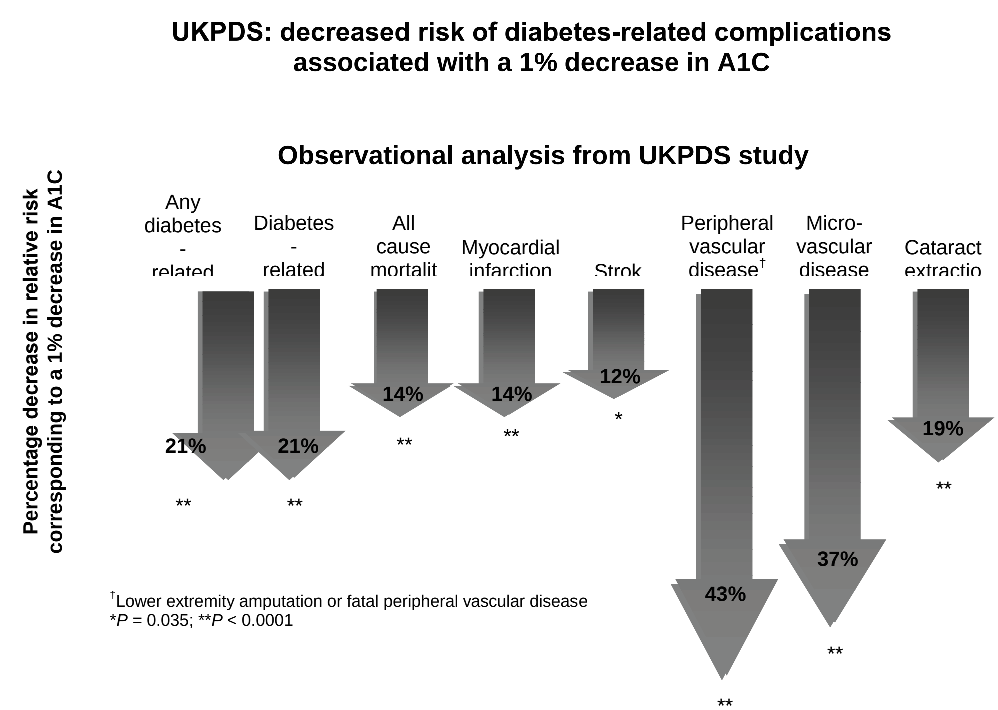
  The business case can be backed with additional data on how the cost of prevention (drugs) is far less than the cost savings associated with reducing the risk of complications associated with diabetes. For instance, the impact of a 1% decrease in A1C is significant and evident in Figure 8.

FUTURE TRENDS

Diabetes is increasing in prevalence globally at alarming rates. We believe the INET solution represents a useful model for effectively enabling the control of this disease so that its sufferers may enjoy a high quality lifestyle. Looking forward, INET's research data indicate that using the Mobile e-Health Project delivery model will increase ICT project success in health care. To realize and test this, INET plans to map the player's form and INET diabetes mobile e-health project (use case scenario) to the model. To show how this may work, review the following mapping exercise. The bold text in black is a project player, and the text in brackets relates to the sections of the model presented in Figure 1.

- **Physician Mobile e-Health Project Lead:** [Actualize physician-led innovations in disease management component in Figure 1]. Physicians provide the linkage to the medical model to enhance disease management programs (wireless Diabetes Program) to enhance patient care and safety, improve research and education, increase health care quality, and reduce health care costs. These are the project deliverables [Health Care Deliverables component in Figure 1].
- **Commercial sponsor(s) [wireless and mobility commercialized fund needs/requirements component in Figure 1]:** The project delivers information and communication solutions for:

Figure 8. Impact form reducing AIC levels



Adapted from Stratton IM, *et al.* UKPDS 35. *BMJ* 2000; 321:405–412.

  - ◦ Consumers wishing to improve their quality of life with an enhanced relationship with their health care providers' (i.e., family) physicians.
  - ◦ Pharmaceutical firms looking to increase revenues with e-compliance programs.
  - ◦ Government/insurers investigating ways to significantly reduce administration and health care costs and shorten health care delivery time cycles (wait times.)
  - ◦ Employers wanting to increase productivity and avoid absenteeism with a healthier workforce.
- **Research sponsor(s) [wireless and mobility research data collection needs/requirements component in Figure 1]:** The project develops intellectual property for researchers in the fields of:
  - ◦ Patient and health care provider relationships
  - ◦ Wireless medical informatics
  - ◦ Therapeutic compliance business case
  - ◦ Wireless information technology usability
- **An INET Mobile eHealth Project delivery team:**
- **Health care delivery team [field a wireless application component in Figure 1]:** For a wireless diabetes program, the players may include:
  - ◦ Health care Consumer: People with Diabetes
  - ◦ Community Care: Nurse Specializing in Diabetes
  - ◦ Primary Care: Family Physician
  - ◦ Acute Care: Endocrinologist
- **Business process analyst [validate a business case component in Figure 1]**
- **Privacy and security consultant [confirm mobile trust policies component in Figure 1]**
- **Programmer using a wireless ASP [utilize a wireless IT infrastructure component in Figure 1]:**
  - ◦ Wireless network and devices
  - ◦ Device and application transcoding
  - ◦ Application service provider
  - ◦ Back-end connection

In conclusion, INET is looking forward to further advancements in the mobile e-health project delivery model to:

- Achieve rapid advancements in health care delivery.
- Improve diabetes management.
- Enhance therapeutic compliance.
- Realize significant health care cost savings[6].

INET is planning to continue its role as a source of use case scenarios for the model with the delivery Mobile e-Health Projects.

CONCLUSION

Health care in the United States and globally is at a crossroads. It is facing numerous challenges in terms of demographics, technology, and finance. The health care industry is responding by trying to address the key areas of access, quality, and value. M-health, or mobile e-health, provides a tremendous opportunity for health care to make the necessary evolutionary steps in order to realize its goals and truly achieve its value proposition. What is important is to ensure m-health excellence. By an in-depth analysis of the rich and longitudinal data of INET, we have developed an integrative macro-level model to facilitate the achievement of m-health excellence. To the best of our knowledge, it is the first such model, and while it is certainly not a panacea, it does help to set the stage and outline the key issues that must be addressed in a systematic fashion so that a successful m-health initiative might ensue. Health care globally must embrace the advances of wired and wireless ICT use to provide superior health care delivery. In such an environment, an imperative becomes successful implementation of these wired and wireless initiatives. The Wi-INET integrative model serves to fill this critical void. We close by strongly urging more research in this area that will further test our framework.

KEY TERMS

Health Care Value Proposition: The areas that must be addressed to ensure that the health care solution(s) provides value to the patient.

ICT (Information Communication Technology): The combination of computers, hardware, software, networking, and telecommunications technologies.

IT Infrastructure: The technology and networking foundations required to support the m-health solution.

Mobile Health Care: The delivery of health care solutions that incorporates wireless or mobile technology.

Web of Players: The multidimensional group of players required in the delivery of health care solutions.

Current Issues and Future Trends of Clinical Decision Support Systems (CDSS)

Matthew Wills
Dakota State University, USA

INTRODUCTION

Computer-based clinical decision support systems (CDSSs) leverage developments in information technology to support healthcare providers with clinical decisions as they relate to the improvement of diagnostic, therapeutic, quality and safety processes and outcomes. In the last 50 years there have been significant advances with CDSSs, and the potential for a substantial role in the future of healthcare delivery remains likely. During this time, there have been three main stimulating factors for the development of CDS: (1) the intellectual challenge, (2) the need to address issues relating to patient safety, quality and access to healthcare, and (3) the business and policy reasons relating to the allocation of limited resources and control of spiraling healthcare costs (Greenes, 2006).

The undeniable intellectual challenge to understand and improve upon the human cognitive process has been and continues to be a major driving factor for the development of CDSSs. The human mind has become the model for developing complex systems capable of broadly interactive decision support. At the same time, efforts to reduce medical errors, and increase quality and patient safety have been championed as potential benefits of CDS. Estimates from a 1999 report, by the Institute of Medicine (IOM) indicated that as few as 48,000 and as many as 98,000 people die each year in the U.S., at a cost of more than $6 billion per year, as a result of medical errors (IOM, 1999). Similarly, a recent 2001 IOM report made a passionate plea for closing the quality gap between best practices and actual practices (IOM, 2001).

In this regard, the objective of the article is twofold: (1) to provide a framework for understanding CDSS and within this framework address a number of the current issues facing CDSS, and (2) to suggest likely directions for future research and clinical application.

BACKGROUND

A number of definitions for CDSS exist in the literature. For example, Peleg and Tu (2006) define CDSS as "any computer program to help health professionals make clinical decisions" while Musen, Shahar, and Shortliffe (2001) refer to CDSS as tools for information management, for focusing attention, and for providing patient-specific recommendations. More specific definitions include CDSSs as computer systems designed to impact clinician decision making about individual patients at the point in time when the decisions are made (Berner & La Lande, 2007) and CDSS as computer-based systems for bringing relevant knowledge to bear on the healthcare of the patient (Greenes, 2006). In effect, a CDSS provides patient-specific alerts and reminders, supports differential diagnosis through the interpretation of clinical results and user input, and provides methods to retrieve intelligently filtered knowledge that is medically relevant to the decision making process. Regardless of a particular definition, it is evident that CDSS are *computer-based* systems that leverage *medical knowledge* and *patient-specific data* to respond to a request for decision support by providing *recommendations* with the ultimate goal of improving the quality of the service provided to the *patient*. Figure 1 depicts the key elements in a CDSS. It should be noted however, that the decision support may be requested by a healthcare professional such as a doctor, a nurse, or a technician, another computer system, or the patient. Moreover, while the diagram depicts knowledge and the processing engine as distinct entities, in practice, depending on the underlying technology, the knowledge and the engine may be closely intertwined.

A FRAMEWORK FOR UNDERSTANDING CDSS

In order to synthesize different perspectives on CDSS research, development, and practical issues, we develop a framework (shown in Figure 2) in this section, building on extant literature.

In this framework, CDSS can be characterized along multiple dimensions, such as the type of support and intervention provided by CDSS, and the type of knowledge and methods employed in these systems (Degoulet & Fieschi, 1997). According to Degoulet, there exist two types of support provided by CDSS: (1) support in assessing the patient's state (e.g., in diagnosis or prognosis), and (2) support in suggesting the best course of action (e.g., recommended tests or treatment). Frequently, CDSS in practice may provide both types of support.

CDSS can also differ with respect to the type of intervention ranging from passive systems to active systems (Degoulet & Fieschi, 1997). In passive mode, the user has to initiate the process by providing a request to the system. Such request can be for an advice regarding a particular case, or for feedback (critique) regarding a particular assessment or planned course of action. On the other extreme, active systems can make decisions in an autonomous manner (i.e., independent of the physician or care giver, e.g., dialysis monitors).

CDSS can be further characterized by the type of knowledge or method employed. As noted by Degoulet, Jean, Engelmann, Meinzer, and Jagermann (1995), knowledge utilized for decision support may come from the medical literature encapsulating academic knowledge, and expertise acquired through medical practice. In many cases, systems encapsulate knowledge from both sources. Observations, while not knowledge per se, play a major role in machine learning techniques, and in validating decision models.

A number of methods have evolved over the years as shown in Table 1. Logical methods seek to represent and evaluate logical conditions, and are often used to generate clinical reminders, alerts, and make diagnostic or therapeutic inferences. Research dating back to the late 1950s suggested that the use of these methods as basic building blocks needed to emulate the medical decision-making process (Ledley & Lusted, 1959). Even today, the contemporary clinical system *Retrogram*, founded on the logic-based PRO*forma* application is being widely used in the UK to manage HIV care. Many existing systems in use today typically utilize the evaluation of logical conditions to narrow the range of possibilities as a precursor to applying probabilistic, heuristic, or other methods.

Figure 1. Clinical decision support systems (CDSS)

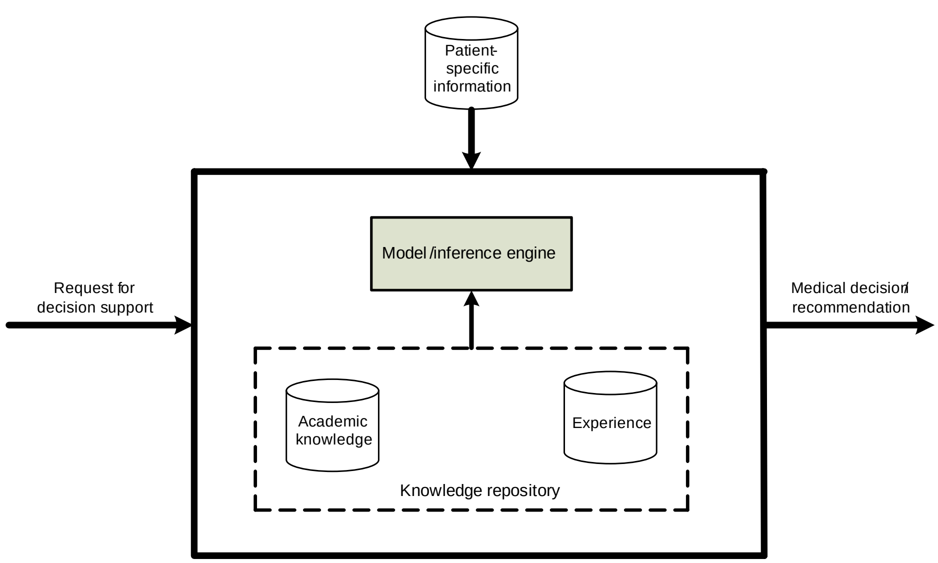

Figure 2. A framework for understanding CDSS

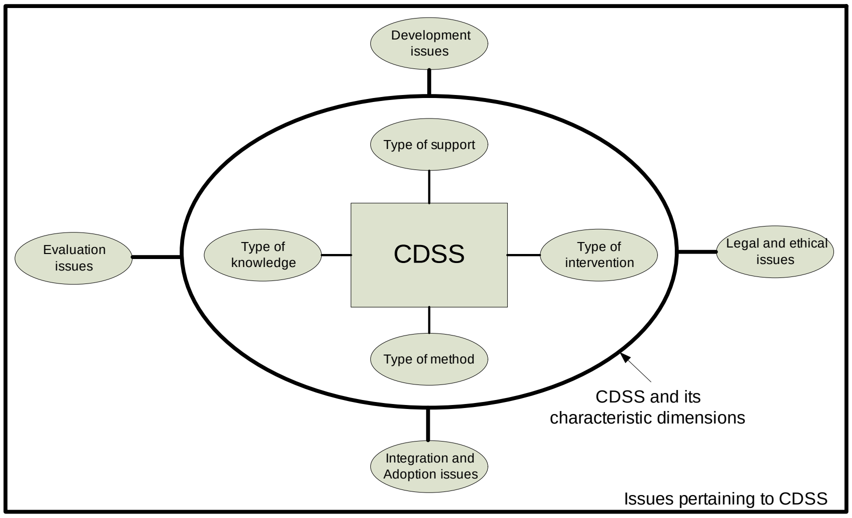

Table 1. Examples of CDSS methods and their uses

CDSS methods	Examples of methods	Examples of uses	Examples of current systems
Logical methods	Decision tables, Venn diagrams, branching logic	Alerts, reminders, inferencing	PROforma Retrogram
Statistical and Probabilistic methods	Decision analysis methods, multiple regression, discriminate analysis, Bayesian belief networks	diagnostic support, therapy evaluation	Markov Models
Heuristics	Expert systems	Diagnostic and therapy support and evaluation, expert systems	Isabel DXPlain
Mathematical models	Discrete and continuous simulation models, optimization models	Modeling complex biological and/or physiological systems	ULAM*
Computational intelligence	Artificial neural networks (ANN), genetic algorithms, fuzzy logic	Diagnostic pathology, therapy evaluations, clinical guidelines	BASS** PAIRS***

Note: Many of the systems listed here use more than one methods.
**BASS: Biopsy Analysis Support System based on a modular neural network architecture.*
***PAIRS: Physician assistant Artificial Intelligence System.*
****ULAM: UNOS Liver Allocation Model, which uses discrete event simulation models to model the process by which transplant candidates and organs are listed.*

Statistical and probabilistic approaches to medical diagnosis dates back to early 1960s. Warner and his colleagues developed one of the first medical applications to use a decision support system based on Bayesian probabilities to describe how to change one's beliefs in light of new evidence, and to incorporate concepts like uncertainty and degrees of beliefs (Warner, 1961). Other relevant statistical methods have also been applied (e.g., multidimensional classification techniques) such as cluster analysis, where a case is identified to belong to a particular class (e.g., diagnosis) based on the values of certain parameters.

Unlike a probabilistic methodology, however, systems that employ heuristic modeling are based on a clinician's experience and thus present evaluations that are easier for other clinician's to interpret. Heuristics in this context attempts to capture elements of human expertise and cognition as a basis for modeling the reasoning process. Because such a methodology uses expert knowledge or heuristics in the form of rules, they are also referred to as *rule-based systems* or *expert systems*. MYCIN was the first instance of a medical application founded on the idea of creating production rules based on heuristic modeling and was designed to assist with the selection of appropriate antimicrobial therapies (Shortliffe & Buchanan, 1990). A recently developed CDSS, known as Isabel, can work with electronic health records, and encapsulates over 6,500 diagnoses (Ramnarayan, Maheshwari, Britto, Vyas, Wilson, & Thomas, 2003). Isabel uses heuristic rules to filter diagnoses based on age, gender, and other groupings. The DXplain system has been in use for over 20 years, and uses heuristic scoring rules to develop its diagnoses.

Likewise, a variety of mathematical modeling methods have been used in CDSS over the past several decades. The objective of the model is to describe a complex biological or physiological system often through a discrete or continuous simulation model. Optimization models are also used to address questions such as optimum dosage.

Last but not least, computational intelligence refers to techniques such as artificial neural networks (ANN), fuzzy logic, and genetic algorithms. ANN's enable systems to learn from previously documented examples of disease, treatment and outcomes. For instance, neural networks accomplish this through recognizing patterns in the input data and classifying them. Examples of this technology include automatic interpretation of cardiac images and pulmonary gas exchange parameters (Peleg & Tu, 2006).

Completing the framework for understanding CDSS are a number of issues, as shown in Figure 2. The following sections provide a brief treatment of these issues.

CURRENT ISSUES

CDSS Integration and Adoption

Despite the practical and theoretical advances in CDS, widespread use is still not taking place in the U.S. There is, however, substantial evidence that CDS can provide enhanced safety, quality, adherence to clinical guideline-based care, improved patient monitoring and decrease in medication-related errors (Chaudhary, Wang, Wu, Maglione, Mojica, & Roth, 2006). Why then, has CDS not been more widely adopted in the healthcare community? Researchers such as Peleg and Tu (2006), who have investigated the success factors for CDS, emphasize that: CDS should be computer-based; CDS intervention should occur in a timely manner; and the costs and clinical effects should be consistently and quantitatively evaluated. Wetter (2002) further suggests that CDSSs must be flexible and respond to users needs, and clinicians should be able to update the knowledge base.

Integration of CDSSs into the healthcare IT environment has been slowed by the lack of computerized clinical data sources, such as Electronic Health Records (EHR). The healthcare industry has only recently begun utilizing EHRs as the standard for maintaining detailed health information.

CDSS Development

The increasing confidence in CDSSs to improve the quality and safety of healthcare delivery has encouraged considerable development in the technology in recent years. At present, development is focused on better understanding the medical reasoning process, developing knowledge representation standards, improving knowledge acquisition capability, machine learning, ontologies and clinical vocabulary standardization, among others. Developing robust CDSSs will require significant investments in research and product development activities, and healthcare IT vendors will need to respond with innovative strategies for product development, research, and evaluation methods.

CDSS Evaluation

There are a variety of ways to define evaluation. In its most basic form, CDSS evaluation is concerned with assessing the effectiveness of a decision support tool. Does the system function as required? Does it improve clinician performance and patient outcomes? How these questions should be answered is matter of ongoing debate. Two relevant research methodologies include: the *positivist*, natural science model that mandates quantitative evaluation of CDSSs, and the *interpretivist* approach, primary approach used in social sciences that attempts to understand and interpret the social and cultural context in which people and technology coexist. Evaluation frameworks that adopt both of these methodologies have been proposed, and may prove to be the most effective method for CDS evaluation.

The suggested benefits of CDS include improved patient safety, quality of care, and improved efficiency of healthcare delivery (Sintchenko, Gilbert, Coiera, & Dwyer, 2002). The nature of CDSS design, experimental as it is, complicates the matter of evaluation. Different software systems, different users, environments, vocabularies, and methods of representing knowledge and clinical guidelines contribute to the problem (Osheroff, Teich, Blackford, Steen, Wright, & Detmer, 2006). The assumptions underlying CDSS evaluations have to be considered carefully for accurate interpretation of the results. For example, in a 2003 study of 55 CDSS evaluations, it was found that less than 25% of the evaluations involved a randomized controlled trial, where users' before and after perceptions were emphasized to a greater degree (Sintchenko & Coiera, 2003).

Another marker that is essential to effectively evaluating CDSSs is patient outcome. Few studies to date have shown any significant clinical impact on patient outcome (Garg, Adhikari, McDonald, Rosas-Arellano, Devereaux, & Beyene, 2005). One could assume that once CDS is used on a large scale, the reduction of medical errors and improved safety and quality will indeed impact clinical outcomes. Nevertheless, until such benchmarks are developed through targeted research that quantitatively measures improved patient outcomes, evaluation of CDSSs will be lacking.

Legal and Ethical Issues

The use of CDSSs in practice has not yet been undertaken on a large scale. Because of this, the U.S. courts have not specifically considered the liability issues arising from their use (Rustad, 2004). This is certain to change as CDS becomes more widely adopted. Currently, of the more than ten thousand categories of medical devices in use in the U.S., more than half of them functionally rely on embedded software, and for this reason, consideration of the legal implications of the use of software is important (Gage & McCormick, 2004).

U.S. Tort law, which differentiates liability issues into two camps—negligence and strict liability—represent the most generally accepted legal approaches available to the plaintiff (Miller, Schaffner, & Meisel, 1985). In medicine, negligence refers to treatment that does not follow the established standards of the medical community. Strict liability, which is the basis for the canon of product liability in the U.S., only acknowledges whether or not the defendant's action caused harm, and does not consider the intentionality of the act.

By which standard will the individuals, manufacturers, and organizations involved in healthcare delivery be held? Who will assume responsibility for developing systems that harm patients, and how will the individuals and organizations take steps to ensure their systems are safe? These are some of the legal challenges facing CDS.

In many ways, the ethical considerations for CDS are similar to other issues raised with respect to the use of technology in medicine. As consumers of healthcare we are concerned about our privacy as patient health records are digitized and integrated with billing, insurance and other business functions. As with other types of technological medical interventions, CDSS poses a risk to the misuse of health information. The capacity for CDSSs to contain vast quantities of knowledge, health-related statistics, prognoses and outcomes, greatly complicates the scenario. Who will have access to this information, and how will it be used? Can we assume that everyone in the healthcare field has our best interests at heart? How will genetic data and related health information impact employability or insurability? The risk of bias and discrimination based on our health information is a matter of serious concern. CDSS developers and users must be careful to ensure that the rapid pace of development and implementation of CDSSs does not overshadow the potential to do harm. Goodman (2007) suggests that CDSS users need to be educated extensively on its use, and points out the potential for emergence of ethical issues when systems are not used for their intended purpose.

FUTURE TRENDS

To realize the potential of CDS, there are several key research and development areas worthy of attention:

1. **Development of standardized best practice implementation strategies for CDSS:** The variety of types of CDSSs in use along with a lack of standards for features, vocabularies, and methods of representing knowledge present challenges for successful implementation of CDSSs.

2. **Development of standardized CDSS interventions and integration strategies for focused, high-impact clinical conditions:** Focusing our efforts initially on high-impact health conditions such as diabetes, CHF, asthma, and so on will place CDSS in a position to have a substantive economic impact in terms of improvement of chronic health conditions, disease maintenance and the associated cost-savings.
3. **CDSS workflow studies:** Modern CDSSs have tended to move away from their original goal of producing stand alone decision tools. The attention now is on building highly focused, interactive systems that are placed contextually within the complex and demanding workflow of today's clinician, as well as the healthcare information system as a whole, so as to provide more opportunities to prevent errors (Garg et al., 2005).
4. **Central clinical knowledge repository research:** Investment pertaining to the development of a medical community-based, noncommercial central knowledge repository would facilitate the organization, development and standardization of medical knowledge that could be accessed by a variety of systems using a variety of technologies to provide CDS.
5. **Development of standards for the practical representation of clinical knowledge and data:** Over the past decade, ontologies have been used to symbolically represent and reason about clinical knowledge, thus playing a vital role in the establishment of clinical practice guidelines. When represented in a formal language such as frames or description logic, relationships can be identified in existing data and inferences made (Peleg & Tu, 2006).
6. **Development of best practices for documenting and assessing the quality of CDSS content:** Physician performance, patient outcomes and system use ultimately reflect the quality of CDSS content. Research specifically designed to develop best practices for documentation and assessment of content quality, as well as the impact of that quality, is needed to ensure that CDSS is relevant, safe, and contributing to the improvement of healthcare.

CONCLUSION

In sum, there is significant interest in the use of CDSSs to support clinical decision tasks. CDSSs have been shown to reduce medical errors, improve clinician performance, and increase the quality of care. CDSSs employ a variety of methods and formalisms, each of which contributes in unique ways. There are a number of issues surrounding the use of CDSSs, including development, implementation and adoption, ethical and legal concerns, and evaluation issues, which need further attention from researchers and practitioners.

KEY TERMS

Active CDSS: Active CDSSs make decisions and interact without input or request by the user.

Artificial Neural Networks: A network of simple processing elements which can exhibit complex global behavior, determined by the connections between the processing elements and element parameters.

Fuzzy Logic: Based on fuzzy set theory, deals with complex systems where reasoning is approximate, due to complexity or incomplete data.

Genetic Algorithms: A genetic algorithm is a search method used in computational intelligence to find true or approximate solutions to optimization and search problems.

Heuristic: An algorithmic technique designed to solve a problem that ignores whether the solution can be proven to be correct.

Inference Engine: The component of a CDSS program that formulates inferences from a knowledge repository.

Passive CDSS: Requires the user to initiate a process by providing a request to the system.

INTRODUCTION

The passive electrical properties of biological tissue have been studied since the 1920s, and with time, the use of Electrical Bioimpedance (EBI) in medicine has successfully spread (Schwan, 1999). Since the electrical properties of tissue are frequency-dependent (Schwan, 1957), observations of the bioimpedance spectrum have created the discipline of Electrical Impedance Spectroscopy (EIS), a discipline that has experienced a development closely related to the progress of electronic instrumentation and the dissemination of EBI technology through medicine.

Historically, the main developments in EIS related to electronic instrumentation have been two: first, the progressive shift from "real studies," where only resistance is measured, to "complex studies," where the reactance is also measured. Second, the increasing upper limit of the measurement frequency makes it possible to perform studies in the whole β-dispersion range (Schwan, 1957).

Basically, an EBI measurement system obtains the relationship between voltage and current in an object, obtaining the impedance or the admittance according to Equations 1 and 2. In EBI, most of the systems measure the impedance of the tissue, therefore injecting a known current and measuring the corresponding voltage drop in the biological sample. See Figure 1(A).

$$\boldsymbol{Z} = \frac{\boldsymbol{V}}{\boldsymbol{I}} \tag{1}$$

$$\boldsymbol{Y} = \frac{\boldsymbol{I}}{\boldsymbol{V}} \tag{2}$$

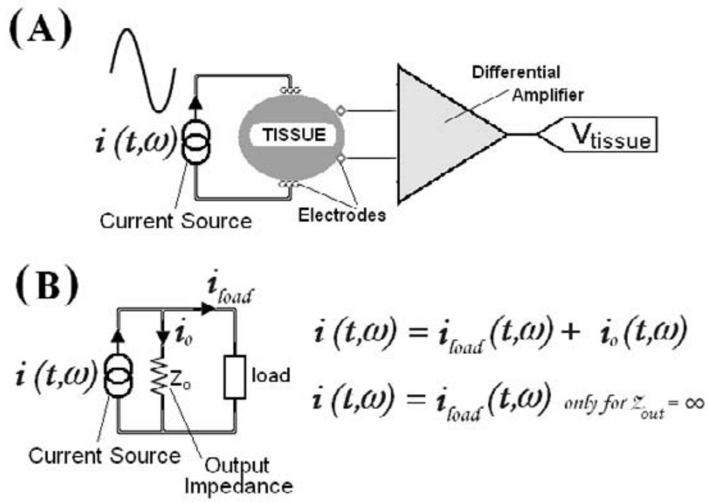
In an EBI measurement system, the current source plays a very important role, and its features are critical for the overall performance of the measurement system—especially for the frequency range of operation and the load dynamic range that the system is able to measure. The use of current driving instead of voltage driving is the most extended approach (Morucci & Rigaud, 1996), which applies an intrinsically safe current-limiting mechanism and reduces the possible nonlinearities. Given that the signal generator usually provides a voltage at its output, the current driver often is a Voltage Controlled Current Source (VCCS).

BACKGROUND

The functional purpose of a current source is to generate an electric current signal with a specific magnitude. Therefore, the output current is the most important characteristic of a current source, and parameters related to the output current define the performance of the source.

An ideal current source will provide exactly the same current to any load independently of its value at any frequency. To fulfil this aim, the output impedance Z_{out} must be very large, ideally ∞, at all frequencies. See Figure 1(B).

Figure 1. (A) An ideal representation of a four-terminal voltage over current EBI measurement system; (B) representation of an ideal current source



In practice, the frequency range is limited to an operational frequency range at which the value of the output impedance of the source is very large in comparison with the value of the load. In bioimpedance applications, a commonly accepted value is at least 100 kΩ.

As a safety measure in biomedical applications, when current is injected into the body, the accumulation of electrical charges is avoided as much as possible. Therefore, the DC component of the stimulating current should be zero.

Over the years, there have been two main approaches in current source design: voltage-based structures and current-based structures. In voltage-based structures, what is responsible for the generation of the output current is the voltage in one or more nodes of the active circuit (e.g., the virtual ground in the case of Op-Amps). In a current-based structure, the output current is generated by an active device with intrinsic current-mode operation (e.g., Transconductance Amplifiers and Current Conveyors).

Voltage-Based Structures

Howland-based circuits and Load-in-the-Loop structures are the most common approaches to implement VCCS, and both are based on a single Op-Amp circuit. Another family of VCCS is based on a differential amplifier with unity gain and positive feedback.

Load-in-the-Loop

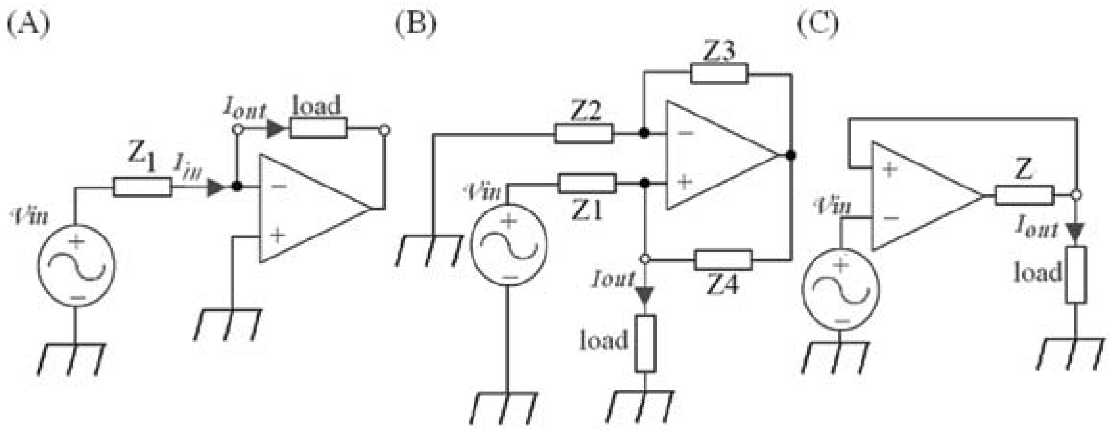
This current source design is one of the approaches first used to implement current sources with floating load (Sheingold, 1966). In Figure 2(A) it is possible to observe the principle of operation for the output current generation and the importance of the Op-Amp circuit. Note that as long as the Op-Amp provides a virtual ground and infinite input impedance, the output current is independent of the value of the load (i.e., the output impedance is infinite). Since the characteristics of an Op-Amp circuit are frequency-dependent, the output impedance of the current source exhibits a similar dependence. Equation 3 shows the analytical expression for the output impedance, Z_{out}, of the current source circuit in Figure 2(A), considering the frequency dependence of the differential gain (Seoane et al., 2007). Z_0 and Z_{in} are the output and input Op-Amp impedances, and Z_i is the impedance which determines the transconductance of the VCCS, Z_1 in Figure 2(A).

$$\boldsymbol{Z_{out}} = \left(\boldsymbol{Z_o} + \left(\boldsymbol{Z_{in}} \mathbin{//} \boldsymbol{Z_1}\right)\left(\boldsymbol{A_d(s)}+\mathbf{1}\right)\left(\mathbf{1} - \frac{\mathbf{1}}{\mathbf{2CMRR(s)}}\right)\right) \tag{3}$$

Howland Source

This circuit topology (Sheingold, 1964) is probably the structure most used as a current source in EBI. Figure

Figure 2. (A) A Voltage Controlled Current Source implementation with Load-in-the-Loop. (B) A Voltage Controlled Current Source implemented with the original Howland current circuit. (C) VCCS based on a differential amplifier with positive feedback



2(B) shows the original circuit for the Howland source. When the impedance bridge is balanced (i.e., Z_1 x Z_3 = Z_4 x Z_2), the output current is proportional to V_{in} and only dependent on the value of Z_2 (4). Regarding the output impedance, as long as the bridge is balanced the output impedance of the current source is infinite; see Equation 5.

$$I_{out} = \frac{V_{in}}{Z_2} \quad (4) \qquad Z_{out} = \frac{Z_1 \times Z_2 \times Z_4}{Z_2 \times Z_4 - Z_1 \times Z_3} \quad (5)$$

The expression in Equation 6 is the output impedance of the Howland source, considering the frequency dependence of the differential gain of the Op-Amp circuit.

$$Z_{out}(s) \left(1 \quad \frac{A_d(s)}{1+\frac{Z_3}{Z_1}} \right) \left(Z_1 \| Z_3 \right) \quad (6)$$

Even using perfectly matched resistors, there is a degradation of Z_{out} due to the Op-Amp frequency response. In addition, resistors' tolerance imposes a finite Z_{out} even at low frequencies. Note that, for the sake of simplification of the final expression, it is assumed that $Z_2 = Z_1$ and $Z_4 = Z_3$, which also balance the bridge.

The Howland circuit has been studied for many years and enhancements on this topology have been implemented and tested (Bertemes-Filho, Brown, & Wilson, 2000).

Structures Based on a Differential Amplifier

Several VCCS structures can be reduced to a differential amplifier with unity gain and positive feedback, as depicted in Figure 2(C). As shown in Equation 7, in the case where the amplifier differential gain A_d is equal to 1, the output current I_{out} is load-independent, (i.e., the output impedance of the current source is infinite).

$$I_L = \frac{(A_d - 1) \times V_L - A_d \times V_{in}}{Z} \Rightarrow I_L \Big|_{A_d = 1} = -\frac{V_{in}}{Z} \quad (7)$$

The differential amplifier admits several implementations, monolithic or with discrete Op-Amps, and typically with classical structures having one, two, or three devices. The output impedance of the resulting VCCS is not ideal, and depends on the accuracy of the condition $A_d = 1$, as shown in Equation 8.

$$Z_{out}(s) = \frac{Z}{1 - A_d(s)} = \frac{Z}{\varepsilon} \frac{1+\frac{s}{\omega_o}}{1+\frac{s}{\omega_0 \varepsilon}} \quad (8)$$

At very low frequency, its value is $Z_0 = Z/\varepsilon$, with ε being the relative error in A_d. The first pole of Z_0 depends on the first pole of A_d and again on ε. Both this error and its frequency behaviour will depend on the structure used to build the differential amplifier, on the tolerance of devices, and on the frequency response and the common mode rejection ratio (CMRR) of the Op-Amps.

Current-Based Structures

Current sources based on current-mode structures (Toumazou, Lidgey, & Haigh, 1989) involve a transconductor at device level (e.g., transistor) or at circuit level. The resulting VCCS circuits normally use less passive components and are simpler than those based on Op-Amps, making them more suitable for integrated implementations. Their frequency bandwidth is higher than that obtained with Op-Amps based on the same technology. Most circuits based on current-mode devices are open-loop structures, which limits their accuracy. The core of circuit-level current-mode structures is usually a current-conveyor (CCII) or an operational transconductance amplifier (OTA). Both could be directly used to build VCCS circuits.

Current Conveyors

The current conveyor (CCII) (Sedra, Roberts, & Gohh, 1990) is a current-mode building block whose acronym stands for second generation current conveyor. CCII is a three-port device with two inputs (X, Y), and an output (Z). Figure 3(A) displays its symbol, and Figure 3(B), the simplified diagram of the usual implementation. The Y input is a high-impedance node whose voltage is copied to X, the low-impedance node. The input current at X node is copied to the Z high-impedance output node. To implement a VCCS with a CCII, a voltage generator V_i is connected to the Y node, and a resistor R between ground and the X node. Thus, node Z generates the current replicated at node X, providing a large output impedance. Note that, since $i_x = V_i/R = i_{out}$, R is the VCCS transconductance. The main limitation on its use is the lack of commercial availability (e.g., Analog Devices AD844, TI-Burr-Brown OPA660). There are several EBI and EIT instruments that include CCIIs in their structure (Casas, Rosell, Bragos, Lozano, & Riu, 1996; Yerworth, Bayford, Cusick, Conway, & Holder, 2002).

Transconductance Amplifiers

In essence, an operational transconductance amplifier (OTA) is an amplifier that generates an output current linearly proportional to its voltage differential inputs, as expressed in Equation 9. The gain of an OTA is not just gain, but transconductance, denoted by g_m and adjustable by the value of input currents I_{abc} and I_{bias}. See Figure 3(C).

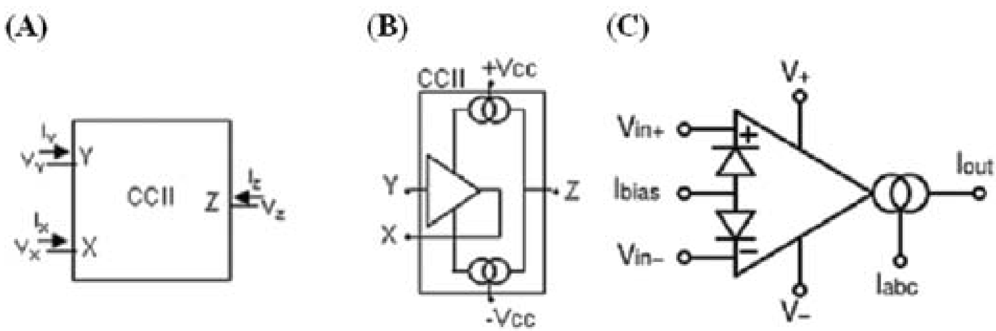
$$I_{out} = (v_{in+} - V_{in-}) \times g_m \qquad (9)$$

Since the OTA is a current output device, its output impedance should be very large. Therefore, considering its ideal features of output current controlled by voltage with a linear relationship and high output impedance, the OTA circuit is the perfect VCCS.

The Effect of Parasitic Capacitances

Parasitic capacitances can be found associated with many elements of an impedance measurement system.

Figure 3. (A) Current conveyor: symbol; (B) current conveyor simplified schematic; (C) OTA, schematic symbol for an operational transconductance amplifier



They may be associated with the output of the current source, C_o, the stimulating leads, C_m, and the sensing leads, C_{in}, as well as between the electrodes, C_{ie}, the system's ground and earth, C_{is} and even the patient and earth, C_{bg}.

All these parasitic capacitances create pathways for the current to leak away from the tissue for measurement (e.g., the patient). The origin of such capacitances and their effects have been studied in detail by several authors (eg., Scharfetter, Hartinger, Hinghofer-Szalkay, & Hutten, 1998).

The main effect of parasitic impedances associated with the current source is to reduce the output impedance of the source with frequency. This effect may be negligible in the frequency range of operation of the measurement system, but otherwise the parasitic capacitances set the frequency limit of operation of the impedance meter, especially in those without a reference current measurement. The output impedance can be affected severely by parasitic capacitances associated with the output, C_o (Seoane, Bragos, & Lindecrantz, 2007), but also by parasitic capacitances intrinsic to the current source circuitry (ibid.). In practice, circuits without active capacitance compensation exhibit a certain output capacitance, including CCII and OTA, typically of 3–5 pf. This fact limits the output impedance to 50 kΩ at 100 kHz.

CHALLENGES AND DESIGN TRENDS FOR CURRENT SOURCES IN EIS SYSTEMS

The selection of a specific approach for the design of the current source reduces, in most of the cases, the versatility of the measurement instrument. Therefore, current source design usually is application-specific. Currently, electronic instrumentation for wideband multifrequency measurements is an important research area within electrical bioimpedance spectroscopy, pursuing the goal to widen the frequency band of operation of the EIS measurement systems.

Multifrequency Measurements

Biological tissue, due to its structure and the electrical properties of its constituents, presents an electrical impedance that varies with frequency (Schwan, 1957). Therefore, the impedance at a certain frequency is often different from that at another frequency, and for the same reason the impedance spectrum of a tissue or subject may provide information regarding the status of the tissue or its composition (e.g., body composition and skin cancer screening).

Currently, there are two methods to obtain the impedance spectrum of a tissue: using true multifrequency systems or sweeping frequency systems. The latter uses an excitation signal containing just one tone, sometimes two or even three, at a specific frequency. The spectrum impedance is obtained after several excitations by sweeping the frequency of the applied tone to cover the frequency range of measurement. In contrast, multifrequency systems use an excitation signal containing several tones, often a multisine (Bragos, Blanco-Enrich, Casas, & Rosell, 2001), obtaining the impedance spectrum of the sample after only a single excitation.

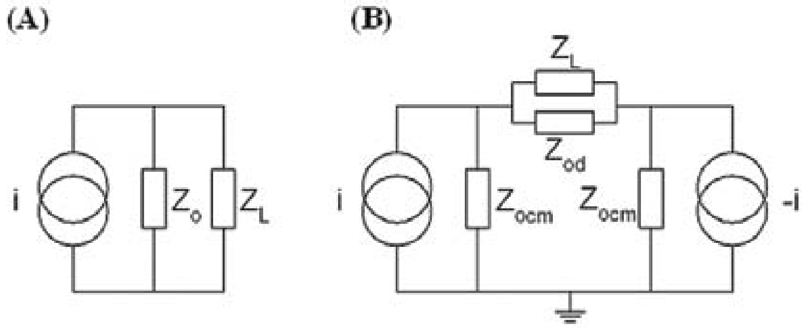
These two methods impose different requirements on the current source. Multifrequency systems need a current source able to provide a large output impedance simultaneously in the complete frequency range of measurement, while current sources for sweeping systems only need to provide a large output impedance at the frequency of the tone or tones contained in the excitation signal.

Enhancing Design Approaches

There are many factors that influence the performance of an impedance measurement system, and each type of current source exhibits an intrinsic robustness to different sources of errors. For instance, in previous paragraphs we have introduced the effect of parasitic capacitances that shunt the stimulating current away from the measurement tissue or patient. Just by selecting one type of current source, the robustness against certain parasitic effect can be improved (e.g., load-on-the-loop structures are more robust against leads' parasitic capacitance than grounded-load structures, like Howland). Such improvement is often slight, although in some cases, it is enough to obtain a suitable current source for a specific application.

In most cases, circuit design approaches for current sources are used to specifically minimize or even eliminate sources of error in EBI systems, such as parasitic capacitances.

Figure 4. (A) Floating current source; (B) implementation based on two equal sources referred to ground



Symmetrical Current Sources

The use of symmetrical current sources allows us to minimize the common mode voltage at the load, thereby reducing the errors, due to limited CMRR of the voltage measuring differential amplifier. The previously described current sources are referred to ground, except the load-in-the-loop source, which is floating but not symmetrical. Symmetrical current sources are presently implemented by connecting the load between the outputs of two complementary current sources as in Figure 4. The current at a given moment is injected by one of the sources and drained by the other one. The unavoidable impairment between both sources creates a differential current which finds a path to ground through the common mode output impedance Z_{Ocm} of the current sources. This fact would generate again a large common mode voltage at the load, unless a common mode feedback (CMFB) circuit is used (Casas et al., 1996, Goovaerts, Faes, Raaijmakers, & Heethaar, 1999).

Negative Impedance Converters

There are several different circuit topologies to implement: Negative Impedance Converters (NICs). Figure 5(A) shows a well-known NIC topology (Sedra & Brackett, 1979), widely used in EIS and EIT (Lee, Cho, Oh, & Woo, 2006; Ross, Saulnier, Newell, & Isaacson, 2003). Such topology is able to synthesize an inductance between the points *a* and *b* with the value given by Equation 10.

$$L = \frac{R_1 \times R_3 \times Z_4 \times C_1}{Z_2} \qquad (10)$$

Therefore, by connecting the NIC circuit in parallel to the output of the current source as in Figure 5(B), it is possible to obtain an equivalent output impedance that is only resistive, eliminating any capacitance associated with the output Z_{eq}, independently of its origin. Tuning the discrete components of the NIC to make *L* comply with Equation 11, the capacitive part of *Zeq* in Figure 5(B) can be cancelled at any specific frequency, ω_S. This yields at ω_S an output impedance only real and significantly large, in the order of Ω (Ross et al., 2003).

$$L\Big|_{IM\{Z_{eq}\}=0} = \frac{1}{\omega^2 \left(C_o + C_{par}\right)} \qquad (11)$$

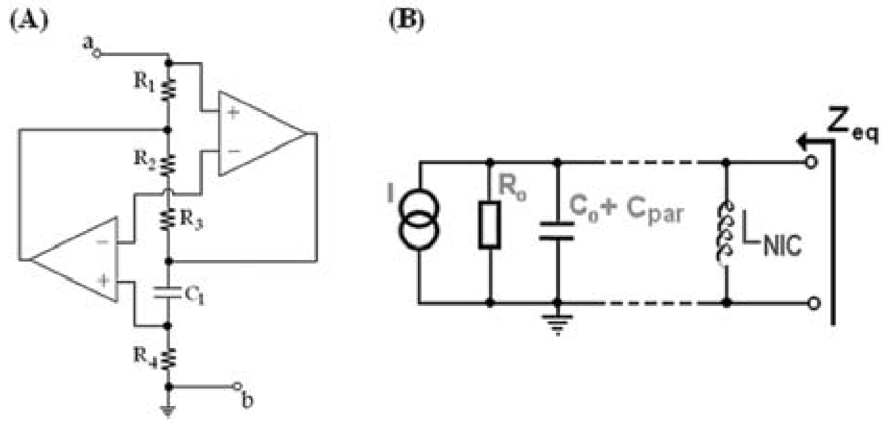
Despite the possibility to obtain a current source with virtually no reactive component, the use of NIC**s** is limited for several reasons:

- An NIC increases the instability of the system.
- NIC circuits need to be trimmed for each frequency before each measurement, limiting the use of the VCCS to only sweeping systems.
- The trimming process introduces unpractical time delays between measurements, and when the measurement system incorporates an automatic trimming block, such a block may be as complex as the rest of the measurement system.

Single Op-Amp Basis

Some of the sophisticated alternatives in the VCCS design appeared to overcome the drawbacks of single Op-Amp circuits implemented with the available Op-Amps at that time. Modern voltage and current-feedback

Figure 5. (A) Circuit schematic for a generalized impedance converter for inductances. (B) Equivalent circuit for the connection of the NIC circuit to the output of the current source.



amplifiers, with gain-bandwidth products of hundreds of MHz, allow us to retrieve these structures with good results for not highly demanding applications.

Current Conveyor + Load-in-the-Loop

Combining basic structures in cascade, where the CCII feeds current to a secondary current source, it is possible to obtain a VCCS circuit that is simple and has extraordinary performance, exhibiting large output impedance values at frequencies higher than 1 MHz (Seoane et al., 2007). The simplicity of this approach allows an easy microelectronic implementation avoiding any parasitic capacitance associated with internal connections and discrete components of the VCCS. The drawback of this design is that it does not allow the implementation of a symmetric current source; thus, it requires an external CMFB circuit to minimize the common voltage at the load.

Differential Difference Amplifier

A modern approach to the implementation of the VCCS based on a differential amplifier with unity gain is that which uses a Differential Difference Amplifier (DDA) to implement the differential amplifier. This structure allows high bandwidth and the unity gain is not compromised by resistors matching. (Ramos-Castro & Bragos-Bardia, 2004) describe an isolated front-end for cardiac applications whose current source is built with the AD830. (Riu, Anton, & Bragos, 2006) describe a symmetrical current source based on differential amplifiers with unity gain built around AD8130 with intrinsically high pass response, which ensures lower transconductance at low frequencies to improve safety.

FUTURE DEVELOPMENT TRENDS

Modern mixed-mode ICs (e.g., A/D and D/A converters, DDS, programmable gain amplifiers) usually have differential inputs and outputs, including current outputs in some cases. Differential floating architectures can then be more easily implemented at whole system level. Integrated implementations (Terzopoulos, Hayatleh, Hart, Lidgey, & McLeod, 2005) will help to reduce parasitic capacitances, but not the intrinsic output capacitance related to devices' loop-gain falling at high frequency. Only active capacitance compensation could allow a further improvement of output impedance. Proposed structures are, however, useful at only a single or a discrete set of frequencies, when using a parallel array of NIC circuits (Lee et al., 2006).

CONCLUSION

The incessant developments in electronic technology, especially in circuit integration and bandwidth of operation, together with the increasing numbers of applications making use of electrical bioimpedance spectroscopy, guarantee continuous improvement in the performance of electronic instrumentation for electrical bioimpedance measurements, including the current source. Classical structures can be retrieved with enhanced performance, and new building blocks allow wide operational bandwidths and large output resistances. Parasitic output capacitance is still a bottleneck, unless active capacitance compensation is used, but the reduced bandwidth of this technique limits its application in multifrequency EIS.

KEY TERMS

Current Source: A two-terminal analog electronic building block which generates an electrical signal with constant current amplitude independently of the load connected at the terminals.

Differential Amplifier: An amplifier whose output depends on the difference between two inputs through a gain (differential gain), and residually on the mean voltage between both inputs.

Electrical Bioimpedance: The physical magnitude that indicates the total impediment that a biomaterial offers to the flow of free electrical charges and the orientation of bounded electrical charges towards an existing electrical field.

Negative Impedance Converter: Type of electric circuit that can generate any impedance between two points—capacitances or inductances.

Operational Amplifier: Differential amplifier with a high open-loop gain which allows the implementation of accurate circuits by using voltage feedback.

Parasitic Capacitance: A capacitance usually defined between a node and ground, due to wires, tracks, pads, and p-n junctions in the signal path.

Transconductance: A contraction of *transfer conductance*, the relation between the voltage at the input of an electric system and the current at the output. It is denoted by g_m and measured in Siemens units.

The Current State of Bionanotechnology

INTRODUCTION

Bionanotechnology is a combination of three terms: "bios" meaning "life," "nano" (origin in Greek) meaning "dwarf," and "*technologia*" (origin in Greek—comprised of "*techne*" meaning "craft," and "*logia*" meaning "saying"), which is a broad term dealing with the use and knowledge of humanity's tools and crafts. Biomolecular Nanotechnology—or Bionanotechnology—is a term coined for the area of study where nanotechnology has applications in the field of biology and medical sciences. One can also say that "Bionanotechnology" is derived by the combination of two terms: "nanotechnology," and "biotechnology."

BACKGROUND

The principles of physics, as far as I can see, do not speak against the possibility of maneuvering things atom by atom. It is not an attempt to violate any laws; it is something, in principle, that can be done; but in practice, it has not been done because we are too big.

By saying the above lines, Richard Feynman, Nobel Prize winner in Physics, clearly expressed the importance of decreasing the size of a material to very small scale.

In mathematics, "nano" is defined as one billionth of a meter or 10^{-9} meter. However, the term "nanotechnology" has no one definition attached to itself. If you ask a number of scientists and scholars to define the meaning of nanotechnology, you are bound to receive a range of definitions for the term. However, a basic definition of nanotechnology can also be stated as "**engineering of** functional systems at the molecular scale."[1] The following two lines help in expressing the idea of how small a nanometer really is:

1 meter = 1 billion nanometers[2]
Width of Human Hair = 80,000 nanometers[3]

Nanotechnology is often referred to as a general-purpose technology. That is because in its advanced form it will have significant impact on almost all industries and all areas of society. It offers better built, longer lasting, cleaner, safer, and smarter products for the home, for communications, for medicine, for transportation, for agriculture, and for industry in general.

Imagine a medical device that travels through the human body to seek out and destroy small clusters of cancerous cells before they can spread. Or a box no larger than a sugar cube that contains the entire contents of the Library of Congress. Or materials much lighter than steel that possess ten times as much strength.

- U.S. National Science Foundation

Nanotechnology being one of the most promising and growing industry today, a large amount of work that is being carried out in this area. Bionanotechnology is currently in its prime with researches being carried out all over the globe in this field. However, in the past few years, there also have been some great discoveries and inventions in this area of study.

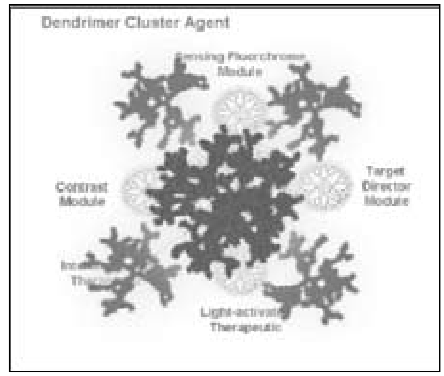
APPLICATIONS OF BIONANOTECHNOLOGY

Bionanotechnology deals with nanomaterials and their applications in life sciences. The applications[4,5] of bionanotechnology are vast. However, the bionanotechnology applications (Lin & Datar, 2006) can be broadly categorized into two main areas: therapeutics and diagnosis.

Nanotherapeutics

Nanotherapeutics is an application of bionanotechnology in which the diseases can be treated by the use of various techniques at molecular level. Nanotheraputics can be categorized into three main areas of study and development: *drug therapy, gene therapy, and immunotherapy*. However, the current research is being conducted mainly in the former two areas of nanotherapeutics. In *drug therapy*, the potential of water-insoluble drugs or unstable drugs can be greatly enhanced by reducing the size of the drug or by encapsulating the drug particle. In *gene therapy*, functional genes can be efficiently delivered to correct genetic disorders like hemophilia. This can be done by condensing the DNA into nanoparticles,[6] and hence controlling its composition for effective gene delivery.

Figure 1. Baker's dendrimer: Multifunctional cancer treatment (Courtesy: Nanotechnology takes on cancer)



Nanodiagnosis

Because of nanotechnology, diagnosis of a disease will become not only easy, but also highly effective. We will be able to detect a malfunction in even a single cell at the very moment it becomes defective. As a result, we will be able to diagnose a disease effectively in its prime stage which would thus result in an early treatment of the disease, like cancer (Grodzinski, Silver, & Molnar, 2006; Jain, 2005), hence increase the chances of survival.

The reason for early diagnosis due to the implementation of nanotechnology is that nanotechnology operates on the same scale as biology. Moreover, due to of the small size of nanoparticles, they will be able to gain access to areas of the body—such as the brain and individual cells—that have proved difficult to reach with current technologies.

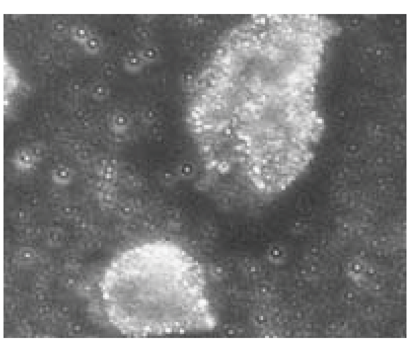
In the paragraphs to follow, there has been an attempt made in order to give an insight of what is currently being done in the field of Bionanotechnology.

- **Dendrimers:** (Svenson & Tomalia, 2005; Figure 1) It is a three-dimensional, branched nanoscale molecule resembling the structure of a "*tree*." The term "dendrimer" comes from a Greek word meaning "tree." It can act as a good *drug delivery agent* as well as a *time-release delivery agent*. It is normally used in therapeutic developments which are targeted to cancer cells (Baker, 2003). Researchers at Northwestern University are working on cancer detection, and stopping it before it starts using dendimers.
  Dendritic polymers are also used for the development of nanosensor/NEMS systems for noninvasive, continuous monitoring of astronauts for the biologic effects of space travel.
- **Patient-specific medicine (Baba, 2006):** Every individual has a different genetic structure which is responsible for things like color of the hair, eye's color, shape of nose, and so on. Hence, each human being has a distinct predisposition to a disease. Therefore, personalized medicine or patient-specific medicine simply means the *prescription of specific therapeutics best suited for an individual*. Xiaolian Gao, professor of chemistry, has developed a chemical process for building a device that could help doctors predict a patient's response to drugs or screen patients for thousands of genetic mutations and diseases, all with one simple lab test—on a DNA chip. The ultimate vision of this research is the development of patient-specific medicine.
- **Bionanosensors[7]:** Researchers in many universities and R&D laboratories are trying to develop sensors based on nanotechnology, which, when implanted under the skin of a human being, will be able to detect the level of glucose, hormones, or cholesterol. Nanosensors (Clark, Singer, Korns, & Smith, 2004; Jain, 2005; Kohli & Martin, 2005; Kvennefors & Persson, 2004) can play a vital role in the treatment of genetically based diseases like sickle cell anemia, due to their characteristics of

have high sensitivity and specificity. Moreover, the study of this kind of technology has demonstrated that the cancer cells can be easily identified. Recently, New Mexico Tech researchers have developed a nanosensor which can be used to analyze and identify individual components of single strands of DNA and RNA. This sensor is based on optical properties of nanoparticles.

- **Smart Drugs[8,9]:** Drugs when injected inside the human body will be able to predict the specific location where the human cells have been contaminated and then release a precisely targeted drug dose (Peppas). Belgian chemists have developed "self exploding" microcapsules which will be able to precisely release drugs inside the human body weeks or even months after injection.
- Biochemist Susan Hardin, and four University of Houston colleagues, are developing a new technology for direct molecular sensing that could be used to sequence an individual's entire genome—the gathering of all the genetic information contained in a person's DNA—in less than 24 hours, rather than 2–3 days. When fully developed, the technology could offer doctors a more rapid and more thorough way to determine who is at risk for certain genetic diseases, or which people might react adversely to a particular drug.
- **Gold nanoshells:** (Figure 2) They are nanoparticles made of silica (glass), which are completely coated with gold (Ha, Jeong, & Chung, 2005; Jain, 2005). Their diameter can vary from 100 nm to as large as several hundred nanometers. Researchers are trying to make use of gold nanoshells for the detection as well as treatment of cancerous cells.

Figure 2. Gold nanoparticle (Courtesy: When gold becomes a catalyst by staff writers)



- **Quantum dots[10]:** (Figure 3) "Quantum dots" are nanoparticles made out of semiconductors having unique electrical and optical properties (Chan, 2006; Jain 2005; Jiang, Papa, Fischer, Mardyani, & Chan, 2004; Weng & Ren, 2006). They emit distinct colored when exposed to light depending upon their size. The smaller the quantum dots, the brighter the color. They are specifically used for *imaging purposes* inside the human body. They demonstrate extremely high sensitivity. Imagine a single protein tracked in a living cell by the use of the optical properties of quantum dots.
- **Silver nanoparticles:** (Figure 4) As the term suggests, they are nanoparticles derived from silver atom. A study conducted by the University of Texas and Mexico University, found that silver nanoparticles can kill HIV-1, and is likely to kill virtually any other virus.

Figure 3. Electron micrographs reveal arrays, shown in false color, of spherical and cubic quantum dots made of lead selenide and lead telluride (Courtesy: A. Norman, S. Ahrenkiel, A. Hicks, J. Murphy/NREL)

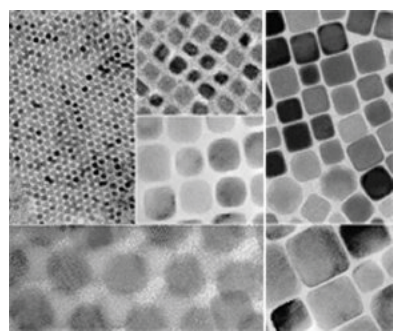


Figure 4. Silver nanoparticles

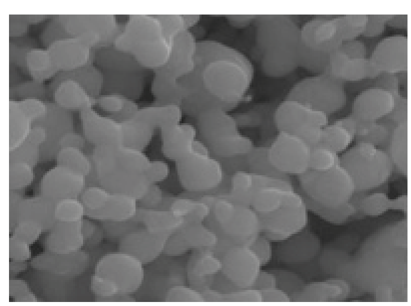

- **Regenerative medicines:** (Emerich, 2003; Rajangam, Behanna, Hui, Han, Hulvat, Lomasney, & Stupp, 2006; Yamato & Okano, 2006) Regenerative medicine helps natural healing processes to work faster, or uses special materials to regrow missing or damaged tissue. Scientists at Northwestern University are working towards the development of regenerative medicines. They have successfully *grown nerve cells* using an artificial three-dimensional network of nanofibers. They have also developed a liquid that forms a gel-like mass of nanofibres on contact with, water which could provide the most promising vehicle yet for the *regeneration of damaged spinal cords*. Many scientists working in the area of regenerative medicine are trying to develop *artificial scaffolds* that store or attract cells, and then control their growth and final identity.

FUTURE TRENDS OF BIONANOTECHNOLOGY

As we see, nanotechnology has a large number of applications in the field of biology and life sciences. Due to this, bionanotechnology is receiving huge amount of funds from not only the government, but also private lenders like the Venture Capitalists. In fact, bionanotechnology has become one of the top areas of funding by the Venture Capitalists.

The future trends of nanotechnology seem to be definitely increasing. Medical device applications, research, technological applications, and so on are being increasingly approved and funded. "*As of mid-2006, 130 nanotech-based drugs and delivery systems and 125 devices or diagnostic tests are in preclinical, clinical or commercial development.*"[11] According to the U.S. National Science Foundation (NSF) (2001), by 2015, about a half of all the pharmaceutical industry products, which is over $180 billion per annum, will be produced by nanotechnology.

Many market researches have been conducted on the future of bionanotechnology. Here we shall describe only a few.

Research conducted by *Lux Research Inc.*[12] (Figure 5 & 6) shows that R&D, conducted throughout the globe, in all the sectors of nanotechnology approximated around $9.6 billion in 2005. It also projected that share of nano-enabled drug delivery in the market will rise from $980 million in 2005 to approximately $8.6 billion by 2010. Nanotherapeutics approximated $28 million in 2005, and is bound to grow to $310 million by 2010, while the nano-enabled diagnostics which were $56 million in 2005 will grow to about $1 billion by 2010.

Figure 5. Results of research conducted by Lux Research Inc.

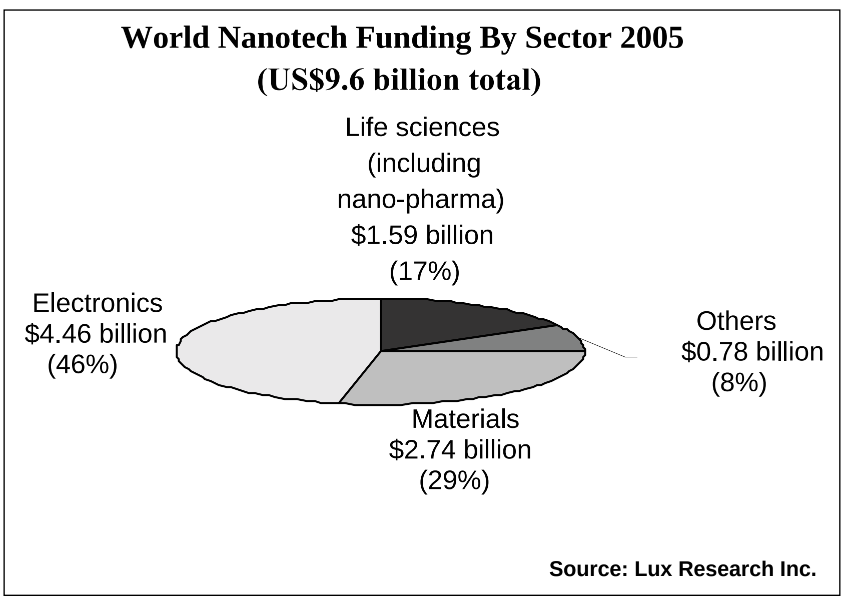

Figure 6. Results of research conducted by Lux Research Inc.

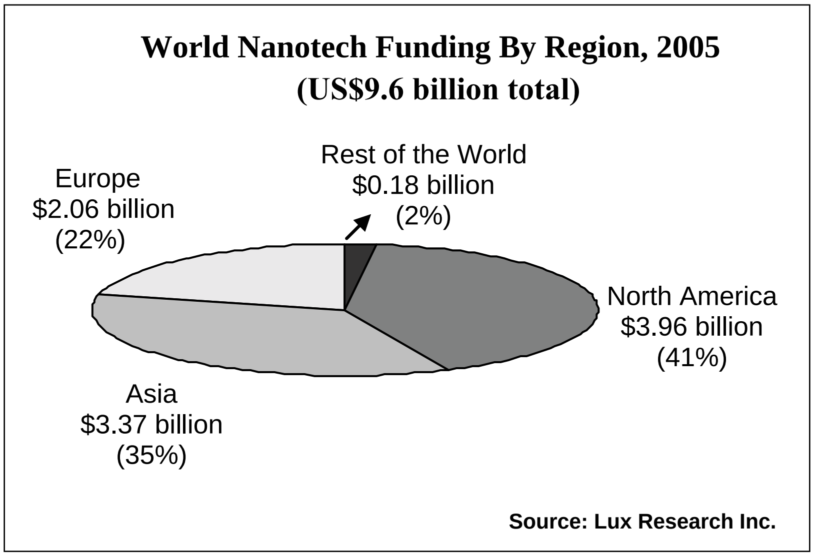
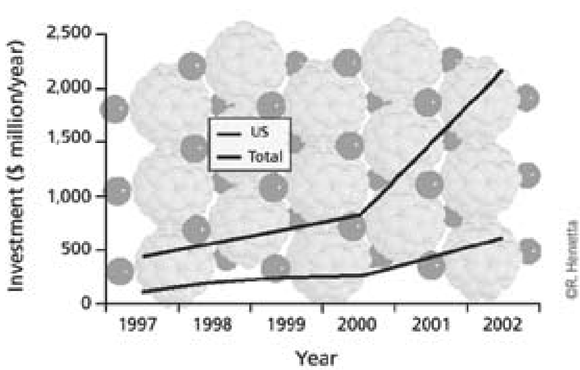


New analysis from *Frost & Sullivan*[13] (Figure 7), World Nanobiotechnology Market, reveals that sales of nanomaterials for use in *nanobiotechnology* applications generated revenues of *USD 750.0 million in 2004*. This figure is projected to reach *USD 2,056.5 million in 2011*.

U.S. National Science and Technology Council[14] estimated nanotechnology products to be around $1 trillion/year by 2015 with a breakdown in electronics and communication of $300 billion, materials and processing of $340 billion, life sciences of $180 billion, and sensors and instrumentation of $22 billion.

Analyzing the data from all the three researches mentioned above we can say that the future of bionanotechnology is extremely bright and flourishing.

Figure 7. Analysis from Frost and Sullivan[13]



CONCLUSION

Nanotechnology shows an extremely enormous potential for phenomenal works in the fields of medicine and biotechnology. In future, nanotechnology can help in the early and effective diagnosis of various diseases like cancer, Alzheimer, and so on.

The most significant applications of bionanotechnology lie in two major fields of therapeutics and diagnostics. We have discussed above some of the most prominent and researched applications of bionanotechnology like dendimers, personalized medicines, bionanosensors, regenerative medicines, quantum dots, gold nanoshells, silver nanoparticles, smart drugs, and so on.

Apart from studying the applications of bionanotechnology, we have also shown the future prospects of bionano. Currently, bionanotechnology is in the phase of being discovered and researched upon. In spite of its huge number of applications and being funded generously, it has very few products available in the market as of today. However, with the next five to 10 years, it is predicted that around 200 products based upon bionanotechnology will be FDA approved.

KEY TERMS

Bionanotechnology: Area of study where nanotechnology has applications in the field of biology and medical sciences.

Nanodiagonisis: Application of bionanotechnology for detection of diseases at molecular level.

Nanotechnology: Engineering of functional systems at the molecular scale.

Nanotherapeutics: Application of bionanotechnology in which the diseases can be treated by the use of various techniques at molecular level.

Nanoshell: A spherical core consisting of a particular compound, which is surrounded by a shell of a few nanometer of thickness.

Personalized Medicine or Patient-Specific Medicine: The prescription of specific therapeutics best suited for an individual.

Quantum Dots: Nanoparticles made out of semiconductors having unique electrical and optical properties.

Regenerative Medicine: Helps in natural healing processes to work faster, or uses special materials to regrow missing or damaged tissues.

D

Dealing with the Primacy of Knowledge in an In-Patient Mental Health Setting

Ivor Perry
de Montfort University, UK

INTRODUCTION

This article brings together three strands of interest to IS researchers: the problem of managing knowledge, particularly deep experiential knowledge; the opportunities and limitations of process and process-based systems (PBS); and the interplay of organizational culture across both. Similar work has been done in medically oriented departments, such as pediatrics and admissions, where a link between PBS and changes in organizational culture has been observed (Perry, 2003) and where an argument has been developed that PBS actively contribute to the creation of organizational knowledge (Perry, 2004).

Healthcare processes can be complex, and often appear to be unique to the patient (Smith, 2000). Although case mix systems and, in the last few years, electronic patient record (EPR) systems, have become common (Smith, 2000), the problem of handling highly iterative, possibly idiosyncratic processes remains. Although "care pathways" can be defined and often executed with little change, many treatments nevertheless are composed largely of ad hoc patient-carer interactions where the carer may be using a large amount of experience and expertise, overlaying their training (Ward, 1992).

A mental health unit was selected as the setting for this particular piece of research because it displays characteristics that are qualitatively different from those other areas of health care (Altschul, 1997). Mental health units, due to the nature of their work, deal with a myriad of variables in terms of physical, behavioral, and cognitive disorders, and staff appear at least to use a high degree of tacit knowledge (Clarke, 1999).

The results, it will be argued, point toward the value of PBS rather than the more static use of databases. On the other hand, the problem of interpreting system-generated data, unaccompanied by interpretive clues from other members of the community of practice, still remains.

Kakabadse, Kakabadse, and Kouzmin (2003) discuss a continuum of types of knowledge that runs through data-information-realization-action-wisdom. Substantially, they identify a deepening complexity and usefulness of knowledge as more and more cognitive and interpretive processes are deployed. At the far end of the continuum, wisdom therefore becomes a mode of symbolic processing by a highly developed will (Kakabadse et al., 2003) Importantly, intention and personality, including life experience, are essential to make the most use of knowledge. It is this aspect of knowledge management that forms a key issue to be dealt with in this article.

PROCESS-BASED SYSTEMS

PBS can be defined broadly as systems that enact business processes. They may be highly prescriptive, like some of the insurance claims applications in large financial institutions, where agents have little choice in the order and number of steps they must follow. They may be ad hoc systems, like some groupware applications. They may be what has been described as proto-PBS (Perry, 2004), systems such as electronic patient records that do not automatically move from one stage to another but indicate when a new stage may be necessary (e.g., viewing the results of a hematology report).

Additionally, the EPR records themselves constitute the content of a number of organizational processes, particularly in the area of patient care. Systems that *address processes rather than transactions* have been an area of research focus for some time (Doherty & Perry, 1999). The argument has been that these systems accrete organizational knowledge as they move through their process; in this way, they help to create and expand organizational knowledge by bringing existing and new data together and prompting staff to look afresh at the available information (Perry, 2004).

An example of a proto-PBS in a mental health setting is discussed by Bloomfield (2005), who describes the electronic whiteboard used by a number of District Health Boards (DHBs) in New Zealand. This system—officially termed the Current Customer View (CCV)—acts as a metalayer for existing mental health systems. It permits staff at a DHB to view important patient data that may be held on the systems of other DHBs. This is significant, as mental health patients may well move abruptly and without informing their doctor; in such situations, clinicians in a new area need current information about the patient's history, recent problems, behavior, and medication (Bloomfield, 2005).

Managing knowledge in health care

A general problem in the discussion of knowledge management in any complex social setting is to understand the nature of the knowledge being created, manipulated, or communicated. Polanyi (1958) was among the first to identify the significance of tacit knowledge, while Nonaka (1990) reinterpreted the concept, asserting that tacit knowledge could be made explicit. Hitt and Tyler (1991), studying the behavior of business executives, concluded that they use automatic and nonconscious processes. Further, they believed that these processes drew upon experientially established cognitive structures (Hitt & Tyler, 1991). We can see how significant tacit knowledge can be; these processes and structures were being used in making *strategic business decisions*. Later, Nonaka (1994) noted how people used stories, metaphors, and analogies in order to share and communicate tacit knowledge. This sharing of oblique or interpreted knowledge is central to the problem of complex knowledge management, since health care includes not only medical evidence but also opinion and experience, particularly in relation to patient care (Priebe & Slade, 2002).

CULTURE AND CLIMATE

Organizational culture is most often revealed in how it and the organization are perceived by organization members (Schein, 1999). In large health care organizations and even within hospitals, it is to be expected that a variety of cultures will exist (Helms & Stren, 2001; Hofstede, Neuijen, Ohayv & Sanders, 1990). Additionally, research seems to show that whatever the type of culture, it will affect the perceptions of the staff. Similarly, major organizational changes will affect staff attitudes and practices, and this will affect culture (Schein, 1999). In the NHS (the United Kingdom's National Health Service), a study during intense change was carried out by Litwinenko and Cooper (1994). They found not only that the proposed changes cut across traditional beliefs and expectations held by the health care worker, but also that all types of culture present in the organization were changing (Litwinenko & Cooper, 1994).

A critical element of nursing practice and knowledge transfer is 'organizational climate'. (R. B. Brown & Brooks, 2002) This is associated with but different from organizational culture, which is the broad set of commonly held attitudes, beliefs, and assumptions that characterize an organization (Brown, 1998; Sathe, 1985; Schein, 1999; Smircich, 1983). Organizational climate refers to the atmosphere that employees perceive in their organizations. It is created by practices, procedures, and rewards, and may differ markedly from one hospital department to another. Organizational climate is also associated with shared emotion or feelings. This emotional dimension has been shown to be both a social influence on the behavior of individual staff members and on their collective actions (Brown & Brooks, 2002). As a result, Brooks and Brown identify emotional climate as an important social construct in the interaction among staff. While their study does not specifically address knowledge management or creation, it does make it very clear that individual and group self-identification both stem largely from stories and from shared experience. For students of knowledge transfer, this observation is highly significant. In a nursing environment, we have to consider not just the transfer of explicit knowledge or the passing on of know-how, as defined by Nonaka (1991). We are also dealing with feelings and emotions, which are sometimes very deep-seated and contribute to the identity of the unit.

MANAGING KNOWLEDGE IN MENTAL HEALTH

Scott (2005), in an informative paper on knowledge workers as part of a social network, makes some initial points: "Their daily work may be unpredictable, multidisciplinary, and nonrepetitive. The jobs assigned to them have long term goals and, due to the relatively standard ambiguity and complexity of the task, require knowledge workers to routinely collaborate with co-workers to utilize multiple viewpoints to solve problems" (Scott, 2005). This accords well with the observed pattern of work in mental health care; standard mental health nursing texts refer frequently to the need to act as a team, to discuss findings with colleagues, to prepare handovers for other team members as they come on shift, and to discuss issues with patients both within and outside of formal interviews (Ward, 1992).

This raises the question not only of interstaff knowledge transfer, but also of staff-patient knowledge transfer in a mental health setting. Traditional, authority-based approaches to psychiatry changed markedly from the 1960s (Clarke, 1999). The nonjudgmental counseling of Carl Rogers emphasized the acceptance of the client's behavior and attitudes, underscoring the essential place that tacit knowledge, in its broad sense, occupies in mental health care. The work of rigorously postmodern psychiatrists such as R.D. Laing in the 1960s threw the central position of tacit knowledge into sharp relief. Effectively, he deconstructed traditional medical discourse and offered an alternative vision where indeterminacy and paradox created unexpected but liberating states of mind (Clarke, 1999).

Laing's approach to psychiatric knowledge was not dissimilar to Foucault's conviction that knowledge, or rather the socialized use of knowledge, is a primary source of power. Like Foucault, Laing was of the opinion that the construction of knowledge can be observed in the discourse that is employed by social groups, and that the discourse of the powerful can then be deconstructed to provide alternative interpretations of reality that will effectively give power to the disenfranchised (Butler, 2002; Seidman, 1998).

Meanwhile, mainstream mental health care has become increasingly evidence-based since the 1980s, although this should not be taken to mean that all evidence is simplistically statistical in nature (James & Burns, 2002). On the one hand, evidence-based medicine has been and is being used to demonstrate cost efficiencies and savings (James & Burns, 2002). On the other hand, the postmodern legacy has been to challenge the objectivity of scientific medicine and to highlight the evidence of patients. Laugharne (2002) contends that although clinicians are educated in the scientific method, the practice of mental health care should not be a scientific exercise but an exercise in humanity, informed by ethical and moral choices.

If evidence-based practice is being seriously questioned (or at least the type of evidence is being seriously questioned) in mental health practice, where does that leave the issue of knowledge management in this area? Unsurprisingly, perhaps, researchers such as Allard (2002) believe that progress in this area is inextricably linked with discovering the hidden assumptions and agendas at play in mental health research. His call is for evidence that takes into account the value systems of users/survivors (of mental health care) (Allard, 2002).

METHODOLOGY

Knowledge management is studied seriously within the health care environment, but it appears that comparatively little is discussed in mental health care, which appeared to use a large element of tacit knowledge. Also (speculatively) perhaps *because* other branches of health care can benefit so quickly and directly from the introduction of explicit knowledge management, general medicine and explicit knowledge handling have occupied a good deal of attention in the literature.

In order to form some understanding of the relationship (if any) between the available literature and the actual practice and perceptions of practitioners in mental health, it was decided to follow Churchill's (1991) approach and undertake an exploratory study. A specific choice was therefore made to begin with a discrete unit. A mental health unit within a large general hospital in the United Kingdom was selected, and nursing staff was interviewed at intervals over a three-month period.

In order to obtain a broad perspective and to elicit staff's own views, it was decided to employ a mixed methods approach in order to provide a degree of triangulation, as described by Flick (2004) and Hildebrand (2004). Central to this concept was the framework of grounded theory (Hildebrand, 2004) on several grounds. First, it offers a conceptual framework in which multiple data streams from literature, observation, and narrative can be drawn together through a recursive sense-making process. Second, it engages the contribution of practitioners and their perspectives, for example, through both ethnographic and phenomenological studies. Finally, it allows space for the interplay between researcher and practitioner in order to develop new, independent perspectives (Leonard & McAdam, 2001).

Within a longitudinal timeframe, as recommended by grounded theory concepts, the interviews were considered and assessed using a modified form of discourse theory. The exploratory nature of the research, for example, did not permit extended time to revisit conversations more than once in order to gain multiple and deeper insights into the emotional cognition of the actors in the mental health unit (Mangham, 1998). On the other hand, some techniques of discourse theory proved very useful (e.g., to allow an interviewee to feel relaxed so that when he or she was describing his or her world, his or her perception was as useful as the worlds being described by others. Further, discourse theory allows the researcher to examine the positioning of himself or herself as interpreter, and of the interviewee as storyteller. Both these positions are relevant to knowledge transfer and to knowledge creation, as they form the building blocks of mixed explicit and tacit knowledge (Davies & Harre, 2001).

Throughout the interviews, cognizance was taken where possible of nonverbal communication in order to compare with the language dimension offered by discourse analysis. Within this area, attempts were made to compare nonverbal styles with task, authority, and gender roles (Remland, 2000).

RESULTS

One of the most remarkable findings was the strength of feeling (i.e., emotional climate) surrounding the awareness of group identity. Comments such as "Mental health nursing isn't like anything else—even in the NHS, they don't realize how different it is" were usually accompanied with nonverbal stresses of hand or eye movements, or raised voices.

Nurses also identify with the patients as much as with the concept of being clinical staff. "When someone says they're depressed, we know what they mean. There's no point in telling them that they're not depressed, because that's a particular medical diagnosis, and they're suffering from something else." It appears that, mirroring de Pinheiro and Spink's (2004) findings, meanings are being sought and negotiated to avoid the therapeutic relationship becoming trapped into technical rationality.

It became evident that this unit, so far as the nursing staff were concerned, were functioning as a community of practice (Wenger, 1998): "Coffee breaks and handovers are very important. We talk about events and patients, but we're also saying to each other, 'I know what it's like; we're all in the same boat'"; "The way we work is based on best practice—yes, obviously—but we have our own ways of just signaling to each other that a certain patient is having a difficult day, or that a particular doctor is making some daft decisions." The interview responses offered all three of Wenger's community of practice dimensions: (1) nurses saw themselves as engaging in a joint enterprise understood and *continually renegotiated* by the members [emphasis added]; (2) the mutual engagement had bound members (interestingly, patients seemed included, too) into a social entity; and (3) it had developed a *shared repertoire* of communal resources (routines, sensibilities, artifacts, etc.) (Wenger, 1998).

The relevance to knowledge management of this sort of community of practice is quite profound and touches at the heart of the problem that sooner or later information systems must deal with. The group—in fact, the human process that the group enacts—retains knowledge in living ways, unlike a database or manual (Wenger, 1998).

The ways in which knowledge is currently recorded are varied and regarded in different ways. At the moment, the unit has access to the hospital's patient administration system (PAS), although this is regarded at best with a degree of condescension. It is criticized as being often inaccurate and out of date. Therefore, it is rarely relied upon, and staff uses corroborating data when they can, usually from the patients themselves. Much of the useful (i.e., according to the nurses) data are recorded on paper within the unit itself. On the one hand, the PAS is held in low esteem, but on the other hand, computing technology is seen to be advancing rapidly. Again, (perhaps defensively) staff questions whether any form of technology can adequately capture the kind of knowledge they need to impart to colleagues.

DISCUSSION

Although there is comparatively little written on the subject of knowledge management in mental health, there is no shortage of evidence. It is the nature of that evidence that poses problems for the researcher.

Strictly speaking, information systems need not be technology- or computer-driven at all. Most management information systems textbooks will offer a definition that allows for the nonuse or the partial use of technology (O'Brien & Marakas, 2006).

The richness of the evidence surrounding the types of knowledge and the physical expressions of knowledge (e.g., individual behavior, cognitive processes, work processes, PAS, handwritten notes, etc.) should not be seen as a problem for the IS researcher, but rather the beginning of the solution. Blackburn's principle of complementarity (described by Gray)—full understanding of a phenomenon requires the application of a number of complementary theories or descriptions (Gray, 2000)—helps us move forward by recognizing that an array of interpretations of knowledge is probably essential in finding better ways of creating, managing, and transferring it. Information systems must be flexible enough to support these interpretations.

The current consumer view (CCV) used in New Zealand (see Introduction) is very much like a proto-PBS (process-based system) (Perry, 2004) that shares similarities with groupware systems (Ciborra, 1996) in terms of initiating processes, even if those processes are then continued outside the information system itself. The CCV is also significant in knowledge management terms, as it provides the interface between the data management world and the human process world of cognate functions, know-how, and emotions.

Since most other means of handling knowledge in mental health appear to be part of a process or initiate processes, it would appear that the use of technology-based systems with a process capability would be much closer to the way that staff members seem to work. In other words, just as the CCV initiates and, to a limited extent, enacts a process, so IS professionals might start to embed process within their systems wherever possible, not in a prescriptive way, but in a permissive sense that enables the staff to select and use process rather than just extract or load data.

CONCLUSION

This article has explored the interplay between explicit knowledge and the extensive, often hidden environment of tacit knowledge. It has identified the importance of these issues in mental health care as a work environment that utilizes and depends on such tacit knowledge to a greater degree than medical nursing or many other professions. In doing so, it continues a perspective on knowledge management that has been accepted for a number of years already—we should consider the topic of information systems as more of a social science or a sociological subject, not simply a technical one (Galliers, 1993).

While many vendors (CSE-Servelec, 2006; Graphnet Health Ltd, 2006; iSoft plc, 2006) are working on or have produced case work software for mental health practice, all have stopped short of consciously harnessing the potential of the deeply held, frequently unconscious knowledge of nursing staff. The commercial judgments of the vendors are, of course, outside the scope of this article, but it is worth looking at the problems they would face since they are largely the same problems that the IS researcher faces when considering the role of technology-based systems in mental health care.

First, there is the problem of identifying what the tacit knowledge is. Looking at the evidence so far, it is most frequently observed in behavior, both linguistic and nonverbal. It is grounded in the organizational culture, which, as we have seen, may be quite specific in a small, tightly identified or geographically isolated unit (Helms & Stren, 2001). It is also grounded in the emotional climate of that culture, which may be even more specific (Brown & Brooks, 2002).

Second, there are the technological problems of capture, storage, and communication. Some of the case work systems (e.g., Graphnet) routinely use large data objects (X-ray images, scanned document images, etc.) and employ technological standards like XML to capture, sort, and display a variety of data from many different formats.

Speculatively, it may be viable for staff members to record their data as transcript and use video/voice recognition software to encode the data as text; then it can be used easily within conventional systems like EPR. This would leave the video/voice recording as an indicator for colleagues of the emotional content. On the other hand, such systems would perhaps be so far outside the established norms of information requirements that it would be at direct variance with organizational culture, which, as researchers have noted for many years, would result in very strong user resistance, quite likely leading to system failure (Cooper, 1994).

There is also the argument, proposed by a number of psychiatrists and mental health researchers, that the very act of fitting data into neat classifications is problematic when trying to treat patients with mental illnesses. Without going to the extremes of Rogers or Laing, such ideas are now becoming part of mainstream thinking. The more one takes account of human experience, the more difficult it is to utilize the language of diagnostics and therapeutics (Clarke, 1999). The argument even can be made that database-type classifications have dubious authority as knowledge, since each patient has to be viewed as a unique entity.

If knowledge in mental health care is heavily dependent on linguistics and behavior, then what role can information systems realistically play? Should they simply be relegated (as they often are, and as the PAS in this study was) to the storage and retrieval of objective data such as name, date of birth, and address? Should mental health information systems instead be transformed from their (positivist, medical) linguistic basis into (subjectivist) semiotics-based systems? Probably not.

First, information systems developers, in conjunction with users, need to be aware that far more knowledge is at work than currently can be managed technologically. Second, both parties should be aware as they design systems that, especially in mental health, the medically-sanctioned terminology and process will exercise power both of action and of meaning over staff and patients alike.

Second, there is much that can be done to improve existing systems. Whereas the PAS in this study was effectively a straightforward transactional system (Perry, 2003) and therefore did little to support nursing processes, process-based systems like the CCV (Bloomfield, 2005; Orr, 2005) can win considerable enthusiasm by demonstrating that they can act as an expert assistant to the practitioner, to the point of becoming a virtual colleague. As Maier and Remus (2003) point out, such process knowledge management (PKM) systems will, at a functional level, include personalization, contextualization, *navigation from knowledge elements to people* [emphasis added]. There is evidence that process-based systems enable organizational functions to run more easily, conveying not just data, but knowledge, thus changing the normative expectations of users (Perry, 2004). This is in line with Tsoukas' (1996) suggestion that the use of knowledge is conditioned by the normative expectation of people's organizational function.

To return to the paradigm of data-information-realization-action-wisdom (Kakabadse et al., 2003), if wisdom is the highest expression of knowledge and is exercised by the operation of a purposeful will, then successful mental health interventions (by the nature of the knowledge exercised) require wisdom and all the supporting dimensions of knowledge. The evidence seems to point to process-based systems, whether they are EPR, case work, or New Zealand's CCV, to be the most effective means of joining the tacit interpersonal dimension of practice with the explicit, medical, and procedural dimension.

KEY TERMS

Evidence-Based Practice: The use of external evidence, including random trials, rather than a reliance on clinical authority.

Process-Based Systems: Systems that encapsulate or enact business processes. Examples may be workflow systems, CRM systems, groupware, electronic patient records.

Organizational Climate: The atmosphere that employees perceive in their organizations. It is created by practices, procedures, and rewards.

Organizational Culture: The broad set of commonly held attitudes, beliefs, and assumptions that characterize an organization.

A Decision Based Support System Based on GIS Technology

INTRODUCTION

The continuous increase of the national expense for the healthcare services, the necessity to adjust the performance of the service of the National Healthcare System to the change of the demand of health coming from the population, and the necessity to evolve towards a logic of integration along a *"continuum of care,"* push for the reorganization of healthcare services inside the local healthcare district. This should permit:

1. The increase of the efficiency level, by means of economies of scale, know-how diffusion, the elimination of redundant resources;
2. The acquisition of competitive advantage for the network components, which are focused on specific areas and are subject to a smaller competitive pressure, due to the existence of protection mechanisms;
3. The increase of clinical effectiveness; and
4. The increase of the quality of service.

On this basis, it is possible to define the main factors to take into account for the reorganization of healthcare services inside the healthcare district: (1) the territorial distribution of the services; (2) the citizen-customer satisfaction, in terms of expectations and preferences; (3) the centralization of high complexity services as a guarantee of quality and cost sustainability; (4) the appropriateness of the healthcare services, in relationship with the local needs of health.

The study of these factors implies the analysis of a great amount of quantitative and qualitative variables, and the management of different types of data, including geographical information.

According to Hopkins (1977) and Collins et al. (2001), such a problem can be expressed as a complex localization problem, and consists of the identification of the most suitable location, according to specific priorities and to the features of the activities to be performed.

In particular, its application to the integrated healthcare network model consists of the research of the optimal location for local healthcare services.

A useful tool to support the solution of localization problems is represented by Geographical Information Systems (GISs) (Mullner, Chung, Croke, & Mensah, 2004). Such technologies are able to store, process, and represent large quantities of data, combining data management and spatial referencing capabilities. They are also able to screen the set of alternatives, and so, they can provide support when the set of location alternatives is very large (Eastman, Kyem, & Toledano, 1993). Because of this, they can be used as support tools for solving optimisation problems. This can be done by integrating optimisation models in a GIS environment (Lin & Kao, 1998). However, the growing dimension of the problem makes the integration of optimisation techniques into a GIS environment very difficult, increasing the computational complexity.

The application of *multiattribute* and *multicriteria methods* (Chan, 2001), based on heuristic techniques, can be an alternative solution. These methods cannot lead to the optimal solution, but they permit to identify "most suitable" locations, even when the complexity of the problem is high (Malczewski, 2004). They are generally based on criteria weighting techniques, such as Analytic Hierarchy Process (Saaty, 1990) and Simple Additive Weighting (Carver, 1991; Eastman et al., 1993), and their use is suggested when technological limitations do not permit to use more complex methods to calculate the optimal solution (Cromley & Hanink, 1999).

LOCALIZATION METHODOLOGY

The solution of the localization problem of a healthcare network cannot be disjointed from the analysis of all those factors influencing the perception of the health services by the patients. Such factors have both a quantitative dimension (e.g., the distance from the essential service), and a qualitative one (e.g., the perceived quality level of local healthcare services, or the chance to choose the place where to receive assistance).

With reference to this, Fortney, Rost, and Warren (2003) point out five possible dimensions for the analysis: affordability, acceptability, accomodation, availability, and accessibility. The last one tends to be extremely useful for examining the spatial interaction between healthcare services and patients. Nevertheless, the accessibility problem has to be solved, referring to the analysis of the demographic, economic, and social characteristics of the healthcare district, aimed at identifying the health problems and needs of the population (Curtis & Taket, 1996) and pointing out possible situations in which the risk to be not cured, or to be cured late, is very high (Brown, 1988).

According to Harper, Shahani, Gallagher, and Bowie (2004) the localization of the healthcare services is based on eight factors considered relevant for spatial analysis:

1. **Services and clinical speciality:** Analysis of the currently provided services, in terms both of medical, surgical, or diagnostic services, and of resources (namely, number of beds, physicians, nurses, and so on).
2. **Actual location of the healthcare centres:** Analysis of the localization in the examined area of the services with high and low specialization, aimed to identify zones in which it is necessary to locate new services or zones in which there is useless redundancy.
3. **Distribution of the population:** Analysis of the potential patients who reside in the area of the existing healthcare centres, also using social and economic data.
4. **Demand of health:** Analysis of the health demand referred to different healthcare services.
5. **Waiting times for the access to the cares:** It is important to find the trade-off between resources and system performance, in terms of waiting time for the access to cares.
6. **Routes:** It is necessary to assure the accessibility of all patients to given centres.
7. **Estimation of the minimal area:** It is opportune to verify if the potential demand of healthcare services, which characterizes a fixed area, is high enough to justify the location of a new healthcare centre.
8. **Patient preferences:** This concept can be expressed by means of a set of qualitative variables: for instance, the reputation of the healthcare centre, the presence of renowned experts (the patient is usually disposed to wait a long time for a high quality of service), and the perceived quality of services.

Aiming at finding a solution to this complex localization problem—with the specific objective to identify the most suitable location for a new healthcare service in the local healthcare district—a GIS-based methodology has been developed and proposed, adopting the following steps (Digregorio, 2006):

1. Collection of data related to the healthcare district area;
2. Definition of the criteria which affect the choice of the location for a new healthcare service. It is possible to identify two main categories:
    a. the admissibility criteria—the criteria which are considered essentials for eligibility;
    b. the optimality criteria—the criteria which are used for identifying the most suitable location between those who satisfy all admissibility criteria.

    At this step, the analysis considers only basic healthcare services (medicine), such as cardiology, paediatrics, audiology, geriatrics, neurology;
3. Identification of the admissible solutions—the solutions that satisfy the admissibility criteria;
4. Assignation of weights to optimality criteria and the application of the spatial analysis models for the search of the most suitable location (optimal solution)—that is, the admissible location

which receives the highest mark according to the weighted sum of the values for such criteria (Benabdallah & Wright, 1992; Lin & Kao, 1998);

5. Verification of variability and coherence of the optimal solution by means of sensitivity analysis, according to the variation of criteria relative weights;
6. Expanding of the procedure to the localization of surgical and diagnostic services. These services could present some different features from medicine that could affect the eligibility criteria and, consequently, the choice of the most suitable location.

CASE STUDY

A case study is proposed to show how the methodology can be used to investigate a healthcare district which includes 13 municipalities of the province of Bari, in southern Italy, with about 577,000 inhabitants. The existent healthcare services are analysed in detail by means of data provided by the two hospitals which are directly managed by the local sanitary authority. A database is created for demographic, social, economic, and geographical data, related to the spatial distributions of the existing hospitals and outstanding healthcare centres.

The next step consists of defining whether it is opportune to activate new healthcare services (in this case, cardiological services). The parameters which express the waiting time for the access to cardiologic cures are defined in order to measure the actual effectiveness of the service, and, on the basis of historical data, the aggregate rate of cardiovascular illnesses is assumed equal to 5% of the population.

Preliminarily, through the use of GIS tools, the healthcare district has been divided into parcels of area equal to one squared kilometer, characterized by the corresponding amount of potential patients.

Looking for the *admissible solutions* of the problem, the following criteria are chosen, and for each one, a corresponding map of suitable areas is created using a GIS:

a. **Potential patients/kmq:** The suitable areas are those where the density of potential patients is not too low. In particular, the areas which have a density equal or higher than the district average have been considered admissible.
b. **Competence areas:** Based on the current location of cardiology services, on queueing and performance indicators, the areas served by such units are identified: current unit performance and corresponding amount of potential patients are jointly considered. The areas showing an acceptable level of service are not included in the set of admissible solutions. This criterion aims at identifying the areas which particularly need the improvement of service.
c. **Proximity to routes:** The admissible areas are those which are located within a distance of one kilometer from main routes.

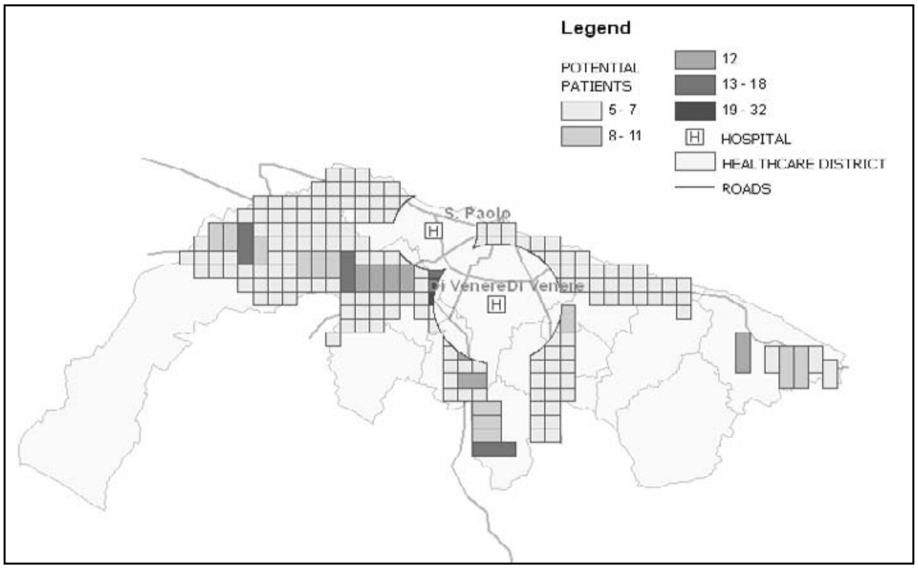
The set of admissible solutions is defined as the intersection of areas verifying the previously mentioned criteria (see Figure 1).

The next step consists of investigating the set of admissible solutions, looking for the *optimal solution* for the location of the new cardiological service. The afterwards procedure is based on the Simple Additive Weighting model (Carver, 1991).

Initially, the following criteria have been chosen:

d. **Distance from indifference areas:** This criterion considers that the part of the population which, according to its own geographical position, cannot choose between a set of healthcare service alternatives is disadvantaged in comparison with those who live within a small distance from more than one healthcare service. We define indifference areas as those within which citizens do not show a particular preference towards a healthcare centre, rather than others. According to such a criterion, the locations which are far from such areas are considered more suitable for locating a new healthcare service.
e. **Proximity to existing centres:** The criterion is based on a cost function which describes the opportunity to locate a new healthcare service where a healthcare centre without such service is already located.
f. **Per capita income:** The criterion is based on considerations of social equity, according to which it is fair to locate a new service in an area where the per capita income is low.

Figure 1. Admissible solutions



g. **Passive mobility of population:** Areas with high passive mobility (i.e., the tendency of inhabitants to use healthcare services located in other areas) are considered more suitable for locating a new healthcare service.

The weights to associate to the four criteria have been determined by applying the AHP methodology (Saaty, 1990), with the aim to express in quantitative information considerations concerning the relative importance of criteria. Relative importance between criteria x and y is assumed to be: 1 – when x and y are equally important; 3 – when x is more important than y; 5 – when x is much more important than y. The resulting optimal weight vector for the above criteria D, E, F, and G is the following:

$\boldsymbol{W^{opt}} = [W^{opt}_D ; W^{opt}_E; W^{opt}_F; W^{opt}_G] = [0.03; 0.32; 0.21; 0.44]$

Then, according to each criterion, the values for every location are calculated. Since they are expressed in different measure units, in order to make them comparable for being summed, they have been translated into a homogeneous scale of integer values between 0 and 8.

It has then been possible to identify the optimal solution, by means of the weighted sum of the values for the four criteria, calculated for each location (Figure 2) by means of GIS spatial analysis functions. The values for each criterion are represented by the map of values associated to possible locations. Obviously, only admissible solutions are taken into consideration. Among such locations, the one with the highest score was chosen as the most suitable area for the location of the new healthcare service.

As a final result, the opportunity of offering new services in an area where such services are not offered—with a low per capita income, well-served by the main routes, and affected by phenomena of population mobility towards other health centres—is pointed out (Figure 3).

Obviously, the choice of the criteria affects the results of site search in a substantial way.

Such an analysis is based on the verification of 13 combinations of weights vectors (W^{opt}_i), representative of all possible logically coherent combinations of weights.

The results show that the solution seems to be more sensitive to the passive mobility criterion than to other criteria. Varying the relative importance of proximity and per capita income criteria does not usually affect the results in a sensitive way. As for the indifference area criterion, it seems to affect the results, but only when its weight is high. Thus, we can assume that for reasonable combinations of the weights vectors the passive mobility criterion is the only one affecting the solution.

Figure 2 . Weighted overlay results

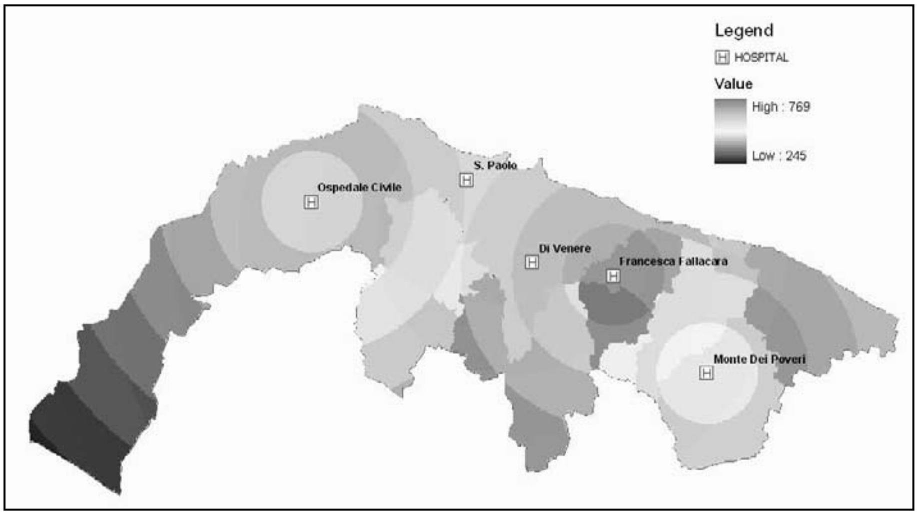


Figure 3 . Optimal solution using W^{opt}

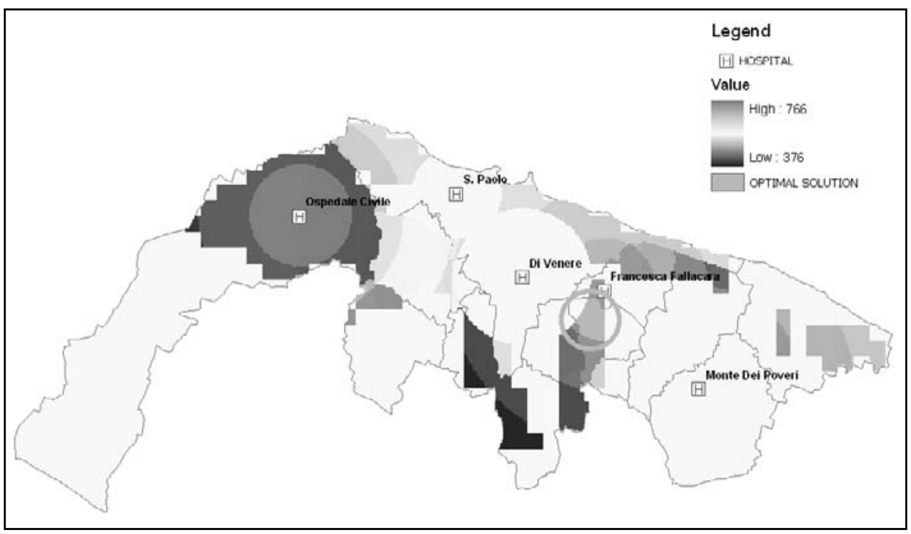

At this stage, the procedure has to be extended to the localization of surgical and diagnostic services. Then, a suitability analysis for adopted criteria is carried out to check whether it is necessary to formulate some of them differently for surgical and diagnostic services.

Regarding to the diagnostic services, the rate of potential patients may be underestimated, because a part of the population may require diagnostic services not related to principal diseases. The per capita income criterion could lose importance with regard to healthcare services which do not provide essential assistance (e.g., plastic surgery).

As a rule, the criteria exclusively based on localization features and/or socio-demographic attributes associated with the healthcare district area, can be considered as independent from the specific healthcare service, and consequently, have general validity. Vice versa, for the criteria which adopt the point of view of the healthcare service provider (local government), it is useful to set the analysis and characteristic parameters according to each case.

Table 1. Sensitivity analysis

In Table 1, the results of the sensitivity analysis conducted to verify the variability of the optimal solution according to the variation of criteria relative weights are shown. W^{opt}_i	Different optimal solutions
W_1= [0.25, 0.25, 0.25, 0.25]	Yes
W_2= [0.55, 0.15, 0.15, 0.15]	Yes
W_3= [0.70, 0.10, 0.10, 0.10]	Yes
W_4= [0.10, 0.10, 0.10, 0.70]	Yes
W_5= [0.07, 0.07, 0.28, 0.58]	No
W_6= [0.03, 0.17, 0.40, 0.40]	No
W_7= [0.03, 0.40, 0.17, 0.40]	No
W_8= [0.04, 0.21, 0.21, 0.54]	No
W_9= [0.07, 0.58, 0.07, 0.28]	No
W_{10}= [0.15, 0.55, 0.15, 0.15]	No
W_{11}= [0.07, 0.58, 0.28, 0.07]	No
W_{12}= [0.04, 0.21, 0.54, 0.21]	No
W_{13}=[0.15, 0.15, 0.55, 0.15]	No

In particular, the geographical proximity criterion originates from the preference for opening new services in existing structures, to reduce the opening cost, depending on infrastructure and facilities costs. In the specific case of surgical or diagnostic services, technology, and accessibility components must be added to the cost function on which is based the proximity criterion. Consequently, it is necessary to implement a much more complex *opportunity/cost function* (C_{opp}), having the following expression:

$$C_{opp}= C_{acc}+C_{op}+C_{tec}$$

where:

C_{acc} = cost which patients have to pay to reach the surgical/diagnostic services;

C_{op} = cost of new surgical/diagnostic services, in term of infrastructures and facilities;

C_{tec} = cost of new medical technology needed.

According to all parameters of surgical service, it is assumed a rate of 2‰ for potential patients and the maps of suitable areas, corresponding to each criterion, are created.

The adoption of the new opportunity/cost function leads to create the new map of suitable areas by overlaying three independent maps, having the same relative importance, each one representing one component of the C_{opp}. In detail, the opening cost (C_{op}) and the accessibility cost (C_{acc}) are assumed to be rising proportionally with the euclidean distance from existing healthcare centres, with the rising ratio of the C_{acc} higher than the C_{op}. The technological cost is considered independent from distance.

As in the previous case, the weight vector used is W_{opt} = [0.03; 0.32; 0.21; 0.44].

The obtained solution is the same as the basic healthcare services (medicine). This demonstrates a quite high level of consistency for the adopted methodology.

With reference to this, it is conducted a new sensitivity analysis as in the first case, with the result that more combinations of weights vectors (W^{opt}_i) compared with the previous case, provided the optimal solution. Then the introduction of the opportunity/cost function seems to increase the effectiveness of the methodology.

FUTURE TRENDS

The previously mentioned trend towards a reorganisation of healthcare services, according to integration criteria, needs the implementation of an adequate system able to monitor network capabilities. GISs will play a key role in the definition of a planning process of healthcare districts able to manage resources in an efficient way and to determine a more coherent distribution of services, by this matching more adequately the population needs.

CONCLUSION

This article proposes an innovative methodology for finding a solution to the problem of localization of healthcare services in a healthcare network. Such a problem has been solved by applying principles and techniques, which are typical of the spatial analysis for localization problems, characterized by quantitative and qualitative, geographical and demographical factors.

The analysis is conducted using GIS technologies, which have great potentialities in terms of management and analysis of a large amount of heterogeneous data. Because of such features, GIS technologies are used as a decision support tool, by means of which the most suitable place for opening a new healthcare service in a healthcare district area has been identified. Such a methodology proves to be robust enough, with respect to the specific context considered, and solutions take into consideration all the main variables of the problem.

KEY TERMS

Geographical Information System (GIS): An information system able to collect both geographical and alphanumerical data.

Location Analysis: A decision-making procedure aimed at identifying the most suitable location within a set (site selection) or without a pre-established set (site search) for a specific purpose.

Multicriteria Analysis: A decision-making approach aimed at optimising different functions/variables at the same time.

Optimisation Problem: A problem consisting in either maximizing or minimizing one or more functions.

Simple Additive Weighting: A multicriteria decision-making technique consisting in assigning to each alternative a sum of values, each one associated to the corresponding evaluation criterion, and weighted according to the relative importance of the corresponding criterion.

Decision Support Systems for Cardiovascular Diseases Based on Data Mining and Fuzzy Modelling

INTRODUCTION

The widespread availability of new computational methods and tools for data analysis and predictive modelling requires medical informatics researchers and practitioners to systematically select the most appropriate strategy to cope with clinical prediction problems. In particular, data mining techniques offer methodological and technical solutions to deal with the analysis of medical data and construction of decision support systems. Furthermore, fuzzy modelling deals with the ambiguity inherent in all medical problems. These methods can be used to design and develop clinical decision support systems (CDSSs), which, after evaluated from the experts, can be integrated into clinical environments.

Cardiovascular diseases (CVDs) are the leading cause of death in many countries worldwide. According to the World Health Organization, CVDs are the cause of death of 16.6 million people around the globe each year. The multifaceted nature of these diseases, combined with a wide variety of treatments and outcomes, and complex relationships with other diseases, for example, diabetes, have made diagnosis and optimal treatment of cardiovascular diseases a problem for all but experienced cardiologists.

This article addresses the decision support regarding cardiovascular diseases, using computer-based methods, focusing on the coronary artery disease (CAD) diagnosis and on the prediction of clinical restenosis in patients undergoing angioplasty. Methods reported in the literature are reviewed with respect to (i) the medical information that are employing in order to reach the diagnosis and (ii) the data analysis techniques used for the creation of the CDSSs. In what concerns medical information, easily and noninvasively-obtained data present several advantages compared to other types of data, while data analysis techniques that are characterized by transparency regarding their decisions are more suitable for medical decision making. A recently developed approach that complies with the above requirements is presented. The approach is based on data mining and fuzzy modelling. Using this approach, one CDSS has been developed for each of the two cardiovascular problems mentioned above. These CDSSs are extensively evaluated and comments about the discovered knowledge are provided by medical experts. The later is of great importance in designing and evaluating CDSSs, since it allows them to be integrated into real clinical environments.

BACKGROUND

Data Mining is the process of discovering patterns and correlations from large amounts of data, using artificial intelligence, statistical, and mathematical techniques (Tan, Steinbach, & Kumar, 2005). Fuzzy logic is the extension of the classical crisp (binary) logic into a multivariate form. Fuzzy logic is closer to the human logic, thus being able to deal with real world noisy and imprecise data (Wang, 1986). CDSSs are computerized tools developed to assist physicians through the process of decision making. A known approach for the development of CDSSs is the use of experts' knowledge combined with an inference engine. However, recent advances in designing CDSSs employ automated knowledge extraction from data, using data mining techniques, while fuzzy logic provides several advantages in designing inference engines, compared to the classical crisp logic. The combination of data mining and fuzzy modelling provides a powerful tool for fully automated creation of CDSSs, experiencing several advantages: (i) transparency in decision making, (ii) addressing the ambiguity inherent in clinical data, and (iii) ability to interpret all decisions in a medical manner. All the above are of great importance for physicians, when performing decision making.

Coronary artery disease (CAD) is the development of atherosclerotic plaques in coronary arteries, resulting in coronary luminal narrowing and subsequently occlusion, and thus leading to myocardial infarction or sudden cardiac death. Coronary angiography (CA) is considered to be the "gold standard" method for the diagnosis of CAD and it is widely used. However, CA is an invasive and costly procedure that needs high level technical experience and technology and cannot be used for screening of large populations or close follow-up of treatment (Escolar, Weigold, Fuisz, & Weissman, 2006). Computer aided methodologies for CAD diagnosis have also been proposed in the literature; in this case the data obtained by some of the above mentioned methods or other sources (i.e., laboratory examinations, demographic, and/or history data, etc.) are evaluated by a computer-based application, leading to a CAD diagnosis. These methodologies can be divided into various categories, based on the type of data they use for subject characterization. Several methods are based on heart sounds associated with coronary occlusions (Akay & Welkowitz, 1993). Also, methods which employ the resting or exercise electrocardiogram (ECG) of the patient, extracting features from it, like the R wave (Szildgyi, Szildgyi, & David, 1997), the QT interval (Ng, Wong, Mora, Passariello, & Almeida, 1998), the T wave amplitude (Sabry-Rizk et al., 1999), the heart rate variability (Tkacz & Kostka, 2000), and the ST segment (Lewenstein, 2001) have been proposed. Furthermore, there are methods using medical images, such as SPECT (Haddad, Adlassnig, & Porenta, 1997), and methods based on arterio-scillography (Pouladian, Golpayegani, Tehrani-Fard, & Bubvay-Nejad, 2005). There exist also methods that employ demographic, history, and laboratory data (Frossyniotis et al., 2001; Mobley, Schechter, Moore, McKee, & Eichner, 2005; Tsipouras et al., 2006) and methods that combine more than one type of data (Kukar, Kononenko, Groselj, Kralj, & Fettich, 1999; Scott, Aziz, Yasuda, & Gewirtz, 2004).

The evolution and widespread adoption of percutaneous transluminal coronary angioplasty (PTCA) represents a major advance in the management of acute coronary syndromes, resulting in a significant reduction in early and late mortality compared to pharmacologic reperfusion therapy. Coronary artery restenosis remains a major limitation of PTCA and is usually defined as ≥ 50% stenosis in the treated segment at follow up, or at least 50% loss of the original gain in the minimal luminal diameter. Many clinical, angiographic, and procedural features have been studied as predictors for restenosis but it has proven difficult to stratify patients with regard to the risk of restenosis. Knowledge of risk factors for restenosis may help to refine indications of PTCA, reduce the frequency of restenosis, and select optimal candidates for a PTCA procedure. Despite lowering the restenosis rate with the implantation of coronary stents, it occurs in approximately 12-60% of the patients within 6 months after intervention depending mainly on the patients' and procedural characteristics. Computer aided methodologies for the prediction of clinical restenosis have also been proposed in the literature. These can be divided into two categories, regarding the data they use for the analysis: methods that employ only CAD risk factors such as demographic, history, and clinical data (Budde, 1999; Tsipouras et al., 2006) and methods that combine CAD risk factors with angiographic features (Maier, Mini, Antoni, Wischnewski, & Meier, 2001; Resnic, Popma, Ohno-Machado, 2000).

CDDSS FOR CARDIOVASCULAR DISEASES

A recently developed method for automated CDSSs creation is based on data mining and fuzzy modeling (Tsipouras et al., 2006). Specifically, in order to create the CDSS, a three stage methodology is used: (i) creation of a rule-based classifier using data mining techniques, (ii) development of a fuzzy logic model, and (iii) optimisation of the fuzzy logic model's parameters. Briefly, in the first stage, a set of crisp rules is generated. This is performed by inducing a decision tree from a training dataset and then transforming the tree into a set of rules. In the second stage, the crisp set of rules is transformed to a fuzzy set of rules, using a membership function instead of the crisp ones and S and T norms instead of the binary AND and OR operators. Finally, in the third stage, all thresholds and parameters involved in the fuzzy model are optimized with respect to a training dataset. The fuzzy model with the optimized parameters comprises the final CDSS. To apply the above methodology in a specific domain, an annotated dataset is required. The quality of this dataset is very important for developing an effective CDSS. This methodology has been used in order to create CDSSs for CAD diagnosis and prediction of clinical restenosis in patients undergoing angioplasty.

Application to CAD Diagnosis

The dataset used for CAD diagnosis included 199 subjects suspected of having CAD and who underwent coronary angiography for the first time. Patients with known CAD were excluded from the study. Of the subjects, 89 had normal angiograms and in the remaining 110 subjects the presence of CAD was confirmed by two experts. In order to characterise each subject, 19 features (shown in Table 1) were used. Two demographic features were recorded: the age and sex of the patient. From the subject's history data, the family history of CAD, smoking history, history of diabetes mellitus, and measurements of hypertension or hyperlipidaemia were used. The incorporated laboratory investigations were creatinine, glucose, total cholesterol, high density lipoprotein, and triglycerides. In addition, Carotid-Femoral Pulse Wave Velocity and Augmentation index were also used as non-invasive indices of arterial stiffness (Van Bortel et al., 2002; Woodman & Watts, 2003). In order to confirm the presence or absence of CAD, coronary angiography was performed by the Judkins technique. All coronary angiograms were visually assessed by two experienced cardiologists to reach consensus agreement. Significant CAD was defined as at least one stenosis of 50% or greater diameter in at least one coronary artery vessel. The absence of CAD was defined as completely smooth epicardial coronary arteries.

In Figure 1 an indicative set of rules is presented. These rules are extracted using data mining and (before fuzzification) were commented by the experts. According to the experts, gender is the most important feature in the produced set of rules. However, this is partially driven from the dataset since 64% of our male population (98/152) was diagnosed with CAD as compared with 25% (12/47) in the female population. Smoking has also been proven to be an important marker for CAD prediction in women; 77% of non smoking women did not suffer from CAD (33/42). In the male population, low HR (i.e., <=49 beats per minute) was found to be an important predictor of CAD; this might be explained by the use of β-blockers (antianginal medications that lower HR) in subjects with very high clinical suspicion of CAD. Also, it appears that elderly males (i.e., age>69 years) with symptoms and signs of CAD have high probability to be diagnosed with CAD, since CAD was found in 92% (24/26) of our elderly male population. In males aged less than 69 years, family history of CAD appears to be a relatively important diagnostic feature for CAD (76% of those with positive family history had CAD, i.e., 26/34). However, some of the derived rules cannot be fully explained based on standard medical knowledge, mainly due to the data-driven nature of the proposed method, which can also discover non important and spurious rules.

In Table 2, several computer aided diagnosis methodologies for CAD are presented. Some of the non-invasive methods, such as computerized tomography or magnetic resonance imaging, suffer from similar problems as CA, that is, being costly and requiring specialized technology and expertise, while they are not widely available (Escolar et al., 2006). Most of the computer based methods are based on the analysis of data obtained by examinations, such as stress ECHO and SPECT, which are also expensive, not widely available, and suffer from technical limitations (Merz, 2005). Exercise stress testing is inexpensive and widely available, but cannot be applied to all patients and has low sensitivity and specificity in the diagnosis of CAD.

Table 1. Features for CAD CDSS

#	Feature	Units
1	Age	Years
2	Sex	male(1), female(0)
3	Family History (FH)	yes(1), no(0)
4	Smoking (Sm)	smoker (2), ex-smoker (1), non-smoker (0)
5	Diabetes mellitus (DM)	FBGC $\geq$ 126mg/dl (1) else (0)
6	Hypertension (HT)	DBP>90mmHg and/or SBP>140mmHg (1) else (0)
7	Hyperlipidemia (HL)	total cholesterol over 220mg/dl (1) else (0)
8	Creatinine (Cre)	mg/dL
9	Glucose (Glu)	mg/dL
10	Total Cholesterol (TC)	mg/dL
11	High Density Lipoprotein (HDL)	mg/dL
12	Triglyceride (TG)	mg/dL
13	Body Mass Index (BMI)	kg/ m^2
14	Waist	Cm
15	Heart Rate (HR)	Bpm
16	Systolic Blood Pressure (SBP)	mmHg
17	Diastolic Blood Pressure (DBP)	mmHg
18	Carotid femoral pulse wave velocity (PWVcf)	m/sec
19	Augmentation Index (AIx)	%

The populations and the parameters collected and analyzed differ among studies; in some of the studies, only male subjects (Lewenstein, 2001; Mobley et al., 2005) or subjects with previous myocardial infarction (MI) or coronary artery bypass grafting (CABG) (Kukar et al., 1999), were included. It should be mentioned that most of the methods reported in Table 2 are based on neural networks (Akay & Welkowitz, 1993, Frossyniotis et al., 2001; Kukar et al., 1999; Mobley et al., 2005; Scott et al., 2004). These methods are not able to provide clear interpretation for their decisions.

Application to Prediction of Clinical Restenosis in Patient Undergoing Angioplasty

The dataset used for prediction of clinical restenosis in patients undergoing angioplasty consisted of 1,000 subjects that underwent angioplasty. In order to characterise the subjects, the 15 features shown in Table 3 were used. Family history, hypertension, diabetes mellitus, current smoking, and hyperlipidemia were defined as for the CAD CDSS. Clinical presentation of CAD was classified as unstable angina, stable angina,

Table 2. Comparison of several computer aided methodologies for CAD diagnosis

Author – Year	Number of subjects	Method – analysis	Se (%)	Sp (%)	Acc (%)
Akay & Welkowitz, 1993	112	Heart sounds – Neural network	78	89	
Haddad et al., 1997	100	SPECT – Case based reasoning	98	70	93
Kukar et al., 1999	327	Subject's data, exercise ECG, SPECT – Neural network	96	84	92
Frossyniotis et al., 2001	139	Exercise ECG, subject's data, indices of arterial stiffness – Neural network	78	75	78
Lewenstein, 2001	776	Exercise ECG	97	98	
Scott et al., 2004	102	SPECT, subject's data – Neural network	88	65	
Mobley et al., 2005	2004	Subject's data – Neural network	100	26	
Pouladian et al., 2005	51	Arterio-oscillography – signal processing	73	90	
Tsipouras et al., 2006	199	Subject's data, indices of arterial stiffness – data mining, fuzzy modelling	80	65	73

or acute myocardial infarction. The vessels treated with angioplasty were the right coronary artery, left main stem, left anterior descending artery, left circumflex artery, and bypass grafts. The patients underwent either angioplasty with balloon alone or balloon followed by stenting with a noncoated metal stent. All patients were followed up for at least 12 months. The composite end point of the study was clinical restenosis manifested as cardiac death, a new non fatal myocardial infarction or a new revascularisation attempt of the stented vessel in less than 6 months after the initial angioplasty procedure.

In Figure 2, some indicative rules are presented. The experts agree that the most important feature in the production of rules for the prediction of clinical restenosis is the number of diseased coronary vessels since 15.4% (i.e., 87/565) of the multivessel cases presented with restenosis in less than 6 months after the percutaneous coronary intervention (PCI) procedure in contrast to only 7.9% (i.e., 29/365) of the single vessel patients. Patients who underwent the angioplasty in a stable condition (i.e., stable angina) had probably a favourable prognosis (only 8.3% of patients with stable angina presented with restenosis in less than 6 months compared to 13.5% of those with unstable coronary syndromes), except perhaps for older (i.e., > 65 years old) or diabetic people. On the other hand, unstable coronary syndromes (i.e., unstable angina and myocardial infarction) are related to worse prognosis in terms of clinical restenosis even in younger ages (i.e., 55 years old) or patients without many severe cardiovascular risk factors. History of a previous PCI procedure and especially history of coronary aortic bypass surgery (occurrence of restenosis in 19.4% of patients with previous CABG compared to 12.2% without CABG history) are associated with increased risk of restenosis after coronary angioplasty. However, some of the derived rules could not be explained based on current medical knowledge on various interactions among the features used in our models.

In Table 4, a comparison of several computer-aided methodologies for the prediction of clinical restenosis is presented. Different datasets were used in each method; therefore a direct comparison is not feasible. Some approaches (Budde, 1999; Tsipouras et al., 2006) are based on noninvasively acquired data, while others employ also data obtained from angiographies (Maier et al., 2001; Resnic et al., 2000), thus being invasive approaches. Data analysis is performed mainly using rule based systems (Budde, 1999, Maier et al., 2001,

FUTURE TRENDS

Researchers have spent great efforts in the design and development of CDSSs for several domains in medicine and health care. Most of the CDSSs try to reduce the effort and time of the experts when performing diagnosis. However, a plethora of systems has been presented for staging, treatment, dose adjustment, and follow-up. An important requirement of this type of system is the transparency regarding the automated decisions and the interpretation they provide. Moreover, experts rely more on systems that their automated decisions coincides with established medical knowledge. Integration of knowledge provided by the experts and knowledge generated using data mining methods, for the creation of more sophisticated CDSSs, is the trend of the future. Established medical knowledge combined with data mining models is the key to increase the effectiveness of these systems and provide advanced tools for computer based clinical medicine.

CONCLUSION

CVDs are among the most life threatening diseases worldwide. A vast amount of patients suffering from CVDs are examined, hospitalized, and treaded every day; this has a major impact in national health care systems. The importance of CVDs has lead to the development of a large number of computer-based CDSSs that mainly focus in diagnosis, treatment, or follow-up. An important requirement of a CDSS is its ability to provide transparency regarding the generated decisions, thus providing a clear insight of their inner process for decision making; this is essential for physicians in order to incorporate such systems in their clinical practice. Another important requisite is an extensive evaluation of a CDSS by medical experts, in order to comment on the functionality of the system and fully exploit its potential. Furthermore, the employment of easily obtained and noninvasive features for decision support is considered an advantage since it facilitates the straightforward application of the system. Most of the CDSSs proposed in the literature do not meet these requirements, thus complicating their application in clinical practice. The CDSSs presented in this article fulfill these issues, making them suitable to be used in clinical practice.

KEY TERMS

Artificial Neural Network: An interconnected group of artificial neurons that uses a mathematical or computational model for information processing based on a connectionist approach to computation.

Clinical Decision Support Systems (CDSS): Computer based methods that aim to assist clinicians in decision making. The core of CDSSs is an inference engine that can generate case specific advice based on medical data.

Clinical Restenosis: Death presumably from cardiac causes, myocardial infarction not attributable to another coronary artery than the target vessel, and target vessel revascularization either by repeat PTCA or CABG.

Coronary Artery Disease: The narrowing of the coronary arteries, sufficiently to prevent adequate blood supply to the heart muscle. It is usually caused by atherosclerosis and may progress to the damage of heart muscle.

Data Mining: The process of extracting previously unknown and potentially useful knowledge, hidden in large volumes of data.

Fuzzy Logic: A way of reasoning that can cope with uncertain or partial information.

Inference Engine: The part of a decision support system that performs the reasoning function.

Definition and Measurement of the Technology Readiness Concept

INTRODUCTION

During the last few decades, various theoretical developments have been carried out with a view to describing the characteristic and distinct behavioral process that lies under any adoption of technological services and products. These developments are based mainly on the Social Psychology approach.

There are three extensive theories within the field of Social Psychology whose ultimate purpose has been to define the internal psychological factors that explain human behavior: the Expectancy-Value Theory, the Cognitive Dissonance Theory, and the Self-Perception Theory. While the Expectancy-Value Theory has been used widely in the research of adoption and usage of information systems, the other two theories have been less recognized.

Of all Expectancy-Value Theory models, we should draw our attention to the Reasoned Action Model (Azjen & Fishbein, 1980), because it underlies many of the studies on usage of technology. The Planned Behavior Model (Azjen, 1985, 1991) represents a reformulation of the Reasoned Action Model, justified by the existence of conducts that, albeit in part, a person cannot voluntarily keep under control. A rough description of both models is presented in this chapter, inasmuch as they served as a basis for the construction of the Technology Acceptance Model (Davis, 1989; Davis, Bagozzi & Warshaw, 1989), known as one of the main models for the technology readiness concept. The Technology Acceptance Model seems to possess a similar or even better explicating power than its predecessors (Davis et al., 1989; Mathieson, 1991; Taylor & Todd, 1995a; Chau & Hu, 2002).

Once we recognize the importance of attitude in predicting the use of technology, we continue by analyzing the Technology Readiness Model (Parasuraman & Colby, 1997, 1998, 2001). During the last few years, this model has been gaining more and more recognition among marketing professionals as a model for the explanation of the technology attitude.

Out of our review, we can make a synthesis of variables related to technology readiness by the analyzed models. The chapter ends with an exposition of the reasons that have led us to choose the Technology Readiness Model as a basic theoretical model to develop a scale of technology attitude.

Expectancy-Value Models

We now proceed with a brief examination of the main Expectancy-Value Models that have served as a theoretical basis for models of use of technology prediction, so we can gain a much better insight of the latter.

The Reasoned Action Model

The Reasoned Action Model (Azjen & Fishbein, 1980), whose ultimate aim is the prediction and understanding of the human behavior determinants, argues that the latter is mostly under the subject's control and, as a consequence, can be forecast by observing the declaration individuals make of their intentions to carry out or not to carry out a particular type of conduct. Also, the behavioral intention directly depends on two factors: a personal one or attitude toward behavior that represents the individual, either positive or negative, evaluation about whether an action should or should not be done; and a social factor or subjective norm that is the personal awareness of social pressures that force us to take that course of action.

Attitudes can be explained by considering the information the individuals possess that shapes their beliefs in the consequences when a certain conduct becomes real. Attitudes do not depend solely on beliefs, but also on the evaluation people make about each of those behavioral beliefs. Therefore, the drive of each belief (degree of certainty that upholds it) is boosted by the negative or positive intensity of the outcome of the conduct. The sum of all products results in an attitude.

Subjective norms can be assessed indirectly from two main components: first, the informative basis of individuals, which establishes normative beliefs, that is to say, beliefs about how other people or institutions (referees) judge how an individual should behave; second, the subject's motivation to observe the referees' directives. Like it happens with attitudes, each normative belief is boosted by the motivation to follow that opinion. The subjective norm is obtained from the sum of all these products.

In this model, we can see a display of another series of external variables or stimulus conditions that affect relationships between intentions and behavior by means of their direct influence on beliefs in the consequences of conduct and in normative beliefs (see Figure 2).

Azjen and Madden (1986) introduced some nuances into the Reasoned Action Model by pointing out that previous experience, attitude, and subjective norm can influence one another; attitudes can influence behavior both indirectly through behavioral intention and also directly; subjective norm can only have an indirect effect on behavior; and previous experience can influence conduct indirectly as well as directly. The results of this investigation also show that the relation between intention and behavior is not as intense as it should be to make trustworthy predictions. Thus, "intentions only forecast behaviors not requiring either special abilities or skills, extraordinary opportunities, nor the other people´s cooperation (Morales, Rebolloso & Moya, 1996, pp. 563-564).

The Planned Behavior Model

Azjen (1985, 1991) reformulated the aforementioned Reasoned Action Model, thus originating the Planned Behavior Model (see Figure 2). The difference between both models lies in the fact that the latter introduces the perceived behavioral control element to improve the behavioral intention forecast. The introduction of this intention-determining factor is justified by the existence of conducts that, at least in part, cannot be kept under the voluntary control of the individuals. That is to say, irrespective of a likely favorable attitude toward a certain behavior and the strong pressure that individuals receive around them urging them to do it, their intention will also influence the subjective likeliness of achieving it or perceived behavioral control.

Figure 2. Reasoned action model (Source: Adapted from Ajzen and Fishbein, 1980)

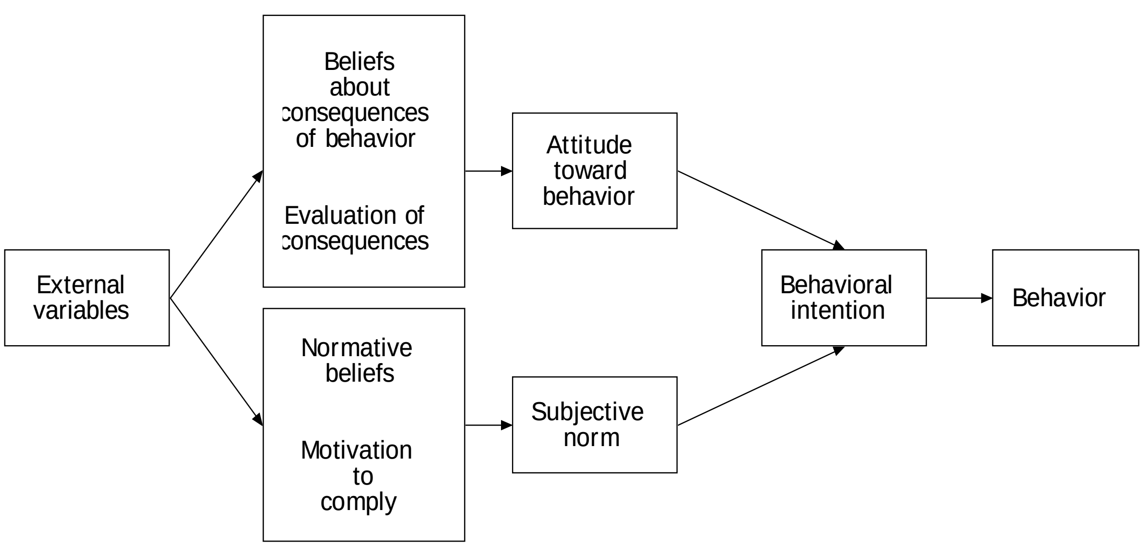

Figure 2. Planned behavior model (Source: Adapted from Ajzen, 1985, 1991)

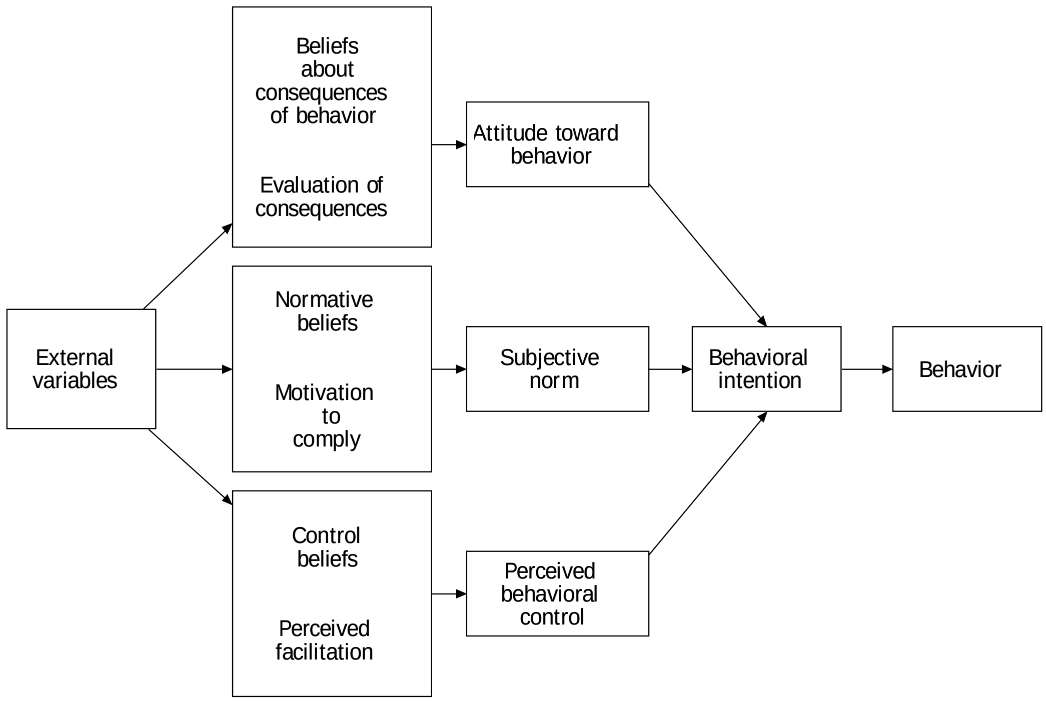


Perceived behavioral control depends on control beliefs, which decide whether individuals possess or do not possess the necessary skills or resources to carry out a certain conduct, and the suitable opportunities. Each control belief is boosted by the enhancing or inhibitory effect of the resource or opportunity dealt with. The final outcome after summing up all these products is the perceived behavioral control.

As the perceived behavioral control nears the control effectively exerted by individuals on their respective conducts, the relationship with the latter is direct.

Prediction Models of Use of Technology

The use of technology represents a generally accepted measure of the success of its widespread presence. Therefore, the aim of many investigations has been to determine which factors influence this kind of behavior.

In this section, we will look into the main theoretical models that aim to describe the characteristic behavioral process underlying the adoption of technological services and products. Through their analysis, we can detect the importance given to technology attitude as a key factor in predictions of use of technology.

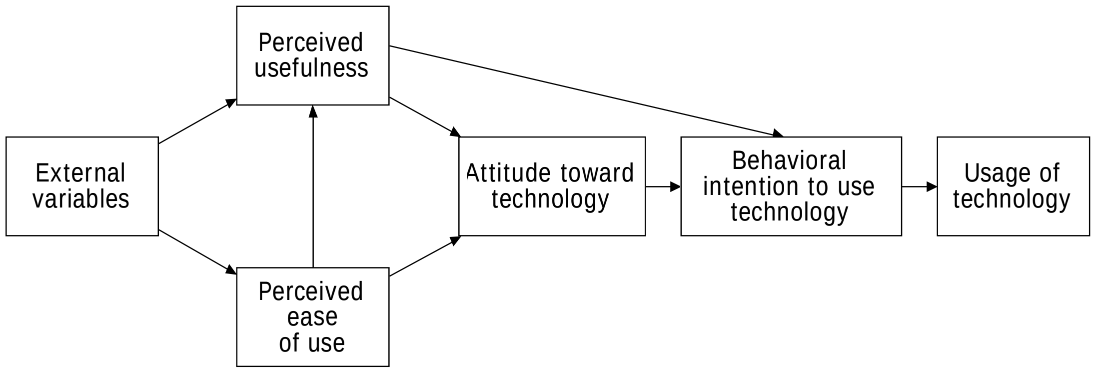
The review of the scientific literature has made clear that technology readiness is a multidimensional concept, although a consensus of opinion about the number and definition of these dimensions does not exist. In any case, such dimensions contain enhancing and inhibitory aspects of technology attitude.

With a view to completing the stage in which the domain of the studied concept is specified, after the exposition of each model, detailed aspects related to measure scales developed in various contexts and with different participants and technologies can be found. The examination of the various aspects of technology attitude (separately detected in the analyzed studies) will allow us to establish the suitability of its addition within the development of a measurement scale of the degree of technology readiness.

The Technology Acceptance Model

The Technology Acceptance Model (Davis, 1989; Davis et al., 1989) is one of the most referred-to models for the explanation of adoption of information technologies. The acceptance of technology is firmly defined by Gattiker (1984) as the psychological state of individuals with regard to their voluntary or desired use of a particular technology.

Figure 3. Technology acceptance model (Source: Adapted from Davis (1989) and Davis, et al. (1989))



Based on the Reasoned Action Model and the Planned Behavior Model, the Technology Acceptance Model put forward the idea that the behavior of adoption of a certain information system is determined by the intention of making use of it. In turn, such a behavioral intention is determined by technology attitude, which is influenced by two factors: on the one hand, beliefs in perceived usefulness, and on the other hand, beliefs in the perceived ease of use of the analyzed technology. Perceived usefulness can be defined as the extent to which individuals think using the information system will improve their working productivity. The perceived ease of use can be defined as the extent to which an individual thinks the use of a system will not require any effort. Although component perceived usefulness has a direct effect on the behavioral intention, the perceived ease of use influences such intention only indirectly.

Furthermore, both types of factors are exposed to the influence of external variables. By operating on these variables, control can be exerted on the beliefs of the information system users, thus indirectly influencing the intentions of use and the effective utilization of technology. The described model is shown in Figure 3.

Technology Attitude Scales with a Theoretical base on the Technology Acceptance Model

The Technology Acceptance Model has been put into practice by making use of different types of technologies as a social object of interchange and considering different user profiles as a sample (see Table 1).

A review of various studies allowed us to note that among their authors there is a widespread inclination to remove the attitude component out of the model. They consider that behavioral intention is determined by two main components: on the one hand, beliefs in perceived usefulness, and on the other hand, beliefs in the perceived ease of use of the analyzed technology. In that way, the perceived usefulness component has a direct effect on the behavioral intention. The perceived ease of use influences such intention, indirectly and directly, through the perceived usefulness component.

Other authors, although considering attitude as a component of the model, identified no significant relation between attitude and behavioral intention.

The results obtained cannot lead us to erroneous conclusions about the dilemma of consideration or non-consideration of attitude as a key factor when predicting the use of technology. In the reviewed investigations, when attitude is taken into account as a component of the model, it is categorized as a one-dimensional concept. That is why simple scales have been applied to measure it, following the ones suggested by Ajzen and Fishbein (1980) introduced in the Reasoned Action Model and Planned Behavior Model. From our point of view, an attitude scale constructed like this lacks validity of content insofar as it does not comprise all possible dimensions and contents of the analyzed concept.

The decision made by various authors to remove the attitude factor from the Technology Acceptance Model and, in its stead, to consider the direct effect of perceived usefulness and perceived ease of use factors on the behavioral intention, suggest to us that we should consider attitude as a multidimensional feature. Therefore, attitude is not something global. It is made up of a combination of a series of variables or dimensions that determine attitude toward technology.

Once we established which dimensions constitute the domain of the attitude concept and made clear that it is a multidimensional one, the priority of the following step was to identify items in accordance with the conceptual dimensions as found. Next, we displayed in Table 2 the items included in the measurement subscale of perceived usefulness in the analyzed studies, whereas in Table 3, we placed the items of the measurement subscale of perceived ease of use.

As we can see in the measurement of perceived usefulness, the use of the following items stands out:

- Using (information technology) increases my productivity.
- Using (information technology) increases my job performance.
- Using (information technology) enhances my effectiveness on the job.
- Overall, I find the (information technology) useful in my job.

Table 1. Application of technology acceptance model in various contexts

Software	User profile	Source
Text-editor	MBA students	Davis (1989)
Text-editor, e-mail	Managers and professionals	Davis (1993)
Spreadsheet	Students	Mathieson (1991)

Data and information retrieval	Professionals	Venkatesh & Morris (2000)
Telemedicine software	Physicians	Chau & Hu (2002)

With regard to the measurement of the perceived ease of use dimension, the items most frequently used are as follows:

- Learning to operate (information technology) is easy for me.
- I find it easy to get the (information technology) to do what I want to do.
- The (information technology) is rigid and inflexible to interact with.
- Overall, I find the (information technology) easy to use.

Limitations of the Investigations with a Theoretical Base on the Technology Acceptance Model

A review of the studies that used the Technology Acceptance Model as a predictive model of the use of new technologies allowed us to identify some limitations of the research carried out. The most outstanding are the following:

- Starting with a selection of the sample to validate the model, we consider that the used samples comprise very specific population profiles. In many of the reviewed investigations, a choice of student groups as a target population stands out, a quite common practice for economic reasons. This fact limits the power of generalization of their results to the population as a whole.
- As for the type of technologies that represent the social object of interchange in the examined studies, we notice how all of them center on the prediction of the use of specific technologies. The analysis of office automation computer programs or system development applications must be pointed out. The circumstance described reduces the generality of the model and questions its applicability to any situation regarding the use of technology.
- The investigations carried out propose the existence of two key factors to take into consideration when user attitude toward the use of a certain technology is assessed. However, there is a unanimous

agreement among authors when they concur that it is necessary to include other components in the model so they can contribute to the explanation of the variance in the use of technology. This suggests that it would be convenient to thoroughly study the dimensionality within the technology attitude concept, redefining and improving some of the variables the various dimensions are made of, and also attempting to identify new ones.

Technology Readiness Model

The limitations encountered by the Technology Acceptance Model suggest a desire for an exhaustive and systematic research on the multidimensionality of the technology attitude concept, bearing in mind perceptions different types of users may have about the use of a wide range of products with a relevant technological content. That is the purpose of investigations carried out by Parasuraman and Colby (1997, 1998, 2001), which ended with the creation of the Technology Readiness Index (TRI) as a tool of measurement of the degree of technology readiness or attitude.

This section deals with the detailed description of the methodology followed by these authors in order to build up a measurement scale of technology attitude, which we consider comprises and enlarges previous formulations. A comparison of the structural model of attitude, seen both from the inside of the Technology Acceptance Model and also the Technology Readiness Model, allowed us to come to such a conclusion.

Description of the Technology Readiness Model

The concept of technology readiness was first introduced in marketing literature by Parasuraman and Colby (1997) and refers to a combination of beliefs related to technology that collectively determine the inclination in a customer, employee, or executive to adopt new technologies in order to reach his or her objectives, both at work and during leisure time. The authors use the term “technology readiness” as a synonym of

Table 3. Perceived ease of use questions

attitude toward technology, the latter being the most frequently used term in the bibliography relevant to this subject matter.

From the concept of technology readiness as adopted, and following Churchill's (1979) directives, in order to create measurement scales, the authors identified those dimensions belonging to the domain of the construct. Parasuraman and Colby (1997, 1998, 2001) formulated a model in which technology readiness is enhanced by two variables and inhibited by the other two, as can be seen in Figure 4.

The model of the technology attitude structure as presented by Parasuraman and Colby (1997, 1998, 2001) is consistent with other authors' proposals that, as we have seen in previous sections, defended the simultaneous coexistence of favorable and unfavorable beliefs toward technology inside the user's mind.

The results of the investigation carried out by Mick and Fournier (1998) back Parasuraman and Colby's (1997, 1998, 2001) conclusions as well, as far as the dimensionality of the proposed concept is concerned. The authors, on the grounds of an extensive qualitative investigation on the reactions of people toward technology, identified eight technology paradoxes the user must face: control/chaos, freedom/enslavement, new/obsolete, competence/incompetence, efficiency/inefficiency, fulfills/creates needs, assimilation/isolation, and engaging/disengaging.

Apart from the bibliographic review, Parasuraman and Colby (1997, 1998, 2001) developed an extensive four-year research program about attitudes toward technology that included another type of qualitative analysis. The authors examined in detail the results of focus group interviews and case studies carried out with clients in various sectors (financial services, telecommunications, e-commerce, education, tourism, etc.) about beliefs related to the use of technology. The results of such studies are consistent with the aforementioned idea with regard to the simultaneous existence of enhancing and inhibitory factors of technology readiness. Flexibility, convenience, efficiency, and enjoyment were some of the emphasized advantages of technology, as well as disadvantages, security problems, obsolescence risks, impersonal treatment, and difficulty of use, to name but a few.[1]

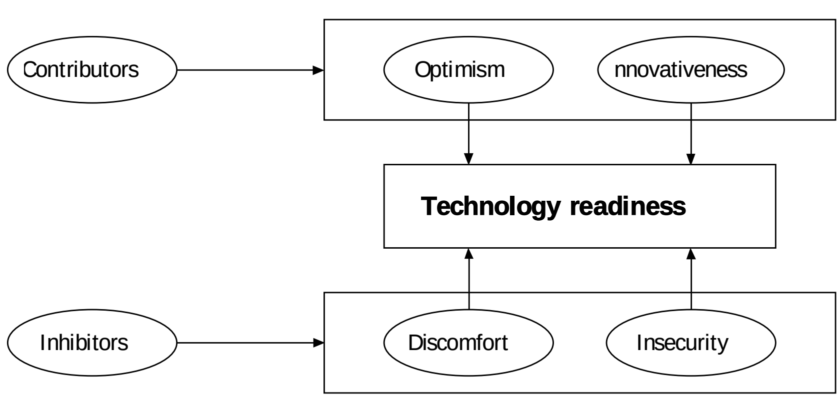
The dimensions of the Technology Readiness Model are described with maximum detail in the following headings.

Optimism

Optimism dimension was defined by Parasuraman and Colby (2001) as "a positive view of technology and a belief that it offers people increased control, flexibility and efficiency in their lives" (p. 32). In particular, the 10 indicators that Parasuraman suggests to measure this latent variable reveal a series of beliefs related to the benefits of technology:

- Acquisition of the latest technology is very convenient
- Computers extend the opening hours of commercial outlets
- Computers are easier to deal with than other people
- Technology increases working efficiency

Figure 4. Drivers of technology readiness (Source: Parasuraman, 2000a)



The positive perception of technology changes with age. In particular, people over 65 years old are more sceptical about the advantages of the use of the new technologies, as they consider them to be overestimated and often produce disappointing results.

Nevertheless, no significant differences appear as far as optimism toward technology among individuals of different sex is concerned. Both men and women show a rather positive vision toward technology, albeit with certain reservations. That is what can be drawn out from the remarks both genders make about the difficulty of doing without human contact when a service with a high technology component is supplied.

Innovativeness

The innovativeness dimension refers to "a tendency to be a technology pioneer and thought leader" (Parasuraman & Colby, 2001, p. 38). People who score high in this dimension are the first ones to adopt technologies and tend to learn to use them by themselves.

Seven indicators are suggested to measure this latent variable (Parasuraman, 2000b), some of them strongly connected with age and sex.

So the older people are, the lower the innovativeness. In this respect, it seems that the tendency to be an opinion leader stands out in individuals in approximately the 30- to 40-year bracket. People who are 50 years and over tend to lag behind when acquiring and using the latest technologies in which they are interested. Also, from that age on, the challenge to fully understand high-tech mechanisms is much less enjoyable, and right then, the aid and assistance of others become necessary. For people living beyond 65 years of age, as they grow older, they are less receptive to learn anything about new technology trends.

In general, innovativeness is much more developed in men than in women. There is a higher possibility of men not lagging behind in the implementation of the most advanced technologies that provide them with some kind of advantage and the desire to understand how they operate. On the whole, it is men who are among the first within their circle of friends to acquire the latest technological breakthroughs. They can usually grasp the new technology services and products without anyone else's assistance. Actually, they are the ones who give advice to others in this matter.

Discomfort

The discomfort dimension can be defined as "a perceived lack of control over technology and a feeling of being overwhelmed by it" (Parasuraman & Colby, 2001, p. 41). A definition like this could lead us to confuse it with the perceived behavioral control factor appearing in the Planned Behavior Model. Nonetheless, once we have analyzed the 10 items related to this dimension (Parasuraman, 2000b), we consider that what it really represents is a lack of a user's comfort when handling technology, which derives from the perceived difficulty of use and the wariness its use arouses.

Individuals with high marks in this dimension reckon technology is something too tricky and difficult to be really useful. They feel overwhelmed because they think technology is not for ordinary people since it demands a continuous updating effort to acquire the necessary knowledge enabling them to take advantage of the latest innovations. This view about technology is more widespread among women as well as elderly people. Thus, we can observe that people aged 65 years and older consider the effort to manage the new technologies not worth doing in comparison with the profit they get in return. Such effort is far more justified by people under 30.

People who score high in this dimension feel a lack of effectiveness in technical assistance services. In particular, they consider the technical assistance they are provided with, either by people or handbooks, not useful inasmuch as things are not explained in intelligible terms. Actually, when interacting with technical assistance staff, they feel as if they were in a disadvantageous position compared with somebody who knows more. Like in the previous case, this set of beliefs is mostly shared by females, even more so as they grow older.

Insecurity

Finally, the insecurity dimension can be defined as "distrust of technology and skepticism about its ability to work properly" (Parasuraman & Colby, 2001, p. 44). There is a certain relationship between the discomfort dimension and some of the nine items used to measure insecurity dimension. Their main difference is that indicators of the insecurity dimension allow us to evaluate specific aspects of technology-based transactions instead of a discomfort with technology, generally speaking.

People who dislike e-business are expected to get high marks in this dimension. They fear that their personal data might be stolen if stored inside a computer. In contrast to the other dimensions of the technology readiness concept mentioned previously, and with regard to beliefs hereby assessed, no differences in age or sex can be observed.

Scales of Technology Readiness

Starting by defining the domain of the construct derived from their exploratory works, Parasuraman and Colby (1997) set an initial batch of 44 items to measure the degree of technology readiness. Next, and having carried out several empirical studies (details are shown in Table 2.4), the scale was filtered until they obtained a measurement tool comprised of 36 items (see Table 2.5) where nearly 50% of them corresponded to positive beliefs toward technology and the rest with negative beliefs.

The decision to measure technology readiness or attitude with beliefs related to use of technology in consideration was already supported by various authors (Cowles, 1989, 1991; Cowles & Crosby, 1990; Eastlick, 1996), who defended the existence of a strong and significant correlation between beliefs and attitude toward technology as shown in Figure 5.

The measurement scale eventually put forward by Parasuraman (2000b) overcomes earlier versions' deficiencies, thus achieving its applicability to different contexts of use of technology. In this particular case, previous investigations had focused on the analysis of the degree of readiness toward the use of computers or the Internet, not toward new technologies as a whole. Also, the scale had been validated by means of very specific samples, which restricted the power to generalize results to all the population.

Parasuraman (2000b) presents his scale of technology readiness as an suitable alternative to assess clients, employees, or executives' attitudes toward the adoption of the new technologies as a whole, with a view to succeeding in their jobs and leisure time. The procedure followed to construct this scale guarantees its validity. Thus, as far as its content validity is concerned, we have to point out that the generated sample was adequate and representative enough of the contents and dimensions of the studied concept by means of a review of written accounts of the focus group interviews previously held (Parasuraman & Colby, 1997) and also the carrying out of new brainstorming sessions. In this way, the initial 28-item scale proposed by Parasuraman and Colby (1997), was enlarged with 38 additional items. Later on, an iterative scale-purification process following Churchill's (1979) methodology was achieved, with a final result of a 36-item measurement scale.

As for the operational features of the scale, for every proposition, interviewees had to express their degree of assent within Likert-type scale of five points (from "strongly disagree" to "strongly agree").

Comparison Between the Technology Readiness Model and the Technology Acceptance Model

We finish the chapter with a comparison between the two predictive models of use of technology previously described. In doing this, we intend to explain why we have chosen the Technology Readiness Model as a theoretical basis to develop a scale of technology attitude.

Starting with the definition of the technology attitude concept that these models respectively formulate, we can observe that the Technology Readiness Model coins a generic name for the type of technologies that constitute the social object of research interchange, not being centered around the analysis of attitude toward a particular technology, as occurs in the case of the Technology Acceptance Model.

With regard to the specification of the concept's dimensions by both models, we notice certain coincidences in some dimensions' contents. Thus, the perceived usefulness dimension (the Technology Acceptance Model) is contained within a definition of the optimism dimension (the Technology Readiness Model), the latter gaining a much wider perspective of the benefits obtained through the use of technologies. The perceived ease of use dimension (the Model of Technology Acceptance) comprises in its definition the contents of the discomfort dimension (the Technology Readiness Model), although the latter includes an evaluation of other overall aspects of technology-based transactions that inhibit its use. The Technology Readiness Model also covers two other attitude dimensions—innovativeness and insecurity—incorporating them into a much wider perspective of all the factors that either encourage or inhibit the use of technology.

Table 4. Comparison of Parasuraman and Colby (1997) study with other TRI replication studies

Study	**Parasuraman and Colby (1997)**	**Parasuraman and Colby (1998) (Study 1)**	**Parasuraman and Colby (1998) (Study 2)**	**Parasuraman (2000b)**
Data collection study sample	Clients of a firm offering a variety of services related to financial assistance for college students and young college graduates (up to age 35)	Clients of a mortgage bank	Clients of an online service provider	Adults (18 years or older)
Sample size	1,200 individuals			1,000 individuals
Response scale	Five-point scale	Five-point scale	Five-point scale	Five-point scale
Questionnaire administration	Mail survey and Web survey			Computer-assisted telephone survey
Analysis techniques	Test of reliability (internal consistency) Confirmatory factor analysis	Test of reliability (internal consistency) Confirmatory factor analysis	Test of reliability (internal consistency) Confirmatory factor analysis	Test of reliability (internal consistency) Confirmatory factor analysis
Basis for initial number of factors extracted	Factors with eigen values greater than 1	Parasuraman and Colby's (1997) four-dimensional structure	Parasuraman and Colby's (1997) four-dimensional structure	Parasuraman and Colby's (1997) four-dimensional structure
Reliability	Cronbach alpha (0.72-0.82) Item-Total Correlation Principal-axis factor analysis followed by varimax rotation	Cronbach alpha (weaker than in Parasuraman and Colby (1997) study for the four subscales) Item-Total Correlation Principal-axis factor analysis followed by varimax rotation	Cronbach alpha (weaker than in Parasuraman and Colby (1997) study for the four subscales) Item-Total Correlation Principal-axis factor analysis followed by varimax rotation	Cronbach alpha (0.74-0.81) Item-Total Correlation Principal-axis factor analysis followed by varimax rotation
Validity	Content validity Construct validity	Content validity Construct validity	Content validity Construct validity	Content validity Construct validity

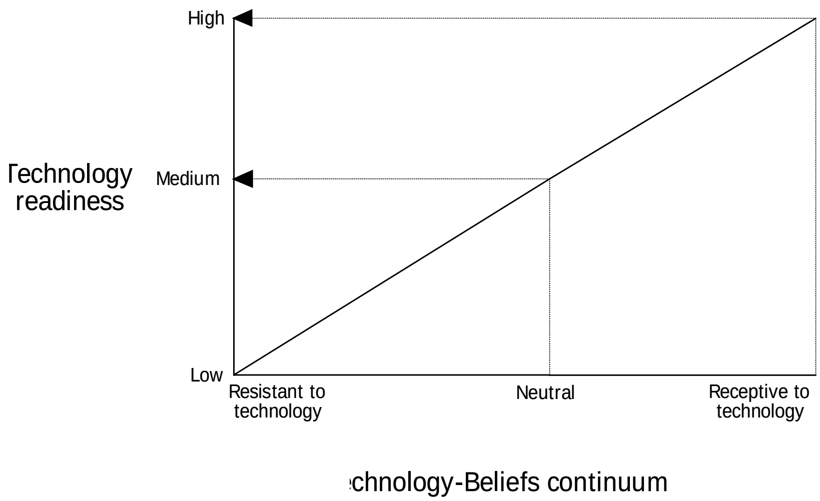
Original TRI item retained	28 items	26 items	16 items	21 items
Number of items obtained	28 items: Optimism (10), Innovativeness (5), Discomfort (8), and Insecurity (5)	26 items	16 items	36 items: Optimism (10), Innovativeness (7), Discomfort (10), and Insecurity (9)

Table 5. Items used to measure technology readiness (1) Parasuraman and Colby (1997); Parasuraman (2000b); (2) Parasuraman (2000b)

TR STATEMENTS	ITEMS	STUDY
OPTIMISM STATEMENTS	Technology gives people more control over their daily lives	(1)
	Products and services that use the newest technologies are much more convenient to use	(1)
	You like the idea of doing business via computers because you are not limited to regular business hours	(1)
	You prefer to use the most advanced technology available	(1)
	You like computer programs that allow you to tailor things to fit your own needs	(1)
	Technology makes you more efficient in your occupation	(1)
	You find new technologies to be mentally stimulating	(1)
	Technology gives you more freedom of mobility	(2)
	Learning about technology can be as rewarding as the technology itself	(2)
	You feel confident that machines will follow through with what you instructed them to do	(2)
INNOVATIVE STATE-MENTS	Other people come to you for advice on new technologies	(1)
	It seems your friends are learning more about the newest technologies than you are [reverse scored]	(1)
	In general, you are among the first in your circle of friends to acquire new technology when it appears	(1)
	You can usually figure out new high-tech products and services without help from others	(1)
	You keep up with the latest technological developments in your areas of interest	(2)
	You enjoy the challenge of figuring out high-tech gadgets	(2)
	You find you have fewer problems than other people in making technology work for you	(2)
INSECURE STATEMENTS	The human touch is very important when doing business with a company	(2)
	When you call a business, you prefer to talk to a person rather than a machine	(2)
	If you provide information to a machine or over the Internet, you can never be sure it really gets to the right place	(1)
	You do not consider it safe giving out a credit card number over a computer	(1)
	You do not consider it safe to do any kind of financial business online	(1)
	You worry that information you send over the Internet will be seen by other people	(1)
	You do not feel confident doing business with a place that can only be reached online	(1)
	Any business transaction you do electronically should be confirmed later with something in writing	(1)
	Whenever something gets automated, you need to check carefully that the machine or computer is not making mistakes	(2)
DISCOMFORT STATEMENTS	Technical support lines are not helpful because they don't explain things in terms you understand	(1)
	Sometimes you think that technology systems are not designed for use by ordinary people	(1)
	There is no such thing as a manual for a high-tech product or service that's written in plain language	(1)
	When you get technical support from a provider of a high-tech product or service, you sometimes feel as if you are being taken advantage of by someone who knows more than you do	(1)
	If you buy a high-tech product or service, you prefer to have the basic model over one with a lot of extra features	(2)
	It is embarrassing when you have trouble with a high-tech gadget while people are watching	(2)
	There should be caution in replacing important people-tasks with technology because new technology can break-down or get disconnected	(2)
	Many new technologies have health or safety risks that are not discovered until after people have used them	(2)
	New technology makes it too easy for governments and companies to spy on people	(2)
	Technology always seems to fail at the worst possible time	(2)

Figure 5. Links between technology beliefs and technology readiness (Source: Parasuraman and Colby, 2001)



With relation to all the items used to measure the technology attitude by means of a theoretical base on the analyzed models, we can remark that contents that represent items most frequently used to measure latent variables perceived usefulness and perceived ease of use are present in the scale of technology readiness.

All in all, we can consider that validations carried out of the Technology Readiness Model possess a higher applicability to different contexts of use of technology than those of the Technology Acceptance Model. That is why we estimate appropriately the use of the Technology Readiness Model as a theoretical basis to develop a measurement scale of technology attitude.

KEY TERMS

Cognitive Dissonance Theory: A theory that discusses how the tension that may result from having two conflicting thoughts at the same time, or from engaging in behavior that conflicts with one's beliefs, or from experiencing apparently conflicting phenomena, can impact actions and/or decision-making.

Expectancy-Value Theory: Explains and predicts individual's attitudes toward objects and actions but is also often the basis for other theories to explain perception and behaviors.

Reasoned Action Model: A model to predict and understand human behaviour determinants.

Self-Perception Theory: Discusses that an account of attitude change can occur by observing our own behavior and concluding what attitudes must have caused them.

Technology Acceptance Model: A model that discusses that perceived usefulness and ease of use are two important factors in influencing the acceptance of a technology by a user.

ENDNOTE

1 The authors also noted that some beliefs toward technology overlapped with criteria that clients use when assessing the quality of service, so the attributes of the SERVQUAL scale (Parasuraman, Zeithaml & Berry, 1988), a tool to measure perceived quality widely cited in marketing literature for its application in a wide range of tertiary activities with very different features.

The Detection of Abnormal Breathing Activity by Vision Analysis in Application to Diagnosis of Obstructive Sleep Apnea

Ching-Wei Wang
University of Lincoln, UK

Andrew Hunter
University of Lincoln, UK

INTRODUCTION

Obstructive Sleep Apnea is increasingly seen as a common and important condition, contributing to sleep disturbance and consequential daytime sleepiness. This has potentially serious consequences for the individual, employers, and society as a whole. Apnea refers to short spells when breathing stops. In obstructive sleep apnea, the throat constricts during sleep, preventing breathing; the apnea episode often ends with a loud snore and/or gasp. Such an event is sufficient to open the throat muscles to allow breathing, and the patient usually falls asleep again so quickly that the event is not remembered. This cycle repeats itself throughout the night as the muscles relax and the throat blocks again, and the frequency of the episode is used to determine the severity of the syndrome.

A wide range of parameters, including EEG (electroencephalogram) sleep staging, snoring, changes in airway resistance, airflow, and inspiratory effort, as well as oxygen saturation and body movement during "normal sleep" in a Sleep Lab, lead to an understanding of the pathophysiology of sleep apnea (Flemons et al, 2003). According to recent research findings (Bennett, Langford, Stradling & Davies, 1998; Kingshott et al., 2000; Pepperell, Davies & Stradling, 2002), the best predictors of morbidity in individual patients, as assessed by improvements with continuous positive airway pressure therapy (CPAP), are nocturnal oxygen saturation and movement during sleep. Moreover, Siven, Kornecki, and Schonfeld (1996) indicate that the results from traditional polysomnography are highly correlated with the video test results.

Video monitoring has been adopted to assist diagnosis on obstructive sleep apnea. However, video monitoring and interpretation are less well developed, both from a recording and analysis viewpoint, due to the relative computational complexity of video analysis and the significant technical challenges. These include the lighting restriction involved with natural night vision and low illumination, including a lack of no color information; the obscuration of the body by a cover; the variation of human size, shape, and behavior; and the massive volume of video and audio data. The diagnosis of sleep disturbances requires a review of substantial amounts of data (including video footage) by clinicians. There is therefore a need for automated monitoring of human breathing activity to diagnose sleep disorders.

BACKGROUND

Current breathing monitoring techniques can be categorized into two types: invasive and noninvasive. The invasive approaches include Polysomnography; the Belt (Hyun Medics, 2006) or Strap (Svetlana et al., 2005), which track changes in body circumference during the respiratory cycle; Stick-on Electrodes as a heart-respiratory monitor (David et al., 2005); and Nasal Temperature Probes (Storck, Karlsson, Ask & Loyd, 1996). Published noninvasive techniques include Audio Analysis to monitor tidal volumes from human breathing activity (Amin, Cigada, Fordyce & Camporesi, 1993), Vibration Sensors (David et al., 2003; Randall, 1995), and Thermal Imaging (Murthy, Pavlids & Tsiamyrtzis, 2004; Zhu, Fei & Pavlidis, 2005).

However, these techniques for monitoring breathing activities have various limitations in application to diagnosis of sleep disorders. The obtrusive nature of invasive monitoring equipment can disturb sleep and therefore compromise results. The thermistors used in Polysomnography sense differences in temperature; however, they do not have a linear relationship with true airflow. Consequently, the thermistors may not be sensitive for detecting hypopneas (Flemons et al., 2003). Nasal pressure has a linear approximation of airflow but can produce false-positive events and low quality signals if patients are mouth breathing (Flemons et al., 2003). Regarding strap systems, if the tension on the strap is not calibrated, the system will not track the respiration motion correctly, so adjustment may be necessary. Moreover, measurements on patients with shallow and abdominal breathing patterns may fail because the sensor cannot track adequately in a reproducible manner if the chest displacements during normal breathing and breath-hold are not distinctly different. Concerning thermal imaging techniques (Murthy et al., 2004; Zhu et al., 2005), there are position limitations and geometric constraints for targeting faces, which will not be applicable for unpredicted human sleep behavior. As a result, an investigation of methods for monitoring human breathing activity is crucial for diagnosis of sleep disorders.

METHODS

In this chapter, we develop a nonintrusive monitoring technique without geometric constraints using infrared video information for identifying abnormal breathing activity in application to diagnosis of obstructive sleep apnea. The proposed technique allows patients to sleep on their back or side, with or without facing the camera. The experiments show that the proposed method obtains promising results in recognizing abnormal breathing events and identifying general body movements. Moreover, the experiments also show that the proposed approach is able to recognize events successfully for patients with shallow and abdominal breathing patterns.

Objectives

The aim of our research is to support the diagnosis of obstructive sleep apnea. Our primary objective is to detect abnormal breathing episodes based on vision analysis. This also requires us to distinguish breathing movements from other body movements.

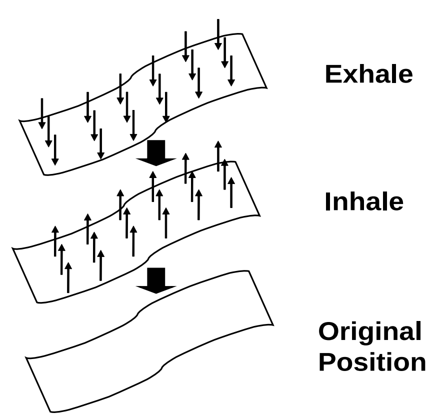
Technical Analysis in Breathing Behavior

In order to recognize abnormal breathing activities, it is necessary to differentiate between general movements and breathing, allowing further identification of normal breathing status and abnormal breathing status. Thus, we first analyze human breathing behavior in comparison with general body movement and find two important features of the breathing activity. The first is cyclic motion; the elements of the entire surface move forward and backward approximately to their previous position in a breathing cycle (see Figure 1). In contrast, elements tend to move toward different positions for general body movements. Second, considering the rate of movement, breathing is a relatively *slow-motion* activity, compared with other body movements. Hence, in order to detect breathing activity, it is necessary to observe differences across several seconds of video.

Design

Following the previous analysis, we attempt to distinguish breathing from general body movements based on variations in movements. As the breathing activity is relatively slow, we use an adaptive background model to identify motion; this allows relatively subtle motion to be detected and accumulated within a period of time.

Figure 1. Cyclic moving flow in a breath



In addition, the duration and degree of motion are used as criteria to assist in distinguishing breathing motion from other motion. Furthermore, a continuously updated 2D breathing template is created for identifying abnormal breathing events.

Adaptive Background Model

The adaptive background model is crucial for distinguishing general body movement and breathing movement. The model updates slowly, and so can determine if the surface moves back to the previous position. Breathing movements produce detectable cycles in the number of pixels different from the background image. The adaptive background model *B(x, y)* is formulated as follows:

$$B_i(x,y) = B_{i-1}(x,y) + \begin{cases} \eta & if \quad P_i(x,y) - B_{i-1}(x,y) > 1 \\ -\eta & if \quad P_i(x,y) - B_{i-1}(x,y) < -1 \\ 0 & otherwise \end{cases} \tag{2}$$

where $P_i(x, y)$ is the intensity value at time *i*; $B_{i-1}(x, y)$ is the adaptive background at time *i-1*; and $B_i(x, y)$ is the updated adaptive background at time *i*.

Continuously Updated 2D Breathing Template

While the body is in general breathing mode, a 2D breathing template is built and continuously updated over time. The template represents general breathing movement. This novel technique is proposed to both assist classification of the current movement as a breath activity or general body movement, and further to determine if the breathing activity is an abnormal one. Figure 2 illustrates how the 2D breathing template is utilized by matching shapes of current movement and the 2D breathing template to determine the class of the behavior (i.e., breathing movement or general body movement).

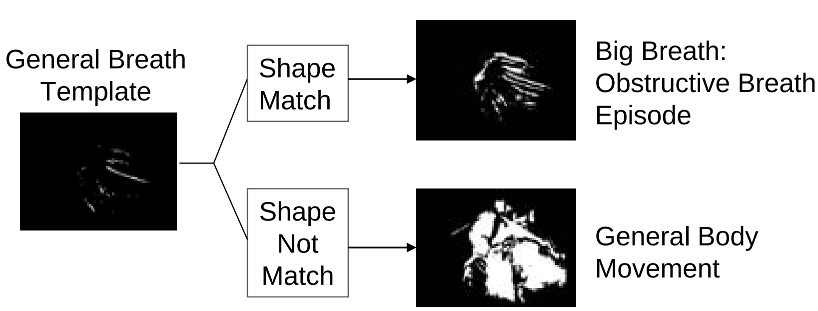
Template Construction. The template represents a combination of shapes of normal breathing movements. It is continuously built over time, and the development does not stop until the status changes to "not general breathing." Figure 3 illustrates the building procedure.

Template Match. As patients with shallow breathing patterns tend to have low-quality breathing templates, a template quality index is created to decide whether the template is mature enough to use. In addition, the degree of movement (*M*) and the duration of the movement (*D*) are employed to eliminate the occurrences of general body movement. The proposed matching method compares the breath template and the shape of the current movement. Given the breathing template $T_i(x, y)$ and the shape of current movement $S_i(x, y)$, the difference between current frame and the adaptive background image, at time *i*, an index *E* is the ratio W_2/W_1, where W_1 is the number of pixels of overlap between the template and the current shape of movement, and where W_2 is the number of pixels that are in the current shape not in the template (see Equations 3, 4, and 5). The index *E* is then used to determine the type of current event (i.e., Apnea or general body movement) (see Table 1).

$$E = W_2 / W_1 \tag{3}$$

$$W_1 = \left| T_i(x,y) \cap S_i(x,y) \right| \tag{4}$$

Figure 2. Breathing template for classification on current activity



$$W_2 = \left| \left(-T_i(x,y) \right) \cap S_i(x,y) \right| \qquad (5)$$

Experimental Setup

Two SONY infrared camcorders (DCR-HC-30E) are utilized to capture a number of video clips from three shooting angles. The infrared video frames were acquired at 15 frames per second, with resolution of 320*240. The video and audio data are first captured with the WMP9 compression algorithm to minimize storage size, and then decompressed for off-line analysis. Moreover, in order to simulate the environment for diagnosis on sleeping disorders, there was no visible lighting in the filming room, and the subjects were partially covered by a sheet. Furthermore, the experimental data were collected from two subjects with mainly three different postures (i.e., lying on the back, sleeping on one side and facing the camera, sleeping on the other side with back facing the camera). The data were also collected on different days with the subjects wearing different clothing. Activities such as general breathing, obstructive apnea, and body movement were simulated by the subjects.

Experimental Results

To evaluate the proposed method for monitoring human breathing activity, the experimental video contents are first analyzed by human observation, defining the real events and marking the frame number of the beginning and ending point for an individual event to produce a reference standard. To facilitate that, the observer was allowed to play the video in slow motion. The results of these analyses are lists of events with the associated frame numbers.

The analysis outputs of the proposed method on sequences of event type and the frame numbers of cutting points among events are then compared to the reference standard. Figure 4 presents the experimental results of the proposed method and manual observation on fifteen video clips, which demonstrates that the proposed vision analysis model achieves high accuracy in recognizing abnormal breathing activities and general body movements.

Figure 5 illustrates the analysis results of three video samples. In the upper area, the motion degrees in temporal space are presented with the number of episodes marked. The lower area shows system procedures. For example, there are seven episodes in the first sample, representing Episode 1: continuously construct a breathing template; Episodes 2 and 3: use the template built in episode 1 to do template matching and define the event as obstructive apnea; Episode 4: build a new breathing template; Episode 5: use the template built in episode 4 for template matching and define the event as a general body movement event; Episode 6: build a new breathing template; Episode 7: use the template from episode 6 and define the event as obstructive apnea.

FUTURE TRENDS

We are investigating more automatic ways to obtain the threshold values and adapt them to individual subjects in order to accommodate human variations. More detailed experimental analysis using real rather than simulated episodes of Apnea will be conducted. We are also planning to support the video analysis of human breathing activity by adding audio analysis.

CONCLUSION

In this chapter, we present a noninvasive approach for recognizing abnormal breathing activity in assisting diagnosis of obstructive sleep apnea. The proposed approach utilizes infrared video information and avoids imposing geometric constraints or position limitations. The method is validated with limited experiments simulating the real environment for diagnosis of sleep disorders. Although the presented approach is mainly developed for diagnosis of obstructive sleep apnea, we believe that it can be utilized in other medical applications that require monitoring of the breath activity.

ACKNOWLEDGMENT

The PhD scholarship of Ching Wei Wang is jointly supported by the United Lincolnshire Hospital NHS Trust and University of Lincoln. We thank Dr. Neil Gravill and Dr. Simon Matusiewicz for their valuable comments in obstructive sleep apnea.

KEY TERMS

Continuous Positive Airway Pressure Therapy (CPAP): A therapy that delivers air into the patient's airway through a specially designed nasal mask or pillows. It is considered the most effective nonsurgical treatment for the alleviation of snoring and obstructive sleep apnea.

Hypopneas: Reductions in airflow or respiratory effort during sleep.

Infrared: Infrared light lies between the visible and microwave portions of the electromagnetic spectrum. It is used in night-vision equipment when there is insufficient visible light available.

Oxygen Saturation: A measure of how much oxygen the blood is carrying as a percentage of the maximum it could carry. It can be obtained from pulse oximetry.

Polysomnography (PSG): A diagnostic test in which a number of sensor leads are placed on the patient during sleep to record brain activity; eye, jaw muscle, and leg muscle movements; airflow; respiratory effort; heart rhythm; and oxygen saturation.

Sleep Apnea: A sleep disorder that causes breathing to stop during sleep for anywhere from 10 seconds to several minutes.

Thermal Imaging: An analogue pictorial representation or visualization of temperature differences.

APPENDIX

Pseudo-Codes

Inputs:
P*i* (*x*, *y*), the intensity value at location (*x*,*y*) at time *i*.
M0: Threshold to determine events as body movement
D: Threshold for time duration of the apnoea event
TQ: Threshold to use/not use the current template
M2: Threshold to switch from "not general breath" to "general breath" state
N: Noise filtering threshold for each individual pixel P*i*(*x*, *y*)
M3: Motion threshold for initializing S [step 4.1]
nt1: Number of frames with low motion degree for initializing S [step 4.2]
nt2: the number of the frame for template matching
nt3: the number of the frame for updating M1
t2, t3: threshold for template matching

Output:
Predicted result Ri at time i, where R = { 0: Apnea, 1: Body Movement, 2: Breath}
Parameter:
S: (0: not general breath, 1: general breath)
F1: (0: template match On, 1: template match Off)
F2: (0: define current event On, 1: define current event Off)
M1: Motion threshold to switch from "general breath" to "not general breath" state
B*i* (X,Y); the adaptive background at time *i*
T*i* (X,Y), the breath template at time *i*
S*i* (X,Y), the shape of current movement at time *i*
M: the degree of current movements
C1, C2, C3, C4, C5: counters
tqi: Template quality index (the number of data points) in the breath template

Steps:
1. Initialise background: B1(X,Y) = P1(X,Y)
2. Update the background: if i % 3= 0, then update the background (Adaptive Background Model)
   2.1 ΔI(*x, y*) = P*i* (*x, y*) – B*i-1*(*x, y*)
   2.2 if ΔI(*x, y*) > 0, then
      2.2.1 if(ΔI(*x, y*) < 1), then B*i* (*x, y*) = B*i-1*(*x, y*) + 1

Detection of Gait Patterns in Challenging Environments

FALLS AND AGEING HEALTH CARE

One in three individuals over the age of 65 years (elderly) will fall at least once a year (James, 1993). This probability increases to one in two adults over 80 years (DHA, 2005). Consequently, gait modifications associated with ageing have been linked with increased falls' probability (Berg, Alessio, Mills, & Tong, 1997; Lord, Sherrington, & Menz, 2001). Despite an increasing research interest in recent times into the aetiology of falls, particularly in the elderly (>65 years), falls continue to be a major public health concern in Australia and worldwide. Fall-related injuries are the leading cause of accidental death in the elderly population, and account for the largest cause of hospitalisation for this population (Lord et al., 2001), with many elderly individuals experiencing physical, social, or functional ramifications following a fall. Consequently, the economic cost of falls to the public health system is escalating, with the total cost of fall injuries reported to be higher than road traffic injuries (DOH, 2004). The majority of falls associated costs include physician consultation, hospital stays, nursing homecare, rehabilitation, medical equipment, home modification and care, community based services, and prescription drugs and administration (DOH, 2004; Lord et al., 2001). Healthcare and related costs associated with falls are expected to double over the next 50 years (Close & Lord, 2006).

GAIT CHARACTERISTICS AND TRIPPING

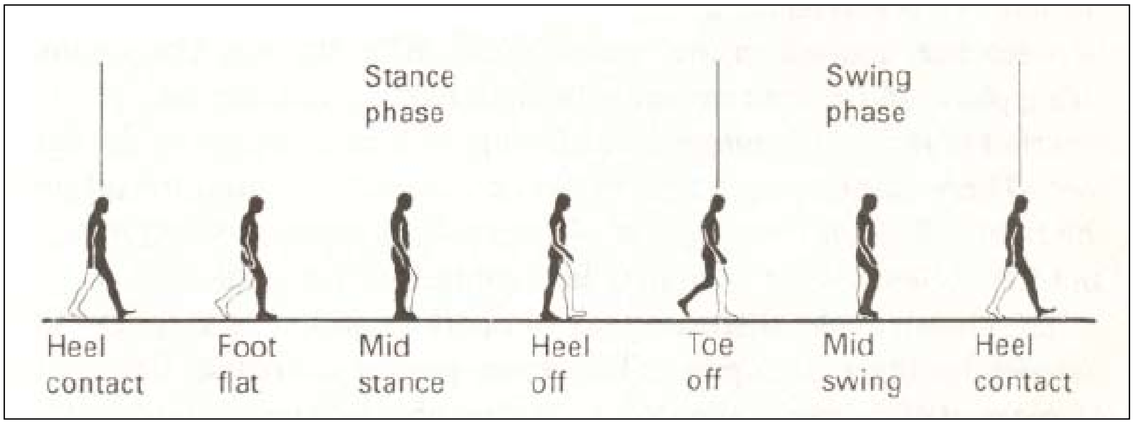
Walking or gait is the most common form of locomotion. A gait cycle is defined as the interval of time linking two successive occurrences of repetitive events of locomotion (most commonly foot contact/strike) (Kaufman & Sutherland, 2006; Whittle, 2003). The two main features of a gait cycle are standing and stepping, which are more technically known as stance and swing phases, respectively illustrated in Figure 1.

Typically the stance phase comprises approximately 60% of the gait cycle and is defined as the period when the foot is in contact with the ground. The swing phase makes up the remaining 40% of the cycle and is defined as the period between toe off to the second ipsilateral foot strike (i.e., when the foot is not in contact with the ground) (Kaufman & Sutherland, 2006; Russek, 1996; Winter, 1991). The purpose of the swing phase is to progress the body (most often in a forward motion), through sufficient clearance of the ground and to align the foot for the forthcoming heel contact. This is accomplished with the foot being swung through the air at a fast velocity and at a distance close to the ground (Perry, 1992; Winter, 1991).

Tripping refers to an unintentional disruption to the locomotion of the swing limb during a gait cycle, and consequently momentary suspension of the limbs' locomotion. This disruption can occur through an altercation with either the walking surface (ground) or an obstacle (e.g., mats, electrical cords) (AGC, 2002). Tripping is usually associated with two consequences: (i) stumble (in which balance is momentarily lost, however recovery occurs, and consequently does not result in a fall) or (ii) fall.

For safe uninterrupted trajectory during swing (to avoid tripping), the distance between the hip and the toe needs to be less than the distance between the hip and the ground surface or tripping hazard (Moosabhoy & Gard, 2006). The movements of the swing limb are a

Figure 1. The events of the gait cycle (Adapted from Whittle, 1991)



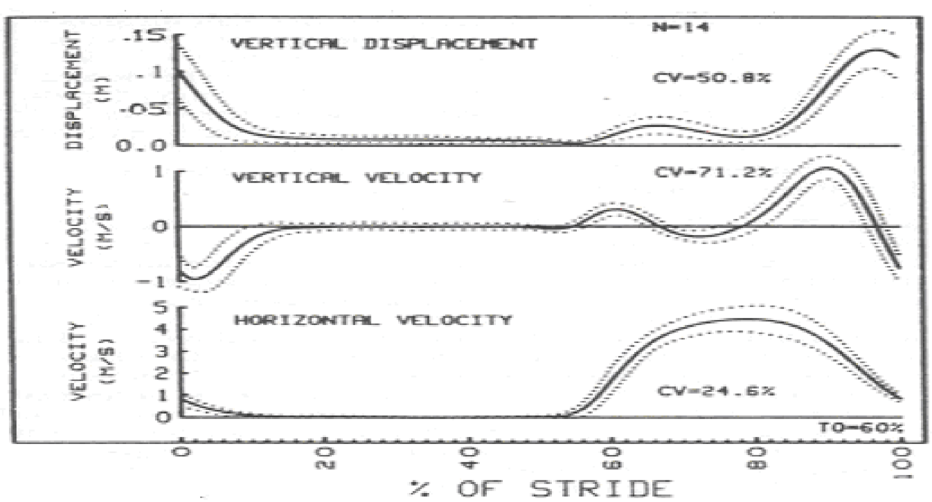
precise coordinated movement that is dependent upon a multisegment motor control chain of both stance and swing limbs (Winter, l991).

During the swing phase (60-100% of the gait cycle), the toe vertical trajectory undergoes two peaks as illustrated in Figure 2. Aforementioned, tripping avoidance is dependent upon adequate clearance of obstacles; it is the depression in vertical height between the two peaks in toe trajectory that is critical in order to avoid tripping (Weerdesteyn, Nienhuis, & Duysens, 2005; Winter, 1991). This drop in height is termed minimum toe clearance (MTC) and is a measurement between the lowest point of the foot (most commonly the toe) to the gradient of the walking surface during swing (Moosabhoy & Gard, 2006). The objective of MTC is to propel the limb forward with minimum energy expenditure (Perry, 1992). As a result of the timing, positioning, and velocity of the foot during low toe clearance, MTC height is the main contributing factor in tripping (Begg, Best, Dell'Oro, & Taylor, 2007; Murray & Clarkson, 1966; Winter, 1991).

Unfortunately gait modifications associated with ageing have been linked with an increased tripping risk and the ability to recover. Consequently, tripping is attributed as being the highest precipitating factor in elderly falls (35-40%) (Berg et al., 1997; Lord et al., 2001).

Prior investigations (Begg, Best, Dell'Oro, & Taylor, 2007; Winter, 1991) have found that the elderly demonstrate a lower MTC than the young and thus have an

Figure 2. Illustrates the mean vertical displacement and vertical and horizontal velocity for the period of one cycle of nine participants walking a natural cadence in Winter (1991)



increased risk of tripping. This combined with studies on ageing characteristics associated with an increased possibility of a trip becoming a fall (i.e., higher tripping frequency, delayed reaction time), provides a possible explanation for the high preponderance of falls in the elderly.

Winter (1991) calculated that at the precise moment of MTC height is controlled not only by the dorsiflexion/plantarflexion of the ankle, but is also equally influenced by four other motions, that is swing and stance knee flexion, stance ankle dorsiflexion/plantarflexion, and stance hip abduction/adduction.

ENVIRONMENTAL CIRCUMSTANCES

The control of MTC is not exclusively influenced by the events of the ankle joint however, but rather it is a pinpoint ballistic movement, controlled by lower limb joint kinematics of both the stance and swing limbs (Winter, 1991). Consequently, MTC can be affected and influenced by both intrinsic (internal) and extrinsic (external) modifications. Intrinsic factors that could possibly influence MTC height include changes associated with neurological diseases, deterioration in peripheral vision, and modifications associated with ageing. Extrinsic factors include shoes, visibility, and terrain characteristics (Butler, Druzin, & Sullivan, 2006; DOH, 2004). Typically a fall is a multifactorial phenomenon which occurs through a breakdown in an individual's ability (intrinsic) to successfully negotiate the environment (extrinsic).

GAIT MODIFICATIONS ASSOCIATED WITH AGING

Spatial-Temporal Gait Parameters

As previously mentioned, the two main features of the gait cycle are the stance and swing phases. During analysis of elderly and young adult groups on a flat surface, the elderly have been found to display longer stance duration than the younger adult group, and consequently a shorter swing phase. As a result of the shorter swing phase, the elderly group were also found to exhibit relatively longer double support duration (time when both feet are in contact with the ground) (Barela & Duarte, 2006; Mills & Barrett, 2001). It is possible however, that this increased stride duration is a result of the reduced walking velocity displayed by the elderly. For example, when Mills and Barrett (2001) accounted for velocity differences through normalization, the stance duration discrepancies were no longer significant. It is also plausible to suggest that the elderly have increased stride duration to allow a longer double support time to regain balance and control.

Lower Limb Joint Kinematics: Elderly

Barela and Durate (2006) analysed the differences in biomechanical characteristics between elderly individuals (age: 70 ± 6 years) and young adult individuals (age: 29 ± 6 years) whilst walking on a flat surface. Barela and Durate (2006) found that elderly individuals had a significantly smaller range of motion at the ankle joint than the young adult group. As a result, the elderly group had significantly less dorsiflexion than the young adults at the beginning of the swing phase. Research by Kerrigan, Lee, Collins, Riley, and Lipsitz (2001), however, revealed no significant differences between their elderly group (age: 73 ± 5.6 years) and their young group (age: 28.1 ± 4.2 years) in the ankle and knee joint angle kinematics. Kerrigan et al. (2001) did, however, find significant reductions in elderly peak hip extension in comparison to the young group, even when walking at a similar velocity. Due to this, elderly individuals with reduced peak hip extension will display reduced stride length.

GAIT MODIFICATIONS ASSOCIATED WITH SLOPED SURFACES

Spatial-Temporal Gait Parameters: Sloped Surfaces

Modifications to gait have been observed whilst walking on sloped surfaces; this is not surprising considering the constraints imposed on the individuals are different from those imposed on a flat surface. These include variations in gait in order to raise and lower the body's centre of mass to coordinate the vertical displacement of lower limbs during each stride and to ensure sufficient foot clearance (Leroux, Fung, & Barbeau, 2002; McIntosh, Beatty, Dwan, & Vickers, 2006). Although there is a substantial degree of literature dedicated to gait modifications in both the ageing and environmental situations, there is little, if any, literature dedicated to elderly individuals walking on sloped surfaces.

During analysis on eight healthy adult males (age 34 ± 9.4 years) who walked at a self selected pace on a treadmill with five inclines between -10% to 10%, Leroux et al. (2002) discovered modifications between all inclines for temporal-spatial data. Leroux et al. (2002) determined that during positive slope walking, there was a significant increase in stride length as the gradient angle increased. Leroux et al. (2002) also observed a progressive decrease in stride length as the gradient decreased from 0% to -10%. Research by McIntosh et al. (2006) indicated that during positive slope walking, there was a significant linear trend of decreasing cadence as the gradient angle increased from -10° to 0°. Cadence was also found to decrease from 0° to +10°, however, the change was not significant. Similarly a significant increase in speed occurred during this gradient modifications. Leroux et al. (2002), however, found that the proportion of stance/swing time, relative to cycle duration, was not affected by modifications in the slope

Lower Limb Joint Kinematics: Sloped Surfaces

Research focused on lower limb joint angle kinematics in slope walking discovered a number of significant modifications in comparison to level walking.

During analysis of upslope walking, research investigations found augmented increased flexion across the three lower limb joint angles (ankle, knee, and hip) from mid swing to early stance (Leroux et al., 2002) as the slope became progressively steeper. More specifically, during analysis on uphill walking Hansen, Childress, and Miff (2004) discovered the ankle to be the main adapting joint with the ankle significantly more dorsiflexed for the first 50% of the gait cycle to account for the increased gradient of the walking surface. The ankle is also dorsiflexed during the latter part of the swing to ensure the toe is raised higher than the ground surface in order to prevent a trip. The change at the ankle joint alone is not sufficient enough to ensure toe clearance of the raised gradient and the modifications to the trajectory of the swing limb are dependent upon modifications of both the stance and swing limb (Lay, Has, & Gregor, 2005)

Consequently, research conducted by Lay et al. (2005) found the knee to increase flexion at heel strike during upslope walking. However, increased extension was observed at mid stance in order to lift the body up the incline. Additionally, modifications of increased flexion and extension at the hip joint were also observed to ensure safe trajectory of the limb up the incline.

Modifications to the hip, knee, and ankle joint during down slope walking were (Leroux, Fung, Barbeua, 2002). However, the knee was determined to be the main adapting joint for downhill walking (Kuster et al., 1995; Leroux, 2002; McIntosh et al., 2006). Through increased knee flexion during stance, the length on the stance leg is shortened to allow for the swing leg to appropriately accept the ramp surface. According to Hansen et al. (2004), this is logical, as if only ankle plantarflexion was altered, the person would roll to the end of the stance foot and the swing limb would be inappropriately positioned to accept a level surface, resulting in an uncontrolled transition to the next foot, which would produce a tripping reaction.

The above findings indicate that the human locomotion pattern is highly adaptable to varying terrain (Leroux, 2002; Shkutatova, et al., 1999). These findings, however, were conducted on young healthy adult populations and consequently populations that lack range of motion at the hip, knee, or ankle joints (e.g., elderly, limited hip ROM), may have to compensate with an increased range of motion in their other joints, in order to sufficiently propel the body up and down the incline (McIntosh et al., in press).

MTC MODIFICATIONS ASSOCIATED WITH AGEING AND SLOPED SURFACES

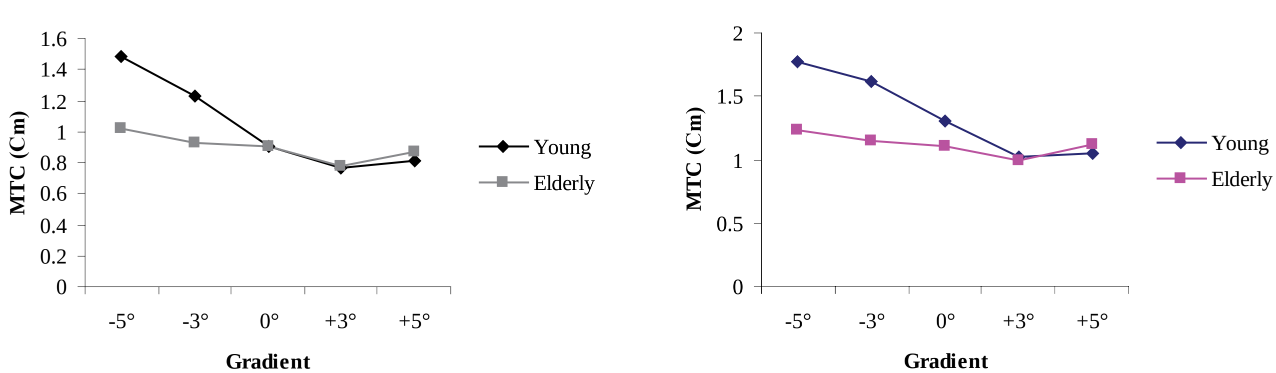
This following section is a comparative analysis of the modifications to MTC height for both elderly and young as a result of the challenges imposed by walking on a sloped surface. It is reasonable to hypothesise (given the results of previous sections) that there would be modifications to elderly MTC height as a result of both walking on a slope and also due to ageing effects. In order to test this hypothesis, we conducted our analysis on nine healthy young (18-35 years) and nine healthy elderly (65+) female adults. All participants walked at a self-selected speed at slopes of -5°, -3°, 0°, +3°, and +5° on a motorised treadmill. Note that each participant selected a speed that was consistent and walked across all gradients. Participants walked at each grade for approximately 7.5 minutes, in order to balance a sufficient number of cycles to obtain an accurate representation of the participants walking pattern without fatigue. Through the creation of imaginary markers (a point established through coordinates without the presence of a real marker) in Northern Digital Inc. (NDI) Toolbench, three imaginary markers were placed at the medial, frontal, and lateral locations at the front of the shoe, with the medial and lateral markers overlying the first and fifth-metatarsal phalangeal joint. An Optotrak Certus (an active-marker optoelectronic motion analysis system, NDI, Waterloo, Canada) was used to analysis gait kinematic data and through the use of a custom made Qbasic program, MTC height was calculated for each participant (Begg et al., 2007).

Limb movements of gait are asymmetrical (Taylor, 2003), and consequently in our study all participants' limbs displayed asymmetrical MTC heights, throughout all testing conditions. This indicates that one limb is travelling closer to the ground; hence one limb is at a higher risk of tripping. As tripping risk is largely influenced by MTC height, the events which occur on the low limb (section a of Figure 4) are more crucial in assessing tripping risk than the high limb. Hence, low limb characteristics will be the focal point of the following sections.

The negative gradients resulted in an increased MTC for both elderly and young groups. A repeated measure ANOVA found that the changes in MTC height between 0° and -3° (p=0.08) and 0° and -5° (p=0.15) gradients were not significant. The change, however between 0° and -5° was significant (p=0.02), suggesting there is a decreased probability of tripping at -5° gradient in comparison to a flat surface (0°). The modifications in the elderly group were neither as large nor as consistent with the modifications to gradient change in the young group. The young group increased MTC by 37% between 0° and -3° (0.90cm to 1.23cm). A further increase in MTC occurred between -3° and -5° (1.23cm to 1.48cm) of 20%, resulting in an overall increase of MTC height between 0° and -5° gradient of 63%. The modifications to MTC were considerably smaller in the elderly group. The elderly group only increased MTC by 2% between 0° and -3° gradients (0.91cm to 0.93cm), whilst despite the smaller gradient change the elderly group further increased MTC by 10% between -3° and -5° (0.93cm to 1.02cm), resulting in an overall MTC increase of 12% between 0° and -5°. This suggests perhaps ageing is associated with a reduced ability to appropriately alter gait to the constraints imposed by negative gradient modifications.

In contrast to walking on negative slope, a trend in MTC heights between positive slopes for both elderly and young was not apparent. Also inconsistent with the negative slope was the reduction in MTC height, in comparison to 0°. A repeated measures ANOVA indicated that groups significantly reduced MTC height between 0° and +3° (p=0.04). The height of both the young and elderly groups at +3° was 0.76cm and 0.78cm respectively. This lower MTC in itself suggests an increased likelihood of tripping at +3°, in contrast to the four other analysed gradients. The MTC height at +5° gradient was less than MTC at 0°, but larger than MTC at +3°, for both groups and limbs. However, no significant differences occurred between MTC values at 0° and +5°, and +3° and +5°. This suggest the toe is

Figure 4. Modifications to MTC height for elderly and young groups across all gradients: (a) Low limb, (b) high limb.



travelling closer to the ground at +5° in comparison to 0°, but higher from the ground at +5° in contrast to +3°. Similar to the other analysed gradients, the young group MTC height variations when compared to a flat surface 0° were larger than the elderly group (0.04cm).

Increasing MTC height results in higher energy expenditure (Begg, et al., 2007), whilst to successfully negotiate walking on raised surfaces increaed flexion and extension is required to elevate the limb above the raised suface (Prentice et al., 2004). This suggests positive gradients require higher energy expenditure than 0° gradients. This possibly serves as an explanation for the reduced MTC at positive gradients, as it suggests the body is unable to sufficiently match the mechanical demands for walking up a sloped surface. In this research study design, participants were required to walk for a considerably long period of time at the elevated gradient (approximately 7.5 minutes), which may have had an effect on the extent of increased energy expenditure. If however the reduced MTC is a consequence of the demands of the raised surface, it serves as no explanation for the lower MTC at +3°, in comparison to +5°. One suggestion, however, is that +3° is not a large enough modification to gradient for participants to consciously adjust gait, and as a result the limb travels closer to the ground.

COMPUTATIONAL INTELLIGENCE IN GAIT ANALYSIS

Computational intelligence (CI) in gait analysis generally refers to the fusion of machine learning paradigms and computer science resulting in powerful classifiers which learn data relationships. Popular CI techniques have focused on supervised learning and include artificial neural networks (Haykin, 1994), support vector machines (Vapnik, 2000), neurofuzzy classifiers (Abe, 1997), and hybrid models. In supervised learning, a classifier learns the implicit relationship between input data and the predefined class labels. This relationship may be a function describing a complex biomechanical system; for example, balance control in the lower extremities during locomotion. While prior linear discriminant analysis investigated distribution characteristics of particular gait variables, newer CI techniques offer more powerful nonlinear analysis methods.

CI techniques have only recently been applied to research in human movement sciences and gait analysis when it was realised that locomotion was vital in our daily activities and our perceived quality of life (Whittle, 2003). Numerous gait variables such as joint angles (Oberg, Karsznia, & Oberg, 1994) and ground reaction forces (Begg, Sparrow, & Lythgo, 1998) can be recorded making feature selection an important aspect of gait data classification. CI has been recently used to study normal gait biomechanics (Barton & Lees, 1997; Barton, Lisboa, Lees, & Attfield, 2007) and detect gait pathologies arising from lower extremity injuries and imbalance disorders due to cerebral diseases such as Parkinson's (Morris, Iansek, Matyas, & Summers, 1994) and Cerebral Palsy (Kamruzzaman & Begg, 2006).

Falls in the elderly are another major health concern since they cause serious injuries and can be fatal, hence motivating the need for newer prediction and prevention techniques (National Safety Council, 2005). Recently CI techniques have been used to detect and predict elderly persons at risk of falling using gait variables such as the minimum toe clearance (Begg, Lai, Taylor, & Palaniswami, 2005; Khandoker, Lai, Begg, & Palaniswami, 2006).

Example: Classification of Elderly and Young from Inclined Walking

We present a classification example to examine the issues involved in the application of CI to gait problems. In this example, we hypothesize that minimum toe clearance (MTC) measurements could better discriminate healthy elderly from young gait if the subjects were made to walk on different ground inclinations. Statistical parameters of the MTC data were computed and used as input features to train a Support Vector Machine (SVM) classifier.

Altogether, seven statistical features were computed from the MTC data distribution which included the mean, standard deviation, skewness, kurtosis, median, first quartile (Q1), and third quartile (Q3) values. The SVM was trained using the linear, polynomial, and Gaussian kernel over a range of $C=\{0.1,1,10,100,1000\}$. The best accuracy results are reported in Table 1 and suggest wide variation in success rates offered by the classifiers across the different inclinations. The results also indicate that the SVM is able to better differentiate the two age groups with an accuracy of 82.35% using MTC characteristics at positive 3º inclination. This accuracy rate, although moderate, is higher than those detected using MTC characteristics from flat

Table 1. Best leave one out SVM classification accuracies for various inclinations. Flat –flat or 0º walking surface, p3- positive 3º, p5- positive 5º, n3- negative 3º, n5- negative 5º

		LOW		
p5	p3	Flat	n3	n5
52.94	58.82	64.71	64.71	64.71

		HIGH		
p5	p3	Flat	n3	n5
58.82	82.35	47.06	52.94	76.47

(0º) walking condition. These results were obtained using a small sample size that might have affected the outcomes and, therefore, this need to be checked using a larger sample size and also using various other inclination angles in future studies. Nevertheless, these results are encouraging in the future applications of computational intelligence approaches for modelling gait data for the detection of ageing effects on gait control and falls risks.

FURTHER WORK

The application of CI techniques in gait analysis has not kept pace with other biomedical areas and further research is required to make them routine in clinical and rehabilitative settings. In particular, fuzzy and genetic algorithm type techniques have yet to be investigated in detail for gait problems. Further research in this area using various signal processing techniques and CI techniques is required to investigate the accuracy of detecting changes in gait due to negotiation of challenging environments.

KEY TERMS

Computational Intelligence: The fusion of machine learning paradigms and computer science resulting in power classifiers which learn data relationships.

Elderly: Adults over the age of 65 years.

Falls: To leave a standing or erect position suddenly, whether voluntarily or not, and succumb to either a sitting, kneeling, or lying position.

Gait: A particular way or manner of walking.

Minimum Toe Clearance: The measurement between the lowest point of the foot (most commonly toe) to the gradient of the walking surface.

Stance: The period of time when the foot is in contact with the ground during gait.

Swing: The period of time between toe off to the strike of the same foot during gait.

Developing Medical IT Systems that Save Lives and Significantly Reduce Hospital Healthcare Costs

Robert J. Mockler
Tobin College of Business, USA

Dorothy G. Dologite
Baruch College, USA

INTRODUCTION

This chapter originated with strategic management work done at Jamaica Hospital in Queens, New York, and the Jewish Home and Hospital for the Aged in Manhattan, New York. As background for the project, the initial phase involved industrywide studies of health care institutions throughout the United States and abroad. During these studies, which involved both field research and a review of the research literature, many samples of which are given throughout this chapter, it became apparent that advances in hospital information technology (IT) are having a dramatic impact on improving patient health care services.

BACKGROUND

By creating the "Digital Hospital," a number of hospitals in this country are leading the way in developing and using information systems to solve plaguing industry problems, including the fact that manually kept records were not up-to-date, were incomplete, were misplaced, or were illegible due to physicians' handwritten prescriptions (Clark, 2004; Information Technology, 2005a, 2005b). Errors resulting from these problems alone have been estimated to kill more than 7,000 U.S. hospital patients yearly and drive up health care costs by an estimated $2 billion (Evans, 2004; Marks, 2004; Turner, 2004). Even though major costs are involved, plans are underway to do the same in overseas hospitals; for example, in England. Evidently, in 2004, not enough U.S. hospitals were moving into the digital area. As a result, in mid-2004, Tommy Thompson, Secretary of Health and Human Services, supported by President Bush, unveiled an ambitious 10-year initiative to transform hospitals in this country more aggressively and rapidly (Bush, 2004; Turner, 2004). Individual states (e.g., Massachusetts) were also considering both government and private financial support for this effort (Peter, 2004). The focus of this initiative will be on computer entry of prescriptions, improved intensive-care unit (ICU) staffing, and easier access to individual patient records for both the patient and hospital staff by integrating patient and other hospital records into integrated databases.

ROLE OF ADVANCED AND BASIC INFORMATION TECHNOLOGY APPLICATIONS AS IMPROVED HOSPITAL HEALTH CARE ENABLERS: A FRAMEWORK

The discussion in the following section provides an overview framework developed from this study, a framework that might help provide guidance to those thinking about understanding, developing, and introducing IT systems into their hospital environments. This framework is outlined in Figure 1.

CLIENT/PATIENT ORIENTATION

Hospitals face specific problems, such as the difficulty to coordinate and integrate diverse customer interactions in a way that (a) makes individual customers feel they were being treated as individuals and (b) enables the hospital to coordinate its services to these individuals. Hospitals have many divisions, such as radiology, emergency room care, test labs, prescriptions, medical nursing assistance, hospital rooms, and kitchens and

Figure 1. Major areas in which medical IT systems are generally developed

Other IT-Related Systems

food service, that provide services to patients. The doctors deal with these various divisions as well as with individual patients, as do nurses and other staff members whose time needs to be scheduled and managed. Tracking is needed to bill patients, preferably in a coordinated way; to maintain staff schedules; and to manage all operational areas efficiently and effectively. Interestingly, many hospitals studied do not even have an integrated billing system for patients, who still receive separate bills for various department services and room accommodations. This creates some confusion among patients and their insurance companies.

AN INTEGRATED ACCESSIBLE ELECTRONIC DATABASE

Based on hospital experiences with information technology development, the starting point almost always involves building accessible integrated electronic databases, especially in relation to individual patient information, as suggested in the preceding section. The most significant applications of such databases are in the prescription writing and delivery area and in the Intensive Care Unit (ICU) area. These findings are consistent with the authors' studies of individual hospitals and the areas that might benefit most from improvements.

Prescription Writing and Delivery

Probably the most visible evidence of the new digital systems at the Children's Hospital in Pittsburgh is the trolley used by physicians when visiting individual patients. The trolley has a laptop computer and wireless network card, which physicians use to log into a program containing all the clinical information on each of their patients. The physicians fill out medication orders online and send these orders from the ward on the seventh floor to the in-house pharmacy in the basement, where a robot puts the prescribed drugs in an envelope for the nurses to dispense. All of this is made possible by the electronic patient database. This laptop-enabled system significantly reduced the major problems encountered from medication errors under the old paper-based system. While medical information technology applications do not necessarily eliminate all errors (in fact, they introduce some new ones), they do substantially reduce these errors (Conn, 2005; Marks, 2004).

INTENSIVE CARE UNITS (ICUS)

Another major benefit of medical IT systems is found in the management and running of ICUs. For example, in late 2004, intensive care patients at Inova Alexandria Hospital were scheduled to be monitored around the clock by doctors and nurses at their bedside as well as through digital cameras, microphones, and special software from miles away (Salmon, 2004). This system will enable these distant caregivers to remotely monitor heart rates, blood pressure, respiratory rates, and other vital signs of critically ill patients even more closely than the on-site duty staff can and thus provide guidance to that duty staff. An IT-based ICU system, where one doctor and nurse can keep a 24-hour watch over as many as 200 critically ill patients at once, can boost chronically short-staffed on-site care. In addition, studies have reported as much as a 50% drop in ICU mortality and 17% shorter stays since the first such system was set up at Virginia's Sentara Health care a few years ago (Allen, 2004; Salmon, 2004).

TELEMEDICINE/TELESURGERY

One early IT development area has been telemedicine. For example, the U.S. military in Iraq set up a field hospital unit connected by computer systems to well-staffed hospital units located elsewhere. This new technology enables treating injured people in remote locations using local staff guided by expert professionals located elsewhere (Hasson, 2004). Kaplolani Medical Center for Women & Children in Hawaii has begun broadcasting live surgeries to physicians around the world. This telesurgery technology allows specialists worldwide to observe and consult with Kapiolani surgeons during emergency and other procedures. It also involves not having to move critically ill patients needing surgery, which is a major cost reduction factor and can help avoid additional medical problems caused by traveling. In addition, it enables an auditorium of medical students to observe live surgeries.

HEALTH CARE FACILITIES AND THEIR FINANCING

Hospitals need sufficient finances to obtain and operate these new facilities as well as to hire and maintain expert professional staff at all levels and put into place the IT digital framework to service everyone. A variety of financial factors affect a hospital's ability to do this. For example, a hospital is dependent on insurance company payments for a substantial portion of their income. A patient's ability to pay also has an impact; and there are limits to the number of lawsuits a hospital can pursue to recover delinquent accounts, and such lawsuits are time consuming and expensive. In addition, many communities expect or require hospitals to provide services for the poor.

IT solutions can be very helpful in the financial area. They enable more accurate billing of patients, faster collection of accounts payable, and easier coordination with insurance companies and government agencies, as well as better tracking of and control of staff usage (Paulik, 2004). In a very significant way, it has led to major reductions in cost-per-patient services, enabled improved health care service delivery, and reduced unnecessary loss of life.

OTHER IT-RELATED SYSTEMS

Integrated IT systems enable other individual patient health care service improvements. The following happened at Allegany General Hospital in Pittsburgh: nurse Candice Bena thought a 76-year-old patient needed a new intravenous line but couldn't get the radiology department to install one immediately (Wysocki, 2004). Fearing the patient would develop an infection, the nurse eventually contacted the Chairman of Medicine directly. The chairman immediately contacted the head of the Radiology Department electronically, who within two hours installed the new IV line himself. The result of such problem identification and process analysis was a 90% drop in the number of infections after just 90 days of using the system. As an additional bonus, the new system saved almost $500,000 a year in ICU costs.

THE BENEFITS CAN BE SUBSTANTIAL AND IMPRESSIVE

In addition to these benefits already discussed, Cincinnati Children's Hospital Center, for example, won the 2003 Nicholas E. Davies EMR (Electronic Medical Record) Recognition Award of Excellence after implementing an integrated clinical information system (ICIS) to provide clinical decision support tools, including Siemens Medical Solutions (INVISION®). The results were elimination of transcription errors, a 50% reduction in medication errors, a 52% improvement in medication turnaround times, a 24% reduction in verbal orders for controlled substances, and 100% compliance with pain assessment documentation requirements defined by state regulatory agencies (Siemens, 2005).

Delnor Community Hospital also showed impressive results with HeartMath's customized technology Freeze-Framer®. After the first year, the overall employee turnover was reduced from 28% to 20.9%, which led to $800,000 in annual savings. Medicare length of stay decreased by 9%, equaling a $1.4 million savings annually, customer satisfaction improved from the 73rd percentile to the 93rd percentile, and the hospital was ranked first in employee satisfaction based on a Sperduto and Associates study. During the second year, the results were maintained with turnover down to 14%, and the hospital was ranked second in employee satisfaction (HeartMath, 2005).

Other benefits included reducing patient waiting times; slashing wheelchair inventories; preparing operating rooms faster; and moving patients through a hospital stay or doctor visit more quickly, seamlessly, and error free, creating major cost reductions along the way in addition to improving patient health care, and in many instances actually reducing the death rate.

IMPLEMENTATION PROBLEMS

Although substantial gains from introducing and using medical IT systems are documented, major problems have been encountered. For example, outside physicians at many hospitals have resisted and in some instances even scuttled new medical IT systems (Turner, 2004). It is far easier to use a pen to write a prescription order or tell a nurse what to do than it is to have to learn a whole new system, no matter how fast or easy it may eventually be to use. The training needed to ease entry of the new systems takes many forms, depending on the staff involved. As Rob Turner points out, patience and persistence is the primary requirement, combined with a keen sense of individual needs in specific hospital situations (Turner, 2004). For example, at a university hospital where most of the physicians are on staff and thus are more controlled by hospital management, the transition has been easier than at hospitals where the majority of physicians are outsiders and thus more independent.

There are also group-training tools that can aid in implementation (Bandarouk & Sikkel, 2005). As might be expected, for example, the various characteristics of users centralized within an existing medical department (e.g., ICU) and those of distant (decentralized) users of any new system had a major impact on the managerial support tools needed to make the implementation successful. The successful management support tools differed in several areas: time allocated (more for the decentralized group); feedback and learning opportunities (different channels and leadership styles used for each group), and autonomy and responsibility (differs by individual as well as group).

A second key problem area is the high cost of such systems. The essence of making such systems work is the integrated computer systems and databases that provide the data/information and facilitate the processing of it. This veritable digital hub involves a substantial financial investment to develop. Again, in spite of the documentable savings, time is needed to study the application of other hospitals' experiences to one's own hospital. And once an appropriate transformation plan is developed, raising the money and convincing others of the investment's value is still a long hard road to travel (Bandarouk & Sikkel, 2005; Turner, 2004).

Given the varying situation-specific needs and financial constraints, effective planning and implementation require identifying individual situation requirements in conjunction with determining the specific components of the planned medical IT system, as well as the order in which the IT transformation steps will take, based for example on analyses similar to the ones given in the previous framework (Figure 1). This is, in a sense, defining the "migration path" to be followed and the basic management principles, from planning and leadership to measurement, guiding this migration (Amatayakul & Lazarus, 2004; Skinner, 2003).

FUTURE TRENDS

The growing interest in medical IT systems is not limited to the United States. In the United Kingdom, the National Health Service (NHS) signed 10-year contracts worth close to $10 billion in 2004 to provide electronic patient records, e-booking, e-prescribing, and electronic ordering of tests in arguably the world's biggest civil IT procurement—one that will cover all 50 million patients in England and one million staff. The program should also see digital images replace X-ray film, making remote consultation about a patient's condition possible. Even if all goes smoothly, it will take until 2008 at the earliest for the system to be operational. But the first NHS hospital to become virtually paperless—University College Hospital in central London—should complete this transformation in 2006. Other examples of countries that have been successful in implementing IT systems in hospitals are Germany, Sweden, and Thailand (Becker, 2004). Several U.S. hospitals have already made this transition, and many, if not most, are expected to follow once financing has been arranged. What is described here, then, is an international phenomenon that will revolutionize hospital medical delivery practices worldwide, which in turn will affect the health care industry in the United States.

Since predictions were that IT spending in health care would reach $47.5 billion by the end of 2006, many firms are entering the field. General Electric Medical Systems and Siemens Medical Systems (INVISION®) are two major corporations that have medical IT development divisions. Computer giants such as IBM, SAP, Hewlett-Packard, and Dell, as well as niche software specialists such as Cerner of Kansas; VISICU of Baltimore; Eclipsis of Florida; HeartMath of Boulder Creek, California; MercuryMD; Infocrosing, Inc.; and the merged Picis and Ibex, Inc. have also entered the field to gain a foothold in what is expected to be a very large market (Clark, 2004; Information Technology, 2005a, 2005b, 2004, 2005).

CONCLUSION

While it is important to review industry practices, the ultimate decision then is a situational one. Individual hospitals have their own special needs. For example, Jamaica Hospital and the Jewish Home and Hospital were each very distinct in the services they provided and the kind of clients they served; as a result, the IT systems they developed were different in many ways. Kapolani Medical Center in Hawaii was uniquely situated to develop its telesurgery program. At university hospitals, their close relationship with their physicians on staff on occasion enabled them to move more quickly into automated prescription processing.

External circumstances can also have an impact, as seen in Massachusetts where the state government support was expected to encourage and facilitate medical IT systems development.

In almost all instances, available finances will have an impact on the nature and pace of medical IT systems development, as will the leadership skills of hospital managers in overcoming resistance to change encountered at almost all operational levels.

In light of these problems, currently less than 2% of all American hospitals have fully implemented electronic medical records. At this time, however, 40 hospitals have portions of such a system and many more are considering introducing such systems. This slow development pace is in spite of the fact that experience shows that these systems can save lives and dramatically affect improvement of health care services delivery at hospitals. Hopefully, studies such as this one, as well as government programs and incentives, will help broaden and accelerate the growing trend toward continuing medical IT systems development worldwide.

KEY TERMS

Database: One possible definition is that a database is a collection of records stored in a computer in a systematic way, so that a computer program can consult it to answer questions. For better retrieval and sorting, each record is usually organized as a set of data elements (facts). The items retrieved in answer to queries become information that can be used to make decisions. The computer program used to manage and query a database is known as a database management system (DBMS). The properties and design of database systems are included in the study of information science.

Digital: The word *digital* is most commonly used in computing and electronics, especially where real-world information is converted to binary numeric form, as in digital audio and digital photography. Such data-carrying signals carry either one of two electronic or optical pulses, logic 1 (pulse present) or 0 (pulse absent). The term is often used with the prefix "e-" as in e-mail and e-book, even though not all electronics systems are digital.

Information Systems: The study of information systems is usually a commerce and business administration discipline, and frequently involves software engineering, but it also distinguishes itself by concentrating on the integration of computer systems with the aims of the organization. The area of study should not be confused with computer science, which is more theoretical in nature and deals mainly with software creation, or computer engineering, which focuses more on the design of computer hardware.

Information Technology: IT, also known as Information and Communication(s) Technology (ICT) and Infocomm (especially in Asia) is a broad subject concerned with technology and other aspects of managing and processing information, especially in large organizations. In particular, IT deals with the use of electronic computers and computer software to convert, store, protect, process, transmit, and retrieve information. For that reason, computer professionals are often called IT specialists, and the division of a company or university that deals with software technology is often called the IT department. Other names for the latter are information services (IS), management information services (MIS), or managed service providers (MSP).

Network Card: A network card, network adapter, or network interface card (NIC) is a piece of computer hardware designed to allow computers to communicate over a computer network.

Telemedicine: Telemedicine is the delivery of medicine at a distance. The term is composed of the Greek word *τελε* (*tele*) meaning "far," and *medicine*. Telemedicine may be as simple as two health professionals discussing a case over the telephone, or as complex as using satellite technology and videoconferencing equipment to conduct a real-time consultation between medical specialists in two different countries. Telemedicine generally refers to the use of communications and information technologies for the delivery of clinical care.

INTRODUCTION

The acceleration due to gravity at the surface of a planet varies directly as the mass and inversely as the square of the radius. This follows directly from Newton's law of universal gravitation.

The Moon is 384,403km distant from the Earth. Its diameter is 3,476km. The acceleration due to gravity is 1.62 m/s^2 because the Moon has less mass than Earth. It is approximately 1/6 that of the acceleration due to gravity on Earth, 9.81 m/s^2.

Mars and Earth have diameters of 6,775km and 12,775km, respectively. The mass of Mars is 0.107 times that of Earth. This makes the gravitational acceleration on Mars $3.73 m/s^2$, as expressed on Equation 1:

$$gm = 9.8 \times 0.107 \times (12775/6775)^2 = 3.73 m/s^2 \qquad (1)$$

Therefore, if a body weighs 200N on Earth, it is possible to calculate how much it would weigh on Mars. Knowing that the weight of an object is its mass (m) times the acceleration of gravity, we can have W = m x g; 200 = 9.8 x m; m = 20.41kg. This mass is the same on Mars, so the weight on Mars is Wmars = 3.73 x 20.41 = 76.1N.

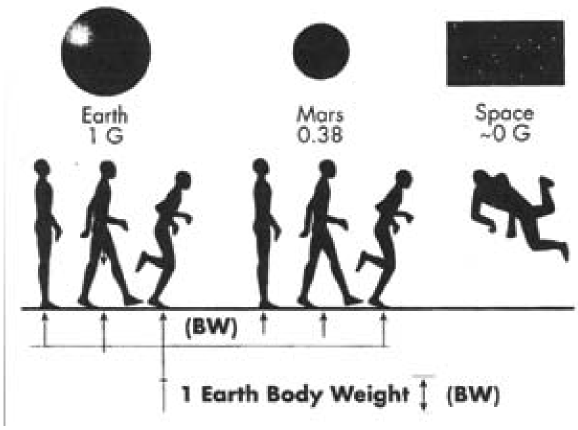
Figure 1 illustrates the change in body posture of an individual on Earth, on Mars, and in space (microgravity).

BACKGROUND

There are three primary techniques for simulating partial gravity: water immersion (neutral buoyancy), parabolic flight, and **body suspension device** (BSD) models.

Underwater Immersion. During tests, a neutrally buoyant subject is ballasted to simulate the desired partial gravity loading. For example, one-sixth of the subject's body mass is added in ballast if a lunar simulation is desired. Water immersion offers the subject freedom from time constraints and freedom of movement, but the hydrodynamic drag is disadvantageous for movement studies.

Figure 1. Schematic representation of body posture in different gravitational environments. (www.nasa.gov)



Parabolic Flight. NASA KC-135 aircraft or Russian IL-76 aircraft are typically used to simulate partial gravity by flying Keplerian trajectories through the sky. This technique provides approximately 30s and 40s for lunar gravity and Martian gravity tests, respectively. Parabolic flight is the only way to effect true partial gravity on Earth, but experiments are expensive and of limited duration.

Body Suspension Device (BSD) Models. BSDs have been developed and used worldwide to study human physiology during partial or total simulation, such as the Zero Gravity Locomotion Simulator (ZLS) (Cavanagh, McCrory, Baron & Balkin, 2002) and the Zero Gravity Simulator (ZGS) (D'Andrea & Perusek, 2005).

The Cleveland Clinic Foundation and Penn State University built the ZLS, which is mounted vertically in a freestanding frame and includes padded straps that support a runner under the head, torso, arms, and legs. In this position, there is no gravitational force between the runner and the machine.

In physiotherapy, body suspension devices provide patient and therapist security, giving increased freedom of movement to accomplish technical and facilitative maneuvers. Manual assistance is necessary to promote the postural adjustment in patients with neurological injury that uses a gait training system (Boehrman & Harkema, 2000).

Virtual reality offers potential for the development of evaluation and training systems, allowing precise control of a stimulus. Researchers have utilized gait training on a treadmill body suspension system with virtual reality. They found that people with multiple sclerosis increased the gait velocity, and their balance was improved after two months of treatment with the Body Weight Suspension and Treadmill (BWS/TM) system (Fulk, 2005). The virtual reality technology employed was based on navigation. Three virtual environments representing the soils of Earth, Mars, and the Moon were developed. The hypotheses were (1) the reduction of the gravitational force alters gait kinematic parameters; (2) the utilization of a Head Mounted Display (HMD), virtual reality glasses, while walking on a treadmill influences the postural balance of the user.

MAIN FOCUS OF THIS STUDY

The main objective of this research was to develop a secure and efficient system for **gait evaluation** that can be used for research purposes in aerospace medicine, physiotherapy, computer science, and rehabilitation medicine. A system was developed to evaluate **walking patterns** in **hypogravity simulation**, which was called SAMSH. This consisted of the improvement of a body suspension device and the instrumentation of a treadmill that served as a platform to assess a physical locomotion technique in a virtual environment.

Details of the equipment developed for this study are presented as follows:

The body suspension device (3000 mm x 2660 mm wide and 2000mm high) has a counterweight system of 20 bars (5kg each). The subject wore a harness (Advanced Air Sports Products; Lake Elsinore, CA), which was suspended by a steel wire and designed to support massive tensions (Figure 2). A load cell permitted the measurement of the mechanical stress by means of Wheatstone bridge.

Equation 2 demonstrates how to calculate the relative mass of a subject in a simulated gravitational field, where RM = relative mass (kg), BM = body mass on Earth (kg), SGF = simulated gravitational force (m/s^2) and 1G = 9.81 m/s^2.

Equation 3 gives the counterweight (CW, kg) necessary to simulate body mass for a preset hypogravity level.

$$RM = \frac{BM \times SGF}{1G} \qquad (2)$$

$$CW = BM - RM \quad (3)$$

A moving platform was based on the instrumentation of an electrical treadmill. The velocity of the treadmill was controlled using a communication protocol with a frequency inverter Movtrack07 (SEW). It was also necessary to develop an electrical interface RS232/485 to provide communication between the computer and the inverter. Treadmill velocity was at 40m/min throughout the tests (Figure 3).

The toolkit Small VR (developed by the Virtual Reality Group of PUCRS, based on OpenGL and GLUT libraries) was developed to represent the Martian, Terrestrial, and Lunar surfaces. MS visual C++ 6.0 software (C and C++ Programming Language) was used. The route followed by the subject was predetermined. The subject was instructed to walk forward at 40m/min for approximately 2.15min. Dimensions for the virtual environment vertices were set at 10m by 10m. A proportional equation allowed the individual's height to be kept the same independent of his position, creating a realistic environment. Soil textures of Earth, Mars, and the Moon were extracted from graphic computation libraries (Figure 4).

Figure 3. Schematic view of the electronic velocity control of the treadmill

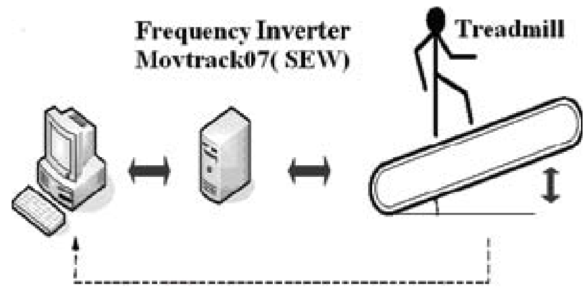

Figure 4. Virtual Mars environment

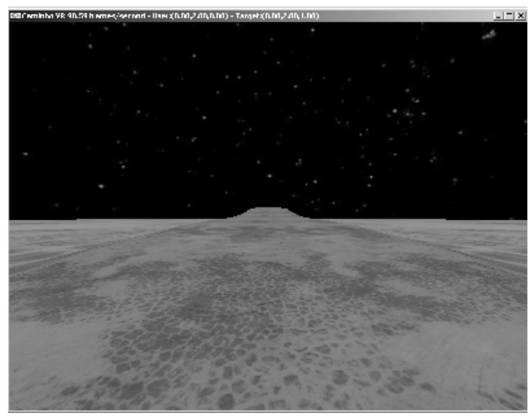
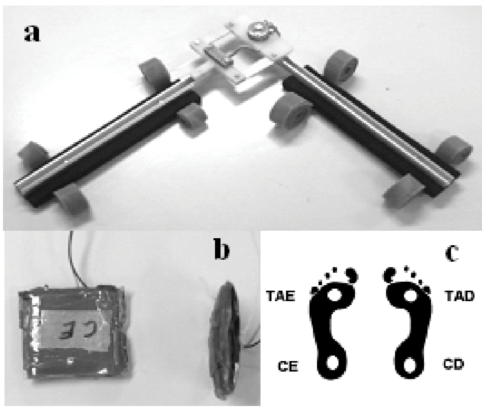


Kinematic gait was performed using spatial and temporal patterns. Electrogoniometers were used to evaluate the angular displacement of the knee and ankle (Figure 5a). Each electrogoniometer consists of two aluminium bars covered with rubber material and connected by a 10KΩ potentiometer. They were fed by a 5V power source. Calibration was performed before the beginning of each experiment using a manual goniometer. Data was acquired by means of DataQ. The linearity of the electrogoniometers has been evaluated previously (Gurgel, Porto, Russomano, Castro, Bertoglio & Schroeder, 2004).

Foot switches were developed for the measurement of temporal parameters that would determine the phases of the locomotion cycle. When a region of the foot was in contact with the surface, a short circuit supplied a level of tension that was captured by the DataQ and stored for subsequent processing (Figures 5b and 5c).

Figure 5. Electrogoniometer (a); Foot switches placed on the front (TAE, TAD) and back (CE, CD) part of the plantar region (b and c)



The study protocol was approved by the PUCRS Research Ethics and Scientific Committees. Each subject provided written informed consent before participating in the experiment.

A preliminary assessment of the system was conducted with the participation of one subject. The subject experienced two different conditions of body weight reduction: 30% for Mars and 60% for the Moon. Descriptive and angular variables related to kinematic gait evaluation were measured. Displacement of the subject's head into the three planes of movement was measured using the head mounted display (HMD) on x, y, and z axes (Pitch, Yaw, and Roll). The length, duration, speed of the stride, cadence, and duration of the stance phase were recorded.

VARIABLES EVALUATED DURING WALKING ON MARTIAN AND LUNAR GROUND-BASED SIMULATION BY MEANS OF A BODY SUSPENSION MODEL

The stride time (TS) is the time between the first and the second contact of the same foot region on the ground. The stride length can be calculated using the equation ($v = d/t$). Cadence was determined by the number of steps per minute of the gait cycle. The stance phase could be determined by knowing the contact time (CT) of the feet regions instrumented by the foot switches. It was observed from the time between the initial and the final contact of each region (front and back part of the plantar region) of each foot during a stride. The aerial time (AT) is the time between the toe-off and ground contact of the opposite foot, representing the swing phase. This is more significant in hypogravity environments than at 1G (Newman, 2000).

Angular variables were evaluated by the electrogoniometers, which determine the ankle dorsal flexion (0º to 30º) and ankle plantar flexion (0º to 50º), flexion (-10º to 90º) and extension (90° to -10º) of the knee.

The statistical analysis was made using SPSS (version 10.0), ANOVA, and t-tests. Significance level adopted was about 5%.

The findings of this study demonstrated that SAMSH adequately simulates the gravitational forces of Mars and the Moon for the study of the walking patterns in hypogravity environment, and the use of electrogoniometers and foot switches allowed the evaluation of walking variables.

Stride time, length stride, and stance phase increased progressively from 1G to Mars simulation and then the Moon simulation. The opposite was observed in the cadence, which was higher at 1G and lower on the Moon simulation. Aerial time was 0,69s on the Moon, 0,63s on Mars, and 0,50s on Earth.

Ankle dorsal flexion at Earth was 29º, increasing to 69.7º on Mars and to 67.9º on the Moon simulations. The ankle plantar flexion showed an opposite pattern, being bigger on the Moon and lower on the Earth. Flexion of the knee was 93.6º on the Moon simulation and 66.8º at Earth. The extension of knee was bigger on Earth (61.8º) and lower on the Moon (28.4º).

HMD data suggested that head movement was more prominent at the X axis (pitch, head up and down) on the Earth, Y axis (yaw, right and left inclination) on Mars simulation, and Z axis (roll, left and right rotation) on the Moon simulation.

FUTURE TRENDS

The era of manned space flight began on April 12, 1961, with the launch of Yuri Gagarin aboard Vostok-1 by the former Soviet Union for a very short space mission that lasted less than 2h. This historic mission was followed by a series of American- and Soviet-manned space programs. Space tourism, a recent phenomenon, is the term that has come to be used to mean ordinary members of the public buying tickets to travel to space and back. They have been called space tourists, citizen explorers, public spaceflight participants, and astourists.

Tourism in space has been considered a fledgling industry, born out of necessity, yet driven by the same curiosity and ambition that took humanity to the Moon. In Russia, Europe, and the United States, private companies are already vying to become space tourism leaders.

It was clear since the first manned space flight that the main objectives of space life science research are to adapt man to the environment of space and readapt him when back to Earth. The evaluation of human walking patterns in hypogravity environments is then mandatory.

CONCLUSION

According to the present study, the greater the reduction of body weight, the longer the stride time. This reflects findings in previous other studies (Newman, 2000). Further, the time of contact diminishes with body weight reduction.

During the simulation of the Moon, steps were longer and less frequent than at 1G. A similar change in locomotion has been noted in aquatic environments (Degani & Barela, 2001). Reduction in subject body weight also influences ground reaction force (Amadio, 1996). There is a significant reduction in the peaks of force during locomotion in partial gravity (Newman, 2000).

Qualitative and quantitative data obtained by HMD and video cameras showed that head movements were predominantly on the z axis. Lateral trunk inclination was observed during body weight reduction (30% and 60%) as a result of limit movements of the trunk and pelvic region. This reflects findings of Rose and Gamble (1998), who observed increased lateral trunk inclination in proportion with increases in stride length. A protective extension reaction, a postural reflex to avoid lost of body balance, was also observed with the utilization of HMD (Bobath, 1978).

Kinematic evaluation of gait variables on Earth without HDM (control) were speed 0.67 m/s, cadence 86 steps/min, length of stride 96 cm, knee angular variation 66.8º (flexion) and 5.2º (extension), ankle angular variation 27º between dorsal flexion (73º) and plantar flexion (100º). These results are similar to the ones obtained by Winter (1991), who states that the normal speed at 1G should range from 1.16 m/s to 1.67 m/s. However, the gait speed in this research was slower in order to allow the subject to use the HDM safely. No data regarding walking patterns with virtual reality were found in the literature for comparison.

INTRODUCTION

Osteoporosis, usually silent until a fracture occurs, is among the most common health problems facing elders worldwide. By definition, osteoporosis is a "systemic" skeletal disease characterized by a low bone mass and a micro architectural deterioration of bone tissue, with a consequent increase in bone fragility and susceptibility to fracture ("*The Burden of Musculoskeletal Conditions*," 2003). The incidence of osteoporotic hip fracture increases exponentially with age, and the increase in older persons globally could dramatically increase the number of hip fractures, posing a devastating increase in disability and cost for elders worldwide. Therefore, it is imperative that diagnostic and treatment measures be developed and instituted worldwide to support preventative measures for osteoporosis and consequential fractures. Toward that purpose, the World Health Organization (WHO) has declared 2002–2011 as the *Decade of the Bone and Joint*, uniting nations throughout the world in the commitment of energy and resources to accelerate progress in bone health and prevention of fractures. Keeping in mind this global context, this discussion includes information about the prevalence and impact of osteoporosis, its signature pathology (including bone remodeling), factors which place individuals at risk for developing osteoporosis, and the role of diagnostics, therapeutics, and informatics in the realm of osteoporosis. Encouraging information is also provided about recent innovative technological developments that may enhance our ability to detect and treat osteoporosis earlier, in time to reduce and better manage its unwelcome sequelae.

PREVALENCE AND IMPACT

The WHO estimates that up to 70% of women older than 80 years of age have osteoporosis ("*The Burden of Musculoskeletal Conditions*," 2003). One in every two women and one in every five men over 50 years of age experience an osteoporotic fracture during their lives, and more women die from the after-effects of osteoporotic fractures than from cancer of the ovaries, cervix, and uterus together. There are 1.5 million osteoporotic fractures in the U.S. each year, 20% hip fractures, 50% vertebral fractures that lead to height loss, and 30% at the wrist and other sites. One fourth (25%) of all postmenopausal women will develop a vertebral deformity and another 15% will sustain a fractured hip, numbers that could triple by 2040 ("*Bone Health and Osteoporosis: A Report*," 2004).

Hip fractures are the most severe consequence of osteoporosis, and are associated with lengthy hospital admissions, difficulty in performing activities of daily life, nursing home placement, and a high rate of mortality. The annual worldwide incidence of hip fracture is projected to grow to 2.6 million by 2025 and to 4.5 million by 2050. Virtually all persons in the U.S. with hip fractures are hospitalized, and 25% of those who sustain hip fractures require long-term nursing home care. Spine fractures are considerably less problematic in terms of cost, with only 10% requiring hospitalization and less than 2% being admitted to a nursing home. However, they account for 66,000 physician office visits and at least 45,000 hospital admissions each year.

The economic burden of osteoporosis to society is immense. Each year in the U.S., osteoporotic fractures result in more than 500,000 hospitalizations, 800,000 emergency room visits, more than 2.6 million physician office visits, and the placement of nearly 180,000 individuals in nursing homes. It is estimated that each hip fracture represents approximately $40,000 in total medical costs. Care to white women comprises the majority of these costs, but men and nonwhite women of all ages account for $1 billion in direct costs of osteoporotic fractures. Due to the late age at which the expenses related to care occur, osteoporosis accounts for 14% of all nursing home days. Given that 75% of all hip, spine, and distal forearm fractures occur in persons 65 years and older, the direct costs are largely borne by society, in the form of social reimbursement programs. In the United States, Medicare pays approximately one half of these costs, and Medicaid covers an additional one-fourth of the expense.

But the impact of osteoporosis on the personal lives of the patients and their families is even greater. Nearly one in five persons who sustain a hip fracture end up in a nursing home, and about 20% will die before a year has passed. Two-thirds of hip fracture patients never return to their prefracture level of function, and many lose their ability to walk. More than one-third (37%) lose their ability to dress themselves, 58% lose their ability to move from their chair to standing, and 60% lose their capacity to walk across the room. Approximately half of the individuals who sustain hip fractures never walk independently again, even if they were ambulatory before their fracture (Gueldner, Burke, Wright, & Newman, 2007).

PATHOLOGY

Osteoporosis is not only the result of accelerated bone loss during aging, but may also develop because of suboptimal bone growth in childhood and adolescence, or by the use of certain medications (most notably steroids) for the treatment of other health problems. Fracture risk is currently estimated by measuring bone mineral density (BMD), with the risk of fracture increasing sharply as BMD declines. The estimated life-time risk for wrist, hip, and vertebral fractures is 15%. Hip fracture rate is used to calculate the osteoporosis fracture burden. Prior fracture is one of the most important predictors of future fracture. The risk of hip fracture after a wrist fracture increases 1.4-fold in U.S. women, 1.5-fold in Swedish women, and 1.8-fold in Danish women. Wrist fracture is an even stronger predictor of hip fracture in men; U.S. men who had a wrist fracture were found to be 2.3 times more likely to sustain a hip fracture, and Swedish men with wrist fracture were 2.8 times more likely to sustain hip fracture.

Although an individual's height and unique bone structure are developed by late adolescence, new bone continuously replaces old bone throughout life in a process referred to as bone remodeling. Through the remodeling process, approximately 10% of the skeleton is replaced each year, with most of the adult skeleton being replaced every 10 years. The skeleton consists of 80% cortical (compact) bone, which is located predominately on the outer surfaces of the bone, and the remaining 20% is inner trabecular (spongy) tissue, which forms a large portion of the vertebrae, proximal femur, and distal radius. If less new bone is formed during the remodeling process than the amount of old bone removed, a net loss of bone occurs, and the resulting fragile bone is more likely to break with less trauma, as is the clinical problem with osteoporosis. Remodeling occurs in both types of bone, but most (80%) occurs in the trabecular bone. Thus fractures in regions of high trabecular area such as the hip, spine, and wrist are more likely to occur.

In the complex bone remodeling sequence, bone cells lie quiescent until osteoclasts (bone resorbing cells) are stimulated to resorb (remove) a small volume of bone. While some details of the actual remodeling process remain unclear, it is thought that this resorbing activity is increased by a number of factors, including parathyroid hormone (PTH) and thyroxine, and that it is decreased by estrogen, testosterone, vitamin D, calcium, high phosphorus levels, and sometimes by cytokines from osteoblasts (bone forming cells). Localized prostaglandins and interleukins may also exert a stimulatory or inhibitory effect on this remodeling process. A low calcium intake stimulates the secretion of PTH, which in turn activates the osteoclasts to release lysosomal enzymes which digest bone matrix, causing the release of calcium and other bone minerals and proteins. After the resorption cavity is formed, a cement line is laid down by macrophage-type mononuclear cells, limiting further resorption of bone in that particular area. The cement line is rich in osteopontin, which may serve to shut off osteoclast (resorption) activity and stimulate osteoblast (rebuilding) activity. A growing number of pharmaceutical modalities have been developed with the goal of reducing bone loss or increasing bone formation to maintain bone health by inhibiting osteoclast action on bone resorption, or by allowing formation to continue.

DIAGNOSTIC TECHNOLOGIES IN OSTEOPOROSIS

Osteoporotic fractures are preventable, but appropriate diagnostic tools are crucial in the early assessment and treatment of osteoporosis. Bone densitometry has made it possible for health care providers to diagnose osteoporosis before the first fracture occurs; and to reliably predict fracture risk in postmenopausal women and others at high risk. It can also be used as a surrogate marker to determine the effectiveness of therapies and to evaluate those patients that might not respond to osteoporosis therapy. BMD measurements correlate strongly with the load bearing capacity of the hip and spine, and can detect osteoporosis before a fracture occurs, predict fracture risk, assess the rate of bone loss with repeated measures, and monitor the effectiveness of treatment for osteoporosis. The two technologies most frequently used for bone density testing are heel ultrasound (HUS) and dual x-ray absorptiometry (DXA).

HUS uses change in speed of sound and waveform attenuation to create a number that correlates with bone density. A T-score is created by comparing this extrapolated value to a normative database, and this value has been shown to predict fracture risk at the hip and spine. The WHO classifies normal bone density as a T-score of -1 or above, osteopenia as a T-score between -1 and -2.5, and osteoporosis T-score -2.5 or below ("*The Burden of Musculoskeletal Conditions,*" 2003). HUS has some chief advantages, including portability, no radiation, and low cost. This makes it an appealing technology for patients as well as primary care offices. But a major disadvantage to HUS is that a significant proportion of patients will need a DXA in addition, for two reasons, including indeterminate results and a need for ongoing monitoring of low bone density or treatment effectiveness.

On the other hand, DXA is currently considered the "gold-standard" fracture risk assessment tool. Used to measure BMD in the hip, spine, or wrist, the DXA takes about 10 minutes to perform with low radiation exposure (one-tenth of a standard chest x-ray). The results are also reported in T-scores. However, DXA is not universally available for screening for osteoporosis, partly because the equipment is large and expensive, and is not transportable, which often poses a barrier to access for persons who live in nonurban areas. However, mobile DXA modalities have just started to emerge and their large-scale adoption and long-term feasibility remain to be seen (Newman, Olenginski, Perruquet, Hummel, Indeck, & Wood, 2004).

THERAPEUTIC TECHNOLOGIES IN OSTEOPOROSIS

In terms of preventative treatment technologies, padded hip protectors had received some earlier attention based on their promise for decreasing fracture during falls in elderly populations, but recent evidences seem to point that their value in fracture prevention in persons with severe osteoporosis is minimal (Parker, Gillespie, & Gillespie, 2006). There are also a growing number of nonpharmaceutical muscle calf muscle pump stimulation modalities under study and development that hold potential for helping to reduce bone loss and stimulate bone growth exogenously. One such modality is direct electrical stimulation, whose efficacy in preventing bone loss and even increase bone mass, by means of calf muscle pump activation, has been widely studied in individuals with spinal cord injury (Belanger, Stein, Wheeler, Gordon, & Leduc, 2000; Claydon, Steeves, & Krassioukov, 2006; Eser, de Bruin, Telley, Lechner, Knecht, & Stussi, 2003; Sampson, Burnham, & Andrews, 2000). Current clinical evidence suggests that, at least conceptually, direct electrical stimulation of the musculature may have potential as a means to prevent bone loss. However, electrical stimulation is not conveniently applied, can be painful or induce discomfort, and often leads to rapid muscle fatigue, factors that may significantly limit its applicability as a long-term prevention strategy for osteoporosis.

As a means of bypassing the complications of direct electrical stimulation of muscle contraction, investigators have recently begun pursuing the concept of using reflex-mediated pathways to indirectly trigger muscle activity. Micromechanical stimulation of the plantar surface stimulates the cutaneous somatosensory mechanoreceptors, which subsequently initiate calf muscle contraction (Kennedy & Inglis, 2002; Madhavan, Stewart, & McLeod, 2004). This strategy has been implemented in a device which can be placed in front of a chair, or under a desk, so that the user can readily obtain calf muscle pump stimulation in a sustained manner, in either the home or workplace.

Studies utilizing this technology have shown that calf muscle pump activation can be readily enhanced, with significant increases in lower body fluid flow (Stewart, Karman, Montgomery, & McLeod, 2005) and venous return from the lower limbs, resulting in reversal of orthostatic hypotension and orthostatic tachycardia (Madhavan, Stewart, & McLeod, 2005). Consistent with these observed effects on lower limb muscle pump activity, sustained plantar stimulation has been shown to significantly increase lower limb muscle strength in humans (Russo et al., 2003; Torvinen et al., 2003). Correspondingly, these effects on the musculature have been observed to affect bone density over the long term in animal models (Rubin, Turner, Bain, Mallinckrodt, & McLeod, 2001), children (Ward, Alsop, Caulton, Rubin, Adams, & Mughal, 2004), and adults (Rubin, Pope, Fritton, Magnusson, Hansson, & McLeod, 2003; Rubin, Recker, Cullen, Ryaby, McCabe, & McLeod, 2004). These preliminary results, combined with the ease of use of this technology, suggest that this technology may, in the near future, form the basis of a convenient, noninvasive, nonpharmacologic means to prevent or reduce age-related bone loss and osteoporosis.

HEALTH INFORMATICS IN OSTEOPOROSIS

The United States health care infrastructure is increasingly recognizing the potency of information technology in significant cost savings (Hillestad et al., 2005; Walker, 2005), and health outcomes ("*Crossing the Quality Chasm*," 2001), especially for the care of the elderly population. Health information technology has relevant application to osteoporosis, both in terms of providing educational information to increase the public's awareness and knowledge of lifestyle habits that promote bone health, and in providing system linked quick reference information and pop up medical records and reminders for primary health care providers as they see their patients.

The Institute of Medicine has declared information technology as the structural component of health care most likely to improve the process of health care delivery ("*The Computer-Based Patient Record*," 1997). There has long been consensus that accurate and consistent use of a computer by the clinician is essential to the monitoring of outcomes, and the recommended standards were quickly exceeded within general practice. However, the literature confirms that the quality of the data seen in such innovative systems has not yet occurred in relation to the prevention of osteoporotic fractures, which is surprising, given the extraordinary health care costs associated with fragility fractures (Bayly, 2005). Rather, incident fractures are not being commonly managed systematically in either secondary or primary care (Chen, Brown, Archibald, Aliotta, & Fox, 2000).

It has been pointed out that general practice is probably best placed to manage those at risk, because it is they who see the patients in time to institute early diagnosis and preventative measures. However, data quality in primary care regarding osteoporosis has been found to be lacking and inconsistent, particularly in regard to data related to fracture. Thus front line clinicians represent a fertile area for instituting improvements in both availability and use of medical informatics. This can be accomplished through two mechanisms: the acquisition of clinical information and the process of monitoring the continued delivery of care by electronic rather than paper-based ways.

TECHNOLOGY NEEDS OF THE FUTURE

Worldwide, the number of persons who sustain hip fractures every year is more than 1.3 million people, and that number is predicted to double by 2020. This dramatic increase in hip fractures alone will have a devastating effect on disability and cost for elders worldwide. However, other important chronic diseases are also projected to increase due to the significantly aging society (including dementia, cancer, cardiovascular disease, and diabetes), and some of these conditions already generate more cost and disability than musculoskeletal disorders, chiefly osteoporosis. And in some areas of the world, acute health problems are so pressing that little attention can be paid to insidious conditions such as osteoporosis. For instance, the 70 million people estimated by WHO to have osteoporosis pales when compared with the two billion persons infected with tuberculosis (McGovern & Bond, 2003), three million deaths each year from diarrheal diseases (Murray & Lopez, 1996), and 1 million deaths from malaria (Gelb & Hol, 2002). Given the simultaneous worldwide toll from these widespread and equally devastating diseases, it seems that osteoporosis preventative strategies will have to rely primarily on cost-effective public health measures. And it is in this aspect that the fields of engineering and information technology can and must take the lead, through the development of cost-effective diagnostic, therapeutic, and information system solutions. Representative areas of applications include provision of patient-tailored reminders related to the skeletal health status, with indications to diagnostic measures, customized therapeutic options, and portable electronic preventative health care records. Further, it is equally vital that sophisticated but user friendly health informatics be developed to provide educational outreach about bone health to individuals, families, and the community.

CONCLUSION

Osteoporosis is a devastating public health problem that affects all strata of the global community. But healthy women and men in the age range of 50-65 years still have time to engage in osteoporosis preventing behaviors to minimize bone loss and fractures. It is critical that concerted efforts be directed toward community education and the development of new diagnostics, therapeutics, and informatics to liberate towns and communities worldwide of the ravages of osteoporosis, as our predecessors have spared modern society from the devastation of polio and rickets. Toward this goal, it is imperative that additional research be conducted to find cost-effective diagnostic, treatment, and information technology measures, in order that both professionals and the general public can be better informed about preventative aspects of musculoskeletal health care.

INTRODUCTION

Obesity has been a known problem for over 60 years. As early as 1943, Metropolitan Life Insurance Company declared "Overweight is so common that it constitutes a national health problem of the first order." In 1952, the American Heart association identified obesity as a cardiac risk factor (AHA, 1952). In 1974, obesity was identified as "the most important nutritional disease in the affluent countries of the world" (LANCET editorial, 1974).

Over a few decades, the obesity epidemic has continually been creeping up in all developed countries around the world; this has accelerated rapidly in the last decade, and it appears to have reached a crisis level with unprecedented numbers, particularly in America, joining the overweight or obese categories (Anderson, Konz, Frederich, & Wood, 2001; Mokdad, Serdula, Dietz, Bowman, Marks, Koplan, 1999).

In 2003, the U.S. Surgeon General Richard Carmona said in addressing the House of Representatives, "I welcome this chance to talk with you about a health crisis affecting every State, every city, every community, and every school across our great Nation. The crisis is obesity. It's the fastest growing cause of death in America."

To add to the problem, from 1952 until 2003, the ratio of food prices to all other goods dropped by 12%, making it easier to overindulge in our favorite foods (Philipson, Dai, Helmchen, & Variyam, 2004). In recent years, fresh fruit and vegetables have become more expensive as a proportion of disposable income, while foods with refined grains, sugars, and fats have become cheaper (Sturm, Dai, Helmchen, & Variyam, 2005). Females trying to balance work and family life often turn to the convenience of prepackaged foods with short preparation times, and take-away foods (Lin, Guthrie, & Blaycock, 1996; McCrory, Fuss, Hays, Vinken, Greenberg, & Roberts, 1999; Schluter & Lee, 1999). These tend to be high in calories (Nielsen, Siega-Riz, Popkin, 2002). The environment has become obesogenic (Hill, Wyatt, Reed, & Peters, 2003); Ulijaszek (2007) has called this a "disorder of convenience" (p. 185).

Fast food does not normally equate with healthy food. Certain foods can be high in fat, salt, sugar, and calories. They can also be low in nutrition. Salt in burgers and chips, and phospohorous found in soft drinks, contribute to calcium losses. Sugar causes leaching of calcium, magnesium, and B vitamins. Foods kept warm for long periods experience loss of Vitamin C. Cooking causes losses of B and C vitamins, while fried foods increase our need for the antioxidants A, B, C, E, and zinc.

Weight management has tended to be based on calorie counting (Dietary Guidelines Advisory Committee Report, http://www.health.gov/dietaryguidelines/dgq2005/report/PDF/D2_Energy.pdf) with percentages of calories being split between the three elements: protein, carbohydrates, and fat. But the diet for optimum health also needs to consider the levels of essential vitamins and minerals being consumed. The requirements of all these elements, vitamins and minerals vary with age and gender. This makes it very difficult to monitor your diet without the help of diet monitoring software.

Note: For convenience, the term obesity is used in this article to mean overweight or obese.

BACKGROUND

According to the World Health Organization, more than one billion adults are overweight worldwide, and more than 300 million of these are classed as obese (http://www.who.int/dietphysicalactivity/publications/facts/obesity/en/).

An estimated 17.6 million children under five years old are overweight worldwide; this has doubled since 1980, while the number of overweight adolescents have trebled over the same period.

The body mass index (BMI) measurement is used to identify whether a person is overweight or obese. This is a statistical measure that was developed between 1830 and 1850 by the Belgian polymathematician Adolphe Quetelet. The BMI is still widely in use today. The BMI formula is BMI = weight in kilos, divided by height in meters squared. In general, overweight people are defined as having a BMI over 25, obese people over 30, and morbidly obese people, over 35. BMI measurements tend to increase amongst middle-aged and elderly people, which significantly contribute to osteoarthritis.

Overweight and obesity are defined as having excessive body fat that may impair the health of such individuals. This body fat is normally accumulated over many years of energy imbalance between the calories consumed and the calories expended—in other words, due to overeating and a sedentary lifestyle. A pound of body fat is achieved by consuming 3,500 calories more than the calories being burned off as energy. Even adding one plain biscuit containing 65 calories to your daily diet will make you gain almost 7 pounds per year. Over time, this accumulates into stones. Dieting to lose weight without doing any physical activity causes muscle loss, and can be harmful to an individual's health. Muscle cells contain mitochondria cellular organelles which consume fat. The more muscle you have, the more mitochondria also increases in number, consuming more fat. Consuming less fat causes the mitochondria to use up the fat cells stored in your body as their source of fuel.

Obesity differs between countries with China, Japan, and some African nations at one end of the scale, falling below 5%, while at the other end, the incidence in urban Samoa rises above 75%.

To add to the confusion regarding the number of calories you need to maintain weight, our muscles start to deteriorate by 1% per year by the age of 45 (Sceppa & Layne, 2005). Less muscle lowers the metabolic rate, and that means fewer calories are required at the resting rate. So maintaining exactly the same diet and exercise regime will see individuals overeating without even realizing it. Sceppa's research into reversing muscle loss examines protein deficiency that forces the body to use the amino acids from muscle tissue, leading to muscle loss. The researchers are now reassessing the adult dietary protein requirement, which is currently 0.8 grams per kilo of body weight.

Becoming overweight can adversely effect temperature regulation and put strain on the body's organs and systems over time. This often leads on to high blood pressure, high blood cholesterol and triglycerides, and insulin resistance. Continuing into obesity is known to increase the risk of serious health problems in some individuals, and the more excess fat you have, the higher your risk of chronic disease and disability (Must, Spadano, Coakley, Field, Colditz, & Dietz, 1999). These risks include respiratory difficulties, chronic musculoskeletal problems, skin problems, and infertility at the less serious end, Type 2 diabetes and high blood pressure at the middle of the range, to life-threatening diseases such as some forms of cancer, gallbladder disease, heart disease, and stroke at the most serious end. Other less life-threatening diet related ailments include anemia, ulcers, constipation, irritable bowel syndrome, and kidney stones.

According to the World Health Organization, heart disease and stroke are the world's number one cause of death in the developed world with an estimated 17 million people each year being struck down prematurely (World Health Organization FactSheet, 2006).

Table 1. Recommended dietary allowance of calories for sedentary lifestyle

Age	**Female**	**Male**
0-5 months	108 * weight	108 * weight
5 – 12 months	98 * weight	98 * weight
1 – 3 years	102 * weight	102 * weight
4 – 6 years	90 * weight	90 * weight
7 – 10 years	70 * weight	70 * weight
11 - 14 years	47 * weight	55 * weight
15 – 18 years	40 * weight	45 * weight
19 – 24 years	38 * weight	40 * weight
25 – 50 years	36 * weight	37 * weight
51 and over	30 * weight	30 * weight

Analysis in the World Health Report, 2002 claims that around 58% of diabetes, and 21% of ischaemic heart disease, and between 8 and 42% of certain cancers globally occurred in people with a BMI measurement over 21. So the premise that eating a sound, balanced diet is more likely to lead to a much healthier and longer life has been well proven by medical researchers.

In 1977, the Dietary Goals report recommended food labeling (Senate Select Committee, 1977). This has been adopted in all developed countries.

Knowing the number of calories in food allows you to compare similar food products. But how do you know how many calories you actually need? Table 1 gives the figures to maintain your current weight if you lead a low-activity lifestyle. The figures are based on the RDA data courtesy of National Academies Press (http://www.nap.edu) published reports issued by National Academy of Sciences, National Academy of Engineering, Institute of Medicine, and National Research Council, all operating under charters granted by the Congress of the United States. The weights used in Table 1 are in kilograms. These figures are guidelines only, and there are many other variations. If you monitor your weight and count your calories, you will be able to determine how many calories your body actually requires.

If you do medium activity, then add 400; if you do heavy work, then add 900.

Vitamins and minerals are also required from the food we eat. These are required to maintain health and ward off disease. There is a Recommended Dietary Allowance (RDA) for most vitamins and minerals. The RDA was developed during World War II by Lydia J. Roberts, Hazel K. Stiebeling, and Helen S. Mitchell under the auspices of the National Research Council (Committee on Food and Nutrition, 1941). There was a strong possibility that food would need to be rationed, and the governing bodies needed to know the minimum requirement of each element to maintain health. The original RDAs were introduced in 1941 with a built-in "margin of safety." RDA levels have been adjusted throughout the years since then as new research becomes available. More recent research has shown that taking several vitamins above the RDA may prevent heart disease, cancer, osteoporosis, and other chronic diseases (Giovannucci, Ascherio, Rimm, Stampfer, Colditz, & Willett, 1995; Holick, 2004; Weber, 2001)

Until recently, it was thought that taking multivitamin supplements was not essential for health if you ate a healthy diet. A healthy diet consists of lots of whole grains, fresh fruit and vegetables, nuts, seeds, legumes, unprocessed oils, flesh, and dairy produce should contain an abundance of vitamins and minerals. However, many are lost in the modern processing procedures. Over farming on depleted soils, use of chemical fertilizers, growth hormones, pesticides, artificial ripening, extended storage, milling, heating, cooking, exposure to light and air all have a detrimental effect on vitamins and mineral content. Vitamins contained in fresh fruit and vegetables also deteriorate with time in storage before consumption. Nowadays, it is recommended that most adults take a daily multivitamin as a nutritional safety net. This allows for these variations in the nutrients of food.

To complicate things further there is the protein, carbohydrate, and fat balance in our diet—this is called the PCF ratio. The PCF ratio differs according to your age, height, and muscle mass. Tables 2 to 4 provide the accepted Macronutrient Distribution Ranges (AMDR) for each element's ratio for disease avoidance.

Proteins are broken down by your digestive system to amino acids that help keep your immune system healthy.

Table 2. AMDR protein requirements for each age group

Age	Female	Male
0-6 months	9.1	9.1
7 – 12 months	13.5	13.5
1 – 3 years	13	13
4 – 8 years	19	19
9 – 13 years	34	34
14 - 18 years	46	52
19 – 30 years	46	56
31 and over	46	56

Table 3. AMDR carbohydrate requirements for each age group

Age	Female	Male
0-6 months	60	60
1 – 3 years	130	130
8 and older	130	130

Proteins are also essential to the structure, function, and regulation of the body and help build muscle, which in turn, increases your metabolism. Protein can be found in beef, whole grains, and beans.

Carbohydrates are essential for energy. We tend to think of bread and sugar as being high in carbohydrates, but vegetables and fruit consist mainly of carbohydrates too, and after all, fruit and vegetables are our main source of vitamins and minerals that are so important for good health.

Fats are also known as lipids, and are substances that are insoluble in water. There are three main categories of lipids found in food: cholesterol, saturated fats, and unsaturated fats (poly and mono). All fats are high in calories, and should be eaten sparingly. Unsaturated fats stay liquid at room temperature. They are healthier than saturated fats that are known to increase cholesterol levels and clog arteries.

Mono-unsaturated fat is the healthiest type of fat, and includes olive oil, which remains stable at high temperature, and does not easily become saturated. Foods containing mono-unsaturated fats include almonds, avocado, Brazil nuts, and cashews. Mono-unsaturated fats are believed to lower cholesterol, and thus, your risk of heart disease. Poly-unsaturated fat includes vegetable oils, which provide essential fatty acids for a healthy skin, and for the development of body cells. Polyunsaturates that are rich in omega-3 such as flax oil, walnuts, or oily fish are considered healthy.

Saturated fats are found in whole milk, cheese, butter, lard, and hard margarine. Trans-fatty acid is also a saturated fat. Saturated fats remain solid at room temperature, and are bad for your heart arteries.

Table 4. AMDR fat requirements for each age group

Age	Female	Male
0-6 months	4.9	4.9
7 – 12 months	7.7	7.7
1 – 3 years	7.7	7.7
4 – 8 years	10.9	10.9
9 – 13 years	11	13.2
14 - 18 years	12.1	17.6
19 - 30 years	18.1	18.6
31 – 50 years	15.1	18.6
51 and over	15.1	18.6

Anyone who has ever been in a diet knows how tedious it is just to count the calories they are consuming. If you also had to ensure the PCF ratio was adhered to, and that you were getting the correct amount of 33 different vitamin and minerals—monitoring your diet would be a full-time job. The Balance Your Diet monitoring software described in this article does all that for you.

BALANCE YOUR DIET: DIET MONITORING SOFTWARE

The Balance Your Diet software application described in this article is for people who want to maintain the ultimate balanced diet for good general health, longevity, and well-being. Balance Your Diet allows you to add the food items consumed throughout your day. The information about the food items come from an adapted version of the USDA food database that contains over 6,000 food products, each having information on 33 different nutrients the product contains. The person using the software chooses the products they consume; these are added to the Food Product Description list, which is found under the date at the left hand side of the Main screen (see Figure 1). This makes it easier to select food consumed during the current day, as most people only eat from a few hundred different products.

Balance Your Diet also calculates the recommended daily allowances for the age and gender provided by the dieter, and displays these amounts in the rightmost column. This allows the dieter to know what to aim for.

Figure 2 shows the adapted USDA database from Balance Your Diet. The food is kept in their prospective categories, which are displayed as option buttons along the top. This makes products easier to find. There is also a search engine that will list all products from the whole database that contain the search word (see Figure 3).

Balance Your Diet is the ultimate diet tool, not just for weight maintenance, but for anyone who is concerned about whether or not their diet is healthy. By comparing the nutrients consumed with the recommended daily allowances of all the nutritional components that are essential for health, it can alert you to deficiencies in any vitamin or mineral. It also keeps track of your protein–carbohydrate–fat ratio for the particular diet you are following.

Figure 1. The RDA amounts for calories, main elements, and minerals that optimize your diet for health

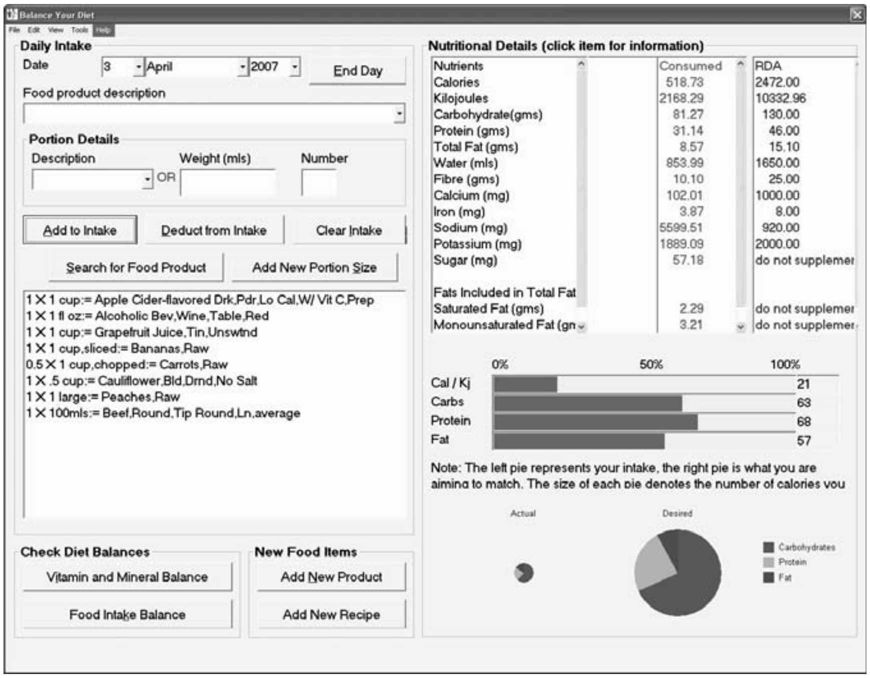

Figure 2. Adapted USDA database showing the food groups available and some of the products available when you choose dairy and egg products

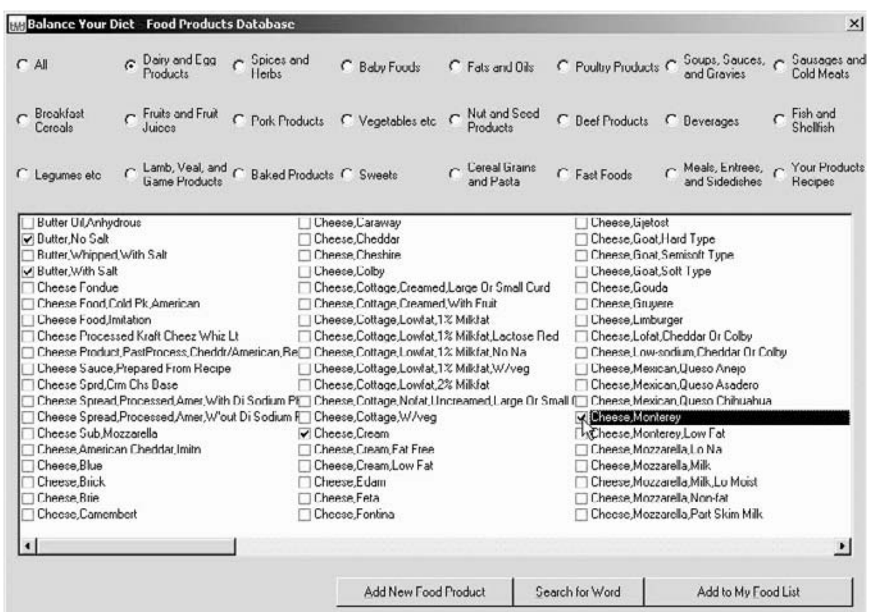

D

Figure 3. Searching for a word from a food product displays any product from the full database that contains that word

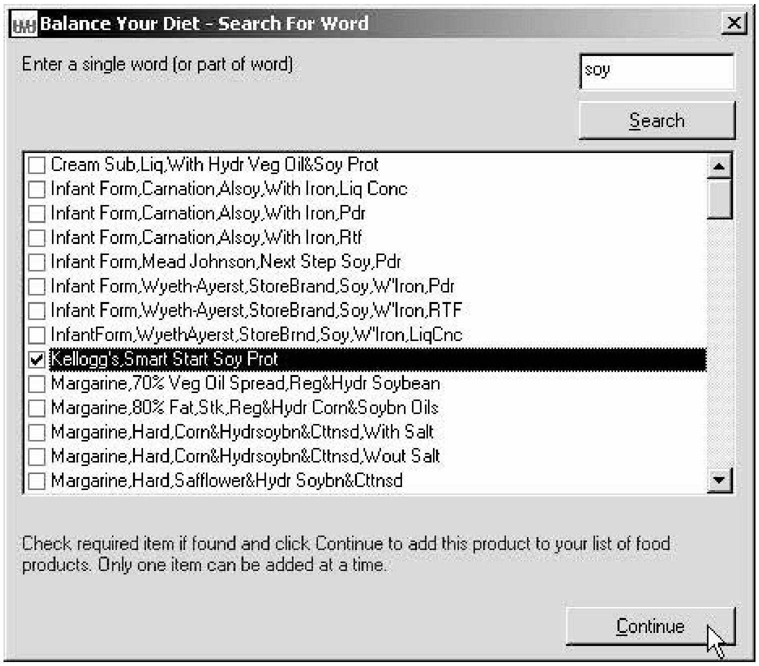

Figure 4. Selecting your frame type will display your ideal weight according to your personal details

Balance Your Diet will also calculate your BMI information. Table 5 shows the BMI figures color-coded from underweight to obese. The top table uses meters and kilograms, while the bottom table uses feet and pounds.

The tables show that there is a range of BMIs in each category. For instance, people with a height of 1.60 meters are in the ideal category, if their weight lies between 50 kilograms (BMI 19.5) and 60 kilograms (BMI 23.4).

Balance Your Diet adjusts the BMI further by taking a person's frame type into account. Entering a wrist or elbow measurement displays the appropriate frame type. If you know your frame type, you can select it from a drop-down box, and immediately, the dialog will be updated to display the ideal weight for your height and gender (see Figure 4).

Knowing your height, weight, and frame type Balance Your Diet can calculate your exact BMI and ideal weight range. Figure 5 shows the information displaying this information. The frame type can be calculated by entering your wrist or elbow measurement.

Balance Your Diet provides the number of calories required to maintain the current weight, based on the RDA. It also allows a goal weight to be entered, and

Pounds

Directions: Find your weight along the bottom of the chart, and move straight upwards until you come to the row that matches your height. Green marks ideal BMIs, while orange marks overweight, red obese, and yellow underweight.

the date the goal is to be achieved. It calculates the calories per day to achieve this, and the person can choose to work towards this by choosing to display the goal weight calories in the main screen. Figure 6 shows the Personal Details screen with both the RDA and the goal calorie numbers on display.

Balance Your Diet calculates the RDA vitamins and minerals required, according to personal details provided (see Figure 6). Figure 7 shows the vitamin and mineral intake over one day's consumption. The aim is to achieve a bar that is further than the first RDA area. The table shows the amounts actually consumed compared with the RDA recommendations. The last column gives the maximum safe levels to give the person reassurance that they are not going to come to any harm.

Figure 5. BMI information based on the personal information provided

Figure 9. Foods can be ordered according to a specific nutrient; this figure shows foods being ordered according to their levels of calcium

Figure 10. Pie charts showing the actual consumption compared with the desired consumption

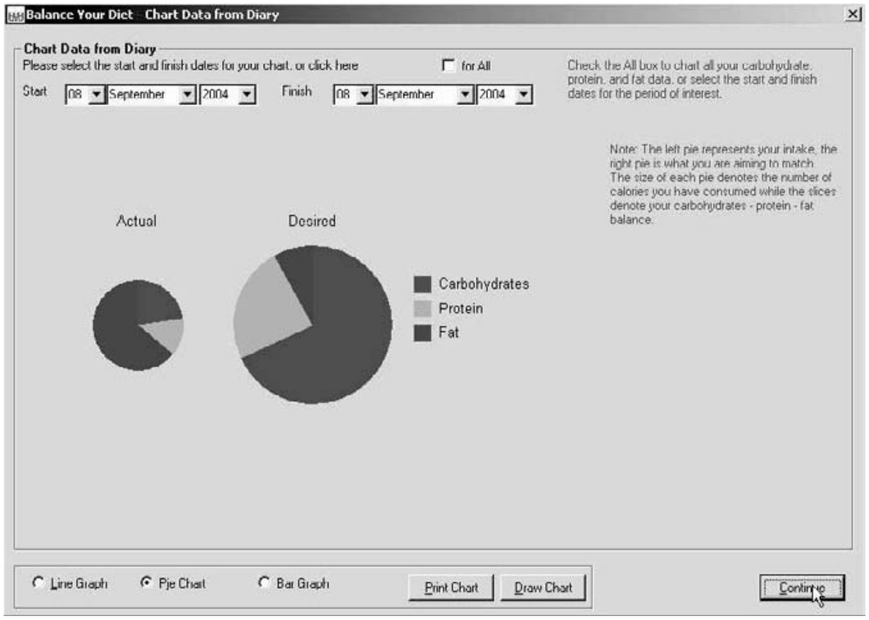

Table 6. Popular diets and their PCF ratios

Diet Name	Protein %	Carbohydrate %	Fat %
National Research Council US	15	55	30
California Diet	18	54	28
Pritiken Program	12.5	80	7.5
Atkins	46	13	15.1

Figure 8 shows the nutrients listed for four different food products. This allows you to pick the one that gets you the closest to your optimal diet.

If you are unsure what foods contain a particular nutrient, you can sort foods from the whole database in high-to-low or low-to-high order. Figure 9 shows foods containing calcium, ordered from high-to-low.

Figure 10 shows two pie charts. The pie on the left represents the food being consumed that day. The pie on the right is the desired result by the end of the day. The slices represent the three PCF ratios, and the size of the pie represents the calories consumed.

Different diets usually are variations of the PCF ratios. Table 6 gives four popular diets. It appears that if you reduce one of the components you lose weight. Whether or not it is safe to do so is another discussion.

FUTURE TRENDS

There is no quick solution to the obesity epidemic. Dieting appears to be something that most people rebound from, and end up bigger (and worse off) than they were when they started. How do you stop people from eating high calorie food when it is more convenient to serve up? How do you get people to walk when they have a car? How do you get people to climb stairs when there is an elevator? How do you get people to change their habits? How do you educate people about food?

People do not often react until they have some severe medical problem, but by then, it is too late. For example, if people are at a high risk of Type 2 diabetes, surely it makes sense to go on a sensible diet now, rather than wait for the inevitable. After the diagnosis, their diet is going to be restricted anyway, and they will be denied the odd binge. The message to obese people should be that prevention is better than cure.

Governments are looking at extra taxes on food manufacturers based on the amount of fat they are including in their products—a fat tax. They are also considering restricting advertisements aimed at children. But the supermarkets are still displaying candy and potato chips at the checkouts, nice and low so that little prying eyes cannot miss. These are also tempting for the adults who are stopped there, waiting to be served.

CONCLUSION

BYD Software is designed to help you achieve a balanced and healthy diet. Doing the research for this software package, we came to understand how complicated it is to fully understand what is healthy for you. Balance Your Diet allows you to:

- Count calories as part of your weight loss program
- Monitor vitamin and minerals in food products for conscious nutrition
- Monitor the PCF ratio in your diet

However, the first step in overcoming the obesity problem is to convince overweight and obese people that they need to go on a diet. The second step is to get them exercising. The third step (and the hardest) is to change their old habits, and keep them on the straight and narrow path to a healthier existence. It is all-too-easy to slip back into the sedentary lifestyle with the take-away food.

KEY TERMS

Body Mass Index (BMI): A measurement used to identify whether a person is overweight or obese.

Chronic Disease Risk: Likelihood of contracting a chronic disease, such as diabetes.

Diet: Total combination of food intake.

Minerals: Naturally occurring substance required by living organisms for a healthy diet.

Nutrition: A science to explain the metabolic and physiological responses of the body to diet.

Obesity: Excessively overweight.

Overweight: Above average weight.

PCF: Ratio of protein, carbohydrates, and fats.

Vitamins: An organic compound required by living organisms.

D

Distributed Medical Image and Volume Registration

Roger Tait
Nottingham Trent University, UK

Gerald Schaefer
Aston University, UK

INTRODUCTION

The ability to visualise hidden structures in detail using 3-D volume data has become a valuable resource in medical imaging applications (Maintz & Viergever, 1998). Importantly, the alignment of volumes enables the combination of different structural and functional information for diagnosis and planning purposes (Pluim, Maintz, & Viergever, 2003). Transform optimisation, resampling, and similarity calculation form the basic stages of a registration process (Zitova & Flusser, 2003): During transform optimisation, translation and rotation parameters which geometrically map points in the reference (fixed) image/volume to points in the sensed (moving) image/volume are estimated. Once estimated, pixel/voxel intensities which are mapped into nondiscrete coordinates are interpolated during the resampling stage. After resampling, a metric is used for similarity calculation in which the degree of likeness between corresponding volumes is evaluated (Tait & Schaefer, 2008). Optimisation of the similarity measure is the goal of the registration process and is achieved by seeking the best transform. All possible transform parameters therefore define the search space. Due to the iterative nature of registration algorithms, similarity calculation represents a considerable performance bottleneck which limits the speed of time critical clinical applications.

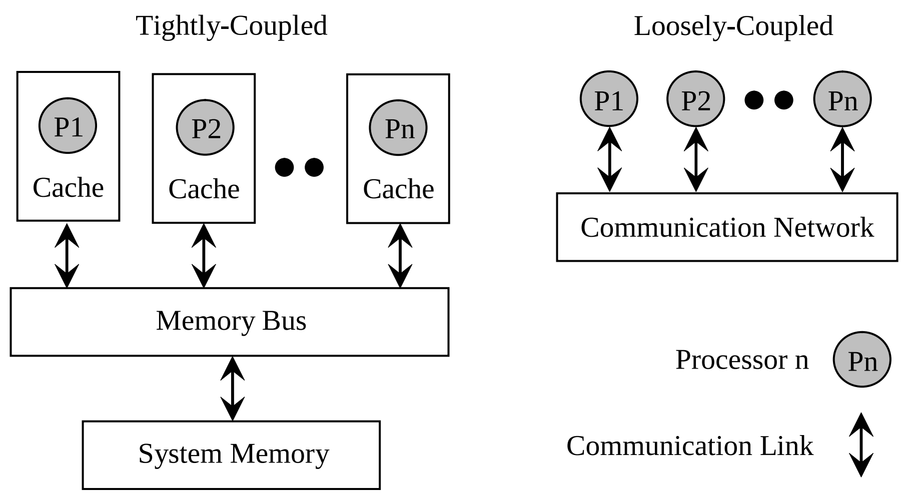
The use of parallel computing to overcome these time constraints has become an important research area (Nicolescu & Jonker, 2000). Conveniently, many of the similarity calculation strategies employed in medical registration are inherently parallel and therefore well suited to distribution. An important consideration when adopting a parallel processing approach is the architecture of the host system. In a computer constructed of multiple processors with shared-memory, data distribution is not required. These systems are viewed as tightly-coupled architectures. In contrast, a loosely-coupled architecture consists of multiple computers in different locations. Loosely-coupled architectures therefore require data distribution, communication, and accumulation mechanisms. Importantly, the most effective distribution scheme will depend on the architecture of the host system (Seinstra, Koelma, & Geusebroek, 2002). The two contrasting architectures of host systems are illustrated in Figure 1.

BACKGROUND

In the context of parallel processing, registration of medical data has been achieved by Warfield, Jolesz, and Kikinis (1998) who introduced a nonrigid algorithm based on the work-pile paradigm. Their goal was to develop an interpatient registration algorithm which can be applied without operator intervention to a database of several hundred scans. In an initial step, each scan is segmented using a statistical classification method. This preprocessing stage is used to identify different tissue types including skin, white matter, grey matter, and bone structure. Once segmented, a transform which brings these features into alignment is estimated. The system employs a message passing interface and cluster of symmetric multiprocessors to execute parallel similarity calculation operations using multiple threads. Crucially, work is dynamically load balanced. Results published by the group show that successful registration of 256 × 256 × 52 volume brain scans can been achieved in minutes rather than hours.

Christensen (1998) compares two nonthreaded architectures, Multiple Instruction Multiple Data (MIMD) and Single Instruction Multiple Data (SIMD). The work presented raises implementation issues and timing analysis for the registration of 32 × 32 × 25, 64 × 64 × 50 and 128 × 128 × 100 volume datasets. During

Figure 1. Tightly vs. loosely-coupled architectures. Data is either fetched from main memory via a memory bus, or is transferred over a communications network.



each clock cycle, the SIMD implementation performs calculations in which all processors are performing the same operation. The MIMD implementation, in contrast, breaks an algorithm into independent parts which are solved simultaneously by separate processors. The movement of data in both shared-memory systems is unrestricted and during execution each processor has access to the whole memory. The main performance bottleneck associated with both approaches was reported as scalability of hardware with increasing numbers of processors. Crucially, the MIMD implementation is recorded as being approximately four times faster than its SIMD counterpart. Reduced performance of the SIMD implementation is reportedly caused by overheads during serial portions of the registration algorithm.

More recently, the demands placed on registration algorithms when aligning deformable structures in 3-D space have been discussed. Salomon, Heitz, Perrin, and Armspach (2005) introduce deformable registration of volumes which involves optimisation of several thousand parameters and typically requires several hours processing on a standard workstation. Based on simulation of stochastic differential equations and using simulated annealing, a parallel approach that yields processing times compatible with clinical routines is presented. The approach represents a hierarchical displacement vector field which is estimated by means of an energy function. The energy function is scaled in relation to the similarly measure and is re-evaluated at the end of each transform parameter optimisation cycle. The algorithm is reportedly suited to massively parallel implementation and has been successfully applied to the registration of 256 × 256 × 256 volumes. Again, the results published demonstrate how alignment can be achieved in minutes rather than hours.

In the next section, a coarse-grained approach to parallelism is described which increases flexibility and allows the issues of fine-grained parallelism to be ignored. Building on a distributed blackboard architecture, the approach adopted supports multiple distributed agents organised in a worker/manager model. Crucially, the basic alignment steps are allocated to individual processors, the most computationally intensive of which are performed concurrently.

SIMILARITY CALCULATION USING A DISTRIBUTED BLACKBOARD ARCHITECTURE

Formally the inputs to a volume-based registration process can be defined as the fixed volume, the moving volume, and the transform used to map voxel coordinates. The goal of the registration process is recovery of a spatial mapping that brings the two volumes into alignment (Yoo, 2004). To achieve this, a metric is employed to generate a measure of similarity based on how well aligned the transformed moving volume is with the fixed volume. The measure of similarity produced forms a quantitative criterion which can be optimised in a search space defined by transform parameters (Penney, Weese, Little, Desmedt, Hill, & Hawkes, 1998). Importantly, by employing a gradient-descend optimisation technique the metric can be used to produce derivatives of the similarity measure with respect to each transform parameter. Using the resulting derivatives, updated transform parameters can be estimated and evaluated.

To parallelise the registration process, both fixed and moving volumes require division into segments and distribution. The similarities between corresponding volume segments can then be estimated concurrently. To achieve this, transform parameters are propagated to all processing nodes in the distributed processing network. On receiving transform parameters, each node computes derivatives of the similarity measure for the segments allocated to it. The local derivatives computed are then accumulated and summed into a global derivative. This allows the transform parameters to be updated based upon the similarity of complete volumes. Convergence testing is then performed using the newly updated transform parameters. Depending on the success or failure of convergence testing, propagation of updated transform parameters and hence evaluation of new parameters can occur.

The iDARBS Framework

Distributed Algorithmic and Rule-based Blackboard System (DARBS) is a distributed blackboard architecture based on a client/server model (Nolle, Wong, & Hopgood, 2001). In DARBS, the server functions as a blackboard and client modules as agents. In general, each agent represents a structure in which rules and algorithms can be embodied. Imaging DARBS (iDARBS), an underlying framework (Tait, Schaefer, & Hopgood, 2006a) on which registration algorithms can be hosted (Tait, Schaefer, & Hopgood, 2006b), consists of Distributor, Worker, and Manager Agent types:

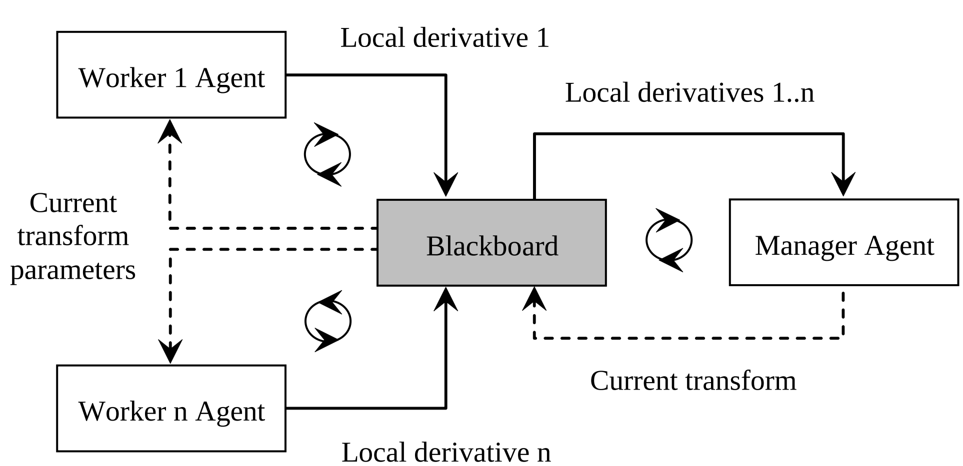
- The Distributor Agent splits selected volumes into segments which are placed on the blackboard.
- Worker Agents take segments from the blackboard and perform local processing.
- The Manager Agent supervises Worker Agent activities.

The accumulation of local derivatives by the Manager Agent and the propagation of updated transform parameters to Worker Agents are illustrated in Figure 2.

Initialisation of the Alignment Process

The Distributor Agent places predefined parameters associated with the optimisation process on the black-

Figure 2. The flow of local derivatives and current transform parameters between framework components



board. The parameters include an initial step length, a minimum step length, and the maximum number of iterations to be performed. Logically, the initial step length is used to initialise the optimisation process. Convergence of optimisation and hence the selection of final transform parameters is controlled by the minimum step length.

To start the alignment process, the Distributor Agent calculates an initial centre of rotation and a translation. Employing both fixed and moving volumes, initial parameters are estimated using centres of mass computed from intensity levels. Once estimated, the fixed volume centre is set as the rotational centre of the initial transform. The translation component, in contrast, is set as the vector between the fixed and moving volume centres. To simplify calculation, no rotation is specified in the initial transform. Crucially, the use of centres of mass over geometrical volume centres results in a robust estimate of the initial transform.

Estimation of Local Derivatives

For similarity between segments to be calculated, the Worker *n* Agent employs a region of interest and current transform parameters retrieved from the blackboard. First, the region of interest is used to identify the fixed segment without borders. Then, for all voxel coordinates within the fixed segment, corresponding moving segment coordinates are computed using the current transform. If the transformation of fixed segment voxel coordinates results in a corresponding location that falls inside the moving segment, the number of valid voxels is incremented and a contribution to the local derivative is made. Otherwise the voxel is considered invalid and the next fixed segment voxel coordinates are processed. By evaluating all voxels, local derivatives of the similarity measure with respect to each transform parameter are generated.

The contribution to a local derivative represents a summation of intensities, from a moving segment gradient image, around the mapped voxel coordinates. Using a recursive Gaussian filter, a gradient image is created from the moving segment. The gradient image represents a vector field in which every vector points in the direction of its nearest edge, an edge being a rapid increase or decrease in neighbouring intensities. Each vector has a magnitude proportional to the second derivative of the intensity in the direction of the vector. Created once after retrieval of the moving segment, the gradient image is used for all iterations of the optimisation process.

Advancing the Transform Parameters

To update the current transform parameters, a gradient-descent optimisation scheme is employed to advance the current transform in the direction of the global derivative. If the direction of the global derivative changes abruptly, it is assumed that an optimum has been encountered and the step length is reduced by a half. Once the step length becomes smaller than the predefined minimum, the optimisation process is considered as having converged. This allows the precision of final transform parameters to be specified. If optimisation of the transform parameters fails to reach the desired precision, the maximum number of iterations is used to halt the optimisation process. Understandably, large numbers of iterations and long computational times result when the initial step length chosen is small. Large step lengths, in contrast, may result in the optimum transform parameters being missed.

EXPERIMENTAL TESTING

Efficiency tests are presented and demonstrate the performance increase of volume registration in nondistributed and distributed processing environments. To determine the accuracy of alignment between volumes, a normalised correlation similarity metric was selected for testing purposes. Timing of an experiment started when the Manager Agent propagates transform parameters to all Worker Agents. Timing stopped when the Manager Agent places the final transform parameters on the blackboard. A sequential algorithm, constructed of the same components, was used as a performance benchmark for comparison. The datasets used for testing, two MRI T1 volumes of an anatomically normal male head (Stark & Bradley, 1999), contain $180 \times 218 \times 180$ voxels with a known translation and rotation. The volume pair was registered three times and average processing times calculated.

Computed using all voxels, normalised correlation calculates the cross-correlation of the volumes to be registered. Once calculated, the cross-correlation is normalised by the square root of the autocorrelation of each volume. Suited to volumes of the same modality, appealing properties of the metric include the

D

Box 1.

$$\frac{\partial S}{\partial p} = -\frac{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}\left(F\left(x_{ij}\right)\frac{\partial M\left(T\left(x_{ij},p\right)\right)}{\partial p}\right)-b\sum_{j=1}^{Q_i}\left(M\left(T\left(x_{ij},p\right)\right)\frac{\partial M\left(T\left(x_{ij},p\right)\right)}{\partial p}\right)\right]}{a}$$

$$= -\frac{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}\left(F\left(x_{ij}\right)\frac{\partial M\left(T\left(x_{ij},p\right)\right)}{\partial p}\right)-b\sum_{j=1}^{Q_i}\left(M\left(T\left(x_{ij},p\right)\right)\frac{\partial M\left(y\right)}{\partial y}\bigg|_{y=T\left(x_{ij},p\right)}\frac{\partial T\left(x_{ij},p\right)}{\partial p}\right)\right]}{a}$$

production of a search space containing sharp peaks and well defined troughs. The accurate alignment of volumes results in values near one being produced by the metric. Misalignment, in contrast, produces values of less than one. The distributed normalised correlation measure of similarity *S(F,M,T)* is defined as:

$$S\left(F,M,T\right) = -1\frac{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}\left(F\left(x_{ij}\right)-M\left(T\left(x_{ij}\right)\right)\right)\right]}{\sqrt{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}F\left(x_{ij}\right)^2\sum_{j=1}^{Q_i}M\left(T\left(x_{ij}\right)\right)^2\right]}} \tag{1}$$

where *F* and *M* are fixed and moving segment intensity functions respectively, *T* is a spatial transform, and x_{ij} is the j^{th} voxel of segment *i* from the fixed volume. *R* is the number of segment a volume is divided into and Q_i is the number of valid voxels mapped between segments identified by *i*. The derivative of the distributed similarity metric with respect to transform parameter *p* is computed as shown in Box 1.

In keeping with the equation shown in Box 1:

$$a = \sqrt{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}F^2\left(x_{ij}\right)\sum_{j=1}^{Q_i}M^2\left(T\left(x_{ij},p\right)\right)\right]}$$

and

$$b = \frac{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}F\left(x_{ij}\right)M\left(T\left(x_{ij},p\right)\right)\right]}{\sum_{i=1}^{R}\left[\sum_{j=1}^{Q_i}M^2\left(T\left(x_{ij},p\right)\right)\right]}$$

where $M(T(x_{ij},p))$ represents a discrete input which has been interpolated using a B-spline interpolation scheme. $\partial T(x_{ij},p)/\partial p$ is the transform Jacobian which is used to estimate variations in the mapped voxel coordinates with respect to transform parameter *p*. Importantly, when a voxel location that maps outside of the moving segment is encountered, its contribution to the local derivative is discarded.

Figure 3 shows results, plotted as time against number of Worker Agents, obtained whilst performing volume registration with normalised correlation as a similarity metric. As can be seen, average processing time of registration was reduced from 68 minutes to approximately 10 minutes when 10 Worker Agents were employed. The distributed algorithm was observed to converge after 54 iterations with transform parameters which matched those computed by the sequential algorithm.

FUTURE TRENDS

Deformable registration is based on the assumption that an evenly spaced mesh of control points can be placed over fixed and moving volumes. A transform is then used to estimate the displacement necessary to map between corresponding control point locations. In order for registration to be performed, each control point plus underlying intensities are transformed and compared with their counterpart until an acceptable level of similarity is achieved. Such algorithms have recently emerged in distributed processing environments and are achieved by assigning subsets of control points to individual processing nodes. Conveniently, the use of free-form deformations permits the independent movement of control points and removes the need for processor-to-processor communications (Loeckx, Maes, Vandermeulen, & Suetens, 2004). Crucially, the resulting implementations are designed to address the computational burden associated with the estimation of transform parameters for locally deformed volumes.

CONCLUSION

Registration is an important step in medical analysis tasks where information is extracted from a combination of sources. Traditionally, volume registration algorithms have been implemented using single processor architectures which are limited by memory and speed constraints. Such limitations have a negative impact in clinical applications where real-time processing allows physicians to monitor the progress of treatment while a patient is present. Importantly, the most successful registration algorithms employ intensity-based correlation as a measure of similarity (Maintz & Viergever, 1998; Zitova & Flusser, 2003). Although a variety of similarity metrics have been developed, in practice they represent a considerable computational burden during the alignment process. The main reason for this is the high cost associated with multiple evaluations of a complex transform and the interpolation of non-discrete intensity coordinates. The surveyed literature makes clear that concurrent similarity calculation can be achieved and provides better performance than non-parallel approaches (Christensen, 1998; Salomon et al., 2005; Warfield et al., 1998). The large speedups reported are, however, difficult to obtain and only specialised hardware is capable of maintaining such efficiencies when scaled. As a consequence, the applications developed to address the problem of slow volume registration speeds are restricted to high-cost specialised architectures found predominantly in the research environment.

While various approaches to distribution have been employed, it is fine-grained parallelism that achieves the best results (Hastings, Kurc, Langella, Catalyurek, Pan, & Saltz, 2003; Ourselin, Stefanescu, & Pennec, 2002; Rohlfing & Maurer, 2003). These methods are based on the low level decomposition of an algorithm within a tightly-coupled architecture. Understandably, such algorithms are difficult to implement and minimise computational expense by eliminating the exchange of data between processors. In this article, a novel coarse-grained approach to high performance intensity-based volume registration has been presented. The approach adopted has been shown to significantly improve processing speed, clearly outperforming sequential versions of the same algorithm. By employing an intensity-based algorithm, the complicated segmentation of features fundamental to landmark-based registration methods have been avoided. As a consequence, the algorithm distributed does not require user intervention. Unlike other high performance volume registration applications, the decoupling of algorithm components allows transforms of any type to be incorporated. This explicit separation also permits different similarity calculation and transform parameter optimisation strategies to be employed with only minor modifications to the existing framework.

KEY TERMS

Blackboard Architecture: An artificial intelligence application based on and analogous to a group of experts seated in a room with a large blackboard working as a team to solve a common problem.

Coarse-Grained Parallelism: A term used to describe an algorithm that has been divided into high-level components, each of which can be hosted by a separate processor.

Distributed Agents: Software entities designed to execute as independent threads and on distributed processors, capable of acting autonomously in order to achieve a predefined task.

Fine-Grained Parallelism: A term used to describe an algorithm that has been divided into low-level components, each of which can be hosted by a separate processor.

Image Registration: The process whereby two images, differing by a spatial transformation, are brought into geometric alignment.

Parallel Processing: The concurrent execution of the same task, split into components, on multiple processors in order to achieve faster processing speeds.

Similarity Metric: A measure used to quantitatively judge how well a transformed sensed (moving) image fits a reference (fixed) image by comparing intensities.

Echocardiographic Image Sequence Compression Based On Spatial Active Appearance Model

Sándor Miklós Szilágyi

Zoltán Benyó
Budapest University of Technology and Economics, Hungary

INTRODUCTION

Echocardiography is a popular medical imaging modality due to its noninvasive and versatile behavior. There are no known side effects, and the measuring equipment is small and inexpensive relative to other options, such as MRI or CT. Reducing storage requirements and making data access user friendly are two important motivations for applying compression to ultrasound images, with the retention of diagnostic information being critical (Chiu, Vaisey, & Atkins, 2001).

A typical echocardiography image consists of a nonrectangular scanned area and a passive background, which may contain patient related text or limited graphics (e.g., a single channel ECG signal). The resulting spatial variation in image statistics presents a hard task to coding methods that use a single partition strategy. For example, many modern image compression algorithms, such as zero-tree coding (Shapiro, 1993) and set partitioning in hierarchical trees (SPIHT) (Said & Pearlman, 1996), are based on the wavelet transform, which partitions the input images into frequency bands whose size decreases logarithmically from high frequencies to low ones. This kind of decomposition strategy works well when the input images are statistically homogeneous, but not in the case of echocardiography image sequences.

Usually the medical applications do not tolerate much loss in fidelity, so the distortion free methods, such as context-based adaptive lossless image coding (CALIC) (Wu & Memon, 1997) have been recently adapted to "near-lossless" situations (Wu & Bao, 2000) with good results. Erickson, Manduca, Palisson, Persons, Earnest, and Savcenko (1998) have compared SPIHT and JPEG methods to compress magnetic resonance imaging (MRI) and ultrasound images. They concluded that wavelet-based methods are subjectively far superior to JPEG compressed at moderately high bit rates. Medical images are typically stored in databases, so it is possible for computers to extract patterns or semantic connections based on a large collection of annotated or classified images. Such automatically extracted patterns can improve the processing and classifying performance of the computers.

In the recent past, researchers in the image analysis community have successfully used statistical modeling techniques to segment, classify, annotate and compress images. Particularly, variations of hidden Markov models (HMMs) have been developed and successfully applied for image and video processing. The key issue in using such complex models is the estimation of system parameters, which is usually a computationally expensive task. In practice, often a tradeoff is accepted between estimation accuracy and running time of the parameter estimation method (Joshi, Li, & Wang, 2006).

Such a statistical information-based estimation highly depends on biological parameters. In our case, the most important task in efficient echocardiography image compression is the accurate detection of QRS complexes from the simultaneously measured ECG signal. Due to the quasiperiodic behavior of the ECG signal and echocardiography image sequences, the parameters of the patient model can be more precisely estimated.

Active appearance models (AAM), introduced by Cootes, Edwards, and Taylor (2001), are promising image segmentation tools that may provide solutions to most pending problems of echocardiography, as they rely on both shape and appearance (intensity and/or texture) information. Bosch et al. (2002) proposed a robust and time-continuous delineation of 2-D endocardial contours along a full cardiac cycle, using an extended AAM, trained on phase-normalized four-chamber sequences.

To understand the physiology and patho-physiology of the heart, not only the electrical activity and spatial distribution of its structures is important, but also their movement during normal and abnormal cardiac cycles. The ECG signal is measured simultaneously with echocardiography sequence recording in order to localize the investigated events (Szilágyi, Szilágyi, & Benyó, 2007b).

Several papers in the literature have already reported the usage of spatial AAM (Mitchell, Bosch, Lelieveldt, van der Geest, Reiber, & Sonka, 2002; Stegmann & Pedersen, 2005). The present work has the following contributions:

- We developed a heart reconstruction algorithm including time dependent wall boundaries in order to estimate the image variances that allow a better compression rate at a fixed image quality than conventional methods.
- Reported techniques classify ultrasound images only as belonging to systolic or diastolic interval. Our approach distinguishes normal and extra beats, and processes the corresponding images accordingly.

MATERIALS AND METHODS

Simultaneous echocardiography sequence recording and ECG signal measurement were carried out using a 2-D echocardiograph that produces 30 frames per second, and a 12-lead ECG monitoring system that samples at 500 Hz frequency and 12-bit resolution. Each image frame received a time stamp, which served for synchronization with ECG events. Two different series of measurements were recorded. The first series, which served for AAM training, consisted of 35 patients (12 of whom having extraventricular beats), 20 ultrasound sequences for each patient, of 10-15 seconds length each sequence, with previously established transducer placements. Based on these data, an a priori information database was created, which organized the ultrasound images grouped by corresponding ECG events.

The second series of measurements, which involved eight patients, consisted of two stages. In the first stage, the same measurements were performed as were performed in the first series, in order to provide patient-specific training data for the AAM. In the second stage, several measurements were performed using different placements and positions of the transducer. In this order, image sequences were recorded at eight parallel cross sections in horizontal and rotated (45° to the left and to the right) positions with a 1 cm inter-slice distance. We used 10 common axis planes that were placed at front, lateral and back side of the torso. For each patient a total number of $10 \times 8 \times 3 = 240$, at least 2-3 second long image sequences were created.

The duration of the recorded image sequences was restricted by the quasiperiodic behavior of the ECG signal. The spatial movement of the heart is constrained by the course of the depolarization-repolarization cycle (Szilágyi, Szilágyi, & Benyó, 2007a). For example, normal and ectopic beats imply different spatial heart movements. The studied ECG parameters were: shape of QRS beat, QT, and RR distances. These parameters characterize the nature of a QRS complex, and were determined as presented in Szilágyi et al. (2007a). ECG event clustering was accomplished using Hermite functions and self-organizing maps (Lagerholm, Peterson, Braccini, Edenbrandt, & Sörnmo, 2000). Two main event clusters were created: normal and ventricular extra beats. This latter group, because of the patient specific manifestation of ventricular extras, had to be dealt with separately patient by patient. QRS beats not belonging to any cluster were excluded from further processing, together with their corresponding ultrasound sub-sequences. A further condition for normal QRS complexes to be included was having RR distance between 700-800 ms and QT distance between 350-400 ms. A detailed presentation of ECG processing is presented in section (a) in Figure 1 (Szilágyi et al. 2007a).

The time-varying evolution of the cardiac volume is determined by the interconnection of electrical and mechanical phenomena. In a whole cardiac cycle there are two extremity values. The maximal volume can be coupled with the starting moment of ventricular contraction. The moment of minimal volume shortly precedes the termination of ventricular contraction, but is much more difficult to identify, due to the dead time of a normal cardiac cell. This delay is caused by the property of a regular cardiac cell, whose electric response precedes with 60-80 ms the mechanical contraction (Winslow, Hinch, & Greenstein, 2005). The combination of the electrical and mechanical properties of the heart and the usage of knowledge-base allowed us to create a performance evaluation module that determines the most probable wall position, as shown in section (b) of Figure 1.

Figure 1, section (b) presents an overview of the image processing and volumetric reconstruction procedure. The first algorithmic step is noise elimination. Speckle noise represents a major difficulty to most ultrasound imaging applications (Evans & Nixon, 1996). In our case, the suppression of such phenomena was accomplished using the well-known motion adaptive spatial technique presented in Szilágyi et al. (2007b). Due to the measuring technique of traditional echocardiography, the obtained images are distorted. In order to become suitable input for 3-D processing, they need to go through a normalization transform. Every recorded ultrasound slice is represented by a plane whose spatial alignment depends on the position and rotational angle of the transducer. The normalization process also takes into consideration the distance of each image pixel from the transducer.

The training data of the AAM is constructed based on the spatial position of each echocardiography slice recorded in the first measurement series. By averaging these spatial distributions, a mean base 4-D heart shape model is obtained, which will be the starting point of the AAM (Bosch et. al., 2002; Lelieveldt, van der Geest, Mitchell, Bosch, Sonka & Reiber, 2002). Landmark points are determined using the technique proposed by Mitchell et al. (2002). The sparse character of the obtained spatial description model doesn't allow the landmark points have 3-D texture information. That is why we restricted the texture to 2-D.

Subjects have their own specific, time dependent inner structure, which cannot be approximated properly

Figure 1. (a) Schematic representation of the ECG signal filtering, processing and compression, (b) Schematic representation of the data recording and analyzing procedure. All echocardiography and ECG data go through the same processing module. The AAM is constructed from the measurements of series 1, and fine tuned afterward using the patient specific data resulting from series 2 stage 1. Stage 2 data serve for the detailed cardiac volumetric analysis. Reconstructed 3-D objects are finally aligned using an iterative LMS-based algorithm.

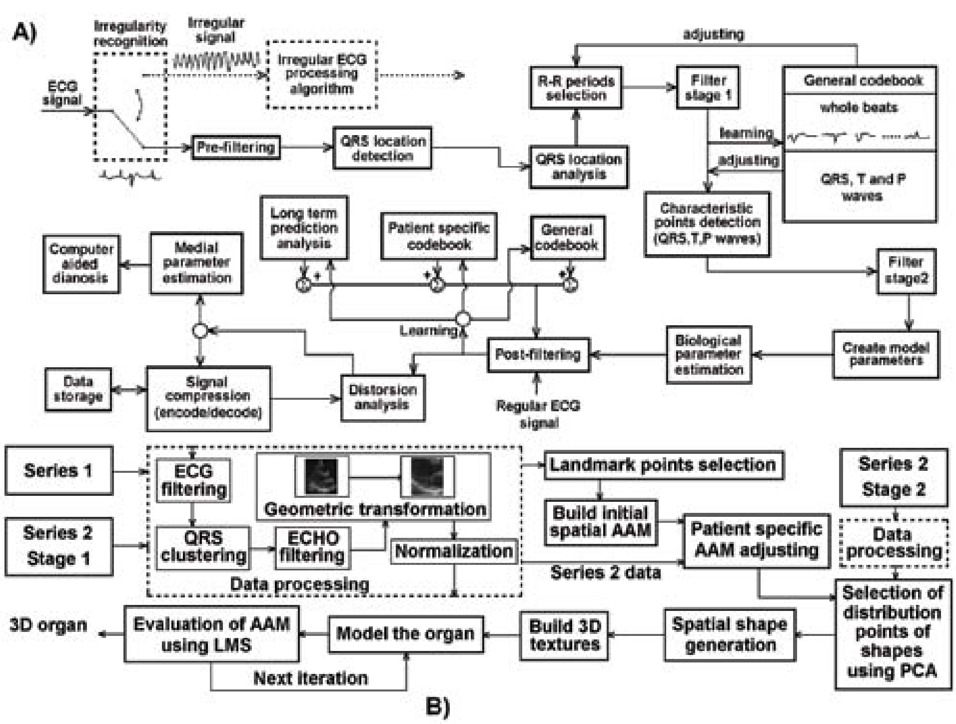

Figure 2. Separation of an echocardiographic scene into: (a) nonrectangular echocardiographic image area, (b) one lead of ECG signal, (c) static text and graphic labels, and (d) variable text. In section (a) is presented the origin point, the distance r from origin and the angle θ. The origin's coordinate is deductible from positions of bottom left-right and top left-right points. (e) Schematic representation of residual data construction and distortion analysis. The residual signal calculation process uses the recorded image, heart beat phase information and AAM-based 4D organ shape to determine the most probable image in the next measuring moment. As the y(n+1) output signal is obtained, a WDD and PRD-based distorsion analysis is realized, where the image features are determined from AAM.

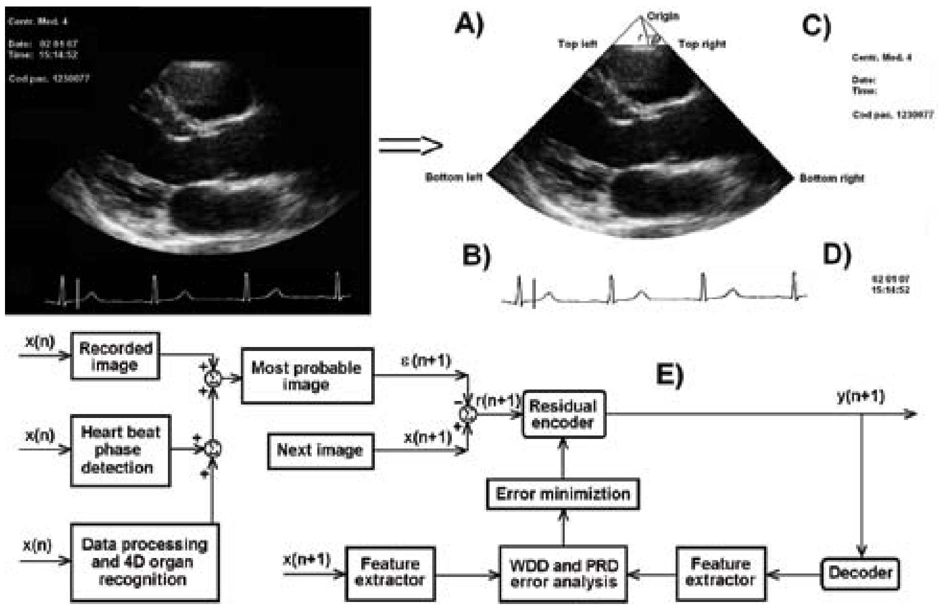

from a population of few dozens of individuals. In order to make further adjustments to the AAM, the base structure was adjusted to the patient using the measurements made in the second series, first stage. The landmark points determined on the images recorded during the second stage of the second measurement series allow us to create a 3-D distribution point model, which was established according to (Mitchell, 2002). Having the distribution points established, the AAM will be enabled to adjust itself to a diversity of biological factors like the phase of ECG and breathing. A detailed description of the manifestation of these phenomena and the model adaptation is given in (Stegmann & Pedersen, 2005). Our algorithm acts similarly, but it treats the cardiac cycle differently: not only systolic and diastolic phases are distinguished, but also a QRS complex clustering is performed to give different treatment to normal and ventricular cardiac cycles.

Spatial texture maps are determined via averaging (Stegmann & Pedersen, 2005). The visual aspect of the heart and its environment, because of their mutual motion, is changing in time. AAM models only include information on the texture situated within the model. The time dependent representation of the ultrasound slices obtained from the large stack of sequences enabled us to accurately determine the 4-D structure of the heart (Mitchell, 2002). The iterative algorithm of the AAM demands the comparison of measured and expected shapes. The AAM was adjusted using a quadratic cost function, until the desired accuracy was obtained.

Due to its adaptive behavior, the compression method is able to handle patient-dependent data, and has a capability to efficiently separate the measured artifacts from the useful signal.

The proposed signal compression algorithm can be divided into the following steps:

- Intelligent image sequence analysis and filtering (that involves the automatic recognition of echocardiography image, ECG signal, and various changing and constant labels and letters that appear on the recorded image sequence);

- Background selection (the constantly dark region);
- ECG signal processing (see section (a) of Figure 1);
- Segmentation of echocardiographic image (see section (b) of Figure 1);
- Calculation of the heart's 4D shape (3D+time) using AAM;
- Estimation of probable image;
- Residual signal estimation, entropy coding (encode and decode), and back-estimation.

The compression evaluation was implemented in two ways, using percentage root mean square difference (PRD) and weighted diagnostic distortion (WDD) (Zigel, Cohen, & Katz, 2000). WDD measures the relative preservation of the diagnostic information (such as location, duration, intensity, shapes, edges) in the reconstructed image. These diagnostic features were determined by physicians. The distortion estimation and signal (ultrasound image and all auxiliary data) coding process is presented in Figure 2e.

As sections (a) through (d) of Figure 2 present, it is possible to separate logically the various image regions and in function of its behavior apply a separate compression scheme.

RESULTS

Section (a) of Figure 3 presents two series of ultrasound slices indicating the contour of the left ventricle of the second patient, detected during a ventricular contraction. The two rows of slices show two different angle views, having a 60° angle difference. The four slices in each row represent subsequent images of the sequence, showing the approximately 100 ms duration of the ventricular contraction. Section (b) of Figure 3 shows two different reconstructed 3-D shapes of the left ventricle.

Figure 4 presents the decoded and feature-base corrected echocardiographic images at various compression rates. The variation of RMSE level against inverted compression rate is shown in section (e) of Figure 4. The RMSE graph was created for a normal QRS beat shape and average RR and QT distances. We can observe a pronounced performance advantage of the method for normal beats due to its higher incidence.

DISCUSSION

The recognition of the relation between echocardiography images and simultaneously recorded ECG signal is a key element in efficient image sequence compression (see Table 1). However, various events like aspiration and expiration may influence the measured data. During a whole cardiac cycle, the shape and volume of the left ventricle changes considerably. It is difficult to determine the performance of the reconstruction method for the sporadically occurred ventricular extra-systolic beats. Even for patients that produce at least five extra beats with similar shapes in each minute the reconstruction performance remains well below the normal QRS cluster's accuracy, due to the sparse distribution of the processable slices.

Figure 3. Results of shape reconstruction: (a) Time varying 2 D contour of the left ventricle, (b) reconstructed 3-D structure of the left ventricle

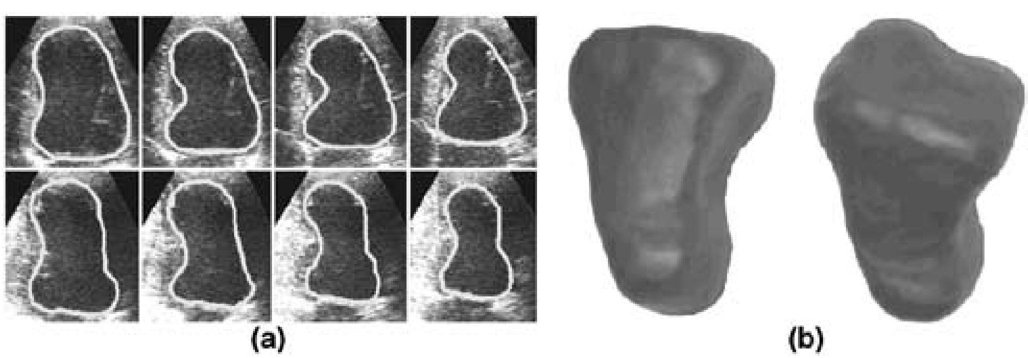

Figure 4. Results of image reconstruction: (a) Original image, (b) decoded image at 1/22 compression rate, (c) decoded image at 1/39 compression rate, (d) decoded image at 1/54 compression rate, (e) representation of root mean square error (RMSE) in function of inverted compression rate, (f) feature-base corrected image, b, (g) feature-base corrected image, c, (h) feature-base corrected image, d

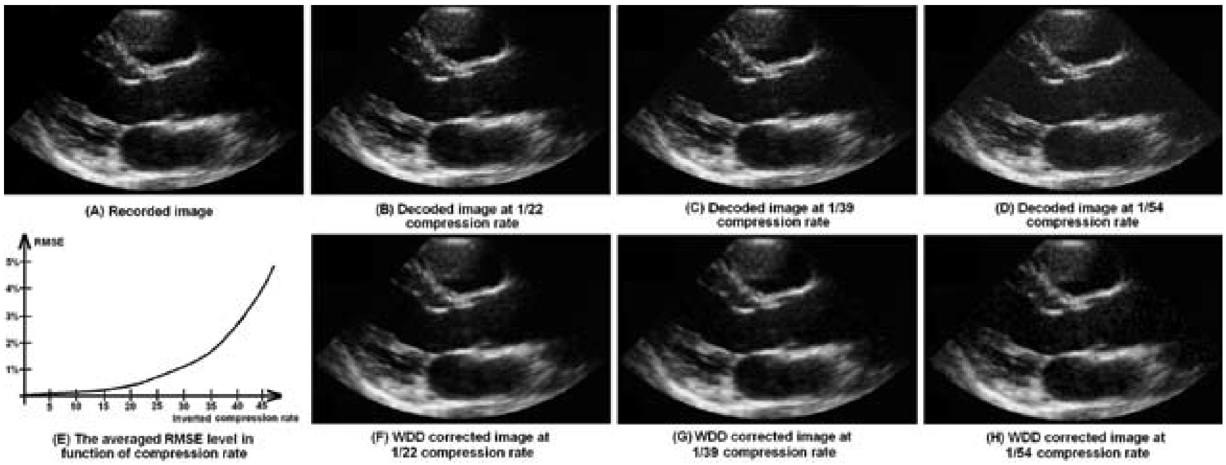

From image 4 we can observe that even a well-working WDD correction method cannot handle a compression rate better than 1/60 without a serious image distortion that can lead to wrong medical diagnosis. Table 1 demonstrates the higher perfomance of the image compression method, that exist due to the advanced QRS beat analysis and spatial AAM-based organ reconstruction. Such an analysis can lead to a much better *estimated image* quality that reduces the amplitude of the residual signal.

CONCLUSION

The investigation of simultaneously recorded ECG and echocardiography images enables us to study the relations between the electrical and mechanical phenomena concerning the heart. The compression method presented in this article performs well in case of normal and almost as well for ventricular beats. This kind of approach to the problem may result in deeper understanding of electrical and mechanical properties of the heart that enable a much more efficient compression than the results obtained from algorithms using less a priori information.

KEY TERMS

Active Appearance Model (AAM): A computer vision algorithm for matching a statistical model of object shape and appearance to a new image.

ECG Analysis: A collection of ECG signal processing methods aiming at the determination of medical parameters.

Echocardiogram: Image of the heart created with ultrasound imaging technology.

Hidden Markov Model (HMM): Astatistical model in which the system being modeled is assumed to be a Markov process with unknown parameters, and the challenge is to determine the hidden parameters from the observable parameters.

Image Compression: Compression of the data contained by an images. The objective is to reduce the image's redundancy, which assures an efficient storage or transmission of the recorded data.

QRS Complex: A structure on the ECG signal that corresponds to the depolarization of the ventricles.

Weighted Diagnostic Distortion: A weighted measurement of signal distortion in term of changes of medical parameters.

Electrical Bioimpedance Cerebral Monitoring

Fernando Seoane
University College of Borås, Sweden

Kaj Lindecrantz
University College of Borås, Sweden

INTRODUCTION

Electrical Bioimpedance (EBI) is now a mature technology in medicine, with applications in clinical investigations, physiological research, and medical diagnosis (Schwan, 1999). The first monitoring application of bioimpedance techniques, *impedance cardiography*, date back to 1940. Since then, bioimpedance measurements have been used in several medical applications, from lung function monitoring and body composition, to skin cancer detection. A complete historical review is available in Malmivuo and Plonsey (1995). A medical imaging modality based on bioimpedance, *Electrical Impedance Tomography* (EIT) has also been developed (Bayford, 2006).

EBI has been used to study the effect in the brain of spreading depression, seizure activity, asphyxia and cardiac arrest since 1950s and 1960s (Ochs & Van Harreveld, 1956), but the most important activities in electrical cerebral bioimpedance research has been during the last 20 years (Holder, 1987; Holder & Gardner-Medwin, 1988). Examples of areas of study are *brain ischemia*, *spreading depression*, *epilepsy*, *brain function monitoring*, *perinatal asphyxia*, *monitoring of blood flow, and stroke*.

BACKGROUND

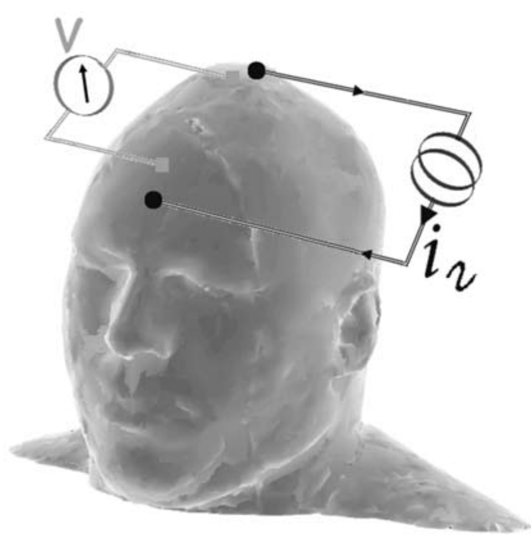
The basic functional units of an EBI measurement system for cerebral monitoring are the following: an electric current generator, a voltage meter, the surface electrodes for current injection and voltage pick up as well as the connecting electrical leads. The injected current causes a voltage drop in the tissue that is sensed and the measured bioimpedance is calculated from the resulting quotient from voltage over current, know as Ohm's Law. See Figure 1 and Equation 1.

$$Z(\omega) = \frac{V(\omega)}{I(\omega)} \quad (1)$$

An important feature of the application of EBI for cerebral monitoring is that it is applicable in some of the situations where brain is particularly at risk as well as for long-term monitoring situations where available imaging techniques: *MRI, CT-scan* are not suitable (*e.g., during an ongoing cardiopulmonary by-pass operation, in intensive care, for acute stroke assessment in ambulances*).

Other features of bioimpedance technology are that it is harmless for the patient, portable and very affordable in comparison with other monitoring techniques already in used. These specific features place EBI as the technology of choice to fill the need for brain monitoring in the medical scenarios mentioned above and several others.

Figure 1. Functional diagram of a measurement system for electrical bioimpedance cerebral monitoring



Electrical Properties of Biomaterials and Bioimpedance

Biological material, tissue, and cells have electrical properties (conductivity *σ* and permittivity *ε*) that allow electrical current to flow in the presence of an electric field (Cole, 1968). These electrical properties depend of the constitutive elements and structure of tissue; therefore, changes in structure or biochemical composition modify the electrical properties, *σ* and *ε,* of the tissue, and consequently the electrical impedance changes.

Every type of tissue and body fluids in the human body exhibits specific values of conductivity and permittivity that are frequency dependent. Therefore, each tissue can be characterized by its particular electrical impedance spectrum, and measurements of electrical impedance can be used to differentiate between tissues or to assess the state of the tissue. The most complete compilation of the dielectric properties of biological tissues is found in (Gabriel, 1996).

Electrical Impedance Tomography

EIT exploits the fact that the electrical properties differ between tissue types to create an image representing the conductivity distribution of a volume conductor. Despite its name, EIT does not reconstruct and object slice by slice, because electrical current cannot be confine in to a plane; instead, the current will flow through the whole volume conductor following the gradient of the electrical field.

As several conductivity distributions may provide the same voltage boundary detected by the sensing electrodes, reconstruction of the impedance image requires that some assumptions are made, and also that a model is used for fitting the voltage boundary data.

There are two methods for EIT imaging: absolute and difference imaging. The first one, also known as static method, obtains a conductivity image from a set of impedance measurements. The difference imaging method uses a set of two measurements taken at two different times to create a conductivity image of the differences. This method is used for dynamic studies, for monitoring changes in the tissue.

EIT imaging exhibits a poor spatial resolution as compared to other imaging techniques but the time resolution, in the order of microseconds, is unique for EIT. Affordable, portable, and noninvasive are other exclusive features to EIT within brain imaging monitoring. For a deep understanding of EIT, see a recent review (Bayford, 2006).

Electrical Impedance Spectroscopy Analysis

One straight-forward effect of the frequency dependency of electrical properties of tissue is the effect of the cellular membrane. Figure 2 shows the influence of the frequency on the current path lines. The capacitive effect of the membrane contributes to the electrical properties of tissue and depends of many factors: the number of cells, the size of the cells, the thickness of the cell membranes, type of cells, and so on.

Because the plasma membranes of the tissue cells act as a capacitive element, most of a direct current (DC) in biological tissue, flows through the extracellular space (*e.g., interstitial fluid, plasma, and so on*). Hence, the impedance at DC is mainly determined by the conductivity of the extracellular fluid, the available surface to the electrical field for the charges to flow through, and the length of the propagation path. See Figure 2 and Equation 2. At higher frequencies the capacitive effect shunts the electrical current, allowing the electrical current to propagate also via the intracellular space and the tissue conductivity can be modelled as in Equation 3.

$$\boldsymbol{g}_{DC} = \sigma_e \frac{2(1-\boldsymbol{f})}{(2+\boldsymbol{f})} \qquad (2)$$

$$\boldsymbol{g} = \sigma_e \frac{2(1-\boldsymbol{f})\,\sigma_e + (1+2\boldsymbol{f})\left(\dfrac{\sigma_i\,(\sigma_m + i\omega \boldsymbol{C}_m)a}{\sigma_i + (\sigma_m + i\omega \boldsymbol{C}_m)a}\right)}{(2+\boldsymbol{f})\,\sigma_e + (1-\boldsymbol{f})\left(\dfrac{\sigma_i\,(\sigma_m + i\omega \boldsymbol{C}_m)a}{\sigma_i + (\sigma_m + i\omega \boldsymbol{C}_m)a}\right)} \qquad (3)$$

Equations legend: $\boldsymbol{g}$ is the complex conductivity of tissue, $\boldsymbol{\sigma}_e$ is conductivity of the extracellular fluid, S×m^{-1}, $\boldsymbol{\sigma}_i$ is conductivity of the intracellular fluid S×m^{-1}, $\boldsymbol{\sigma}_m$ is the membrane conductivity, S×m^{-1}, $\boldsymbol{c}_m$ is the surface membrane capacity, Farads×m^{-2}, ω is the angular frequency, radians×s^{-1}, $\boldsymbol{i}$ is the imaginary number √-1, $\boldsymbol{a}$ is the cell radius and $\boldsymbol{f}$ is the volume fraction of concentration of cells.

N.B. the expression for $\boldsymbol{g}_{DC}$ corresponds to the general expression for $\boldsymbol{g}$ when ω = 0 and $\boldsymbol{\sigma}_m$ is approximate to 0.

Notice in Equation 3 that the conductance of tissue depends not only on the dielectric properties of the constituents but its morphology and frequency. For this reason, each tissue has specific electrical properties and consequently presents a specific impedance spectrum. This fact allows the differentiation between tissues and assessment of health state by spectrum analysis of the tissue impedance. This is the principle behind several impedance-based medical applications (*e.g.*, *skin cancer screening* (Aberg, Nicander, Hansson, Geladi, Holmgren, & Ollmar, 2004), and *breast cancer assessment* (Assenheimer & Laver-Moskovitz, 2001)).

Potential Applications

There are several areas of neurology that may benefit from the application of EBI technology as a means to obtain useful indicators about the undergoing activity of brain threatening mechanism.

Brain Monitoring during Cardiac Surgery

The high vulnerability of brain tissue to hypoxia (Acker & Acker, 2004) together with the ability of impedance measurements to detect hypoxic cell swelling (Seoane, Lindecrantz, Olsson, Kjellmer, Flisberg, & Bågenholm, 2005) place EBI technology as a candidate method for early detection of hypoxic brain damage during cardiac surgery.

Perinatal Asphyxia

It has been proven (Seoane et al., 2005) that the cell swelling associated with hypoxic-ischemic injury can be sensed and measured via EBI.

Brain Function and Epilepsy

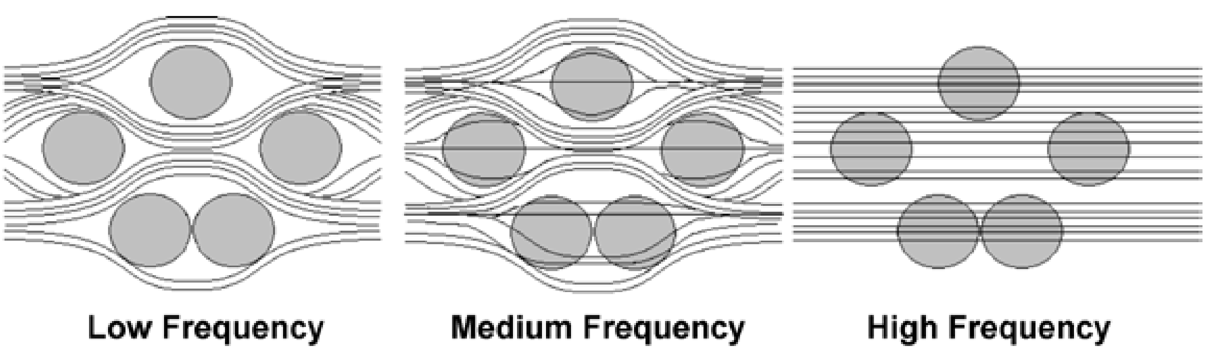
The electrical properties of the cell membranes are nonlinear (Hodgkin, 1947) and during neural depolarization the opening of the voltage-sensitive ion channels modify the membrane impedance (Holder, 1992).

The principle behind detection of epilepsy using EBI measurements relies on the fact that the impedance of an epileptic region will be appreciably different of the rest of the brain because of the large electrical activity associate to the epileptic seizure, accompanied by local cell swelling and ischemia (Olsson & Broberg, 2006).

Stroke

There are two kinds of stroke, ischemic stroke, and haemorrhagic stroke. Both result in alterations in the composition and the structure of the affected area. In the case of ischemic stroke the blood flow to an area of the brain is interrupted and consequently there is a lack of blood and oxygen that results in ischemic cell swelling. In the case of haemorrhagic stroke, the rupture of blood vessels allows the leaking of blood from the cerebrovascular system to accumulate in the intercellular space causing a haematoma. These two different sequences of pathophysiological events alter the electrical properties of the affected area and the alteration can be detected by means of noninvasive electrical impedance measurements (Liu & Dong, 2006).

Figure 2. The effect of the cell membrane capacitance in the current path lines



Cerebral Blood Flow Monitoring

Autoregulation of cerebral blood blow is a protective mechanism that stabilises cerebral perfusion during changes in blood pressure, often induced as a consequence of intracranial hypertension or cerebral ischemia. The use of intracranial measurements of EBI can detect cerebral blood blow autoregulation (Bodo, Pearce, Baranyi, & Armonda, 2005), suggesting that rheoencephalography could be developed into a non-invasive method for early detection of brain injury.

CURRENT RESEARCH ISSUES IN ELECTRICAL BIOIMPEDANCE CEREBRAL MONITORING

Electrical bioimpedance technology provides useful features for cerebral continuous monitoring and encouraging results have been seen in various clinical applications. However, there are still many issues to be addressed before the technology is developed into a clinical tool for cerebral monitoring.

Biophysical Understanding

Generally, there is a lack of understanding about the relationship between the underlying pathophysiological mechanisms associated to a particular insult (*e.g., cell swelling, intracranial haemorrhage, and so on*), and the influence on the electrical properties of tissue. The knowledge about impedance dynamics and the injury or adaptation mechanisms is still coarse. The ultimate effect of the damaging insult on the electrical properties of the tissue is relatively well-known, and the fundamental hypotheses are supported by experimental results. However, the effect on the electrical properties of the tissue constituents, of the biochemical and histological processes active during the corresponding adaptation or injury mechanism is, in most cases, completely unknown.

Impedance Data for Tissue Spectra Characterization

The specific electrical properties of each biological tissue confer an impedance spectrum virtually unique to each particular tissue. Available biological dielectric data is compiled and available in (Gabriel, 1996). As the origin of the data is mostly excised animal samples and human corps, the values of these data are not necessarily representative for in vivo tissue.

A proper spectral characterization of healthy tissue will empower the identification and classification applications based in EBI spectroscopy. It is essential to have spectral information of healthy tissue, as well as enough spectral data to fully characterize the impedance spectra of the injured tissue.

Current Density Distribution in the Head

There are several factors that determine the current density distribution within the head. These factors influence the current density distribution directly or indirectly. The ultimate direct factor is the electrical impedivity distribution in the head. The frequency and the placement of electrodes are factors that indirectly affect the current density distribution.

Effect of the Skull

When current is injected into the head, the current density is much smaller in deep intracranial region than in the superficial layers, skin, and scalp (Malmivuo, Suihko, & Eskola, 1997; Seoane, Lu, Persson, & Lindecrantz, 2007). Recent simulations with a realistic model have shown that the effect of the skull is less shielding than earlier believed (Seoane et al., 2007), and it has been shown that the current density distribution depends largely on the electrical properties of each specific tissue. A smaller current density in the intracranial structures is explained, not only by the shielding layer of low conductive bone. The conductive extracranial layer of muscle tissue, together with the large area available for the current to flow within the brain, are also responsible for the small intracranial current density.

Volume under Study, Placement of Electrode and Sensitivity Maps

Electrode placement significantly influences in the current density distribution, as seen in Figure 3, thus a particular arrangement of electrodes will be better for the study of a certain region. Not only the position of the pair of injecting electrodes, but also the position of the pair of sensing electrodes is important. The arrangement of the injecting and sensing electrodes determines the sensitivity map; therefore, different placement of the pairs of electrodes gives different sensitivity maps. These maps may contain positive and negative as well as null regions (*e.g., if the pair of electrodes were overlapping each other, the sensitivity map will be only positive*). For this reason, some electrode arrangements are more suitable for study of certain phenomena than others. An adjacent placement of electrodes will give information mainly from the cortex, desirable for the study of certain pathologies (*e.g., epilepsy*), while the same electrode arrangement will provide very little information from the centre of the brain, less favourable for detection of haemorrhage in the brain ventricles for instance.

In EIT, the placement of electrodes is determined by the selected measurement strategy: opposite method, cross method, neighbouring method, and adaptive method. The corresponding sensitivity maps associated with each of them have been studied in Kauppinen, Hyttinen, and Malmivuo (2006).

Spatial Resolution in EIT

The main limitation of EIT is the poor spatial resolution. The accuracy of the image has improved as new processing methods have been introduced, but it is still poor compared to traditional imaging methods used in clinical practice like MRI, CT, Ultrasound, and so on.

Number of Channels

A progressive increase in the number of measurement channels of the EIT systems, from 16 electrodes used back in 1987, up to with 128 electrodes (Gang, Lim, George, Ybarra, Joines, & Liu, 2006), has contributed to improve the quality and the resolution of the impedance images (Mengxing, Wei, Wheeler, McCormick, & Xiuzhen, 2002), as expected.

Reconstruction Algorithms

The reconstruction algorithm contains several simplifications and assumptions that worsen the accuracy of the reconstructed image, thus the selection of a specific algorithm and its components are critical for the spatial resolution of an EIT image.

The complexity of the models used for the forward problem has been increased from simple heterogeneous 2D-spherical models to 3D-layered concentric sphere, and even realistic anatomic models based in MRI-images (Liston, Bayford, Tidswell, & Holder, 2002). The increase in the complexity of the models has been accompanied with the corresponding improvement in resolution and quality of the image (Bagshaw & Liston, 2003; Liston et al., 2002).

The work done in reconstruction algorithms for EIT during the last decade and the generated scientific literature is immense, and part of it is contained in the review work done by Lionheart (2004).

FUTURE TRENDS

Researchers and physicians have realized of the potential of EBI technology for monitoring of the brain; consequently, the proliferation of bioimpedance techniques targeting the dynamics of basic pathophysiological mechanism is natural and expected.

A better biophysical understanding of the dynamics of EBI during the aetiologies of interest along with a good knowledge regarding the current density distribution and the impedance sensitivity maps in the brain will most probably lead to the development of aetiology-specific operation modes in EBI measurement systems.

The Promising Magnetic Induction EIT

Magnetic Induction Electrical Impedance Tomography, MI-EIT, is a modality of EIT. In MI-EIT, the current is not directly applied into the tissue through electrodes—it is magnetically induced by coils (Al-Zeibak & Saunders, 1993). This way, it is possible to reduce the effect of the low conductivity of the skull bone and eliminate certain limitations related to the electrodes (Scharfetter, Casanas, & Rosell, 2003).

MI-EIT has been under study and continuous development for the past years (Al-Zeibak & Saunders, 1993; Rosell, Casanas, & Scharfetter, 2001; Scharfetter et al., 2003), and recently, its application in cerebral monitoring has been intensified.

CONCLUSION

Changes in the electrical properties of brain tissue do reflect certain physiological activities in the brain. These activities may originate from normal processes (*e.g., the membrane depolarization during an evoked potential*), or it might be the result of brain damage (*e.g., ischemic oedema after stroke*), or it might be the injury mechanism itself (*e.g., hypoxic cell swelling*). Therefore, the use of electrical bioimpedance measurements of the brain can play an important role supporting early diagnosis of several brain-related conditions.

The development of electrical bioimpedance technology has been intense and continuous, especially during the last decade, but it has not been enough to reach the necessary status to be applied in clinical practice as brain monitoring tool yet. However, through experimental research results, hardware developments, and simulation studies, there may be a breakthrough soon.

KEY TERMS

Bioimpedance Tomography: Also known as Electrical Impedance Tomography, it is a medical imaging technique in which an image of the dielectric properties of biological tissue is inferred from surface electrical measurements.

Brain Stroke: A cerebrovascular accident that occurs as a consequence of brain ischemia or cerebral haemorrhage; ischemic stroke and haemorrahagic stroke respectively.

Electrical Bioimpedance: The physical magnitude that indicates the total impediment that a biomaterial offers to the flow of free electrical charges and the orientation of bounded electrical charges towards an existing electrical field.

Electrical Conductivity: A dielectric property that indicates the ability of a material to allow the flow of electrical charges.

Epilepsy: A neurological disorder in which abnormal electrical activity in the brain causes seizures.

Hypoxia: Reduction of oxygen supply to tissue below physiological level.

Ischemia: A low blood flow state leading to hypoxia in the tissue.

Seizure: Abnormal electrical activity in the brain tissue, which is usually accompanied by motor activity and/or sensory phenomena. Its origin can be epileptic or nonepileptic.

INTRODUCTION

Hospital-acquired infections (HAI) are defined as infections that are neither present nor incubating when a patient enters the hospital (Bourn, 2000). Their effects vary from discomfort to prolonged or permanent disability and they may contribute directly or substantially to a patient's death. HAI's are estimated to cost the National Health Service (NHS) in England £1 billion annually (Bourn, 2000) with as many as 5,000 patients dying as a result of acquiring such an infection (Anon, 2001). Not all hospital-acquired infections are preventable but Infection Control Teams believe that they could be reduced by at least 15%, with yearly savings of £150 million (Anon, 2001). Central intravascular catheters have been found to be a common source of infection. Catheters can become infected via a number of different routes with the infection proliferating in multiple areas along the catheter surface. It has been reported that over 40% of the identified micro-organisms causing hospital-acquired infection were *Staphylococci*, an organism that is typically found on the natural skin flora (Bourn, 2000).

If an infection associated with the device is suspected, clinicians can either treat the infection with antibiotics or replace the catheter. Both of these methods increase patient discomfort, place an additional workload upon hospital staff, drain hospital resources, and increase the patient's length of stay within the hospital. It would be hugely beneficial to patients and clinicians if the onset of subclinical biofilm formation on medical implants could be detected, and thus treated, at an early stage.

The idea of using impedance to monitor bacterial growth is not a new one; indeed impedance microbiology was first introduced over 100 years ago (Stewart, 1878). Traditional impedance microbiology involves the application of a sinusoidal voltage or current typically across two-electrodes and the resulting impedance (or conductance) response is monitored at only one-frequency during the growth of the micro-organism under investigation. Although the area has shown promise, advances have been limited. The majority of published works have focused on changes in the bulk electrolyte with few studies examining the electrode-electrolyte interface and only a few recent studies have examined the development of sensors for monitoring bacterial growth (Gomez, Bashir, & Bhunia, 2002; Gomez et al., 2001; Oliver et al., 2006; Yang, Li, Griffis, & Johnson, 2004).

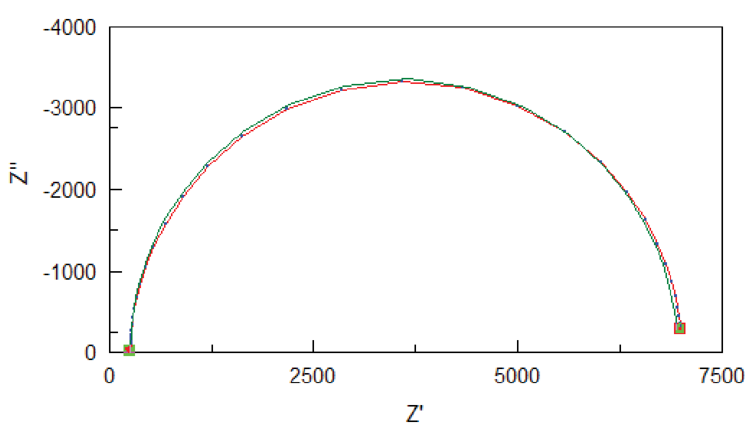
An alternative to monofrequency measurements is Frequency Response Analysis using Electrical Impedance Spectroscopy (EIS) and equivalent circuit modelling. When used to study electrochemical systems, EIS can give accurate, kinetic, and mechanistic information using a variety of techniques and output formats. For example, consider a small alternating voltage of known angular velocity, (ω) and small amplitude (v) applied to the system under investigation. The current response (i) and phase difference (φ) of the resultant waveform is measured for a range of applied frequencies (ω). The relationship between the applied voltage and resultant current waveform is the impedance (Z) of the system. During measurements, the amplitude of the applied perturbation waveform is carefully controlled to ensure minimal disturbance to the test system. EIS is therefore considered to be a nondestructive and safe method for studying biological systems. Established AC and electrochemical theory can be used to characterise the impedance of the electrochemical cell and to represent it in terms of an equivalent circuit model.

BACKGROUND: IMPEDANCE MICROBIOLOGY

The need to monitor bacterial growth effectively is apparent in the areas of food science, water quality, and medicine. However, there have been relatively limited advances in improving the means of detecting microbial growth. Conventional detection methods require long sample turnaround times, have low reproducibility, produce high error rates, and are costly in terms of labour (Noble, 1994). Automating microbiological detection would be advantageous as it would increase productivity and relieve human beings from having to perform mundane, menial, and repetitive tasks (Trotman, 1978). Impedance microbiology has been presented as a mechanistic alternative to monitoring the growth of bacteria and has become an accepted method of monitoring growth of micro-organisms in the brewing industry. Although this acceptance has been a promising advance, the monofrequency method used to date limits the potential of the technique. In the microbiology field, there have been relatively few studies which have explored the multifrequency impedance analysis method. It is proposed that a multifrequency approach will not only facilitate the monitoring of microbial growth rates but will also provide a means of monitoring microbial-environment interactions.

Electrical impedance spectroscopy differs from traditional impedance microbiology measurements in that it measures the impedance response over a wide range of frequencies and the data can be modelled using an equivalent circuit which can be interpreted in terms of the electrochemical reactions occurring within the system. The combination of a multifrequency approach, improved electrode design, and the use of meaningful equivalent circuit modelling enables the simultaneous examination of the electrode-electrolyte interface and

Figure 1. A typical complex impedance plot showing one partial semi-circular arc



the bulk properties of the electrolyte. Data is typically presented on a complex impedance plot (Z real component vs. Z imaginary component) and, generally, over the relatively limited frequency ranges available with the commercial devices (Hz to MHz), forms one or two partial semicircular arcs (Figure 1). Over an extensive frequency range several such arcs should be observed. The Bode Plot presents both the log |Z| and the phase angle (φ) against log frequency (ω) (Figure 2). The most appropriate circuit model is then applied to the data. It is important that data is viewed in a number of different plot formats so that the appropriateness of the circuit model can be established. In the case where the Randles equivalent circuit (Figure 3). is the model of choice, the bulk resistance of the solution is examined through analysis of the series resistance. The properties of the interface are examined by monitoring changes in the parallel resistance and capacitance (or constant phase element). Solution resistance dominates at high frequencies and the electrode-electrolyte interface at low frequencies, provided that data is collected over the appropriate frequency range.

THE BULK PROPERTIES OF THE MICROBIAL SOLUTION

The processes occurring in the bulk of the solution are very different from the processes that occur at the electrode surface. In solutions there is a two-way flow of ions, that is, positive ions are attracted to the negative cathode and negative ions are attracted to the positive anode. The movement of ions in an electrolyte is altered by the application of an electric field. The solution resistance measures the opposition to current flow travelling through the solution by the migration of ions and is represented in equivalent circuit modelling by the series resistance (R_s). The mobility of the ions directly affects the bulk resistance measurement.

Growth media consists of strong and weak electrolytes and includes proteins, carbohydrates and minerals. When the electrolyte concentration of the growth medium changes as a result of bacterial metabolism, larger molecules are broken down into smaller ions (Cady, 1978; Ur & Brown, 1975). This eases the flow of current through the solution/media and results in an increase in conductivity or a decrease in the bulk

Figure 2. Bode Plot for an electrochemical cell, showing the modulus of the impedance and the phase angle against the log of frequency

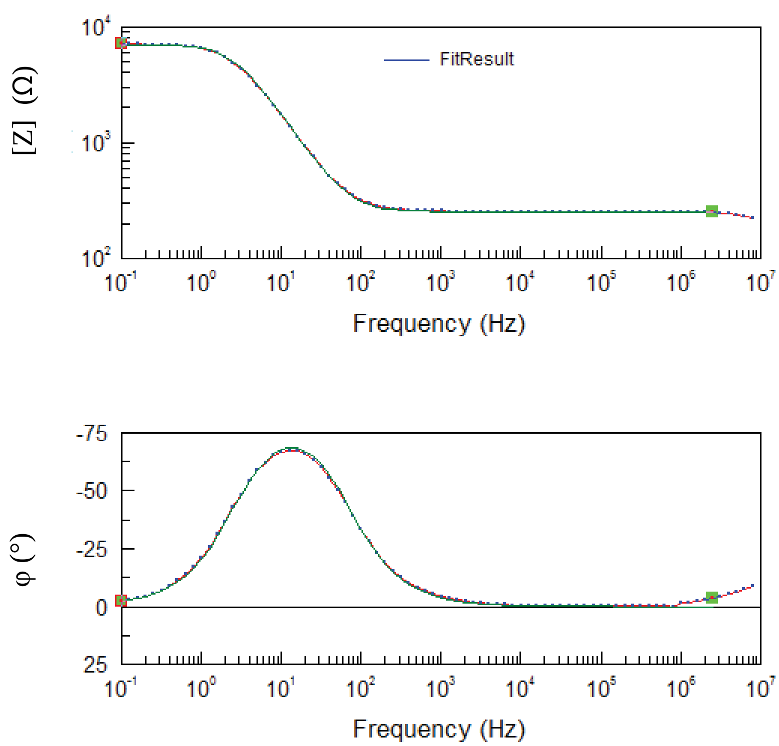


Figure 3. Equivalent circuit model sometimes referred to as the Randles circuit model

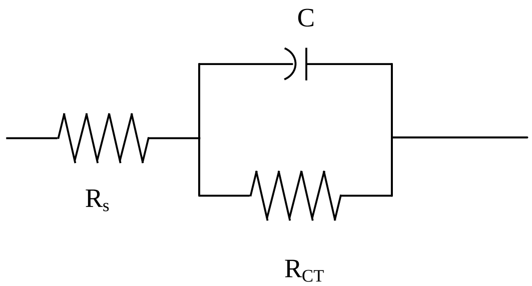

resistance. Given the large and varied amount of components of the growth medium, it is not possible to calculate the number of ions either completely ionised or dissociated during microbial growth. Owens (1985) had difficulty trying to accurately predict the change in conductivity as a function of carbon source, growth conditions, and pH buffers. However, it was his belief that conductivity could be maximised by considering separately the factors that both increase and decrease the conductance of a medium. The significance of this was that culture media could be formulated that maximised the observed changes in conductivity or bulk resistance. The choice of media is therefore considered of paramount importance when examining changes in the resistance of the bulk solution (R_s).

THE ELECTRODE-ELECTROLYTE INTERFACE IN MICROBIOLOGY

The environment at the electrode interface is very different from the growth medium/bulk solution. At the electrode-electrolyte interface, there is transference of charge from the electrons in the metal electrode to the ions in the solution. At the electrode-solution interface, an electric double layer is formed, which contains a nonuniform distribution of charges. Helmholtz (1853), as cited by Macdonald (2005), compared the double layer to a molecular parallel plate capacitor, where one plate represents the charges in the metal and the other plate represents the ions (at a minimum distance) in the solution. The Helmholtz model is only valid for high concentration electrolyte solutions. In more dilute solutions the transition will not be so abrupt and the thickness of the double layer increases. Helmholtz's model predicts that changes in capacitance are due to dielectric permittivity or the distance between the plates. Alternative models have been developed that do not agree with Helmholz's theories. Two studies (Chapman, 1913; Gouy, 1909) proposed that an electrode submerged in a liquid is surrounded by an ionic cloud rather than considering the interface between an electrode and a liquid as rigidly fixed charge as Helmoltz had proposed. In this case the counterion atmosphere will be more like the ionic atmosphere around an individual ion which is termed the diffuse layer. Gouy and Chapman's model takes into account thermal motion which influences the equilibrium of the distribution of counterions. The ions around the electrode diffused exponentially into the liquid medium as distance increased from the electrode (Macdonald, 2005). The limitations of the Gouy-Chapman model have been identified (Bockris & Reddy, 1970) where it was established that the Gouy-Chapman model estimates capacitances with reasonable accuracy provided solutions have very low numbers of ions. Stern (1924) amalgamated the Helmholtz and Gouy-Chapman models by suggesting that the diffuse layer is divided into an inner layer (Stern, 1924) and an outer layer (Chapman, 1913; Gouy, 1909). There have been a number of modifications and extensions to the original Helmholtz model, thus indicating the complexities of the electrode-electrolyte interface in the field of electrochemistry.

In equivalent circuit modelling, the double layer of charge at the electrode interface is often termed the double layer capacitance C_{DL}. The DC current that manages to cross the electrode-electrolyte interface experiences a charge transfer resistance, R_{CT} where the expression for R_{CT} (Equation 1) is derived from the Butler-Volmer equation used in electrochemistry;

$$R_{CT} = \frac{RT}{nF}\frac{1}{i_0} \qquad (1)$$

Where R is the gas constant, T is the temperature (K), F is the Faraday constant, n is the number of electrons involved in the electrode reactions, and i_0 is the exchange current density.

For systems that exhibit ideal capacitive behaviour at the electrode-solution interface, the estimation of the double layer capacitance is relatively simple using techniques such as impedance spectroscopy. In practice, most systems do not exhibit ideal behaviour and show noncapacitive behaviour at the interface as a result of surface roughness on the electrode and diffusion/adsorption at the electrode interface (Bard & Faulkner, 2001; Macdonald, 2005). "Distributed" elements such as the Warburg element and the constant phase element (CPE) prove useful when describing these non-ideal processes. The Warburg element describes diffusion related events and the CPE accounts for the non-ideal capacitive properties of the system. Diffusion related events are rarely seen in the impedance microbiology area and for this reason will not be described here. Many theories have been proposed in electrochemistry to describe the electrode-solution interface; few theories have emerged to describe the electrode-bacterial interface.

ELECTRICAL IMPEDANCE SPECTROSCOPY OF MICROBIAL BIOFILM FORMATION

EIS was used to monitor the growth of *Staphylococcus* epidermidis RP62A over a period of 24 hours. Circuit modelling provided information on the growth mechanisms of *S. epidermidis.* An electrode system designed using a flexible implantable substrate (Polyimide) is tested and presented as a possible system for monitoring the growth of *S. epidermidis* on medical implants. All experiments were thermostatically controlled using an incubator at 37°C ± 0.1°C and sterile brain heart infusion (BHI) media (Oxoid). Culture dishes containing 2 ml sterile BHI media were inoculated with 200 μL of an overnight culture of *S. epidermidis*. Electrodes were immersed in the sterile media two hours prior to inoculation. Electrodes were fabricated by deposition of gold on polyimide (PI). 125 µm Du Pont Kapton™ was plasma cleaned using helium plasma (60 W for 2 minutes). A 20 nm titanium interlayer was sputter-deposited on the polyimide, followed by a 200 nm layer of gold. A series of photolithographic steps were used to form the electrode pattern shown in Figure 4. The electrode array was designed so that it could be used for two and three-electrode techniques although only the results obtained using a two-electrode technique are presented here. The two-electrode technique measured the impedance response between electrodes B and C (electrode A was not used for measurements). Electrodes B and C are identical in size (1 mm^2) and shape.

Before impedance measurements the electrodes were cleaned with Piranha solution ($H_2SO_4 : H_2O_2$ 3:1) then rinsed thoroughly with sterile distilled water and dried in N_2 atmosphere. An oscillating AC potential of 20 mV was applied to the system (0 V DC-bias) over the frequency range 10 Hz to 1 MHz using a Solartron 1260 frequency response analyzer combined with a Solartron 1287 electrochemical interface. Impedance measurements were taken every 30 minutes for a period of 24 hours following inoculation of BHI media with *S. epidermidis*. A control cell was setup containing sterile BHI media without bacteria and measurements were taken at the same intervals for comparison. All measurements and analysis was performed using the Zplot and Zview software provided by Solartron Inc.

The charge transfer resistance is considered to be in series with the solution resistance R_s and in parallel with the double layer capacitance. Commercial software packages are available (e.g., Gamry, Scribner and Solartron) providing equivalent circuits models such as Figure 5 to model the experimental data. A constant phase element (CPE) was used instead of a pure capacitance to fit the experimental data because biological responses produce a depressed semi-circular arc, where the intercept angle at high frequencies is not 90° as expected for a pure capacitance. The use of CPE for biological systems has produced much better fits with experimental data than a pure capacitance as the electrode/solution interface exhibits non-capacitive properties (McAdams & Jossinet, 1996). The impedance of a CPE is defined in equation 2 where *K* is a measure of the magnitude of Z_{CPE} and has units of Ω s$^{-\alpha}$, j is the imaginary unit ($j = \sqrt{-1}$), ω is the angular frequency ($\omega = 2\pi f$) and α is a constant which has a value between 0 and 1. Any complex plot where $\alpha<1$ is more accurately modelled by a CPE. There is no

Figure 4. Miniature EIS probes made by gold deposition onto polyimide

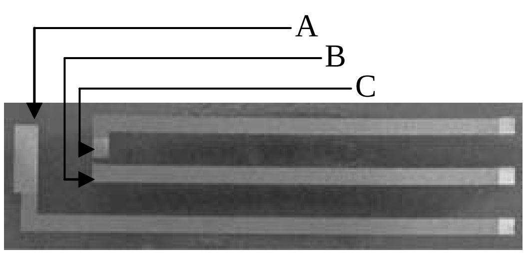

Figure 5. Equivalent circuit model, showing the bulk resistance R_S, the charge transfer resistance R_{CT} and a constant phase element CPE

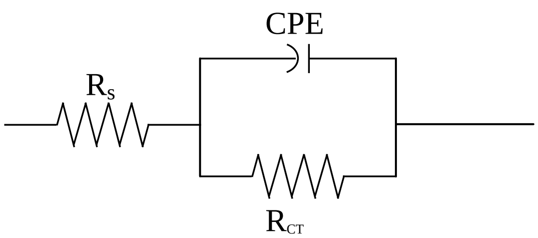

Figure 6. Complex impedance plots (resistance Z' vs. reactance Z") for sterile media (1), inoculation (2) and during biofilm growth (3)

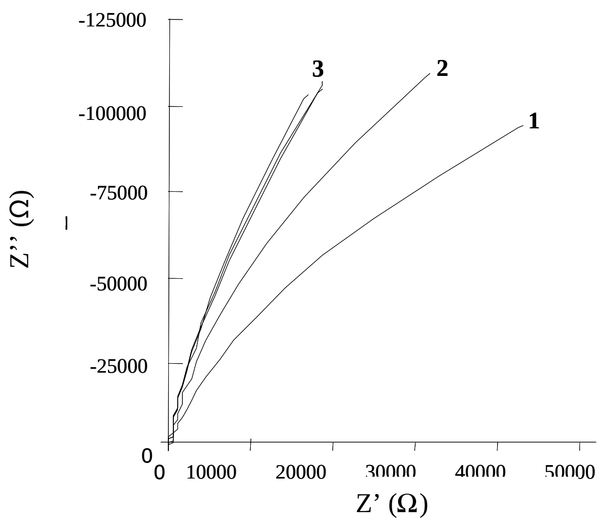

possibility of estimating the double layer capacitance C_{DL} from K values (Zoltowski, 1998).

$$Z_{CPE} = \frac{1}{K(j\omega)^{\alpha}} \qquad (2)$$

It is important to remember that the CPE exhibits no capacitive behaviour and the assumption that the double layer capacitance C_{DL} = K is incorrect and results in inaccuracies in all other modelled parameters (McAdams, 1996; MacDonald, 2005; Zoltowski, 1998).

RESULTS

Staphylococcus epidermidis RP62A adhesion to the gold electrode surface was visually confirmed following impedance measurements by staining the biofilm with crystal violet. This procedure stains the biofilm cells deep purple. Figure 6 shows plots for blank media, inoculation point (t = 0 h) and during microbial biofilm formation. The shape of the data plots are different for pre and post inoculation. The major differences are observed between the blank and culture plots at the lower frequency end of the spectrum, where charge transfer resistance (R_{CT}) dominates. Figures 7-9 show the modelled data for all complex plots for the 24 hour measurement period. The bulk resistance (R_s) of the media decreased over the 24 hour measurement period as shown in Figure 7 at t = 0 h R_s = 264 Ω and at t = 24 h R_s = 170 Ω, a decrease of 94 Ω. This is explained by the theory proposed by Cady (1978) which states that bacterial metabolism causes the breakdown of large organic molecules in the media into smaller more conducive ions which gives an increase in media conductivity over time. The decrease in bulk resistance was not as marked in the blank media, however R_s did show a decrease with time, at t=0 R_s=187Ω and at t=24 R_s=175 Ω, a decrease of 12 Ω.

Values for K did not change markedly over time and remained relatively constant at 0.15 μΩ$s^{-\alpha}$ for the inoculated solution (Figure 8). Values of K for the blank media were higher (0.2 μΩ $s^{-\alpha}$) compared to that of the inoculated media (0.15 μΩ $s^{-\alpha}$) at all time points, which shows that the presence of the bacteria decreased the impedance of the CPE at the interface. R_{CT} was observed to increase dramatically in the first few hours of biofilm formation (Figure 9). A magnitude of 0.6 MΩ was recorded at inoculation which doubled after 2 hours to 1.2 MΩ and continued to increase for the duration of the experiment. There was a small initial decrease in R_{CT} for the blank media in the first 30 minutes and thereafter the value remained constant at ca. 0.1 MΩ for the duration of the experiment. It is important to note that the complex impedance plots for this set of experiments (Figure 6) are not complete semicircular arcs and therefore values produced by the commercial software for R_{CT} are an approximation and subject to error. Comparing the data for R_{CT} during biofilm growth with R_{CT} values for blank media there is a marked difference in their pattern and magnitude (Figure 9). Further investigation at lower frequencies is required

to determine if a change in R_{CT} could be used to detect initial biofilm adhesion and recruitment.

CONCLUSION

Microbial biofilms are defined as a matrix-enclosed bacterial population adhered to a surface or each other. An organic matrix protects these sessile organisms (Dominguez-Benetton & Castaneda, 2005; Costerton, 1995; Marshall, 1971; Poulsen, 1999). Biofilms are characterized in part by the production of a network of highly hydrated extracellular polysaccharides (EPS). The EPS matrix has a number of functions, one of which includes facilitating initial attachment of bacteria to the surface. The EPS matrix has been reported to change the surface charge and free energy on the surface to be colonized and may account for changes observed in R_{CT} (Poulsen, 1999). Changes in R_{CT} can be explained by microbial adhesion where adhesion to the surface is usually characterized by two phases (Marshall, 1971): (i) The reversible phase which occurs when the bacteria are very near to the surface but not in direct contact and includes electrostatic, hydrophobic interactions, and Van der waals forces, (ii) the irreversible phase where binding to the surface is complete and includes dipole-dipole interaction and covalent bonding. It is possible that changes in R_{CT} in the first few hours of microbial growth (Figure 9) relate to the reversible stage of the biofilm formation with the continuing increase in R_{CT} relating to the second phase of biofilm formation. An increase in R_{CT} was not observed in the sterile media. However, partial arcs in complex plots do not allow for a good approximation of R_{CT}, and future work should include an investigation of lower frequencies (<10 Hz). Changes in the double layer are often related to biofouling and biocorrosion, of metal electrodes (Dominguez-Benetton and Castaneda 2005). In this set of experiments, the gold surface of the electrode did not become corroded. Within the field of biocorrosion, biofilm formation is monitored sometimes over a period of thirty days and in future experiments impedance monitoring will take place over longer periods of time. The observed decrease in the magnitude of R_s over time follows Cady's theory where the breakdown of metabolites in the media due to bacterial respiration and growth causes an increase in the net conductance of the media and consequently a decrease in R_s. Future sensor design should take into account that the biofilm does not adhere well to the substrate, preferring the gold electrodes; this biological parameter may be exploited to improve the sensitivity of the impedance technique. However, one must also be careful not to promote biofilm recruitment on implantable devices. The electrode-medium interface warrants further investigation to determine the most effective parameter for monitoring biofilm formation and bacterial growth. This study confirms that electrical impedance spectroscopy is a possible method for the in-situ or possible *in vivo* monitoring of biofilm recruitment and/or bacterial growth.

FUTURE TRENDS

The use of EIS and equivalent circuit modelling to monitor microbial growth has shown great promise for routine microbiology and also in medical applications. In routine detection it offers the ability to monitor microbial interactions in the bulk solution and at the electrode interface with potentially much faster response times than traditional methods and with a greater degree of automation. More work will be required using different strains of micro-organism to confirm these exciting early findings. In order for EIS to be routinely used by microbiologists, there would need to be a simplification of the technology and further studies could exploit developments in micro-electronics to produce more portable impedance monitoring systems.

KEY TERMS

Biofilm: Microbial biofilms are defined as a matrix-enclosed bacterial population adhered to a surface or each other. An organic matrix protects these sessile organisms. Biofilms are characterized in part by the production of a network of highly hydrated extracellular polysaccharides (EPS).

Charge Transfer Resistance (R_{CT}): The DC current that manages to cross the electrode-electrolyte interface experiences a charge transfer resistance. The expression for R_{CT} is derived from the Butler-Volmer equation where:

$$R_{CT} = \frac{RT}{nF}\frac{1}{i_0}$$

R is the gas constant, T is temperature (K), F is the Faraday constant, n is the number of electrons involved in the electrode reactions, and i_0 is the exchange current density.

Constant Phase Element: In order to facilitate equivalent circuit modelling, the ideal capacitance is often substituted by an empirical constant phase element (CPE). The CPE is not physically realisable with ordinary lumped electric components but it is usually described as a capacitance that is frequency dependent. The use of a CPE reflects the nonhomogeneity of the system under investigation.

Hospital-Acquired Infections (HAI): Infections that are neither present nor incubating when a patient enters the hospital. Effects vary from discomfort to prolonged or permanent disability where HAI's may contribute directly or substantially to a patient's death.

Impedance: The opposition to flow of an alternating current. Impedance is a complex entity that describes all resistance to current flow. Impedance is composed of resistance (the real component) and capacitive and or inductive reactance (the imaginary components).

Solution Resistance (R_s): The opposition to current flow through the solution/electrolyte by the migration of ions. In general, the solution resistance is considered to decrease with increase in microbial growth.

Electrocutaneous Stimulation of Skin Mechanoreceptors for Tactile Studies with Functional Magnetic Resonance Imaging

INTRODUCTION

In many simulation and exploration tasks such as exploring the real and virtual environment, tactile information is necessary to get surface information of objects. Moreover, in rehabilitation and sensory prostheses training, this kind of sensory information is indispensable (Yarimaga, Lee, Lee, & Ryu, 2005).

Since the 1980s, electrotactile stimulation has been considered a possible way to reproduce the glabours skin tactile sensations, first by using intracutaneous electrodes inserted into the nerves and then by using transcutaneous electrodes placed in contact with the skin.

Electrotactile stimulation is a potentially useful method for sensory augmentation or substitution and permits accurately controlling the perceived stimulus intensity that is fundamental in any tactile communication system. In several virtual reality applications, the electrostimulation could be a viable solution in substituting for tactile displays, increasing the augmented reality performance.

If it could be possible to elicit selectively each kind of skin afferent fibers using analogously to mechanical stimulus, any sensation could be evocated by combining specific inputs.

To evoke specific sensations related to specific types of *mechanoreceptors,* we consider here the possibility of using electrotactile stimulation, varying the amplitude and the frequency of the stimulating electric signal, but maintaining the same waveform. According to a different specificity of the mechanoreceptors at different mechanical stimulus (Kaczmarek, Webster, Bach-y-Rita, & Tompkins, 1991), there might exist receptor specificity for different amplitude and frequency of electrical stimulus. In this case it could be possible to stimulate specifically several types of mechanoreceptors maintaining the same waveform and varying only its amplitude or frequency, with the possibility of creating a different sensation for tactile studies and augmented reality applications.

BACKGROUND

The *microstimulation* technique of tactile receptors by using electric current has been largely used to study the specific role of several types of mechanoreceptors and characterize their functional properties (Vallbo, Olsson, Westberg, & Clark, 1984). Passing small electric currents through microneurography electrodes placed directly on the nerve ending of the receptors, it is possible to evoke several localized sensations such as flutter or pressure.

Many authors have proposed several techniques to record this sensation in awake human: Trulsson Francis, Kelly, Westling, Bowtell, and McGlone (2001) demonstrated that intraneuronal microstimulation of single afferents produces robust hemodynamic responses in somatosensory cortex that can be measured using the *functional Magnetic Resonance Imaging* (fMRI) technique.

Another technique of electrical stimulation of skin receptors is known as "electrocutaneous stimulation": with the term electrocutaneous (or electrotactile) is intended the evocation of a tactile sensation using an electric current flowing through the skin, via electrodes placed on the skin surface. A device that stimulates nerve afferents within the skin by electric current is known as "electrocutaneous display" and can be constituted by several surface electrodes.

Because their small size, longer durability, energy efficient, and ease of use, electrocutaneous displays are superior to mechanical tactile displays.

Several papers report the use of this technique in sensory substitution system for blind or deaf persons (Bak, Girvin, Hambrecht, Kufta, Loeb, & Schmidt, 1991; Eisenberg, Maltan, Portillo, Mobley, & House, 1987) and in training for prostheses use. Electrocutaneous stimulation has been also used in augmented reality and telepresence in order to provide the user with tactile information (Nojima, Sekiguchi, Inami, & Tachin, 2002).

The mechanism of tactile stimulation was first described in literature approximately in 1960 and the first tactile display was proposed in 1970 (Strong & Troxel, 1970). It was based on the principle that an electric current pulse from surface electrodes generates an electric field inside the skin, which induces nerve activity.

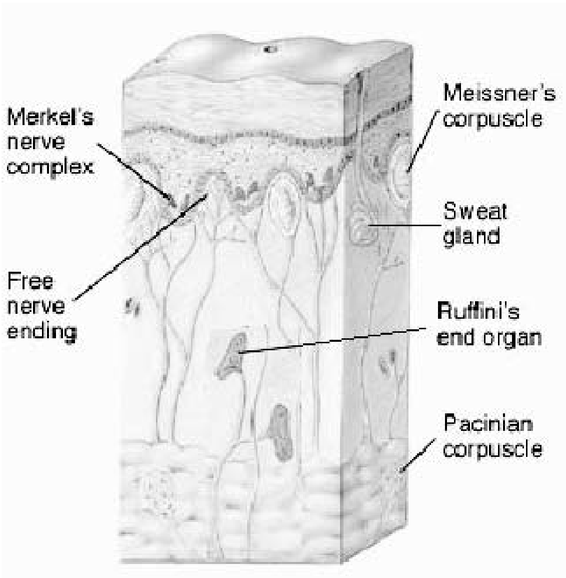
Approximately 44% of mechanoreceptors lying into the human hand are found to be slowly adapting (SA) (i.e., they also respond with a sustained discharge to static tissue deformation), while the remaining are fast adapting (FA), only responding to the rate of skin indentation and its higher derivatives. Depending on the extension of their receptive fields, SA and FA tactile units can be subdivided into two categories: type I have restricted and sharply defined receptive fields and type II have larger fields and less precise contours. The correspondence between SAI and *Merkel's complexes,* FAI and *Meissner's corpuscles,* SAII and *Ruffini's endings*, and FAII and *Pacinian corpuscles* is widely accepted (Johnson, 2001).

Each class of mechanoreceptors responds to skin deformation and motion in a different way (Kaczmarek et al., 1991). If it could be possible to find the electric current which is able to elicit selectively each kind of afferent fibers analogously to mechanical stimulus, any sensation could be evocated by combining specific inputs.

Kajimoto, Hawakami, Maeda, and Tachi (2002) have already shown that electrical selective stimulation is possible using anodic or cathodic current: they called the specific stimuli "tactile primary colours" in analogy to the visual system and its primary colours (red, green, and blue). In their paper the authors show that Meissner corpuscles can be selectively stimulated in

E

Figure 1. Skin mechanoreceptors



a specific setup of electrical stimulation but Pacinian corpuscles can not be selectively stimulated because the electrical signal inevitably co-activated the shallow parts also.

To evoke specific sensations related to specific types of mechanoreceptors, we considered the possibility of using electrotactile stimulation varying the amplitude and the frequency of the stimulating electric signal, but maintaining the same waveform. We only focus on Merkel and Meissner corpuscles which are at less depth in the skin respect to Pacinian and Ruffini afferents.

In order to verify the evocation of a tactile sensation by means of the electrical signal, it is possible to use the fMRI technique. This technique allows localization of blood flow variations and oxygen consumption due to neuronal firing, then it is possible to visualize the active brain regions during perception and processing of a sensory impulse from a given body district (Hammeke & Yetkin, 1994).

DESIGN OF AN ELECTROCUTANEOUS DISPLAY

Safety Criteria

As the microstimulation is performed by an electric device, *safety criteria* for electric safety, in terms of high voltage and pulsed current, were considered and studied.

Predicting the current flow in the skin is very difficult because of the many factors which influence it, for example, whether the body skin is moist or dry, the contact area, and pressure. A good review of physical basis for the design of efficacious and safe protocols for electrical stimulation is in Merrill, Bikson, and Jefferys (2005).

Moreover, electrochemical reaction could be occurring at the electrode interface and then they have to be considered for the choose of electrode material (Brummer & Turner, 1977).

The design of the electric microstimulator was developed in accordance to results from *MR safety and compatibility* studies. The observance of these criteria is a crucial aspect in view of performing specific experiments inside the MR scanner during a fMRI acquisition of brain functional activation.

Before introducing any device into the MR suite, MR safety and compatibility of the device and its operation in the magnetic field should be carefully verified according to systematic rules and procedures (Shellock, 1998). Hence, in order to design a new device which allows tactile stimuli inside the MRI scanner environment during fMRI studies, definitions and classifications regarding MR safety and compatibility and the interaction between MRI primary components and mechatronic devices have been considered. The Food and Drug Administration (FDA) document (1997) on medical device interactions with Magnetic Resonance Imaging systems reports the most descriptive definitions and classifications regarding MR safety and compatibility that should be used for experimental protocols of compatibility evaluation.

Methods

The stimulator device is supplied by low power batteries and is able to generate high voltage pulses; it is equipped with two independent channels for stimulation of both hands. By means of a couple of potentiometers for each channel, it is possible to set the output voltage amplitude and frequency values, in order to vary the kind of the stimulus and obtain different sensations due to specific classes of stimulated mechanoreceptors.

The output voltage ranges from 0 to 450 V, while frequency varies between 90 and 110 Hz; however because of the very high skin impedance, the electric

Figure 2. Photo of designed electrical stimulator internal

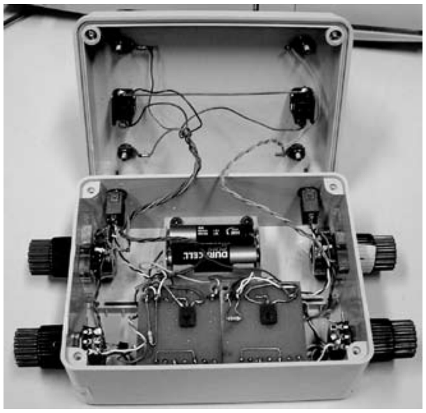


Figure 3. Stimulator pad with two aluminum electrodes and their position on the index fingertip

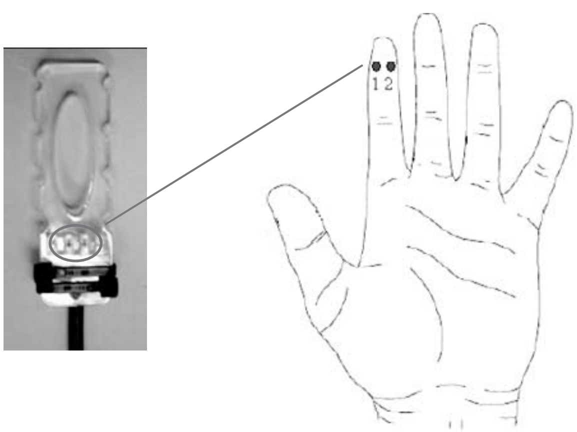


current flowing is 1-2 mA. The output waveform is a pulsed decreasing exponential wave. This permits to reduce the Joule effect produced by the electric current flow through the skin.

According to the electric safety criteria the stimulator device is floating and supplied by batteries.

According to the MR safety and compatibility criteria, the part which should be placed within the scanner room does not present metallic materials. For this reason, the stimulator pad is created choosing MR-compatible and nontoxic materials, Plexiglass and Aluminum, because it has to be placed on the subject hand inside the scanner room. Two 1mm x 1mm Aluminum square electrodes, at distance of 5 mm, are fixed on the pad.

Coaxial cables are used to connect the two stimulator electrodes inside the MR scanner room with the device inside the console room in order to minimize RF interferences.

Device Set Up

Before testing the device during a fMRI acquisition, we performed several psychophysical experiments in laboratory. A group of subjects, stimulated by an electric current which was varied in amplitude and frequency, was asked to report the perceived tactile sensation. Specifically, starting from the lowest amplitude and highest frequency, the electric current was firstly increased in intensity up to subjects felt some sensation. In 95% of the cases, the sensation was defined like a slipping, vibration sensation.

Afterwards, we decreased the frequency of the electric current down to subjects were able to feel a different sensation. In 90% of the cases, this second sensation was defined like a pin-prick sensation.

According to Johnson (2001), *Meissner* corpuscles (RA1 afferents) are very sensitive to dynamic skin deformation and they transmit a robust neural image of skin motion. For this reason, we can hypothesize that the specific value of amplitude and frequency used in the first case, in which subjects perceived slipping sensation, could elicit RA1 receptors.

Instead, *Merkel* corpuscles (SA1 afferents) are more sensitive to points, edges, and curvature, which is a consequence of their selective sensitivity to strain energy density. They are responsible for shape, orientation, and texture perception. Therefore, we can conjecture that the specific value of amplitude and frequency of the electric current achieved in the case where subjects felt pin-prick sensation could be responsible for eliciting SA1 receptors.

MR Safety and Compatibility Test

The designed device was examined in a MR environment (Signa Horizon 1.5T, GE Medical Systems) during image acquisition in order to test its MR safety and compatibility.

We placed the device inside the console room and the stimulator electrode inside the scanner room on the patient bed in the right position for the stimulation task on a patient (the cable that connects the stimulator electrode to the device passed through the wire guides of the MR shield).

During the test we scanned a spherical phantom of $CuSO_4$ solution, using a GE-EPI (gradient echo, eco planar imaging) with the following parameters: TE/TR 40/3000 msec, bandwidth 62.5 kHz, FOV 24 cm, resolution 64x64 pixels, Flip angle 90°, Slice thickness 5 mm, number of slices 25, 25 volumes acquired. This is a common use sequence for fMRI studies. After the images acquisition the signal to noise ratio (SNR) was calculated (Sijbers, Den Dekker, Van Audekerke, Verhoye, & Van Dyck, 1998). As a second parameter we estimated the standard deviation of the image intensity time course (SD) in each image sequence.

We looked for differences between image sets acquired with no device (reference images) and the image sets acquired with the electrode placed on the patient bed in several conditions: no electric current and electric current with different amplitude and frequency for different sensation stimulations. In order to evaluate the device compatibility with the MR environment, it is not sufficient to compare the two sets of images because several artifacts are not visible, so we used statistical t and z tests to detect parameter differences (Gassert et al., 2006). The analysis of these images and the application of the statistical tests to the images confirms the compatibility in MR-environment and the absence of unexpected and dangerous effects.

fMRI Acquisition on a Subject

After the evaluation of MR safety and compatibility of the device, we performed a pilot fMRI study on one subject.

The subject was a female 27 years old: she had been lying down on the sliding bed and the operator placed the birdcage head coil around her head. The stimulator electrode was placed on the subject's left index finger and fixed in order to avoid relative movements.

First of all we acquired the anatomic image of the subject brain and subsequently we performed a functional study using a classical fMRI sequence (GE-EPI: TE/TR 40/3000 msec, bandwidth 62.5 kHz, FOV 24 cm, resolution 64x64 pixels, Flip angle 90°, Slice thickness 5 mm, number of slices 25, 25 volumes acquired).

In order to explore brain activity during electric stimulation by using fMRI, we used a block design approach with a stimulation of 10 seconds, an interstimulus interval of 20 seconds, an initial and a final baseline condition of 25 seconds each (total number of stimulation interval=8). The choice of this experiment block designed was guided by safety criteria (for example the Joule effect presence) and analysis criteria (the stimulus intervals have to be short to avoid saturation effects on the receptors).

The fMRI acquisition involved the following runs:

- ***Run 1*****:** stimulation with specific value of amplitude and frequency of electrical signal in order to obtain a relative slipping sensation between the electrode and the subject finger.
- ***Run 2*****:** subject finger stimulation moving, by an operator in the scanner room, a piece of velvet in order to obtain a functional activation of a real tactile sensation.
- ***Run 3*****:** stimulation with specific value of amplitude and frequency of electrical signal in order to obtain a pin prick sensation on the subject finger.

Before the acquisition, a calibration of the device was made asking to the subject what kind of sensation she perceived.

Experimental Results

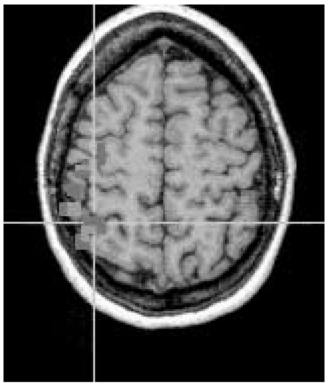
For every one of the three stimulation runs performed, a robust hemodynamic response was observed. Figure 4 shows the results for run 1, which are typical of all data acquired.

In correspondence of the primary sensorimotor cortex (SI) area (Hammeke & Yetkin, 1994), the statistical analysis, performed using AFNI (Cox, 1996), shows a neuronal activation; this confirms the hypothesis that the electric current caused a tactile sensation.

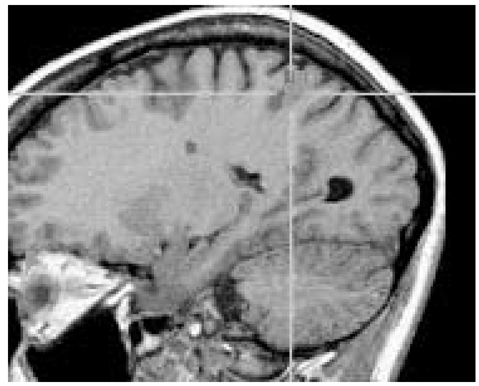
The graph in Figure 5 shows the correlation between the stimulation block and the intensity level for an image pixel that corresponds to the hemodynamic response: it is possible to note the good correlation between the stimulus intervals (red line, high intervals) and the activation.

Low frequency fluctuations are usually observed in fMRI time series. These may be related to long range physiological changes or slow movements of the subjects' head. For acquisition lengths of some minutes, these changes can be modelled with a linear ramp. The raw data in Figure 5 show an offset linear with time. Neural activity related to signal changes are small with respect to the baseline level and may be hidden by

Figure 4. Cortical activation during run 1 (slipping sensation). (a) axial view, (b) sagittal view



a)



b)

noise. In this task, even electrode displacement due to subject finger movement may occur. For this reasons, it is difficult to judge signal behaviour related to each single event, and the correlation between the entire time series and the stimulus paradigm must be evaluated.

These results demonstrate unequivocally that the electric stimulation really produces a robust hemodynamic response in the SI cortex, where touch resides, and it can be measured using fMRI.

FUTURE TRENDS

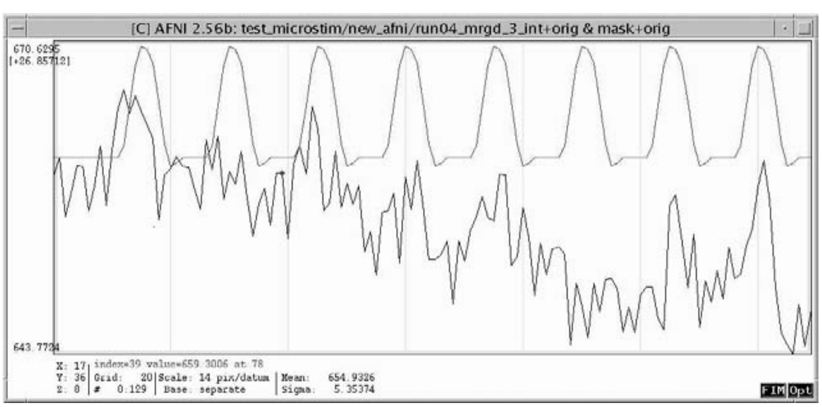
Future developments will concern a more accurate discrimination of the specific sensations reproduced using the electric current and major efforts will be focused in finding a reliable relationship between mechanical and electric stimuli eliciting mechanoreceptors. It would be interesting to stimulate different locations in order to study how different the elicited patterns are.

CONCLUSION

The goal of our work was to investigate the possibility of stimulating selectively different mechanoreceptors to evoke specific tactile sensations by means of injection of electric current through the finger skin. Possible fields of application are fMRI tactile studies or augmented reality technology. In this preliminary work, we described the first prototype of an electric stimulator, verifying the MR safety and compatibility, and performed a preliminary experiment with a subject under fMRI exam.

In the device design the electric and magnetic safety criteria was followed in order to avoid every

Figure 5. Activated area pixel intensity (bottom black line) and electrical stimulus (up red line) time evolution



dangerous effect due to the use of electric current in the human body.

The MR safety and compatibility of the prototype has been demonstrated using a statistical test to the localization of eventual artefacts in the MR images. Finally, the prototype was tested on a subject during a fMRI examination in order to analyze the functional brain activation due to the tactile sensation caused by the electric current through the electrode. The AFNI analysis showed the effective activation of the primary and secondary sensorimotor areas in which the touch resides, and a good correlation between the stimulation block paradigm and the brain specific areas activity. These preliminary results demonstrate that electrocutaneous stimulation performed by means of our device produces robust and focal hemodynamic responses in somatosensory cortex that can be measured by fMRI technique.

Future developments will concern a more accurate discrimination of the specific sensations reproduced using the electric current and major efforts will be focused in finding a reliable relationship between mechanical and electric stimuli eliciting mechanoreceptors. It would be interesting to stimulate different locations in order to study how different the elicited patterns are.

Key Terms

Electrocutaneous (or electrotactile) Stimulation: The evocation of a tactile sensation using an electric current flowing through the skin, via electrodes placed on the skin surface.

Electrocutaneous Display: A device that stimulates nerve afferents within the skin by electric current and can be constituted by several surface electrodes.

Functional Magnetic Resonance Imaging (fMRI): Imaging technique based on blood oxygenation level dependent (BOLD) effect that allows localization of blood flow variations and oxygen consumption due to neuronal firing.

Intracutaneous Electrodes: Electrodes directly inserted into the nerves.

Mechanoreceptors: Cutaneous receptors that are sensitive to mechanical stimuli that are skin motion, skin stretch, pressure, vibration, points, edges, curvature.

Meissner Corpuscles: Rapidly adapting (RA) afferents that innervate the skin densely and are sensitive to dynamic skin deformation. They transmit a robust neural image of skin motion.

Merkel Cells: Slowly adapting (SA) afferents that are sensitive to points, edges, and curvature. They are responsible for form and texture perception.

Transcutaneous Electrodes: Electrodes placed in contact with the skin.

Electronic Test Management Systems and Hospital Pathology Laboratory Services

INTRODUCTION

Pathology can be described as the branch of medicine that deals with the nature, causes, and process of disease (McGrath, 2003). Pathology laboratories consider clinical and pathologic data and integrate them within an ever-changing context and then transmit a meaningful answer back to doctors and patients. In doing so, pathology laboratories play a key role in translating data into meaningful information (Hardwick, 1998). Pathology services are information intense organisational bodies that rely heavily on the proficient administration of information for patient care purposes (Travers, 1997). It is estimated that 70% of all important decisions affecting a patient's life involve a laboratory or pathology test, and pathology data represent an average of 70% of documents residing in electronic repositories (Becich, 2000).

Yet, pathology services are still widely seen as a backroom function with many people unaware of their importance. Pathology has been dubbed the "hidden science that saves lives" by the Royal College of Pathologists in England (The Royal College of Pathologists, 2000). Pathology departments are facing challenges from new information and communication technology (ICT) advances and the advent of managed care approaches to health care planning and delivery. The Review of NHS Pathology Services in England in 2006 emphasised the key role of pathology services in patient pathways that begins with the choice of the most suitable test or investigation, and proceeds to the interpretation and supply of clinical advice across clinical specialties (Review of NHS Pathology Services in England, 2006). ICT developments are behind many of the moves aimed at extending the role of pathology services beyond the basic request and reporting cycle (Friedman, 1996).

BACKGROUND

In the last 10 years, there has been much emphasis on the potential for computerised provider order entry (CPOE) systems to improve the provision and quality of health care (Doolan & Bates, 2002; Sittig & Stead, 1994). CPOE systems provide clinicians with the ability to place orders directly into computers linked to databases containing specific clinical information and decision-support software (Birkmeyer, Lee, Bates, & Birkmeyer, 2002). Many health care systems internationally are involved in the implementation of CPOE systems (Humber, 2004; NSW Government Action Plan for Health, 2002; The Leapfrog Group for Patient Safety, 2003). These systems are cornerstones for the establishment of electronic medical records (Hwang, Park, & Bakken, 2002).

Even though there has been substantial support for the implementation of CPOE systems (The Leapfrog Group for Patient Safety, 2003) along with a growing evidence base of their impact on the delivery of health care (Birkmeyer et al., 2002; Doolan & Bates, 2002) and its efficiency (Mekhjian et al., 2002), uptake has been neither rapid nor even (Ash, Gorman, Seshaddri, & Hersh, 2004). Some of the initial enthusiasm for

CPOE systems has been tempered by high profile cases of physician resistance (Berger, 2004), and implementation difficulties (Dykstra, 2002) along with concern about the huge investment and costs involved (Ash & Bates, 2005). Moreover, evidence about the unintended consequences of CPOE systems (Ash, Berg, & Coiera, 2004; Campbell, Sittig, Ash, Guappone, & Dykstra, 2006) and their potential to facilitate new types of errors (Koppel et al., 2005) have led to a renewed focus on the importance of evaluation (Ammenwerth & de Keizer, 2005; Friedman & Wyatt, 1997; Gell, 2001) as a means to improve their design and implementation.

So far the attention of the research and evaluation literature has tended to focus on high profile issues like medication errors, with less attention to areas like pathology laboratories and medical imaging, which together make up a major proportion of hospital orders (Abelson, Connelly, Klee, Maag, & Smith, 2001; Georgiou, Williamson, Westbrook, & Ray, 2007). CPOE is by definition a system-wide phenomenon with implications for the way the whole hospital and related entities work and function. These issues and challenges cannot be addressed by silo-based approaches where departments are considered independently of each other (Georgiou & Westbrook, 2006; Stablein et al., 2003). Pathology services are themselves made up of a number of organisational subparts each with their own ways of operating and functioning (Davidson & Chismar, 1999b), that will be affected by (and in turn affect) CPOE implementation (Wears & Berg, 2005). In the following sections, we draw on existing research evidence and literature reviews (Georgiou & Westbrook, 2006; Georgiou et al., 2007) alongside our own research experience to formalise an evaluation framework that can be used to assess the impact of CPOE on pathology services.

EVALUATING THE IMPACT OF CPOE ON PATHOLOGY PROCESSES

A systematic review by Georgiou et al. (2007) conceptualised three stages in the pathology test management process beginning with: (a) the decision of the doctor or responsible clinician (doctor or other delegated health professional) to order a pathology test; followed by (b) the processing of the test order in the pathology laboratory and ending with (c) a result that is communicated to the clinician and health care team responsible for the care of the patient, which will then be used as part of the clinical decision-making process (Georgiou et al., 2007). Each of these stages involves a dimension of time (Howanitz & Howanitz, 2001) which can be measured by turnaround time (TAT) indicators involving a number of measures including: (1) Laboratory TAT - the time taken for the test order to be processed in the laboratory before a result is issued, and (2) Total TAT—the total time it takes for an order to be placed, processed and a result issued (Georgiou et al., 2007).

Test Order Stage

Each of the stages in the pathology test order process can be assessed with a range of indicators that have been used to monitor the impact of CPOE systems on pathology services and patient care (Georgiou et al., 2007). The ability of CPOE systems to provide decision support will most likely have an effect on the first stage of the pathology test order process involving the clinician's decision about which test to order. Some researchers have paid particular attention to the ability of decision support systems to affect clinical compliance with practice guidelines (Overhage, Tierney, Zhou, & McDonald, 1997; Solomon et al., 1999). Decision support may also affect the appropriateness and volume of tests ordered. This is particularly the case for "redundant" tests, that is, tests that are repeated within an inappropriate time frame and provide no additional information (Bates et al., 1998; van Walraven & Naylor, 1998). The volume of tests can in turn be measured in different ways, for example, the number of tests per day (Hwang et al., 2002), or for a specified period, or per patient/admission (Tierney, Miller, & McDonald, 1990; Westbrook, Georgiou, Dimos, & Germanos, 2006). The volume of tests is likely to have a significant effect on test costs which can also be measured in various ways such as: total laboratory costs (Nightingale, Peters, Mutimer, & Neuberger, 1994) or per admission (Tierney et al., 1990). Some research has concentrated on the effect that CPOE systems have on work practices of clinicians and pathology services staff. One of the most important issues in this area involves quantifying the time spent ordering tests and its impact on other tasks (Shu et al., 2001). Another key concern in the area of work practices is ensuring that the new technology does not foster practices which affect the quality and safety of the ordering process (Koppel et al., 2005).

Test Processing Stage

Few studies have looked at the impact of CPOE on the pathology test processing stage (Georgiou et al., 2007). In part, this may be because existing laboratory quality control processes are used to ensure the accuracy and reproducibility of results (Tetrault, 2001), and CPOE is not expected to greatly impact this area. The greatest number of errors that occur during this stage are a result of incorrect transcriptions and specimen errors (Bonini, Plebani, Ceriotti, & Rubboli, 2002; Plebani & Carraro, 1997). CPOE is expected to affect this area because it provides a template for accurate and legible ordering by clinicians and eliminates the need for laboratories to record orders (Georgiou et al., 2007). One method that has been used to monitor the impact of CPOE systems in this area is to record the level of telephone activity between wards and the laboratory as a means of ascertaining whether computerised test management systems reduce the need to chase up missing or unclear documentation details (Ostbye, Moen, Erikssen, & Hurlen, 1997).

Test Result Application

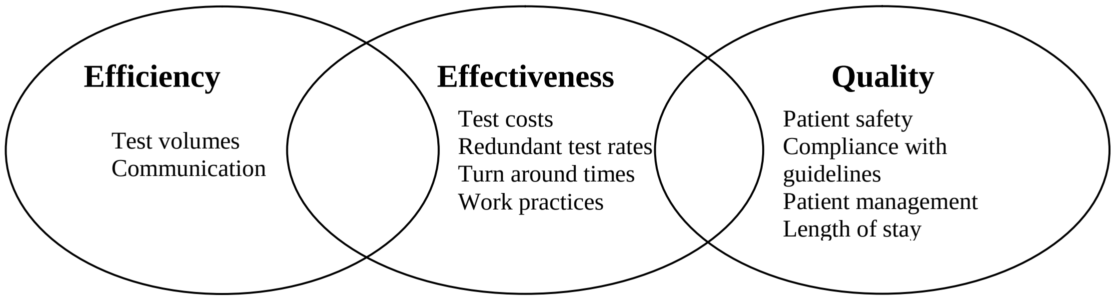
The final stage of the process involves the application of test results as part of delivery of patient care. This is the stage where the test process impacts directly on the outcomes and quality of patient care (Nevalainen et al., 2000). Evaluation of the role of CPOE in this stage of the test management process can include comparison of the time it takes to reach a diagnosis (Smith & McNeely, 1999) or to initiate treatment (Kuperman et al., 1999) when using a CPOE system. It is also possible to monitor the length of stay of patients (Neilson et al., 2004) and aspects of patient safety such as adverse events and mortality (Kuperman et al., 1999). CPOE systems have been shown to be successful at improving the speed with which test results are made available to clinicians. However, little research attention has been given to how individual clinicians are able to manage high volume and rapid transfer of clinical information (Kilpatrick & Holding, 2001; Murff et al., 2003; Poon et al., 2004).

FUTURE TRENDS: EVALUATION FRAMEWORK

The various measures of CPOE performance and impact provide a framework (see Figure 1) with which to assess (a) efficiency (value and efficacy of services in terms of cost, time and standards of practice) (Potter, 2000; Scriven, 1991); (b) effectiveness (the best possible outcome) (Potter, 2000) or success of the intervention (Scriven, 1991); and (c) quality (ensuring that the right thing is performed well (Brook & Kosecoff, 1988; Donabedian, 1988) and that the system meets identified needs and other relevant standards (Davidson, 2005)). But as the interconnected components of Figure 1 illustrate, the domains of efficiency, effectiveness and quality are not mutually exclusive and involve measures that clearly straddle domains (e.g., length of stay). One of the limitations of existing literature in this field is that evaluations are often based on indicators measured in isolation and disconnected from each other. It is important to maintain a holistic overview of indicator measurements, understanding that the net effect of any particular information system will consist of a balance of positives and negatives, and possibly successes and failures (Pawson, 2004).

The framework outlined in Figure 1 concentrates on quantitative measures of evaluation. In recent years there has been a growing number of researchers (Ammenwerth et al., 2004; Ash, Sittig, Seshadri, Dykstra, Carpenter, & Starvi, 2004; Greatbatch, Murphy, & Dingwall, 2001; Kaplan, 2001; Stoop & Berg, 2003) who have employed qualitative research methods to evaluate health information systems, including CPOE systems in pathology (Callen, Westbrook, & Braithwaite, 2006; Davidson & Chismar, 1999a; Georgiou, Westbrook, Braithwaite, & Iedema, 2005; Georgiou, Westbrook, Braithwaite et al., 2007). These approaches have contributed to a better understanding of the context (e.g., effect on the hospital and clinical environment) (Callen, Braithwaite, & Westbrook, 2006) and processes of ICT implementation including their impact on communication channels between departments and disciplines (Aydin, 1989; Dykstra, 2002). Together with quantitative research, they can add a valuable multimethod dimension to evaluation studies (Georgiou, Westbrook, Braithwaite, Iedema, Dimos, & Germanos, 2005; Westbrook, Braithwaite, Iedema, & Coiera, 2004).

Figure 1. Framework for assessing the impact of CPOE on pathology services



CONCLUSION

The implementation of CPOE systems is increasing internationally and there is a strong evidence base about their ability to contribute to the efficiency and effectiveness of health care delivery. However, this evidence has tended to be concentrated in a small number of United States' hospitals (Chaudhry et al., 2006; Shekelle, Morton, & Keeler, 2006). This means that the generalisability of this evidence is limited because these hospitals often have home grown systems that are not commercially available and which evolved over many years, mostly in academic teaching hospitals (Classen, Avery, & Bates, 2007). This has underscored the drive to extend and systematise the evaluation of CPOE systems across a range of diverse settings (Classen et al., 2007) including pathology services. Evaluation frameworks built upon existing evidence and utilising the experience of skilled practitioners and researchers can help to orient the evaluation process and provide comparative and generalisable data with which to optimise the effect of CPOE systems on patient care delivery.

KEY TERMS

Electronic Decision Support Systems: Access to knowledge stored electronically to aid patients, carers, and service providers in making health care decisions (National Electronic Decision Support Taskforce, 2003).

Computerised Provider Order Entry: Electronic systems that allow physicians (or other authorised staff) to enter hospital orders directly into a computer.

Evaluation: To determine the merit, worth, or value of something, or the product of that process (Scriven, 1991).

Impact: Change or (sometimes) lack of change caused by an evaluand (that which is being evaluated). Similar in meaning to outcome and effect (Davidson, 2005).

Indicator: A factor, variable, or observation that is empirically connected with the criterion variable (Scriven, 1991).

Pathology: Clinically-led diagnostic, laboratory, and post mortem services that cover a range of tests on blood and other human materials necessary for diagnosis and monitoring of a wide range of clinical conditions so that appropriate treatment can be given (Department of Health, 2004).

Quality: Merit or the extent to which an evaluand meets identified needs and relevant standards (Davidson, 2005).

Redundant tests: A reordered or repeated laboratory test that is ordered within an inappropriate time frame and provides no additional information (Bates et al., 1998; van Walraven & Naylor, 1998).

Turnaround Times (TAT): A frequently used measure by pathology services. Total TAT can be defined as the time of physician order request to when the physician reviews the result. Laboratory TAT measures the time a specimen arrives at the laboratory to the time of results dispatch.

Emerging Technologies for Aging in Place

Shirley Ann Becker
Florida Institute of Technology, USA

Frank Webbe
Florida Institute of Technology, USA

INTRODUCTION

Extraordinary societal changes in the United States have taken place from both human and technological perspectives. Life expectancy continues to increase, due to improvements in both medical care and technology. Older adults, 65 years plus, comprise about 12.4% of the United States population with about one in every eight Americans being in this age group (U.S. Administration on Aging, 2002). By 2030, the percentage will have increased to 20% of the total population representing twice the number as in 2000. Those 85 years and older represent the fastest growing group (He, Sengupta, Velkoff, & DeBarros, 2005).

Older adults in the United States not only are living longer, but many are staying longer in their homes before entering institutionalized care. Compared to past generations, an unprecedented number of adults sixty years and older are aging in place. In 1985, there were approximately 5.5 million functionally disabled elderly living in their communities and an additional 1.3 million living in nursing homes. Each of these figures is projected to double to 10.1 million and 2.5 million; respectively, by 2020 (Manton, 1989). This is significant from both individual and national perspectives in terms of the burden of skyrocketing healthcare costs.

The U.S. Bureau of the Census (Fields & Casper, 2001) has reported that more than 55% of older adults live at home with their spouse. The number of adults living *without* a spouse increases with age, with about 50% of women aged 75 years and older living alone at home. Many older adults prefer to age in place rather than in an assisted living facility (Riche & MacKay, 2005), citing independence and social interaction as being critical to their well-being (Hirsch, Forlizzi, Hyder, Goetz, Kurtz, & Stroback, 2000). Complicating the choice to age in place are health and other personal limitations that necessitate continuous care. About seven million older adults over 65 years are estimated to have mobility or self-care limitations (U.S. Administration on Aging, 2002).

Similar to other nations, the United States faces a critical challenge in dealing with an aging population that has unprecedented life expectancies. Emerging technologies offer the hope of allowing older adults to remain in their homes longer by empowering individuals to manage daily activities while dealing with chronic health conditions and age-related diseases. These technologies increasingly target a home environment whereby on a regular basis an individual can obtain assistance in performing daily living activities, stay connected to family and friends, manage medication, and be monitored for health-related changes. As important as these assistive technologies are for individuals and families, their potential for positively impacting the United States economy by changing the model of healthcare delivery is equally huge.

BACKGROUND

Recent advances in "assistive technologies" offer older adults the ability to function independently and to age with dignity in their homes and communities. The U.S. Administration on Aging (2005) formally defines an assistive technology as being any service or tool that helps the elderly or disabled perform activities they have always done, but must now do differently. Assistive technology includes communication equipment, computer access, tools for independent living, education, and mobility aids, among others. Table 1 provides a summary of current and emerging assistive technologies.

The availability of assistive technologies for an older adult often determines whether he or she is able to live independently or must move to an institutionalized environment. The National Council on Disability (1993) found that 80% of older adults who used assis-

Table 1. Types of assistive technologies with emerging trends

Type	Assistive Technology
Adaptive Switches	Devices that are used to adjust home systems, including air conditioners, computers, answering machines, and power wheelchairs among others. Emerging technologies include "smart homes" with sensing systems that manage the overall home environment.
Communication Aids	Technology that promotes social interaction, telecare, and other types of communication to promote functional independence. Emerging technologies include the use of Personal Digital Assistants (PDAs), personal computers, and tablets to connect an older adult to an external support system of family, friends, or healthcare personnel.
Computer Accessibility Devices	Software or hardware that supports computer and Web accessibility. This includes screen reader devices, specially designed keyboards, and others. Emerging technologies include user-interface designs of computer, handheld, and mobile devices that promote universal access.
Home Modifications	Construction or modifications that allow an older adult to overcome a physical barrier that might impede living at home. Emerging technologies are illustrated by sensor devices in the floors to detect falls.
Independent Living Aids	Technology that allows an older adult to function independently in the home. Grab bars in bathrooms and hallways are more traditional illustrations of this type of technology. Emerging technologies include medication management (e.g., talking medicine cabinet), and electronic prompts (e.g., close refrigerator), among others.
Mobility Aids	Technology that supports an older adult being mobile within and external to the home environment. Emerging technologies include Global Positioning Systems (GPS) built into mobile devices as a means of identifying a person's location outside the home.

tive technology were able to reduce their dependence on others. Assistive technologies not only support the aging adult, but also the family and friend caregivers. Most often, technologies that increase the independence of an older adult will decrease the time required for caregiving assistance (Mann, 2001). Assistive technology and home modifications have also been found to provide caregivers immediate relief from burden, reduce their stress, and help them provide care more easily and safely (Gitlin, Corcoran, Winter, Boyce, & Hauck, 2001). This is significant from an aging in place perspective, given that many adults with chronic conditions and age related diseases are cared for by an aging spouse may also suffer from a chronic medical condition.

Many of the emerging technologies are being developed to be used in both home and community environments. They provide an opportunity to improve independence, and safety thus promoting aging in place initiatives (Tran, 2004). Some research efforts are building on existing technologies in order to take advantage of communication and information infrastructures. The Internet along with online information sources, for example, offer a means for older adults to engage in lifelong learning and healthcare management thus promoting quality of life while aging in place. Recent advances in wireless and wired communication provide the technology for home monitoring systems, social interaction, and the potential for virtual support systems linking an older adult to geographically dispersed family and friends. Emerging areas of technology include artificial intelligence and robotics with the opportunity of providing intelligent feedback to the elderly living at home.

EMERGING TECHNOLOGIES

Two types of technologies are being developed currently that promote aging in place depending on the *category of impairment* associated with the individual. (Refer to the definitions in Appendix A of this article for a description of the three levels of impairment). Becker and Webbe's (2006b) Buddy Coordinated Healthcare System, and Scott and Gabrielli's (2005) Ho'alauna ("Good Neighbor") Tablet projects focus on older adults who have mild or moderate levels of impairment. The underlying concept is to utilize technology to promote independent functioning in both home and community environments. These projects are considered "noninvasive" in that the individual has control over data gathering and dissemination using the proposed technologies (Becker & Webbe, 2006a).

Other research projects, such as the Digital Family Portrait (Mynatt, Rowan, Craighill, & Jacobs, 2001) and the CareNet Display (Consolvo, Roessler, & Shelton, 2004; Consolvo & Towle, 2005) would support more severe levels of impairment through a home monitoring environment that utilizes sensors to gather information about daily living activities. Such detection provides the means to keep members of a support network (e.g., family, friends, and healthcare personnel) informed of the older adult's daily activities. These types of "invasive" technologies do not provide the older adult full control over data gathering and dissemination activities. These are automated as part of the home monitoring system that is put in place. (Table 2 further describes the aforementioned noninvasive and invasive technology research projects as illustrative of emerging technologies.)

These are only several of a significant number of research projects currently being conducted in university and laboratory settings. Many related projects have been or are being developed to promote aging in place. Academia and industry partners have answered the call to innovate technologies to address the looming healthcare crisis, due to the aging baby boomer population in the United States. One of the biggest obstacles, however, is that many emerging technologies are not being translated into products and services that are made available to older adult users. Eric Dishman of Intel Corporation (Beck, 2004) told the Senate Special Committee on Aging, "Our biggest problem nationally is an imagination problem, not a technology problem," in terms of government sponsoring research on assistive technologies for older adults with corporate investment opportunities.

Table 2. Assistive technologies illustrating the use of information and communication technologies (ICT) to promote aging in place

Project	Description
Buddy Coordinated Healthcare System	Handheld technology is used by the aging adult caregiver to assist in caregiving activities and monitor his or her own well-being and that of the older adult for whom care is provided. A PocketPC is used to gather information about daily living activities, emotions of the caregiver, behaviors displayed by the person receiving care, medication management, and other support systems. The PocketPC has the capability to transparently and unobtrusively link to the Internet thus sharing information gathered on the device via a family and friend web site. Family and friends use the Web site to foster sharing of the responsibilities associated with caregiving. Family and friends may otherwise not be actively involved due to geographic distance, work, children, and other commitments (Becker & Webbe, 2006b).
Digital Family Portrait	This project is part of Georgia Tech's Aware Home Research Initiative (http://www.awarehome.gatech.edu/). It provides a virtual connection between geographically distant family members to an older adult living at home. The technology, when fully developed, utilizes sensors to gather data about the older adult's health, relationships, and activities. This information would be shared electronically via the ambient display placed in a distant relative's home. The ambient display, presented as a digital picture frame, provides user access to detailed information. The information presented to the user is similar to information typically observed by a neighbor or another member living in the older adult's household (Mynatt et al., 2001).
Ho'alauna Tablet	The Ho'alauna Tablet project utilizes ICT to assist with nutrition, healthcare, financial management, and leisure activities, among others (Scott & Gabrielli, 2004). It is proposed that a TabletPC along with specialized software supported by Internet access assist older adults living at home to interact socially with family and friends, search the web, control home technology, receive emergency information and assistance, track health-related information, and participate in community events, social activities, and educational programs.
CareNet Display	This project uses the concepts of ambient display and home sensors to build a support network of family and friends (Consolvo et al., 2004). The ambient display, an interactive digital picture frame, provides information to a support network regarding the status of meals, medications, outings, activities, mood, falls, and schedules. The ambient display allows the user to view an older adult's daily activities and interactively access data through touch screen capability. Unlike the Digital Family Portrait, it allows for the sharing of sensitive data regarding medication and activities performed. The older adult would control shared access to personal information. The CareNet Display allows for data sharing of other members in the support network.

We have identified four underlying issues that are directly related to the crisis associated with technology transfer from the academic research setting to those who could benefit from these technologies. These issues have the potential to pose barriers to continued research on emerging technologies, thus impeding the efforts to promote aging in place. As such, these issues must be addressed to facilitate the development of assistive technologies. The issues and directions of development are described briefly:

1. **Usability in a real world setting:** Researchers need access to older adult volunteers to identify potential usability barriers that would impede technology transfer. Although the new technologies can be prototyped with young volunteer users, the special demands of the older end-user require in-vivo testing and iterative hardware and software modifications before introduction into a home environment.
2. **Patient safety:** Research that introduces new assistive technologies into the home environment must complement the human caregivers and take into account an increase in safety concerns. For example, existing caregivers may assume that the new technology and its keepers "looks out" for them and their family member so that normal precautions are reduced, including contact with their medical professionals. It is incumbent upon the researchers to train the caregivers that the new technology is truly *assistive* to them and under their control.
3. **Interoperability:** Currently, many projects are developed in isolation of one another, even though they may ultimately coexist within common venues. There must be a substantially greater national push for interoperability of technologies, even at the university level during the developmental phases. The field of assistive technologies is too fragile at the moment to host a "CDMA vs. GSM" type of competition.
4. **Social perceptions:** Corporations who shy away from the aging marketplace must be convinced that the potential is significant. The government has to be innovative in providing research funding not only to innovate but to transfer the technology to the commercial sector.

CONCLUSION

The United States and other countries are facing a significant challenge in dealing with the exploding healthcare costs associated with an aging population. There are already 34 million senior citizens in the United States with an impending explosion as the baby boomers begin to enter the retirement phase of their lives. There has to be an increased effort to provide both invasive and noninvasive assistive technologies to manage proactively the health and well-being of the aging population. This includes a significant emphasis on aging in place in order to reduce the costs associated with assisted living facilities and hospitals when older adults no longer can remain in their homes and communities.

Emerging technologies for aging in place provide additional benefits to a younger population with disabilities and chronic diseases. For many middle aged adults with chronic health conditions, assistive technologies provide the means to monitor healthcare proactively. For diseases such as diabetes, hypertension, arthritis, and others, assistive technologies offer the hope of better living from both longevity and quality of life perspectives. It would be important to address the issues of usability, safety, interoperability, and social perceptions as an integral part of assistive technology research.

Researchers, nonprofit organizations, industry, and the government are initiating collaboration in order to address these issues. Although more needs to be done to promote this collective effort to innovate technologies for aging in place, two recent initiatives serve as prototypes of the productive coalitions can be formed. The American Association of Homes and Services for the Aging (http://www.AAHSA.org) and Intel Corporation, for example, initiated the launching of the Center for Aging Services Technologies (CAST) with the objective of advancing technologies for older adults. The Alzheimer's Association along with industry partners has developed the Everyday Technologies for Ahzheimer's Care (ETAC) consortium to bring university researchers, nonprofit organizations, government, and industry together to advance assistive technology development while addressing the underlying issues identified in this article. These models both show the feasibility of academic/industrial/agency coalitions, and also through their already considerable outcomes show what products can ensue.

KEY TERMS

Aging in Place: Older adults remain in their homes and communities through the support of technology and assisted living services.

Assistive Technology: A device or system supporting an individual in performing a task that otherwise could not be done, or increases the ease and safety with which it is done.

Impairment Categories: The U.S. Department of Health and Human Services (http://www.hhs.gov) provides three categories of impairments with varying assistive technology needs. The *Mildly Impaired* category (e.g., mild arthritis) benefits from assistive technologies that enhance independent living. This may include special devices such as grab bars and modified cooking utensils. The second category, *Moderately Impaired,* include those who are functionally impaired in several daily living activities. For example, a person with arthritis may also have diabetes with circulation problems. Assistive technology supplements other types of support systems (e.g., home caregiver) in order to promote independent living. The third category, *Severely Impaired,* probably will benefit the most from emerging technologies. These individuals have multiple impairments that impact daily living.

Healthcare Technology: This term is typically used to encompass all technologies that are used in the healthcare field inclusive of both medical personnel and patients.

Patient Safety: Institute of Medicine defines patient safety as "freedom from accidental injury;" conversely, error constitutes "the failure of a planned action to be completed as intended or the use of a wrong plan to achieve an aim." (Kohn, Corrigan, & Donaldson, 2000).

Proactive Computing: Applications that are designed to anticipate an individual's needs and to take action to meet the needs on their behalf (taken from http://www.Intel.com's Web site on Health Research and Innovation).

Smart Home Technology: Devices used in a home environment to perform complex tasks that otherwise would be performed by the individual. They facilitate independent living by providing automated support of daily activities, security, building performance, and telecommunications.

Technology Assistance Act: Congress enacted the Technology Related Assistance Act of 1988 (P.L.100-407) to expand the availability of assistive technology services and devices to people with disabilities.

Enhanced Rheoencephalography

INTRODUCTION

A close monitoring of the cerebrovascular parameters is essential in some neurological diseases to prevent secondary brain insults. Persistent rises in intracranial pressure caused by oedema, tumours, or haematomas may decrease the cerebral blood flow (CBF) to values below the minimum required for neuronal survival (Lang & Chesnut, 1994).

As a method to evaluate CBF, Polzer and Schuhfried proposed in 1950 to apply the well-known impedance plethysmography techniques to the head, which was specifically referred to as Rheoencephalography (REG) (Polzer & Schuhfried, 1950). For this purpose, bipolar and tetrapolar electrode arrangements, named as REG I and REG II respectively, were used to measure the impedance changes of the head synchronized to the heartbeat. In REG I, a low-amplitude current is injected through two electrodes attached to the scalp, and the related electric potential difference is measured between these electrodes, whereas in REG II, a second pair of electrodes is used to measure the electric potential difference (Geddes & Baker, 1989). The latter technique reduces eventual artifacts caused by mechanical alterations in the electrode-skin interface of the current injection electrodes.

The REG signal was assumed to be induced by the time-varying nature of the mixture ratio of two biological conductors with different electrical conductivity: namely, blood and brain. According to this, REG would reflect the changes in cerebral blood volume (CBV) associated with the cardiac cycle (Lifshitz, 1970).

However, despite the great efforts made by the scientific community on REG research during three decades, the use of REG was not extended to the clinical practice after all, because REG ability to reflect the CBF was strongly questioned (Basano, Ottonello, Nobili, Vitali, Pallavicini, Ricca, Prastaro, Robert, & Rodríguez, 2001; Perez-Borja & Meyer, 1964). Detractors argued that a significant part of the injected current does not cross the skull, since the electrical conductivity of the skull is approximately 80 times lower than that of the scalp and brain. This means that most of the REG signal reflects the pulsatile changes in the scalp blood volume (SBV), rather than in the CBV (Laitinen, 1968). This disagreement, together with the development of the transcranial Doppler ultrasound technology, led to the abandonment of research on REG.

BACKGROUND

A sound review of the literature reveals that research on REG was very intensive during the fifties and sixties, due to the lack of reliable diagnosis tools for the assessment of cerebral blood flow (Hadjiev, 1972). However, modern neuroimaging techniques provide a great amount of information about the brain metabolism for diagnosis purposes. Yet, the idea of a noninvasive, portable, available-at-bedside, and low-cost device for real-time monitoring of the cerebrovascular system still seems attractive and necessary.

Recently, the physical principles of REG have been analyzed from a theoretical perspective for a better understanding of the mechanisms, by which the extra and intracranial blood flows contribute to the REG signal (Perez, Guijarro, & Barcia, 1999; Perez, Guijarro, & Barcia, 2000; Perez, Guijarro, & Barcia, 2004). The main findings of these theoretical studies explain the initial controversy on the origin of the REG signals, and can be summarized as follows: (i) most of the REG I signal is caused by the pulsatility of the extracranial blood flow; (ii) in some subjects, a set of tetrapolar electrode arrangements may exist to record a REG II free of extracranial information; and (iii) such electrode positions, and even their existence, are strongly dependent on the subject's physical constitution, particularly on his/her scalp thickness. In summary, previous theoretical results suggest that there is no universal electrode arrangement suitable for all individuals to register a REG II free of extracranial contamination.

Therefore, a REG II recorded from an arbitrary tetrapolar electrode arrangement contains information from both intra and extracranial blood flows, mixed in unknown proportions that, furthermore, depend on the used electrode arrangement. Attempts have been made in the past to cancel out the extracranial component from the REG signal. For instance, Seipel (1967) proposed a method to identify the contribution to REG by each one of the intra and extracranial arteries that supply the brain and scalp. It consisted in occluding some of the arteries, and then deducing their contribution by means of simple equations. However, this method was experimentally tested by Masucci, Seipel, and Kurtzke (1970), who did find no value for detecting, lateralizing, or diagnosing cerebral injury.

One unexplored way of extracting intracranial information from a REG signal could be to address the problem using the Blind Source Separation (BSS) approach. In BSS, a set of unknown signal sources is guessed from the analysis of a set of observations, each one of which is a mixture in unknown proportions of the sources. The extraction of the sources from the observations is achieved by taking advantage of some assumed property of the sources (Cardoso, 1998).

A practical example of BSS is the so-called cocktail party problem, in which the statistical independence of the sources is assumed, and its solution is reached by using the well-established Independent Component Analysis (ICA). Let us imagine a room where, for instance, three people are talking simultaneously. Three microphones placed in the same room at different sites will record a mixture of the speakers' voices, whose weights will depend on the speakers' distance to the microphones. This information mixture can be expressed as:

$$x_1(t) = a_{11}s_1(t) + a_{12}s_2(t) + a_{13}s_3(t) \quad (1)$$

$$x_2(t) = a_{21}s_1(t) + a_{22}s_2(t) + a_{23}s_3(t) \quad (2)$$

$$x_3(t) = a_{31}s_1(t) + a_{32}s_2(t) + a_{33}s_3(t) \quad (3)$$

where $s_i(t)$ are the speakers' voice signals, $x_i(t)$ the observations, and a_{ij} the mixture coefficients (i, j = 1,.., 3). Observe that both the mixture coefficients and the sources are unknown in these equations. In this example, it is reasonable to assume the statistical independence of the sources, so ICA can be applied to guess the sources and coefficients. An excellent illustration of the cocktail party problem, and ICA, can be found in Hyvärinen, Karhunen, and Oja (2001).

This mathematical tool could be of great interest in REG since, as commented above, a REG II signal can be regarded as the weighted sum of intra and extracranial information. However, statistical independence cannot be used here to separate the components, since scalp and brain perfusions are caused by the same event: the heart contraction. Therefore, to apply the BSS approach to REG, it is necessary to find a differential property between both components that could be mathematically formulated.

EXTRACTION OF THE INTRACRANIAL COMPONENT FROM THE REG: ENHANCED RHEOENCEPHALOGRAPHY

Mathematical Formulation

Let $R_1(t)$ and $R_2(t)$ be a pair of REG signals recorded simultaneously from a given subject at different electrode arrangements. Assuming the morphological invariability and negligible phase shift of both REG components (Perez, Guijarro, & Sancho, 2005), we can write:

$$R_1(t) = a_{11}C_{En}(t) + a_{12}C_{In}(t) \quad (4)$$

$$R_2(t) = a_{21}C_{En}(t) + a_{22}C_{In}(t) \quad (5)$$

where $C_{En}(t)$ and $C_{In}(t)$ are, respectively, the extra and intracranial components of the recorded REG signals normalized to unit variance (sources), and a_{ij} are the mixture coefficients that depend on the electrode arrangement. Both components and coefficients of the mixture matrix are unknown. Now, by subtracting an arbitrary ratio *K* in (4) from (5), we can define a function $F_K(t)$ as:

$$F_K(t) = R_2(t) - K\,R_1(t) = \\ (a_{21} - K\,a_{11})C_{En}(t) + (a_{22} - K\,a_{12})C_{In}(t). \qquad (6)$$

Then, the goal is to find a *K** value that cancels out the extracranial component term in (6). For this purpose, we exploit the following difference between the intra and extracranial blood perfusions. On the one hand, the quick rise in arterial blood pressure that follows a heartbeat causes an abrupt increment in the extracranial blood volume, which is responsible for the sharp drop of the extracranial component (Perez et al., 2005). In fluid dynamics terms, the extracranial blood flow measured, for instance, at the superficial temporal artery, will show a markedly pulsatile waveform. On the other hand, fast increases in CBV are not allowable within the rigid cranial structure, and therefore, CBF should show, comparatively, a smoother waveform. According to this, since *K* modulates the amount of extracranial blood volume information contained in $F_K(t)$, the searched *K** value will give a minimum value of the function cost:

$$J(K) = \left[\frac{d}{dt}\left(F_K(t)\right)\right]_{RMS}$$

where $J(K)$ measures the pulsatility of the $F_k(t)$ function, and the term RMS refers to the root-mean-square value. Then, the *K** value that minimizes (7) will transform (6) into:

$$F_{K^*}(t) = R_2(t) - K^*\,R_1(t) = (a_{22} - K^*\,a_{12})C_{In}(t) \qquad (7)$$

Although this procedure could be used to extract the morphology of the intracranial component from two REG II signals, a more interesting result can be obtained by using a REG I signal as $R_1(t)$. In this case, and assuming that the REG I signal is caused exclusively by the extracranial blood flow, the a_{12} term in (1) can be considered negligible, and $F_K{}^*(t)$ becomes the intracranial component of $R_2(t)$. This assumption agrees with previous clinical (Perez-Borja & Meyer, 1964) and theoretical (Perez, Guijarro, Sancho, & Navarré, 2006) studies.

Experimental Findings

Current research on this separation method focuses on demonstrating that the extracted REG component is actually of intracranial origin. This requires several approximations because there is no any gold-standard to compare the extracted REG component with other real-time CBV measurements.

In a first stage, the morphological invariability of the extracted component can be studied: since the morphology of the intra and extracranial components are different, the morphology of REG II should be expected to depend strongly on the used electrode arrangement used, whereas the morphology of the extracted component should keep constant throughout the scalp surface. To study this influence, the following experiment was performed on volunteers.

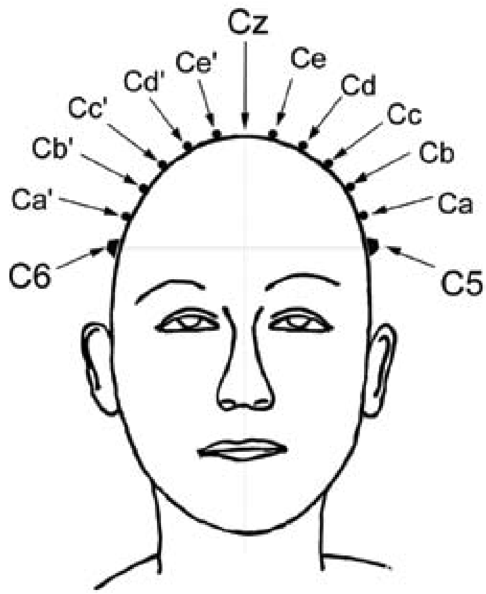
Twelve electrode sites were properly marked and cleaned on the subject's scalp surface: C5; C6; five equidistant electrode sites between C5 and Cz (labelled as Ca, Cb, Cc, Cd and Ce); and other five between C6 and Cz (labelled as Ca', Cb', Cc', Cd' and Ce') (Figure 1). The current injection electrodes were permanently fixed at C5 and C6, whereas the position of the REG II pickup electrodes was changed at each recording. This set of electrode arrangements has been chosen because it matches well with that used in previous theoretical studies (Perez et al., 2000; Perez et al., 2004). An additional pair of electrodes was used to record ECG (Lead I) for synchronization purposes.

Five records of REG I, REG II, and ECG channels were acquired during three minutes. While the current injection electrodes were kept at C5 and C6 during all the experiments, the pairs of pickup electrodes used at each recording stage were placed at sites Ca-Ca'; Cb-Cb'; Cc-Cc'; Cd-Cd'; Ce-Ce'.

To improve signal-to-noise ratio, REG sweeps time-locked with the R wave of the ECG were averaged using a time-window extended from 100 ms prior to the R wave, to 700 ms after it. The aforementioned method was used to extract the intracranial component of the REG II signal for each pair of the five averaged data sets.

Averaged REG I waveforms are shown overlapped in Figure 2a. For clarity, the traces have been normalized to unit variance; in this way, they can be read as $C_{En}(t)$ components if we assume the premise that REG I is of pure extracranial origin. The traces show a morphology very close to that previously identified

Figure 1. Schematic representation of the electrode positions used in the experimental section. Tetrapolar impedances were measured by injecting current through electrodes C5 and C6, whereas electrode pairs symmetrical to the coronal plane were used for voltage measurement



as extracranial REG component (Perez et al., 2005). The time interval in which the impedance rising edge occurs is marked on Figure 2a and transferred to the next figures for comparison. As expected, the morphology of the REG I traces is practically constant along the recordings since the injection electrodes keep invariable throughout the experiment.

On the contrary, a high variability of the $R_2(t)$ traces can be observed in Figure 2b. Statistical analysis of the correlation coefficients between each pair of $R_2(t)$ traces can be found in Perez et al. (2006). Within the time interval of the $R_1(t)$ rising edge previously presented in Figure 2a, replicas of that edge can be observed in the two electrode pairs closer to the injection one (Ca-Ca' and Cb-Cb'). Moreover, a rising edge of the impedance trace can also be observed, but unexpectedly inverted, in the impedance measurement recorded at the electrode pair placed farthest from the injection one (Ce-Ce'). This paradoxical result was predicted in Perez et al. (2004), and means that the sign of the influence (i.e., the sensitivity) of the extracranial component on REG II changes. Finally, all the intracranial $C_{In}(t)$ components extracted from R_2(t) traces show similar morphologies (figure 3). Within the R_1(t) time interval represented in Figure 2a, no sign of the rising edge is observed, the waveforms being similar to the R_2(t) traces recorded at intermediate electrode positions (Cc-Cc' and Cd-Cd').

Several facts suggest an intracranial origin of the extracted component: in particular, the inversion of the extracranial component of the REG II at Ce-Ce' suggests the existence of an electrode arrangement, probably in the neighboring of Cc-Cc' or Cd-Cd', from which a pure intracranial component could be directly recorded; the intracranial components generated by the model are morphologically similar to each other and to those recorded directly at Cc-Cc' and Cd-Cd'; their morphologies coincide with those reported in previous works in which the cerebral impedance changes were measured using intracranial electrodes (Laitinen, 1968); and, finally, the temporal derivative of the extracted component is similar to a typical transcranial Doppler trace.

The intracranial origin of the extracted component can be verified by means of the next experiment, which was carried out on volunteers. In this case, the current electrodes were placed at Cc and Cc' as shown in Figure 1, whereas the REG II pickup electrodes were attached to C5 and C6. In addition to recording the ECG signal for synchronization purposes, four photoplethysmographic sensors were fixed to the scalp surface at the frontal, occipital, and both temporal areas. The sensors consisted of a paired infrared transmitter and receiver, which provides an electronic signal that pulsates synchronized to the cardiac cycle in the same way as the scalp blood volume does.

Once the electrodes and sensors were placed, REG I, REG II, ECG and the four photoplethysmographic signals were acquired during two minutes. Then, a pneumatic cuff was inflated around the volunteer's head until the four photoplethysmographic signals turned flat. This means that the scalp blood flow has been arrested. Subsequently, all the channels were acquired for other two minutes. Like before, signal-to-noise ratio was improved by averaging the acquired data time-locked to the heartbeat as described above.

Preliminary results are summarized in Figure 4. This figure shows, overlapped, the intracranial REG component extracted from the first recording, and the REG I signal obtained when the cuff was inflated, both normalized to unit variance. As it was expected, REG I amplitude fell dramatically during the experi-

Figure 2. Set of five averaged REG waveforms recorded from the subject and normalized to unit variance; (a) REG I traces and time interval during which REG I impedance falls; (b) overlapped REG II traces and previous time interval transferred from A; positive Y axis represents increments in blood volume, and negative Y axis increments in impedance.

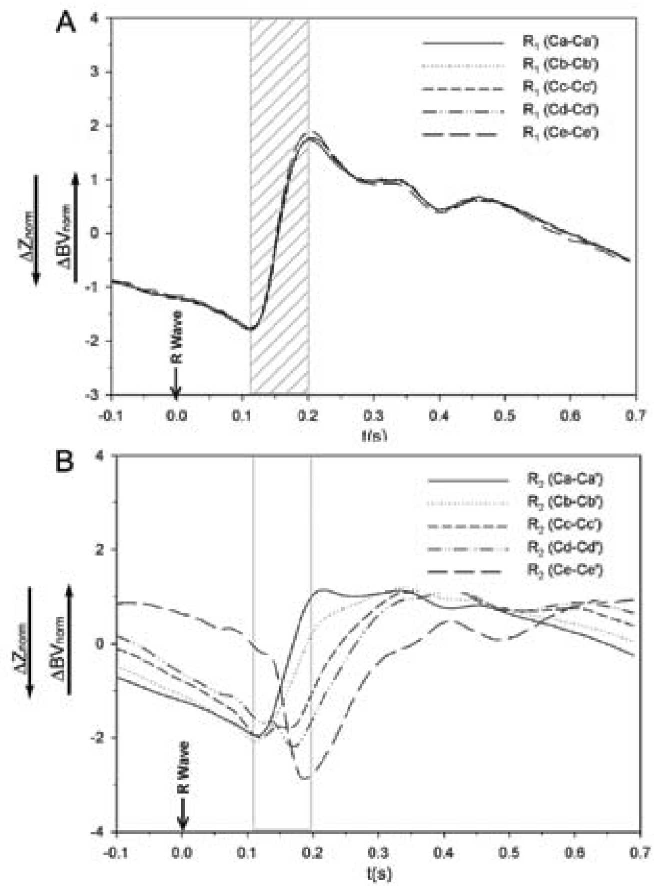


Figure 3. Intracranial components derived from each pair of REG signals by the proposed separation method. Boxed time interval has been transferred from that shown in figure 2A. Positive Y axis represents increments in blood volume and negative Y axis increments in impedance.

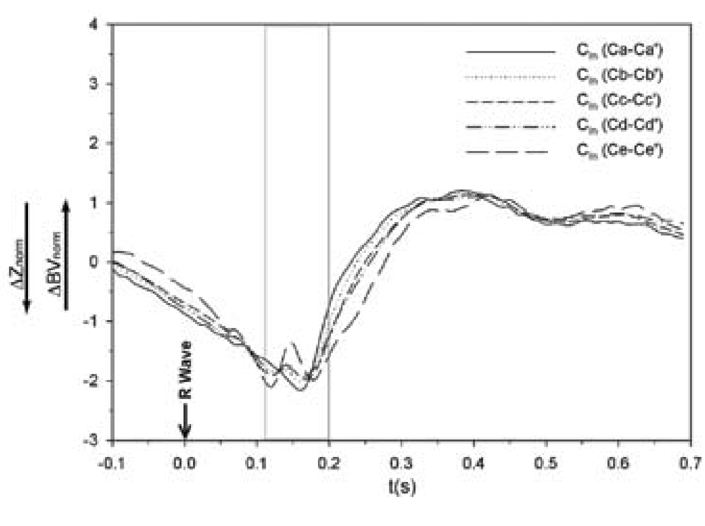

Figure 4. Intracranial component extracted by the separation method from a pair of REG signals ($C_{IN}(t)$) under normal conditions, and REG I recorded during scalp blood flow arrest forced by a pneumatic cuff ($R_1(t)$); boxed time interval has been transferred from that shown in Figure 2a; positive Y axis represents increments in blood volume, and negative Y axis increments in impedance.

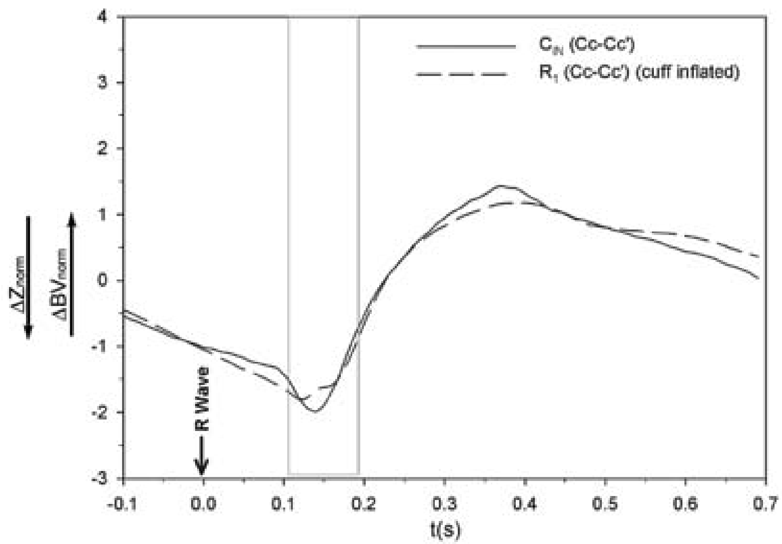

ment when the scalp blood flow was arrested, since the cuff cancelled mechanically the extracranial REG component. Therefore, the residual REG I signal can be attributed to a nonextracranial origin. On the other hand, both waveforms shown in Figure 4 are practically identical to each other, and none of them has signs of the rising edge of the $R_1(t)$ trace impedance. This result suggests that the REG component extracted by the described method is of a true intracranial origin. Finally, since the measured variable is the intracranial impedance changes associated with the cardiac cycle, further analysis is required to find suitable REG signal parameters for application in the clinical practice.

FUTURE TRENDS

An effective separation of the two REG components requires to impose at least two constrains. The separation procedure described here is based on the physiological differences between the intra and extracranial blood flow, and assumes an exclusive extracranial origin of REG I. Although these conditions have proved to be effective, some other boundary conditions can be defined to improve the algorithm. In this sense, some other function cost could yield better results. Therefore, further research on these aspects would be needed.

Indeed, although the intracranial REG component could be completely separated from the raw signal, it is necessary to identify the appropriate parameters of the intracranial component that could be useful in the diagnosis and treatment of neurological diseases.

CONCLUSION

Research on REG was neglected, because the signal was strongly disrupted, and even buried, by an inherent extracranial artifact. Recent contributions to REG knowledge allow understanding its physical basis, and explaining some previous paradoxical results. The separation method of the intra and extracranial REG components described here, along with the preliminary results presented, brings some light to the classical problem of the REG, and makes it possible to set a new approach for further research on REG oriented to the clinical practice.

KEY TERMS

Bipolar Rheoencephalogram (REG I): Pulsatile impedance changes of the head related to the cardiac cycle that are measured by injecting a small current between two electrodes attached to the scalp surface and recording the electric potential difference generated between them.

Blind Source Separation: A part of Signal Processing that studies algorithms to extract a set of unknown signal sources from the analysis of a set of observations, each one of which is a mixture in unknown proportions of the unknown signal sources.

Electrical Impedance: Measure of the opposition to the flow of a sinusoidal alternating electric current.

Extracranial REG Component: Part of a REG signal that is caused by the pulsatility character of the blood flow in the extracranial tissues.

Intracranial REG Component: Part of a REG signal that is caused by the pulsatility character of the blood flow in the intracranial tissues.

Photoplethysmography: Technique to estimate the pulsatile changes of the blood volume in a tissue by means of the measurement of the light reflected on or transmitted through that tissue.

Rheoencephalography: Electromedical technique used to assess the cerebral blood flow (CBF) by noninvasive electrical impedance methods using electrodes attached to the scalp surface.

Tetrapolar Rheoencephalogram (REG II): Pulsatile impedance changes of the head related to the cardiac cycle that are measured by injecting a small current between two electrodes attached to the scalp surface and taking the electric potential difference between another pair of electrodes.

EONS an Online Synaptic Modeling Platform

University of Southern California, USA

INTRODUCTION

The nervous system is composed of billions of interconnected neurons. These neurons communicate with each other primarily through fast chemical synapses. Such category of synaptic transmission involves (i) the conversion from electrical to chemical signal at the presynaptic membrane; (ii) the chemical transmission (diffusion of neurotransmitter) across the synaptic cleft; and (iii) the conversion from chemical to electrical signal at the postsynaptic membrane. Chemical synapses, although representing the smallest unit of communication between two neurons in the nervous system, comprise a complex ensemble of mechanisms. Understanding these mechanisms and the way synaptic transmission occurs and is regulated by activity is critical for our comprehension of central nervous system (CNS) functions in general and learning and memory in particular.

The objective of the work presented here is to develop a computational tool designed specifically for the study of the complex mechanisms that occur at chemical synapses. This tool should enable students and researchers (biologists with very little training in computational biology, as well as experienced modelers) worldwide to study the roles of diverse parameters that impact synaptic transmission from presynaptic to postsynaptic depolarization in an integrated modeling platform, using an easy, user-friendly and modular graphical interface.

BACKGROUND

Computational neuroscience has since its inception been mainly focusing on capturing the essential features of biological systems at multiple spatiotemporal scales, from membrane currents, protein and chemical coupling to network oscillations and learning and memory. These computational models are used to test hypotheses that can be directly verified by current or future biological experiments.

Recent technological advances have provided a better understanding of the mechanisms involved in synaptic transmission and integration; in particular, calcium imaging (Oertner, Sabatine, Nimchinsky, & Svoboda, 2002) and more accurate electrophysiological measurements have provided precise information on calcium concentration and dynamics (Oakley, Schwindt, & Crill, 2001), density, and types of channels and receptors, as well as different molecular pathways.

Likewise, the collection of tools available for computational approaches in biology has also grown significantly in recent years. This collection contains (as a nonexhaustive list): Neuron, ECELL, BioSpice, MCell, Genesis, and Virtual Cell (more information is available on their respective Web sites). Among those tools, modeling platforms have been developed to study complex cellular mechanisms. Some approaches focus on studying very specific mechanisms in simple geometries (Bennett, Farnell, & Gibson, 2000; Matveev, Zucker, & Sherman, 2004), while others study cellular mechanisms in complex and up to three-dimensional geometry (MCell) and offer a much more general framework (virtual cell).

Chemical synapses have been the subject of extensive research very early in the history of neuroscience (Rall, 1974). They have been shown to play a significant role in learning and memory; thus, synaptic structure is a critical determinant of synaptic properties, while temporal changes in postsynaptic calcium concentration and CaMKII or phosphatase activation generated by various stimulation conditions are believed to be good predictors for the induction of Long Term Potentiation

(LTP) or Long-Term Depression (LTD). Furthermore, chemical synapses also constitute a primary target for a multitude of drugs used in pathologies affecting the central nervous system (such as AMPAkines or NMDA receptor antagonist in the case of Alzheimer's disease).

The parameters that affect the efficacy of chemical synapses are numerous. A nonexhaustive list would include presynaptic mechanisms (calcium channels kinetics and distribution, presynaptic calcium binding and buffering mechanisms, kinetics of vesicle cycling, calcium extrusion from the terminal, and so forth), synaptic mechanisms (diffusion of neurotransmitters in the synaptic cleft, reuptake mechanisms, width of the cleft, relative position of the release site with respect to the receptors, and so forth), and postsynaptic mechanisms (receptor affinity and distribution, channel-gated kinetics, second-messenger pathways, postsynaptic spine geometry, and so forth).

Given the complexity of the mechanisms involved and the importance of chemical synaptic transmission in the central nervous system, we believe it is of paramount importance to develop a computational platform to specifically study the contribution of different parameters to synaptic transmission and regulation.

MAIN FOCUS OF THE ARTICLE

Requirements, Architecture of EONS

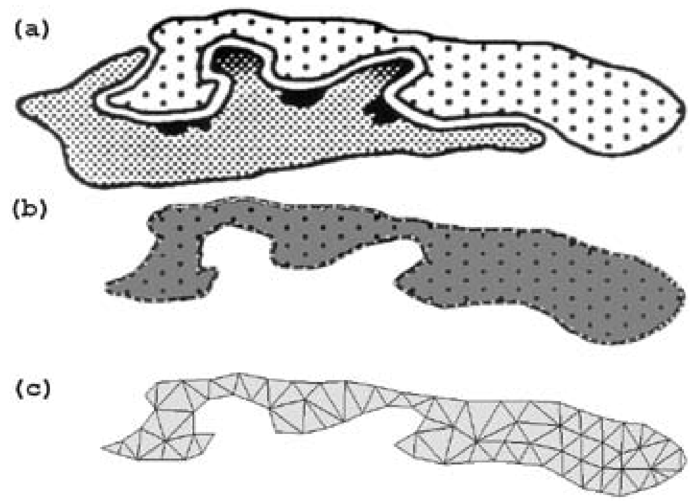
The EONS synaptic modeling platform is an integrated modeling framework that allows the user to specify in a structured environment using a graphical user interface the characteristics of the synaptic elements one wants to study. From a computational standpoint, EONS consists of a Java WebStart application that can be downloaded from the World Wide Web (http://eons.no-ip.info). The application communicates with a central database in which various models and elements are stored. Hence, users can save and retrieve models and/or parts of these models.

The platform contains models, structures, elements, reactions, and simulations. Models are entities in which all simulated components are defined. They represent the whole system one is interested in. This system can be an entire synapse, or simply a calcium channel. Structures are containers for modeling elements. A container can be conceptual (one can think of it as a dimensionless toolbox in which several elements can be grouped) or can become a physical container when associated to a specific geometry. It then adopts the dimensions of the two-dimensional mesh with which it is associated. A model can contain several structures (e.g., presynaptic, cleft, postsynaptic, and so forth). Elements are unitary entities that can be added or removed from the rest of the model. An element contains parameters which can be constant or variable. As an example, an element can be a calcium channel, a calcium pump, or a postsynaptic receptor. Elements interact with their environment. These interactions are described as Reactions in EONS. Reactions represent a set of mathematical expressions that describe the events or interactions occurring in the system. Simulations represent the actual in-silico experiment. A simulation can solely be run on an entire model. Results of a given simulation are observed in the form of graphs and an array of values for every time step of the simulation.

Mathematics

The description of biological models and their subsequent computation often requires mathematical tools. EONS uses the linear algebra module available in jScience (Dautelle, 2006) to generate matrices and calculate the values of its coefficients. This is used in particular for the diffusion process using Finite Element Method (FEM). In the same way, modeling requires the users to define the behavior of the elements they intend on modeling. To do so, EONS allow users to enter their own sets of mathematical expressions and parses these expressions using a mathematical expression parser called Java Math Expression Parser (JEP) (Funk & Morris, 2006). JEP is a Java package for parsing and evaluating mathematical expressions. It supports user-defined variables, constants, and functions. A number of common mathematical functions and constants are included (see reference Web site). To complement the functions available in JEP, a set of mathematical methods has also been implemented to serve the specific needs of physiological and cellular modeling which require the use of different solving methods for ordinary differential equations. Hence, numerical methods such as forward Euler, backward Euler, and Runge-Kutta 2nd and 4th order have also been implemented.

Figure 1. Creation of the 2D mesh. (a) Initial raster contour drawn from the EM picture. (b) Creation of the to-scale contours (white dots around the presynaptic terminal. (c) Output of mesh2D mesh generation program that is used as an input to EONS. The triangles form a mesh through out the geometry, where each vertex in called a node.



Modeling Synaptic Elements

EONS already contains a library of synaptic models. As of the redaction of this manuscript, those elements include calcium channels (L, N and T type channels) as well as postsynaptic elements such as AMPA and NMDA receptor channels. This library can easily be expanded to contain other elements such as calcium pumps, deterministic vesicular release, exchange and reuptake mechanisms, and so forth. The AMPA receptor channels modeled are the 5-states receptor introduced in (Patneau & Mayer, 1991) and the 7-states described in Jahn, Butler, and Franke (1998). The NMDA receptor channel modeled is the 11 states model presented in (Lester, Tong, & Jahr, 1993).

As an example, Figure 2 illustrates the results obtained during the simulation of the 5-states AMPA receptor channel. The input to the model is a pulse of glutamate. In this case, no diffusion is applied to the model (results of the diffusion process will be explained in details in the next section). The model is stated as a set of 5 ordinary differential equations, each represented in EONS using the syntax presented in section (b) of Figure 2.

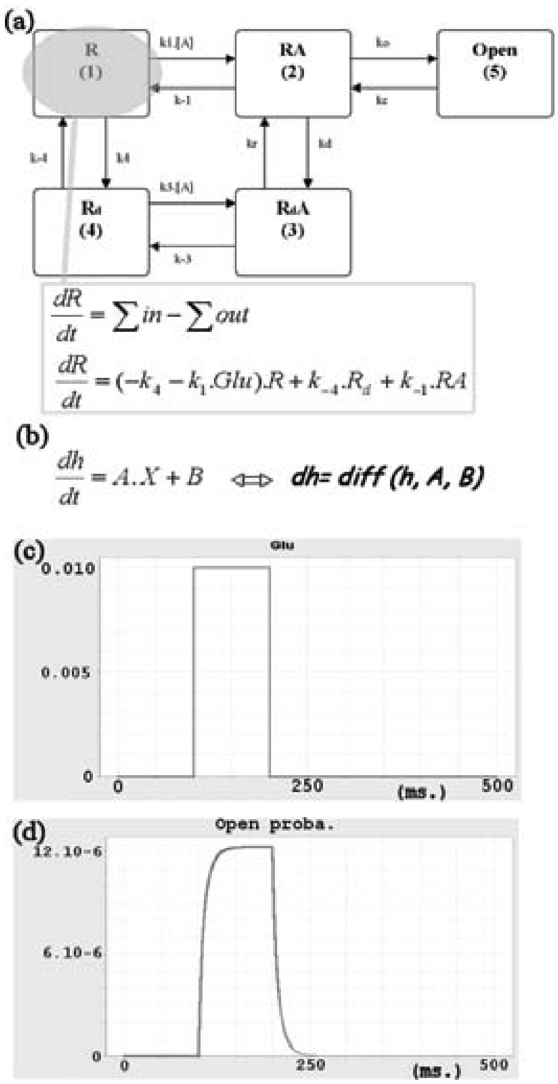
Molecular Diffusion: From Image to Mesh

In most current approaches to modeling relevant to our problem, the regions of interest are often simplified with basic geometrical shapes (Smith, 1996). Hence, information that depends on the spatial organization of molecules and cellular organelles cannot be accommodated.

In EONS, we propose to retain this critical information and to model diffusion in realistic complex geometry using finite element method. The first step in this process consists in tracing the contours of the structure of interest using real geometrical information (i.e., electron microscopy picture) and scaling them to the original size (generally in nanometers). Then, we use an external C program (Karamete, 1992) to generate the mesh which will be uploaded into EONS. These steps are illustrated using a perforated presynaptic terminal (Geinisman, 1993) in Figure 1.

The utilization of this finite element method allows us to discretize the computational domain by approximating the continuum problems (Ghaffari-Farazi, Liaw, & Berger, 1999). The diffusion equation in the continuum structure is:

Figure 2. 5-states AMPA receptor channel modeling in EONS. (a) Kinetic schema of the receptor. The ordinary differential equation generated for state R is represented. (b) Ordinary differential equation and its corresponding syntax in EONS. (c) Input of the model: Pulse of glutamate (10 µM. for a duration of 100 msec during a 500 msec simulation with a 0.01 msec time step). (d) Output of the model: open probability of the associated channel.



$$\frac{\partial c(x,y,t)}{\partial t} = D_c.\{\frac{\partial^2 c(x,y,t)}{\partial x^2} + \frac{\partial^2 c(x,y,t)}{\partial y^2}\} - B(t)$$

where c(x,y,t) represents the concentration function, Dc is the diffusion coefficient (for free calcium ions, its value is 2.2 . 10-6 cm2/sec in the cytoplasm (Jackson & Redman, 2003)). B(t) is the buffering process when it is assumed to be immobile and uniformly distributed.

In the presynaptic terminal, the process of calcium binding to buffers occurs in a much faster time scale than diffusion, and local equilibrium is rapidly reached between free and bound calcium ions (Crank, 1975). Therefore, the above equation can be approximated by:

$$\frac{\partial c(x,y,t)}{\partial t} = \frac{D_c}{1+\beta}.\{\frac{\partial^2 c(x,y,t)}{\partial x^2} + \frac{\partial^2 c(x,y,t)}{\partial y^2}\}$$

where β is the ratio of bound to free calcium in the cytoplasm.

To discretize the computational domain, we define a shape function N such that the value of the concentration is equal to the discrete values of [c] on the points of the mesh, which in the case of one triangle yields:

$$c = \sum_{i=1} C_i.N_i(x,y) = \begin{bmatrix} C_1 & C_2 & C_3 \end{bmatrix}.\begin{bmatrix} N_1 & N_2 & N_3 \end{bmatrix}^T = C.N^T$$

The utilization of Galerkin principle applied to the diffusion equation yields:

$$Dc.\int_S \nabla c.N.n.dS$$
$$- D_c.[c]\int_V (\frac{\partial N^T}{\partial x}\frac{\partial N}{\partial x} + \frac{\partial N^T}{\partial y}\frac{\partial N}{\partial y})dx.dy$$
$$-[\dot{c}].\int_V N^T.N.dx.dy \quad = 0$$

Solving this system gives us the values of $[\dot{c}]$, values of the gradient of concentration in the mesh and hence the values of the concentration at every node at the next iteration.

Modeling Diffusion in EONS

Simulating diffusion in complex arbitrary geometrical shapes can easily be done in EONS. Accessing the diffusion method is done using the following statement:

$$\text{var}\,iable = FEM\,(\text{"}mesh\_name\text{"},\ initial\ concentration,\ diffusion\ coefficient)$$

The effect of this mathematical expression is twofold: (i) it initializes a matrix (named "Variable") according to the specified mesh in which every cell contains the value of the initial concentration provided as second parameter, and (ii) it calculates the diffusion throughout the simulation of a molecule for which the diffusion coefficient in the medium is given as third parameter. In order for a specific element to have an effect on the concentration at a specific location, one must apply the function:

$$inject(mesh\_matrix,\\ \quad position\ in\ the\ mesh,\\ \quad \mathrm{var}iable\ to\ be\ added)$$

For a calcium channel, for example, the increase in concentration observed when the channel is in the open state is added to the mesh matrix at the position where the channel is located. To determine the effect of geometry on synaptic function, it is important to have access to the value of the concentration of a molecule at every position throughout the mesh. To do so, it is possible to simulate a recording electrode at any position on the mesh using the function:

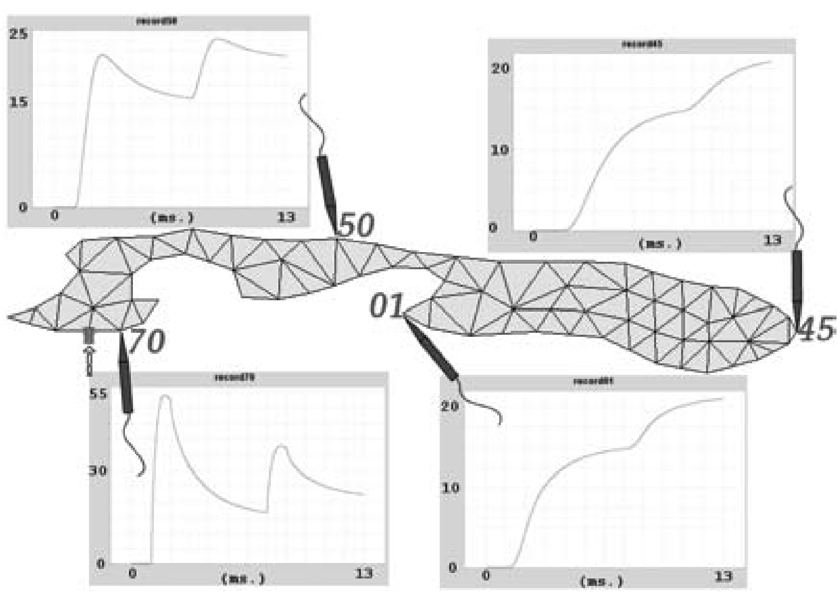
$$record(mesh\_matrix,\\ \quad position\ in\ the\ mesh)$$

Initial results show that the nonoptimized computation time needed to calculate the diffusion in a presynaptic terminal such as the one presented in Figure 3 is equal to 10 minutes for a 12 msec simulation on a 3.2 GHz Pentium workstation (with a time step equal to 0.1 μsec).

FUTURE TRENDS

The current version of the synaptic modeling platform presented here can handle a large number of models as well as reaction-diffusion processes. However, many further enhancements are planned. There is currently no way to specify a nonuniform population of molecules in a physical space, such as calcium-binding molecules in the presynaptic terminal (Matveev et al., 2004). The current library of models will be extended to include more complex molecular pathways involving in particular G protein coupled receptors, second messenger pathways, and endogenous feedback from postsynaptic elements to presynaptic terminals. The

Figure 3. Virtual simulated electrodes and their corresponding plots. These "electrodes" record the concentration of calcium at different locations throughout the presynaptic terminal (mesh containing 86 triangles) following a paired-pulse depolarization (0 mV and 1 msec long with a 6 msec interval) with calcium entering the terminal through one N-type calcium channel with no buffering mechanisms.



addition of more pathways will provide opportunities to study the synaptic system as a whole, but also allow us to simulate pathologies and the effect of drugs on synaptic transmission. In the same way, work will be done with respect to compatibility between EONS and other modeling platforms. This will enable the interchange of models between modeling tools, an example of which would consist in building a realistic neuron with the Neuron platform while incorporating synapses modeled with precise dynamics using EONS. Strong modularity between computational tools certainly bodes well for the future of the field of computational biology.

In its current state, EONS provides both researchers and students with a well-defined environment for testing specific hypotheses about the dynamics of multiple presynaptic mechanisms, such as the type of Ca2+ channels, buffering mechanisms, Ca2+ pumps, diffusion coefficients, binding proteins, and so forth, as well as several key postsynaptic mechanisms, such as the kinetics of AMPA and NMDA receptor-channel subtypes. In addition, one of the unique features of EONS with respect to other neural modeling tools is its ability to preserve the effect of synaptic geometry, for example, the relative locations of presynaptic Ca2+ channels and neurotransmitter release sites, the relative locations of presynaptic release sites and postsynaptic receptor-channels, and the relative numbers and locations of postsynaptic receptor-channels, while integrating mechanisms that are both pre- and postsynaptic.

CONCLUSION

Biological organisms are of extreme complexity. Modeling such complexity is not trivial: first, it involves the precise knowledge of all or at least a large number of the mechanisms involved. Then, once the details pertaining to those mechanisms are understood, one must model them in the most accurate manner. The amount of work involved in these tasks is tremendous and years to come will see many significant advances in the field of neurocomputation. The first challenge will come from the large number of elements, the even higher number of interactions between them and the complexity of interrelated pathways. The second challenge will come from the multihierarchical structure of organisms which span from a multitude of elements ranging from the nanoscopic level to an elaborate structured macroscopic level. Finding solutions to integrate these two levels of complexity will constitute the key to accurately model complex systems.

Although consisting of a single unit of communication between two neurons, chemical synapses are the siege of a very large number of phenomena and molecular interactions which without any doubts help shape the way we perceive, learn and remember. The research presented here provides a representative approach to the problem of modeling chemical synapses. We focused our attention primarily on the EONS synaptic modeling platform as a novel integrated framework containing both presynaptic terminal and postsynaptic density with modular geometry. We described the elements currently modeled and the main characteristics of the approach and presented future research directions that will help extend the features of the platform and further strengthen our knowledge of chemical synaptic transmission and of the mechanisms involved in learning and memory. We also expressed our belief for the need of integrated modeling environments to allow the field of neurocomputation to study beyond unitary mechanisms and take into account interrelated phenomena that code much of the complexity encountered in the central nervous system.

KEY TERMS

AMPA, NMDA, mGluR Receptors: Different subtypes of glutamate receptors. AMPA and NMDA receptors are ionotropic (directly linked to an ion-channel) while the mGluR family of receptors is metabotropic (indirectly linked with ion-channels through signal transduction mechanisms).

Chemical Synapses: Chemical synapses are specialized junctions through which cells constituting the nervous system signal to one another and to non-neuronal cells such as muscles or glands. They represent key elements regulating communication between neurons in neural circuits.

Finite Element Method: Finite element method allows the calculation of diffusion in complex spaces by discretizing the continuous computational domain. The diffusion equation is then solved as a series of differential equations in each discretized element of the domain.

Glutamate: Glutamate is the most abundant excitatory neurotransmitter in the mammalian central nervous system. It is stored in vesicles and its release is triggered by nerve impulses.

Java Webstart Application: Java is an object-oriented programming language developed by Sun Microsystems. It allows the development of Webstart applications that can be downloaded from the Internet and run in a platform-independent manner.

Long Term Potentiation: Long Term Potentiation is generally considered to represent a cellular mechanism underlying certain forms of learning and memory. Long term potentiation consists of an increase in the strength of a chemical synapse that lasts from minutes to several days or weeks following a series of short, high-frequency electrical stimuli.

Postsynaptic Density: The postsynaptic density is a membrane specialization that concentrates neurotransmitter receptors and associated proteins to respond rapidly to the presence of neurotransmitter in the space separating the two neurons (referred to as the synaptic cleft).

Ethical Decision-Making in Biomedical Engineering Research

Monique Frize
Carleton University, Canada
University of Ottawa, Canada

Irena Zamboni
Carleton University, Canada

INTRODUCTION

To be ethical and professional are terms that are synonymous with being an engineer. The work of engineers frequently affects public safety and health, and can influence business, and even politics. Professional Engineering Associations provide ethical guidelines so that engineers will know how to avoid misconduct, negligence, incompetence, and corruption, which could lead to formal complaints and discipline. Knowledge about ethical decision-making guides engineers facing complex and difficult moral dilemmas (Andrews, 2005, pp. 46). Biomedical engineers doing research and development will undoubtedly be involved in projects that impact humans and/or animals, and thus must be informed on all aspects of ethics that guide such research. They should be particularly aware of the specific guidelines of the institution where the work is to be carried-out and be familiar with the application process to obtain a certificate, allowing the research to proceed. There is clearly a need to guide biomedical engineering students and practitioners in performing a balanced analysis of difficult questions and issues, while respecting societal values that may differ greatly from their own (Frize, 1996; Frize, 2005; Saha & Saha, 1997; Wueste, 1997). There exists a number of articles discussing biomedical engineering and ethics specifically aimed at clinical engineers (Goodman, 1989; Saha & Saha, 1986). These are helpful readings for anyone involved in biomedical research or clinical engineering.

RELEVANCE OF ETHICAL THEORIES FOR DECISION-MAKING IN BIOMEDICAL ENGINEERING RESEARCH

Morality is defined as what people believe to be right and good, and the reasons for it. There are typical rules of conduct describing what people ought and ought not to do in various situations. Ethics is the philosophical study of morality. It is a rational examination into people's moral beliefs and behavior, the study of right and wrong, of good and evil in human conduct.

Several ethical theories exist, but some are more relevant for decision-making for engineers than others. For example, theories of Subjective Relativism and Cultural Relativism have limited utility in ethical decision-making, as they encourage decisions based on individual or cultural perspectives. The Divine Command Theory, based on particular religious beliefs which can vary from one religion to the other, also has limited value for this type of decision-making. Theories such as Kantianism, Act Utilitarianism, Rule Utilitarianism, Social Contract, Rights Theory, and Rawl's Theory of Justice appear to be more helpful for decision-making related to biomedical research.

Subjective Relativism (SR): SR is a theory where different individuals or groups of people can have completely opposite views of a moral problem, and both can be considered right. Persons decide right and wrong for themselves. The case for supporting this point of view is that well-meaning and intelligent people can have opposite opinions about moral issues, but the line between doing what you think is right and doing what you want to do is not sharply drawn. For example, we can rationalize bad behavior or allow persons to decide right and wrong for themselves. SR makes no moral distinction between the actions of different people, as, for example, between Hitler and Mother Teresa. SR is based on the idea that there are no universal norms. However, as we see in several of the theories described further, there are some universal moral principles and norms. Examples are: not to kill, not to break promises, to be fair and honest. The self-defeating nature of SR does not make it a workable theory for ethical decision-making in biomedical engineering research (Quinn, 2005, pp. 53–55).

Cultural Relativism (CR): CR is the ethical theory where the meaning of right and wrong rests with a society's current moral guidelines. Folkways get institutionalized into these guidelines. This is based on the fact that in the distant past, survival was a group activity. This can still be true in some instances, as in situations of security against crime, war, or terrorism. CR is folkways turned into customs, traditions which are uniform, universal for the group. But with time, they can become more and more arbitrary and imperative. Morality of the group is the sum of the taboos and prescriptions in the folkways by which right conduct is defined for a particular time. For example, 10,000 years ago, most activity was food gathering. Today, population explosion has created huge environmental problems which can destroy the planet. So we need different rules of conduct in various eras. Anthropologists have documented important differences on what is proper conduct in various epochs and regions. However, just because two societies have different views about right and wrong does not imply that they ought to have different views. Perhaps one society has "good" guidelines, and another has "poor" ones. CR does not explain how an individual determines the moral guidelines of a particular society. Another consideration is the concept of human rights. If CR allows acts that fundamentally breach human rights, then this should not be tolerated. This leads to the next objection to this theory: CR does not explain how moral guidelines evolve. CR suggests there are no universal moral guidelines, and gives tradition more weight in ethical evaluations than facts or reason; it does not provide a framework for reconciliation between cultures in conflict. The value of each society can lead to actions that harm the other, yet cultural relativism says each society's moral guidelines are right. CR does not provide a way for the two sides to find common ground. All societies, in order to maintain their existence, must have a set of core values; for example, caring for helpless newborn babies; telling the truth; prohibition of assault, rape, and murder. CR has significant weaknesses as a tool for constructing ethical evaluations for a diverse audience (Quinn, 2005, pp. 55–59).

Divine Command Theory (DCT): Judaism, Christianity, and Islam are religions based on a god, and DCT is based on the idea that good actions are those aligned with the will of God; bad actions are those contrary to the will of God; we owe obedience to our Creator, and God is all-good and all-knowing, the ultimate authority. There exist many holy books, and some of their teachings disagree with each other. It is unrealistic to assume that a multicultural secular society (separation of state and church) can adopt a religion-based morality. A society's moral guidelines should emerge from a secular authority. Moreover, some moral problems are not addressed directly in scriptures, as, for example, those arising from Internet or information technology. Even if an analogy was to be used, who interprets it? This becomes a subjective process. The fact that the ethical guidelines are not the result of a logical progression from a set of underlying principles is a significant obstacle. So the DCT is not a powerful tool for ethical debate in a secular society, and not a workable theory for our purpose of ethical decision-making in this context (Quinn, 2005, pp. 59–62).

Kantianism (Kant, 1724–1804): This theory, also referred to as the categorical imperative, pertains to actions that are universally considered to be good, and involve good will and duty. We are compelled to act in a certain way because of some moral rule. In his first formulation, Kant defines the categorical imperative: "*Act only from moral rules that you can, at the same time, will to be universal moral laws"* (Quinn, 2005, pp. 63). An example is: Do not make a promise with the intention of breaking it. If everyone broke promises, they would become meaningless. Kant's second formulation states: "*Act so that you always treat both yourself and other people as ends in themselves, and never only as a means to an end"* (Quinn, 2005, pp. 64). This aspect applies well to the question of self-interest in overly ambitious researchers, or to the fact that some researchers do not tell the whole truth to human subjects about the experiments they will perform on them. It is wrong for a person to use another; all interactions must be respectful of the humanity of others. Kantianism is rational; that is, we can use logic to explain the "why" behind a solution to an ethical problem. This theory produces universal moral guidelines that apply to all people for all times. All persons must be treated as moral equals; that is, people in similar situations should be treated equally. Kantianism provides a framework to combat discrimination. A weakness of this theory is that sometimes an action cannot be fully characterized by a single rule. For example, is it acceptable to steal food to feed starving children? This approach does not help to resolve a conflict between rules. How do we rank the importance of these rules? Kantianism does not allow any exceptions to moral laws. This theory mainly supports moral decision-making based on logical reasoning from facts and commonly held views. It is culture-neutral, and treats all humans as equals. It is a workable theory for ethical decision-making in cases where universal principles are concerned (Andrews, 2005, pp. 127–128,130; Quinn, 2005, pp. 62–67).

Act Utilitarianism (Act U): First formulated by Jeremy Bentham (1748–1832), and further developed by John Stuart Mill (1806–1873), Act Utilitarianism is based on the principle of utility. This theory is in sharp contrast to Kantianism: it states that an action is good if it benefits someone, and bad if it harms someone. This is also called the "greatest happiness principle." An action is right (or wrong) to the extent that it increases (or decreases) the total happiness of the affected parties. Happiness is defined as advantage, benefit, good, or pleasure; and unhappiness as disadvantage, cost, evil, or pain. We must weigh positive and negative impacts of an act, or the morality of an action. The focus is on the consequence of the actions. Anyone who can experience pleasure or pain is included in the calculations. The intensity, duration, certainty, propinquity, purity, and the extent of the impact must be compiled. This theory is pragmatic, quantitative to a certain extent, and comprehensive; it considers all elements of a situation. A shortcoming is that, when performing the utilitarian calculations, it is not clear where we draw the line (who is included, for what time period, and so on); yet, where the line is drawn can change the outcome of the evaluation, and can be a difficult task. Moreover, it is not practical to put so much energy into every single moral decision. One practical approach is to develop rules of thumb; for example, "it is wrong to lie." If a rule of thumb does not apply, then we can do all the calculations in detail to assess a unique situation or act. Contrary to Kantianism, Act U ignores our innate sense of duty; all that matters are the consequences of an action; the approach does not take into consideration the fact that people often act out of a sense of duty or obligation, as Kant suggests. Another weakness is that Act U cannot predict unintended consequences, so it applies mainly where consequences are known and controlled. Act U is an objective, rational, ethical theory that allows a person to explain why a particular act is right or wrong, and is a workable ethical theory to evaluate moral problems for biomedical engineers (Quinn, 2005, pp. 67–72).

Rule Utilitarianism (Rule U): John Stuart Mill's development of Rule U simplifies the multiple calculations needed for Act U. This approach holds that we ought to adopt moral rules which, if followed by everyone, will lead to the greatest increase in total happiness. It applies the Principle of Utility to moral rules, while Act Utilitarian applies the Principle of Utility to individual moral actions. Both Rule U and Kantianism are focused on rules, and some of the rules overlap. Both theories support the notion that rules should be followed without exception. However, the two theories derive moral rules in different ways. Rule U states that you follow a moral rule, because its universal adoption would result in greatest general happiness (consequences); whereas Kantianism states that you follow a moral rule, because it is in accord with the Categorical Imperative (motivation and duty). Performing the Rule U calculations is much simpler than for Act U. One weakness is that utilitarianism forces us to use a single scale (units) to evaluate completely different kinds of consequences. Moreover, this approach ignores the problem of an unjust distribution of good consequences. In summary, Rule U treats all persons as equals, and provides its adherents with the ability to give the reasons why a particular action is right or wrong. It is a workable theory for evaluating moral problems facing engineers. We should act so that the greatest amount of good is produced, and distribute the good as widely as possible (Andrews, 2005, pp. 126–127; Quinn, 2005, pp. 72–76).

Social Contract Theory (SC): Thomas Hobbes (1603–1679), in *Leviathan,* wrote that morality consists in the set of rules governing how people are to treat one another, that rational people will agree to accept for their mutual benefit, on the condition that others follow those rules as well. Similar to Kantianism, there are universal rules that can be derived through a rational process. But Kantianism is based on the universality of a rule, whereas SC is based on the benefits to the community, and recognizes the harm that a concentration of wealth and power can cause. It is framed in the language of individual rights, and explains why rational people act out of self-interest in the absence of common agreement. It also provides a clear ethical analysis of some important moral issues regarding the relationship between people and government. A weakness of the theory is that no one signed the social contract. Moreover, some actions can be characterized in multiple ways. SC theory does not explain how to solve a moral problem when the analysis reveals conflicting rights; it may even turn out to be unjust for people who are incapable of upholding their side of the contract, or for people who do not understand the rules (Quinn, 2005, pp. 76–84) .

Rights Theory (John Locke, 1632–1704): Locke's theory states that everyone has rights arising simply from being born; the right to life, maximum individual liberty, and human dignity are all fundamental rights, and other rights arise as a consequence of these. The difference with Kantianism is that for Locke, duty is a consequence arising from personal rights. The principles of Locke's theory are embedded in the "Charter of Human Rights and Freedoms" in many countries; this guarantees to all citizens fundamental freedom of conscience, religion, thought, belief, opinion, expression, peaceful assembly, and association. The legal right to life, liberty, and security of the person, and the right not to be deprived of these rights—except in accordance with principles of fundamental justice—are written in this law. This includes equality rights before and under the law, and the right to equal benefit and protection of the law. This theory is usable in ethical decision-making by engineers, especially with regards to protection of the public and of research subjects (Andrews, 2005, pp. 128–130).

Rawl's Theory of Justice (John Rawl, 1921–): In his *A Theory of Justice*, Rawl wrote that each person may claim a "fully adequate" number of basic rights and liberties, such as freedom of thought and speech, freedom of association, the right to be safe from harm, and the right to own property, so long as these claims are consistent with everyone else having a claim to the same rights and liberties. This resembles the Hobbes SC Theory and Locke's Rights Theory, except that it is stated from the point of view of rights and liberties, rather than from the view of moral rules. Any social and economic inequalities must satisfy two conditions: First, they are associated with positions in society that everyone has a fair and equal opportunity to assume; and second, they are to be to the greatest benefit of the least advantaged members of society (the difference principle). In reality, regarding the first principle, we cannot imagine everyone having the same decisional power and same wealth; it is a certainty that some people will have more power and/or money than others. The second principle is more likely to be applied; an example would be that the poor should pay less tax than the rich. Like Locke, Rawl reaffirms the right to life, liberty, and security of the person, and the right not to be deprived of these rights, except in accordance with principles of fundamental justice. This is a usable theory for decision-making by engineers (Quinn, 2005, pp. 78–80).

It is important to note that ethical decision-making is a dynamic process, as the issues and definitions change with country, historical era concerned, and the appearance of new ethical issues created by new research such as stem cells, designer babies, and cloning. Everyone must keep in mind an unfailing principle that applies to everyone, and for all times: Every human being, of all races, ethnic backgrounds, and sex are equal and must be given respect, dignity, and freedom from harassment and discrimination.

Other tools that can help engineers in their ethical decision making process are codes of ethics and guidelines. Principal codes are: the Hippocratic Oath, the Nuremberg Code, and the Declaration of Helsinki. The Hippocratic Oath is taken by doctors when they graduate, and sets out moral and ethical obligations to patients regarding the sanctity of human life, relief of suffering, and so on. (Illingworth & Parmet, 2006, pp. 173; Miles, 2004, pp. xiii–xiv). The Nuremberg Code, created as a result of the Nuremberg trials at the end of World War II, deals with principles of human experimentation and voluntary informed consent (Illingworth & Parmet, 2006, pp. 505). Understanding of both the Hippocratic Oath and the Nuremberg Code is essential for engineering disciplines involving work with human subjects. The World Medical Association (2004) published the Declaration of Helsinki as a statement of ethical principles to provide guidance to physicians and others when performing research involving human subjects, identifiable human material, or data (Illingworth & Parmet, 2006, pp. 506–509). Even the use of archived data without identifiers needs some form of clearance by ethics review committees. In addition, there are also the Code of Ethics for engineers in various States and Provinces, and the IEEE Code of Ethics. Major granting agencies have policies and guidelines that researchers must follow. Research or academic institutions all have their own review process for all projects involving humans or animals. Ethics Review Boards normally have forms to be completed describing the research project, the recruitment of volunteers, the inclusion and exclusion criteria, appropriate consent forms, and many other important questions regarding the storage of the data and guarantees of privacy and anonymity in reporting results. An ethics certificate is issued for each project with a timeline for which the certificate is valid.

Additional issues to be aware of are: conflicts of interest, plagiarism, protection and respect of intellectual property, confidentiality, privacy, and secrecy. The professional and positive interactions between engineers and physicians is important to ensure that research and development involving technology in a medical environment is successful (Bessenger, 1992; Daniels, 1992; Piehler, 1992). Another important consideration is the assessment of the impact of the planned work on society and on people. New developments, particularly in robotics, genetic engineering, and nanotechnology may raise serious concerns. The Center for the Study of Technology and Society summarizes the issue: “The same technologies that will let us cure diseases, expand the economy and overcome every day inconveniences can theoretically bring about catastrophes. Is the risk of an apocalypse serious enough for us to relinquish the current pace of technological innovation?”(Specht, 2000). Technology is often ahead of the development of societal guidelines and laws. Are we living in an era where technological determinism prevails? Can Society provide sufficient controls and moral and ethical guidance to prevent irreparable harm to our world and the people in it? Engineers must be able to understand how to verify the models that assess the impacts (positive and negative) of their technological development on society, and need a heightened awareness of universal responsibility and interdependability of engineers and society.

Ensuring that research and clinical services are equitable and inclusive of both sexes and various races represented in the population is also an important part of an ethical approach. Until recently, most clinical studies were performed exclusively with male subjects. New studies seem to be more inclusive of both sexes and of various races. However, gender inequalities still exist in all parts of the world, developing and developed, but in various degrees. This pertains not only to research, but to access to clean water, food, health care, education, and all aspects of life and security (Moreno, 2005, pp. 476–483). So in planning new studies, researchers and activists must assess how the planned work or project affects people (women, men, and children), and how the work can improve life on earth for everyone.

CONCLUSION

Performing research on humans or animals, or even on archived data or human material, must follow strict guidelines and protocols to ensure that all ethical principles are respected. This includes applying for an Ethics Certificate for each project, while ensuring that granting agencies’ policies are met, regarding good research practices, as well as all codes of ethics that apply to the particular situation. It may be appropriate to apply ethical theories to examine whether all aspects of the project are deemed ethical. It is also important to keep in mind that technological developments can bring major benefits to society, but may also bring hazards in their wake. Engineers should include in their plans an assessment of negative impacts on society, and attempt to minimize these. Engineers are also well placed to help solve some of the world’s largest problems and challenges as outlined in the United Nations Millennium Development Goals (United Nations, 2005). In the long run, society must institute laws and ethical codes of conduct to guide the direction and impacts of future developments. An overarching principle to keep in mind is the dynamic nature of ethical issues, so guidelines and principles must be reviewed regularly to assess their relevance.

KEY TERMS

Act Utilitarianism (Act U): Theory stating that an action is good if it benefits someone, and bad if it harms someone, also known as the "greatest happiness principle" (individual moral actions).

Cultural Relativism (CR): Ethical theory where the meaning of right and wrong rests with a society's actual moral guidelines.

Declaration of Helsinki: Statement of ethical principles, developed by the World Medical Association, to provide guidance to physicians and others when performing research involving human subjects, identifiable human material, or data.

Divine Command Theory (DCT): Theory based on the idea that good actions are those aligned with the will of God; bad actions are those contrary to the will of God; that we owe obedience to our Creator, and that God is all-good and all-knowing, the ultimate authority.

Ethics: The philosophical study of morality, of right and wrong, of good and evil in human conduct.

Hippocratic Oath: Oath taken by physicians upon graduation, outlining the moral and ethical obligations to patients during the practice of medicine.

Kantianism: Theory also referred to as the categorical imperative, and pertaining to actions that are universally considered to be good, and involve good will and duty. Treat yourself and others as ends in themselves, never as a means to an end.

Morality: Defined as what people believe to be right and good, and the reasons for it.

Nuremberg Code: Code created as a result of the Nuremberg trials at the end of World War II, dealing with principles of human experimentation and voluntary informed consent.

Rawl's Theory of Justice: Theory stating that each individual may claim basic rights and liberties (ex., freedom of thought, speech, right to be safe from harm, and so on), as long as these claims are consistent with everyone having a claim to the same rights and liberties.

Rights Theory: Theory stating that everyone has rights arising simply from being born—the right to life, maximum individual liberty, and human dignity are all fundamental rights. This theory is the basis for the "Charter of Human Rights and Freedoms."

Rule Utilitarianism (Rule U): Theory stating that a moral rule should be followed, because its universal adoption would lead to the greatest increase in total happiness.

Social Contract Theory (SC): Theory based on the benefits to the community, governing how people are to treat one another. It is framed in the language of individual rights, and explains why rational people act out of self-interest in the absence of common agreement.

Subject Relativism (SR): Theory where there are no universal moral norms of right and wrong. Persons decide right and wrong for themselves.

European General Practitioners' Usage of E-Health Services

INTRODUCTION

Technology plays an increasingly critical role in current markets. Diverse technological innovations are significantly changing how services are provided in different industries (Bitner & Brown, 2000). In this regard, new digital and Internet-related technologies are dramatically modifying how companies, employees, and customers interact in service encounters (Alba, Lynch, Weitz, Janiszewski., Lutz, Sawyer, & Wood, 1997; Hoffman & Novak, 1996).

In the health care sector, Internet technologies have the potential to improve the provision of health and patient care services like no other communications medium in the past (Shepherd & Fell, 1997). The health care sector, where interpersonal encounters between health staff and patients determine to a great extent service quality and patient satisfaction, will require diverse modifications, in order to fully benefit from the improvements promised by Internet technologies.

The term e-health is being widely used to refer to "health services and information delivered or enhanced through the Internet and related technologies" (Eysenbach, 2001). Physicians are largely turning to e-health services for gains in efficiency and improved quality of patient care. Factors related to higher constraints on physicians' costs, time, and private practices are currently accelerating Internet adoption among health professionals (Kassirer, 2001).

However, previous research shows that there are significant differences, both at the national and regional level, with regard to the development and adoption of Internet-related technologies (Hamill, 1997). These differences are even observable among developed countries in the European Union. In this regard, individuals from Northern European countries show higher rates of Internet adoption, as well as far more developed digital infrastructures. The unequal access to Internet technologies and slower Internet adoption processes in technologically backward countries ("digital divide") limit the potential positive effects of Internet technologies on the provision of health services in such regions.

Less clear is the influence of other external variables (e.g., gender and age) on physicians' professional use of Internet technologies. Diverse studies have dealt with this issue (Korgaonkar & Wolin, 1999), both in health and nonhealth contexts, with mixed results.

To effectively promote the use of Internet technologies for the provision of patient care services, it is important to understand the nature of physicians' current professional uses of the Internet. This article explores how the public Internet and dedicated networks are currently being used by European General Practitioners, and how external factors affect the degree of physicians' usage of e-health services.

BACKGROUND

Role of Technology and the Internet in Service Sectors

In the services sector, technological innovations have a great potential for improving the provision of diverse services. Parasuraman and Colby introduced the "services marketing pyramid model," which explicitly acknowledges the key role of technology in supporting and facilitating service delivery (Parasuraman & Colby, 2000).

The rapid impact of Internet technologies on service encounters has been documented in several studies (Parasuraman & Zinkhan, 2002). The use of the Internet by companies and consumers is radically changing how services are provided, both in B2C and B2B contexts. As a result, an increasing number of Internet-related studies is being carried out, focusing on the implications of the Internet in service industries (e.g., development of the e-SERVQUAL scale of service quality on the Web) (Zeithaml, Parasuraman, & Malhotra, 2000).

E-Health Research

A review of previous literature evidences that studies analyzing Internet adoption among health professionals are scarce (Sands, 2003). A recent report by the Boston Consulting Group offers one of the most detailed examinations of Internet usage by European physicians (Flanagan, Guy, Larsson, & Saussois, 2003). The main conclusions of this report include: (1) Most of physicians use the Internet for professional purposes, and it has an increasing impact on their professional knowledge, diagnoses, and prescriptions; (2) European physicians perceive the Internet as a very suitable medium for the acquisition of health information, continuous medical training, and complementary source of information for patients; (3) Physicians perceive that Electronic Health Care Records and Electronic Prescribing Systems contribute to an increased efficiency in their professional activities; (4) There is a trend towards more sophisticated Internet uses for increasing the quality of patient care services in the near future.

The review of previous studies evidences that further research is needed, especially empirical studies into the antecedents, current behavior, main purposes, and consequences of Internet usage for health purposes. The results of such studies should be taken into account by European, national, and regional authorities, in order to develop the suitable promotion strategies, aimed at further integrating new information technologies into patient care services.

RESEARCH OBJECTIVES

This research will draw on the main uses of Internet services and dedicated healthcare networks for physicians' professional purposes, in order to identify different segments of Internet users among European General Practitioners. Given the potential to improve doctor-patient relationships and health professionals' daily work, this article strives to clarify the extent to which general practitioners are taking advantage of Internet-related technologies in the European Union.

The following specific purposes have been set for this article:

1. Segmentation of European general practitioners, based on their adoption and actual professional uses of the Internet and General Practitioners networks. Behavioral variables have been selected for the characterization of segments.
2. Analysis of the effects of external variables (country, gender, age, location, and size of the medical practice) on the previously identified groups of Internet users.

The findings of the empirical analyses will clarify the existence and behavioral characteristics of the different segments (more vs. less advanced Internet users). Due to current national and regional differences in Internet adoption, these segments are expected to be differently distributed between European countries. The other covariates included in the study are not expected to exert significant effects on the identified segments.

METHODS

Sample

The empirical investigation is based on the survey "Flash-Eurobarometer Nº 126 – General Practitioners and the Internet" (2002), conducted on a sample of European general practitioners. The Eurobarometer surveys have been regularly carried out on behalf of the European Commission in all EU-countries. Table 1 shows the characteristics of the sample and the sampling procedure.

Statistical Analyses

The following methodology has been selected, according to the purposes of this study:

1. Latent Class Cluster Analysis has been applied, in order to identify homogeneous segments of Internet users among European physicians.

Table 1. Characteristics of the sample

SAMPLE	
Sampling procedure	• Telephone survey, using a "constant fraction" procedure, in order to guarantee the representativity of each national sample for its universe. The sampling has been carried out in each country on the basis of the published lists of General Practitioners.
Dates	• Interviews conducted between May 27th and June 19th, 2002
Sample size	• 3,512 respondents (aprox. 200 per country)
Collected information	• Sociodemographic variables: country, age, gender, location, and size of the medical practice. • Variables related to the use of diverse e-health services by European General Practitioners.

Latent Class Cluster Analysis overcomes some of the barriers involved in traditional clustering techniques. It is especially useful and flexible for dealing with categorical variables, which is the case in this study (Vermunt & Magidson, 2002).

2. The relative distribution of the identified segments with regard to several external variables has also been examined. Significance tests and measures of the association between the covariates and the segments are reported for this purpose.

RESULTS

Identification of Segments

From a total sample of 3,512 participants, the authors selected general practitioners who use Internet-enabling devices in their private practices (e.g., personal computers, laptops, or PDAs) for inclusion in subsequent statistical analyses. In most of doctors' private offices (2,862 or 81.49%) computer equipment is available. With regard to Internet use in the medical practice, a total of 2,264 professionals (64.46%) are currently accessing the Internet—or a General Practitioners network—from their private practices, compared to 96% of health professionals using Internet technologies the United States (Von Knoop, Lovich, Silverstein, & Tutty, 2003).

The Bayesian Information Criterion (BIC) was selected for the identification of the optimal number of segments. According to Biernacki and Govaert, in clustering contexts, the BIC criterion outperforms other classification criteria (Biernacki & Govaert, 1999). Taking into account the changes in BIC between the different cluster solutions (see Table 2), three is the optimal number of segments among European general

Table 2. BIC for different number of segment-solutions

	BIC (based on LL)	Change in BIC[a]
1 Cluster	81607,071	
2 Clusters	59574,165	-22032,906
3 Clusters-OPTIMAL	55693,742	-3880,423
4 Clusters	53417,221	-2276,521
5 Clusters	51889,497	-1527,724
6 Clusters	50682,053	-1207,444
a) Changes refer to the previous number of clusters in the table		

practitioners currently using the Internet or a general practitioners network. The classification error for the three-cluster solution is 2.36%.

Including the group of "Non-Internet Users," European physicians can be classified into four segments, according to their current professional use of the Internet or a General Practitioners network.

Behavioral Characterization of Segments

Segment 1: "Information Searchers" (28.99%)

- The use of Internet-based networks to search for health-related information is the main characteristic of this segment. Internet uses related to the acquisition of health information include: accessing medical associations' Web sites for professional-oriented information; searching for prescribing information; searching information online for the purpose of continuing education; and consulting medical journals.
- These doctors do not transfer patient-identifiable data through the Internet or a General Practitioners network.
- Moderate use of Electronic Health Care Records. EHCR systems are specifically purchased for the medical practice.
- These professionals do not use Web sites for their practices very often.

Segment 2: "Advanced Users" (20.96%)

- Like "Information Searchers," the search of health information for professional purposes through Internet networks is a quite-relevant Internet use for general practitioners of this group.
- The key distinguishing characteristic of this segment relates to the use of the Internet-based networks for transferring patient-identifiable data. Practically all members of this segment send or receive this kind of patient data online. The main purposes of these data transfers include: submitting patient care reimbursement claims; receiving results from laboratories and other diagnostic procedures; transferring administrative patient data to a secondary care provider; and transferring patient medical data to other medical care providers for the purposes of continuity of care.
- E-mail communication with patients is not a widespread activity yet, even for this group of "Advanced Users".
- Internet technologies are rarely used to offer telemedicine or electronic prescribing services to patients.
- The majority of "Advanced Users" does not obtain specific patients' consent, or use electronic signatures in communicating patient medical data online.
- The use of Electronic Health Care Records is moderate.

Segment 3: "Laggards" (14.52%)

This segment shows a less sophisticated use of Internet-based networks for professional purposes in all analyzed areas: limited search for medical information online; these physicians do not transfer patient-identifiable data through the Internet or a general practitioners network; and these physicians rely less frequently on EHCR and Web sites for the private practices.

Segment 4: "Non-Internet Users" (35.54%)

It is important to emphasize the high share of European health professionals that are currently not taking advantage of the new possibilities afforded by Internet technologies for the provision of health care services.

Characterization of Segments According to External Variables

An attempt has been made to characterize the identified segments, according to several external variables. These analyses should contribute to the debate on whether geographic criteria, demographic traits, or job characteristics show significant effects on the acceptance and use of Internet technologies and other technological innovations.

Country

One of the main purposes of this study relates to the examination of potential national differences, related to European physicians' use of the Internet or a general practitioners network. Based on the results of the LC Cluster Analysis, the effects of the "country" variable on the identified groups of Internet users is very significant (Wald=467.5118; P<.001), which suggests the existence of significant national differences between European countries.

It has also been investigated if the four identified segments, including the Non-Internet Users group, show statistical significant differences between countries. The relative distribution of the identified segments in the analyzed countries has been displayed in a contingency table. Again, the results of the chi-square test (chi-square=1,515.977; P<.001) suggest the existence of significant differences between countries.

Nevertheless, in large samples sizes, relationships can be found significant even when the association of variables is very weak. In these cases, measures such as Phi, Cramer's V, or the Contingency Coefficient should be reported, in order to fully represent the real strength of the association between the segments and the covariates. Phi, Cramer's V, and the Contingency Coefficient measure the strength of the relationship between two nominal variables in a contingency table, with values between 0 (no relationship) and 1 (perfect relationship). Phi should be used in 2x2 tables, while Cramer's V or the Contingency Coefficient should be reported when at least one of the variables has more than two categories.

Due to the large sample size in this study (3,512), the authors also provide measures of association between the segments and the covariates. In the case of the "country" variable, the values of Cramer's V and the Contingency Coefficient are 0.379 and 0.549, respectively. These values confirm the existence of strong country influences on the segments.

The following national trends in the use of the Internet and dedicated healthcare networks among European general practitioners can be observed, which can be examined in graphical form in Figure 1:

1. **Laggard countries:** The number of "Non-Internet Users" is very high in these countries. Relatively few "Advanced Users" and "Information Searchers" can be found. Countries included in this group are Greece, Spain, Germany, and Portugal.
2. **Follower countries:** The number of "Advanced Users" and "Information Searchers" is moderate, but the number of "Non-Internet Users" is still quite high. The following countries can be included in this group: Belgium, France, Ireland, Italy, Luxemburg, Holland, and Austria.
3. **Advanced countries:** These countries are characterized by very few "Non-Internet Users." There is a high number of "Advanced Users" and "Information Searchers." Advanced countries include Sweden, the United Kingdom, Finland, and Denmark. Denmark stands out as the country with the highest number of "Advanced Users."

While country differences in the adoption of e-health services resemble, to a great extent, traditional economical and infrastructural differences between European countries, attitudinal, perceptual, or cultural factors also exert significant influences on the acceptance of Internet technologies for health professional purposes. Further research should examine the role and relative importance of physicians' individual characteristics in the adoption of e-health services.

Gender

Based on the results of the LC Cluster Analyses, the effects of "gender" on the identified groups of Internet users are significant (Wald=17.8737; P<.001).

The tests of gender differences between the four segments provided the following results (chi-square=17.821; P<.001; Cramer's V=0.071; Contingency Coefficient=0.071). As suggested by these measures, there is a very weak association between gender of surveyed physicians and their classification in each of the identified segments.

These results show very similar profiles for men and women with regard to the classification of physicians in the different segments. Although the distribution patterns of the identified "clusters" among men and women are very similar, it can be observed that male physicians show a slightly more sophisticated use of Internet technologies for their medical practice. Among users of the Internet or a general practitioners network, there is a higher percentage of women included in the "Laggards" group (18.39%), compared to 13.19% of men. For men, the higher number of "Advanced Users" and "Information Searchers" balances the relative less importance of the "Laggard" group.

As a conclusion, these results confirm previous research, suggesting that gender is becoming less significant in explaining technology usage, especially in highly educated groups, like physicians.

Age

This study has also examined if there are significant age differences in physicians' adoption of Internet-related technologies for professional purposes. According to the results of the LC Cluster Analysis, the effects of "age" on the identified classes of Internet users are statistically significant (Wald=39.8204; P<.001).

Further analysis of age differences between the four segments showed the following results: chi-square=255.258; P<.001; Cramer's V=0.157; Contingency Coefficient=0.262. These measures indicate a moderate association between physicians' age and their classification in one of the identified segments.

There seems to be a clear trend, with regard to the relationship between age and the use of the Internet or a general practitioners network (see Figure 2). Younger physicians (less than 35 years old) show the higher percentage of Internet users. Physicians in ages between 36 and 40 years present the most sophisticated use of e-health technologies (highest number of "Advanced Users" and "Information Searchers"). In general, physicians between 36 and 50 years old show quite similar uses of Internet technologies. The results point to a clear declining trend relating age and the use of Internet-based networks for physicians in ages over 50 years. Physicians between 56 and 60 years old show a very sophisticated use of e-health technologies, but a comparatively less total number of Internet users. Adoption rates of e-health technologies among physicians over 60 years old are very limited.

Location of Medical Practice

The Wald statistic and the z-values for the external variable "location of practice" indicate that this covariate does not exert a statistically significant effect on the identified segments of Internet users (Wald=1.8683; *P*=0.76).

Further tests confirm the existence of very homogeneous usage patterns of technological healthcare networks for physicians working in different settings, whether metropolitan zones, other town, or rural areas (chi-square=24.663; *P*=0.03; Cramer's V=0..048; Contingency Coefficient=0..084).

Although not statistically significant, it is worthwhile to note that general practitioners working in rural settings show more sophisticated usage patterns of e-health technologies than physicians in metropolitan zones, with a higher share of "Advanced Users" and "Information Searchers." Thus, possible concerns about the existence and widening of a "digital divide" between metropolitan and rural areas (Brodie, Flournoy, Altman, & Blendon, 2000) have not been confirmed for European health practitioners.

Figure 1. Distribution of segments in EU-countries

	Belgium	Denmark	Germany	Greece	Spain	France	Irland	Italy	Luxembu rg	Holland	Austria	Portugal	Finland	Sweden	United Kingdom
Non-Internet Users	50,00%	10,50%	58,00%	76,00%	52,43%	24,00%	43,00%	34,88%	45,68%	27,72%	42,50%	60,00%	6,00%	2,50%	2,60%

Figure 2. Age differences

	<35	36-40	41-45	46-50	51-55	56-60	61-65	>66
Non-Internet Users	24,62%	27,72%	31,57%	30,53%	32,84%	38,15%	61,27%	77,89%
Laggards	20,51%	15,28%	12,94%	15,87%	15,85%	14,46%	11,27%	8,42%
Advanced Users	23,08%	22,02%	21,09%	20,91%	24,51%	24,62%	13,38%	6,32%
Information Searchers	31,79%	34,97%	34,41%	32,69%	26,80%	22,77%	14,08%	7,37%

*The exhibit shows the relative importance of the identified segments, separately for each age-group.

Size of Medical Practice

The performed LC Cluster Analysis indicates that the effects of "size of practice" on the identified groups of Internet users are not statistically significant (Wald=6.4271; *P*=0.38).

After the inclusion of "Non-Internet Users" group, further tests suggest the existence of a statistically significant relationship between this covariate and the identified segments (chi-square=326.744; *P*<.001; Cramer's V=0..176; Contingency Coefficient=0..292). The value of Cramer's V points to a weak increasing relationship between size of the medical practice and the usage rates of Internet-based healthcare networks. This association should be interpreted with caution, as the results of the Latent Class Cluster Analysis were not statistically significant.

FUTURE TRENDS

Future research should further clarify how the adoption of Internet-based networks is taking place in the health care sector. The use of perceptual and attitudinal measures towards the Internet, and new digital technologies would offer a richer explanation of the relative role played by physicians' psychological characteristics in the adoption processes of Internet-based networks.

The acceptance of e-health services among health professionals other than general practitioners should also be researched. A sample including surgeons, specialists, nurses, and other professionals would clarify if the acceptance of the Internet or dedicated healthcare networks is affected by the professional category of health staff.

CONCLUSION

Segmentation of European Physicians

This research has identified four segments of European physicians, based on their actual uses of Internet technologies for health-related purposes. It has also been explored how external variables are associated with the use of e-health services by general practitioners.

The identified groups have been labeled as "Information Searchers," "Advanced Users," "Laggards," and "Non-Internet Users," according to the degree and purposes of physicians' health-related Internet usage.

The key distinguishing difference between "Advanced Users" and "Information Searcher" relates to the use of the Internet-based networks by "Advanced Users" for transferring patient-identifiable data. Other behavioral differences between these groups can be observed, related to other professional uses of the Internet or a general practitioners network, but not as significant.

The identification of these segments should provide a valuable basis for the development of suitable Internet promotion strategies, adapted to the needs of the different groups. Strategies targeted at the "Laggards" and "Non-Internet Users" groups should focus on explaining the benefits provided by Internet technologies in general, not only for health purposes. Training should be offered to these groups, where the needed skills for Internet use can be acquired. At later stages, these people should be offered continuous education on the possibilities afforded by Internet technologies for their professional activities. Due to usual time and costs' constraints on physicians, these courses should emphasize the potential benefits of Internet-technologies in terms of efficiency and improved patient satisfaction.

Policies targeted at "Information Searchers" should focus on explaining the potential benefits of using the Internet or a dedicated healthcare network for transfers of patient data. Both "Information Searchers" and "Advanced Users" receive training on how e-mail patient communication, electronic prescribing, and Web sites can help them to improve the management of their professional practices, as these are not widespread activities yet.

Advanced Users' main characteristic relates to the use of Internet technologies for transfers of patient-identifiable data. Nevertheless, the protection of patients' privacy, such as obtaining patients' consent or the use of electronic signatures, seems to be less than desirable. For this purpose, a homogeneous European legal framework should provide clear guidelines on this matter and ensure the protection of patients' privacy. More sophisticated e-health uses, such as telemedicine services, should be continually introduced to more advanced users at later stages.

Country Differences

With regard to the existence of national or regional differences in the use of Internet-based healthcare networks between European physicians, Northern European countries (Sweden, Finland, Denmark, and the United Kingdom) are clearly on the forefront, while Internet adoption by physicians from Southern countries (Greece, Spain, and Portugal) is clearly developing at slower paces.

Although certain health-related Internet uses, such as transfers of patient data online, can contribute to substantial improvements in the provision of patient care services (continuous patient monitoring, communication with patients, contact with dispensing pharmacists, and so on), the differences found between countries can limit the potential benefits of these Internet-related uses. Concerns about patients' privacy protection may slow down the adoption process of such Internet-based services in the health care sector, and different national regulations in this matter may contribute to widen regional disparities in the European Union. In countries like Spain, e-health services are subject to governmental regulations. Thus, generalization of certain services, such as electronic prescribing with full legal protection, is becoming a rather slow process.

It is also worth considering that the "North/South divide" in Internet adoption is also evident, not only among health professionals, but also with regard to the general public. If the potential of Internet technologies for improving the provision of patient care services is to be fully realized on a European basis, European and national authorities should play a key supporting role.

In Europe, the commitment of national and regional authorities with the policies developed by the European Commission will be critical for their success. The eEurope Action Plan 2005, with regard to the promotion of e-health services, aims to build a homogeneous Europe-wide legal framework, which ensures the secure transfer of patient-identifiable data over the Internet and dedicated healthcare networks.

Governmental support should mainly focus on promoting the adoption and use of Internet technologies (e.g., through marketing campaigns and training), developing modern digital infrastructures, and reducing negative attitudes of physicians and patients towards the use of the Internet for health-related purposes (e.g., privacy and security concerns).

Differences in Gender, Age, Location, and Size of Practice

Previous research has provided mixed results on whether external variables such as demographics and geographic criteria are significant predictors of Internet and technology usage. The relative influence of several *covariates* on physicians' use of e-health services has been explored in this study, in addition to the existence of country influences. In general, these external variables have provided rather weak relationships with the identified segments in this research. Of the analyzed variables, only a physicians' age shows a moderate decreasing association with the use of the Internet or a general practitioners network.

Gender, location, and size of the medical practice have not provided significant effects on physicians' use of e-health services. The nonexistence of significant differences in the use of Internet-related technologies for health purposes, based on "location of the medical practice," has important implications, as e-health services have a great potential for improving the protection of patients' health in rural and isolated areas. The prerequisite of the acceptance of Internet-based technologies by health care providers in rural settings seems to have been achieved. In order to ensure the success of e-health services in nonmetropolitan areas, European, national, and regional authorities should further promote Internet use by citizens living in smaller towns and rural areas.

KEY TERMS

Dedicated Networks: Digital networks dedicated to healthcare services.

Digital Divide: Gap between individuals and communities with greater and lesser access to digital technologies.

E-Health: Health services and information delivered or enhanced through the Internet and related technologies.

Electronic Health Care Records: Digital medical records which contain all relevant information of a person's health.

Electronic Prescribing: Use of digital networks and devices to automate the drug prescription process.

General Practitioners: Physicians whose practice is not oriented to a specific medical specialty.

LC Cluster Analysis: Latent class cluster analysis, which represents a robust and flexible statistical methodology for segmentation studies.

Segmentation: Process of identifying subgroups of people with similar behavioral or attitudinal patterns.

Telemedicine: Use of information technologies for the delivery of clinical care (e.g., home monitoring of patients through the Internet).

INTRODUCTION

Preservation of astronaut crew health during an exploration mission to the Moon or Mars will be crucial to mission success. The likelihood of a life-threatening medical condition occuring during a mission to Mars has been estimated by NASA to be 1% per year (Johnston, 1998; Johnston, Campbell, Billica, & Gilmore, 2004). Since basic life support is a vital skill in critical care medicine, plans must be in place for cardiopulmonary resuscitation in both microgravity and hypogravity (i.e., on the surface of the Moon or Mars).

Following the design of a body suspension device to simulate a hypogravity environment, subjects performed external chest compressions in 1G, 0.17G (Lunar), 0.38G (Mars), and 0.7G (Planet X). Chest compression adequacy was assessed by means of rate and depth. Heart rate immediately before and after three minutes of chest compression gave a measure of rescuer fatigue. Elbow flexion was measured using an electrogoniometer in order to assess the use of arm muscles to achieve chest compressions.

This study found that the mean depth (Lunar and Mars) and rate (Mars) of chest compression was below American Heart Association recommendations during hypogravity simulation in the female group. Furthermore, elbow flexion proved to be significantly greater during Lunar and Mars hypogravity simulation than that of the 1G control condition, suggesting that upper arm force may be used to counter the loss of body weight in an attempt to maintain adequate chest compression under these conditions.

BACKGROUND

A new initiative announced by the United States aims to resume manned lunar expeditions with a landing planned for 2015, and ultimately a manned mission to Mars (White House Press Secretary, 2004). Japan's long-term vision resembles those of U.S. President George W. Bush and European space officials, who hope to land astronauts and robots on the Moon as a first step to sending a manned space mission to Mars

(Exploration of Mars and the Moon, 2006; Future of Human Space Flight, 2006). Over the next decade, the Japan Aerospace Exploration Agency (JAXA) plans to call for scientists to develop robots and nanotechnology for surveys of the Moon and design a rocket and space vessel capable of carrying cargo and passengers. By 2015, JAXA will review whether it is ready to pour resources into manned space travel, possibly building a base on the Moon. A decision to try for Mars and other planets would be made after 2025 (Japan Space Flight History, 2005). Plans regarding manned trips to the Moon and Mars are not restricted to the United States and Japan. European and Russian scientists have set out a route map for manned missions to Mars that aims to land astronauts on the Red Planet in less than 30 years. A human mission to the Moon, proposed for 2024, would demonstrate key life-support and habitation technologies, as well as aspects of crew performance and adaptation to long-distance space flight. The ESA has planned two flagship missions to Mars-ExoMars that would land a rover on the planet in 2009, and Mars Sample Return would bring back a sample of the Martian surface in 2011-2014. Other test missions will include an unmanned version of the flight that would eventually carry astronauts to Mars (ESA, 2006).

The diagnosis and treatment of acute and chronic medical conditions have been identified by all space agencies as one of the highest priorities for both current orbital space flight and future exploration class missions to the Moon and Mars. In particular, there is a need for evidence-based guidelines and techniques for management of medical emergencies during such missions. To date, all mortalities in space flight have been the consequence of sudden catastrophic technological failures, which have left no opportunity for corrective action (Telemedical Emergency Management, 2004). However, significant morbidity has occurred, including type I decompression sickness (Apollo 11), urinary tract infection (Apollo 13), cardiac arrhythmias (Apollo 15, Mir station 1987), N_2O_4 pneumonitis (Apollo-Soyuz test project), and prostatitis, sepsis, and hypothermia (Salyut 7). These health issues have thus far not required advanced life support measures but have on occasion required the prophylactic deorbiting of the crew member (Telemedical Emergency Management, 2004).

A higher incidence of acute and life-threatening medical problems may be anticipated with the increasingly longer space missions and extravehicular activity requiring increased physical labor as developmental activity in space progresses. In addition, selection criteria in terms of age and health are in many ways less stringent than those of the early days of human space flight. Thus the rare but potential likelihood of serious medical incidents, such as a life-threatening cardiac event, must be anticipated and adequately prepared for.

Cardiac arrest can be in the form of asystole, pulseless ventricular fibrillation or electromechanical dissociation, which are the results of primary cardiac diseases such as coronary artery disease or a cardiomyopathy, trauma, or secondary to diseases of other systems (e.g., respiratory failure). Since its introduction in the 1960s (Safar, 1961), modern cardiopulmonary resuscitation (CPR) with manual chest compressions at its foundation has been shown to improve survival after cardiac arrest (Cummins, Eisenberg, Hallstrom & Litwin, 1985; Ritter et al., 1985). Many studies have confirmed the haemodynamic significance of delivering consistent, high quality, infrequently interrupted chest compressions (Wiggington, Miller, Benitez & Pepe, 2005).

Basic life support and CPR are essential features of current astronaut training. NASA astronauts are currently trained in two techniques. The first utilizes the Crew Medical Restraint System on the International Space Station to restrain both patient and provider so that chest compressions are performed in a manner similar to the standard terrestrial method. The second is the so-called Hand Stand method (Hamilton, 2003; Jay, Lee, Goldsmith, Battat, Jaurrer & Suner, 2003). These and other available options, such as the Evetts-Russomano technique (Evetts, 2004; Evetts, Evetts, Russomano, Castro, & Ernsting, 2004; Evetts, Evetts, Russomano, Castro, & Ernsting, 2005) developed by the King's College London, UK, and the Microgravity Laboratory PUCRS, Brazil, have been based on previous and ongoing research to address the need to perform CPR in orbital microgravity. In this environment, the delivery of rescue breaths does not present a major technical problem. The main challenge is the application of sufficient force to the victim's chest in the absence of weight, which provides the main source of compression force under the standard terrestrial method. In the absence of data to suggest alternative requirements, all the above methods have aimed to match the terrestrial standards of CPR set by the American Heart Association (2006) and the European Resuscitation Council (Handley, Monsierus, & Bossaert, 2001).

Hypogravity of various magnitudes will be the condition experienced during the planetary or lunar surface elements of future exploration missions. CPR methods developed for microgravity may not be applicable during the surface elements of these missions, as gravity is present, albeit reduced. In addition, the standard terrestrial method, which involves the application of the weight of the provider as the compression force delivered to the sternum, may also not be applicable if weight is reduced to an extent that the force achieved no longer produces adequate chest compressions. Being able to achieve adequate depth is crucial to the effectiveness of external cardiac massage. Since optimally performed CPR provides at best only a third of normal cardiac output (Paradis et al., 1989), even modest deteriorations in performance of the provider may have significant effects on reducing effectiveness (Ashton, McCluskey, Gwinnutt & Keenan, 2002). The American Heart Association guidelines recommend a chest compression depth of 40-50mm at a rate of 100 compressions per minute as adequate, which is currently applied to nonterrestrial cardiopulmonary resuscitation (CPR).

Given the high priority of basic life support in astronaut training, it is important to develop an effective CPR technique for these altered gravitational environments. A previous theoretical study has suggested that if terrestrial standards of chest compression depth were to be adopted, they were unlikely to be efficient in Lunar or Martian gravities. This can only be overcome if the provider is of high mass and the patient's chest of high compliance (Sarkar, 2004).

MAIN FOCUS OF THE CHAPTER

A pioneer study was conducted to evaluate the performance of external chest compressions during hypogravity simulation of different magnitudes at the Microgravity Laboratory/PUCRS.

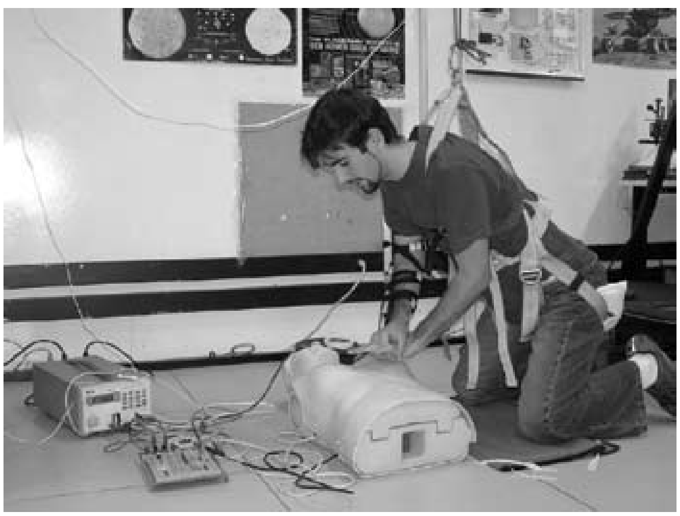
Three gravitational environments were simulated: 0.17G (Lunar), 0.38G (Martian), and 0.70G (Planet X). Planet X was created in order to provide an intermediate gravitational field to help with data analysis.

External chest compression adequacy was studied, along with arm flexion (upper-limb movement) during compressions. This research provides insight into cardiac massage performance in hypogravity and helps to reflect on performance in clinical and training environments.

Details of the equipment developed for this study are presented next.

Body suspension device. A method of simulating a reduced gravitational field has been developed by the Microgravity Laboratory/PUCRS. The body suspension system comprises a body harness, counterweights, and a load cell. The structure is pyramidal and consists of steel bars of 6cm x 3cm thickness. It has a rectangular base area of 300cm x 226cm and a height of 200cm. A steel cable connects the counterweights through a

Figure 1. Male subject performing external chest compression wearing the harness for hypogravity simulation and an electrogoniometer attached to his right arm



system of pulleys to a harness worn by the subject (Figure 1).

It uses a counterweight system consisting of 20 steel bars of 5kg each, placed opposite the subject. The necessary counterweights were calculated as follows: using equation 1, the relative mass of a subject in a simulated gravitational field can be calculated, where RM = relative mass (kg), BM = body mass on Earth (kg), SGF = simulated gravitational force (m/s^2), and 1G = $9.81 m/s^2$. Equation 2 gives the counterweight (CW, in kg) necessary to simulate body mass in a preset hypogravity level.

$$RM = \frac{0.6BM \times SGF}{1G} \quad (1)$$

$$CW = 0.6BM - RM \quad (2)$$

Basic life support training manikin. A standard full-body CPR mannequin (Resusci Anne SkillReporter, Laerdal Medical Ltd, Orpington, UK) was instrumented for measurement of external chest compression depth and rate by the Microgravity Laboratory, PUCRS. A 10KΩ potentiometer was used for chest compression depth measurement, which gave a real-time feedback to the subject by means of a LM3941 component that shows a voltage variation by lighting a line of colored LEDs (light emitting diodes) for depths of 0-28mm (red), 29-39mm (yellow), 40–50mm (green), and 51-60mm (red) (Figure 2). Chest compression frequency was indicated by an electronic metronome set to a frequency of 100/minute.

Load cell. A load cell was attached to the top of the pulley system in order to measure the corrected weight. The load cell consists of an Al 6351 aluminium tube (inner radius of 18mm, external radius of 32mm, and depth of 22mm). The inner part of the tube contains a Wheatstone bridge made with strain gauges, which vary resistance according to either compression or traction of the load cell. Calibration tests were performed to evaluate the linearity of the load cell. Two different weight loads (2kg and 17.45kg) were used for calibration before the beginning of each experiment.

Elbow electrogoniometer. The angle of elbow flexion (upper-limb movement) was measured using an electrogoniometer, which consists of two aluminium bars (20cm x 2.0cm x 0.3cm) covered with rubber material and connected by a 10KΩ potentiometer (Figure 3). A 5V power source was used. Calibration was performed before the beginning of each experiment by attaching a manual goniometer to the electrogoniometer. The full range voltage at 0º and 90º was then recorded.

Data acquisition system. A DataQ acquisition device (DATA-Q Instruments Inc, Akron, OH, USA) with 8 analogue and 6 digital channels, 10 bits of measurement accuracy, rates up to 14400 samples per second and USB interface was used. It supports full-scale range of ±10V and a resolution of ±19.5mV. WinDaq data acquisition software allowing for conversion of volts to the necessary unit was used. Three channels

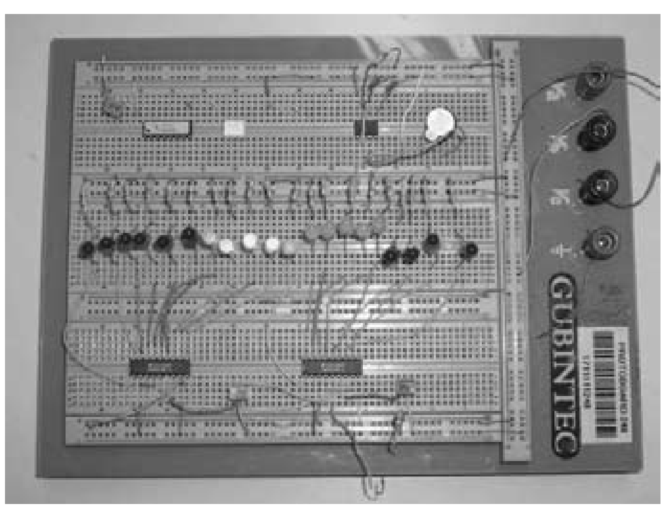

Figure 3. Elbow electrogoniometer

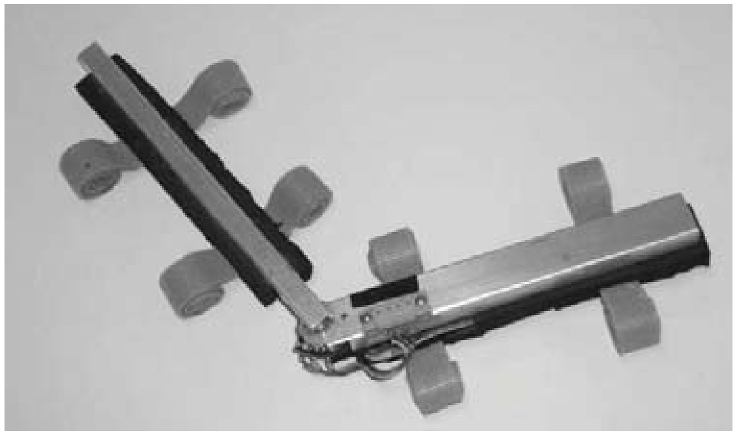

Figure 4. WindaQ during data collection

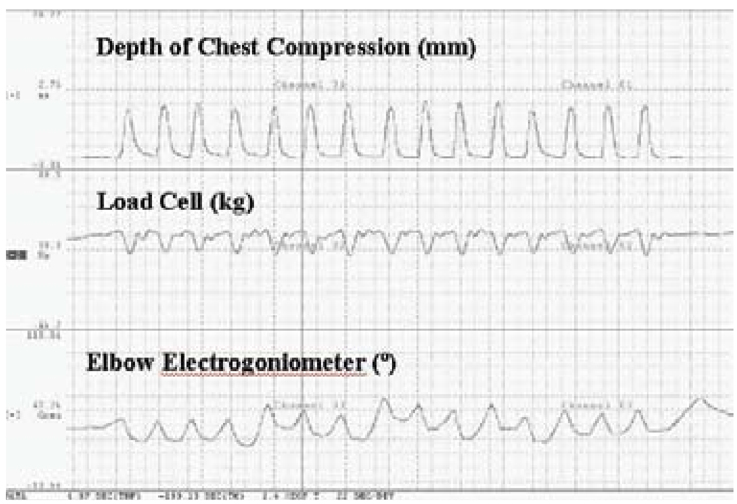

were used during data collection: depth and rate of chest compression, the amplified Wheatstone bridge signal of the load cell, and the elbow electrogoniometer signal (Figure 4).

External cardiac compression measurements were obtained from 10 men and 10 women. Subject characteristics are outlined in Table 1. Subjects followed a protocol of 15 chest compressions alternating with 10 seconds of rest for a total of three minutes. The 10-second rest simulated the time that would be taken for the provision of two mouth-to-mouth ventilations.

A five-minute training session was carried out by all subjects. On different days, a control phase of three minutes at 1G was followed by three minutes of one of three randomized levels of hypogravity simulation: 0.17G (Lunar gravity), 0.38G (Mars gravity), and 0.7G (Planet X).

During each visit, subject weight and height were measured prior to instrumentation with the body suspension harness and elbow electrogoniometer. Heart rate was measured before and immediately after the completion of the chest compressions. Adequacy of external chest compression was assessed by means of chest compression rate and depth.

The study protocol was approved by the PUCRS Research Ethics and Scientific Committees. Each subject provided written informed consent before participating in the experiment.

Statistical analysis was performed using student t-tests and two-way ANOVAs assuming a level of significance of 5%.

Subject characteristics are shown in Table 1. Subjects were matched for age and body mass index.

In all subjects, heart rate increased following three minutes of external chest compression. The magnitude of this increase in heart rate tended to be greater for the female group (Table 2).

The rate of chest compressions was not different between 1G and hypogravity in the male group (Figure 5, Table 3). However, there was a trend toward chest compression rate being slower in the female group in hypogravity as compared with 1G (Figure 5, Table 4). Similarly, male subjects maintained an adequate chest compression depth in the three hypogravity environments. Depth of compression, however, was inadequate in the female group during Lunar and Martian gravitational environments as compared to 1G (Figure 6, Table 4). During hypogravity simulation, there was a significant difference in all groups at all hypogravity values in elbow flexion (Tables 3 and 4).

FUTURE TRENDS

Previous studies on CPR administered under terrestrial conditions have highlighted features of an individual that may affect their ability to deliver effective cardiac massage. These factors include mass, height, gender, and physical fitness of the CPR provider (Ashton et al., 2002; Larsen, Perrin & Galletly, 2002; Lucia et al., 1999). In a study conducted by Ashton et al. (2002) with 40 individuals (20 males and 20 females), rescuer fatigue was investigated during two consecutive three-minute intervals of continuous chest compressions separated by a 30-second break representing a pulse and ECG check. The CPR was to be performed on a Ressusci Anne® manikin at a rate of 100/min with a depth of 40mm to 50mm. The male subjects were significantly heavier and taller than their female counterparts. During the study, the rate of chest compressions were maintained at approximately 100/min by the rescuers; however, the number of satisfactory chest compressions decreased progressively during resuscitation ($p<0.001$) due to fatigue. Female subjects were found to achieve fewer

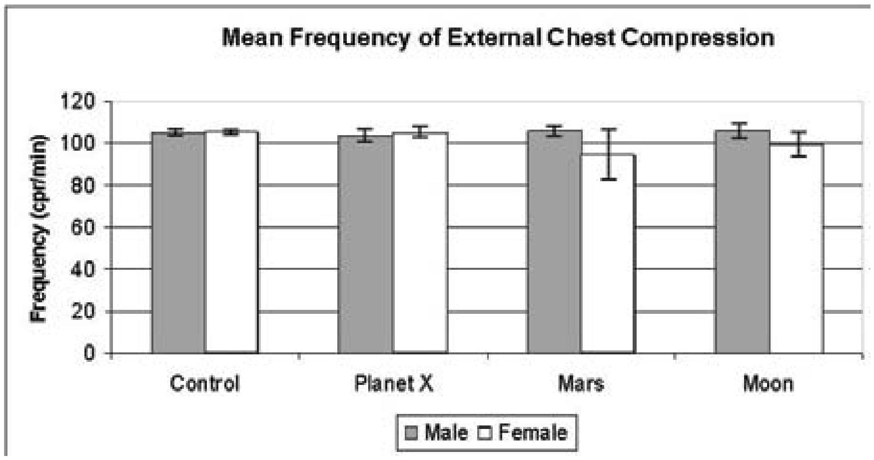

Figure 6. Chest compression depth in four gravitational environments. Values along Y axis represent chest compression depth in millimetres.

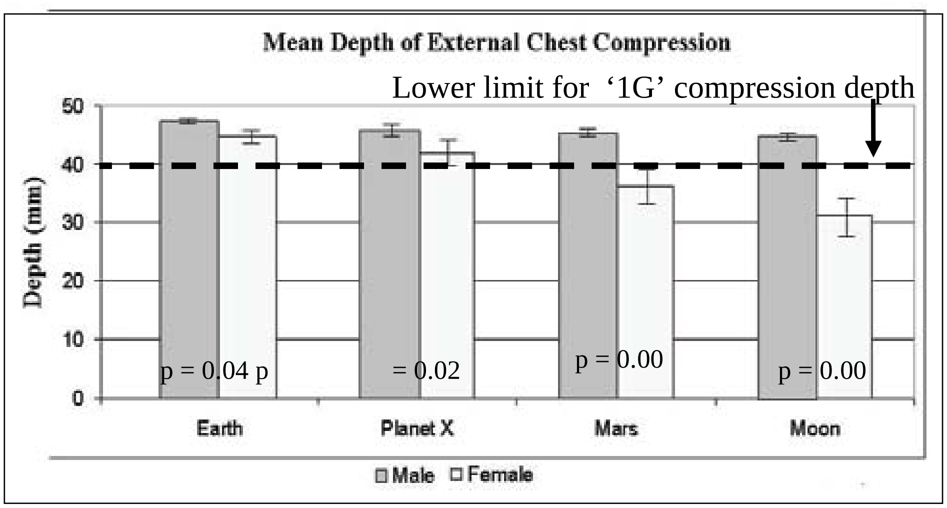

satisfactory compressions compared to males (p=0.03). Additionally, out of the seven subjects who were unable to complete the three minutes of CPR due to exhaustion, five were female. The authors also observed a good correlation between the number of correct chest compressions performed over the study period and subject height (first period: Spearman r=0.40, p=0.01; second period: r=0.32, p=0.05) and weight (r=0.51, p=0.0008; r=0.48, p=0.002). They did not find a significant correlation between CPR performance and age.

In another study of Larsen, et al. (2002), 20 medical students were observed while carrying out four cycles of 15 external chest compressions followed by two ventilations on a manikin. The data illustrated that the depth of compression, time to peak compression, and the regression slope of compression vs. compression number were significantly related to height and weight of the rescuer. Therefore, as well as ascertaining the role of gravity, the effects of these biometric factors (mass, height, gender, and physical fitness) on performance of

chest compression were also ascertained and quantified during the study.

This current study looked at evidence for the effectiveness of the terrestrial method in producing adequate compression depths and rates in these low-gravity environments, and also looked at how these parameters vary with gravity and body mass of the caregiver to allow the determination of “critical gravity” and “critical body mass” where compression depths become effective.

The body suspension device used successfully reduced subject body weight to values close to that expected to be encountered in hypogravity environments such as those of the Moon and Mars. Subjects were able to monitor their depth and rate of chest compressions effectively, a point highlighted by the fact that mean rates of compression were maintained during all conditions with only one exception.

The results clearly show that appropriate depths and rates of chest compression do appear to be possible for stronger/heavier (in this case, male) rescuers when subjected to hypogravity in the region of 0.17Gz to 0.7Gz. Lightweight subjects (predominantly female), however, were unable to achieve adequate chest compression depth in the Lunar and Martian hypogravity environments.

The present study suggests that effort required to perform adequate external chest compressions is greater, as demonstrated by the increase in heart rate following three minutes of CPR. Furthermore, the angle of elbow flexion increases with reductions in hypogravity, suggesting that chest compression force increasingly comes from the arm/shoulder musculature as body weight is reduced. Upper arm strength may therefore be important in achieving adequate external chest compressions in hypogravity.

A study conducted by Ganeshanantham, Russomano, Dalmarco, Calder, Evetts, and Cardoso (2006) aimed to illustrate the role of elbow extension in the maintenance of an effective ECC in a lunar environment. Eight healthy male subjects performed ECC while in the same body suspension device. After training, subjects followed a protocol of 30 ECC to 6s of rest (the time needed for the performance of two ventilations) (AHA, 2005) for 3 minutes. ECC adequacy was assessed by rate and depth of compressions. During compressions, subjects were instructed to maintain the straight arms terrestrial method of performing ECC, with arm braces employed to impair the subject's ability to extend and flex the elbows. Results showed a lower mean elbow angle variation of 5.95 ± 3.4^{o} ($p<0.01$) and concomitantly lower mean depth of compression that fell below the clinical threshold (37±2.9cm, $p<0.01$) in comparison to the present study findings. It can thus be concluded that elbow extension and muscular work of the upper limbs play a vital role for ECC performed in a Lunar environment, without which the current CPR standards cannot be maintained.

CONCLUSION

The PUCRS Microgravity Laboratory body suspension system can reproduce hypogravity conditions such as those expected to be experienced on Mars and the Moon. The results of this study of terrestrial CPR in hypogravity suggest that these conditions lead to an alteration of the manner in which the terrestrial method of external chest compression is performed. It appears that the rescuer arm and shoulder muscular effort by means of greater elbow flexion and extension is increased to counter the decrease in body weight. The study also indicates, however, that smaller, weaker rescuers (in this case, the female subject group) may not be able to apply sufficient elbow extension force to achieve adequate chest compression under these conditions.

KEY TERMS

Cardiac Arrest: Also known as cardiorespiratory arrest, cardiopulmonary arrest, or circulatory arrest, cardiac arrest is the abrupt cessation of normal circulation of the blood due to failure of the heart to contract effectively during systole.

Cardiomyopathy: Disease of the heart in which the heart muscle becomes inflamed and doesn't work as well as it should.

CPR: Cardiopulmonary resuscitation.

Haemodynamic: The dynamic regulation of the blood flow in the brain.

Morbidity: Death.

An Exploration of Demographic Inconsistencies in Healthcare Information Environments

Larbi Esmahi

INTRODUCTION

Healthcare providers typically use technology in a ubiquitous manner. They choose to rely upon the task-specific capabilities of a specific system, rather than the integration of all systems in the solution space. A typical example of this would be the advancement of ultrasound technologies for 3-D modeling. Whilst the capabilities of the imaging solutions are highly beneficial to the individual's unique needs for healthcare, the integration of this system into a greater solution, or system-of-systems, is often overlooked (Maier, 1998; Maier, 2005). As such, the demographic data accompanying the information may be in a format inconsistent with the requirements for the electronic medical record. Workflow Management Systems attempt to simplify and control the primary data entry methods to the data environment (Choennia, Bakkera, & Baetsa, 2003; Graeber, 1997). However, the design of these systems focuses on an interpretation layer to gather data from varying input sources, including voice and text. There is no guarantee that this information will propagate throughout the system-of-systems, as required. Common information protocols such as Digital Imaging and Communications in Medicine (DICOM) (NEMA, 2004) and Health Level Seven (HL7.org, 2006) provide a framework by which medical data is communicated. However, these standard protocols are subject to interpretation that allows for a high degree of variance in the presentation of data. This creates problems of data redundancy, and confuses the authoritative provisioning of data with referential copies.

The electronic healthcare record (EHR) is a merged presentation of the information obtained through various systems in the healthcare enterprise (Hasselbring, Peterson, Smits, & Spanjers, 2000). Imaging and demographic data contribute to the contents. Additionally, the physician comments, markup, and modality reports also contribute to the record. These individual pieces of the EHR are drawn from many disparate systems throughout the enterprise. The record information system (RIS) or alternatively a health information system (HIS) will be the primary demographic repository for patient information. As such, this text and contextual information will be used as the primary data source for downstream comparison. The Picture Archive and Communication System (PACS) will be used as a repository for imaging data (Miltchenko, Pianykh, & D'Antonio, 2002).

As the global economy and global business practices increase, individuals tend to be more transient. Their medical histories are an important precursor to successful health care provisioning. Contingent upon this medical history record is the successful integration of data from varied sources, including the mobile patient's information. This information must be portable, presentable, and independent of the initial data program from which it was obtained. By far, the greatest concern relates to data inconsistency and subsequent inaccuracy in an environment of disparate systems.

In the next section of this article, we will discuss the Health Level Seven communication protocol. In the third section, we will discuss the protocol DICOM. The application of these protocols into solutions for healthcare information repositories is presented in the fourth section, where both PACS and RIS systems are discussed. The problem of Data Disparity that causes inconsistencies in the intersystem communications will be discussed in the fifth section. The design of the XML Bus solution will be presented in the sixth section. The successes and shortcomings of this design are discussed in the conclusion.

HEALTH LEVEL SEVEN

The HL7 protocol provides an information standard for communicating patients and sites level information into and out of a health information system within the system-of-systems model (HL7 Canada, 2002; HL7.org, 2006; Neotool, 2007). HL7 allows for a loosely framed communication standard between medical IT systems. Without the provisioning of this ANSI standard, interoperability between systems was performed in an ad hoc manner.

The HL7 standard is based on the concept of events referred to as triggers (HL7, 2006, 2007). Each of these triggers fires a process that effects some particular communication of information. For example, the relocation of a patient to a new hospital would require the dissemination of information concerning that location throughout the healthcare system-of-systems. This event would be one of such triggers. A trigger may relate to a single record, as in this example, or it may relate to multiple records. A patient may have a name change due to marriage. This would require an update to all existing records in the information system to ensure data consistency.

Each trigger is composed of segments. The segment is a variable length field separated by a discernable character, such as a comma or pipe. In a manner similar to comma separated values (CSV) files, data can be delineated and also referenced externally though API functions. The content of each segment shall contain ASCII characters. The HL7 committee defines the acceptable character set as "The ASCII displayable character set (hexadecimal values between 20 and 7E, inclusive) is the default character set unless modified in the MSH header segment" (HL7, 2006). The HL7 trigger is represented in Figure 1.

Each field may contain multiple subfields, delimited by a caret character. In the case of a name, |*DOE^JOHN^^^^*| the content between the two pipe symbols is the field of data, whereas the data *DOE* and *JOHN* are considered subfields. The MSH is the message header segment, providing basic instructions on the contents within the trigger message.

This example also makes reference to three other key items: the *PID* that is the patient identifier, the EVN identifying that an event is included in this message, and the PV1 filed, which is followed by information about the patient's stay at the hospital.

One of the important contents within this message is the event type. As per the example, the message type provided is A04. HL7 defines many different message types, each with unique content. There are 51 defined Admission, Discharge or Transfer (ADT) events for HL7 in the V2.5 standard. The following table describes some of these events.

Without elaborating further on some of the many messages available to the HL7, it becomes clear that many distinct attributes are communicated in this protocol. Static entities such as Patient ID, Accession number, and event dates are provided in the same framework as dynamic information, such as location. The messaging protocol is also intended to communicate changes in state, through the provisioning of state-in-time attributes that have an expectation of permanence (Evola, 1997). These attributes, such as Patient ID, may have referential integrity for a site perspective. However, in the conglomerate or regional model of healthcare, that identifier now becomes nonreferential from a global viewpoint, and as such, introduces disparity at a higher system-of-systems level.

Table 1. HL7 message types

Message Type	Definition
Admit/visit notification (event A01)	Assign a bed to an admitted patient
Transfer a patient (event A02)	Patient changes their physical location
Discharge/end visit (event A03)	Patient leaves the facility
Register a patient (event A04)	Patient is brought into the facility, but not given a bed
Pre-admit a patient (event A05)	Patient is not admitted (In the facility), but demographic information is registered in the information system prior to their arrival for procedure.
Change an outpatient to an inpatient (event A06)	If a patients status changes, normally due to severity, they will be given a new location at the facility
Change an inpatient to an outpatient (event A07)	As per A06, defines a state change in the patient location.
Update patient information (event A08)	Represents a change to any of the demographic information related to a patient. This may be name, address, or other field.
Patient departing tracking (event A09)	Patient in transit outbound
Patient arriving - tracking (event A10)	Patient in transit inbound

DICOM

DICOM exists as an information distribution mechanism for medical devices (Ratib, Ligier, Rosset, Staub, Logean, & Girard, 2000). It is important to note that DICOM can be viewed as a technical protocol for layer seven communications or a solution to information exchange.

The DICOM protocol was developed in a joint effort between the American College of Radiology (ACR) and the National Electrical Manufacturers Association (NEMA, 2004). The protocol was introduced as a hardware interface, a minimum set of software commands, and a consistent set of data formats for communication between medical devices. This standard was intended to provide a framework to an emerging technology, medical information technology, allowing the sharing of data amongst Picture Archive Communication Systems and compliant sources.

The DICOM protocol is used by a multitude of devices within the hospital enterprise for information transfer, sharing, and coordination (Jung, 2005). Some of the systems that rely on the protocol include modalities (Ultrasound, X-ray, CR, CT, and so on), Picture Archive Communication Systems, Film Printers, and Digitizers (media conversion systems) (Iacucci, Nielsen, & Berge, 2002). Although the implementation of the protocol is proprietary for each manufacturer, the standards as provided by the NEMA organization assist in ensuring general interoperability and definition of expectation for each DICOM function.

The first layer of protocol discussion relates to the negotiation of capabilities between the acquisition device and the subsequent receiver. Two concise roles are defined within DICOM to elucidate the responsibilities of each participant in the information exchange: the Service Class User (SCU) and the Service Class Provider (SCP). The SCU is the requestor of services for the purposes of information storage. In essence, it has information, and solicits a predefined receiver to accept this information. The SCU negotiates the acceptance of the sender's data, typically in one or more ways (Revet, 1997).

The storage transmission starts with a request from the SCU. The SCU identifies itself and asks for a specific function, through a composite request. The request consists of an object and an associated action. For example, a C-STORE message may consist of a request for data storage, and a subsequent object, such as an ultrasound image. The SCP, or storage provider, accepts the association request from the resource, assuming the storage host trusts it.

As illustrated in Figure 2, the bidirectional request-response behavior is typical of the DICOM protocol. The SCP not only accepts the initial request, but also responds with a list of capabilities for that request. The response consists of a list of Service Object-Pair (SOP) classes, reflective of the storage ability of the SCP system. Also included in this request-response exchange is the choice of transfer syntax used for communication. Since there is a multiplicity of available syntaxes in the DICOM standard, some systems require the presence of an explicit value representation in the message. Others rely on an implicit understanding between data dictionary implementations, as provided partly by the DICOM standard, and partly by the SCP developer (McCormick, 2006).

DICOM data is broken into six major groups: File, Study, Acquisition, Image, Object, and Presentation. Each of these groups is well defined in terms of permissible content by the DICOM committee, as published in the DICOM standards and Supplements. Seven major groups are used to categorize DICOM Data elements. Group 0002 identifies file level attributes. Group 0008 identifies attributes relating to the study. Group 0010 identifies the patient attributes. Group 0018 relates to the acquisition of specific attributes related to the image. Group 0020 contains object level information, including the hierarchal relationship attributes that allow the linking of this image or object to the other objects in the series, study, and patient. Group 0028 elements provide display information crucial to the proper visual presentation of the image. Medical software uses this information to apply default settings. Group of Private Data Elements (odd numbered groups), allow the vendor to include information that can be used in a proprietary manner (i.e., to display the images, in case that vendor's system is part of the total System-of-Systems solution).

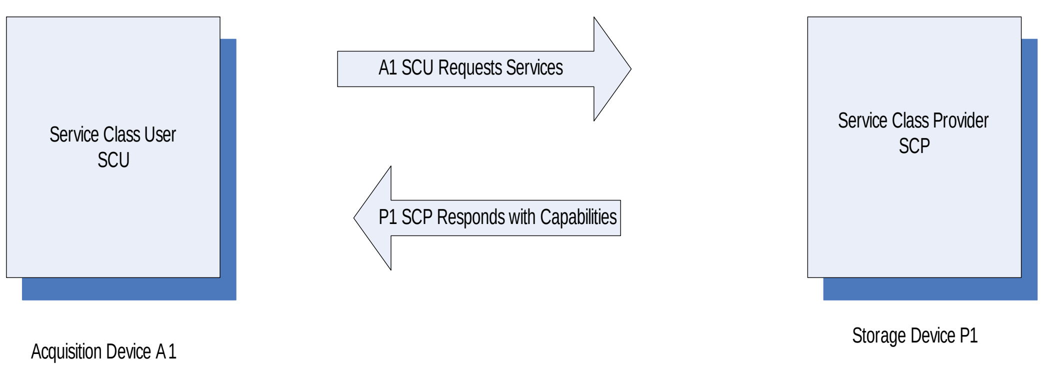
In summary, the DICOM protocol allows not only for the communication of patient, study, series, and image level information, it also defines the mechanism by which that information may be exchanged (Kolesnikov, 1997; Kolesnikov, Kelle, & Kauranne, 1997). This data is the primary source for study information as it related to the patient.

PACS AND RIS

PACS systems are built as a central repository for DICOM information (Gell, 2000). They are typically deployed as a means of replacing typical film based media. Through the implementation of the Storage Class User (SCU) and Storage Class Provider (SCP) mechanisms defined in DICOM, the PACS system receives images for later retrieval. PACS provides an electronic means of long-term storage. This storage serves as the integrated lifecycle management mechanism for a continued inbound stream of data (Miltchenko et al., 2002). The PACS is also the recipient of messages from the RIS. These messages represent unique events, such as a patient name change. Upon reception of such events, the PACS system is expected to start a process that will eventually update the demographic data using the previous name to the new patient name. The PACS answer to subsequent queries related to the updated patient records is subject to the proper interpretation of the data, as identified through the use of explicit data types, as well as the data dictionary. In fact, the use of DICOM data dictionaries allow for explicit metadata definition of data streams received. In the case of PACS, data dictionaries assist in defining the understanding of data content, both by type and content (Kennedy, Seibert, & Hughes, 2000).

Health Information Systems (HIS) organize demographic records for the purpose of centrally collecting a repository of electronic information. Radiology Information Systems (RIS) build upon this purpose for the radiology patient by scheduling orders. As information repositories, these systems (HIS and RIS) are constantly updated with both new and changing information. RIS systems can also provide worklists to modali-

Figure 2. SCU-SCP communications



ties containing patient names and other demographic information of importance. In order for modalities to communicate outwards to information systems, they rely upon the DICOM protocol (Miltchenko et al., 2002; Tornhola, 2004). This may require the HIS system to accept DICOM events. Alternatively, data translation systems occasionally transform DICOM messages to the appropriate HL7 data construct, normally understood by the HIS system. The DICOM standard assists PACS implementations in providing a referential target, but only provides DICOM consistency of the data that is independent of the RIS. The RIS always relies on the HL7 protocol and its messaging mechanism for informing the PACS of changes, as well as receiving events from DICOM devices.

The messaging mechanism between different systems offers the translation medium that serves to both interpret and re-represent the data. However, the interpretation is based on an understanding of the message context inbound. This is a highly subjective interpretation. Resultantly, events and interpretation can result in inconsistency in this messaging based approach.

CAUSES FOR DATA DISPARITY IN THE SYSTEM-OF-SYSTEMS APPROACH

As discussed in the previous sections, the event and messaging framework used in the health enterprise system does not warrant the consistency between different instances or parts of the patient records. In this section, we will examine some of the events that may end with data disparity in the health enterprise system.

Data Silos in Healthcare Information Systems

Protocols such as DICOM and HL7 exist for the purposes of exchanging information within the PACS and RIS information silos in the hospital enterprise. These protocols ensure data confidence for downstream systems, but are not designed to provide referential data cross system in the system-of-systems model. These protocols provide a framework by which medical data is communicated, but are subject to strict programmatic interpretation. System implementations interpret the protocol standards in unique ways, allowing for a high degree of variance in the presentation of data from multiple independent data sources. This creates problems of data redundancy, inaccuracy, and confuses the authoritative provisioning of data with referential copies. By far the greatest concern relates to data inconsistency and subsequent inaccuracy in an environment of disparate systems. Unique data keys used for data alignment or referential integrity may be drawn from human assumptions that are faulty.

Inconsistent Record Identifier for the Patient's Data

Name change: In the system-of-systems, the patient name is always used as a key or part of the key for querying the patient data. Patients sometime change their names, especially after a marriage or divorce. When such an event occurs, demographic references strongly tied to that person's medical history will need to be changed or updated in order to insure the continuous access to relevant historical data.

In order to synchronize a patient's name throughout the system-of-systems enterprise, an HL7 N-event entitled "Patient Update" needs to occur. This type of event will ensure that all records containing "patient name" are updated to reference "the new patient name."

Legacy system for scanning film and paper data: Many of the enterprise records for patients in the hospital exist on documents. Admission, discharge, and transfer records may exist solely on nonelectronic medium. These information sources must be manually updated each time an event occurs, such as a patient name change. More information exists in the way of medical film. Not only is the image data present, but often the demographic information for the patient is burnt into the film.

OCR technologies can be helpful in dealing with the shear volume of ADT records for the patients. However, the electronically introduced data will need to be reconciled with the existing HER records.

Data Inconsistency Generated by Automatic Triggers or Cascading Events

Study cancel: On a less frequent basis, patient examinations are not conducted. This could be due to a myriad of causes, including patient absenteeism, acquisition device failure, as well as general infrastructure failure. In any of these events, a decision is made to cancel the acquisition of data relevant to the patient. In these cancellation scenarios, an N-event message is then scheduled. However, when the message is received by the PACS system, the study or appropriate identifier may not be present, as defined in the N-Event. This may be caused if the study acquisition has not yet begun. Also, the billing system may not receive the correct event-message. As such, we have an event-ordering problem.

Study split or merges: Data flow allows for the division and recombination in the process of medical diagnosis. A patient may have had a very long CT exam that extends into body parts outside the area of expertise for the radiologist. As such, it may be beneficial, both medically and financially, to split the study into two distinct studies for the patient. The inverse may also occur, resulting in a study merge. Study or series acquisition may be interrupted for one or more reasons, including equipment failure, resource contention, or multiple system acquisition. In any of these events, two or more distinct studies may need to be merged into a single study record.

A question arises regarding the synchronization of data between these models. It is unclear whether one or more IS records in this environment would exist for each study. As such, we encountered a many-to-one disagreement. Billing systems would need to be correctly informed that only one, albeit larger, procedure was performed. Also, only one read or transcription should have occurred in this model.

Data Exchange and Transfer of Patient Records

In some medical situations, a patient will need to be relocated from one hospital environment to another. In this dataflow scenario, the patient's records may be imported to the new environment. Alternatively, a new record may be created at the newest site. Also, the imaging data is sometime transmitted to the DICOM SCP of the receiving site's PACS. The transmitted and imported data needs then to be reconciled against the new site's information system in order to correlate records to demographic data, so that any patient movement or other procedures can be referenced to the same patient.

Character Set Translation and Legacy Systems Tagging

ISO_IR disagreement and database character translation: ISO character sets refer to the specific procedure for mapping a sequence of bytes to a sequence of characters. The DICOM standard includes a specific tag necessary to identify the character set used in the header. This is of extreme importance to the demographic consistency of the data interpretation and action throughout the enterprise.

By way of example, consider a query for all patients whose last name starts with Ł (from ISO 8859-2, decimal 163). If the system were not capable of understanding this character, perhaps through a limited understanding of only ISO_8859-1, then this character would escape the query, possibly with undesirable results. Worst yet, any patient name update including the character Ł would also be problematic.

Private DICOM tagging: Many modality vendors choose to include proprietary information in the DICOM header of the images and objects they transmit. This information is only of use to a system that is programmed to take advantage of it. It allows for a tighter sub-system-of-system model, but at the expense of the greater solution.

Time Synchronization

Time is a critical component to a successful diagnosis. All members of the health enterprise solution normally have their own time keeping facility. However, in the system-of-systems, the use of time stamps is critical to insure the coordination of transactions and order of precedence. These time stamps should be synchronized within the whole system-of-systems.

Other Technical Issues

Data reintroduction for disaster recovery purposes: In the event of system failure, one or more entities within the system-of-systems will need to be repopulated with original data. Upon completion of this, a synchronization effort will need to occur between it and one of more members within the environment. This activity requires coordination of the various information systems within the hospital enterprise.

E

RIS feed interruption: The RIS messaging mechanism is a necessary prerequisite in the system-of-systems for data continuity. Upon failure of any RIS system in this environment, the update events will not properly register for all receiving systems in the enterprise, resulting in an environmental data inconsistency.

AN XML BUS FOR RESOLVING SOME OF THE DATA DISPARITY ISSUES

One of the prevalent issues in message-oriented systems is defining one or more protocols by which messages can be processed. Adherence to standards, bridging between protocols and configurations all raise issues in a multiple systems environment. In the healthcare enterprise, the interdependency of systems for successful patient care only serves to exasperate the situation. XML and semantic Web technology presents a great potential for solving some of the disparity issues (Heitmann, 2002; Pianykh, Castañeda-Zuniga, W. D., D'Antonio, & Tyler, 2001a; Pianykh, Miltchenko, & Castaneda-Zuniga, 2001b; Tornhola, 2004). In this section, we present a solution based on the use of an XML bus for data transfer. Figure 3 presents the XML bus design from a dataflow perspective.

The data bus would allow for a common data conduit. The connection to this conduit would be accomplished through adapters that provide common data typing. Each connection into the data bus would require an adapter that allows for consistent conversion from source protocol to XML.

DICOM to XML Conversion

The adapter, as shown in the arrow in Figure 3, is a translation engine that understands both XML and the healthcare-specific protocol, in this case, DICOM. Using open source tools such as DCM4CHE, conversion of DICOM to XML is readily possible.

The following code is a truncated output of the dcm2xml.jar transformation performed on a sample DICOM file.

HL7 to XML Conversion

Version 3.0 of the HL7 standard is a pure XML implementation (Heitmann, 2002). As such, the major concern relates not to the transformation of the trigger, but to the interpretation. This is somewhat addressed in the Reference Information Model of HL7 3.0. In versions prior to 3.0, a methodology is necessary to interpret the trigger events as XML. The HL7 organization has devised rules in order to properly encode the HL7 triggers in XML. These rules would enable an adapter framework to implement commonality of meaning across the data bus, as shown in Figure 3.

Modality to XML Data Bus Adapter

There is commonality between the DICOM to XML Adapter, and the Modality to XML adapter. Both use DICOM as a protocol for communication, and as such, may rely partially on the implementation details for each other. Modalities also have unique features, such as Modality Performed Procedure Steps (MPPS), which must also be taken care of in any successful implementation

(Noumeir, 2005). The modality adapter must be able to communicate these specific events directly to the data bus. Any subsequent queries upon the data bus would then be able to accurately provide procedure start and procedure end dates and times through the Modality to XML adapter shown in Figure 3.

Context to XML

Many applications rely on the Clinical Context Object Workgroup (CCOW) for interoperability notification. This standard and an extension of the HL7 framework allows singular CCOW-aware applications to interact with other CCOW-aware applications for the purposes of information sharing (Grimson, Stephens, Jung, Grimson, Berry, & Pardon, 2001). This standard is extremely beneficial in the system-of-systems approach, as it represents a common notification mechanism for changes in status. It also has value in voice dictation systems as a means of coercing dictation information into the patient framework through the identification of common attributes, such as patient name and study instance-unique identifiers.

Proof of Concept

The following interface provides a rudimentary proof of concept for the Enterprise Healthcare Record Viewer application. The intent of this application is not to commit a full implementation, but rather to provide a framework by which further research may be committed.

Figure 5. Enterprise healthcare record viewer prototype

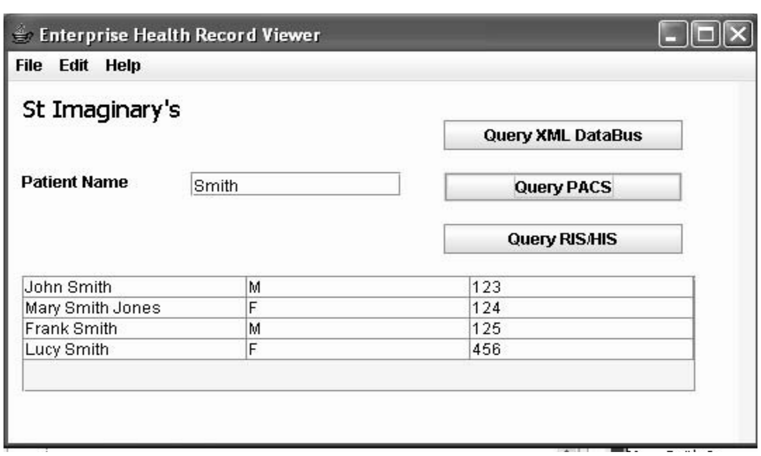

Figure 6. DICOM response from EHR application C_Find

Grp	Elmt	Length	Description	VR	VM	Value
0008	0052	8	query_retrieve_level	CS	1	"PATIENT"
0010	0010	6	patient_name	PN	1	"Smith"
0010	0020	2	patient_id	LO	1	"*"
0010	0040	2	patient_sex	CS	1	"*"

The EHR interface provides three query mechanisms. The XML Data Bus function performs a direct SQL query to the data repository, as stored through a future XML to SQL transformation. The second interface queries the PACS SCP through a standard C_FIND. Figure 6, an excerpt of the DICOM conversation ensuing from that query, details the Group and Element data transferred.

The last query mechanism queries the RIS system. Connectivity to the RIS is accomplished through an HL7 Query message.

CONCLUSION

Medical information systems exist as information silos within the global health enterprise, making the task of designing an effective and accurate Enterprise Health Record Viewer very difficult. Each healthcare enterprise system in the system-of-systems acts as a referential entity for the information it contains, but only for the specific domain for which it is specialized. For each system in the enterprise, downstream distributed applications typically rely on the one specific data silo as a means of identifying and enacting decisions within an application framework. Whilst this ensures one to one consistency of data between the application and a centralized data repository, it does not ensure consistency within the enterprise.

In the enterprise health record, two systems were found to be of importance. Radiological clients communicated primarily with a PACS system via DICOM as a means of obtaining study level data for patients. Radiology workstations communicated with RIS systems via HL7 in order to record patient-level attributes. Data consistency was often accomplished through the implementation of translation systems converting one protocol to another. In fact, protocols such as DICOM, CCOW, and HL7 exist as standards for information sharing, but the exact implementation of message conversion from one standard to another is often an area of information redundancy. Data conversion solutions were also viewed as a possible cause for information loss or inaccuracy due to the incongruity in frameworks between the systems and their protocols. In the translation and representation between systems in the enterprise, data conversion is not always possible. Enterprise inconsistencies also exist as a direct result of data workflow. HIMMS and IHE are leading the way in standardization of data consistency and authority in the healthcare enterprise by defining information pathways and messaging content within the medical information environment.

The development of an Enterprise Record Viewer illuminated the necessity for authority of data. Although protocol translation was seen as a contributing factor to inconsistencies, the production of a solution became reoriented around the creation of a central authority in order to ensure consistency. This hierarchal approach avoided the concern over data consistency in the enterprise by creating another independent silo for data display. Connectivity to the RIS and PACS systems allowed the viewer to query independently of the XML Data Bus in order to allow alternative means of exploring data that may not have been messaged properly.

The production of the framework for the XML data bus is representative of a methodology or approach for an Electronic Healthcare Record. Further effort is necessary to expand upon this singular solution to resolve the data disparity issues driven by the system-of-systems approach in the hospital enterprise. The XML data bus design provides a framework for solving some of the identified causes for data disparity. Patient name changes are addressed through the transmission of this data to the bus. All queries can then be programmed to query via the bus. Similarly, patient moves and study cancellation messages can be communicated into the bus for dissemination and subsequent query. While the bus design alleviates these areas by creating a singular entry point for enterprise systems, other causes for data inconsistency cannot be solely addressed through the XML data bus design. Consistencies in data dictionaries, ISO_IR disagreement and private DICOM tagging practices require future research. These areas may benefit from an assessment of the W3C semantic Web design. Another concern remains with data movement and event ordering. Issues such as time synchronization and RIS message repetition may benefit from an asynchronous transactional approach as implemented through the use of a message queuing. Legacy film based scanning practices would benefit from an examination of form based workflow technologies, and would integrate more readily into an XML construct such as the proposed XML data bus.

Future implementations are recommended to focus on the remote user's requirements as a means of both centralizing data, and also on providing a readily accessible, consistent, and lightweight viewpoint to data. This latter objective will facilitate a successful adoption through the consistent presentation of patient demographic data. As Scotland, England, Estonia, Canada and others begin the process of providing centralized socialized healthcare through the amalgamation and adoption of countrywide healthcare solutions, Enterprise Healthcare Record Viewers and identification of data authorities inside the system-of-systems healthcare enterprise will become critical to the successful provisioning of healthcare to patients.

KEY TERMS

Clinical Context Object Workgroup (CCOW): More commonly known as Clinical Context Management, enables the clinical end-user to experience the simplicity of interacting with one system, when in reality he or she may be using multiple independent applications through varying interfaces. Defined by HL7 standards, CCOW ensures secure and consistent access to patient data from varied sources.

Clinical Document Architecture (CDA): Also known as the Patient Record Architecture (PRA), provides an exchange model for clinical documents (such as discharge summaries and progress notes). CDA brings the healthcare industry closer to the realization of an electronic medical record.

Comma Separated Values (CSV): This file format is often used to exchange data between differently similar applications. CSV files have become somewhat obsolete, due to XML data exchange possibilities.

Digital Imaging and Communications in Medicine (DICOM): A standard for the distribution and viewing of medical images, such as CT scans, MRIs, and ultrasound. It describes a file format for the distribution of images and provides access to Storage Media independently from specific media storage formats and file structures.

Health Level Seven (HL7): A standard for exchanging information between medical applications. It is an event driven protocol that defines the format and the content of the messages that applications must use when exchanging data with each another in various circumstances.

Modality Performed Procedure Steps (MPPS): The MPPS service works in concert with the Modality Work List service to provide exam status updates. MPPS are used for two purposes: updates the exam state of patient and forward messages to another application entity, such as a RIS or other work list provider.

Modality Work List: The Modality Work List service provides patient demographic information to imaging modalities in the form of a work list. Modality work lists also allow technologists to sort their workload by time period, specific date or time, patient name or identifier, and modality.

Network Time Protocol/Simple Network Time Protocol (NTP/SNTP): NTP is an Internet protocol used to synchronize the clocks of computers to some time reference. SNTP (Simple Network Time Protocol) is basically also NTP, but lacks some internal algorithms that are not needed for all types of servers.

Picture Archive and Communication System (PACS): A network of computers dedicated to the storage, retrieval, distribution, and presentation of images. A PACS system provides a single point of access for images and their associated data. It also interfaces with existing hospital information systems, such as the hospital information system (HIS) and the radiology information system (RIS).

Service Class Provider (SCP): In DICOM, the relationship between both partners is defined by the Service Class description. The SCP plays the "server" role to perform operations and invoke notifications during an Association. An example of a Storage Service Class Provider would be an image storage device. The SCP role includes enabling the applications to receive DICOM objects locally from devices (image sources, workstations, servers, and so on) through the DICOM protocol.

Service Class User (SCU): In DICOM, the relationship between both partners is defined by the Service Class description. The SCU plays the "client" role to invoke operations and perform notifications during an Association. An example of a Storage Service Class User would be an image acquisition device. In this case, the image acquisition device will create and send a DICOM image by requesting that a Service Class Provider store that image.

Service Object-Pair (SOP): SOP classes identify the capabilities of the specific distributed processing for a certain Service Class. When partners agree to use a SOP class, both sides must ensure they will play their role as described, using the context of the enclosing Service Class. In each SOP Class definition, a single Information Object Definition or IOD is combined with one or more services.

Workflow Management System: A system that completely defines, manages, and executes "workflows" through the execution of software whose order of execution is driven by a computer representation of the workflow logic. The workflow is concerned with the automation of procedures where documents, information, or tasks are passed between participants according to a defined set of rules to achieve, or contribute to, an overall business goal (Hollingsworth, 1995).

Exploring Information Security Risks in Healthcare Systems

Amy Ray
Bentley College, USA

Sue Newell
Bentley College, USA
Warwick Business School, UK

INTRODUCTION

The volume and severity of information security breaches encountered continues to increase as organizations, including healthcare organizations, struggle to identify more effective security policies and procedures. Publicly available guidelines such as GASSP or ISO17799 that are designed to facilitate development of effective security policies and procedures have been criticized for, among other things, inadequate attention to differences in organizational security needs (Baskerville & Siponen, 2002), and for inadequate attention to the social dimensions of security problems (Dhillon & Backhouse, 2001). In this contribution, we argue that the diversity of organizational security needs, as well as the need to recognize the social dimensions to security problems, will continue to grow as companies move away from employing unique, proprietary approaches to software and network development, in favor of adopting standards-based plug-and-play applications, and related standards-based methods and technologies designed to enable interorganizational as well as local systems interoperability.

We use complexity science and adaptive structuration theory to support our arguments that current security management policies and procedures focus on what technologies are used, and on planned systems use to the exclusion of unplanned—but real—emergent use and emergent development of systems. A more holistic approach to security that adapts to emergent systems developments—and most importantly, addresses alternative, emergent uses of systems—is needed, we argue. Throughout the article, we use examples from the healthcare sector to illustrate our points. We do this because Electronic Health Record (EHR) systems that will enable information to be shared across a variety of organizations (local doctors' offices, hospitals, health insurance providers, research organizations, and so on) and users (doctors, administrators, nurses, researchers, and so on) are at the early stages of adoption in many countries, so that much can be gained by starting with an informed view of what can lead to security risks, so that policies and practices are adopted that can protect the information that is being shared.

BACKGROUND

Software development has been described as a "craft" industry, because software applications are developed one at a time, and labor is by far the most significant cost of any development project. Various *standards*—or generally agreed-upon activities, methods, functions, protocols, interfaces, systems, equipment, materials, services, processes and products (De Vries, 2005)—have been introduced and employed in efforts to reduce the labor costs associated with IT projects, especially in terms of standards designed to facilitate creation of Web applications (e.g., TCP, HTML, HTTP, XML, SMTP, UDDI, SOAP).

These standards are generally referred to as Web standards or Web-based standards, and their power to provide interoperability between two or more systems has been established for decades. However, while these standards have benefits, it is important to recognize that using standards has an unintended consequence. More specifically, it can be argued that, as a result of *successful* use of Web-based standards for local systems development and systems integration, overall systems architectures are more complex, ultimately resulting in an environment of greater information security risk. In the next section, we explain why standards-based development and integration increase the overall complexity of the systems architecture, and subsequently consider how this influences emergent use and architectural complexity, and so information security risk.

INFLUENCES ON ELECTRONIC HEALTHCARE RECORD SECURITY

IT Standards-Enabled Planned Systems Development and Complexity

At a local level, using IT standards simplifies the process of connecting one computer to a network of other computers. For example, employing Web standards, countless computers and computing devices around the world are connected, making the Web infinitely multidimensional and nonlinear. However, while Web standards simplify individual systems integration efforts, they potentially increase the complexity of the overall system architecture by enabling connections among heterogeneous systems.

Complex systems are defined as systems that interweave components in such a way that they display variation without being random, and result in a structure that is more than the sum of its parts (Lissack & Roos, 2000). Complexity science research has shown that many highly complex systems—including systems as diverse as the central nervous system, the biosphere, the stock market, telecommunications systems, and human immune system—are not only multidimensional and nonlinear, but are also made up of many selfsimilar components or properties that, in turn, enable development of more complex systems. EHR systems are good examples of such complex systems.

A number of healthcare data standards (e.g., medical code, individual and entity, and transaction processing standards) are now in place for electronic transmission of administrative data as a result of the Health Insurance Portability and Accountability Act of 1996 (HIPAA). Insurance claims data for a patient may be filed on a laptop computer or handheld device in a physician's office, processed by a claims manager from a terminal at an HMO, and otherwise accessed from any authorized device by a user with legitimate (or stolen) authorization. The challenge of mapping the network of authorized access points to HIPAA information grows as the network grows, and the network grows as the application of standards grows. In addition, in order to comply with HIPAA, many healthcare organizations have outsourced claims processing to healthcare clearinghouses (Ivans, 2003), increasing the complexity of the flow of data, as well as increasing the number of individuals with access to patient data. Thus, applying HIPAA transaction standards to systems integration efforts in healthcare simplifies the process of filing an insurance claim, but increases the complexity of the overall network architectures in healthcare.

Web Standards and Emergent Systems Development and Use

In an organizational or interorganizational context, Web-based standards are used to develop information systems applications in support of particular business processes. However, considerable research now exists which illustrates how actual use of IT is often different from the intended use. Users improvise by adding applications to the original system in order to support local practices (Ciborra et al., 2000; Pozzebon & Pinsonneault, 2005), and/or by simply using the system in ways not initially anticipated (Orlikowski, 2000). structuration theory (ST) (Giddens, 1979) and adaptive structuration theory (AST) (DeSanctis & Poole, 2004) are proven as useful frameworks for demonstrating how technologies are adapted and used by individuals within organizations. ST and AST address how social structures are changed via the interaction between a user and a technology, thus helping to explain the emergence and evolution of system use. In this sense, the real nature of a technology and its consequences emerge from the actions of individuals as they engage with and use the technology in practice (Orlikowski, 2000). These consequences can only partially be planned for in advance, and will vary across time and space as context, history, and process impacts the ways in which users develop knowledge through their reflective practice with the technology.

We again turn to healthcare to provide another example of this phenomenon. Since EHR are typically enabled by Web-based—as well as propriety—standards, and are employed by a highly diverse set of users, they are prime candidates for emergent development and use. EHR are designed to support documentation of clinical healthcare. However, physicians, researchers, nurses, insurance company employees, pharmacists, and many others are users of these systems, so it is reasonable to expect that different uses of the systems will emerge across user groups. For example, insurance companies are in the very early stages of adopting pay-for-performance systems to reward physicians based on information collected from EHR about the efficacy and efficiency of care provided to patients. Similarly, researchers are searching for new opportunities to use data available in the standardized, categorized formats enforced by EHR. In fact, EHRs are actually examples of emergent systems' development efforts as they emerged from foundational efforts to create standards for HIPAA (Fedorowicz & Ray, 2004).

The following are examples of simple, emergent uses or developments that can have a dramatic impact on the complexity, and thus manageability, of the overall information systems:

- A nurse adds a wireless network within a department without notifying the IT personnel.
- An individual doctor loads a set of organizational data on a USB drive to take home and analyze on a home computer.
- A sales manager finds that an application designed for one use (repeat orders) is also useful for another purpose (individualized marketing).

The purpose of these examples is to show that system connections and uses are dynamic, rather than to say that they cannot be secured. If uses are known, then effective security policies and procedures may be put in place. However, in an environment where uses are regularly and frequently emerging, existing security policies and procedures may quickly become inadequate, as discussed in the following section.

Architectural Complexity and Information Security Risk

We have presented arguments that standards-enabled systems development and integration methods ultimately increase the complexity of organizational systems' architectures, and support unintended emergent systems development and use. Current security frameworks do not factor in the consequences of emergent systems and system uses, which exacerbates problems noted by other researchers of inadequate attention to differences in organizational security needs (Baskerville & Siponen, 2002) and inadequate attention to the social dimensions of security problems (Dhillon & Backhouse, 2001).

The use of well-understood standards to develop uniquely complex systems creates a triple threat for security managers. First, standards are well-documented and well-understood, which means that any known flaws are typically documented. Documented flaws, for example the ability to exploit knowledge about the IP standard to spoof an IP address, means that hackers—as well as security professionals—have access to this knowledge. Second, the growing complexity of overall systems architectures that result from standards-enabled extension and integration translates into decreasing abilities to understand and manage systems. Since security managers may not even be aware of emergent systems developments and uses, rendering the ability to set effective policies for secure use impossible. Third, the complexity of systems in an environment where systems managers may not be aware of every development and use can contribute to an insecure environment by allowing hackers more points of access to exploit, as well as potentially providing more opportunities to cover their tracks when using unknown access points into systems.

Information security guidance is typically either strategic-level guidance based on organizational goals and primary uses of data, or focused on highly detailed technical issues, such as protecting access points with effective passwords, protecting networks with properly configured firewalls, and appropriate use of encryption. The latter category dominates organizational spending, and using terminology from complexity theory may be referred to as a reductionist approach where security management strategies involve application of solutions to small fractions of a system at a time (e.g., passwords to secure access to an application, firewalls to protect network traffic, and so on). Evidence suggests that reductionism also drives IT security investment (Ernst & Young, 2005). Even strategic security guidance such as HIPAA and ISO17799 make recommendations based on consideration of methods for securing systems components rather than considering the vulnerabilities based on alternative uses of technology, or from considering risks associated with the overall architectural choices supporting the information systems infrastructure. Reductionism is clearly necessary, but it is also increasingly insufficient for effective security management, because, as we have demonstrated in this contribution, it ignores the ways in which systems architectures and uses are dynamic and increasingly complex.

FUTURE TRENDS

In most countries, national health record development efforts are in their early stages, so there is time to consider the full gamut of potential risks, and to design these systems with appropriate measures of protection, both technical and organizational. However, there is little research that has focused on the creation of security policies in contexts that are emergent, rather than static (Baskerville & Siponen, 2002). Instead, most approaches to security, as we have seen, are reductionist in nature. These reductionist approaches are always going to be limited for the reasons discussed above. Instead, what seems to be important is to develop holistic approaches to security, which encompass social, as well as technical, elements, and which is dynamic, so that security issues are considered each time a new use is adopted, even if this use is not formally instigated. This could include, for example, dynamic monitoring for changes in systems architectures, and comprehensive training to not only educate users about risks from intended uses of systems, but to also provide them with methods for considering risks associated with emergent uses of systems.

In considering how this could be approached in an organizational context, it is important to identify who will be responsible for championing this more holistic approach. One new management position in many organizations with complex systems is the Information Systems Architect, whose job responsibilities include approving new systems development projects, and using whatever tools and processes are necessary to remain knowledgeable about the true architecture of the existing information system. For example, the information systems architect might employ network monitoring tools on a regular basis to ensure that rogue wireless networks are identified and appropriately controlled. We suggest here that either the Information Systems Architect also have security management responsibilities, or that key security managers such as Chief Security Officers at least occasionally adopt a practice of considering security risk management from a holistic perspective to complement existing reductionist security policies and practices. We further suggest that much work needs to be done to ensure that security policies are reviewed and updated frequently, and that appropriate steps are adopted for ensuring that security policies and practices are as adaptive as the complex, emergent systems they must protect. A good starting point is to consider developing metapolicies for adaptive development of security policies, and when they are needed (Baskerville & Siponen, 2002). In keeping with our analysis, it is also important to emphasize the principles of security management during training, so that the various users of complex systems such as electronic health record systems will build in their own security practices as the system evolves, even when the emergent applications have inherent security gaps. Metapolicies would be useful for establishing this practice as well. Research exploring the best ways to achieve this holistic understanding and appreciation of the importance of securing data in large complex EHR systems is clearly going to be an important challenge for the future.

CONCLUSION

Our research contributes to the literature by demonstrating the potential domino effect of Web standards-enabled systems integration and development efforts. Standards facilitate rapid development of planned and emergent systems, but can ultimately lead to overall systems architectures that are very complex to manage. When this happens, organizations are at increased risk of security breach. Including security features in individual application design will only be effective to the extent that the interactions between multiple applications in the larger system have all been anticipated during the design process, and that the system is used only in ways that were originally intended. As our contribution suggests, neither of these conditions is very likely. This suggests the need for a more holistic approach to security management.

We have presented numerous examples in this article to support our analysis, but much research is still needed. We believe such research is critically important, given the early stages of Web standards-enabled systems development efforts and the potential for either tremendous gain or tremendous chaos, especially in the context of highly complex interorganizational healthcare systems. This research agenda is not only theoretically important, but also tremendously important from a practical point of view, especially in industries where data processed is of a sensitive nature, such as in healthcare. Here, the development of electronic heath record systems that connect a wide variety of disparate organizations and users is in its infancy. Developing approaches now which can help to secure these systems from security breaches is likely to provide huge cost savings, avoiding, for example, litigation claims when a patient's data has been inappropriately divulged, or simply human misery when an individual is unable to get a job because an unethical employer has managed to extract some private data from a health record. Research which can identify approaches to security management that take into account the problems associated with system complexity, as outlined in this article, would thus be very timely.

KEY TERMS

Complex Systems: Systems that interweave components in such a way that they display variation without being random, and result in a structure that is more than the sum of its parts.

Complexity Science: The study of complex systems, broadly defined.

Emergent Use: The use of systems in ways not initially anticipated, stimulated by users improvising to add applications to the original system in order to support local practices. Emergent use can be planned or unplanned.

Holistic Information Security Approaches: Security management strategies that encompass social as well as technical elements, and which are dynamic so that security issues are considered each time a new use is adopted, even if this use is not formally instigated.

IT Standards: Generally agreed-upon activities, methods, functions, protocols, interfaces, systems, equipment, materials, services, processes, and products that have been introduced and employed, in efforts to reduce the labor costs associated with IT projects.

Metapolicy: Establish how policies are going to be created in an ongoing way.

Reductionist Information Security Approaches: Security management strategies that apply solutions to small fractions of a system at a time (e.g., passwords to secure access to an application, firewalls to protect network traffic, and so on.).

Fast and Robust Fuzzy C-Means Algorithms for Automated Brain MR Image Segmentation

INTRODUCTION

By definition, image segmentation represents the partitioning of an image into nonoverlapping, consistent regions, which appear to be homogeneous with respect to some criteria concerning gray level intensity and/or texture.

The fuzzy c-means (FCM) algorithm is one of the most widely used method for data clustering, and probably also for brain image segmentation (Bezdek & Pal., 1991). However, in this latter case, standard FCM is not efficient by itself, as it is unable to deal with that relevant property of images that neighbor pixels are strongly correlated. Ignoring this specificity leads to strong noise sensitivity and several other imaging artifacts.

Recently, several solutions were given to improve the performance of segmentation. Most of them involve using local spatial information: the own gray level of a pixel is not the only information that contributes to its assignment to the chosen cluster. Its neighbors also have their influence while getting a label. Pham and Prince (1999) modified the FCM objective function by including a spatial penalty, enabling the iterative algorithm to estimate spatially smooth membership functions. Ahmed, Yamany, Mohamed, Farag, and Moriarty (2002) introduced a neighborhood averaging additive term into the objective function of FCM, calling the algorithm bias corrected FCM (BCFCM). This approach has its own merits in bias field estimation, but it computes the neighborhood term in every iteration step, giving the algorithm a serious computational load. Moreover, the zero gradient condition at the estimation of the bias term produces a significant amount of misclassifications (Siyal & Yu, 2005). Chuang, Tzeng, Chen, Wu, and Chen (2006) proposed averaging the fuzzy membership function values and reassigning them according to a tradeoff between the original and averaged membership values. This approach can produce accurate clustering if the tradeoff is well adjusted empirically, but it is enormously time consuming. In order to reduce the execution time, Szilágyi, Benyó, Szilágyi, and Adam (2003), and Chen and Zhang (2004) proposed to evaluate the neighborhoods of each pixel as a prefiltering step, and perform FCM afterwards. The averaging and median filters, followed by FCM clustering, are referred to as FCM_S1 and FCM_S2, respectively (Chen & Zhang, 2004). Szilágyi et al. (2003) also pointed out that once having the neighbors evaluated, and thus for each pixel having extracted a one-dimensional feature vector, FCM can be performed on the basis of the gray level histogram, clustering the gray levels instead of the pixels, which significantly reduces the computational load, as the number of gray levels is generally smaller by orders of magnitude. This latter quick approach, combined with an averaging prefilter, is referred to as enhanced FCM (EnFCM) (Cai, Chen, & Zhang, 2007). All BCFCM, FCM_S1, and EnFCM suffer from the presence of a parameter denoted by α, which controls the strength of the averaging effect, balances between the original and averaged image, and whose ideal value unfortunately can be found only experimentally. Another drawback is the fact that averaging and median filtering, besides eliminating salt-and-pepper noises, also blurs relevant edges. Due to these shortcomings, Cai et al. (2007) introduced a new local similarity measure, combining spatial and gray level distances, and applied it as an alternative prefiltering to EnFCM, having this approach named fast generalized FCM (FGFCM). This approach is able to extract local information causing less blur then the averaging or median filter, but still has an experimentally adjusted parameter λ_g, which controls the effect of gray level differences.

Another remarkable approach, proposed by Pham (2003), modifies the objective function of FCM by the means of an edge field, in order to eliminate the filters that produce edge blurring. This method is also significantly time consuming, because the estimation of the edge field, which is performed as an additional step in each iteration, has no analytical solution.

In this article, we propose a novel method for MR brain image segmentation that simultaneously aims high accuracy in image segmentation, low noise sensitivity, and high processing speed.

BACKGROUND

The Standard Fuzzy C-Means Algorithm

The fuzzy c-means algorithm has successful applications in a wide variety of clustering problems. The traditional FCM partitions a set of object data into a number of c clusters based on the minimization of a quadratic objective function. When applied to segment gray level images, FCM clusters the intensity level of all pixels (x_k, $k = 1\ldots n$), which are scalar values. The objective function to be minimized is:

$$J_{FCM} = \sum_{i=1}^{c}\sum_{k=1}^{n} u_{ik}^{m}(x_k - v_i)^2 \quad (1)$$

where $m > 1$ is the fuzzyfication parameter, v_i represents the prototype value of cluster i, $u_{ik} \in [0,1]$ is the fuzzy membership function showing the degree to which pixel k belongs to cluster i. According to the definition of fuzzy sets, for any pixel k, we have $\sum_{i=1}^{c} u_{ik} = 1$. The minimization of the objective function is reached by alternately applying the optimization of J_{FCM} over $\{u_{ik}\}$ with v_i fixed, $i = 1\ldots c$, and the optimization of J_{FCM} over $\{v_i\}$ with u_{ik} fixed, $i = 1\ldots c$, $k = 1\ldots n$ (Hathaway, Bezdek, & Hu, 2000). During each cycle, the optimal values are computed from the zero gradient conditions, and obtained as follows:

$$u_{ik}^{*} = \frac{(x_k - v_i)^{-2/(m-1)}}{\sum_{j=1}^{c}(x_k - v_j)^{-2/(m-1)}} \quad (2)$$

and

$$v_i^{*} = \frac{\sum_{k=1}^{n} u_{ik}^{m} x_k}{\sum_{k=1}^{n} u_{ik}^{m}} \quad (3)$$

After adequate initialization of centroids v_i, (2) and (3) are applied alternately until the norm of the variation of vector **v** is less than a previously set small value ε. FCM has invaluable merits in making optimal clusters, but in image processing it has severe deficiencies. The most important one is the fact that it fails to take into consideration the position of pixels, which is also relevant information in image segmentation. This drawback led to introduction of spatial constraints into fuzzy clustering.

Fuzzy Clustering Using Spatial Constraints

Ahmed et al. (2002) proposed a modification to the objective function of FCM, in order to allow the labeling of a pixel to be influenced by its immediate neighbors. This neighboring effect acts like a regularizer that biases the solution to a piecewise homogeneous labeling. The objective function of BCFCM is:

$$J_{BCFCM} = \sum_{i=1}^{c}\sum_{k=1}^{n}\left[u_{ik}^{m}(x_k - v_i)^2 + \frac{\alpha}{n_k}\sum_{r\in N_k} u_{ik}^{m}(x_r - v_i)^2\right] \quad (4)$$

where x_r represents the gray level of pixels situated in the neighborhood N_k of pixel k, and n_k is the cardinality of N_k. The parameter α controls the intensity of the neighboring effect, and unfortunately its optimal value can be found only experimentally. Having the neighbors computed in every computation cycle, this iterative algorithm performs extremely slowly.

Chen and Zhang (2004) reduced the time complexity of BCFCM, by previously computing the neighboring averaging term or replacing it by a median filtered term, calling these algorithms FCM_S1 and FCM_S2, respectively. These algorithms outperformed BCFCM, at least from the point of view of time complexity.

Szilágyi et al. (2003) proposed a regrouping of the processing steps of BCFCM. In their approach, an averaging filter is applied first, similarly to the neighboring effect of Ahmed et al. (2002):

$$\xi_k = \frac{1}{1+\alpha}\left(x_k + \frac{\alpha}{n_k}\sum_{r \in N_k} x_r \right) \tag{5}$$

This filtering is followed by an accelerated version of FCM clustering. The acceleration is based on the idea, that the number of gray levels is generally much smaller than the number of pixels. In this order, the histogram of the filtered image is computed, and not the pixels, but the gray levels are clustered (Szilágyi et al., 2003), by minimizing the following objective function:

$$J_{EnFCM} = \sum_{i=1}^{c}\sum_{l=1}^{q} h_l u_{il}^m (l - v_i)^2 \tag{6}$$

where h_l denotes the number of pixels with gray level equaling l, and q is the number of gray levels. The optimization formulas in this case will be:

$$u_{il}^* = \frac{(l - v_i)^{-2/(m-1)}}{\sum_{j=1}^{c}(l - v_j)^{-2/(m-1)}} \tag{7}$$

and

$$v_i^* = \frac{\sum_{k=1}^{n} u_{ik}^m x_k}{\sum_{k=1}^{n} u_{ik}^m} \tag{8}$$

EnFCM drastically reduces the computation complexity of BCFCM and its relatives (Cai et al., 2007; Szilágyi et al., 2003). If the averaging prefilter is replaced by a median filter, the segmentation accuracy also improves significantly (Cai et al., 2007; Szilágyi, 2006).

FCM with Spatial and Gray Level Constraints

Based on the disadvantages of the aforementioned methods, but inspired of their merits, Cai et al. (2007) introduced a local (spatial and gray) similarity measure that they used to compute weighting coefficients for an averaging pre-filter. The filtered image is then subject to EnFCM-like histogram-based fast clustering. The similarity between pixels k and r is given by the following formula:

$$S_{kr} = \begin{cases} s_{kr}^{(s)} \cdot s_{kr}^{(g)}, & r \in N_k - \{k\} \\ 0, & r = k \end{cases} \tag{9}$$

where $s_{kr}^{(s)}$ and $s_{kr}^{(g)}$ are the spatial and gray level components, respectively. The spatial term $s_{kr}^{(s)}$ is defined as the L_∞-norm of the distance between pixels k and r. The gray level term is computed as $s_{kr}^{(g)} = \exp(-(x_k - x_r)^2 / (\lambda_g \sigma_k^2))$ where σ_k denotes the average quadratic gray level distance between pixel k and its neighbors. Segmentation results are reported more accurate than in any previous case (Cai et al., 2007).

METHOD

Probably the most relevant problem of all techniques presented above, BCFCM, EnFCM, FCM_S1, and FGFCM, is the fact that they depend on at least one parameter, whose value has to be found experimentally. The parameter α balances the effect of neighboring in case of the former three methods, while λ_g controls the tradeoff between spatial and gray level components in FGFCM.

The zero value in the second row of (9) implies that in FGFCM, the filtered gray level of any pixel is computed as a weighted average of its neighbors. Having renounced to the original intensity of the current pixel, even if it is a reliable, noise-free value, unavoidably produces some extra blur into the filtered image. Accurate segmentation requires this kind of effects to be minimized (Pham, 2003).

We propose a set of modifications to EnFCM/FGFCM in order to improve the accuracy of segmentation, without renouncing to the speed of histogram-based clustering. In other words, we need to define a filter that can extract relevant feature information from the image while applied as a prefiltering step, so that the filtered image can be clustered fast based on its histogram. The proposed method consists of the following steps:

1. As we are looking for the filtered value of pixel k, we need to define a small square or diamond-shape neighborhood N_k around it. Square windows of size 3×3 were used throughout this study.
2. We search for the minimum, maximum, and median gray value within the neighborhood N_k, and we denote them by $\min_k$, $\max_k$ and med_k, respectively.

3. We replace the gray level of the maximum and minimum valued pixel with the median value (if there are more than one maxima or minima, replace them all), unless they are situated in the middle pixel *k*. In this latter case, pixel k remains unchanged, just labeled as unreliable value.
4. Compute the average quadratic gray level difference of the pixels within the neighborhood N_k, using the formula:

$$\sigma_k = \sqrt{\frac{1}{n_k - 1} \sum_{r \in N_k} (x_r - x_k)^2} \qquad (10)$$

5. The filter coefficients will be defined as:

$$C_{kr} = \begin{cases} c_{kr}^{(s)} \cdot c_{kr}^{(g)}, & r \in N_k - \{k\} \\ 1, & (r = k) \wedge (x_k \notin \{\max_k, \min_k\}) \\ 0, & (r = k) \wedge (x_k \in \{\max_k, \min_k\}) \end{cases} \qquad (11)$$

The central pixel k will be ignored if its value was found unreliable, otherwise it gets unitary weight. All other neighbor pixels will have coefficients $C_{kr} \in [0,1]$, depending on their space distance and gray level difference from the central pixel. In case of both terms, higher distance values push the coefficients towards 0.

6. The spatial component $c_{kr}^{(s)}$ is a negative exponential of the Euclidean distance between the two pixels *k* and *r*: $c_{kr}^{(s)} = \exp(-L_2(k,r))$. The gray level term depends on the difference $|x_r - x_k|$, according to a bell-shaped function defined as follows:

$$c_{kr}^{(g)} = \begin{cases} \left[\cos\left(\pi (x_r - x_k)/(8\sigma_k)\right)\right]^2, & |x_r - x_k| \le 4\sigma_k \\ 0, & |x_r - x_k| > 4\sigma_k \end{cases} \qquad (12)$$

7. The extracted feature value for pixel *k*, representing its filtered intensity value, is obtained as a weighted average of its neighbors:

$$\xi_k = \frac{\sum_{r \in N_k} C_{kr} x_r}{\sum_{r \in N_k} C_{kr}} \qquad (13)$$

Algorithm

We can summarize the proposed method as follows:

1. Prefiltering step: for each pixel *k* of the input image, compute the filtered gray level value ξ_k, using (10) – (13).
2. Compute the histogram h_l of the prefiltered image.
3. Initialize v_i with valid gray level values, differing from each other.
4. Compute new fuzzy memberships u_{il}, $i = 1 \ldots c$, l $= 1 \ldots q$, using (7).
5. Compute new cluster prototypes v_i, $i = 1 \ldots c$, using (8).
6. If there is relevant change in the v_i values, go back to step 4. This is tested by comparing any norm of the difference between the new and the old vector **v** with a preset small constant ε.

The algorithm converges quickly; however, the number of necessary iterations depends on ε and on the initial cluster prototype values.

RESULTS AND DISCUSSION

In this section we test and compare the accuracy of four algorithms: BCFCM, EnFCM, FGFCM, and the proposed method, on several synthetic and real images. All the following experiments used 3 × 3 window size for all kinds of filtering.

The proposed filtering technique uses a convolution mask whose coefficients are context dependent, and thus computed for the neighborhood of each pixel. Figure 1 presents the obtained coefficients for two particular cases. Section (a) of Figure 1 shows the case, when the central pixel is not significantly noisy, but some pixels in the neighborhood might be noisy or might belong to a different cluster. Under such circumstances, the upper three pixels having distant gray level compared to the value of the central pixel, receive small weights, and this way they hardly contribute to the filtered value. Section (b) of Figure 1 presents the case of an isolated noisy pixel situated in the middle of a relatively homogeneous window. Even though all computed coefficients are low, the noise is eliminated, resulting a convenient filtered value 111. The migration of weights from the local maximum and minimum towards the median

Figure 1. Filter mask coefficients in case of a reliable pixel intensity value (a), and a noisy one (b). The upper number in each cell is the intensity value, while the lower number represents the obtained coefficient. The arrows show, that the coefficients of extreme intensities are contributed to the median valued pixel.

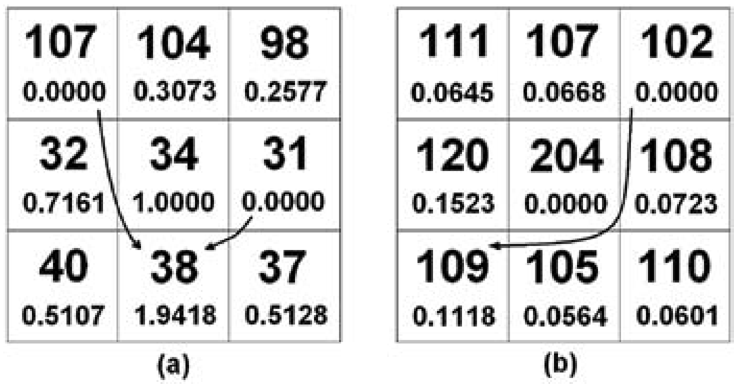

Figure 2. Segmentation results on phantom images: (a) Original, (b) segmented with traditional FCM, (c) segmented using BCFCM, (d) segmented using FGFCM, (e) filtered using the proposed prefiltering, and (f) result of the proposed segmentation.

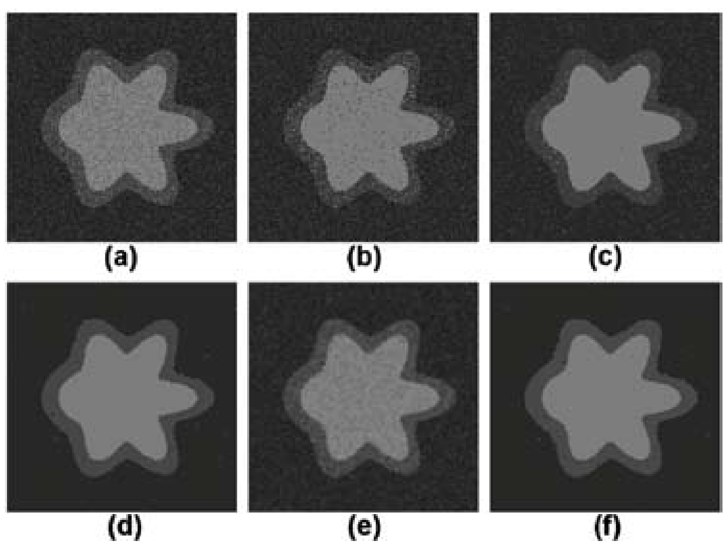


valued pixel, indicated by the arrows, is relevant in the second case and useful in the first.

The noise removal performances were compared using a 256×256-pixel synthetic test image taken from IBSR (Worth) (see section (a) of Figure 2). Figure 2 also shows how much these methods were affected by a high degree mixed noise. Visually, the proposed method achieves best results, slightly over FGFCM, and significantly over all others.

Figure 3 shows the number of misclassifications obtained using three of the presented methods, while segmenting the picture shown in section (a) of Figure 2, corrupted by an increasing amount of mixed noise. Moreover, not only an extra amount of noise is added to the image step by step, but also the original cluster centroids (the base intensities of the clusters) are moved closer and closer. This complex effect is obtained using a weighted sum of three different noisy versions

Figure 3. A comparison of the numbers of misclassifications: Noise level is rising from left to right

	1	2	3	4	5	6	7	8	9	10	11
EnFCM	78	84	103	133	139	150	190	238	306	410	503
FGFCM	40	48	55	66	75	92	108	151	189	270	363
Proposed	38	47	52	61	72	86	106	141	173	219	318

of the same image (all available at IBSR), by changing the weights. Figure 3 reveals that the proposed filter performs best at removing all these kinds of noises. Consequently, the proposed method is suitable for segmenting images corrupted with unknown noises, and in all cases it performs at least as well as his ancestors (Szilágyi, Szilágyi, & Benyó, 2007).

We applied the presented filtering and segmentation techniques to several T1-weighted real MR images. A detailed view, containing numerous segmentations, is presented in Figure 4. The original slice (a) is taken from IBSR. We produced several noisy versions of this slice, by adding salt-and-pepper impulse noise and/or Gaussian noise, at different intensities. Some of these noisy versions are visible in sections (d), (g), (j), and (m) of Figure 4. The filtered versions of the five above mentioned slices are presented in the middle column of Figure 4. The segmentation results of the chosen slice are shown in sections (c), (f), (i), (l), and (o) of Figure 4. From the segmented images we can conclude, that the proposed filtering technique is efficient enough to make proper segmentation of any likely-to-be-real MRI images in clinical practice, at least from the point of view of Gaussian and impulse noises. Table 1 takes into account the behavior of three mentioned segmentation techniques, in case of different noise types and intensities, computed by averaging the misclassifications on 12 different T1-weighted real MR brain slices. The proposed algorithm has lowest misclassification rates in most of the cases.

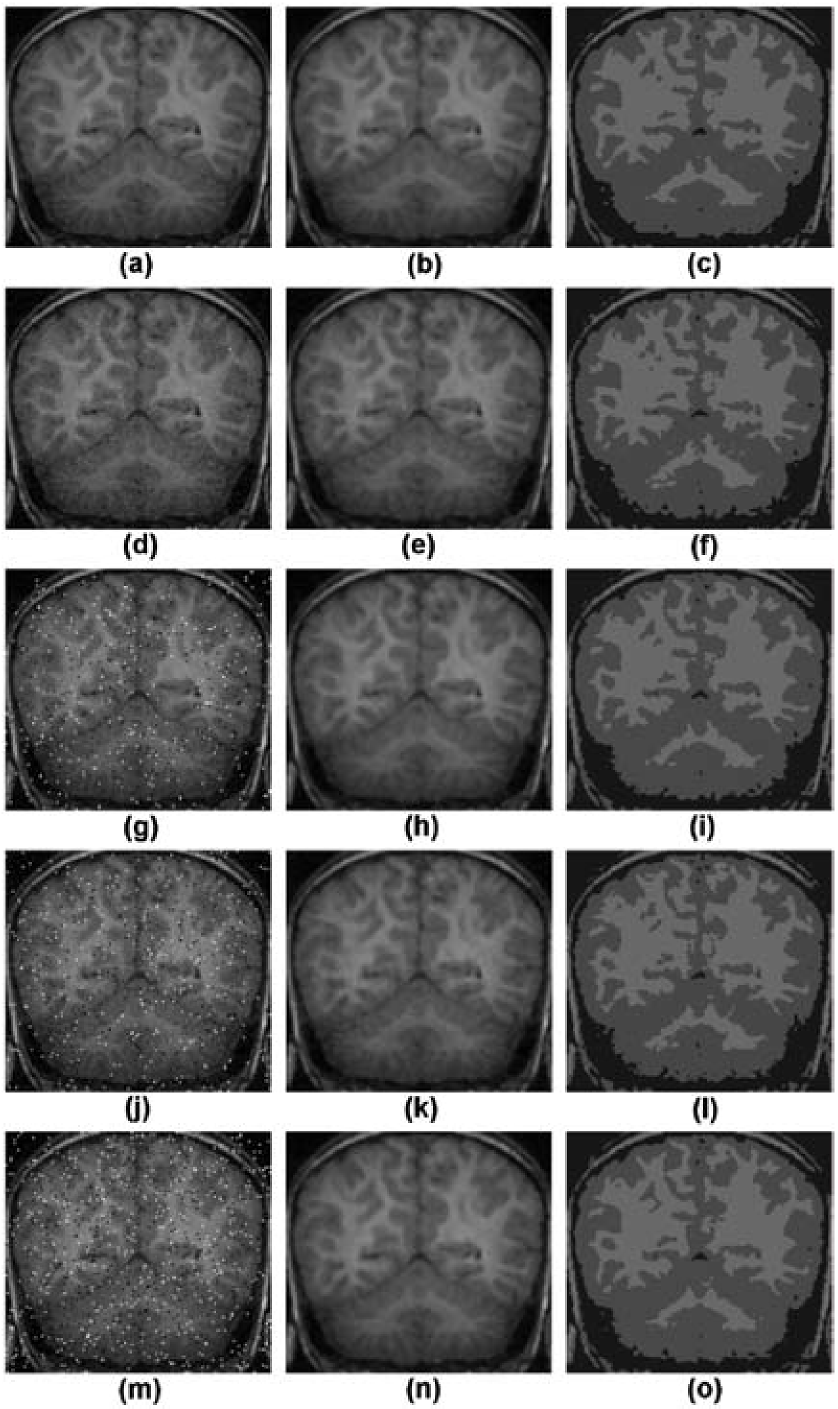
We applied the proposed segmentation method to several complete head MR scans in IBSR. The dimensions of the image stacks were 256 × 256 × 64 voxels. The average total processing time for one stack was around 10 seconds on a 2.4 GHz Pentium 4.

CONCLUSION

We have developed a modified FCM algorithm for automatic segmentation of MR brain images. The algorithm was presented as a combination of a complex prefiltering technique and an accelerated FCM clustering performed over the histogram of the filtered image. The prefilter uses both spatial and gray level criteria, in order to achieve efficient removal of Gaussian and impulse noises without significantly blurring the real edges.

Experiments with synthetic phantoms and real MR images show that our proposed technique accurately segments the different tissue classes under serious noise contamination. We compared our results with other recently reported methods. Test results revealed that our approach outperformed these methods in many aspects, especially in the accuracy of segmentation and processing time.

Figure 4. Filtering and segmentation results on real T1-weighted MR brain images, corrupted with different kinds and levels of artificial noise. Each row contains an original or noise-corrupted brain slice on the left side, the filtered version (using the proposed method) in the middle, and the segmented version on the right side. Row (a)-(c) comes from record number 1320_2_43 of IBSR, row (d)-(f) is corrupted with 10% Gaussian noise, while rows (g)-(i), (j)-(l), and (m)-(o) contain mixed noise of 3% impulse + 5% Gaussian, 3% impulse + 10% Gaussian, and 5% impulse + 5% Gaussian, respectively.



F

Table 1. Misclassification rates in case of real MR brain image segmentation

Noise type	EnFCM	FGFCM	Proposed
Original, no extra noise	0.767 %	0.685 %	0.685 %
Gaussian 4 %	1.324 %	1.131 %	1.080 %
Gaussian 8 %	3.180 %	2.518 %	1.489 %
Gaussian 12 %	4.701 %	2.983 %	2.654 %
Impulse 1 %	0.836 %	0.717 %	0.726 %
Impulse 3 %	1.383 %	0.864 %	0.823 %
Impulse 5 %	1.916 %	1.227 %	0.942 %
Impulse 10 %	3.782 %	1.268 %	1.002 %
Impulse 5 % + Gaussian 4 %	2.560 %	1.480 %	1.374 %
Impulse 5 % + Gaussian 8 %	3.626 %	2.013 %	1.967 %
Impulse 5 % + Gaussian 12 %	6.650 %	4.219 %	4.150 %

FUTURE TRENDS

Further works aim at reducing the sensitivity of the proposed technique to intensity nonuniformity noises and at introducing adaptive determination of the optimal number of clusters.

KEY TERMS

Data Clustering: Partitioning data sets into subsets whose elements share common or similar properties.

Gaussian Noise: Noise having Gaussian distribution.

Image Segmentation: Partitioning images into regions which are homogeneous with respect to some criteria that concern color, intensity, or texture.

Low-Pass Filter or Averaging Filter: Linear smoothing operator that replaces the intensity of each pixel with a weighted average intensity of its neighbor pixels.

Median Filter: A non-linear filtering technique which replaces the intensity of each pixel with the median intensity value found in a symmetrical neighborhood containing an odd number of pixels. It is usually applied to reduce salt-and-pepper noise.

Salt-and-Pepper Noise or Impulse Noise: Scattered black and white pixels replacing actual value.

Feature Selection in Pathology Detection Using Hybrid Multidimensional Analysis

INTRODUCTION

The basic problem of pathology detection is to classify a given observation in one of *m* known classes. A set of features presumably contains enough information to distinguish among the classes. Traditional statistical methods break down partly because of the increase in the number of observations, but mostly because of the increase in the number of variables associated with each observation (Castellanos, Daza, Sánchez, Castrillón, & Suárez , 2006).

Performance in training of pattern recognition systems to detect pathologies can be increased, if proper feature extraction is done. Training procedures usually deal with a high number of features; nevertheless a high dimension input space means significant processing time, higher cost in the collection of biosignal records since more observations are needed, and the well known curse of dimensionality phenomena (Lee, Lendasse, & Verleysen, 2003). As a result, the whole training performance declines. In this sense, effective feature selection should be carried out to select those features with higher discriminant capability, keeping or even increasing the accuracy of classification procedures (Yu & Liu, 2004). Literature shows wrapper type procedures of feature selection that search in a considerably smaller number of subsets. Sequential Forward Floating Selection (SFFS) is a common example found in this type of procedure (Webb, 2002). High-dimensional datasets present many mathematical challenges as well as some opportunities, and are bound to give rise to new theoretical developments (Fodor, 2002). Dimensional reduction techniques such as Principal Component Analysis (PCA), which is an orthogonal representation of data, allow us in some way to find a lower dimension in transformed space based on data variance, but this procedure does not take into account information about class separability, therefore PCA is not suitable because the direction of maximum variance does not necessarily correspond to the direction of maximum separability (Hyvarinen, 1999).

Dimensionality reduction procedures perform well on sets of correlated features while variable selection methods perform poorly. These methods fail to pick relevant variables because the score they assign to correlated features is too similar, and none of the variables is strongly preferred over another. Hence, feature selection and dimensionality reduction algorithms have complementary advantages and disadvantages. Dimensionality reduction algorithms thrive on the correlation between variables but fail to select informative features from a set of more complex features. Variable selection algorithms fail when all the features are correlated, but succeed with informative variables (Wolf & Bileschi, 2005).

In this work, we propose a feature selection algorithm with heuristic search that uses Multivariate Analysis of Variance (MANOVA) as the cost function. This technique is put to the test by classifying hypernasal from normal voices of CLP (cleft lip and/or palate) patients. The classification performance, computational time, and reduction ratio are also considered by comparing with an alternate feature selection method based on the unfolding of multivariate analysis into univariate and bivariate analysis. The methodology is effective because it has in mind the statistical and geometrical relevance present in the features, which does not summarize the analysis of the separability among classes, but searches a quality level in signal representation.

BACKGROUND

Dimensionality reduction is the representation of high dimension patterns in a subspace of less dimensionality based on either a linear or nonlinear transformation. This transformation optimizes a specific criterion in the subspace (Cohen, Tian, Zhou, & Huang, 2002). There is a concept responsible for directing the context of reduction called *relevance*, according to a given *cost function*.

Definition 1 (Cost function): Let the initial set of features be $\boldsymbol{\xi} = \{\xi_i : i = 1,\ldots,p\}$, where the estimated values for ξ_i constitute an element of multidimensional representation called observation. The set of observations is composed by $\mathbf{X} = \{\mathbf{x}_\ell \in \mathbb{R}^p : \ell = 1,\ldots,n\}$ contained in $span\{\mathbf{X}\}$; where with linear or nonlinear transformations spaces of representation $\boldsymbol{\mathcal{X}}_j = \mathcal{G}_j\{\mathbf{X}\} = \{\boldsymbol{x}_\ell \in \mathbb{R}^M : \ell = 1,\ldots,n\}$ are obtained. These spaces of representation are composed by subsets of features $\hat{\boldsymbol{\xi}}_j = \{\zeta_i : i = 1,\ldots,M\}$, such that, $M \le p$ y $j \in \mathbb{N}$. Let $\mathbf{k} = \{k_r : r \in \mathbb{N}\}$ be the set of class labels such that each observation $\boldsymbol{x}_\ell$ is assigned one and only one class label. A function that according to an associated metric finds a corresponding value to the evaluated data is called cost function. This function can be described as:

$$f_{\hat{\xi}_j} : \mathbb{N} \times \mathbf{H}_x \to \mathbb{R}$$
$$(\mathbf{k}, \boldsymbol{\mathcal{X}}_j) \mapsto f_{\hat{\xi}_j}(\mathbf{k}, \boldsymbol{\mathcal{X}}_j)$$

where $\mathbf{H}_x \subseteq \mathbb{R}^M$. In this article, we will take $f_{\hat{\xi}_j}(\mathbf{k}, \boldsymbol{\mathcal{X}}_j) \equiv f_{\hat{\xi}_j}(\mathbf{k}, \hat{\boldsymbol{\xi}}_j)$ to aid notation.

Definition 2 (Relevance): Let the observation set be $\boldsymbol{\mathcal{X}} = \{\boldsymbol{x}_\ell \in \mathbb{R}^M : \ell = 1,\ldots,n\}$ composed by M features, $\hat{\boldsymbol{\xi}} = \{\xi_i : i = 1,\ldots,M\}$. Let $\mathbf{k} = \{k_r : r \in \mathbb{N}\}$ be the set of class labels, such that each observation $\boldsymbol{x}_\ell$ is assigned one and only one class label. Let δ be a threshold of significance according to a metric (geometrical, statistical, etc). $\boldsymbol{\mathcal{X}}$ is relevant according to a metric of significance, if there is a cost function, $f_{\hat{\mathbf{i}}}$ with the associated metric of significance, such that, the obtained value for $f_{\hat{\xi}}(\mathbf{k}, \hat{\boldsymbol{\xi}}) > \delta$.

Observation 1 (Feature selection): It is a particular form of reducing dimensionality, when the obtained cost function value, $f_{\hat{\xi}}$, associated with a metric, is involved in the relevance criteria used in a mapping or transformation function and a feature subset is obtained. This feature subset directly corresponds to the initial space ξ and is oriented towards maximizing the representation capability as well as minimizing cost.

In general, given a set of observations where each observation is associated to one and only one class label from a set of labels **k**, the problem of feature selection is to find a subset $\hat{\boldsymbol{\xi}}_i \subseteq \boldsymbol{\xi}$, such that, if the cardinal of $\hat{\boldsymbol{\xi}}_i$ is M, and all the M-cardinal subsets are in $\breve{\boldsymbol{\xi}}$, the subset $\hat{\boldsymbol{\xi}}_i$ is that which optimizes a cost function $f_{\hat{\xi}_i}$, such as (Webb, 2002):

$$f_{\hat{\xi}_i}(\mathbf{k}, \hat{\boldsymbol{\xi}}_i) = \max_{\breve{\xi} \subseteq \xi} f_{\breve{\xi}}(\mathbf{k}, \hat{\boldsymbol{\xi}}_i) \qquad (1)$$

Additionally, feature selection according to the cost function can be carried out in two ways (Yu & Liu, 2004):

1. *Wrapper:* When $f_{\hat{\mathbf{i}}_i}$ uses information of the classification procedure in an attempt to minimize classifier error with validation observations (different to the observations used in training).
2. *Filter:* It is a preprocessing of the data based on the optimization of $f_{\hat{\mathbf{i}}_i}$ with regard to a given metric. Thus, the irrelevant, redundant, and non discriminant variables are discarded. This process is independent of the classification procedure and has advantages such as simple implementation.

Feature selection can be carried out by means of extensive or heuristic search algorithms. Extensive search algorithms are supposed to obtain an optimal feature subset after searching the input training space thoroughly, being computationally expensive (Dash & Liu, 2003). On the other hand, heuristical algorithms which are based on empirical rules can reduce the computational complexity, even though the final subset may not be optimal but enough for the classification purpose. Such methods require some stopping criteria (cost function) (Webb, 2002).

F

DIMENSIONAL REDUCTION BY HEURISTIC MULTIVARIATE ANALYSIS

Given a p-dimensional initial training feature space, a sequential multivariate analysis is done. This is obtained by adjusting a heuristic search method and its cost function providing search direction and subset construction rules.

In general, floating techniques might be considered since they are based on combining forward and backward selection that may provide a better subset optimizing a cost function. For instance, Δp_+ features are added and $\Delta p_- > \Delta p_+$ discarded (Devijver & Kittler, 1982).

Statistical Relevance Measures

Let $\{k = 1,...,L\}$ be the set of patterns, where each one has n observations. Let $\boldsymbol{\xi} \in \mathbb{R}^p$ be the set of features, for which the subset $\hat{\boldsymbol{\xi}}_i = \boldsymbol{\xi} \cap \overline{\xi_i}$ is constructed, being $\overline{\xi_i}$ the complement of ξ_i in $\boldsymbol{\xi}$. A feature ξ_i is assumed to be strongly relevant for the given cost function $f_{\hat{\xi}}$ if and only if,

$$f_{\hat{\xi}}(\mathbf{k},(\xi_i,\hat{\xi}_i)) \neq f_{\hat{\xi}}(\mathbf{k},\hat{\xi}_i) \qquad (2)$$

In this sense, Multivariate Analysis of Variance (MANOVA) can be used as the cost function (2); here the relevance measure is the separability between patterns for a given feature space. This is a hypothesis test about the equality or inequality of the mean values $\boldsymbol{m}_l$ for each one of the class populations. In this case, the model of multiple analysis of statistical relevance for each p-dimensional vector $\boldsymbol{x}_{ij}$

$$\boldsymbol{x}_{kj} = \boldsymbol{m}_k + \varepsilon_{kj}\ , \qquad \boldsymbol{m}_{ki} = \boldsymbol{m} + \alpha_k$$

where j is the observation and k the patterns; $\boldsymbol{m}_k$ are the mean vectors for each pattern and ε_{kj} is the perturbation model, $\boldsymbol{m}$ is the overall mean and a is the class perturbation across the overall mean. The comparison of the mean vectors for the k patterns to find significant differences is carried out through the hypothesis test:

$$H_0 : \boldsymbol{m}_1 = \boldsymbol{m}_2 = \cdots = \boldsymbol{m}_L,$$
$$H_1 : \exists \boldsymbol{m}_l \neq \boldsymbol{m}_m;\ \forall l, m \in 1,\ldots,L$$

MANOVA does not find the features per se; it is only a way for validating a given set of features, which is why this is only a cost function. Consequently, the following approach to constructing and evaluating feature subsets is proposed.

MANOVA Progressive Approach

The Wilks' test is often used for MANOVA, and consists on the likelihood ratio test of H_0 given by:

$$\boldsymbol{\Lambda} = \frac{|\mathbf{E}|}{|\mathbf{E}+\mathbf{H}|} \qquad (3)$$

which is known as Wilks' lambda; **H** being the hypothesis matrix, which can be understood as a measure of dispersion among the mean values of the patterns. While **E** is the error matrix, that relates to a dispersion measure among observations within the patterns. H_0 is rejected if the dispersion among patterns is greater than the dispersion among observations within patterns, and so $\boldsymbol{\Lambda} \in [0,1]$ tends to be zero. On the other hand, Wilks' lambda can be similar to an F-statistic though in an inverse manner. A large F-statistic rejects H_0 (Rencher, 2002).

The following are steps for a forward sequential search algorithm based on multivariate statistical relevance function:

1. Calculate the F-statistic (transformation of Wilks' lambda) for one-feature subsets. From these values, the feature with the largest F-statistic is chosen and its cumulative probability value is computed using the F distribution.
2. Construct 2-dimensional subsets, combining the feature previously chosen in step 1) with the remaining features. Each one of these subsets is evaluated through the Wilks' test, and its respective F-statistic is updated.
3. Select the 2-dimensional subset with the largest F-statistic. Calculate its respective cumulative probability using the F-distribution. This value must exceed the calculated value in step (1) to update the subset. Otherwise, terminate the search.
4. Construct the feature subset adding one feature to the updated subset. These new analysis groups correspond to the subset selected in step (3) and each one remaining feature.

5. Return to step (3) and update the subset using the same criteria. Continue to step (4) and repeat the updating process over and over. The algorithm stops as shown in step (3) when added features do not increase the cumulative probability. So, the final size of the subset is p' where $p' \leq p$. In this manner, we can select those features that together are more discriminant.

Note that if during the calculations $\boldsymbol{\Lambda} \to 0/0$, there is a linear dependency in the current subset. Then its F-statistic is forced to zero and so the evaluated subset is rejected (Johnson & Wichern, 2002).

DIMENSIONAL REDUCTION BY UNFOLDING MULTIVARIATE ANALYSIS

In this case, the multivariate analysis of statistical relevance is unfolded in multiple analyses of smaller dimension. With these kinds of analyses an alternative feature selection methodology is constructed, which connects a 3 block cascade as follows: univariate analysis of separability, bivariate analysis of correlation, and heuristic search using a classifier as the cost function.

Univariate Analysis of Separability

It is important to assure that each one of the features $\xi_i \subset \boldsymbol{\xi}; \forall i = 1, 2, \ldots, p$ have enough discriminant power. A statistical relevance measure is proposed as a hypothesis test based on the significant differences of features between patterns:

- H_0: There is no significant difference on the observations in the ξ_i feature between patterns. Consequently, the overall difference is zero.
- H_1: There is a significant difference on the observations in the ξ_i feature between patterns. Consequently, the overall difference is not zero.

In particular, the hypothesis test is based on the t-Student distribution. Let $\boldsymbol{x}_{k=1,2} \in \boldsymbol{\xi}_i = \{x_j : j = 1, \ldots, n\}$ be the observation vectors for each k pattern, and unknown mean $\tilde{m}_{\boldsymbol{x}_k}$ and variance $\tilde{\sigma}^2_{\boldsymbol{x}_k}$.

From the set of n observations per pattern $\tilde{m}_{\boldsymbol{x}_k}$ and $\tilde{\sigma}^2_{\boldsymbol{x}_k}$, $k = 1, 2$ are estimated. Assuming gaussian distributions for $\boldsymbol{x}_k$, the confidence interval of the respective mean estimations, for a α significance level are given by:

$$\left(\tilde{m}_{\boldsymbol{x}_1} - \tilde{m}_{\boldsymbol{x}_2}\right) - t_{1-\alpha/2}\{n_1 + n_2 - 2\}\tilde{\sigma}_{\Delta\tilde{m}_x} \leq m_{\boldsymbol{x}_1} - m_{\boldsymbol{x}_2} \leq \left(\tilde{m}_{\boldsymbol{x}_1} - \tilde{m}_{\boldsymbol{x}_2}\right) + t_{1-\alpha/2}\{n_1 + n_2 - 2\}\tilde{\sigma}_{\Delta\tilde{m}_{1x}} \quad (4)$$

being

$$\tilde{\sigma}^2_{\Delta\tilde{m}_{1x}} = \frac{n_1\tilde{\sigma}^2_{\boldsymbol{x}_1} + n_2\tilde{\sigma}^2_{\boldsymbol{x}_2}}{n_1 + n_2 - 2}\left(\frac{1}{n_1} + \frac{1}{n_2}\right)$$

where $t_{1-\alpha/2}\{n_1 + n_2 - 2\}$ represents the percentile value of t-distribution with $n_1 + n_2 - 2$ degrees of freedom (in this case, $n_1 = n_2 = n$). When the confidence interval given by (4) contains zero value, H_0 is not rejected. Otherwise, the alternative hypothesis H_1 is accepted. Thus, it is assumed that there is a significant difference between pattern measures if H_0 is rejected. As result, the dimension of the initial feature set is reduced to $\xi \subset \boldsymbol{\xi} \in \mathbb{R}^{p_1}$, $p_1 \leq p$ (Sharma, 1996).

Bivariate Analysis: Component Analysis

Let $\xi_{1\times p_1}$ be a random vector of features with mean value $E\{\xi\} = \boldsymbol{m}_\xi$, so that the covariance matrix Σ_ξ, of size $p_1 \times p_1$ is:

$$\Sigma_\xi = E\left\{\left(\xi - \boldsymbol{m}_\xi\right)\left(\xi - \boldsymbol{m}_\xi\right)^T\right\}$$

and the correlation matrix P from Σ_ξ is defined as:

$$P(m,q) = \frac{\Sigma_\xi(m,q)}{\sqrt{\Sigma_\xi(m,m)\Sigma_\xi(q,q)}}$$

A null value in the correlation function between the variables ξ_m y ξ_q implies both variables are linearly independent. In the opposite case, the correlation matrix P tends to be singular. Thence, we search for pairs of features that expose larger correlation indexes than \$0.5\$. From each one of these pairs we choose the feature with the smallest overall correlation. Therefore, the new feature subset has dimension p_2, where $p_2 \leq p_1 \leq p$ (Jolliffe, 2002).

Heuristic Search

With the aim of finding a feature subset that minimizes the classification error, a heuristic search is structured. More specifically, we use a forward sequential search algorithm with a cost function based on a Bayesian classifier. Hence, the new subset has dimension p', where $p' \leq p_2 \leq p_1 \leq p$ (Doltsinis, 1999).

EXPERIMENTAL BACKGROUND

A procedure is presented with which the performances of the previously proposed methodologies are evaluated and compared.

Database and Data Preprocessing

The sample contains 90 children recordings (observations) labelled as *normal* and *hypernasal* (45 patients per pattern) and evaluated by specialists. Each recording is composed of five Spanish words: /*coco*/, /*gato*/, /*jugo*/, /*mano*/, and /*papá*/. Signals were acquired under controlled conditions for low ambient noise using a dynamic microphone. The extracted features are based on statistical moments relative to position, scale, and shape per voice parameter (Castellanos et al., 2006). A total of 128 features per word were extracted. Consequently, the initial feature set is 640-dimensional. Data preprocessing is carried out in order to reduce the influence of factors such as systematic acquisition errors, occasional failures of the recording devices, and so forth. Besides, this guaranties the homogeneity of the statistical properties of the training features.

Data preprocessing consists in a hypothesis test (*t*-student) to generate a confidence interval that accepts the data; we discard features when less than 90% of the observations lie within the interval. Kolmogorov-Smirnov test is performed in order to verify normality condition of the data. Those features rejected by this test are transformed using the Box-Cox transform and tested again. Features that are not normal after transformation are rejected.

Both methods proposed (dimensional reduction by heuristic multivariate analysis and dimensional reduction by unfolding multivariate analysis) were compared in three ways: computational time *T*, feature reduction ratio *RR*, and classification accuracy *CA*. To prove the separability of the chosen subsets we used a Bayesian classifier. Eventually, we could compare the results with the extensive search, but having 640 variables the number of subsets is 4.5624e+192.

RESULTS AND DISCUSSION

Results of the comparison between the two methods are shown in Table 1. In Table 1 we can see how the computational time for the first method is longer than the second; nevertheless, these times just illustrate the computational complexity, but this is not a parameter for choosing a method that is performed off-line. Even though the reduction ratio for the first method is a little less than the second, the classification accuracy is higher. It depends on the implementation requirements to choose any of the methods. Accuracy vs. complexity should be the criteria.

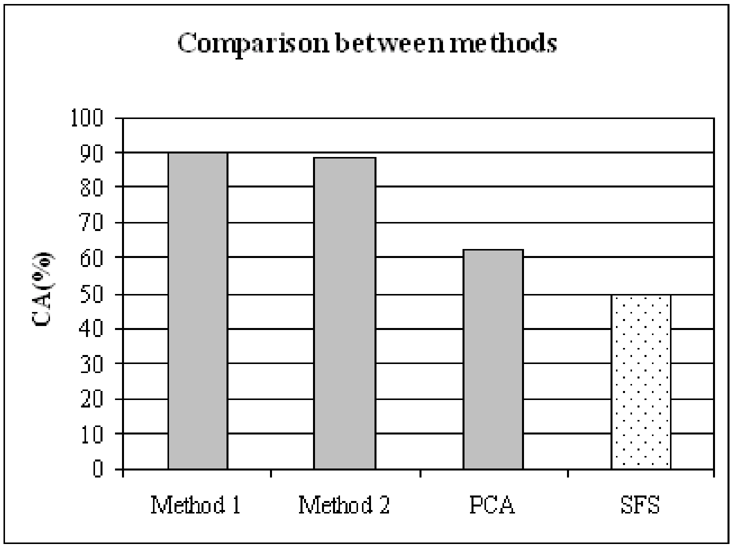
Figure 1 compares dimensional reduction by heuristic multivariate analysis and unfolding multivariate analysis (Method 1 and Method 2 respectively) with traditional methods. We can see that classification improvement is not obtained using only mapping in lower dimension with PCA projection because the direction of maximum separability is not taken into account. In addition to this, SFS algorithm did not converge because the large sets of features generated exhaustive procedures (shown in Figure 1 by the dotted bar).

Both proposed feature selection methods are analyzed for two cases: (a) without data preprocessing and (b) after data preprocessing. From the data preprocess-

Table 1. Comparison of the two methods

Method	T (sec)	RR (%)	CA (%)
Dimensional reduction by heuristic multivariate analysis	19.7	91.26	90
Dimensional reduction by unfolding multivariate analysis	3.81	92.66	88.46

Figure 1. Comparison with traditional methods



ing 36.7% of the original set was discarded by the first test (discard atypical values). The percentage of features that could not be normalized was 25.9%. The results show that in both cases the percentage of reduction is similar although classifier accuracy (CA) increases noticeably when preprocessing is done. This is shown in Table 2 where (—) indicates that the classifier does not converge. Once data preprocessing was done, the initial set was reduced to 47.2%. If we proceed directly to classification after preprocessing the dimension is still too large and the Bayesian classifier does not converge, this is why feature selection is needed.

FUTURE TRENDS

This work allows the study of feature selection to be directed towards different areas of analysis. One of the most important areas of study is the structuring of cost functions, where the efficiency of evolutionary algorithms is proven in the optimization of the solutions. Adjustment of the optimization parameters can be made using regression surfaces, which generate models based on the interaction of the different parameters, thus obtaining the creation of autoadjustable meta-algorithms.

On the other hand, multi-objective MANOVA cost function could be structured such that in a parallel manner it uses measures that not only contain information of separability but also of dependency, redundancy, and irrelevancy of the features.

CONCLUSION

The proposed hybrid methodologies (joint work between multivariate statistical analysis and heuristic search methods for feature subsets), which reduce the initial training space dimension, showed their performance in pathology identification. The methodology is effective because it keeps in mind the statistical and geometrical relevance present in the features, which does not only summarize the analysis of the separability among classes, but also searches a quality level in signal representation. The methodology employed by MANOVA progressive algorithm was the best and it analyzed subsets generated by heuristic principles to avoid exhaustive processes, proposing a decision based on hypothesis testing with low computational cost.

The data preprocessing was a basic stage training system to identify pathologies. In this particular case, the classifier performance does not converge, even employing the best kind of feature selection. In order to comply with all the assumptions of the statistical model imposed, data distribution must be properly analyzed beforehand.

ACKNOWLEDGMENT

This work is within the project titled *"Automatic Hypernasality Detection in Children with Cleft Lip and Palate by Acoustic Analysis"* financed by the Investigations Vice rectory of the National University of Colombia grant 20201004208.

KEY TERMS

CLP: Human pathology characterized by cleft lip and/or palate.

Dimensionality Reduction: Data representation in a lower dimension space by linear or nonlinear mapping.

Heuristic Searching: Feature selection by heuristic measure.

Hypothesis Test: Statistical test for accepting or rejecting something by using a distribution.

MANOVA: Hypothesis test based on multivariate analysis of variance.

PCA: Principal Component Analysis. Orthogonal representation based on data variance.

SFFS: Sequential Forward Floating Selection.
